CARDIAC PACING IN HEART FAILURE

147 Chronic multisite pacing leads to reduced left ventricular volumes in selected patients with congestive heart failure

O.A. Breithardt, C. Stellbrink, B.H. Diem, A. Franke, R. Salo[1], A. Auricchio[2], P. Hanrath. *On behalf of the Path-CHF investigator group; [1]CPI, St. Paul MN, USA; [2]Department of Cardiology, University Hospital Magdeburg; Medizinische Klinik I, RWTH Aachen, Germany*

Multisite pacing offers a new treatment option for patients (pts) with end-stage congestive heart failure (CHF). In the Path-CHF study pts with CHF, QRS > 120 ms and PR-Intervall > 150 ms are treated with VDD pacing at optimized AV delays and pacing sites. 2 DDD pacemakers (PM) allowed VDD pacing either from the right ventricular apex (RV), left ventricle (LV) or both ventricles (BV). After a 3 months cross-over period pts are chronically paced at an individually optimized AV delay and pacing site, determined by measuring acute dp/dt and pulse pressure (PP) changes at pre-implant (PRE). LV volumes and ejection fraction (EF), assessed by echocardiographic biplane volumetry, were compared between PRE and 6 months follow-up (6 M). A change of more than 10% from PRE was considered to be significant.

Results: 18 pts were available for analysis. 2 pts were chronically paced RV, 7 LV and 6 BV. At 6 M 9 pts responded to pacing (R) with a reduction in end-diastolic volumes (EDV), in 4 pts (NR) EDV increased and in 5 pts (S) it remained stable. EF did not change (22% ± 8 vs. 23% ± 7). 2/9 R did not improve in dP/dt and PP at PRE, whereas all NR improved. EDV-PRE was higher in NR compared to R. The 3 largest EDV were measured in 2 NR and in 1 S.

	All pts	R	S	NR
EDV-PRE (ml)	269 ± 102	248 ± 37	256 ± 157	332 ± 74*
EDV-6 M (ml)	258 ± 135	192 ± 76#	257 ± 166	408 ± 90*

*p < 0.05 vs. R, #p < 0.05 vs. PRE

Conclusions: Chronic VDD pacing at individually optimized AV delays and pacing sites reduces left ventricular volumes in selected patients with CHF and bundle-branch block. However, in pts with very large EDV pacing therapy may fail to reduce left ventricular cavity size, even if these pts improve significantly in dp/dt and PP during acute hemodynamic testing.

148 Mortality evaluation in the InSync trial of cardiac resynchronization for heart failure

A. Tang[1], D. Gras[2], P. Mabo[3], C. Bucknall[4], H. Oude Luttikhuis[5], A. Kirstein-Pedersen[6]. *For the InSync Investigators; [1]Ottawa Heart Institute, Ottawa ON, Canada; [2]Clinique du Val d'Or, Paris; [3]Dep. de Cardiologie et Maladies, Rennes, France; [4]St. Thomas Hospital, London, UK; [5]St. Sophia Ziekenhuis, Zwolle, Netherlands; [6]Skejby Sygehus, Aarhus, Denmark*

The InSync™ study is a prospective, multicenter, non-randomized trial evaluating cardiac resynchronization (CR) therapy in patients with advanced heart failure (NYHA Class III and IV), dilated cardiomyopathy (EF < 35%, LVEDD > 60 mm) and ventricular conduction delays (QRS > 150 ms). Mortality was followed in the trial with respect to measured clinical endpoints.

Methods: 96 patients were implanted with the InSync system, which included a transvenous left ventricular lead placed via the coronary sinus, were included in this analysis.

Results: Patient survival was 95% (4 deaths), 84% (13 deaths), and 82% (14 deaths) at 1, 3, and 6 months. There were two additional late deaths: one at 261 days and one at 491 days post-implant, for a total of 16 deaths. 9 of the 16 deaths were classified as sudden. Comparison between survivors (mean follow-up: 157 ± 100 days) and non-survivors (mean follow-up: 97 ± 124 days) did not show any statistical significance for differences in measured parameters. Paired parameters between baseline and the last follow-up visit for each group (*p < 0.05, significant improvement) is shown below:

	Survivors		Non-survivors	
	Baseline	Last FU	Baseline	Last FU
NYHA class	3.3 ± 0.5	2.2 ± 0.8*	3.4 ± 0.5	3.1 ± 0.9
Quality of Life	55 ± 18	35 ± 24*	50 ± 18	35 ± 24
6 min walk test, m	295 ± 112	347 ± 107*	325 ± 99	343 ± 94
QRS duration, ms	180 ± 27	156 ± 24*	177 ± 35	164 ± 32

Conclusion: The InSync trial suggests that permanent cardiac resynchronization may provide improved patient mortality in symptomatic heart failure patients with ventricular conduction abnormalities. While additional follow-up and randomized control studies are needed for validation, poor shortening of QRS duration and limited improvement in 6 min walk test may provide predictors of mortality in this patient group.

149 Can pre- and post-operative ECG data predict the clinical response to multisite biventricular pacing in advanced heart failure?

C. Alonso, C. Leclercq, D. Pavin, H. Mansour, F. Victor, P. Mabo, J.C. Daubert. *Department of Cardiology, University Hospital, Rennes, France*

Biventricular pacing (BiV-P) was recently shown as capable to improve symptoms and exercise tolerance in pts with refractory heart failure related to dilated cardiomyopathy, and broad QRS complex. The aim of this study was to try to identify ECG predictive factors of positive response after BiV-P implantation.

From 08/1994 to 05/1998, 31 pts in NYHA class III or IV (mean age = 67 ± 7 years; mean LVEF = 22 ± 5%) were implanted transvenously with a DDD-BiV PM (pts with normal sinus rhythm; n = 24) or with a VVIR-biV PM (pts with chronic AF; n = 7). 6 months after the implantation pts were classified into two groups depending on the individual response to pacing therapy. Responder pts (Gr I; n = 22) were defined by the association of survival, gain by ≥1 NYHA class and gain by ≥10% in peak VO^2. Non responder pts were classified in group II (n = 9). ECG data were compared before implant during intrinsic conduction and after implant during BiV-P.

	Gr. I (n = 22)	p	Gr II (n = 9)
Age (years)	66 ± 6	NS	67 ± 9
Etiology (ischemic)	9/22	NS	4/9
NYHA class	3.3 ± 0.5	NS	3.1 ± 0.7
LVEF (%)	22 ± 5	NS	21 ± 8
QRS-d (ms) Baseline	178 ± 22	NS	176 ± 30
QRS-d BiV-P	154 ± 15	0.016	177 ± 26
QRS axis Baseline	−27 + 46°	NS	22 ± 90
QRS axis BiV-P	6 ± 93°	NS	0 ± 104

Conclusion: The only ECG predictive factor of positive response was QRS duration after BiV-P with a significantly shorter value in responder pts. So the site of implantation of LV and RV leads has to be carefully selected to provide the shortest paced QRS duration.

150 Cardiac pacing and pulsed Doppler tissue imaging: comparison of myocardial systolic activation and left ventricular end-diastolic diameter in patients during sinus rhythm, DDD and biventricular pacing

M. Gessner, W. Kainz, G. Blazek, M. Gruska, C. Dornaus, G. Gaul. *Department of Cardiology, Hanusch Krankenhaus, Vienna, Austria*

The optimal pacing configuration is the one that best corrects for electromechanical asynchrony within the left ventricle. We evaluated systolic amplitudes, durations, and timings of the basal interventricular septum (IVS), basal lateral left ventricular wall (LW), and posterior wall (PW) by pulsed Doppler Tissue technique (DTI) in eighteen patients during sinus rhythm (SR) and DDD-pacemaker stimulation. These data were compared with the left ventricle enddiastolic diameter [LVEDD] (44–77 mm mean 56 mm). Echocardiographic Images: IVS, LW from an apically four chamber view, PW from the parasternal short axis view.

Results: In patients with enlarged LVEDD and during SR the interval between Q wave in the electrocardiogram and beginning of the systolic myocardial velocities were inhomogenous between the PW and IVS (r = 0.62; p = 0.006). During DDD stimulation the differences of the onset of the systolic velocities from the ventricular impulse (VI – Sb) between LW and IVS showed a significant correlation with the LVEDD (r = 0.60; p = 0.009). In one patient (LVEDD 77 mm) an extreme mechanical asynchrony between the intervals of the onset of the Q wave and beginning of the systolic myocardial velocities in IVS (136 ms), LW (184 ms) and PW (220 ms) was documented during SR. A biventricular pacemaker system (InSync 8040 Medtronic) was implanted. During biventricular pacing (BVP) VI–Sb intervals were homogenous in IVS (220 ms), LW (224 ms), PW (222 ms). Stroke volume increased from 54 ml (SR) to 61 ml (BVP) and peak myocardial systolic velocities measured by pulsed DTI were higher in case of BVP (IVS: 2.8 vs. 4.8 cm/s; PW: 2.3 vs 3.1 cm/s).

Conclusion: 1) If heart failure symptoms occur in dilated cardiomyopathy, pulsed DTI can be used to identify patients with inhomogenous systolic function of the left ventricle. 2) If highly inhomogenous systolic activation is documented by pulsed DTI, biventricular pacing should be taken into consideration to improve hemodynamics by synchronizing left ventricular myocardial systolic contractility. 3) Pulsed DTI technique may be the method of choice for selection of candidates for BVP and monitoring of cardiodynamics and hemodynamics changes during follow up.

151 Abnormal renal haemodynamics and neurohormones in heart failure patients treated with biventricular pacemakers

R. Chatoor, C. Bucknall, P. Holt. *Cardiology – 6th Floor East Wing, St Thomas' Hospital, London, UK*

Aim: Biventricular pacing improves symptoms and functional capacity in heart failure. There is however little information on its effect on the neurohumoral axis, which has clear prognostic implications.

Methods: We prospectively assessed atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP), endothelin-1 (E-1),plasma renin activity (PRA) and noradrenaline (N) levels in 14 patients who underwent biventriclar pacing for heart failure. All patients received a Medtronic Biventricular Pacing System programmed optimally. We also measured sodium excretion and creatinine clearance on 24 hour urine collections and performed cardiopulmonary exercise tests and echocardiograms.All tests were done at baseline, 1 and 3 months, with no changes in drug therapy during this period.

Results: There were notable correlations between neurhormones and echocardiographic parameters. ANP correlated with transmitral filling time ($r = -0.54$ $p = 0.06$),BNP with fractional shortening [FS] ($r = -0.49$ $p = 0.15$), E-1 with stroke distance ($r = -0.66$ $p = 0.02$) and filling time ($r = -0.67$, $p = 0.02$),noradrenaline with LV systolic dimension ($r = 0.58$, $p = 0.038$).

Results: These are summarised in the accompanying table.There were no significant changes in ANP, BNP, PRA, N or sodium excretion at 1 and 3 months.Endothelin-1 levels however rose significantly with a concurrent fall in creatinine clearance.

Neurohumeral changes

Parameter	Baseline	1 month	p value	3 months	p value
Exercise Duratn/min	6.4 ± 2.3	8.2+/3.2	0.05	8.7 ± 3.2	0.05
VO_2 max ml/kg/min	16.4 ± 5.2	19.9 ± 8.2	0.04	17.7 ± 6	0.03
FS /%	10 ± 2.6	13 ± 3.8	0.004	15 ± 1.8	0.04
ANP pg/ml	76 ± 30	88.6 ± 31	0.7	66 ± 38	0.5
BNP pg/ml	63 ± 40	73 ± 40	0.4	81 ± 30	0.7
E-1 pg/ml	5.7 ± 0.6	5.8 ± 0.8	0.65	6.2 ± 0.9	0.04
Noradrenaline nmol/ml	3.5 ± 1.6	3.4 ± 2	0.9	3.4 ± 11.9	0.2
Creat. Clearance ml/min	66 ± 28	57 ± 26	0.46	50 ± 29	0.08
Sodium Excretion/24 hr	84 ± 39	102 ± 58	0.15	101 ± 57	0.1

Conclusion: Despite significant haemodynamic improvement, these changes in glomerular filtration rate and endothelin levels, suggest an adverse effect of biventricular pacing. This may in part, explain the lack of prognostic benefit.

152 Is an altered heart rate increase responsible for the functional exercise capacity in dilated cardiomyopathy? Implications for rate adaptive pacing

B. Nowak, S. Geil, T. Lewalter[1], D. MacCarter[2], S. Genth-Zotz, O. Przibille, C. Zellerhoff, B. Lüderitz, J. Meyer. *II. Medical Clinic, University, Mainz; [1]Dept. of Cardiology, University of Bonn, Germany; [2]ELA Medical, Minneapolis MN, USA*

In pts. with dilated cardiomyopathy (DCM) the anaerobic threshold (AT) is frequently not detected due to reduced exercise capacity. We studied, whether those patients can be characterized by a different exercise heart rate (HR) response, offering the potential for therapy with rate adaptive pacemakers.

Methods: We studied 40 pts (31 m, 9 f, aged 50 ± 13 y) with DCM and an ejection fraction (EF) < 0.40 (0.27 ± 0.08). All were on stable medication consisting of digitalis, ACE-inhibitors and diuretics, but without beta-blocking agents. They performed a symptom-limited cardiopulmonary peak exercise test on the bicycle using a ramp protocol starting at 20 W with an increase of 10 W/min. The HR to work rate (WR) slope was determined using linear regression analysis.

Results: In group 1 (n = 16, EF 0.29 ± 0.09) exercise was terminated before the AT could be detected. The HR increased from a resting value of 90 ± 17 bpm to a maximum of 132 ± 22 bpm at a WR of 93 ± 31 W. In group 2 (n = 24, EF 0.27 ± 0.07) the HR at rest was 86 ± 15 (n.s.), and increased at AT to 114 ± 20 (WR: 73 ± 42 W) and at peak exercise to 138 ± 19 bpm (WR: 107 ± 50 W). In group 1 the HR/WR slope from rest to peak exercise was 0.54 ± 0.28 bpm/W. This slope was not different from those pts who achieved the AT: 0.62 ± 0.30 bpm/W, but was steeper than the slope known for normals with 0.37 ± 0.13 bpm/W. Above the AT to peak exercise, no further increase occurred in group 2: 0.68 ± 0.38 bpm/W (n.s.).

Conclusion: During exercise in patients with dilated cardiomyopathy, functional capacity is dependent upon an elevated heart rate increase relative to metabolic demand. Compared to values published for healthy subjects, both groups showed a steeper heart rate to work rate slope. Therefore a more agressive rate response factor programming is suggested in order to meet metabolic demands.

SINGLE AND MULTISITE PACING IN ATRIAL FIBRILLATION

153 Biatrial synchronous pacing for atrial arrhythmia prevention: the SYNBIAPACE Study

P. Mabo, V. Paul, W. Jung, J. Clémenty, A. Bouhour, J.C. Daubert. *Department of Cardiology, University Hospital, Rennes on behalf of the SYNBIAPACE Study Group, Rennes, France*

Biatrial synchronous pacing (BASP) was introduced some years ago as a new pacing modality for atrial arrhythmia (AA) prevention and was shown to be technically feasible and safe. The SYNBIAPACE Study was a prospective randomized crossover trial comparing 3 pacing modes during 3 periods of 3 months each: BASP at a basic pacing rate of 70 bpm, single site high right atrial DDD pacing à 70 bpm, and the same at 40 bpm ("inhibited" mode) used as reference mode. Criteria for inclusion were long lasting history (≥1 year) of recurrent and drug refractory AA associated with atrial conduction block as defined by a P wave duration ≥ 120 ms and by interatrial conduction time ≥ 100 ms. BASP was provided by using a specific coronary sinus lead (Medtronic SP 2188) and a specific algorithm loaded into the RAM memory of the device (Chorus 7034, Ela Medical). The primary end-point was to compare the time to first AA reccurence as monitored by the Holter functions of the pacemaker (specific algorithm of intracardiac electrogram storage) among the 3 pacing modes.

Results: 43 pts (M = 24; F = 19), mean age 64 ± 12 years, were included from March 1995 to December 1997. The mean P wave duration was 148 ± 31 ms.

	BASP	DDD 70	Inhibited
Time to 1st AA (days)	62 ± 24	37 ± 22	39 ± 22
Time in AA (days)	4 ± 10	7 ± 16	5 ± 13

Concerning the primary end-point no statistically significant difference was found between the 3 pacing modes.

Conclusion: despite a trend to a reduction in the incidence of AA during BASP, no real benefit of this pacing mode was demonstrated in this selected population.

154 Biatrial pacing as an effective therapy of lone atrial fibrillation

J. Witte, R. Reibis[1], H.J. Bondke, G. Baumann. *Medical Department I, Humboldt-University (Charité-Mitte), Berlin[1]Berlin, Germany*

For effective management of drug-refractory atrial fibrillation (AF) as the most common arrhythmia new methods are needed. In case of existing interatrial conduction disturbance the use of biatrial pacemaker with standart right atrial lead and additive coronary sinus lead for left atrial pacing shows an antiarrhythmic effect due to atrial resynchronisation. In order to demonstrate the antiarrhythmic effect of biatrial pacing from November 1997 to February 1999 51 pts. (19 f/32 m, mean age 63.6 ± 8.8 y) received a biatrial pacemaker (AAD-mode, AV-delay 0 msec., LOGOS, Fa. BIOTRONIK). All patients had a prolongation of P-wave duration more than 100 msec (mean 125 ± 21 msec).

Preoperatively 5/51 (9.8%) pts. had monthly, 31/51 pts. (61%) had weekly, and 9/51 pts. (17.6%) had daily episodes of atrial fibrillation. Permanent atrial fibrillation >6 month was seen in 3/51 pts. (5.8%, preoperative cardioversion) and syncopal episodes due to paroxymal AF in 3/51 (5.8%) pts.

The intraoperative right atrial pacing threshold was 0.95 ± 0.7 V (0.5 msec pulse width), the atrial signal amplitude 2.4 ± 0.9 mV. Voltage recording in the coronary sinus showed a pacing threshold of 1.5 ± 0.8 V (0.5 msec pulse width) and a potential of 3.5 ± 1.4 mV. The obtained P-wave duration reduced for 35 ± 20 msec.

In 9/51 pts. (17.6%) we found a dislocation and in 3/51 pts. (5.8%) an excessive high pacing threshold of coronary sinus lead >4 V/0.5 msec. All pts. with dislocated lead were reoperated. There were no perforations and thromboses of coronary sinus.

The intervention leads to a significant inhibition of atrial fibrillation in 15/51 pts. (29.4%) without and in 4/51 pts. (7.8%) with antiarrhythmic drugs. 18/51 pts. (35.2%) had a reduction of episodes without and 7/51 pts. (13.7%) with concomitant medication. The treatment did not have any influence on the prevalence of atrial fibrillation in 7/51 pts. (13.7%).

In conclusion, the implantation of biatrial pacemaker leads to a significant reduction of atrial fibrillation episodes and has proven practicable and safe for clinical use.

155 Prevention of atrial arrhythmias by overdriving and the rest rate: preliminary results from the PROVE study

R.C. Funck, A. Capucci[1], L. Kappenberger[2], L.C. Slegers[3], D. Galley[4], B. Kriebel[5], B. Maisch[5], A. Hümmer[6], E. Mouton[7]. *Clinic of Cardiology, Philipps University, Marburg, Germany; [1]Ospedale Civile, Piacenza, Italy[2]C.H.U.V., Lausanne, Switzerland[3]St. Joseph Ziekenhuis, Veldhoven, Netherlands[4]CHG, Albi, France[5]Clinic of Cardiology, Philipps University, Marburg[6]Ela Medical, Munich, Germany[7]Ela Medical, Paris, France*

In the literature short-term data suggest that atrial overdrive prevents or reduces atrial arrhythmia episodes (AA). The aim of the PROVE study is to evaluate this hypothesis in a population of patients (pts) implanted with Chorum® and Talent® pacemakers (Ela Medical Montrouge France) during 2 phases (I and II) of 3 months each.

Methods: All patients (pts) are monitored during 1 month (Phase 0) with the Memory Function (AIDA) of the pacemaker in order to identify the number of AA during this period.

Thereafter, the pts are classified in 2 classes and randomized with respect to the order in which two different pacemaker settings are applied. Class I (CI): pts with at least 2 fallback mode switch episodes and Class II (CII): all other pts.

Class I pts are programmed with a) their basic rates (BR) at 60 bpm or b) set with an atrial overdriving (O) at 10 bpm over the mean atrial rate stored by AIDA, with the automatic rest rate being activated, and the rate responsive mode enabled.

Class II pts are programmed c) with a higher basic rate of 70 bpm associated with the rest rate in comparison to d) a standard DDD(R) programming at 60 bpm. Within each group the two pacemaker settings are applied in a random order. The results of Phase I are compared to Phase II within both classes of pts. AIDA is activated during the entire study.

39 patients (pts) were included: 14 in CI (5 males, 73 ± 7.8 years), 1 had AV block (AVB), 4 sinus node dysfunction (SND), 4 brady-tachy syndrome (BTS), 4 AV block and SND, 1 other indication implantation. 11 pts had a previous history of AA and 10 pts received antiarrhythmic drugs (AAD). 25 pts were included in CII (17 males, 72.2 ± 7.1 years), 8 had AVB, 9 SND, 2 BTS, 6 AVB and SND. 7 pts had a previous history of AA and 11 pts received AAD.

Results: 12 out of 14 pts of CI developed AA during both phase I and II. During the phase with *O* the number of fallbacks (FMS) was reduced by 58% (62 to 44) and the total duration of the episodes by 72%. In CII only 1 pt developed AA during both phases and 3 pts developed AA in one phase.

Conclusion: These preliminary results seem to show that Overdriving combined with automatic Rest Rate are useful to prevent AA since they reduce the number of FMS by 58% and the total duration of the episodes by 72%. More data have to be collected before statistical significance and definite conclusions can be given.

156 Long-term results of a pilot study on biatrial synchronous pacing for prevention of drug-refractory atrial tachyarrhythmias

G. Revault d'Allonnes, F. Victor, D. Pavin, P. Mabo, J.C. Daubert, C. Leclercq. *Department of Cardiology, University Hospital, Rennes, France*

Results of previous studies suggest that atrial resynchronization with multisite atrial pacing may contribute to prevent recurrences in pts with drug-refractory atrial tachyarrhythmias (AT) and significant atrial conduction block.

To assess this hypothesis, a pilot study was conducted in a single center between Jan. 1989 and Nov. 1997 in 86 pts, mean age 66 ± 10 yrs. Inclusion criteria were P-wave duration ≥ 120 ms with interatrial conduction time ≥ 100 ms, and history of multiple recurences of AT (mean = 7 ± 3 episodes) evolving in a persistent mode from at least 6 months despite optimized drug treatment (mean = 2.7 ± 1/pt). Pts were chronically implanted with a pacing system providing permanent biatrial pacing with two atrial leads, one placed in the high right atrium and the other into the mid or distal part of CS. P wave duration decreased from a mean value of 187 ± 29 ms before implant to 106 ± 14 ms ($p < 0.0001$) during biatrial pacing.

After a mean follow-up time of 33 months (range: 6–109), 55 pts (64%) remained in stable sinus rhythm, including 28 pts (32.6%) without any documented recurrence and 27 pts with one or more recurrences in a paroxysmal or in a persistent form. In those pts, drug treatment was significantly reduced in comparison with the pre-implantation period (1.4 ± 0.6 vs 1.7 ± 0.5 drug/pt; $p = 0.01$). Other 31 pts went to chronic AT after a mean time of 26 months. The only predictive factor of positive response was P wave duration > 160 ms at baseline.

These results are consistent with a preventive effect of permanent biatrial pacing in recurrent and drug-refractory AT associated with atrial conduction block.

157 Coronary sinus – a site for chronic left atrial pacing? An electrophysiological and anatomical study

J. Neuzner, B. Weuster[1], H.F. Pitschner, R.M. Bohle[1]. *Kerckhoff-Klinik, Bad Nauheim; [1]Institut für Pathologie der Justus Liebig Universität, Gießen, Germany*

Multisite pacing strategies for prevention of atrial tachyarrhythmias may include left atrial pacing via the coronary sinus (CS). The aim of the study was to evaluate the electrophysiological and anatomical conditions of the CS with respect to chronic pacing therapy.

Methods: EP-study: 20 consecutive patients were studied during a routine EP-study. The left atrial and ventricular pacing thresholds (LAP/LVP), and signal amplitudes (LAA/LVA) were measured in four different parts of the CS using steerable EP catheters. Pathology: Formalin-fixed postmortem hearts of 40 adults (age: 17–78 years; weight: 250–910 g) were evaluated. CS, adjacent epi- and myocardium were dissected from the AV sulcus and completely cross sectioned in 3–4 mm thick tissue blocks (HE, Goldner's, Trichrome).

Results:

	Posterior CS	Post-lateral CS	Lateral CS	Antero-lat. CS
LAP (V/0.5)	1.0 ± 0.4	1.6 ± 1.3	3.8 ± 2.0	4.1 ± 1.3
LVP (V/0.5)	>7.5	>7.5	5.0	6.1 ± 0.4
LAA (mV)	2.9 ± 1.0	2.9 ± 1.2	1.5 ± 0.8	1.4 ± 0.8
LVA-(mV)	0.4 ± 0.4	0.6 ± 0.5	0.9 ± 0.6	1.2 ± 0.8

Histological examinations show that the CS was concentrically surrounded by cardiac muscle tissue from the os to the lateral aspect of the CS but not in lateral and anterolateral parts of the CS. Cardiac muscle surrounding the CS were connected to LA myocardium. The length of "muscularized" CS, ranging from 1.9 to 5.4 cm, was correlated with the heart weight ($r = 0.54$; $p < 0.001$).

Conclusions: The differences in proximal and distal sections of the CS wall regarding muscular connections to LA myocardium is the explanation for the observed increase in LA-pacing thresholds and reduction in LA signal amplitudes in the more distally parts of the CS. These findings may have importance for the design of chronic pacing leads for LA-pacing via the CS.

158 To prevent or to induce fibrillation? A new concept in the non-pharmacological therapy of refractory paroxysmal atrial fibrillation

Jean-François Leclercq, Olivier Thomas, Patrick Attuel, Antoine Leenhardt, Philippe Coumel. *Lariboisière University Hospital, Paris; Val D'Or Center, Saint Cloud, France*

The benefit of atrial pacing (AP) in preventing atrial fibrillation (AF) has been suggested only for patients (pts) with sick sinus syndrome and vagally-induced AF. We tried AP in 25 highly symptomatic pts (18 m., 7 f., aged 65 ± 11 years) with paroxysmal AF and normal sinus node, occurring at least weekly despite drug treatment of amiodarone + flecainide. A 4-step protocol was used:

- implant of a DDD-R pacemaker with 75 bpm minimal rate
- specific pause-prevention algorithm (Medtronic Inc)
- induction of AF by repetitive systematic 64 Hz atrial pacing
- His bundle ablation (HBA) procedure.

Each step of the protocol was done in case of persistance of symptoms and documented AF with the previous one.

After a follow-up of 12.5 ± 5 months, simple AP was clinically efficient in 17 pts. Pause-prevention algorithm was efficient in 1 case, and 3 pts developped spontaneous permanent AF, with a clinical improvement due to relief of palpitations. One pt refused AF-induction step and preferred HBA. Only 3 pts reached AF-induction step. It was efficient in only 1 pt but sinus rhythm recurred 1 week after cessation of 64 Hz pacing; in 1 pt AF could be induced only at night, and in the 3rd pt only atrial tachycardia was obtained, without true AF.

Conclusion: A preventive effect of AP is frequent, even in non bradycardia-dependent AF and should be systematically tried before HBA. Induction of permanent AF, desirable in some pts to decrease symptoms, is not so easy than expected from animal experiments, suggesting a lack of remodelling process in highly diseased atria.

ATRIAL BEHAVIOUR AFTER ELECTRICAL CARDIOVERSION

159 Antiarrhythmic drug effect on the left atrial mechanical properties post electrical cardioversion of persistent atrial fibrillation

E. Sotiropoulos, C. Avgeropoulou, K. Gatzoulis, D. Chrissos, G. Andrikopoulos, G. Zervopoulos, D. Richter, A. Androulakis, J. Gialafos.
State Cardiac Department, Hippokration Hospital, Athens, Greece

The atrial contractility is known to improve after electrical cardioversion (EC of atrial fibrillation (AF). We investigated the effect of antiarrhythic drugs prescribed to maintain sinus rhythm (SR) on the mechanical properties of the left atrium (LA) in patients (pts) with persistent AF.

Methods: Fifty-seven pts, 34 males (mean age 61 ± 8 years), underwent EC for AF (mean duration 3.9 ± 3 months). Pts with LVEF < 40%, LA > 55 mm, thyrotoxicosis, unstable coronary artery disease or valvular heart disease were excluded. The pts were allocated to propafenone (n = 23), sotalol (n = 12) and amiodarone (n = 18). Left atrial active emptying (LAAE), atrial wave flow velocity integral (LAFV), pulmonary vein atrial reverse velocity (PVAR) and pulmonary vein systolic wave integral (PVSW) were prospectively evaluated at 0, 15, 30 and 90 days post cardioversion.

Results: Of the 57 pts, 53 were successfully cardioverted and after a follow up period of 13 ± 6 months, 25 (47.2%) of the cardioverted pts maintained SR. Mean age, LVEF, LA size, AF duration, electrical energy required and SR maintenance rate were not significantly different between the three groups.

		Day 0	Day 15	Day 30	Day 90	0 vs 15	15 vs 90
Group 1	LAAE (%)	14 ± 9	28 ± 12	32 ± 11	32 ± 15	0.006	0.647
(Propafe	LAFV (cm)	3.1 ± 1.7	5.9 ± 1.1	6.7 ± 2.1	6.7 ± 2.2	0.007	0.552
none)	PVAR (cm/s)	5 ± 9	26 ± 4	29 ± 7	27 ± 5	0.001	0.631
	PVSW (cm)	6 ± 4	14 ± 2	17 ± 6	19 ± 6	0.001	0.115
Group 2	LAAE (%)	11 ± 5	23 ± 10	35 ± 6	29 ± 6	0.044	0.298
(Sotalol)	LAFV (cm)	1.7 ± 1.2	4.7 ± 0.5	5.3 ± 0.5	5.5 ± 0.8	0.011	0.302
	PVAR (cm/s)	10 ± 16	7 ± 14	30 ± 4	29 ± 7	0.109	0.228
	PVSW (cm)	9 ± 5	16 ± 3	17 ± 4	15 ± 6	0.123	0.935
Group 3	LAAE (%)	8 ± 9	25 ± 11	28 ± 6	33 ± 10	0.022	0.028
(Amioda	LAFV (cm)	2.8 ± 3.0	5.4 ± 0.7	7.3 ± 2.7	7.4 ± 2.1	0.085	0.054
none)	PVAR (cm/s)	16 ± 5	28 ± 5	31 ± 6	28 ± 3	0.088	0.526
	PVSW (cm)	10 ± 6	16 ± 6	17 ± 6	16 ± 5	0.002	0.601

Conclusions: 1) Left atrial contractility seems to already improve by day 15 post cardioversion. 2) However, in propafenone and sotalol groups it flattens out after day 15, possibly due to the drugs' negative inotropic effect. 3) On the contrary amiodarone seems to continue to exert its beneficial effect until day 90.

160 Postcardioversion atrial stunning after electrical cardioversion is caused by atrial fibrillation itself

R. Rabahieh, W. Jung, H. Omran, C. Wolpert, S. Spehl, B. Schumacher, B. Lüderitz. *Department of Cardiology, University of Bonn, Bonn, Germany*

Background: Electrical cardioversion of atrial fibrillation may cause postcardioversion atrial stunning. The hypothesis of this prospective study was that atrial chamber and appendage stunning after electrical cardioversion is not caused by the applied energy but is related to the duration of atrial fibrillation (AF).

Methods: Transesophageal echocardiography (TEE) was performed in 9 patients with acute AF (duration 14 ± 3 h) and 9 patients with chronic AF (127 ± 104 days) to assess the effect of electrical shocks on left atrial chamber and appendage function. Peak emptying velocities of the left atrial appendage (LAAv) and spontaneous echo contrast (SEC) were assessed before and after the procedure. Seven patients with paroxysmal AF and spontaneous restoration of sinus rhythm (SR) during a TEE examination served as controls.

Results: In patients with spontaneous cardioversion, SEC was detected neither before nor after restoration of SR. In addition, LAAv were not affected by spontaneous restoration of SR (0.7 ± 0.13 m/s versus 0.7 ± 0.14 m/s). Likewise, restoration of SR after electrical cardioversion of acute AF did not affect the degree of SEC and LAAv (0.61 ± 0.15 versus 0.57 ± 0.22). In contrast cardioversion of chronic AF resulted in the intensification and/or generation of SEC in 5 of 9 patients and LAAv decreased from 0.36 ± 0.11 m/s to 0.25 ± 0.09 m/s (p = 0.002) after the procedure. Furthermore, ineffective shocks during both acute and chronic AF affected neither LAAv nor SEC.

Conclusions: Atrial chamber and appendage stunning after electrical cardioversion is caused by AF itself and is related to its duration. These findings have important clinical implications for anticoagulation therapy in patients with paroxysmal AF.

161 Transthoracic echocardiography for the exclusion of left atrial chamber and appendage thrombi before cardioversion of atrial fibrillation/flutter

H. Omran, W. Jung, R. Schimpf, R. Rabahieh, S. Illien, C. Troatz, B. Lüderitz.
Department of Cardiology, University of Bonn, Bonn, Germany

Background and methods: Transesophageal echocardiography (TEE) prior to cardioversion of atrial fibrillation (AF) is a reliable but expensive procedure to exclude atrial thrombi. To evaluate the value of current transthoracic echocardiographic systems (TTE) and TEE for detecting atrial thrombi and assessing atrial function prior to cardioversion, 87 patients with atrial fibrillation (AF) and 32 patients with atrial flutter (AFl) were investigated prior to the procedure by two different investigators by both methods.

Results: Transthoracic imaging of the atrium was considered adequate in 75 of 87 patients with AF and in 28 of 32 cases with AFl. In patients with AF, TTE disclosed 5 thrombi in the left atrium. In patients with AFl thrombi were not detected. The transthoracic exclusion and detection of thrombi were confirmed by TEE in all cases with adequate transthoracic echogenicity. In patients with transthoracic exclusion of atrial thrombi, thromboembolic complications after cardioversion did not occur. Transthoracic recording of the flow velocity profile over the appendage was feasible in 69 patients with AF (0.36 ± 0.16 m/s) and in 27 patients with AFl (0.48 ± 0.12 m/s).

Conclusions: If transthoracic echogenicity of patients is optimal, new generation transthoracic echocardiographic systems allow the detection or exclusion of atrial thrombi with a high degree of confidence prior to cardioversion. TEE examinations may therefore be limited to cases of suboptimal transthoracic imaging or where there is clinical concern despite negative transthoracic results.

162 Coagulation indicators in patients with non-valvular atrial fibrillation: a comparison with transoesophageal echocardiography (a prospective 4 years study)

C. Pandullo, C. Giansante[1], N. Fiotti[1], C. Mazzone[2], S. Scardi[2], G. Guarnieri[1]. *Trieste; [1]University of Trieste, Institute of Clinical Medicine, Trieste[2]Centro Cardiovascolare, Trieste, Italy*

Background: Both left atrial appendage (LAA) spontaneous echo contrast and thrombus are associated with major risk of thromboembolism in patients (P) with nonvalvular atrial fibrillation (NVAF). However, their coagulation determinantshave not been fully elucidated. Furthermore, the predictive value of coagulation indicators has not been yet explored in term of thromboembolic events.

Aim of the study. (a) To verify whether NVAF is associated with abnormalities of fibrinogen, D-dimer and fibrinopeptide A (FpA)plasma levels;

(b) to verify if there is a relationship between those coagulation indicators and echocardiographic finding of LAA thrombosis or prothrombotic condition;

(c) to verify whether echo data, D-dimer or Fibrinopeptide A can be usefull predictors of thromboembolic events.

Methods: We determined fibrinogen, D-dimer and FpA in 77 consecutive P with chronic NVAF who were undergoing to TEE the same day and in 117 matched controls. P were followed for a 4-years period.

Results: LAA thombus was found in 27 P (35%), a spontaneous echocontrast alone in 14 P (18%). Fibrinogen, D-dimer and FpA were significantly higher in study population than in control group (Fibrinogen 335 ± 106 vs 283 ± 71 mg/dl $p < 0.05$, D-dimer 436 ± 271 vs 306 ± 271 ng/ml $p < 0.01$, FpA 8.6 ± 6.2 vs 2.0 ± 0.4 ng/ml $p < 0.001$).

In study population P with LAA had higher FpA plasma levels (10.2 ± 3.5 vs 5.3 ± 2.5 ng/ml $p < 0.01$).

Thromboembolic events: P with a lower LAA flow profile during the follow up demonstrated a relative risk of 2.0; P within the upper tertile of FpA have a relative risk of 8.2 times.

Conclusions: Abnormal plasma levels of fibrinogen, D-dimer and FpA indicate that the coagulation system is activated in P with chronic NVAF.

FpA plasma levels are significantly higher in P with LAA thrombosis than in other groups. FpA is the most efficient predictors of embolic events after 4-years follow up.

163 The role of transthoracic echocardiography before cardioversion of atrial fibrillation in patients at low thromboembolic risk

G. Marti, G. Sarasso, M. Pistono, C. Pedrigi, L. Airoldi, M. Rizzotti, P. Paffoni, C. Vassanelli. *Divisione Chnicizzata di Cardiologia, Ospedale Maggiore e Università degli Studi del Piemonte Orientale, Novara, Italy*

Transesophageal echocardiography (TEE) is currently used to identify patients (pts) with atrial fibrillation (AF) at low risk for embolism after cardioversion (CV). However, TEE is not always available and feasible; moreover, pts without significant heart disease are considered to be at low thromboembolic risk even in the setting of AF $\geq$ 3 days. In this subset of pts also transthoracic echocardiography (TTE) might accurately identify pts at low risk cadidates to short-term anticoagulation for CV. On January 1998 we started a prospective protocol aimed to evaluate the safety of CV for AF after short-term anticoagulation with warfarin (plus calcic heparin until INR > 2.0) if admission TTE ruled out mitral stenosis, significant mitral regurgitation, left atrial size (LAS) > 50 mm, left ventricular end-diastolic diameter (LVEDD) > 60 mm, ejection fraction (EF) < 45%, or other significant heart disease. Evidence of heart failure, previous thromboembolism, or stroke were also exclusion criteria. We identified 51 out of 172 consecutive pts (mean age 69.2 $\pm$ 11.0 years, 24 males, 27 females) with AF $\geq$ 3 days (mean 24.0 $\pm$ 45.4 days), who underwent successful CV (pharmacological 25, electrical 26); 33 (65%) pts were hypertensive. Mean LAS was 46 $\pm$ 3 mm, mean LVEDD 53 $\pm$ 3 mm, mean EF 51 $\pm$ 3%. TEE was also performed in 15 pts (30%) and in no case showed left atrial thrombus or features contraindicating CV. The mean duration of pre-CV anticoagulation was 3.8 $\pm$ 3.1 days; No patient had in-hospital complications. The length of hospital stay was 4.1 $\pm$ 1.0 days. Oral anticoagulation continued for 18 $\pm$ 9 days after CV. At follow-up (mean 80 $\pm$ 42 days) no thromboembolic or hemorrhagic complications occurred; 38 pts (75%) were free of recurrence of AF or new hospitalizations for cardiac causes. In conclusion, TTE can accurately identify pts at low thromboembolic risk who can receive short anticoagulation for CV. However, larger prospective randomized trials are warranted.

164 Antioxidant therapy can influence the recovery of left atrial contraction after external electrical cardioversion

G.M. Costa, C. Pizzi, L. Gabrieli, O. Manfrini, G.L. Magri, E. Cordioli, A. Borghi, R. Bugiardini. *Service of Cardiological Intensive Care, University of Bologna, Italy*

Recent studies have shown that in pts. with atrial fibrillation (AF), external electrical cardioversion (EEC) induces a state of atrial stunning that follows for several days. It is well known that direct current (DC) shock generates free radicals that may contribute to atrial mechanical dysfunction. The aim of the study was to evaluate the effects of an antioxidant therapy on atrial function recovery in pts. with non rheumatic AF.

Methods: we enrolled 51 consecutive pts. who underwent successful EC for AF. A standard medical treatment was given in 25 pts. (G1). Three days before EC the remaining 26 pts. (G2) received an antioxidant therapy (Glucose 20% 500 cc with regular insuline 20 UI, K+ 40 mEq, MgSO4 24 mMol, vitamine C 2 gr). A single 25 mg dose of Captopril before EEC and Vitamin E 300 mg/die during the following 21 days was also given. Pulsed doppler indices of left atrial mechanical function were measured within 1 hour (T0), at 1 day (T1), three days (T2), one week (T3), and three weeks (T4) after DC shock.

Results: At T1 and T2 G2 showed a significant increase ($^*p < 0.001$) of peak A wave velocity (PA), integrated late atrial velocities (A-VTI), atrial contribution to total transmitral flow (AVTI/VTI), and atrial ejection force (AEF). At T4 there was no more significant difference betwen G1 and G2.

	T0		T1		T2		T3		T4	
	G1	G2	G1	G2	G1	G2	G1	G2	G1	G2
PA	39±3	38±4	46±6	53±5*	50±4	62±5*	61±4	63±6	62±5	64±4
AVTI	5±2	5±4	5.7±2	6±2*	5.2±2	6.5±2*	6.5±2	6.8±2	6.6±2	6.9±2
AVTI/VTI	28±5	28±5	29±5	33±5*	30±4	35±4*	35±3	36±2	36±3	36±4
AEF	5±2	4.8±2	5±3	8±3*	6±2	10±3*	10±3	13±4*	13±2	14±3

Conclusions: Our findings suggest that an antioxidant therapy can accelerate atrial mechanical recovery from stunning after EEC. This could have a favorable impact on the risk of embolic complications due to atrial disfunction following EEC.

ARRHYTHMIAS IN ISCHAEMIC AND NON-ISCHAEMIC CARDIOMYOPATHIES

165 QT interval dynamicity in idiopathic dilated cardiomyopathy: relationships with haemodynamic status and prognostic value

L. Fauchier, D. Babuty, M.L. Autret, P. Poret, P. Cosnay, J.P. Fauchier. *Service de Cardiologie B, Trousseau University Hospital, Tours, France*

QT dispersion has shown to be a poor predictor of cardiac death in patients with idiopathic dilated cardiomyopathy (IDC). QT interval dynamicity has been proposed as another tool for assessment of the risk of cardiac events or ventricular arrhythmias. This study evaluated the relationships of QT interval dynamicity with hemodynamic status and assessed its usefulness for risk stratification in patients with IDC.

Methods: We performed 24-h ECG recording in 100 patients with IDC who were in sinus rhythm (WHO criteria; mean age 50 years; range 18–70; 75 men; left ventricular ejection fraction 35 $\pm$ 12%) and in 60 healthy subjects. The QT intervals (QT end and QT apex) were measured automatically with a validated computerized Holter system (Elatec, Ela medical, France). The rate dependence of repolarization was evaluated over 24 hours, during a daytime period (9 AM–9 PM) and during a nighttime period (11 PM–6 AM) with measurement of QT/RR slopes.

Results: QTend/RR slopes (24 hours, day and night) were significantly increased in patients with IDC ($p < 0.001$) whereas QTapex/RR slopes were not different from control subjects. All the QT/RR slopes were related to left ventricular end systolic diameter (R range 0.22 to 0.36, p = 0.04 to 0.001) and inversely related to left ventricular ejection fraction (R range −0.25 to −0.47, p = 0.03 to 0.0001). With a follow-up of 54 $\pm$ 39 months, 15 patients died (10 progressive CHF, 5 sudden deaths) and 11 underwent heart transplantation. Among QTc durations and QT/RR slopes, using multivariate analysis (proportional hazards model), the only independent predictor of cardiac events (cardiac death or heart transplantation) was an increased QT end/RR slope during the daytime period (p = 0.02). For this parameter, a cutoff level of 0.22 distinguished 2 groups of patients with significantly different survival curves of cardiac events (p = 0.008).

Conclusions: QT dynamicity is related to the hemodynamic status and provides a risk stratification of cardiac events in patients with IDC. Among the several parameters of QT interval dynamicity, an increased QT end/RR slope during the daytime is the most powerful predictor of cardiac events in these patients.

166 Clinical relevance of heart rate variability versus repolarization dispersion for the non-invasive electrocardiographic risk stratification in patients with ischaemic cardiomyopathy

A. Meissner, J.-Y. Min, N-E. El-Mokhtari, B. Hayen, R. Simon. *Department of Cardiology, University of Kiel, Germany*

Heart rate variability (HRV) as well as repolarization dispersion (QT/JT dispersion) have been proposed as non-invasive risk indicators in patients (pts) with ischemic cardiomyopathy (ICM) but their prognostic value as predictors of sudden cardiac death and pump failure death remains controversial. The aim of the present prospective study was to assess the clinical relevance of HRV versus QT/JT dispersion in predicting cardiac events in ICM pts with chronic heart failure.

Methods and Results: A total of 115 pts with ICM and a left ventricular ejection fraction (LVEF) < 40% were included between June 1995 and March 1998. During follow-up (21 $\pm$ 11 months, range 3–38 months), 9 pts died of sudden cardiac death, 9 pts had ventricular tachyarrhythmic events, 8 pts died of pump failure death and 10 pts had a heart transplantation. Kaplan-Meier analysis and Cox regression model identified SDNN and QTd/JTd as the most predictive parameters for all cardiac events. However, none of the tested parameters proved to be sensitive for predicting sudden cardiac death.

	Dichotomy points	Log rank	P value
JTd	≥70 ms	13.01	0.0003
QTd	≥80 ms	10.4	0.0008
SDNN	≤100 ms	8.65	0.0017
LnLF	≤2.5	6.89	0.0022
LVEF	≤25%	6.46	0.0028
PCWPm	≥15 mmHg	3.08	0.032

JTd = JT interval dispersion, QTd = QT interval dispersion, SDNN = standard deviation of normal-to-normal RR intervals, LnLF = natural log of low frequency power, PCWPm = mean pulmonary capillary wedge pressure.

Conclusion: HRV and QT/JT dispersion are sensitive and equipotent parameters for the assessment of over-all cardiac risk in pts with ischemic cardiomyopathy.

167 Improved predictive ability of signal-averaged electrocardiogram by combined time and frequency domain analysis in patients with ischaemic cardiomyopathy

A. Economou, G. Kazianis, S. Feggos. *Cardiology Department, 7th IKA Hospital, Athens, Greece*

Background: Although the prognostic value of late potential (LP) in signal-averaged electrocardiogram (SAECG) following acute myocardial infarction (AMI) is well established the independent prognostic significance of SAECG is controversial. The aim of this study was to assess the prognostic value of an abnormal SAECG in time domain (Td) or frequency domain (Fd) analysis in pts with ischemic cardiomyopathy.

Methods: We prospectively studied 310 consecutive pts in sinus rhythm, aged 63.6 ± 0.58 (SE) yrs, with ischemic cardiomyopathy due to an old (>6 months from acute phase) myocardial infarction and echocardiographically estimated EF < 35%. Pts with atrial fibrillation were excluded. SAECG (ART, 40 Hz filtered, noise < 0.5 μV) was recorded in all pts. As LP in Td analysis in pts with QRS in surface ECG < 120 ms the following values were taken fQRS > 114 ms and either LAS > 38 ms or RMS < 20 μV whereas in pts with QRS ≥ 120 ms values were taken fQRS > 155 ms and either LAS > 55 ms or RMS < 17 μV. In Fd analysis spectral, temporal mapping (STM) was considered abnormal (abn) if a normality factor of <30% was derived from analysis (ART, FFT plus, TM software) of x, y or z lead. Eighty-two pts had prior CABG surgery. The infact size was estimated from surface ECG by QRS score based on Q and R wave duration and R/Q and R/S ratio.*

Results: During a follow-up period of 32.45 ± 1.27 (SE) months there were 119 (38.3%) cardiac deaths. In univariate analysis the following parameters were significant predictors of mortality: age, EF, absence of CABG, fQRS, RMS, FFT plus Y, LP, STM and the combination of LP + STM. In multivariate logistic regression analysis the independent predictors, in the following order of importance, were: age (x^2 = 25.6, p = 0.000), EF (x^2 = 16.36, p = 0.000), combined LP and abnSTM (x^2 = 11.4, p = 0.0008), CABG negatively (x^2 = 5.44, p = 0.020), LP (x^2 = 4.88, p = 0.027) and abnSTM (x^2 = 4.85, p = 0.028).

Conclusions: In pts with ischemic cardiomyopathy in addition to age and EF the combination of LP and abn STM is the next most powerful independent predictor of mortality. The combined Td and Fd analysis improve the prog-nostic value of SAEG.

168 Arrhythmia risk stratification in idiopathic dilated cardiomyopathy based on echocardiography, ECG, signal-averaged ECG and 24-hour Holter ECG

W. Grimm, J. Hoffmann, V. Menz, C. Glaveris, H.H. Müller[1], G. Hufnagel, B. Maisch. *Department of Cardiology; [1]Medical Center for Methodology and Health Research, Institute of Medical Biometry and Epidemiology, Philipps-University of Marburg, Marburg, Germany*

This prospective observational study was designed to investigate prediction of arrhythmic events in idiopathic dilated cardiomyopathy (IDC) by the following 11 predefined variables: age, gender, NYHA class, LV end-diastolic dimension (LVEDD) and LV ejection fraction (EF) by echocardiography, atrial fibrillation and left bundle branch block on ECG, time domain and spectral turbulance analysis of the signal-averaged ECG, frequent VPDs and nonsustained VT (NSVT) on Holter.

Methods: Between 1992 and 1997, 202 patients with IDC (age: 50 ± 13 years, EF: 30 ± 10%) without previous sustained VT or VF and without antiarrhythmic drugs were prospectively enrolled in this study.

Results: During 32 ± 15 months follow-up, arrhythmic events including sustained VT, VF or sudden death occurred in 32 pts (16%). By multivariate Cox regression analysis, after adjustment for medical therapy including antiarrhythmic drug treatment during follow-up, only LVEDD ≥ 70 mm and NSVT on Holter were identified as significant arrhythmia risk predictors: relative risk (RR) for LVEDD ≥ 70 mm: 2.8 (95% CI: 1.2–6.5, p = 0.015); RR for NSVT: 5.1 (95% CI: 2.3–11, p = 0.0001); RR for the combination of LVEDD ≥ 70 mm and NSVT: 14 (95% CI: 2.3–90). When EF ≤ 30% was forced to remain in the Cox regression model, only EF ≤ 30% and NSVT on Holter were found to be significant arrhythmia risk predictors: RR for EF ≤ 30%: 2.7 (95% CI: 1.1–6.5, p = 0.028); RR for NSVT: 5.4 (2.2–11, p = 0.0001), and RR for the combination of EF ≤ 30% and NSVT: 14 (95% CI: 2.2–97).

Conclusions: The combination of LVEDD ≥ 70 mm and NSVT as well as EF ≤ 30% and NSVT identify a subgroup of patients with IDC with a 14-fold increased risk for subsequent arrhythmic events. These findings have important implications for the design of future studies evaluating the role of prophylactic defibrillator therapy in IDC.

169 Heart rate variability and risk stratification for major arrhythmic events in idiopathic dilated cardiomyopathy

L. Fauchier, D. Babuty, P. Poret, M.L. Autret, J.P. Fauchier, P. Cosnay. *Service de Cardiologie B, Trousseau University Hospital, Tours, France*

Previous studies have shown that heart rate variability could predict arrhythmic events and sudden death in post infarction patients, but the prognostic value of heart rate variability for arrhythmic events or sudden death in patients with idiopathic dilated cardiomyopathy has not been established. This study was designed to evaluate the prognostic value of heart rate variability for sudden death, resuscitated ventricular fibrillation or sustained ventricular tachycardia in patients with idiopathic dilated cardiomyopathy. Time and frequency domain analysis of heart rate variability on 24-h electrocardiographic (ECG) recording was assessed in 116 patients with idiopathic dilated cardiomyopathy (WHO criteria, 91 men, age 51 ± 12 years, range 18–70; left ventricular ejection fraction 34 ± 12%). Patients had conventional treatment with ACE inhibitors, diuretics and/or digoxin.

Results: Mean follow-up was 53 ± 39 months. Sixteen patients reached one of the defined study end points (sudden death, resuscitated ventricular fibrillation or sustained ventricular tachycardia) during follow-up. Using multivariate analysis, only reduced SDNN (p = 0.02) and ventricular tachycardia during 24-h ECG recording (p = 0.02) predicted sudden death and/or arrhythmic events. For SDNN, a cutoff level of 100 ms seemed the best for the risk stratification.

Conclusion: This study is the first one to suggest that a decrease in heart rate variability is an independent predictor of arrhythmic events and sudden death in idiopathic dilated cardiomyopathy, whether the mechanism of sudden death is ventricular tachyarrhythmia or not, and to suggest that this method is of interest for stratification of major arrhythmic events in CHF without coronary artery disease.

170 Non-invasive identification of patients prone to ventricular fibrillation with dilated cardiomyopathy even in the presence of bundle-branch block or atrial fibrillation by T-wave spectral variance

P. Steinbigler, R. Haberl, A. Spiegl, G. Jilge, E. Moroder, M. Trautnitz, W. von Scheidt, G. Steinbeck. *Medical Hospital I, University of Munich, Munich, Germany*

Background: Conventional noninvasive risk stratification by Holter-ECG-recordings in patients with dilated cardiomyopathy prone to ventricular fibrillation (VF) having atrial fibrillation (AF) or bundle branch block (BBB) is difficult. We therefore investigated whether spectral assessment of beat-to-beat alternations of repolarisation in these patients is associated with ventricular fibrillation.

Methods: Twenty-four hour ECG-Holter recordings in 60 patients with dilative cardiomyopathy were used. 30 patients survived VF and 30 patients had no VF. In each group 10 patients had AF, 10 had BBB and 10 had sinus rhythm and no BBB. In each patient 1024 consecutive T-waves were aligned using cross-correlation methods. Two-dimensional Fourier transform (2D-FFT) uses the data matrix of 1024 consecutive 200 ms-segments centred to the T-wave peak. Power spectra of the 2D-FFT revealed the frequency content of the T-wave in the 1.dimension and the periodicity of this frequency content in the 2.dimension. The ratio between periodic frequency contents and the sum of non-periodic and periodic frequency contents between 0.5 and 50 Hz gives the T-wave-spectral variance (TWSV). Thereby TWSV = 0 means all 1024 T-waves identical and TWSV = 1 means 1024 T-waves are totally variable.

Results: The TWSV was significantly higher in patients with VF (0.93 ± 0.14) than in patients without VF (0.53 ± 0.13, p < 0.01). The best cut-off between patients with and without VF was TWSV = 0.75 (sensitivity = 89%, specificity = 86%). However, no significant differences were observed between patients with and without AF or with and without BBB.

Conclusions: Thus, spectral assessment of T-wave alternations by TWSV using two-dimensional fast Fourier transform in Holter-ECG recordings allows to identify patients with dilated cardiomyopathy at risk of VF even in the presence of BBB or AF.

INFECTION AND INFLAMMATION IN CORONARY ARTERY DISEASE

184 Fibrinogen correlates with angiographically proven extent of coronary artey disease: cause or consequence? Evaluation of a possible mediator role of inflammation markers and adhesions molecules

S. Blankenberg, H.J. Rupprecht, C. Bickel, C. Espinola-Klein, G. Hafner[1], G. Rippin, N. Meciki, J. Meyer. *II. Medical Clinic; [1]Clinic of Clinical Chemistry, University-Clinic Mainz, Germany*

Background: Fibrinogen (fib) is established as an independent risk factor for developement of coronary artery disease (CAD). An increase of fib serum level in acute coronary syndrome and an influence on the degree of restenosis after PTCA has already been demonstrated. We evaluated the influence of fib on the extent of angiographically proven atherosclerosis and the influence of elevated fibrinogen levels on inflammation markers and upregulation of adhesion molecules.

Methods: 1033 patients (pts) admitted to our hospital with suspected CAD underwent angiography. Vessel disease (VD) was defined as at least one stenosis > 50%. We divided pts in having 0 (without CAD), 1, 2, and 3 VD. Before angiography we determined serum levels of fibrinogen [mg/dl], soluble Intracellular Adhesion Molecule (sICAM) [ng/ml], high-sensitive C-reaktive Protein (CRP) [mg/l] and Tumor Necrosis Faktor α (TNF) [pg/ml].

Results: In 874 (84.6%) CAD could be evidenced. In pts without CAD geometric mean of fib was 310 (*25/75% percentile:* 265/352), in 1 VD 324 (274/387), 2 VD 342 (289/435), and 3 VD 342 (287/423) (p = 0.001; Jonckheere Terpstra Test). Elevated levels of fib correlate with the elevation of inflammation markers high-sensitive CRP (Spearman cor. coef. (SC): 0.564; p = 0.0001), TNF (SC: 0.188; p = 0.0001) and with upregulation of sICAM (SC: 0.143; p = 0.0001).

Conclusions: Serum level of fib correlates with the extent of CAD. Furthermore, serum level of fib is associated with the elevation of high-sensitive CRP and TNF as serum markers for an ongoing inflammatory process. In pts with high fib levels an increase of sICAM could be demonstrated. These results could be interpreted as an atherogenetic ability of Fib. Fib has not only to be considered as an acute phase reactant but also as an atherogenetic risk factor for CAD.

185 Intra-individual long-term variability of C-reactive protein in the MONICA-Augsburg project

W. Koenig[1], M. Sund[2], M. Fröhlich[1], H. Löwel[3], W.L. Hutchinson[4], M.B. Pepys[4]. *[1]Dept. of Internal Medicine II, Cardiology, University of Ulm Medical Center, Ulm; GSF, National Research Center for Environment and Health, [2]MEDIS Institute; [3]Institute of Epidemiology, Neuherberg, Germany;; [4]Immunological Medicine Unit, Imperial College School of Medicine, Hammersmith Hospital, London, UK*

C-reactive protein (CRP), a sensitive marker of systemic inflammation has been shown to be an independent predictor of cardiovascular risk in several prospective studies. In all of these studies, risk prediction was based on a simple ("baseline") measurement and no data are available on the long-term variability of this risk marker.

To determine variability over time, we measured CRP (high-sensitivity IRMA) in 936 men aged 45–64 years from a random sample of the population in 1984/5 and remeasured it 3 years later in 704 men (response rate 75%) from the same cohort.

The CRP mean difference (bias) was practically zero. However, as expected for this classical acute phase reactant with a plasma t $\frac{1}{2}$ of 19 h and a 10,000 fold dynamic range, the 95% range of agreement was rather large with a ratio of 0.12–8.6. Nevertheless the reliability coefficient (R) was 0.53 (0.47–0.58) for the average of 3 measurements, which compares favourably with other well established risk factors. Stratified analyses of reliability in various groups revealed similar coefficients.

Our results suggest that, based on the concept of "regression dilution", the true association between CRP and cardiovascular risk is likely to be underestimated by single CRP measurements, and that for prognostic use in clinical practice, several serial CRP measurements would be desirable.

186 Infections and the risk of premature ischaemic heart disease

M. Gattone, L. Iacoviello[2], F. Soffiantino, M. Colombo[1], A. Gramoni[1], A. Di Castelnuovo[2], M.B. Donati[2], P. Giannuzzi. *Cardiology Department; [1]Laboratory Unit, "S. Maugeri" Foundation IRCCS, Veruno; [2]Department of Vasculare Medicine and Pharmacology, "Istituto M. Negri Sud", S. Maria Imbaro, Italy*

Infectious agents may be associated with ischemic heart disease (IHD).

Methods: to investigate the role of infections by Chlamydia pneumoniae (Chlam), Cytomegalovirus (CMV) and Herpes virus 1 (HSV-1) in promoting the premature onset of IHD, IgG specific antibodies to these pathogens and C-reactive Protein (C-react P) as a marker of flogosis were measured in 120 patients (pts), less than 50 years old, and in 120 age-matched controls (C).

Results: seropositivity (sero+) to Chlam and HSV-1 and elevated titres of anti-CMV IgGs (≥100 EU/ml) were more frequent in pts than in C ($p < 0.01$), whereas sero+ to CMV was similar. After adjustment for age, sex, traditional risk factors, educational level and occupation, the risk of premature IHD was 2.4 (95%CI = 1.3–4.6, p = 0.007) for Chlam infection, 2.9 (95% CI = 1.5–5.8, p = 0.002) for CMV and 10.4 (95%CI = 2.4–46, p = 0.002) for HSV-1. Sero+ to Chlam increased the risk of premature IHD in smokers (OR = 3.7, CI = 1.8–7.6, p = 0.001) but not in ever smokers (OR = 0.5, CI = 0.1–2.6, p = 0.7) and the risk was higher in subjects with both elevated anti-CMV titres and increased levels of C-react P (SI = 3.4, 95%CI = 0.9–13.6). The combined sero+ to all three pathogens increased the risk of four times as compared with subjects with sero+ to two of them (OR = 4.1 95%CI = 1.8–9.4 $p < 0.001$). The most unfavourable combination of infections was sero+ to Chlam associated with elevated CMV titres (35% of pts vs 8% of C, p = 0.001), which increased the risk of about 12 times as compared with subjects without any of the two infections (OR = 12.5, 95%CI = 4–38.9), and about 5 times if only one was present (OR = 4.9, 95%CI = 2.2–10.9). Furthermore, C-react P was higher in carriers of this combination than in pts without any infection ($p < 0.01$).

In conclusion: after adjustment for traditional coronary risk factors and socioeconomic status, Chlam, CMV and HSV-1 infections all increase the risk of premature IHD. The combination of seropositivity to Chlam and elevated titres to CMV, is associated with an abnormal inflammatory response and represents the most unfavourable immunologic profile for increased risk of premature IHD.

187 Chlamydia pneumonia and Helicobacter pylori are present only in human atherosclerotic plaques but not the healthy segments

Bora Farsak[1], Aylin Yıldırır[2], Yakut Akyön[2], Ahmet Pınar[2], Erkmen Böke[1], Mehmet Öç[1], Sırrı Kes, S. Lale Tokgözoğlu. *Hacettepe University Dept. of Cardiology; [1]Cardiovascular Surgery; [2]Microbiology, Ankara, Turkey*

Background: Recent epidemiological and serological studies suggested chronic infections with C. pneumonia (C) and H. pylori (H) to be associated with the development of the atherosclerotic plaque. However seropositivity does not correlate with the presence or extent of atherosclerosis.

Methods: To asses the direct involvement of these organisms, the prevalence of C and H in the arterial wall was determined in 58 patients (age 60 ± 9, 53 M, 5 F) undergoing vascular surgery of the coronaries, carotids and abdominal aorta. Forty specimens from atherosclerotic lesions and 18 specimens from healthy regions of the ascending aorta were excised. The patients were clinically evaluated for stable/unstable angina, other risk factors and presence of peptic ulcus due to H. The presence of microorganisms in arterial wall was assessed by polymerase chain reaction technique.

Results: C was present in 27.5% of lesions and none of the healthy vascular wall specimens (p = 0.01) while H was found in 32.5% of lesions and none of the controls (p = 0.003). Either C or H was positive in 47.5% of patients and none of the controls (p = 0.00036). The presence of C and H did not differ between those with stable or unstable clinical manifestations of the patient. While H was evenly distributed, C was found more frequently in plaques from the abdominal aorta location (p = 0.022).

	Coronary (%)	Carotid (%)	Abdominal (%)	*p* value
C (+)	18	27	55	0.022
H (+)	29	21	43	0.058

Conclusion: The absence of C and H in healthy vascular wall and the presence in the atherosclerotic vessel specimens supports the role of these microorganisms in the development of atherosclerosis. Since the distribution of C was preferentially in the abdominal location whereas H was evenly distributed these microorganisms may have different roles in the pathogenesis.

188 Chlamydia pneumoniae in association with cardiovascular risk factors: innocent bystander or pathologic agent?

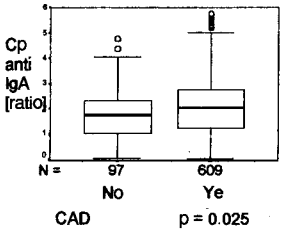
S. Blankenberg, H.J. Rupprecht, C. Bickel, J. Lotz[1], H. Kronenbusch, G. Rippin, J. Meyer. *[1]II. Medical Clinic, Clinic of Clinical Chemistry; Institute for Medical Statistics, University-Clinic Mainz, Germany*

Introduction: The association between Cp-seropositivity and coronary artery disease (CAD) is documented, less is known between the correlation of Cp infection and inflammation markers and adhesion molecules. We evaluated, whether Cp infection is associated with elevated inflammation markers, activated coagulation system and up-regulation of adhesion molecules.

Methods: In 706 patients (pat) with suspected CAD coronary angiography was performed. CAD was defined as at least one stenosis > 50%. Antiplasmin-plasmin-complex (APP), thrombin-antithrombin III complex (TAT), soluble intracellular adhesion molecule (sICAM), CRP and fibrinogen (Fib) were determined. Anti *Cp* IgA (chronic active infection) and anti IgG (previous infection) were measured by ELISA.

Results. In 609 pat (86.3%) CAD was diagnosed.

Risk marker	Cp_IgA−	Cp_IgA+	p**	Cp_IgG−	Cp_IgG+	p
CRP [mg/l]	4	4	*0.238*	4	4	*0.797*
Fib [mg/dl]	328	332	**0.028***	331.5	331	*0.322*
APP [ng/ml]	432	450	*0.246*	425	455	*0.766*
TAT [ng/ml]	3.3	3	*0.475*	3.2	3	*0.370*
sICAM [ng[ml]	272.8	274.1	*0.623*	265	274	*0.038**



In conclusion seropositivity of Cp IgA can be considered as a rf for CAD. Furthermore there is a significant association of Cp infection and increase of fib level. No association could be demonstrated between Cp infection and an activated coagulation system, whereas seropositivity of Cp correlates with an up-regulation of sICAM.

189 Epidemiology of Chlamydia pneumoniae, Helicobacter pylori, herpes simplex virus and cytomegalovirus in patients with peripheral arterial occlusions considering markers of inflammation

C. Buss, K. Kroeger, G. Rudofsky. *Department of Angiology, University of Essen, Essen, Germany*

Background: Chronic inflammations due to Chlamydia pneumoniae, Helicobacter pylori, herpes simplex-virus and cytomegalovirus has been supposed to be associated to the origin and progress of atherosclerosis. Such chronic infections may correlate with changes in markers of inflammation. We investigated the role of earlier infection and markers of inflammation in patients with peripheral arterial occlusive disease.

Methods: In 227 patients with severe peripheral arterial occlusive disease (PAOD) due to advanced atherosclerosis we analysed the presence of antibodies for Chlamydia pneumoniae, Helicobacter pylori, herpes simplex-virus and cytomegalovirus. In addition to this we analysed fibrinogen, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and the presence of diabetes mellitus. The mean age was 61.7 ± 12.5 years. According to Fontaine classification 6 were in stage I, 23 in stage II a, 117 in stage II b, 14 in stage III and 67 in stage IV of PAOD. In 171 patients (75.3%) there were antibodies against chlamydia pneumoniae, all of them showed IgG-antibodies, but only 5 had also IgM-antibodies.

Results: The mean age of patients with antibodies for Chlamydia pneumoniae was 62.7 ± 11.9 years, of the patients without 58.8 ± 13.7 years. Fibrinogen was 445.1 ± 160.2 mg/dl, CRP was 2.1 ± 2.9 mg/dl and ESR was 28/47 mm (Westergreen) in the group of patients with negative serology. If there were antibodies for chlamydia pneumoniae fibrinogen was 444.6 ± 177.8 mg/dl, CRP was 2.7 ± 4.3 mg/dl and ESR was 29/48 mm (Westergreen). A higher rate of diabetes mellitus, that could favour an infection with chlamydia pneumoniae, could not be seen. There was a high rate of additional IgG-antibodies for helicobacter pylori (48.0%), herpes simplex-virus (94.7%) and cytomegalovirus (72.5%).

Conclusion: The patients with and without antibodies for chlamydia pneumoniae did not show specific differences. Fibrinogen was nearly equal in both groups, as well as CRP, ESR and the rate of diabetic patients.

NEW ASPECTS OF OLDER PEOPLE

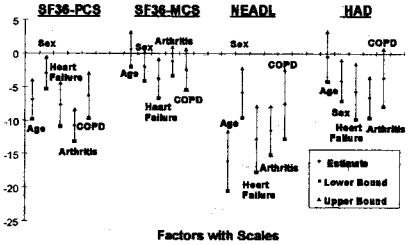
190 Functional status and quality of life in older people with heart failure – a community-based study

Shu F. Ho, M.S. O'Mahony, J. Steward, M. Buchalter[1], M. Burr[2]. *[2]University Departments of Geriatric Medicine and Cardiology; [1]Public Health and Epidemiology, Cardiff, UK*

There is increasing emphasis today on not just extending life but also improving quality of life (QoL) of our ageing population. We have examined the effects of age, gender and chronic illnesses such as heart failure on function and QoL in older people in the community.

Methods: A stratified random sample of 500 subjects was drawn from a population of 5002 subjects aged 70years and over living at home. Nottingham Extended ADL (NEADL), Hospital Anxiety and Depression Scale (HAD) and a generic QoL measure (SF-36) were administered and clinical assessments were performed. Scores for SF-36 were aggregrated into physical (PCS) and mental (MCS) cumulative summative scores. Arthritis was self-reported, chronic obstructive pulmonary disease (COPD) was defined as FEV1/FVC < predicted normal and heart failure was defined as left ventricular systolic dysfunction on echocardiogram. Data were analysed by multivariate analysis of variance.

Results: 452 of the 500 (90%) participated in the study. The population prevalence amongst older people of significant dyspnoea (MRC Grade 3–5) was 33%, arthritis 36%, COPD 11% and heart failure 8%. The 95% confidence intervals for the effects of advancing age, sex and chronic illnesses on function and QoL are shown in the figure, scores expressed as percentage differences.



In conclusion, heart failure has the greatest effect after age, on daily functioning in older people. It also has a significant adverse effect on QoL Improving recognition and treatment of heart failure should be a major priority for health services to reduce disability and improve QoL in older people.

191 Effect of age on tilt-induced collapse patterns in those with syncope of unknown origin

A.S. Kurbaan, A.-C. Franzén, T.R. Williams, D. Heaven, T.J. Bowker, S. Kaddoura, R. Sutton. *Chelsea & Westminster Hospitals, ICSM, London, UK*

In those with syncope of unknown origin the tilt induced collapse patterns (i.e. heart rate (HR) and arterial pressure (AP)) were assessed.

Methods: Using the 45 min. 60° head up Westminster protocol 102 consecutive patients were studied. Sublingual GTN 300 μg was given to those with a negative passive tilt. VASIS collapse patterns were compared between those <35 years (YG) with those >65 years (OG).

Results: In a total of 330 patients there were 114 YG (age mean 25.1 years ± standard deviation 6.8, 58 female) and 115 OG (age 74.1 ± 5.8, 44 female). Tilt testing was tolerated in 97% of YG vs. 89% of OG and negative despite the use of GTN 17% vs. 21%. Comparing the distribution of the VASIS classes between YG and OG in those with a positive result. *Type 1* mixed Arterial Pressure (AP) and Heart Rate (FIR) fall without severe bradycardia- 47% (YG) vs. 53% (OG), p = non-sig. *Type 2A* cardioinhibition AP falls before HR- 8% vs. 18%, p < 0.05. *Type 2B* cardioinhibition HR falls before or coincident with AP- 37% vs. 5%, p < 0.01. *Type 3* AP falls without HR fall- 0% vs. 10%. p < 0.05. *Exception 1* chronotropic incompetence – 0% vs. 13%, p < 0.05. *Exception 2* excessive HR rise – 7% vs. 1.3%, p = non-sig.

Conclusion: There are differences in the collapse patterns in the two age groups. In those ≤ 35 there is greater cardioinhibition (IIA and IIB) and excessive HR rise suggesting that collapse may a consequence of an exaggerated neurocardiogenic reflexes. Conversely, in those ≥65 few had cardioinhibition and there was a chronotropic incompetent subgroup. This suggests that with increasing age collapse may be the consequence of diminished neurocardiogenic reflexes.

192 Total and HDL cholesterol predict coronary heart disease mortality in elderly men in Finland, Italy and the Netherlands

S. Houterman, W.M.M. Verschuren, E.J.M. Feskens, D. Kromhout. *Chronic Disease Epidemiology, Natl. Inst. of Public Health, Bilthoven, Netherlands*

Serum total and HDL cholesterol are important predictors of coronary heart disease mortality in middle-aged men. Whether this relationship holds in the elderly is not clear. It is also important to know whether the relation between serum cholesterol and coronary heart disease mortality in elderly men differs between countries. We studied the relationship between serum total and HDL cholesterol and 10-year coronary heart disease mortality in elderly men in different European countries.

The FINE Study is a prospective follow-up study in 2132 elderly men aged 65 to 84 years in Finland, The Netherlands and Italy. During 10 years of follow-up 140 men in Finland, 88 men in The Netherlands and 48 men in Italy died from coronary heart disease. Relative risks (RRs) were estimated using Cox's proportional-hazard analysis with time-dependent covariates.

Total cholesterol was positively related to coronary heart disease mortality in all three countries. This association was statistically significant in The Netherlands (RR = 1.29; 95% Confidence Interval 1.07–1.56). The combined relative risk for the total population of the FINE Study was 1.17 (95% CI 1.06–1.29) for each 1.00 mmol/L increase in total cholesterol. HDL cholesterol was inversely related to coronary heart disease mortality in Finland, but not in The Netherlands and Italy. In Italy, an interaction was noted between HDL cholesterol, body mass index and alcohol intake. There was an inverse association between HDL cholesterol and coronary heart disease mortality in lean men (body mass index < 25 kg/m^2) with no or moderate alcohol intake (<40 g/day) (RR = 0.76; 95% CI 0.59–0.97, per 0.10 mmol/L increase) and a significantly positive association in overweight men (body mass index ≥ 25 kg/m^2) with a high alcohol intake (≥ 40 g/day) (RR = 1.25; 95% CI 1.07–1.46, per 0.10 mmol/L increase). In a combined analyses of all three countries HDL cholesterol was inversely associated with coronary heart disease mortality in lean men with no or moderate alcohol intake (RR 0.92; 95% CI 0.86–0.99, per 0.10 mmol/L increase).

Serum total and HDL cholesterol are important predictors of coronary heart disease mortality in elderly men in different European countries, although the effect of HDL cholesterol seems to be confined to lean men with no or moderate alcohol intake.

193 Mitral annular calcification and significant internal carotid artery stenosis in elderly: is there a link?

F. Antonini-Canterin, A. Manfroni, M. Brieda, S. Bitto, F. Macor, D. Pavan, G. Martin, E. Manes, G.L. Rellini, G.L. Nicolosi. *Cardiology Dept. ARC, Pordenone, Italy*

Background. It has been recently suggested that mitral annular calcification (MAC) could be a cardiac manifestation of atherosclerosis in elderly; an association between MAC and both coronary artery disease and aortic atheroma has been indeed observed. Furthermore a relationship between MAC and stroke has been found, but it is still unclear if MAC can be considered an independent risk factor of stroke. With regard of this hypothesis little information is available in the literature about a possible association between MAC and carotid artery disease.

Methods. Consecutive patients (pts) with a diagnosis of MAC and with a carotid Echo-Doppler examination done within 1 year of echocardiogram were identified from a prospective clinical database (Group MAC+: 128 pts, 69 females, 59 males, aged 74 ± 7 years). As control group, 128 age/sex-matched pts with absence of MAC and similar clinical indication to carotid Echo-Doppler examination were randomly selected from the database. In the two groups the prevalence of stenosis ≥ 50% of the internal carotid artery were blindly assessed.

Results. A carotid artery stenosis was found in 43.8% of MAC+ pts and in 22.6% of controls ($p < 0.001$). The difference was significant in both sexes: among males 50.8% vs 28.8% ($p < 0.05$), among females 37.7% vs 17.4% ($p < 0.05$). A higher prevalence of carotid artery stenosis in MAC+ group was observed both in pts ≥75 years (47.1% vs 25.0%; $p < 0.05$) and in pts <75 years (40.0% vs 20.0%; $p < 0.05$). The Table shows the prevalences of carotid artery stenosis in different age/sex groups.

	MAC+ group	Control group	
Males < 75 years	16/29 (55.2%)	7/29 (24.1%)	p < 0.05
Females < 75 years	8/31 (25.8%)	5/31 (16.1%)	p = ns
Males ≥ 75 years	14/30 (46.7%)	10/30 (33.3%)	p = ns
Females ≥ 75 years	18/38 (47.4%)	7/38 (18.4%)	p < 0.05

Conclusion. MAC is an important echocardiographic marker of significant carotid artery stenosis in elderly. The association seems to be particularly relevant in males <75 years and in females >75 years. Further studies are needed to evaluate if the increased risk of stroke observed in pts with MAC is related to MAC itself or to the associated carotid artery stenosis.

194 Direct infarct intervention in octogenarians: a step in the right direction?

A. Bhaskaran, R. Siegel, B. Barker, P. Underwood, W. Breisblatt, T. Khalil, A. Nuttall, J. Vermillion, D. Swanson. *Advanced Cardiac Specialists & Phoenix Memorial Hospital, Phoenix AZ, USA*

With increasing longevity of the population, octogenarians presenting with acute myocardial infarction (MI) are becoming increasingly frequent. The elderly patients have a reported higher mortality following acute MI. This clinical subset is routinely treated less aggressively than younger patients, since they are believed to be at higher risk for complications. We report the clinical course and mortality rate for up to 1 year in patients aged ≥80 years, following direct coronary intervention (d-PTCA) for acute MI. From 1/96 to 12/98, 54 patients in this age group (mean age 83.5) underwent d-PTCA within 24 hours of onset of acute MI. This included 49% females; 40.8% with a history of angina, 37% with history of CHF, and 31.6% with a history of smoking. Prior MI was reported in 16.7% and 7.4% had prior CABG surgery. The LAD was the culprit vessel in 39%; 63% lesions were ostial or proximal, subtending large territories of myocardium. Intracoronary stenting was performed in 15 patients (27.8%) electively or for suboptimal result. Adjunctive IABP support was employed in 51.9% cases. Indications for IABP use included poorly protected large volume of myocardium, pulmonary edema, shock, LVEF ≤ 25%, severe multivessel disease, large clot burden, and "slow-flow" post-PTCA. Oral GP IIb/IIIa inhibitors were used in 24% cases.

Results: Procedural success (residual stenosis ≤ 20%; TIMI 3 flow) was achieved in 52 patients (96.3%). Mean time to reperfusion was 10.2 hours from onset of chest pain. There was 1 acute reclosure requiring re-PTCA. There were no in-hospital deaths. There were no acute neurological events or subacute stent thrombosis. Mean hospital stay was 2.98 days. Mean global LVEF at discharge was 43.7%*.

12-month Follow-Up [95.4% complete; Mean Follow-Up 6.74 months]

Re-MI	Re-PTCA	CABG	Stroke	Death	Event-Free	Mean LVEF
1 (1.9%)	1 (1.9%)	1 (1.9%)	2 (3.7%)	4 (7.4%)	47 (87%)	52.0%; *p = 0.046

Conclusions: (1) The strategy of direct infarct angioplasty that is effective in younger patients is also effective in octogenarians. (2) It is a safe therapeutic option with high procedural success and low incidence of in-hospital cardiac events. (3) Favorable 1-year event-free survival is obtained. (4) Improvement in global LV systolic performance was *statistically significant*, suggesting that prompt and successful salvage of substantial at-risk myocardium may have contributed to improved long-term outcomes. (5) Our series supports the view that age in itself is not a contraindication to an invasive strategy in octogenarians presenting with AMI. In fact, given the high mortality and poor outcomes historically associated with AMI in this age group, aggressive therapeutic strategies may be particularly warranted.

195 Coronary stenting in patients over 75 years: clinical profile, initial outcome and long-term evolution

J.C. Muñoz, J.J. Alonso, F. Gimeno, J.M. Durán, B. Ramos, I. Garcimartín, Mar de la Torre, J. Bermejo, I. Gómez, F. Fernández-Avilés. *Hospital Universitario, Valladolid, Spain*

To assess the clinical profile and the evolution after stenting of pts over 75 years, we compared two groups of consecutive pts. Group A included 80 pts (87 lesions) over 75 years (77 ± 2.4 years; range: 76–86) and group B consisted of 903 pts (1024 lesions) under 76 years (60 ± 10 years; range: 27–75). Group A had a lower rate of smokers (29 vs. 59%, $p < 0.001$) and a higher incidence of heart failure (12 vs. 5%, $p < 0.01$). Angioplasty indication for unstable angina was more frequent in group A (80 vs. 60%; $p < 0.001$). The rest of clinical, angiographic and procedural variables did not differ between the two groups.

Although clinical success (angiographic success without events at one month) was similar for both groups (A = 89%, B = 94%, p = 0.08), hospital death was higher among pts over 75 years (8 vs. 2% p = 0.006). There were no differences in the incidence of angiographic restenosis (Gr A: 22%, Gr B: 28%). Clinical follow-up was completed in 94% of pts at 3.0 ± 1.5 years. Death during follow-up occurred in 15% of pts from group A and in 6% of pts from group B (p = 0.005). Need of new revascularization was less frequent in pts older than 75 years (9% vs 18%, $P < 0.05$). The incidence of major adverse cardiac events was similar for both groups (A = 27, B = 27%). A multivariate analysis from the data of group A identified previous myocardial infarction, hypertension and acute myocardial infarction during the procedure as independent predictors of further events.

Thus, patients over 75 years have a less favourable baseline profile and higher hospital and long-term mortality. However, the incidence of major adverse cardiac events in the short and long-term is acceptable and similar to that of younger pts. These data suggest that coronary stenting is a reasonable therapeutic alternative for patients older than 75 years.

ANGIOGENESIS: EXPERIMENTAL AND CLINICAL

208 Intramuscular injection of plasmid DNA encoding fibroblast growth factor-1 induces angiogenesis in a rabbit hindlimb model of peripheral ischaemia

B. Witzenbichler, A. Mahfoudi[1], F. Soubrier[1], D. Branellec[1], J.M. Isner[2], H.-P. Schultheiss. *Cardiology, University Hospital Benjamin Franklin, Berlin, Germany; [1]Rhone/Poulenc Rorer, Vitry-Sur-Seine, France[2]Cardiovascular Research, St. Elizabeth's Medical Center, Boston, USA*

The purpose of this study was to evaluate the usefulness of direct intramuscular (i.m.) injection of a plasmid encoding FGF-1 (= acidic FGF) to augment collateral formation and tissue perfusion in a rabbit ischemic hindlimb model. Truncated FGF-1 (residues 21–154) fused to the human fibroblast interferon signal peptide was expressed from an expression vector with a conditional origin of replication (pCOR-spFGF1). Rabbits injected with pCOR plasmid encoding b-galactosidase served as control group.

Results: Successful transgene expression could be demonstrated by FGF-1 immunostaining and X-Gal staining at different time points after gene application. 500 and 1000 μg pCOR-spFGF1, when injected into ischemic muscle areas of rabbits (n = 8 each) 10 days after ligation of the external iliac artery, exhibited a pronounced therapeutic effect on collateral formation to the ischemic hindlimb in a dose-depending manner, as assessed by physiological (Doppler-derived blood pressure ratio, maximal intraarterial Doppler Flow) and anatomical (angiographic score, histologic evaluation of capillary density) measurements 30 days after therapy, compared to b-galactosidase control plasmid, as shown in the table. Application of 100 μg pCOR-spFGF1 was not sufficient to induce any beneficial effect.

Angiogenic Potency of FGF-1

Day 30	b-galactos.	500 μg spFGF-1	1000 μg spFGF-1
Limb BP ratio (isch./normal)	0.57 ± 0.04	0.74 ± 0.04*	0.82 ± 0.02#
Max. intraart. Doppler flow	30.7 ± 3.1	42.4 ± 3.8*	50.6 ± 3.6#
Angiographic Score	0.54 ± 0.04	0.68 ± 0.02*	0.81 ± 0.04#
Capillary density [/mm^2]	169 ± 10.0	220 ± 18.7*	242 ± 17#

* = $p < 0.05$; # = $p < 0.005$

In conclusion, our results demonstrate the angiogenic potency of FGF-1 gene transfer. Intramuscular FGF-1 gene application could be useful to stimulate therapeutic angiogenesis in a situation of chronic periperal ischemia.

209 Vascular endothelial growth factor expression is down-regulated in human chronic heart failure

R.A. de Boer[1], D.J. van Veldhuisen[1], R.H. Henning[2], R.A. Tio[1], W.H. van Gilst[2], H.J.G.M. Crijns[1]. *Department of [1]Cardiology; [2]Clinical Pharmacology, University of Groningen, Netherlands*

Increased gene expression of growth factors, leading to enhanced angiogenesis, is a compensatory mechanism to myocardial hypoxia. In chronic heart failure (CHF), myocardial hypoxia may be caused by increased wall stress and endothelial dysfunction. Thus we investigated whether growth factors are expressed at higher levels in CHF, since such a phenomenon could potentially reverse myocardial hypoxia.

Methods. Right ventricular tissue biopsies from 27 patients with idiopathic dilated cardiomyopathy (NYHA class II–IV, mean LVEF: 31%) and 13 controls (con) were harvested and total RNA was isolated. Expression of vascular endothelial growth factor (VEGF), isoforms 121, 165, and 189, VEGF-receptor 2 (VEGF-R2), basic Fibroblast Growth Factor (bFGF), Atrial Natriuretic Peptide (ANP), and Sarcoplasmic Reticulum Ca^{2+}-ATPase (SERCA) was determined by semi-quantitative PCR, expressed as a ratio to the co-amplified glyceraldehyde-3-phosphate dehydrogenase (GAPDH).

Results. In CHF patients, VEGF 121 mRNA is expressed at a lower level ($p < 0.001$). In addition, isoforms 165 and 189 also tended to be decreased ($p = 0.05$ and 0.10, resp). VEGFR-2 and bFGF were unchanged. Increased ANP and decreased SERCA expression, typical for CHF, were found. GAPDH expression did not differ between groups. See table for results.

	VEGF 121	VEGF 165	VEGF 189	VEGFR-2	bFGF	ANP	SERCA
Con	1.30	2.74	1.92	1.35	0.66	0.06	0.99
CHF	0.61*	2.21	1.56	1.29	0.64	0.59*	0.79*

*: $p < 0.05$, CBF vs. control.

Conclusion. These data suggest that VEGF expression, translating into angiogenesis, does not compensate for hypoxia reported in CHF. Moreover, the observed diminishing of VEGF mRNA in cardiomyocytes could further contribute to the imbalance of oxygen deprivation and vascularization.

210 Endogenous, local, vascular endothelial growth factor production in patients with chronic total coronary occlusions: further evidence for its role in angiogenesis

H. El Gendi, A.G. Violaris, S. Panikker, T.F. Ismail, V.K. Gulati[1], R.S. More, R.A. Foale, D.J. Sheridan. *Div. of NHLI, St Mary's Hospital, Academic Cardiology Unit, London; [1]St Mary's Hospital, Dept. of Medicine, London, UK*

Background: Intracoronary administration of Vascular Endothelial Growth Factor (VEGF) has been explored as a means of increasing collateralisation in patients with end-stage coronary artery disease. However, to date, no study has examined the role of endogenous VEGF production in the development of collaterals in patients with chronic total coronary occlusions. The aim of our study was to assess local, in vivo, VEGF production in patients with total occlusions and to compare this to patients with non-occlusive stenoses.

Method: VEGF levels in the coronary circulation and periphery were prospectively examined in 14 patients (7 patients with stenoses, 83 ± 6% (mean ± SEM) diameter stenosis, mean age 63 ± 2, 4 males and 7 patients with occlusion mean age 65 ± 4, 4 males) undergoing elective left coronary system intervention. Local (coronary sinus) and systemic (femoral) venous samples were obtained prior to coronary intervention. Blood samples were centrifuged and plasma separated for further analysis. The level of VEGF in plasma samples for the 14 patients was then determined using an enzyme-linked immunosorbent assay (ELISA) (R & D Systems, UK).

Results: There was a significant difference in the level of VEGF between local and systemic samples in the whole group (251.8 ± 94.8 vs 93.6 ± 14.1, P = 0.025). The difference was chiefly attributable to a four-fold increase in mean VEGF levels between the coronary sinus and periphery in the occlusion group (400.2 ± 176.7 vs 111.9 ± 22.9, P = 0.073) compared to the stenosis group (103.3 ± 19.8 vs 75.2 ± 15.1, P = 0.5). The basal VEGF level was significantly higher in the coronary sinus samples of patients with occlusions compared to those with stenoses (400.2 ± 176.7 vs 103.3 ± 19.8, P = 0.026).

Conclusion: Our study provides the first direct evidence for increased local VEGF production in the diseased coronary circulation. The high local endogenous level of VEGF in patients with total coronary occlusions suggests a potential role for this growth factor in pathophysiologic collateral formation and supports its use as a therapeutic tool for angiogenesis in patients with inoperable coronary heart disease.

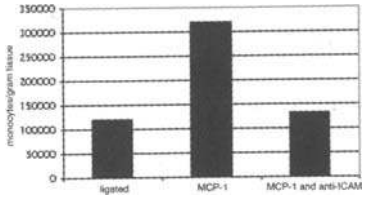
211 Attraction of loaded monocytes via MCP-1: a novel strategy for therapeutic arteriogenesis

I. Buschmann, N. Van Royen[1], I. Hoefer, M. Heil, E. Katzer, R. Braun-Dullaeus, J.J. Piek[1], W. Schaper. *Experimental Cardiology Dept, Max-Planck-Institute, Bad Nauheim, Germany; [1]Department of Cardiology, Academic Medical Centre, Amsterdam, Netherlands*

Introduction: Local infusion of MCP-1 after femoral artery occlusion in the rabbit hindlimb enhances arteriogenesis via attraction of circulating monocytes. This stimulatory effect of MCP–1 could be further enhanced by delivering arteriogenic proteins directly to the place of action via loaded monocytes resulting in high local concentrations of the arteriogenic protein. This study evaluates whether the selective attraction of microsphere loaded monocytes to the growing collateral artery can be promoted with MCP-1.

Methods: 12 rabbits were treated with local infusion of either MCP-1 alone or MCP-1 plus monoclonal ICAM-antibodies via osmotic minipumps after ligation of the a. femoralis. Non-ligated animals and ligated animals infused with PBS served as control. Isolated rabbit monocytes were loaded with fluorescent microspheres (*2 mm) and reinfused intravenously. 48 hours after reinfusion animals were killed and biopsies were taken of the adductor and quadriceps muscle in both hindlimbs. With FACS analysis the total number of monocytes/gram tissue was quantified.

Results: Number of monocytes: unligated; 35,000 ± 7,200, ligated; 120,000 ± 10,500, MCP-1 treatment: 320,000 ± 28,000, MCP-1 treatment and anti-ICAM antibodies; 132,000 ± 11,000. The number of monocytes was significantly different for all groups except for the ligated group and the group treated with the combination of MCP-1 and anti-ICAM antibodies (see figure).



Conclusion: This study shows that MCP-1 is a potent chemoattractant for loaded monocytes homing to collateral arteries. This process can be blocked by ICAM-antibodies. This new concept of selective local enhancement and blocking of accumulation of circulating loaded monocytes may be the base of a new therapeutical concept to enhance arteriogenesis.

212 Intramyocardial application of vascular endothelial growth factor induces angiogenesis but does not augment myocardial perfusion in the rat heart

E.R. Schwarz, M. Speakman, S.L. Hale, R.A. Kloner. *Heart Institute, Good Samaritan Hospital, Univ. Southern California, Los Angeles CA, USA*

Background. Direct application of the plasmid of vascular endothelial growth factor (VEGF) has been shown to augment collateral flow and induce new vessel formation in models with peripheral ischemia. Controversy exists concerning the ability to induce angiogenesis and enhance coronary flow in the myocardium.

Objective. We investigated the effects of direct intramyocardial injection of the plasmid encoding VEGF in the border zone of myocardial infarct tissue in rat hearts.

Methods and Results. Sprague-Dawley rats received a ligation at the base of the left coronary artery to induce myocardial infarction. At 4 weeks, the rats were injected with VEGF plasmid (500 ug DNA, n = 24) or saline (n = 16). After one month, the hearts were excised and examined histologically. Twentythree/24 VEGF-treated hearts showed macroscopic angiogenesis with angioma-like structures at the injection site while controls did not. By histology, 21/24 VEGF-treated hearts showed increased focal epicardial blood vessel density and angioma-like formation, whereas only 1/14 control hearts showed increased vessel density ($p < 0.001$). Quantitative morphometric evaluation of vascular density in a subgroup of 20 VEGF-treated and 10 saline-treated control hearts revealed 44.4 ± 10.5 vascular structures per field in VEGF-treated hearts versus 21.1 ± 3.0 in controls ($p < 0.05$). Regional myocardial blood flow ratios between the injection site and non-infarcted area were measured by radioactive microspheres in 18 rats and did not demonstrate any difference between VEGF-treated hearts (0.9 ± 0.2) and saline-treated hearts (0.7 ± 0.1).

Conclusion. Injection of DNA for VEGF in the border zone of myocardial infarction in rat hearts induced angiogenesis. Moreover, angioma occurred at the injection site. However, that did not contribute to regional myocardial blood flow.

213 VEGF induces integrin expression and L-selectin shedding in human monocytes

M. Heil, M. Clauss[1], I. Buschmann, E. Katzer, I. Hoefer, E. Deindl, N. van Royen, W. Schaper. *Experimental Cardiology Dept, Max-Planck-Institute, Bad Nauheim; [1]Dept. of Molecular Cell Biology, Max-Planck-Institute, Bad Nauheim, Germany*

Monocyte invasion into the perivascular tissue of developing collateral vessels is the first morphological sign of arteriogenesis (rapid proliferation of collateral arteries). Therefore the arteriogenic potency of growth factors is dependent on its monocyte-attractant activity. However, monocytes are also known to be involved in angiogenesis, which is, in contrast to arteriogenesis, the sprouting of new capillaries. VEGF is known to be a very effective inducer of angiogenesis. In this study we investigated the monocyte stimulatory effect of physiological VEGF concentrations (100 ng/ml). Therefore, the expression of several monocytic activation markers were analyzed via FACS-analysis. Monocytes were isolated from healthy blood donors using a Beckman elutriation chamber and cultured for 24 hours, incubated either with medium alone, with VEGF or, as a positive activation control, with LPS. Monocyte activation was detected via FITC conjugated monoclonal antibodies against CD11b/CD18 (Mac-1), L-Selectin and Tissue Factor.

Results:

	L-Selectin	CD 11b	CD18	p-value
Unstimulated	42.7	116.9	562.2	
VEG	20.1	316.4	853.5	<0.005
LPS	10.2	429.6	1518.8	<0.005

Conclusion: This is the first report about upregulation of integrins on the monocyte surface after exposure to physiological VEGF concentrations in vitro. These data indicate that VEGF has monocyte activating and thereby potentially arteriogenic properties.

NON-INVASIVE RISK ASSESSMENT IN ACUTE CORONARY SYNDROMES

214 ST-segment monitoring with continuous 12-lead ECG identifies patients at high risk for subsequent cardiac events after an episode of unstable coronary artery disease

T. Jernberg, B. Lindahl, J. Chronblad, L. Wallentin. *Dept. of Cardiology, University hospital, Uppsala, Sweden*

Patients with unstable coronary artery disease (UCAD) still have a high risk of subsequent cardiac events. However, this is a heterogeneous population in which early risk stratification is essential. The aim of the present FRISC II substudy was to evaluate the prognostic value of continuous 12-lead ECG in this population.

Method: Continuous 12-lead ECG (ST-Guard, Marquette medical systems) was performed in 189 patients with UCAD included in the FRISC II trial and randomized to a non-invasive policy. Monitoring was performed from admission and for 12–24 h. Follow up concerning death and MI has so far been completed for 6 months.

Results: ST-episodes, defined as transient ST-segment deviations of ≥ 0.1 mV, lasting ≥ 1 minute, were present in 51 (27%) patients. Predictive values of detecting death and death or MI during follow up:

		No ST-episodes	ST-episodes	Log-rank p
Death	14 d	0	6%	0.04
	30 d	0	6%	0.04
	180 d	0	8%	<0.001
Death/MI	14 d	3%	12%	0.02
	30 d	4%	12%	0.06
	180 d	9%	16%	0.13

Conclusion: ST-segment monitoring with continuous 12-lead ECG provides important prognostic information early after admission, especially concerning short term outcome.

215 Prognosis of silent ischaemia after acute myocardial infarction: the Danish Trial in Acute Myocardial Infarction, DANAMI

W.B. Nielsen, J.K. Madsen[1], P. Grande[1], K. Saunamaki[1], P. Thayssen[2], E. Kassis[3], T.T. Nielsen[4], T. Hagfeldt[2], S. Haunso[1], K. Rasmussen[5]. *The Heart Centre 2012, Rigshospitalet, Copenhagen; [1]The Heart Centre, Rigshospitalet, Copenhagen[2]Dept. of Cardiology B, Odense Sygehus, Odense[3]Dept. of Cardiology P, Gentofte Amtssygehus, Copenhagen[4]Dept. of Cardiology, Skejby Sygehus, Aahus[5]Dept. of Cardiology, Aalborg Sygehus, Aalborg, Denmark*

The purpose of the present analysis is to identify risk factors for cardiac morbidity in patients with post-MI silent ischemia.

The DANish trial in Acute Myocardial Infarction (DANAMI) study randomized 505 patients to conservative treatment after thrombolytic treated first MI.

A total of 287 patients had silent post infarct inducible ischemia during a symptom-limited bicycle exercise test. The one year incidence rate of combined cardiac endpoints defined as death, re-infarction or admission with unstable angina was 22% among patients with silent ischemia. According to level of maximum ST-change during stress-test, patients were categorized into three groups: A: ST-elevation (n = 51, 1-year event rate 15%); B: ≥ 1, <2 mm ST-depression (n = 85, 1-year event rate 21%) and C: ≥ 2 mm ST-depression (n = 145, 1-year event rate 26%). In both a univariate and multivariate Cox regression model, predictors of cardiac endpoints were angina prior to the index infarction (relative risk (RR) = 1.75, p = 0.04 versus no angina) and levels of ST-depression during stress-test (RR = 3.6, p = 0.04 (group C versus group A).

In conclusion, patients with silent post infarct inducible ischemia have a substantial one-year risk of cardiac morbidity. The level of maximum ST-depression during stress-test differentiate between high and low risk groups among patients with silent ischemia.

216 Exercise electrocardiography and pharmacological stress echo for long-term prognosis after uncomplicated myocardial infarction

R. Bigi, A. Galati[1], A. Desideri[2], R. Rambaldi, C. Coletta[1], G. Occhi, J.J. Bax[3]. *Cardiology Dept, E. Morelli Hospital, Sondalo; [1]Cardiology Dept, S. Spirito Hospital, Rome[2]Cardiology Dept, S. Giacomo Hospital, Castelfranco Veneto, Italy[3]Cardiology Dept, University Hospital, Leiden, Netherlands*

Background: the prognostic value of inducible ischemia after myocardial infarction (MI) is controversial. Stress echocardiography (SE) has been proposed as adjunctive test to exercise ECG (ExT); however, their relative role is not definitely established. Aim of the present study was to assess the long-term prognostic value of SE and ExT in pts. with uncomplicated MI using a probabilistic model including clinical data first, clinical data+ExT second and clinical data+ExT+SE last.

Methods: four-hundred ninty six patients undergoing maximal ExT and SE (406 dobutamine and 90 dipyridamole) within 15 days of MI were followed-up to 753 days (range 14–2255) for spontaneous events (reinfarction, unstable angina and cardiac death). Patients undergoing revascularization were censored at the time of the procedure.

Results: ExT was positive in 162 (33%) patients and low-threshold positive (<100 W) in 91 (18%). SE was positive in 239 (48%) patients (194 with dobutamine and 45 with dipyridamole). Concordant result was obtained in 311 cases (agreement = 63%, kappa value 0.24, 95%CI 0.15 to 0.33). Sixty-nine events (14 cardiac death, 26 reinfarction and 29 unstable angina requiring hospitalization) occurred, whilst 126 patients underwent revascularization (39 PTCA and 87 CABG). SE was significantly ($p < 0.05$) more sensitive (49% vs. 35%) and less specific (68% vs. 52%) than ExT. Incremental ROC curve analysis showed SE to add significantly, as compared to clinical data, in predicting the outcome; moreover, a 5-fold increase in risk was observed in patients with positive SE among those with high-threshold (>100 W) positive ExT. Finally, the event-free survival of patients having both positive tests was significantly ($p < 0.05$) lower than that of patients with just one positive test or with both negative tests.

Conclusions: 1) SE provides additional prognostic information to clinical data and ExT after uncomplicated MI. 2) The greatest gain is obtained in patients with high-threshold positive ExT.

217 Risk stratification following myocardial infarction: incremental value of an index of global myocardial function

M.I. Burgess, P. Atkinson, S.G. Ray. *Department of Cardiology, Wythenshawe Hospital, Manchester, UK*

Aims: Systolic and diastolic dysfunction have been used individually as prognostic markers after myocardial infarction (MI) but a composite parameter of global myocardial function may provide optimal information. We evaluated the use of a simple index of global myocardial performance (IMP) to investigate if it provides incremental prognostic information compared to conventional echocardiographic methods.

Methods and results: We studied 135 patients within 4 days of MI and 56 matched controls. Systolic performance was assessed by ejection fraction (LVEF) and wall motion score (WMS). Diastolic function was assessed by the mitral deceleration time (MDT). The IMP was derived by dividing the sum of the left ventricular isovolumic contraction and relaxation times by the left ventricular ejection time. Feasibility of measurement in the MI group was 76% for LVEF, 80% for WMS, 83% for MDT and 100% for the IMP. LVEF and WMS differed between controls, patients with uncomplicated MI and patients with MI complicated by pulmonary oedema (60 ± 6, 47 ± 14, 40 ± 15 and 2.0 ± 0, 1.35 ± 0.39, 1.11 ± 0.37 respectively; $p < 0.05$ between all groups). IMP also differed between these groups (0.53 + 0.11, 0.59 + 0.17, 0.69 + 0.22 respectively; $p < 0.05$ between all groups). At a mean follow-up of 8 months there had been 10 cardiovascular deaths and 33 patients had developed heart failure (NYHA III/IV). Patients with an IMP value of >0.75 (mean + 2 SD in controls) had a lower survival than those with an IMP of ≤0.75 (relative risk 39, 95% CI 6 to 257; $p = 0.0001$). They were also more likely to have heart failure (relative risk 11, 95% CI 3 to 40; $p = 0.0002$). The IMP was the most powerful of the clinical and echocardiographic parameters in predicting death or heart failure.

Conclusion: The IMP is simple to perform and is the best single predictor of death and heart failure in the medium-term following MI. It is more predictive of adverse outcome than indicators of systolic or diastolic function alone.

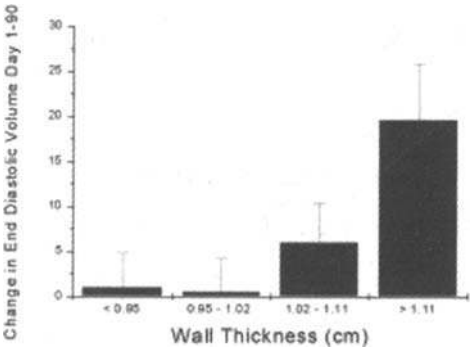
218 Baseline left ventricular wall thickness is a predictor of subsequent left ventricular remodelling after anterior myocardial infarction: the Healing and Early Afterload Reducing Therapy (HEART) trial

H. Jilaihawi, S. Greaves, R. Glynn, U. Ajani, J. Rouleau[1], F. Menapace[2], G. Timmis[3], M. Arnold[4], M. Pfeffer, S. Solomon. *Cardiovascular Division, Brigham and Women's Hospital, Boston MA, USA; [1]Montreal Heart Institute, Montreal, Canada[2]Geisinger Medical Center, Danville PA[3]William Beaumont Hospital, Royal Oak MI, USA; [4]Victoria Hospital, London Ontario, Canada*

Objectives: To investigate the relationship between left ventricular hypertrophy (LVH) and post-MI remodeling.

Methods: We analyzed echocardiographic and clinical data from the Healing and Early Afterload Reducing Therapy (HEART) Trial, a study of early versus late ACE inhibition following anterior Q-wave myocardial infarction. Patients underwent echocardiography within 24 hours of MI, at 14 days and 90 days. LV wall thickness at day 1 was calculated from measured endocardial and epicardial borders from the short axis view of 129 patients at both the mitral and papillary muscle level by a single investigator in a blinded fashion. Data from three separate high quality cardiac cycles were averaged.

Results: Baseline average LV wall thickness was related to subsequent change in LV end diastolic volume from day 1 to 90 post-MI ($p = 0.001$), and this association remained significant after adjusting for age, sex, history of diabetes, history of hypertension, baseline end-diastolic volume, and HEART drug randomization group ($r = 0.31$; $p < 0.001$). Wall thickness was also related to maximal CK, an enzymatic estimate of infarct size ($p = 0.006$, $r = 0.24$).



Change in EDV with wall thickness.

Conclusion: Left ventricular hypertrophy predisposes to increased enzyme release and LV remodeling after myocardial infarction.

219 The prognostic value of myocardial viability recognized by low-dose dobutamine echocardiography in medically treated patients with chronic ischaemic left ventricular dysfunction

R. Sicari, A. Ripoli, E. Picano, A.C. Borges, A. Varga, W. Mathias, L. Cortigiani, R. Bigi, J. Heyman, S. Polimeno. *Institute of Clinical Physiology, Pisa, Italy*

Aim of this, large scale, prospective, multicenter, observational study was to assess the impact on survival of myocardial viability recognized by low dose dobutamine echo in medically treated patients with global left ventricular dysfunction. Thus, 204 patients (mean age 61 ± 10) with angiographically proven coronary artery disease, previous (>3 months) myocardial infarction and severe left ventricular dysfunction (ejection fraction < 35%, mean: 27 ± 7) underwent low dose (up to 10 μg/kg/min) dobutamine for the detection of myocardial viability. Myocardial viability was identified as rest-stress variation (D) in the wall motion score index (WMSI), each segment scored from 1 = normal to 4 = dyskinetic in a 16 segment model of left ventricle. Patients were followed up for a median of 36 months. The only end-point analyzed was cardiac death. Kaplan-Meier survival estimates showed a better outcome for patients with large viability (D WMSI > 0.4) compared to those with a small extent (DWMSI < 0.4) or with no myocardial viability (D WMSI = 0).Using Cox proportional hazards model, delta WMSI (HR 0.1, 95%CI 0.02–0.7, p = 0.022) exerted a protective effect on survival.

In medically treated patients with severe global chronic left ventricular dysfunction, myocardial viability identified by low dose dobutamine is associated with a better survival. The viability response should be titrated according to the entity and extent of contractile recovery.

MECHANISMS OF PLAQUE INSTABILITY

220 Cell proliferation and apoptosis during atherosclerotic lesion progression in human coronary arteries

M. Berrozpe, L. Badimon. *Cardiovascular Laboratory, Cardiovasc.Res.Cter.IIBB/csic-HSCSP, Barcelona, Spain*

Background: Proliferation activity and apoptotic cell dead in atherosclerotic plaques has been documented as an essential determinant of lesion formation in animal experiments and human advanced lesions from aorta and carotid atherectomy specimens. In human coronary atherosclerotic plaques the role of either apoptotic or proliferative activities in distinct phases of the disease, especially in the earlier plaques, is undefined.

Methods: 60 human coronary plaques (obtained from excised hearts at transplant) were classified from intimal thickening (AIT) to type VIII lesion (AHA classification). 5 mm sections were incubated with antibodies anti CPP32, (ICE-like enzyme responsible for the initiation of apoptosis in mammalian cells), and Ki67 (proliferation marker expressed during all phases of the cell cycle except in quiescent Go cells). Specimens were evaluated by image analysis (Visilog 4.1.5. Noesis.) A ratio of the number of positive nucleus versus the number of total nucleus in 15 high magnification (600x) fields of each coronary was calculated. As cellular markers a-actin (smooth muscle cells), CD31 (endothelial cells), CD68 and Ham56 (monocites/macrophages), Cathepsin G(neutrophils), and CD45RO (Lymphocytes) were used. As secondary antibodies, anti mouse IgGs labeled with biotin, FITC and TRITC were used. DNA fragmentation of apoptotic cells was detected by TUNEL technique.

Results: Lesions type IV, V and VI show a significant amount of TUNEL positive cells, especially in the atheromatous core, while the others types of lesions show scattered positive nucleus in the neointimal area. CPP32 positive cells are present even in early lesions, reach a maximum in type V-VI ($p < 0.001$) to decrease in more advanced lesions. Ki67 shows low levels of expression in cells of plaques from AIT to type V. It shows a significant increase in expression in cells of type VI lesions ($p < 0.05$) and a significant reduction in type VII and VIII lesions ($p < 0.05$). Lesion cellularity (nucleus/unit surface) was not directly related to either one of the markers.

Conclusions: We found a low level of proliferative cells in atherosclerotic plaques. Type VI plaques that trigger thrombotic complications, showed a significantly higher proliferative state. Type V and VI show the highest index of cells initiating programmed cell dead. Atherosclerotic plaque progression is therefore highly regulated and vulnerable plaques, associated with presentation of acute coronary syndromes, show the highest index of cell activity not related with higher cellularity.

221 Inflammation and restenosis: immunohistological study of coronary atherectomy specimens

M.M. Rozek, R. Wojnicz[1], B. Chandrasekar, C. Chang, O. Rivera, R.S. Kiesz. *Medicine/Cardiology Dept., UTHSC, San Antonio TX, USA; [1]Silesian Centre of Heart Disease, Zabrze, Poland*

The current knowledge of the coronary restenosis following percutaneous intervention suggests that inflammation play a central role in this process. To assess the inflammatory component in restenosis, we studied 97 specimens obtained by directional coronary atherectomy from 93 patients. Based on the presence of internal elastic lumina and cellular density of the sections (>30 cells per high power view), 40 specimens were selected (21 de novo, 19 restenotic). The presence of HLA class II antigens (DR), ICAM-1 (CD 54), macrophage (HAM 54), and SMC were assessed using monoclonal antibodies and an avidin-biotin complex method (LSAB"+/AP from DAKO). The intensity of staining was analyzed semi-quantitatively: 0 negative staining, 1+ mild staining, 2+ moderate and 3+ heavy staining. Only cells with staining indexes ≥ 2+ were considered to be positive and were used in calculations for this study. Quantitative analysis included images from sections digitized using a video 3CCD Sony camera (24 bit RGB resolution, TIFF format) and analyzed with Lucia 3.51 software. Positive cells were counted from three different images on the same slide (image area 200,000 pixels). The mean value was used for statistical analysis using the t-test for independent samples.

Quantitative analysis

	De novo	Restenotic	p value
HLA-DR	9.5 ± 2.9*	6.9 ± 3.4	0.04
ICAM-1	7.8 ± 1.1	6.6 ± 0.7	0.004
Mø	9.0 ± 2.5	6.0 ± 3.1	0.01

*Mean number of cells ± SD

Both HLA-DR and ICAM-1 immunoreactivity were prevalent on macrophages and endothelial cells from de novo lesions compared to restenotic lesions. No immunoreactivity for HLA-DR or ICAM-1 was present on smooth muscle cells in de novo or restenotic lesions.

Conclusions: De novo lesions express a significantly higher level of inflammatory component surface antigens than restenotic lesions. The inflammatory process appears to be mediated by macrophages and endothelial cells but not by smooth muscle cells. The inflammation appears to play less important role in restenosis that previously thought.

222 Clinical presentation of restenosis is associated with the extent of atherosclerotic inflammation of the initial coronary lesion

M. Meuwissen, S.A.J. Chamuleau, J.J. Piek, K.T. Koch, A.C. van der Wal, A.E. Becker. *Cardiology Dept., Academic Medical Center, Amsterdam, Netherlands*

Background: There is limited information regarding the association between the extent of atherosclerotic inflammation and the incidence of restenosis after coronary angioplasty.

Methods: A total of 110 patients with stable (n = 46) or unstable angina (n = 64), according to Braunwald's classification, underwent directional coronary atherectomy (DCA). Cryostat sections of atherectomy specimen were immunohistochemically stained with the monoclonal antibodies, a-actin (smooth muscle cells; SMC), CD-68 (macrophages; MAC), CD-3 (T-cells) and C3/43 (HLA-DR molecules; HLA). The extent of atherosclerotic inflammation of the initial lesion was determined by MAC and HLA-DR, planimetrically quantified as the percentage immunopositive tissue area of the total tissue area. T-cells were counted and expressed per mm^2. Patients were followed for one year after the procedure. Clinical restenosis developed in 35 patients (32%), presenting as stable angina in 19 patients and unstable angina in 16 patients.

Results: MAC and SMC areas were not different in patients with or without restenosis. (MAC: 16.1 ± 12.1 vs. 18.8 ± 13.9, SMC: 26.1 ± 14.7 vs. 25.9 ± 16.2). The table shows initial plaque inflammation in patients with clinical restenosis, presenting with either stable or unstable angina.

Table

	% MAC	T-cells/mm^2	% HLA-DR	% SMC
Stable (n = 19)	8.5 ± 4.6	13.2 ± 7.2	11.2 ± 7.8	30.1 ± 16.4
Unstable (n = 16)	25.1 ± 12.1*	24.5 ± 4.2#	19.5 ± 12.6#	21.4 ± 11.2

*$p < 0.0001$ compared to group stable, # $p < 0.05$ compared to group stable.

Conclusion: The extent of initial plaque inflammation is not related to the development of clinical restenosis, but shows a positive association with the severity of recurrent anginal symptoms.

223 Smooth muscle cell heterogeneity in coronary lesions: functional implications

J. Martinez-Gonzalez, M. Berrozpe, O. Varela, L. Badimon. *Cardiovascular Laboratory, Cardiovasc.Res.Cter-IIBB/CSIC-HSCSP, Barcelona, Spain*

Mural thrombosis is associated to the presentation of acute ischemic events, progression of atherosclerosis and coronary revascularization procedures. In these processes platelets-released products (PR) seem to play a key role. Smooth muscle cells (SMC) phenotypic heterogeneity has been described but its relative importance in human lesions and its functional role in lesion progression is not known. We have studied SMC heterogeneity in human coronary lesions and their differential response to PR.

Methods and Results: Human coronary arteries from explanted hearts at transplant operations (HSCSP) were process for immunohistochemical analysis. All advanced lesions (type VI to VIII) analyzed (n = 15) displayed positive cells for a specific fibroblast surface protein (FSP) that did not co-localized with a-smooth muscle actin (a-SMA). FSP positive cells were absent in non-atherosclerotic areas (arterial intimal thickening). Cell cultures that express FSP (fibroblast-like cells, FB-like cells) or a-SMA (SMC), were isolated from atherosclerotic plaques. PR were obtained from platelets activated with either 10 μmol/L ADP, 5 μg/mL collagen or thrombin (4 or 10 U/mL) for 5 min. Cells were synchronized by incubation in serum-free media for 48 h and subsequently stimulated with PR in the presence of [^{3}H]-thymidine to measure cell DNA synthesis for 24 h. FB-like cells exhibited higher response (8 to 26-fold) to PR from all agonists than SMC either from non-atherosclerotic segments or atherosclerotic plaques. Only PR from thrombin (10 U/mL) differentially induce mitogenic response on SMC from atherosclerotic lesions (3.4-fold over unstimulated cells) and non-atherosclerotic segments (1.2-fold over unstimulated cells). PR induced by thrombin triggered significantly higher DNA doubling than those of the other platelet agonists and it was the only agonist that showed direct proliferative effects on human vascular cells.

In conclusion, we have identified a fibroblast-like cell subpopulation from human primary atherosclerotic lesions which strongly responds to human PR. FB-like cells could modify the responsiveness of atherosclerotic plaques to mitogenic stimuli.

224 Inflammatory and immune response markers in patients with stable angina pectoris, acute coronary syndromes and healthy controls

R. Gök, B. Klein, M. Vater, M. Kempf, R. Winkler, B.U. Böhm[1], J. Senges, B.R. Winkelmann. *Herzzentrum Ludwigshafen; [1]Universitätsklinikum Ulm, Germany*

Background: Inflammatory markers are known to be elevated in acute coronary syndromes. However their role in stable angina pectoris has been studied less extensively.

Methods: We investigated the inflammatory markers interleukin 4, 12, c-reactive protein (CRP), fibrinogen, ferritin, leukocytes, lymphocytes in 486 patients (29% female) with stable and unstable CAD and in controls who underwent coronary angiograpy (CA). Healthy controls were defined as patients without stenosis of coronary arteries in CA, stable angina was defined as effort chest pain and documented CAD in CA (≥50% stenosis) and negative troponin T. Acute coronary syndrome was defined as chest pain at rest, positive troponin T and documented CAD, including patients with acute myocardial infarction. Patients with infections within 4 weeks were excluded.

Results:

	Health controls n = 169	Stable Angina pectoris n = 454	Acute coronary syndromes n = 32	p all groups
Age	56 ± 12	63 ± 9**	60 ± 11	<0.001
Sex (% female)	48	23	2	<0.001
Interleukin 4 (ng/l)°	0.3 (0.02/0.8)	0.21 (0/0.69)*	0.35 (0.07/1.29)	0.029
Interleukin 12 (ng/l)°	69 (47/98)	78 (52/102)*	77 (55/102)	0.16
CRP (mg/l)	0.25	0.38	2.24	<0.001
Fibrinogen (mg/dl)	331 ± 67	378 ± 93**	537 ± 125	<0.001
Ferritin (ng/ml)	141	151	263	<0.001
Lymphocytes (%)	30 ± 8	27 ± 8**	23 ± 8	<0.001
Leukocytes (/nl)	6 ± 2	7 ± 3**	8 ± 2	0.002

°Median; *p < 0.05; ** < 0.001 vs healthy controls

Conclusions: As expected acute phase markers were most increased in acute coronary syndromes. Howeverr, even in stable angina there were noteable changes in these markers compared to controls. Especially of interest is a decrease in interleukin 4 and lymphocytes indicating an important role of the immune system.

225 Significant association of cagA positive Helicobacter pylori strains with risk of myocardial infarction

M.C. Gunn, J.C. Stephens, J.R. Thompson[1], B.J. Rathbone, N.J. Samani[2]. *Department of Gastroenterology, Leicester Royal Infirmary, Leicester; [1]Department of Opthalmology, University of Leicester, Leicester[2]Department of Cardiology, Glenfield Hospital, Leicester, UK*

A potentially clinically and pathophysiologically important association of Helicobacter pylori (H. pylori) infection with coronary heart disease (CHD) has been reported. However, different studies have produced conflicting results. We examined whether genetic diversity of H. pylori influenced the association and specifically whether the risk was confined to infection with the more virulent strains (Type 1) bearing the cytotoxin-associated gene-A (cagA) antigen.

Methods and Results: Serological status for cagA and H. pylori were determined in 342 cases of acute myocardial infarction (MI) and 214 population-based control subjects free of clinical CHD. 38.0% of cases and 30.8% of controls were cagA seropositive (p = 0.08). In subjects < 65 years old (153 cases, 153 controls), cagA seropositivity was associated with a 1.80-fold (95%CI: 1.07–3.03, p = 0.02) increase in MI risk, which increased further to 2.25-fold (95%CI: 1.12–4.53, p = 0.01) in subjects < 55 years. Logistic regression analysis showed a significant interaction (p = 0.03) between age and effect of cagA seropositivity on risk of MI with an average 30% decline in the odds ratio per decade. There was no significant association of cagA status with classical CHD risk factors. 60.2% of cases and 53.7% of controls were H. pylori seropositive (odds ratio 1.12(0.83–1.51, p = 0.43). H.pylori seropositivity was not increased in young cases and did not show any interaction with age.

Conclusion: The association of H. pylori infection with risk of MI appears to be restricted to Type I cagA bearing strains. The association is age-dependent and stronger in younger subjects. Genetic heterogeneity of H. pylori may explain some of the discordant findings with regard to the association of H. pylori with CHD.

NEW INSIGHTS IN HYPERTROPHIC CARDIOMYOPATHY

226 Prepartecipation military screening and echocardiographic (phenotypic) prevalence of hypertrophic cardiomyopathy

S. Nistri, G. Thiene[1], C. Basso[1], D. Corrado[2], R. Scognamiglio[2], B.J. Maron[3]. *Sanitary Service, Arma dei Carabinieri; Dept. of [1]Pathology; [2]Cardiology, University of Padova, Padua, Italy; [3]Minneapolis Heart Institute Foundation, Minneapolis MN, USA*

Hypertrophic cardiomyopathy (HCM) is an important cause of sudden death (SD) in young people. It has been shown that an early identification of HCM during athletic screening can successfully prevent SD due to HCM. Because military duty is compulsory in Italy, every young male from the age of 17 undergoes medical screening, including history, physical examination, chest radiogram and 12-lead ECG. Thus we have assessed the prevalence of HCM in conscripts examined for cardiovascular abnormalities at the Military Hospital in Verona, January 1992 to July 1996. Of 8853 conscripts, 2596 (29.3%) were referred for echocardiography because of a positive initial screening, and 15 (age 18.6 ± 2.5 years; range 17–27) ultimately showed definitive evidence of HCM on echocardiography with otherwise unexplained left ventricular hypertrophy (prevalence 0.16%). In 9 patients (pts), HCM was diagnosed for the first time during the military screening; in these pts reasons for echocardiography included ECG abnormalities in 6 (one of whom had VPB at Holter monitoring), systolic murmur in 2, and a familial history of HCM in 1. None of these pts participated in competitive sports. In 6 pts HCM had been previously diagnosed, in 5 during preparticipation athletic screening and in 1 because of systolic murmur. All pts but one were asymptomatic. The maximal left ventricular thickness was 19.5 mm (range 15–35 mm).

In conclusion, preparticipation military screening shows a prevalence of HCM very similar to that previously reported in the general population (0.16–0.17%). Cardiovascular screening of a general military population identified HCM for the first time in young males who did not practice competitive sports. Screening programs based largely on electrocardiogram are an effective means to detect HCM in general population.

227 Atrial fibrillation is an important determinant of outcome in patients with hypertrophic cardiomyopathy

I. Olivotto, F. Cecchi[1], G. Santoro[1], A. Dolara[1], T. Gohman[2], B.J. Maron[2]. *Emergency Department, Azienda Ospedaliera Careggi, Florence; [1]Cardiologia 2 San Luca, Azienda Ospedaliera Careggi, Florence, Italy[2]Minneapolis Heart Institute Foundation, Minneapolis MN, USA*

The clinical impact of atrial fibrillation (AF) in patients with hypertrophic cardiomyopathy (HCM) is largely unresolved, with some studies suggesting that AF often leads to clinical deterioration, cardiac failure and systemic embolism, while others may have underestimated the consequences of this arrhythmia. In this study, we analyzed the prevalence and prognostic implications of AF in two large unselected populations of patients with HCM from Italy and the USA. Methods. Clinical documentation of AF and outcome in terms of cardiovascular mortality and stroke were analyzed in 480 patients with HCM (M/F 292/188) followed for 9.1 ± 6.4 years. Survival of those patients with AF was compared with that of a subgroup of HCM patients in sinus rhythm matched for the age, gender and NYHA class present at the time of first onset of AF, using the Cox regression analysis. Results. AF was documented in 107 of the 480 patients (prevalence 22%): 25 were in AF at the time of the first HCM diagnosis, whereas 82 developed AF subsequently, at a rate of 9 new cases or 1.9% per year. AF was exclusively paroxysmal in 45, paroxysmal leading to chronic in 32 and exclusively chronic in 30. Although its prevalence increased markedly with age, AF was present in a substantial proportion of younger patients (12% of patients < 50 years of age). AF was associated with an increased risk of HCM-related death (p < 0.0001), due to an excess stroke- and heart failure-related mortality, but sudden death occurrence was similar among patients with and without AF. At multivariate analysis, AF, age and NYHA were independent predictors of HCM-related mortality; odds ratio for AF was 3.7 (95% CI, 1.7–8.1, p < 0.002). Embolic events including stroke were nearly 9 times more frequent in patients with AF as compared to those in sinus rhythm (25% vs. 3%, p < 0.0001). Patients with AF also had a higher probability of developing severe functional limitation during follow-up (relative risk of a final NYHA class 3–4 was 2.8; 95% CI, 1.8–4.5, p < 0.0001). Conclusions. In an unselected population with HCM, atrial fibrillation 1) had a prevalence of 22% over a 9-year follow-up; and 2) was associated with disease progression, almost a 4-fold independent increase in cardiovascular mortality and a 9-fold increase in embolic events.

228 Prognostic value of non-sustained ventricular tachycardia in adult patiens with hypertrophic cardiomyopathy

L. Monserrat, P.M. Elliott[1], M. Penas-Lado, A. Castro-Beiras, W.J. McKenna[1]. *[1]St George's Hospital, London, UK; Hospital "Juan Canalejo", A Coruña, Spain*

Background: Non-sustained ventricular tachycardia (NSVT) during Holter monitoring is associated with an increased risk of sudden death (SD) in adult patients with hypertrophic cardiomyopathy (HCM). It is suggested that NSVT is only of prognostic significance when repetitive, prolonged and/or associated with symptoms. This study assessed prognostic significance of NSVT and NSVT characteristics in adult patients with HCM.

Methods: We studied 532 patients with HCM (324 male, aged 39 ± 15 years, 96% in functional class NYHA I–II; 20% with exertional chest pain). Maximal left ventricular wall thickness (MLVWT) was 21 ± 7 mm, and 29% had a left ventricular outflow tract gradient ≥ 30 mmHg. All patients underwent ambulatory ECG monitoring (mean 41 ± 11 hours). NSVT was defined as ≥3 beats at ≥120 beats/min.

Results: 104 patients (19.5%) had NSVT. Mean follow up was 47 ± 32 months (range 1 to 157 months). There were 51 deaths in the 532 included patients (24 SD). We found no relation between NSVT characteristics and prognosis. There were no significant differences in the incidence of sudden death or all cause mortality between patients older than 30 with and without NSVT. In patients younger than 30, sudden death risk and all cause mortality were higher in patients with NSVT (Log Rank Test: sudden death $p = 0.04$; all cause mortality $p < 0.0001$). Five years cumulative survival was 54% in patients younger than 30 with NSVT versus 91% in patients older than 30 with NSVT ($p < 0.0001$). In a multivariate Cox regression mortality analisys, NSVT was a significant independent risk factor for all cause mortality after adjusting by MLVWT, left ventricular outflow tract gradient, abnormal blood pressure response, syncope or family history of SD.

In conclusion, NSVT is an important risk factor for sudden death and all cause, mortality in young adult patients (≤30 years old) with HCM. There is no direct relation between NSVT characteristics and sudden death risk.

229 A mutation of the cardiac troponin T gene causes familial hypertrophic cardiomyopathy with normal left ventricular mass

A. Varnava, F. Coccolo, F. Davison, P. Elliott, M.J. Davies, W.J. McKenna. *London, UK*

The hallmark of familial hypertrophic cardiomyopathy is unexplained myocardial hypertrophy with disarray. However cases of widespread disarray in the absence of hypertrophy have been described. We screened the cardiac troponin T gene in the affected surviving relatives of such a family, in whom 4 members had died suddenly and unexpectedly before the age of 45. Heart weights and macroscopic appearance were normal in all 4 hearts. Histology however revealed widespread fibrosis with marked myocyte disarray.

Methods: A DNA based method for screening of the cardiac troponin T gene was devised. PCR products for each transcribed exon were screened by direct sequencing.

Results: A novel missense mutation of exon 9 (position 94 in the amino acid chain) resulted in a new restriction site for the enzyme Alu I. The mutation co-segregated with the disease and was confirmed in DNA extracted from fixed cardiac tissue of a family member who had died suddenly. This mutation at an evolutionary conserved site, results in a non conservative substitution of the amino acid arginine to leucine with an associated charge change. No mutation was found in the DNA of 100 normal control subjects.

Discussion: Patients with a mutation of a sarcomere protein may develop hypertrophic cardiomyopathy in the absence of an increase in LV mass detectable at the clinical or pathological level. These patients appear at high risk of sudden death and yet fail to exhibit the characteristic increase in wall thickness usually seen at clinical diagnosis.

230 Combined anterior mitral leaflet extension and myectomy in hypertrophic obstructive cardiomyopathy: long-term results

C. van der Lee, M.J. Kofflard, L.A. van Herwerden[1], F.J. ten Cate. *Department of Cardiology, Thoraxcenter, University Hospital Rotterdam, Rotterdam; [1]Department of Thoracic Surgery, University Hospital Rotterdam, Rotterdam, Netherlands*

Aim of the study: To examine the clinical and functional long-term results of combined septal myectomy and anterior mitral leaflet extension (MLE) in patients with hypertrophic obstructive cardiomyopathy (HOCM).

Background: MLE is a new surgical approach to the treatment of patients with HOCM. The procedure entails grafting a glutaraldehyde-preserved autologous pericardial patch onto the center portion of the anterior mitral leaflet. MLE in combination with septal myectomy provides more satisfactory haemodynamic results compared to those of myectomy alone. However, the long-term results of this new technique are not known.

Methods: Twenty-eight patients with HOCM underwent combined mitral leaflet extension and septal myectomy. Pre-operative data (NYHA functional class, width of the interventricular septum, left ventricular outflow tract gradient, severity of mitral insufficiency graded on a scale from 0 to 4+ and severity of the systolic anterior movement of the mitral valve graded on a scale from 0 to 3+) were compared to the postoperative findings at the latest outpatient follow-up.

Results: There were no deaths associated with surgery. One patient was re-operated within 3 months because of dehiscence of the pericardial patch. One patient died suddenly 2 years after surgical therapy. After a mean follow-up (± SD) of 3.4 ± 2.1 years (range 3 months–7.7 years), NYHA functional class had improved significantly (2.7 ± 0.5 preoperative vs. 1.3 ± 0.4 postoperative, $p < 0.05$). Furthermore, there was a reduction in width of the interventricular septum (23 ± 4 vs. 17 ± 2 mm, $p < 0.05$), a decrease of the left ventricular outflow tract gradient (100 ± 21 vs. 18 ± 14 mm Hg, $p < 0.01$) and a reduction in the severity of mitral insufficiency (2.6 ± 0.7 vs. 0.5 ± 0.6, $p < 0.01$) and systolic anterior motion of the mitral valve (2.9 ± 0.3 vs. 0.5 ± 0.7, $p < 0.01$) postoperatively.

Conclusions: MLE in combination with septal myectomy is an effective surgical approach to the treatment of patients with HOCM. The long-term results show sustained improvement in functional and haemodynamic parameters.

231 Remodelling after percutaneous transluminal septal myocardial ablation in hypertrophic obstructive cardiomyopathy results in ongoing outflow tract gradient reduction

H. Seggewiss, L. Faber, P. Ziemssen, H. Buschler, L. Krater, A. Meissner, U. Gleichmann. *Dept. of Cardiology, Heart Center NRW, Bad Oeynhausen, Germany*

PTSMA by alcohol induced septal branch occlusion in pts. with HOCM results in acute reduction of left ventricular outflow tract gradients (LVOTG) in >90% of the pts.. We report on short- and midterm follow-up results.

In 159 symptomatic pts. (79 men; age 51.9 ± 15.8 years; 52 pts. with prior syncope; NYHA class 2.8 ± 0.5) reduction of LVOTG from 61.4 ± 35.4 to 21.3 ± 22.2 mmHg at rest and from 132.1 ± 50.2 to 65.2 ± 43.6 mmHg at stress (each $p < 0.00001$) was achieved by PTSMA. 14 (9%) pts. required a DDD-pacer due to permanent AV block. We report on 3 months follow-up in all 159 pts. and 1 year follow-up in 102 pts..

1 pt. had temporary atrial fibrillation 2 and 9 months after PTSMA, each. No other cardiac complications were observed during follow-up. After 3 months 150 (94.3%) pts. showed clinical impovement (NYHA 1.3 ± 1.0; $p < 0.00001$) with an increase of workload from 83.5 ± 55.3 to 114.2 ± 39.8 Watts ($p < 0.001$). 4 pts. underwent successful re-PTSMA. 98 (61.6%) pts. showed further LVOTG reduction to 9.3 ± 12.1 mmHg at rest ($p < 0.0001$) and to 31.6 ± 36.4 mmHg at stress ($p < 0.0001$). After 1 year 56 (50%) pts. showed further LVOTG reduction and ongoing symptomatic improvement (NYHA 1.2 ± 1.0). 36% of the pts. after 3 months compared to 62% of the pts. after 1 year had no LVOTG at rest and stress ($p < 0.001$). Furthermore, we observed significant reduction of left posterior wall (LVPW) thickness from 13.9 ± 2.3 to 12.7 ± 2.1 mm ($p < 0.0001$) after 3 months and to 11.9 ± 1.8 mm after 1 year ($p < 0.0001$).

Conclusion: After PTSMA pts. showed ongoing clinical improvement without increased risk of cardiac complications. Remodeling after circumscribed septal infarction results in further LVOTG reduction in >50% of the pts. and significant reduction of LVPW thickness.

MEDICAL AND INTERVENTIONAL TREATMENT OF VALVULAR HEART DISEASE

232 More pronounced unloading effect of long-term therapy with enalapril in patients with aortic than with mitral severe chronic regurgitation

A. Goda, T. Goda, A. Kastrati. *Dept. of Cardiology, University Hospital Center "Mother Theresa, Tirana, Albania*

Previous studies demonstrated a favorable unloading effect of long-term therapy with enalapril (E) on asymptomatic pt with severe chronic aortic (AR) or mitral regurgitation (MR). To compare this effect on these two models of LV chronic volume overload we enrolled consecutively 60 pt with AR (n = 30) and MR (n = 30). After randomization 15 pt with AR (gr. ARE) and 15 pt with MR (gr. MRE) were allocated to enalapril therapy (26 + 6 mg/day) and 15 pt with AR (gr. ARC) and 15 pt with MR (gr. MRC) served as control (C). Changes (delta) of LV performance parameters were compared between ARE and MRE as well as between ARC and MRC groups after 6 months of therapy.

Results: There were no difference in baseline Echo parameters of LV diameters, volumes and mass between AR and MR groups and between E and C groups. After 6 months pt receiving E had a significant reduction in mean wall stress (MWS) (AR: 370 ± 93.6 to 284.2 ± 53.3 kdyne/cm2, $p < 0.001$; MR: 253.0 ± 36.1 to 223.6 ± 26.8 kdyne/cm2, $p < 0.01$), LV mass (AR: 214.0 ± 58.0 to 167.4 ± 37.7 g/m2, $p < 0.001$; MR: 176.5 ± 41.0 to 151.4 ± 22.6 g/m2, $p < 0.02$), EDVI (AR: 136.6 ± 28.9 to 113.9 ± 21.9, ml/m^2, $p < 0.001$; MR: 115.9 ± 21.4 to 102.9 ± 13.6 ml/m2, $p = 0.02$) and ESVI (only AR: 53.3 ± 19.6 to 42.6 ± 13.8 ml/m2, $p < 0.001$). In addition, there were a clear difference between E and C groups in MWS (AR: 284.2 ± 53.3 vs 365.9 ± 97.0 kdyne/cm2, $p < 0.01$; MR: 223.6 ± 26.8 vs 257.3 ± 31.0 kdyne/cm2, $p < 0.01$), LM mass (AR: 167.4 ± 37.7 vs 226.1 ± 51.5 g/m2, $p < 0.01$; MR: 151.4 ± 22.6 vs 168.3 ± 29.5 g/m2, $p < 0.05$), EDVI (AR: 113.9 ± 21.9 vs 143.4 ± 34.4 ml/m2, $p < 0.01$; MR: 102.9 ± 13.6 vs 117.9 ± 28.2 ml/m2, $p < 0.05$) and ESVI (only AR: 42.6 ± 13.8 vs 57.5 ± 19.6 ml/m2, $p = 0.02$) after 6 months. Changes (delta) of EDVI (22.7 ± 13.1 vs 13.0 ± 17.8 ml/m2, $p < 0.05$), ESVI (10.7 ± 8.9 vs 3.1 ± 11.4 ml/m2, $p < 0.05$), LV mass (46.6 ± 34.2 vs 25.1 ± 32.7 g/m2, $p < 0.05$) and MWS (85.8 ± 56.4 vs 29.4 ± 35.9 kdyne/cm2, $p < 0.05$) were more pronounced in ARE compared to MRE groups. Between ARC and MRC groups there were no any change on LV performance parameters after 6 months.

In conclusions: Unloading effect of long-term therapy with E in asymptomatic pt with severe chronic AR or MR reduce LV size and mass. This effect is more pronounced in AR than in MR groups of patients.

233 Vasodilatation with felodipine in chronic asymptomatic aortic regurgitation

L. Sondergaard, J. Aldershvile[1], P.R. Hildebrandt[2], H. Kelbaek[3], F. Stahlberg[4], C. Thomsen[5]. *DRCMR 340, Hvidovre Hospital, Hvidovre; [1]Medicine B2142, Rigshospitalet, Copenhagen[2] Medicine E, Frederiksberg Hospital, Copenhagen[3] Medicine B2013, Rigshospitalet, Copenhagen, Denmark[4] Radiation Physics, Lund Hospital, Lund, Sweden[5] Radiology X3023, Rigshospitalet, Copenhagen, Denmark*

In aortic regurgitation, vasodilatation reduces the volume overload upon the left ventricle and may thereby delay the need for valve replacemant. In the present study, the acute and long-term hemodynamic effects of vasodilatation with felodipine in chronic asymptomatic aortic regurgitation were examined in a randomized double-blind, placebo-controlled trial.

Methods: Sixteen patients with chronic asymptomatic aortic regurgitation were randomized to either intravenous bolus of felodipine 0.3 mg or placebo followed by 3 months treatment with felodipine 10 mg or placebo orally once daily. The hemodynamic effects of the intervention were monitored by magnetic resonance (MR) imaging at baseline, 30 minutes after the intravenous bolus, and after 3 months of orally treatment. Forward and regurgitant volume flow through the aortic valves were quantified by MR velocity mapping, whereas left ventricular dimensions were measured using MR multislice technique. Wilcoxon's test for paired samples was used to evaluate the effects of intervention in each of the groups. The significance level was defined as $p < 0.05$.

Results: The intravenous felodipine bolus caused a statistically significant reduction in systemic vascular resistance from (mean ± SD) 1162 ± 399 to 976 ± 317 dyne s cm^{-5} ($p < 0.05$), regurgitant volume index from 1.5 ± 0.8 to 1.3 ± 0.8 L min^{-1} m^{-2} ($p < 0.05$), and regurgitant fraction from 0.31 ± 0.15 to 0.26 ± 0.14 ($p < 0.05$). Furthermore, the forward cardiac output index increased from 3.2 ± 0.9 to 3.5 ± 0.7 L min^{-1} m^{-2} ($p < 0.05$). No significant changes occurred the placebo group.

Three months orally treatment with felodipine caused a corresponding, but more pronounced change in systemic vascular resistance from 1162 ± 399 to 885 ± 335 dyne s cm^{-5} ($p < 0.05$), regurgitant volume index from 1.5 ± 0.8 to 1.2 ± 0.7 L min^{-1} m^{-2} ($p < 0.05$) and regurgitant fraction from 0.31 ± 0.15 to 0.25 ± 0.11 ($p < 0.05$). In addition, the forward net cardiac output index increased from 3.2 ± 0.9 to 3.6 ± 0.7 L min^{-1} m^{-2} ($p < 0.05$). Again no signifant changes were registered in the placebo group and, furthermore, left ventricular end-diastolic and end-systolic volumes, ejection fraction, and mass remained unaffected by the treatment in both groups.

Conclusions: In chronic asymptomatic aortic regurgitation, felodipine causes beneficial hemodynamic effects with an increased forward cardiac output and decreased regurgitant volume, although the total work load upon the left ventricle is unaffected. These results indicates, that felodipine may be able to delay the need for valve replacement in chronic asymptomatic aortic regurgitation.

234 Vasodilator treatment in aortic regurgitation: an echocardiographic follow-up

A. Evangelista, M.P. Tornos, J. Guerra, M.T. González, M. Mateos, H. Garcia, J. Soler-Soler. *J. Cardiology, Vall d'Hebron Hospital, Barcelona, Spain*

Vasodilator agents are considered to be the treatment of choice in medical management of aortic regurgitation (AR). The aim of this study was to evaluate the benefit of treatment with nifedipine or enalapril in a blind follow-up by Doppler echocardiography. 76 patients (age 57 ± 17 y., 60 male, 16 female). with severe AR and a high-quality echo examination were included and randomly assigned to one of the following treatments: enalapril 20 mg/day (n = 28), nifedipine 40 mg/day (n = 22) or placebo (n = 26). The same observer performed an echo examination one day before the start of treatment and 2 years later. Left-ventricle end-diastolic (EDd) and end-systolic (ESd) diameter, mass index (MI), wide of the AR jet, and regurgitation fraction (RF) were measured. During follow-up, 4 patients underwent surgery (3 treated with enalapril, 1 with nifedipine). 8 patients abandoned nifedipine (36%) and one enalapril because of side effects.

Results ($^*p = 0.007$, $^\#p = 0.03$):

	EDd	ESd differences*	RF	RF difference$^\#$
Placebo	64 ± 5	2.6 ± 3	60 ± 13	2 ± 6
Enalapril	68 ± 6	−0.7 ± 5	62 ± 14	−3 ± 8
Nifedipine	64 ± 6	1.8 ± 3	59 ± 13	2 ± 7

There were no significant changes in ESd. When real treatment was considered, the results were the same, except for jet width, which decreased with enalapril 2 ± 3 mm and with nifedipine 1 ± 2 mm, versus placebo, 0 ± 3, $p = 0.03$. nifedipine did not improve EDd, but decreased MI (−10 ± 28) vs enalapril (16 ± 37) and placebo (21 ± 26).

Conclusions: After 2 years of treatment, enalapril has a favourable effect on decreasing left-ventricle end-diastolic diameter and aortic regurgitation. Nifedipine is tolerated worse, but also decreased aortic regurgitation and mass index.

235 Results of percutaneous mitral valvotomy with a metallic commissurotome in patients with a high echocardiographic score

G. Derumeaux, H. Eltchaninoff, R. Koning, C. Tron, R. Douillet, S. Chassaing, C. Giron, A. Cribier. *For the investigators of the multicenter registry; Hôpital Charles Nicolle, University of Rouen, France*

Severe mitral calcifications and retracted sub-valvular apparatus leading to a high echo-score (Sc) usually represent a poor indication to percutaneous balloon valvuloplasty for mitral stenosis. A new metallic commissurotome was developed and used in a series of 492 patients (Pts) divided into 3 groups: 242 Pts with low Sc (Sc < 8/16), 159 Pts with mid Sc (Sc: 8–9/16) and 73 Pts with high Sc (Sc ≥ 10/16).

The purpose of this study was to compare the 24-hour post-valvotomy results in the high Sc group with the low Sc and mid Sc groups.

In the high Sc group, Sc was 10/16 in 55%, 11/16 in 21%, 12/16 in 12% and ≥13/16 in 12%. Thickening of mitral valve was scored 3/4 in 71% and 4/4 in 9%. Calcifications were scored 3/4 in 33% and 4/4 in 11%. Sub-valvular apparatus was severely retracted 78%. Pts with high Sc were significantly older and 27% had a previous balloon valvotomy vs 10% in low Sc and 16% in mid Sc ($p < 0.01$). Pre-valvotomy mitral valve area (MVA, cm^2) by planimetry was similar in high Sc (0.88 ± 0.2), in low Sc (0.93 ± 0.22) and mid Sc (0.92 ± 0.2). Number of openings (2 to 4) was similar in the 3 groups and maximal opening size (40 mm) was used in 81% of low Sc, 91% of mid Sc and 87% of high Sc ($p = 0.01$).

The procedure was successful (MVA > 1.5 cm^2 and mitral regurgitation (MR) ≤ 2/4 of Sellers classification) in 97% of low Sc, 96% of mid Sc and 89% of high Sc ($p < 0.05$). Mean absolute increase in MVA (cm^2) was 1.25 ± 0.37 in low Sc, 1.2 ± 0.35 in mid Sc and 1.07 ± 0.36 in high SC ($p < 0.01$). Post-valvotomy MVA was slightly lower in high Sc (1.95 ± 0.38) than in mid Sc (2.12 ± 0.3) and low Sc (2.17 ± 0.33) ($p < 0.0001$). Double commissural splitting was obtained in 88% of low Sc, 83% of mid Sc and 78% of high Sc (ns). Severe MR occurred in 1 Pt with low Sc, 2 Pts with mid Sc and 2 Pts with high Sc (1 valve replacement).

Conclusion: Percutaneous mechanical mitral valvotomy appeared feasible, efficient and safe in Pts with a high echo-score who are usually considered as poor canditates to balloon valvotomy.

236 Haemostatic changes in patients with mitral stenosis: immediate impact of balloon mitral valvuloplasty

A. Zaki, M. Salama, M. El Masry, M. Abou Freikha, D. Abou-Ammo, M. Sweelum, E. Mashhour. *Departments of Cardiology, Internal Medicine, and Clinical Pathology, Cairo; Tanta Faculties of Medicine,, Cairo; Tanta, Egypt*

Recent evidence suggests that left atrial coagulation activity may be increased in mitral stenosis (MS). This study was conducted to assess regional right and left atrial hemostatic status in patients with MS and to investigate whether balloon mitral valvuloplasty (BMV) has favorable effects on hemostatic parameters.

Methods: Right and left atrial biochemical markers of platelet [Platelet factor 4 (PF4) and B thromboglobulin (BTG)], coagulation [thrombin-antithrombin III complex (TAT)], and fibrinolytic [D-dimer] systems were measured in 28 patients with MS and no left atrial thrombus before and 30 minutes after BMV. Right atrial levels were also measured in 20 control subjects

Results: Optimal BMV results (mitral valve area > 1.5 cm2, left atrial pressure < 10 mm Hg, and no mitral regurgitation) was reported in 16 patients (gp. I) and good results (mitral valve area > 1.5 cm2, left atrial pressure > 10 mm Hg, and no mitral regurgitation) in 12 patients (gp. II). Right atrial PF4, BTG, TAT and D-dimer levels were significantly higher in patients with MS than controls. Only TAT levels were significantly higher in the left atrium than in the right atrium of patients before BMV 7.01 ± 3.66 Vs 8.35 ± 3.89 ug/L, P < 0.0001). Right atrial levels of PF4, BTG, and TAT showed significant reduction in group I only after BMV than before the procedure (from 33.09 ± 11.16 to 23.18 ± 11.08 IU/ml, p = 0.001; from 212.19 ± 32.30 to 193.13 ± 34.39 IU/ml, p = 0.004; and from 7.98 ± 4.39 to 5.51 ± 1.64 ug/L, p = 0.007 respectively). The left atrial levels showed similar significant decrease after the procedure (from 34.53 ± 8.24 to 26.34 ± 8.74 IU/ml, p = 0.0001; from 224.69 ± 40.84 to 195.94 ± 28.47 IU/ml, p = 0.001; and from 9.51 ± 4.68 to 6.51 ± 1.46 ug/L, p = 0.013, respectively). Left atrial spontaneous echo contrast (LASEC) emerged as the only significant predictor of increased regional left atrial coagulation activity (p = 0.001) on multiple logistic regression analysis.

Conclusions: These data indicate that platelet, coagulation and fibrinolytic markers are increased in patients with MS in the absence of left atrial rombus. Regional left atrial coagulation activity is increased in such patients. Optimal BMV has favorable immediate hemostatic effects.

237 Incidence and types of valve dysplasia in 155 pulmonary valvuloplasty procedures

J. Simon-Lamuela, J. Casaldaliga, J. Sanmarti, J. Girona, M. Murtra. *Cardiology Dept., Vall d'Hebron Hospital, Barcelona, Spain*

Balloon pulmonary valvuloplasty (PV) is the ideal treatment for typical pulmonary valve stenosis. Howewer, the results of PV had been controversial when dysplastic valve stenosis is present. Our purpose is to study this problem in a large series of patients.

The existence of valve dysplasia was evaluated following angiographic criteria. Several degrees were considered. The data obtained were related with PV results. PV was performed in 155 ocasions in patients aged 0.1 to 51 years divided in 3 groups depending on angiographic anatomy. Group I, without dysplasia: 106 patients; group II, slight and moderate dysplasia: 34 patients and group III, severe dysplasia: 15 patients. In group I, pulmonary systolic gradient (PG) droped from 75.4 ± 22.3 to 24.6 ± 14.5 mmHg (P < 0.0001); echo-doppler follow-up showed even more decrease in PG (18.5 ± 10.6 mmHg). In group II, PG was reduced from 79.0 ± 30.7 to 25.5 ± 15.6 mmHg (P < 0.0001); follow-up by echo showed maintenance of similar PG (26.2 ± 16.1 mmHg). Howewer, in group III, reduction in PG was not significant (pre PG = 79.0 ± 28.9 mmHg; post PG = 74.1 ± 29.0 mmHg; echo-doppler PG = 73.2 ± 29.3 mmHg). Balloons were inflated several times at its maximum size and balloon/annulus ratio was 1.3 ± 0.25. In most patients an indentation was seen which was abolished easily in group I, with dificulty in group II, and was persistent in group III. Twelve patients in group III had to be operated on, and severe dysplasia was confirmed by surgeron.

In conclusion, PV is a very effective technique in patients with no or slight dysplasia. Howewer, this procedure has not been succesful in patients with severe grade of valve dysplasia. Severe dysplasia of the pulmonary valve has been stated with the typical morphology with nodular and uneven thickening of th valve, no doming, valve ring hypoplasia and no poststenotic dilatation. But some cases with severe and uneven valve thickening with no leaflets mobility had to be considered as severe types, even with good annulus and pulmonary artery size. The results of PV will be always dependig on the existence and the grade of valve dysplasia.

GENE EXPRESSION IN HEART FAILURE

248 Impaired cardiac function and bioenergetics in old transgenic mice overexpressing bovine growth hormone gene

E. Bollano, E. Omerovic, M. Bohlooly, M. Bassetti, J. Törnell, V. Kujacic, Å. Hjalmarson, B. Soussi, O. Isaksson, J. Isgaard. *Wallenberg Laboratory; Sahlgrenska University Hospital, Dept. of Physiology and RCEM, Göteborg University, Gothenburg, Sweden*

Substantial evidence indicates the importance of growth hormone (GH) for cardiac structure and function. The aim of the study was to evaluate cardiac function and myocardial energy status in mice with a long exposure to high levels of GH.

Methods: Female, eight months old transgenic mice (TG), expressing bovine growth hormone (bGH) gene (n = 11) and aged matched controls (n = 11) were used. Cardiac function was evaluated using transthoracic echocardiography. The animals were examined with 31P magnetic resonance spectroscopy to determine the cardiac energy status. The levels of apoptosis were also assessed.

Results: TG had a significantly higher body weight (BW), 53.2 ± 2.4 *vs.* 34.6 ± 3.7 g (p < 0.0001) and increased heart mass in relation to BW (HW/BW) compared to non-transgenic mice (5.6 ± 1.6 *vs.* 2.7 ± 0.2 mg/g, p < 0.01). bGH overexpressing mice were associated with significant decreases in several indexes of systolic function compared with control mice such as shortening fractions (25 ± 3.0% *vs.* 39.9 ± 3.1%), ejection fraction (57 ± 9% *vs.* 77 ± 5%), normalized mean velocity of circumferential shortening (4.7 ± 0.8 *vs* 6.4 ± 1.1 circ/sec), p < 0.01. Creatine phosphate-to-ATP ratio was lower in bGH mice in comparison to normal mice (1.3 ± 0.08 *vs.* 2.1 ± 0.23 p < 0.05). There was no sign of an increased number of apoptotic nuclei in myocytes from TG mice compared to controls.

Conclusions: Although short term treatment with GH may improve cardiac function, long term exposure to high levels of GH leads to increased BW, HW/BW and impaired systolic function. Moreover, these changes are associated with altered myocardial energy metabolism.

249 Decreased expression of insulin-like growth factor mrna in muscle biopsies from patients with chronic heart failure

P.C. Schulze, V. Adams, A. Linke, S. Gielen, R. Hambrecht, G. Schuler. *University of Leipzig, Heart Center Leipzig GmbH, Leipzig, Germany*

Background: Patients with chronic heart failure (CHF) show a reduced exercise capacity at least partially associated with metabolic and structural changes in the skeletal muscle. In CHF, an impairment of the GH/IGF-I axis has been demonstrated but no data are known about peripheral abnormalities in IGF-I mRNA expression. Therefore, the aim of this study was to investigate the local expression of IGF-I mRNA in skeletal muscle in pts. with CHF.

Methods: Skeletal muscle biopsies were obtained from 10 pts. with CHF and 6 normal controls. Total RNA was isolated and a RT-PCR with specific primers for human insulin-like growth factor I was performed. The expression of IGF-I was quantitated by densitometrical analysis of the ethidium bromide stained bands and expressed as ratio IGF-I/GAPDH.

Results: In skeletal muscle biopsies from pts. with CHF (body mass index 27.2 ± 3.0, age 63 ± 4 years, ejection fraction 20 ± 6%), the expression of insulin-like growth factor I mRNA was significantly reduced (0.02 ± 0.02 vs. 0.32 ± 0.4 arbitrary units, p = 0.015 vs. control) as compared to normal controls (body mass index 31.3 ± 5.3, age 54 ± 9 years, ejection fraction 73 ± 8%).

Conclusion: Peripheral expression of IGF-I mRNA is downregulated in pts. with CHF suggesting that a decreased local expression of growth factors might be involved in the loss of muscle bulk and the development of cachexia in CHF.

250 Effect of angiotensin II on extracellular matrix protein synthesis in the human heart

C. Kupfahl, D. Pink, K. Friedrich, H.R. Zurbrügg[1], M. Neuß, K. Graf, J. Fielitz, E. Wellnhofer, R. Hetzer[1], E. Fleck, V. Regitz-Zagrosek. *Innere Med./Kardiologie, Virchow-Klinikum, HU und DHZB; [1]Klinik Herz-Thorax-und Gefäßchirurgie, DHZB, Berlin, Germany*

The pathways by which Ang II induces fibroblast proliferation and extracellular matrix protein synthesis in the human heart are still unknown. We investigated whether Ang II directly alters the synthesis of collagen and fibronectin mRNAs after 4 hrs in isolated human myocardial preparations or after a longer stimulation period of 24 hrs in cardiac fibroblasts and whether the growth factors TGF-β1 and osteopontin are involved in this process.

The effect of 4 h Ang II stimulation on collagen I, TGF-β1, osteopontin, AT1 and AT2 mRNA was measured with quantitative RT-PCR in fresh strips of human atrial myocardium. The viability of the preparations was assessed by their adenine nucleotide content. In addition, the effects of 24 h Ang II or TGF-β on collagen I, III and fibronectin mRNA and on proliferation in isolated human cardiac fibroblasts were determined.

After 4 h, Ang II-stimulated atrial samples gave a significantly higher TGF-β1 mRNA expression (268 $\pm$ 52% of control, $p < 0.02$) and osteopontin mRNA expression (474 $\pm$ 174%, $p < 0.05$) than controls. In contrast, the expression of the collagen I mRNA or the reference gene PDH was not sign. altered. After 4 h AngII, AT1 and AT2 mRNAs were increased to 259 $\pm$ 67% and 247 $\pm$ 63% of con ($p < 0.005$ and $p < 0.05$). In human cardiac fibroblasts Ang II caused a dose-dependent stimulation of proliferation but did not affect collagen I, III or fibronectin mRNA synthesis after 24 h. In contrast, TGF-β1 stimulation sign. increased collagen I and III mRNA expression to 124 $\pm$ 5% and 128 $\pm$ 5% of control ($p < 0.002$).

Ang II does not directly increase collagen gene mRNA in the human heart. However, AngII induces the synthesis of TGF-β1 and osteopontin. Since TGF-β1 induces collagen I and III mRNA in cardiac fibroblasts, it probably mediates the effects of Ang II on collagen gene expression.

251 Myocardial inducible nitric oxide synthase gene expression modulates left ventricular contractile response to β-adrenergic stimulation in transplant recipients and in patients with dilated cardiomyopathy

M. Vanderheyden, C. Heymes[1], W.J. Paulus. *Cardiovascular Center, OLV-Ziekenhuis, Aalst, Belgium; [1]Inserm U127, Hopital Lariboisiere, Paris, France*

Nitric oxide(NO) derived from NO-donor or coronary(Cor) endothelium(Endo), modulates left ventricular(LV) function of the human heart through a LV relaxation hastening effect, which reduces LV end-systolic(ES) pressure(P) without change in LV+dP/dt. Pretreatment with dobutamine(dob) potentiates these effects. In the present study, LV contractile effects of NO produced by myocardial inducible(i) NO Synthase(S) were investigated in pts with non ischemic dilated cardiomyopathy (DCMP) and transplant (Tx) recipients and correlated with iNOS mRNA gene expression in simultaneously procured LV endomyocardial biopsies. Micro-tip LV pressure recordings before and during IV-dob(15 microg/kg/min) and endomyocardial biopsies, on which quantitative RT-PCR of iNOS mRNA was performed, were obtained in 17 patients. Dob-induced changes (D) in LV contractile performance (LVPSP = LV Peak Systolic Pressure; LVEST = LV Electromechanical Systole Time = Time from onset of QRS to LV-dP/Dt) were correlated with iNOS-mRNA molecules/microg total RNA in the endomyocardial biopsies.

iNOS and adrenergic stimulation

	DCMP (n = 9 pts)	Tx (n = 8 pts)
D-LVPSP vs iNOS	p = 0.10; r = −0.62	p = 0.07; r = −0.65
D-LV+dP/dt vs iNOS	p = 0.69; r = −0.17	p = 0.98; r = 0.98
D-LVEST vs iNOS	p = 0.03; r = −0.76	p = 0.52; r = 0.18
(D-LV+dP/dt)/(D-LVEST) vs iNOS	p = 0.01; r = −0.81	p = 0.007; r = −0.86

In DCMP pts iNOS gene expression was inversely correlated with D-LVEST. The inverse relation between iNOS gene expression and the ratio of D-LV+dP/dt divided by D-LVEST in DCMP and Tx pts implies a larger dob-induced abbreviation of LV contraction for a similar dob-induced rise in LV+dPdt at higher iNOS gene expression. This potentiating interaction between iNOS and beta-adrenergic stimulation on the onset of LV relaxation could result from additive effects on myofilamentary calcium sensitivity of a NO-induced rise in cGMP and a beta-agonist induced rise in cAMP.

252 The overexpression of the Na/Ca exchanger compensates for partial inhibition of the sarcoplasmic reticulum Ca ATPase in ventricular myocytes from transgenic mice

C.M.N. Terracciano, K.D. Philipson[1], K.T. MacLeod. *National Heart & Lung Institute, Imperial College School of Medicine, London, UK; [1]Department of Physiology and Medicine, University of California Los Angeles, Los Angeles, USA*

In heart failure a reduced expression of SERCA is often associated with an overexpression of the Na/Ca exchanger. The role of this overexpression in relation to a reduction in SERCA function was investigated in cardiac myocytes from transgenic mice overexpressing the Na/Ca exchanger (TR) and littermates (NON). Cytoplasmic [Ca] was monitored using indo-1. To partially inhibit SERCA, 200 nM thapsigargin (TG) was used. Ca transients were faster in TR compared with NON (time-to-peak + time-to 50% relaxation in TR = 234 $\pm$ 6 ms, n = 14; in NON = 332 $\pm$ 11 ms, n = 24, $p < 0.01$, mean $\pm$ SEM). Application of TG to TR slowed Ca decline until the time course of the Ca transient was equal or slower than the one measured in NON. The degree of inhibition of SR Ca uptake needed to produce an equal rate of Ca decline in the two groups was quantified by calculating Ca flux via SERCA (JSR). This, together with Ca flux mediated by the exchanger (JNa/Ca), was obtained as follows. Stimulation was stopped and Na-free/Ca-free (0/0) solution was applied for 2 s. The same solution containing 10 mM caffeine (0/0+caff) was then applied for 1 s producing an increase in Ca. Returning to 0/0 solution produced a decline in Ca mediated by SERCA. After 10 s, 0/0+caff was again added for 1 s and a second increase in cytoplasmic Ca was observed. Superfusate was then changed to 1 mM Ca +10 mM caffeine solution and maintained for a further 10 s. In this case Na/Ca exchange was responsible for the decline of Ca. In TR myocytes Vmax of JNaCa was 255 $\pm$ 45% (n = 9) of the one measured in NON myocytes. Vmax for JSR in TR had to be reduced to 72.4 $\pm$ 5% (n = 8) by TG application in order to obtain the same duration of the Ca transient measured in NON.

SR Ca content was also calculated as follows. Cells were voltage-clamped at −75 mV, 10 mM caffeine rapidly applied and a transient inward current recorded. The integral of this current allows quantification of Ca released from the SR upon caffeine application. In TR in control conditions the SR Ca content was larger than in NON (SR Ca in TR = 122 $\pm$ 9 μM/l non-mitochondrial volume, n = 15;in NON = 91 $\pm$ 6 μM/l,n = 12, $p < 0.02$). When TG in TR myocytes produced a twitch of similar duration to the one recorded in NON, the SR content was similar to the one recorded in NON (SR Ca in TR in TG = 98.4 $\pm$ 10 μM/l, n = 10; in NON in control = 91.4 $\pm$ 6.3 μM/l, n = 12). In conclusion, a 2.5 fold overexpression of the Na/Ca exchanger allows for ~30% reduction of the SR Ca uptake to take place before the Ca transient is slowed and the effect is accompanied by a return of the SR Ca content to NON myocyte values.

253 Differential gene expression in the systemic and pulmonary myocardium during mouse heart development: the left/right paradigm?

D. Franco, P. Zammit[1], R. Kelly[1], M. Campione[2], N.A. Brown[3], R. Harvey[4], M. Blum[2], M. Buckingham[1], A.F.M. Moorman. *Anatomy & Embryology Dept, Academic Medical Center, Amsterdam, Netherlands; [1]Department of Molecular Biology, Pasteur Institute, Paris, France[2]Institute of Genetics, Forschungzentrum Karlsruhe, Karlsruhe, Germany[3]Dept. of Anatomy & Develop Biology, St. George's Medical School, London, UK[4]VictorChang Cardiac Research Institute, St Vincent's Hospital, Sydney, Australia*

Differential gene expression among five embryonic cardiac compartments, the inflow tract, atria, atrioventricular canal, ventricles and outflow tract, has been widely demonstrated for several sarcomeric genes. We have previously described differences between left/right sides of the embryonic atria and ventricles in transgenic mice carrying regulatory sequences of myosin light chain (MLC) 1F/3F locus. In these mice, transgene expression becomes confined to the embryonic left ventricle (LV), atrioventricular canal (AVC) and right atrium (RA) just after cardiac looping. MLC3F transgene expression in situs inversus remains confined to the morphological LV, AVC and morphological RA. This data suggests that specification of the left/right ventricular identity is mainly dependent upon anteroposterior positional cues.

In order to get insight into the nature of the regionalization of gene expression in the developing left/right sides of the heart, we have investigated the expression pattern of various sarcomeric genes (MLC isoforms) and transcription factors (dHAND, eHAND, Nkx2.5, pitx-2 and chisel) by means of whole-mount in situ hybridization and radioactive in situ hybridization on tissue sections.

Expression of Nkx2.5 is observed in all myocardial cells of the embryonic heart (E10.5), whereas expression of chisel, a downstream target of Nkx2.5, is confined to the ventricular and atrial working myocardium, but not expressed in the outflow tract (OFT), AVC or the inner curvature connecting both segments. Pitx-2 transcripts are mainly confined to the right ventricle (RV) and left atrium (LA), a pattern complementary to that observed in the MLC3F transgenic mice. Atrial myosin heavy chain and MLC isoforms are firstly expressed throughout the myocardium but, as they become confined to the atria, a transient difference between left/right ventricles is observed.

Taken these data into account, we now report that the "primary myocardium" is characterized by the expression of Nkx2.5 whereas the pattern of chisel expression suggests a role in the development of the working atrial and ventricular myocardium. We further propose that the MLC3F transgene expression domain, i.e. the systemic myocardium, represents the evolutionary-conserved primitive heart, whereas pulmonary heart (LA and RV) is newly added to provide a double- pumping system; the expression of pitx-2 is in line with this notion. We further envisage that temporal differences in right/left ventricular myocardium are due to differences in maturation of the distinct cardiac chambers.

INTRAVASCULAR DIAGNOSIS AND INTERVENTION

254 Diagnostic and predictive intravascular images for successful thromboendoarterectomy in patients with thromboembolic pulmonary hypertension

Y. Okano, S. Takamoto[1], N. Nagaya[2], S. Kyotani[2], T. Satoh[2], T. Kunieda[3], S. Ichiyama. *Clinical Laboratory Medicine, Kyoto University Hospital, Kyoto; [1]Cardiovascular Surgery, Tokyo University, Tokyo[2]Cardiology Dept., National Cardiovascular Center, Osaka[3]Internal Medicine Dept., Ise-Keio Hospital, Mie, Japan*

Thromboembolic pulmonary hypertension (CTEPH) often leads to a severe disability and fatal outcome. To define the surgical accessibility in patients with CTEPH, bilateral lesions in the proximal (main or lobar) pulmonary arteries(PA) should be accurately assessed. Recent studies have shown that intravascular imaging provides direct evidence of lesions in PA as well as coronary and peripheral arteries. In order to examine whether intravascular images have diagnostic and predictive values for successful surgery in CTEPH, we analyzed the images obtained from 40 patients (25 with CTEPH and 15 with the other conditions which potentially affect the pulmonary circulation such as plexogenic, congenital and valvular diseases). An angioscopy (XPF30AL,Olympus,Tokyo,Japan) with an inflatable balloon on the distal tip and a mechanically rotated intravascular ultrasound (IVUS) system (SSD550, Aloka, Tokyo, Japan) were utilized. Angioscopy was useful in determining the location and extent of organized thrombi and thickened intima, recognized by the deformity of the intima and lumen in CTEPH. In contrast, a relatively smooth and uniform surface of intima and regular and round lumina were seen in the proximal PA in the others. A three layered structure with an intermediate echo-lucent zone was clearly demonstrated in CTEPH compared with a single 0.5 mm- to 1.0 mm-thick echogenic layer in the others by IVUS images. In addition, a thickening of the intima-media complex more than 1.0 mm in the proximal PA was the reliable predictor for complete thromboendarterectomy in CTEPH. In conclusion, direct visualization with intravascular imaging could disclose the diagnostic features in PA and lead to successful surgical treatment in CTEPH.

255 Intravascular ultrasound as a new approach for the anatomic and functional evaluation of primary pulmonary hypertension

J. Rodés, E. Domingo, A. Roman, I. Anivarro, J. Angel, C. Bravo, F. Padilla, J.C. Tardif[1], J. Soler-Soler. *Hospital General Universitari Vall d'Hebron, Barcelona, Spain; [1]Montreal Heart Institute, Montreal PQ, Canada*

The use of intravascular ultrasound (IVUS) for the study of pulmonary vessels has been limited to the evaluation of secondary pulmonary hypertension and pulmonary embolism. The purpose of our study was to analyze by IVUS the structural and functional characteristics of pulmonary vessels in the setting of primary pulmonary hypertension (PPH). In 11 patients with PPH (8 female, mean age of 37 years) we performed heart catheterization and simultaneous IVUS of pulmonary artery branches at baseline and after infusion of epoprostenol (EPO). By IVUS, two pulmonary lobes per patient were studied and the following parameters analyzed: presence of intima + media thickening (>0.2 mm), vessel diameter, mean wall thickness (WT), wall area (WA), area circumscribed by the external elastic membrane (EEM), lumen area in systole (LAs) and dyastole (LAd). Vessel distensibility (Dist) was calculated as: LAs-LAd/LAd. At baseline pulmonary resistance (PR) was 1709 $\pm$ 817 dyn.sec.cm^{-5}, with a mean pulmonary artery pressure (PAP) of 72 $\pm$ 21 mmHg and a cardiac index (CI) of 2.1 $\pm$ 0.7 L/min/m^2. Mean vessel diameter was 4.0 $\pm$ 0.8 mm and the presence of intima + media thickening was observed in all cases, being eccentric in 73% of them; with WT = 0.48 $\pm$ 0.1 mm, WA = 4.4 $\pm$ 1.2 mm2, WA/EEM = 36 $\pm$ 6%, and Dist = 15 $\pm$ 6%. With EPO infusion, PR decreased by 31% ($p < 0.001$), CI increased by 53% ($p < 0.001$) and there was no change in PAP (75 $\pm$ 34 mmHg). Dist had a mean increase of 88% ($p = 0.01$), irrespective of PAP changes. The severity of morphological findings did not correlate with haemodynamic variables at baseline or with changes induced by EPO.

In conclusion, IVUS demonstrates an intima + media thickening in all cases of PPH, predominantly eccentric, with >30% narrowing of the vessel lumen. However, the severity of these changes did not correlate with haemodynamic variables. The increase in vessel distensibility by epoprostenol as determined by IVUS suggests another beneficial effect of this drug in PPH.

256 Relation between pulmonary artery compliance and pulmonary artery pulsatility assessed by IVUS in primary pulmonary hypertension patients

E. Domingo, J. Rodés, F. Padilla, A. Román, C. Bravo, J. Angel, I. Anivarro, J. Soler-Soler. *Cardiology and Pneumology, Hospital Vall Hebron, Universitat Autonoma Barcelona Barcelona, Spain*

The non-invasive estimation of Pulmonary Artery Compliance, C (SV/Pulse pressure, ml/mmHg) correlates well with pulmonary vascular resistances in pacients with primary pulmonary hypertension (PPH) that undergo an acute vasodilator test by the intravenous infusion of epoprostenol. The aim of the study was to investigate the relationship of pulmonary artery compliance (C) and pulmonary artery pulsatility assessed by changes in luminal area measured by intravascular ultrasound (IVUS) during the performance of a vasodilator test with epoprostenol in PPH patients.

Methods: eleven patients with PPH underwent an acute vasodilator test with epoprostenol. During right-heart catheterization oxymetric samples were obtained and calculations of cardiac output (CO), stroke volume (SV), systemic vascular resistances (SVR), pulmonary vascular resistances (PVR) were performed at every increasing dose of the drug. Compliance was estimated by the ratio between SV/Pulse Pressure. Pulmonary intraluminal area was measured in 2 to 4 mm diameter vessels by IVUS (Endosonics®, vision-five cahteter), performed at baseline and at the end of the test (maximal tolerated drug dose or achievement of a 30% reduction in PVR), and pulsatility was calculated (sistolic area-diastolic area/diastolic area).

Results: Compliance increased from a baseline value of 0.75 $\pm$ 0.5 to 1.18 $\pm$ 0.77. Arterial pulsatility increased from 0.14 $\pm$ 0.06 to 0.23 $\pm$ 0.063. No correlation was found between C and Pulsatility at baseline (R 0.29 $\pm$ 0.50, p = 0.37 (ANOVA)) nor at the end of the test (R 0.128 $\pm$ 0.80, p = 0.70). We did not found correlation between proportional changes in C and Pulsatility either (R 0.50 $\pm$ 0.52, p = 0.117).

Conclusions: In PPH patients that underwent a vasodilator test, no correlation was found between pulmonary arterial pulsatility assessed by IVUS and compliance estimated by hemodinamic parameters. This may be explained by the heterogeneous distribution of the disease, by the fact that the non-invasive estimation of C explains the behaviour of the pulmonary arterial tree as a whole, whereas IVUS measurements are focused only in small arteries, and because the degree of pulsatility could be preserved with increased pressure (low compliance) or with normal pressure (high complicance).

257 Prognostic role of temporary caval filters in patients with acute major pulmonary embolism

K.H. Scholz, A.B. Buchwald, J. Stade, S. Vonhof, G. Hasenfuß. *Department of Cardiology, Center for Internal Medicine, Georg-August-University of Göttingen, Germany*

Background The aim of this study was to assess the prognostic role of implantation of temporary vena cava filters in patients with acute major pulmonary embolism.

Methods and Results We present the clinical course of 115 consecutive patients with acute major pulmonary embolism presenting with hypotension (systolic aortic pressure $\leq$ 90 mmHg) or shock and diagnosed by pulmonary angiography between January 1987 and December 1998. In all patients, baseline therapy consisted of Heparin and thrombolysis (if not contraindicated), 7 patients were treated with pulmonary thrombectomy. Since its first use in 1991, an increasing number of patients additionally received temporary vena cava filters, which were systematically used in all patients since January 1995.

In patients treated between 1987 and 1990 (group I: no use of caval filters; n = 39), in hospital mortality was 38.5% (15/39 patients). Mortality of resuscitated patients was 71.4% (10/14 patients). During the first 6 days of treatment, recurrent pulmonary embolism was observed in 17.9% (7/39 patients), which directly caused death in 2 patients.

In 36 patients treated between 1991 and 1994 (group II: sporadic [n = 12] use of temporary caval filters), in hospital mortality was 38.8% (14/36), and early recurrent embolism occurred in 11.1% (4/36 patients; all of them no caval filter) leading to death in 2 patients.

In patients treated between 1995 and 1998 (group III: use of caval filters in all patients; n = 40), in hospital mortality was 30.0% (12 of 40 patients) [vs. 38.5% in group I, $P = 0.46$], and no patient suffered recurrent pulmonary embolism during the first 6 days of treatment with caval filters in place. In group III, mortality of resuscitated patients was 45% (9/20) [vs. 71.4% in group I, $P = 0.13$].

In the total of 115 patients with acute major pulmonary embolism, mortality was 42.9% (27/63) in patients with no use of temporary caval filters, but 26.9% (14/52) in patients treated with temporary caval filters ($P < 0.05$).

Conclusions: These results suggest that use of temporary V. cava filters may reduce the rate of recurrent pulmonary embolism and may favorably affect the clinical outcome in patients with major pulmonary embolism, especially in resuscitated patients.

258 Clinical evaluation of the pathophysiology of acute and chronic pulmonary thromboembolism by observing with intravascular ultrasound and angioscopy

C. Kato, H. Matsuyama, M. Iwase, M. Kimura, A. Koide, H. Yamamoto, A. Nagasaka, T. Kondo, M. Nomura, H. Hishida. *Internal Medicine Dept., Fujita Health University, Toyoake, Japan*

Purpose: By observing with intravascular ultrasound(IVUS) and angioscopy(AS) pulmonary artery thrombi and parietal lesions in patients with acute and chronic pulmonary thromboembolism(APTE,CPTE), we investigated the differences in the pathophysiology of the two entities.

Material and Methods: At the time of right heart catheterization IVUS and AS were performed in 15 patients with pulmonary thromboembolism (PTE)(mean age 58 $\pm$ 18 years old, APTE n = 5, CPTE n = 10).

Results: In APTE without underlying disease no intimal thickening was noted and good pulsality was shown. On AS red thrombi could be directly observed, the surface was white-colored and smooth, and no parietal thrombi were found. In CPTE, the cases could be classified into the three groups: (1) Poor extensibility of the vessel wall and intimal thickening were noted on IVUS, while on AS relatively fresh parietal thrombi consisting of a mixture of red blood cell and fibrin, and spider web-like thrombi were found. (2) On IVUS, crescentic parietal thrombi and wall irregularity were seen, while on AS probably organized thrombi with a mixture of red and white surface were seen. (3) On IVUS, marked and echo-rich intimal thickening and poor extensibility were noted, while on AS intimal surface irregularities and yellowish changes were observed. All of the acutely deteriorating cases in the chronic phase belonged to (1), (2).

Conclusion: 1) IVUS and AS are useful in characterizing the thrombi and related pulmonary artery lesions in pulmonary thromboembolism. 2) The pulmonary artery intima and thrombus differ between APTE and CPTE, and among CPTE cases. 3) Unstable pulmonary artery lesions might be present and lead to acute deterioration.

259 Diagnose of pulmonary hypertension reversibility degree using transvascular pulmonary puncture-biopsy (by a new invented method registered in Romania)

I. Benedek, R. Togăanel[1], T. Hintea, E. Făgărăşanu[2]. *Department of Cardiology, Mures Clinical Hospital; [1]Clinic of Paediatric Cardiology, Târgu-Mureş; [2]Clinic of Cardiovascular Surgery Târgu-Mureş, Romania*

It is well known that in the congenital heart diseases that develop high pressures and increased blood volumes in pulmonary circulation, the results of surgical treatment are correlated with the reversibility degree of pulmonary circulation alteration. To estimate this reversibility degree, the most accurate method is the histologic examination of the pulmonary tissue, but the intraoperatory or percutaneous pulmonary biopsy presents a high risk. The aim of our study was to elaborate a repeatable method for prelevating pulmonary tissue, without the risks and the complications of the other methods.

Methods: We experimented the method on 35 dogs and 20 corpses, using a biopsy catheter specially create by us for this purpose. For this biopsy-catheter and for the method, the Romanian Office for Inventions and Marks conferred us in 1990 the invention patent nr. 100812. Using the right cardiac catheterization way, after we fixed the catheter in a ram of pulmonary artery, we prelevated samples of pulmonary tissue. The animals were hemodyamicaly monitored.

Results: In all cases, we obtained samples of pulmonary tissue with 3–5 mm. length (average 3.8 mm) and 2–3 mm height (average 2.4 mm), among 3 and 5 samples in each case. The samples were large enough for microscopic examinations, which permitted to distinguish constitutive elements of pulmonary structures. After performing biopsies, we effectuated a segmentotomy of the punctured lobe together with the catheter and we examined this macro- and microscopic. We did not find any significant traumatical injuries at the site of the puncture.

In conclusion, transvascular pulmonary biopsy can be a very useful method to follow the modifications of pulmonary circulation in cardiac diseases and to diagnose the reversibility degree of pulmonary hypertension. This method presents the advantages that it can be repeated and implicates no risks, and can be extended in future in other fields of medicine, for instance in pulmonary tumours.

PATIENT EDUCATION IN HEART FAILURE AND OTHER CARDIAC PATIENTS

275 Study of nursing intervention in practice

R.H. Stables, J. Booth, J. Welstand[1], A.M. Wright, O.J.M. Ormerod[1], W.R. Hodgson[1]. *Clinical Trials & Evaluation Unit, Royal Brompton & Harefield NHS Trust, London; [1]Department of Cardiology, The John Radcliffe Hospital, Oxford, UK*

Background: A number of initiatives have employed nurses in roles traditionally associated with the medical profession but few have been formally evaluated. We have tested the performance of a Nurse Practitioner (NP) trained to prepare patients for diagnostic cardiac catheterisation.

Method: This was a prospective randomised study. Consecutive patients attending pre-admission clinic for daycase cardiac catheter were screened. Consenting patients scheduled for elective cardiac angiogram were randomised to preparation by either the NP or medical house officer (HO). The principal outcome measure was the combined rate of in-hospital major adverse clinical events (death, MI, emergency cardiac surgery, emergency interventional procedure, CVA, vascular surgery). Secondary outcome measures included (i) combined rates of in-hospital minor adverse clinical events (ii) senior angiographic operator (SAO) assessment of patient preparation and (iii) patient satisfaction.

Results: During April 1997 to May 1998 a total of 355 patients were screened, of these 347 patients were eligible. A total of 339 patients consented to participate and were randomised to NP group (n = 161, age mean $\pm$ SD 62.6 $\pm$ 10.2, male 73%) or HO group (n = 175, age mean $\pm$ SD 60.8 $\pm$ 10.5, male 71%). The rate of major adverse events was lower in the NP group compared to the HO group (NP 0.0% v's HO 1.2%, risk difference −1.2% upper limit of 90% CI +2.0%). The rate of minor adverse evnts was higher in the NP compared to the HO (NP 2.3% v's HO 0.6%, risk difference +1.7% upper limit of 90% CI = +6.2%). The SAO assessment of patient preparation was similar in both groups. Overall patients were satisfied but the proportion of patients grading their care as "very satisfied" was higher in the NP group (NP 94.3% vs HO 86.8% p = 0.02).

Table 1: Results from the SNIP Study

	NP	HO	Risk diff	UL 90% CI	P
Major adverse events	0.0%	1.2%	−1.2%	+2.0%	0.23
Minor adverse events	2.3%	0.6%	+1.7%	+6.2%	0.37
Patient satisfaction	94.3%	86.8%	–	–	0.02

Risk diff = risk difference, UL 90% CI = upper limit of 90% confidence interval

Conclusions: A trained NP can safely prepare patients for cardiac catheterisation. Patients have a higher level of satisfaction with the NP.

276 Nurse-led heart failure clinics in Sweden

A. Strömberg, J. Martensson[1], B. Fridlund[1], U. Dahlström. *Department of Cardiology, Linköping[1] Department of Primary Health Care, Göteborg University, Göteborg, Sweden*

Nurse-led heart failure clinics have been proven cost-effective and improving the patient's quality of life. The aim of this study was to describe the nurse-led heart failure care in Sweden.

Methods: A questionnaire was sent to all 86 hospitals in Sweden, treating heart failure patients. All hospitals completed the questionnaire, which contained questions about presence of heart failure nurses, their education and delegation, how patient education was provided, presence of a heart failure clinic and if so, how it was organised.

Results: Fifty-nine hospitals (69% of all hospitals) had nurses specially trained to take care of heart failure patients, in total 148 heart failure nurses. The nurses were involved in patient education. In all hospitals the heart failure patients were given both oral and written information. The patients were additionally shown a video about heart failure in 24 hospitals, and in 23 hospitals the patients had access to an interactive computer based information. Seven hospitals had group information. Fifty-seven hospitals (66% of all hospitals) had nurse-led heart failure clinics. The clinics provided follow up after hospitalisation, telephone counselling and drug titration. In 40 hospitals the heart failure nurses had a delegation for making protocol led changes in medications such as ACE-inhibitors, β-blockers, stop medication with interactive drugs usually potassium sparing drugs and decrease or increase the dose of diuretics. The majority of the clinics registered the number of visits to the clinic, and the largest clinic had up to 1000 visits annually. Some of the clinics also evaluated their clinic in concern of patient satisfaction, quality of life and the number of readmissions to hospital.

In conclusion, the first nurse-led heart failure clinic started in Sweden in 1990 and since then the concept has been spread to two thirds of the Swedish hospitals.

277 Cardiac patients perceived education and use of sub-lingual glyceryl trinitrate upon commencement of outpatient cardiac rehabilitation

Shirley Ingram, Joan Love. *The Adelaide & Meath Hospital incorporating The National Children's Hospital, Dublin, Ireland*

Purpose: Patients leaving hospital with a discharge diagnosis of myocardial infarction (MI) or angina will be on a variety of cardiac medications. As glyceryl tri-nitrate (GTN) is in the front line of treatment with which cardiac patients can self-medicate with, the question arises as to the education and practical use of this drug amongst angina sufferers. This study was designed to assess patients use of sub-lingual GTN and to discover how they came by this knowledge prior to attendance at outpatient cardiac rehabilitation.

Methodology: Upon attending their first visit to the cardiac rehabilitation outpatient clinic 50 successive patients with a diagnosis of (MI) or angina were interviewed using a closed questionnaire. All patients consented verbally to participate.

Results: Of the 50 patients questioned 35 (70%) complained of post discharge angina. (34%) of this group did not receive a prescription upon discharge. Only 14 patients remember receiving any advice or information about sl-GTN. Patients who had suffered angina while an in-patient were more likely to receive a prescription for GTN pre-discharge (21 out of 22). However this did not necessarily mean receiving education as only 13 remembered receiving any advice as to the correct use of this medication.

Conclusions: The findings of this study suggest that cardiac patients do not know enough about SL GTN and require more education if they are to manage their own health. As cardiology nurse specialists education of the cardiac patient begins with admission and should encompass medication advice alongside that given by medical and pharmacy staff.

278 Cardiac rehabilitation in an outpatient clinic managed by nurses quality assured by computers, doctors and patients

L. Koch, S. Stender[1], J. Glenthoj[2], C. Torp-Pedersen. *Department of Cardiology, University Hospital of Cph., Gentofte, Hellerup; [1]Department of Clinical Biochemistry, University Hospital of Cph., Gentofte, Hellerup[2]Merck Sharp & Dohme, Glostrup, Denmark*

Purpose: To establish a method for cardiac rehabilitation that makes it possible to reduce the modifiable risk factors for development of ischemic heart disease and at the same time follow the efficacy of the treatment.

Methods: The nurses make use of a computer programme and a detailed manual for all procedures in the clinic.

Based on the values for blood cholesterol, blood pressure, body weight and smoking habits the computer programme generates instantly at each consultation a patient report. The patient report graphically depicts all previous and present values as well as the target values for the treatment on a single sheet given to the patient. The patient report is used as a basis for the consultation with the nurse, who focuses on lifestyle changes as well as drug treatment.

In addition the computer generates automatically an updated clinic report.

The clinic report graphically depicts the effect of the treatment on the modifiable risk factors for the entire population of patients. The clinic report also depicts the number of consultations per month, the average time between the visits as well as the total patient time below the individualised targets for the blood cholesterol level.

The manual describes in details the logistic and all the procedures in the clinic.

After the treatment goals have been achieved the treatment is continued by the general practitioner. It is possible for the general practitioner to continue the patient report containing values both from the hospital and from the general practitioner.

Results: The system has been in use for 1 year. One nurse (34 hours per week) has seen 300 patients with established ischemic heart disease and compiled 100 treatment years. The mortality has been 6%. The LDL-cholesterol has decreased by 15%, the HDL-cholesterol has increased by 15%. There has been a 20% reduction in total risk score for the development of ischemic heart disease.

Conclusion: We have developed a nurse-managed system with automatic quality assessment. One nurse has treated and monitored 300 patients with 1.000 consultations in 1 year with a significant reduction in the patients risk profile.

279 Effects of a multidisciplinary, home-based intervention on unplanned readmissions and survival among chronic congestive heart failure patients: a randomized controlled study

S. Stewart, J.E. Marley[1], J.D. Horowitz. *Cardiology Dept., The Queen Elizabeth Hospital, Adelaide; [1]General Practice, University of Adelaide, Adelaide, Australia*

Hospital admissions among individuals with congestive heart failure (CHF) represent a costly burden to the health-care system. We evaluated a post-discharge, multidisciplinary, home-based intervention (HBI)specifically designed to identify and address the precipitants of clinical deterioration among such patients (pts) in order to reduce the frequency of unplanned readmission.

Methods: Hospitalised CHF pts were randomised to either usual care (UC: n = 100) or to HBI (n = 100) and followed-up for a minimum of 6 months. The primary end-point of the study was frequency of unplanned readmission plus out-of-hospital death within 6 months. Secondary end-points included duration of event-free survival and survival alone, frequency of multiple readmissions, cost of hospital-based care and quality of life.

Results: During 6 months follow-up the major end-point occurred more frequently in the UC group (129 vs. 77 primary events; P = 0.02). More HBI pts remained event-free (38 vs. 51; P = 0.04) and had accumulated fewer unplanned readmissions (68 vs. 118; P = 0.03) and associated days of hospitalisation (460 vs. 1173; P = 0.02). Hospital-based health-care costs for the HBI group were approximately half those of UC ($A490,300 vs. $A922,600; P = 0.16). The mean cost of HBI was $A350 per patient, whilst other community-based health care costs were similar for both groups. The overall distribution of unplanned readmissions was significantly different for the two groups (P = 0.04) with fewer HBI pts being readmitted (42 vs. 54) and requiring 3 or more readmissions (5 vs. 19). In a subgroup of 68 pts, heart failure-specific (P = 0.04) and general quality of life scores (P = 0.01) at 3 months were most improved among HBI pts. Assignment to HBI was both an independent predictor of event-free survival (RR 0.66; P = 0.03) and survival at 6 months (RR 0.54; P = 0.046).

Conclusions: In this controlled study, among a cohort of previously hospitalised CHF pts, a relatively inexpensive HBI was associated with reduced frequency of unplanned readmission plus out-of-hospital death, more prolonged event-free survival, fewer health-care costs and improved quality of life.

280 Comprehensive medical and nursing management decreases hospital care of heart failure

C. Lucas, J.-M. Van Dantzig, G. Cleuren, E.C. Cheriex, H.J.J. Wellens. *Cardiology Dept, Academisch Ziekenhuis, Maastricht, Netherlands*

The number of patients with congestive heart failure (CHF) is increasing rapidly. Due to financial constraints, means of reducing hospital care are of prime importance. A program of intensified outpatient care, comprising systematic patient instruction and follow-up by a specialized nurse and dedicated outpatient department has been proposed as a means to decrease hospital care of CHF. Accordingly, we investigated the effect of institution of such a program in our department on hospital admissions. Since 1998, a nurse and cardiologist specialized in protocolized care of CHF collaborate within the framework of a dedicated outpatient clinic in our hospital, with a reference area of 200.000 people. We compared data regarding admissions and readmission rate from 1998 to historical data from 1995–1997. Clinical characteristics were unchanged over these years (age 73 ± 12, 56% male, LVEF 40 ± 16%). Results are presented in the Table. There was no change in the number of first admissions, but the readmission rate was dramatically reduced.

	1995	1996	1997	1998
First admission	324	349	338	316
Readmission	80	78	106	53

Thus, our results suggest that in the face of an unchanged incidence of CHF in our catchment area (unchanged number of first admissions), our program was succesful at decreasing hospital care of congestive heart failure (decreased number of readmissions).

TREATMENT OF IN-STENT RESTENOSIS

281 Randomized trial of rotational atherectomy vs. balloon angioplasty for in-stent restenosis (ROSTER): interim analysis of 150 cases

S.K. Sharma, A. Kini, T. King, G. Dangas, T.P. Cocke. *Division of Cardiology, Box 1030, Mount Sinai Hospital, New York NY, USA*

Based on our preliminary experience with rotational atherectomy (RA) for treatment of diffuse in-stent restenosis (ISR), a randomized trial comparing RA versus high pressure (12–16 atm) balloon angioplasty (BA) with IVUS guidance was started in 11/96.

Results: Baseline variables were compared between the two groups. RA group: burr size 2.2 mm, burr number 2.2, burr-to-artery ratio 0.72 & mean post dilatation balloon pressure 4.8 atm. BA group: mean balloon size 3.4 mm & mean inflation pressure 13 ± 4 atm. IVUS data revealed larger post-procedure lumen area gain after RA vs. BA (4.2 ± 1.8 vs. 3.6 ± 1.9 mm^2: p = 0.02) with predominant contribution by plaque debulking in the RA group (54%) vs. plaque compression/extrusion in the BA group (62%). There was no major procedural or clinical complications and 8% in the RA group and 36% in the BA group required re-stenting (p < 0.01). At a mean follow-up of 12 ± 4 months there has been one death & two CABG in each group. Clinical restenosis, defined as angiographic restenosis, target vessel revascularization or recurrent angina class III-IV, has occurred in 20% in the RA group and 43% in the BA group (p = 0.01).

Interim analysis of ROSTER trial

Variable	RA (n = 75)	BA (n = 75)	p
Ref vessel diam (mm)	3.1 ± 0.4	3.1 ± 0.3	NS
MLD Pre (mm)	0.8 ± 0.2	0.9 ± 0.4	NS
MLD Post (mm)	2.8 ± 0.4	2.5 ± 0.3	0.03
Clinical restenosis (%)	20	43	0.01

Conclusion: In the ROSTER trial for ISR, RA resulted in better luminal gain, lower incidence of stent use and lower clinical restenosis compared to PTCA. Thus RA appears to have an advantage over BA for the treatment of diffuse ISR.

282 In-stent restenosis: excimer-laser angioplasty, rotational atherectomy or conventional balloon angioplasty?

B. Lauer, E. Schmidt, H. Ambrosch, K. Diederich, R. Hambrecht, H. Krankenberg, A. Kuhn, P. Sick, R. Zotz, G. Schuler. *Heart Center, University of Leipzig, Germany*

Background: Conventional balloon angioplasty (PTCA) for treatment of in-stent restenosis results in high re-restenosis rates after 6 months. Tissue debulking with excimer-laserangioplastie (ELCA) or rotational atherectomy (PTRA) may be more efficious than PTCA alone. Therefore, the present study evaluates the acute and long-term results after ELCA, PTRA or PTCA for in-stent restenosis.

Methods: 314 lesions (L) with in-stent restenosis were treated with ELCA (124 L), PTRA (124 L) or PTCA (238 L), respectively. After tissue debulking with ELCA or PTRA, additional PTCA was performed to achieve optimal acute procedural results. Coronary angiogramms were analyzed by quantitative angiography (QCA).

Results: QCA data are given in the table.

	Acute intervention				Long-term results	
	n	MLD before intervention	MLD after debulking	MLD after intervention	n	MLD at follow-up (6 months)
ELCA	124	0.93 ± 0.48	1.74 ± 0.42	2.60 ± 0.72	72	1.21 ± 0.86
PTRA	124	0.92 ± 0.55	1.75 ± 0.42	2.57 ± 0.54	75	1.51 ± 0.86*
PTCA	238	0.84 ± 0.51	-	2.31 ± 0.58	118	1.30 ± 0.75

MLD: minimal lumen diameter (mm), *: p < 0.05 for PTRA vs ELCA or PTCA, respectively

Conclusions: ELCA and PTRA for in-stent restenosis result in significant ablation of restenotic tissue. After 6 months, MLD was greater after PTRA than after ELCA or PTCA, respectively

283 Treatment of diffuse in-stent restenoses with the "cutting" balloon: acute angiographic and clinical results

D.G. Mathey, T. Rau, H. Kedra, J. Schofer. *Center for Cardiology Othmarschen, Hamburg, Germany*

At present, the treatment of diffuse (>10 mm) in-stent restenosis by established procedures such as balloon angioplasty, laser angioplasty or rotablation is unsatisfactory. Use of the "cutting" balloon (CB) promises an improvement of acute and long-term results.

Between 3/98 and 10/98, we treated 111 diffuse in-stent restenoses (50 LAD, 41 RCA, 18 LCx, 2 ACVB) in 105 patients (78 m, 26 f; 61 ± 10 years) with the CB. The procedure was performed within a median of 6.4 months of stent implantation; in 31 lesions (28%), it had been preceded by at least 1 angioplasty, while no intervention had preceded the CB approach in the other lesions.

Results: Intervention with the CB was angiographically successful in all cases (visual estimation of residual stenosis <20%). Additional stent implantation was required in 22 lesions because of a dissection (n = 14) or a significant residual stenosis (n = 8). One patient in whom LAD and LCx had been treated with the CB in close vicinity to the main stem and another vessel had been dilated conventionally, died in cardiogenic shock within 8 hours of the procedure. There were no more acute complications. To date, follow-up angiography within 6 months had been performed in 35 patients (33%); a diameter stenosis ≥ 50% was found in 14 (40%).

Conclusions: Treatment of diffuse in-stent restenoses with the CB results in the majority of patients in an excellent acute angiographic outcome. The safety of the procedure in lesions located close to the main stem needs to be established. Final data on the late angiographic outcome are forthcoming.

284 Long-term clinical and angiographic follow-up of coronary stenting for patients with in-stent restenosis

F. Alfonso, A. Cequier, J. Zueco, C. Moris, C.P. Suarez, T. Colman, E. Esplugas, M.J. Pérez-Vizcayno, C. Fernández, C. Macaya. *San Carlos H, Madrid; Bellvitge H. Barcelona; Valdecilla H, Santander, Asturias H, Oviedo, Spain*

Background: Restenosis (RE) of a previously implanted stent (ST) constitutes a therapeutic challenge affecting a growing number of patients (P). Conventional angioplasty (PTCA) and new debulking devices are currently used in this setting. However, the role of a new ST implantation (ST intra ST) remains unclear.

Methods: Of 361 consecutive P requiring intervention for in-ST RE, 65 P (18%) (mean age 62 ± 11 years, 12 female) underwent repeat ST implantation (42 elective, 23 unplanned). In-ST RE was diffuse (>10 mm) in 60% of P.

Results: Angiographic success was obtained in all P. During hospitalization 1 P died (refractory heart failure) and 2 had non-Q-wave myocardial infarctions (1 side-branch occlusion, 1 subacute ST thrombosis treated with PTCA). At follow-up (mean 17 ± 11 months) 1 P died (noncardiac death) and 9 (14%) required target vessel revascularization (5 PTCA, 4 surgery). Kaplan-Meier event-free survival (from death, myocardial infarction or target vessel revascularization) at 1 year was 84%. With Cox analysis, P with unstable symptoms, shorter time to repeat ST, non-elective ST, and B2-C lesions, tended to have poorer prognosis. However, after adjustment, only non-elective ST was associated (RR 2.9, 95% CI 0.82–10.3, p = 0.09) with adverse outcome. On quantitative angiography (centralized cor lab) RE was found in 13 (30%) of 43 P (75% of those eligible). Logistic regression analysis identify 2 factors: RE length (RR 1.43, 95% CI 1.04–2.14, p = 0.04) and time to RE (RR 0.67, 95%CI 0.47–0.94, p = 0.01) as the only independent predictors of RE.

Conclusions: 1) In P with in-ST RE, both elective and unplanned stenting provide excellent initial results. 2) The long-term clinical and angiographic outcome of P treated with this new strategy (ST intra ST) also appears favorable.

285 β-radiation for the treatment of recurrent in-stent restenosis

A.L. Gijzel[1], M. Sabate[1], I.P. Kay[1], A.J. Wardeh[1], W.J. van der Giessen[1], V.L.M.A. Coen[2], P.C. Levendag[2], P.W. Serruys[1]. [1]*Heartcenter-Thoraxcenter;* [2]*Daniel den Hoed Cancer Center, Rotterdam, Netherlands*

Introduction: Recurrent in-stent restenosis after balloon angioplasty (BA) poses a serious management problem. Previously γ-radiation has been shown to be effective in this subgroup, however the role of β-radiation (β-rad) remains undefined. We studied the feasibility, safety and efficacy of β-rad in patients with recurrent in-stent restenosis.

Methods and Results: From May 1997 until December 1998, 12 male and 6 female patients (mean age 63 years, range 44–75) were treated with either (BA) or laser debulking (L) followed by β-rad. Quantitative coronary angiography (QCA) was performed post procedure (Post) and at 6 month follow-up (FU). Vessels treated were as follows: Left Anterior Descending: (n = 5), Circumflex: (n = 4), Right Coronary Artery: (n = 6), Saphenous Vein Graft: (n = 3). Frequency of previous restenosis were as follows: 2nd restenosis = 10, 3rd restenosis = 7, 4th restenosis = 1. The average time interval for recurrence of symptoms was 3 months (range 1–12). The mean lesion length was 16 mm and mean stent-length was 25 mm (range 9–39 mm). Eleven lesions were diffuse. Patients were treated with BA (n = 8) or L (n = 10), followed by intracoronary β-rad at a prescribed dose of 16 Gray, using the Betacath™ System (Novoste Co. USA). Two treatment failures occurred secondary to myocardial infarction and uncovered distal dissection, both complications of L. Six-month FU has been completed in 14 patients to date: mean minimum lumen diameter (mm) (pre = 0.80 ± 0.38, post = 1.86 ± 0.33, FU = 1.41 ± 0.66), late loss index = 0.36. Restenosis (> 50% DS) was seen in 6 patients (43%). Target lesion revascularisation was performed in 5 patients.

Conclusion: Intracoronary β-radiation for recurrent in stent restenosis in long lesions appears to be a safe and feasible management strategy in a difficult treatment group.

286 Intravascular ultrasound for the selection of patients at risk of recurrent restenosis after repeat intervention for in-stent restenosis

François Schiele, Nicolas Meneveau, Marie-France Seronde, Liu Ping-Ming, Sanjiv Gupta, Jean-Pierre Bassand. *University Hospital Saint-Jacques, Besançon, France*

Background: Adjunctive therapy, like coronary radiation after repeat angioplasty for in stent restenosis seems promising, mainly for pts at risk of recurrent restenosis or clinical adverse event after repeat intervention. Selection criteria for this high risk population are needed.

Population: Clinical, angiographic and intravascular Ultrasound data were recorded before and after repeat angioplasty in 70 pts to determine predictors of one year event free survival (EFS). Forty pts with focal lesion were treated by balloon angioplasty and 30 by combination of rotablator and balloon for diffuse lesion. Clinical event were defined as death, myocardial infarction or need for lesion revascularization.

Results: Clinical event occurred in 14 pts. Lesion length, elapsed time between stent implantation and repeat angioplasty, or severity of the restenosis were not different in the group with vs. without event. Conversely, the lumen cross sectional area (L-CSA) and the percent of neo intimal tissue within the stent after repeat angioplasty were univariate predictors of EFS. By multivariate analysis, only the L-CSA was independent predictor of EFS; the odds ratio was 4.5 (95% confidence interval = [1.1; 18], p = 0.03) per additional mm^2. The cut-point determined by discriminant analysis was set at 4.7 mm^2. EFS of pts with L-CSA < 4.7 mm^2 was 69 ± 15% vs. 91 ± 8% in pts with L-CSA > 4.7 mm^2 (p = 0.008 by Mantel-Cox test), whatever the treatment strategy used.

Conclusion: L-CSA assessed after repeat angioplasty for in-stent restenosis, was the only independent predictor of EFS. Pts with L-CSA < 4.7 mm^2 have high probability of adverse clinical event within one year and may be good candidates for brachytherapy.

CORONARY DISSECTION: TO STENT OR NOT TO STENT

287 Short and long-term evolution of unstented non-occlusive coronary dissection after coronary angioplasty

Alberto Cappelletti, Alberto Margonato, Giuseppe Rosano, Alessandra Mailhac, Antonio Colombo, Sergio L. Chierchia. *Department of Cardiology, Istituto Scientifico H S Raffaele, Milan, Italy*

We assessed the short and long term clinical and angiographic outcome of non occlusive unstented dissection after coronary angioplasty (PTCA) and its correlation with restenosis. We studied 129 consecutive patients (103 male, mean age 55 ± 11 yrs) undergoing elective PTCA (147 lesions, 66 LAD, 49 CX, 32 DX). All underwent coronary angiography 24 hours and 6 months after PTCA. Lesions were measured by QCA and coronary dissection was graded using the NHLBI classification (type A–D; Huber Am J Cardiol 1991; 68: 467). Study subiects were matched with 60 other patients in whom elective stenting was performed for the presence of dissection. In the first "unstented group" mean stenosis was 85 ± 11% before and 20 ± 7% immediately after PTCA (p < 0.001). Residual stenosis was not significantly different at the 24 hrs restudy (24 ± 5%). Non occlusive coronary dissection (flow TIMI grade 3 in all pts) was seen in 49/147 lesions (33%) and evolved as follows:

Dissection (grade)	Immediate 49 (33%)	24 hrs 41 (28%)	6 months 18 (12%)
A	33	27	10
B	10	8	5
C	4	4	2
D	2	2	1

At follow-up, restenosis was seen in 51/147 dilatation sites (34%), of which 5/41 (12%) occurred in dissected lesions, while 46/106 (43%) were present in vessels with no obviuos dissection (p < 0.001). B, C, and D dissection grade occurred respectively in 56, 32 and 12% of the "stented" patients. In this group restenosis rate was 25% (15/60). In both groups no cardiovascular events or recurrence of symptoms were recorded in the absence of restenosis.

Conclusions: 1) non occlusive dissection after PTCA usually improves after 6 months; 2) in the absence of flow impairment and ischemia this complication does not require any further interventiuon; 3) non occlusive dissection is not associated with increased incidence of restenosis.

288 Clinical outcome after balloon-induced vessel dissection without protective stent implantation

H. Mahrholdt, A. Baumbach, S. Schröder, A. Athanasiadis, M. Oberhoff, K.R. Karsch. *Medical Clinic, Division of Cardiology, University of Tübingen, Germany*

IVUS guided PTCA results in the use of larger diameter balloons. This technique is associated with a higher luminal gain, a lower restenosis rate and a higher incidence of dissections. Aim of this study was to evaluate the clinical effects of not flow limiting dissections on the acute- and longterm outcome. In our trial the only indication for stent implantation were severe dissections resulting in persisting limitation of antegrade flow.

Methods: 252 patients with 271 lesions underwent IVUS guided PTCA in our lab. In 189 of these patients dissections were detected by IVUS postinterventionally. All dissections were classified in mild (n = 30), medium (n = 36) and severe (n = 123) by IVUS criteria. In 4 patients only additional stent implantation due to flow limitation was necessary. MACE were defined as cardiac death, CABG, RePTCA and Q wave MI in the target vessel.

Results: Acute MACE in hospital occurred in 5 (2%) patients. One patient with medium and one patient with severe dissection had a total occlusion which could be managed successfully by repeated PTCA followed by stent implantation. 3 other patients had had an acute MI without showing evidence of vessel wall dissection. One of them underwent emergency CAGB and died subsequently.

All patients had a clinical follow up after 12 month. During this period MACE occurred in 2 (8%) patients with mild, 3 (8%) patients with medium and 5 (4%) patients with severe dissections, 10 (13%) MACE's were observed in 82 patients without dissections (p = 0.02).

Conclusion: The high incidence of dissections in our patient population did not lead to an increase of acute events. The low rate of longterm events suggests that substantial dissections and an altered remodeling provides a favorable clinical longterm result, most probably due to a "beneficial" remodeling process.

289 A plea for plain old balloon angioplasty with a low rate of provisional stenting: an unselected consecutive group of 1058 patients

J.M. ten Berg, J.C. Kelder, M.J. Suttorp, E.G. Mast, E. Bal, J.M.P.G. Ernst, F.W.A. Verheugt[1], H.W.M. Plokker. *St Antonius Hospital Nieuwegein; [1]the University Hospital Nijmegen, Netherlands St Radboud*

Background: In most PTCA trials selected groups of patients are studied. We prospectively studied the 1-year results of all consecutive patients referred for PTCA of a native coronary artery. A policy of provisional stenting was used. Events were death, myocardial infarction and reintervention.

Results: A total of 1058 patients underwent PTCA between March 1996 and November 1997. Baseline characteristics: mean age 60 ± 10, male sex 78%, diabetes 9%, hypertension 21%, hypercholesterolemia 74%, smoking 31%, previous myocardial infarction 39%, previous PTCA 15%, angina class III or IV (CCS) 69%, multi-vessel disease 33%, EF < 50 percent 18%, LAD lesion 46%, calcified lesion 24%, angulation > 45 degrees 21%, total occlusion 9%, mean lesion length 12 ± 6 mm. In 369 (35%) patients a stent was placed. The stents were placed for dissection in 72% of these patients of which 24% were bail-out situations. The events in all 1058 patients were:

Events – No. (%)	In-hospital	Total at 1 year
Death	3 (0.3)	12 (1.1)
Myocardial Infarction	35 (3.3)	35 (3.3)
Q-wave	11 (0.9)	11 (0.9)
Non-Q-wave	24 (2.3)	24 (2.3)
Coronary bypass surgery	3 (0.3)	22 (2.1)
Target lesion angioplasty	35 (3.3)	148 (14.0)
Target lesion revascularization	38 (3.6)	163 (15.4)
Any event	48 (4.5)	193 (18.2)

Conclusion: The strategy of Plain Old Balloon Angioplasty with a low rate of provisional stenting yields excellent results for all comers.

290 Is "bail-out" stenting the effective option? The widest trial

D.S. Fluck, P. Chenu[1], J. Street, R. Balcon, C.A. Layton. *Cardiology Dept, The London Chest Hospital, London, UK; [1]Cardiology, Clinique Universtaire de Mont Godinne, Yvoir, Belgium*

Three hundred patients needing a single vessel angioplasty for stable angina were randomised, 146 to undergo angioplasty alone (POBA) and 154, angioplasty plus stent (STENT) in a European multi-centre study. There were no significant differences in the baseline variables between the 2 groups. Two POBA patients received no treatment because of regression of the lesion and 44 (30%) crossed over to stenting, 37 because of some degree of lesion dissection and 7 for a 'suboptimal' result. The procedure failed in 5 (3.4%). 146 (94.8%) of the STENT patients had the stent successfully implanted. There were 5 (3.2%) failures and 3 (1.9%) crossovers. There were severe adverse events (death, MI, vessel occlusion, CABG and repeat angioplasty) in 3.4% in POBA patients and 3.9% in STENT at the initial procedure. The only death was in the POBA group. The post procedure drug management was decided by the patient's physician and included anticoagulation in some of the early cases but more frequently was ticlopidine and aspirin.

The event rate at 1 year was POBA 19.2% and STENT 20.8%, not significantly different. 92.9% (263) of available patients underwent repeat angiography and quantitative analyses performed by an independent core laboratory were available for comparison in 213 (81%) of these. As expected the acute gain in minimum lumen diameter (MLD) was significantly greater in the STENT group (1.68 mm vs 1.3 mm). A similar gain of 1.72 mm was seen in the PTCA crossovers compared to 1.1 mm in the remainder of that group.

Restenosis (more then 50% diameter stenosis at follow-up angiography) rates were not significantly different (17.3%, POBA vs 21.6% STENT)

Conclusions: The outcomes in this study in terms of acute complications, 1 year event and restenosis rates are similar to other published studies. The crossover rate of 30% in the POBA patients was however higher reflecting clinicians attitudes to the perceived value of stenting during the period of randomisation. The final result suggests that adopting a policy of stenting when the initial angioplasty result is not thought to be satisfactory is as effective as stenting all patients for de novo lesions. This approach would have a marked effect on stent implantation rates and thus the cost of intervention. It would also reduce the incidence of in-stent restenosis and 'imprisonment' of branches both of which have no satisfactory treatment at present.

291 "Real-world" in the PTCA-cathlab: high stent-rates and only little differences between the follow-up restenosis rates of stent- and lone-balloon angioplasty

H.-P. Bestehorn[1], J. Petersen[1], H. Roskamm[1], P. Stürzenhofecker[2], E. von Hodenberg[3], J.P. Monassier[4], A. Verdun[5]. *[1]Herz-Zentrum Bad Krozingen; [2]Herz- und Gefäßklinik Bad Neustadt; [3]Herz-Zentrum Lahr, Baden; [4]Centre Hospitalier Mulhouse; [5]Clinic St. Joseph Colmar, Bad Krozingen, Germany*

Recently, rather high restenosis rates in stented Non-Benestent/Stress-lesions were reported. In order to scrutinize these preliminary data, we performed an blind interims analysis of the ongoing multicentre PTCA-Restenosis VESPA-Trial (VESPA = Verapamil high dose Early administration Slow release for Prevention of major cardiovascular events and restenosis after Angioplasty). Up to 1999 January 520 of 700 patients were randomised and in 261 of these follow-up angiography had been already performed (6 months after PTCA). The stentrate in the 5 centres varies between 60% and 92% (average 81%). The stentrates in the different lesion-types were: A: 56%; B1: 80%; B2: 84% and C: 81%. Only 9.6% were A-lesions. The QCA-evaluation of 261 Verum- and Placebo-patients (blind) showed the following data for minimum lumen diameter (MLD) and %-stenoses immediately post PTCA and at follow-up for the balloon- and stent-treated patients:

	Balloon-PTCA (n = 53)	Stent-PTCA (n = 208)	
MLD (mm):			
Post PTCA	2.10 ± 0.05	2.70 ± 0.03	p = 0.0000
Follow-up	1.65 ± 0.11	1.81 ± 0.05	n.s.
Lumen loss	0.45 ± 0.10	0.89 ± 0.05	p = 0.0001
Reference	2.89 ± 0.07	3.11 ± 0.04	p = 0.01
%-Stenose:			
Post PTCA	26.2 ± 1.80	12.2 ± 0.97	p = 0.0000
Follow-up	43.2 ± 3.45	41.1 ± 1.58	n.s.

Conclusion: In daily routine, the follow-up results of the balloon- and stent-treated patients differ far less than reported in the randomised trials. Reasons are the selection of good balloon-results (PTCA-technique not randomized) and the frequent stent-use especially in more complex Non-Benestent/Stress-lesions, which are more proness to renarrow.

292 Decrease in target lesion revascularization after PTCA: due to more liberal stenting?

E. Schroeder, P. Chenu, O. Gurné, G. Perot, C. Desonniaux, J. Mortou, C. Randour, J. Ramos de Olival, J. Jamart, B. Marchandise. *Cardiology Unit, University Hospital of Mont-Godinne, Université Catholique de Louvain, Yvoir, Belgium*

A reduction of restenotic events after primary stent implantation has been proved in selected study populations. The impact of stenting in clinical outcome is less well documented in routine practice. We therefore assessed three different groups of consecutive patients undergoing PTCA for a first de novo lesion. Stents were used only for correction of suboptimal results.

Methods:

Group I (1996): 375 patients – 430 segments
Group II (1997): 410 patients – 499 segments
Group III (1998): 224 patients – 266 segments

Demographic and clinical variables and pre-PTCA angiographic data (DS (%), MLD, reference diameter) were similar in the 3 groups. The use of stents increased markedly overtime. In-hospital major cardiac events (MACE: death, CABG, infarction and repeat PTCA) and target lesion revascularization (TLR) procedures during a follow-up of 7 months were assessed.

Results:

	Group I (1996)	Group II (1997)	Group III (1998)	Trend
% Stents/segment	22	46	53	
MLD post (mm)	2.42 ± 0.82	2.57 ± 0.76**	2.74 ± 0.71**	
DS post (%)	17 ± 15	14 ± 13***	12 ± 12*	
In-hospital MACE (%)	13.6	10.0	5.8	p < 0.01
TLR (%)	12.5	9.8	6.7	p < 0.05

Group II vs I – Group III vs II: *p < 0.05; **p < 0.01; ***p < 0.001

On the basis of this study performed in an unselected patient population, we conclude that liberal stenting in the case of suboptimal results improves immediate angiographic results and reduces significantly in-hospital and restenotic events. This strategy permits to reduce the need for repeat procedures to an unexpectely low level even in routine practice.

CARDIOVASCULAR EFFECTS OF ANGIOTENSIN-CONVERTING ENZYME INHIBITORS AND ANGIOTENSIN RECEPTORS BLOCKERS

329 Angiotensin II type 1 receptor gene polymorphism predicts left ventricular function in healthy adults

E. Reissell, M. Perola[1], P. Koskinen, J. Virolainen, M. Kupari. *Division of Cardiology, Helsinki University Central Hospital, Helsinki; [1]National Institute of Public Health, Helsinki, Finland*

Angiotensin II acts as a potent vasoconstrictor and a modulator of myocardial growth and contractility exerting most of its cellular actions through type 1 receptor (AT1R). The cytosine (C) over adenosine (A) allele predominance in the 1166 position of AT1R gene has been implicated as a risk factor for coronary events and hypertension, and there is some evidence that it may also predict left ventricular (LV) hypertrophy and decreased systolic function.

We evaluated the association of AT1R A1166C polymorphism with LV structure and function in a random sample of population (n = 83, 39 men) aged 36 to 37 years free of heart disease. LV diameters, mass and systolic function were measured by M-mode echocardiography. Doppler velocimetry of transmitral flow was used to assess LV diastolic function. AT1R polymorphism was determined by restriction enzyme digestion of PCR products. Subjects genotyped as AC or CC were compared as one group (n = 23) with the AA group (n = 60). Statistical analyses were made with Students t-test and multiple linear regression.

The presence of C allele was associated with longer mean (SD) end-systolic LV diameter, 35.1(4.0) vs 32.6(4.5) mm (P = 0.022), lower peak diameter shortening rate, 79(11) vs 84(12) mm/s (P = 0.048) and lower fractional shortening 30.9(5) vs 33.8(4.5)% (P = 0.016). The differences were independent of sex, body mass index, regular physical activity, smoking, ethanol consumption and sodium intake. Heart rate, blood pressure, Doppler indices of LV filling or LV mass [130(23) g vs 134(33) g, P = 0.59] did not differ between subjects with and without C allele.

We conclude that AT1R A1166C polymorphism predicts variation of LV systolic function in healthy adults. The mechanism remains unknown but the known contraction-promoting effects of AT II on the vasculature and myocardium may play a role.

330 Preventing the effects of angiotensin II in human arteries: angiotensin-converting enzyme inhibition or angiotensin II–AT1 antagonism?

A.A. Voors, M. Oosterga, H. Buikema, M. Mariani, J.G. Grandjean, W.H. van Gilst. *Dept. of Clinical Pharmacology and Dept. of Thoracic Surgery, University of Groningen, Netherlands*

Background: We recently demonstrated a non-ACE angiotensin (Ang) II forming pathway in human internal mammary arteries. This implicates differential Ang inhibitory effects of ACE-inhibition and Ang II–AT1 receptor antagonism.

Aim and Methods: The aim of the present study was to compare effects of an ACE-inhibitor (captopril (CAP) 1 mM to 10 μM) and an Ang II-AT1 receptor antagonist (irbesartan (IRB) 0.1 nM to 0.1 μM) on the contraction responses to increasing doses Ang I (1 nM–1 μM), in internal mammary arteries from 25 patients undergoing coronary bypass surgery. In addition, a chymase inhibitor was used (1 μM soybean trypsin inhibitor, STI). Responses were expressed as the percentage of a control response to 10 μM phenylephrine.

Results: Organ bath experiments showed that CAP did not change the maximum response to Ang I (control: 46.3 ± 6.3%, CAP: 43.0 ± 4.6%). In contrast, 0.1 μM IRB competely blocked the response to Ang I (from 45.8 ± 6.7% to 1.9 ± 1.9%, $p < 0.001$). Although maximum responses did not change, 100 μM CAP shifted the −logEC50 from 7.50 ± 0.10 to 7.01 ± 0.09. However, addition of STI to CAP more effectively shifted −logEC50 than CAP alone (0.47 ± 0.06 vs. 0.91 ± 0.13, p = 0.01).

Conclusion: Ang I mediated effects are much more effectively inhibited by Ang II-antagonism than by ACE-inhibition. The incomplete effects of CAP on the inhibition of Ang II formation are caused by alternative Ang II forming enzyme(s), as was demonstrated by the additional effects when STI was added to CAP.

331 Attenuated coronary vasoconstrictive effect of angiotensin II and enhanced vasodilatory effect of ACE inhibitor in chronic heart failure

Yuji Oikawa, Tomiyoshi Saito, Kazuaki Tamagawa, Kazuhira Maehara, Yukio Maruyama. *First Dept. Intern. Med., Fukushima Med. Univ., Fukushima, Japan*

Background: Increased angiotensin II (Ang II) would modulate coronary circulation in chronic heart failure (CHF), however, the effect has not been directly examined. We investigated the effect of Ang II on coronary circulation in CHF induced by rapid pacing, using Ang II, Ang type 1 (AT1) or type 2 (AT2) receptor blocker and ACE inhibitor.

Methods: Seven Beagle dogs were used. A Doppler flow probe was implanted around the left anterior descending coronary artery, and the atrioventricular node was permanently blocked by formaldehyde injection. Before (baseline study) and 3 weeks after pacing at 240 beats/min, hemodynamic measurements were performed under anesthesia. Coronary flow dynamics were evaluated by coronary pressure-flow relationships (PF·R) during long diastole by transient pacing-off state, before (basal state) and after intracoronary injection of Ang II (10 ng/kg), AT1 blocker (L158809, 0.1 mg/kg), or AT2 blocker (PD123319, 0.2 mg/kg), and ACE inhibitor (enalaprilat, 0.2 mg/kg). The slope of linear regression line of P-F·R, and perfusion pressure at which coronary blood flow ceased (Pf = 0) were evaluated.

Results: After rapid pacing, cardiac output decreased (1.54 ± 0.12 to 0.75 ± 0.07 L/min, $p < 0.05$) and plasma AngII levels increased (28 ± 10 to 318 ± 178 pg/ml, $p < 0.05$). In baseline study, Ang II significantly reduced the slope of PF·R (1.17 ± 0.13 to 0.81 ± 0.11 mL/min/100 g/mmHg, $p < 0.05$) and increased Pf = 0 (27 ± 1 to 31 ± 1 mmHg, $p < 0.05$), while L158809, PD123319, or enalaprilat did not change them. After rapid pacing, the slope of PF·R did not change (1.17 ± 0.13 to 1.20 ± 0.08, N.S.) and Pf = 0 increased (27 ± 1 to 31 ± 1, $p < 0.05$) in basal state. Ang II changed neither the slope of P-F·R (1.20 ± 0.08 to 1.18 ± 0.07, N.S.) nor Pf = 0 (31 ± 1 to 32 ± 1, N.S.) in contrast to the response in baseline study. On the other hand, enalaprilat significantly increased the slope of PF·R (1.25 ± 0.09 to 1.46 ± 0.08, $p < 0.05$) and decreased Pf = 0 (32 ± 1 to 29 ± 1, $p < 0.05$), while neither L158809 nor PD123319 changed them.

Conclusion: The vasoconstrictive effect of Ang II on coronary circulation would be significantly attenuated, vice versa, the vasodilatory effect of the ACE inhibitor presumably via bradykinin would be augmented in CHF.

332 Bradykinin and the vasodilator effects of enalapril compared with losartan in patients with heart failure

A.P. Davie, J.J.V. McMurray. *MRC Clinical Research Initiative in Heart Failure, University of Glasgow, Glasgow, UK*

Angiotensin converting enzyme (ACE) inhibitors have been shown to potentiate the effects of exogenous bradykinin (BK) by inhibition of its breakdown. Despite this there is little evidence that inhibition of endogenous BK breakdown actually contributes to the effects of ACE inhibitors, or indeed other inhibitors of the renin-angiotensin-system such as angiotensin II receptor (AT1) antagonists, and no evidence at all that it does so in patients with heart failure.

Methods: 12 patients with heart failure (11 male, 1 female, ages 59 to 81 years) were randomised to double-blind crossover treatment with enalapril 10 mg bd followed by losartan 25 mg bd, each for 5 weeks, or the reverse. At the end of each treatment period, forearm blood flow was measured by venous occlusion plethysmography during an intra-brachial infusion of BK before and after an intra-brachial infusion of Hoe-140 (a potent, selective and long-acting BK antagonist).

Results:

	Enalapril	Losartan
Vasodilatation to BK	357 ± 67%	230 ± 46%
Vasoconstriction to Hoe-140	4 ± 2%	−4 ±6%
Vasodilatation to BK after Hoe-140	192 ± 35%	66 ± 13%

Conclusions: Inhibition of endogenous BK breakdown does not appear to contribute significantly to the effects of ACE inhibition or AT1 antagonism in the forearm of patients with heart failure at rest, despite the marked effect of ACE inhibition compared with A2 antagonism on exogenous BK breakdown.

333 Effects of ACEI and calcium antagonists on minute-to-minute sympathetic nerve traffic variability in heart failure

G. Grassi, G. Seravalle, R. Dell'Oro, C. Turri, M. Magnoni, G. Mancia. *Clinica Medica, University of Milan, Osp. S. Gerardo, Monza; Centro Fisiologia Clinica, IRCCS, Milan; Istituto Auxologico Italiano, IRCCS, Milan, Italy*

Purpose: It has been previously shown that congestive heart failure (CHF) is characterized by a marked increase in muscle sympathetic nerve traffic (MSNA) and by a reduction in its min-to-min spontaneous oscillations. It is unknown, however, whether this impaired MSNA variability is irreversible or it can be favourably affected by drugs commonly employed in CHF treatment.

Methods: In 16 CHF patients treated with diuretics and/or digitalis (NYHA class II–III; age: 64.3 ± 1.8 yrs, mean ± SEM), we measured mean arterial pressure (MAP, Finapres), heart rate (HR, EKG) and MSNA (microneurography at a peroneal nerve) during a 20 min resting period. MSNA was calculated as bursts incidence over time (bursts/min) and as min-to-min variability, expressed as variation coefficient (VC). In 8 patients measurements were repeated after a 2 month benazepril (10 mg/die) administration while in the other 8 after a 2 month amlodipine (10 mg/die) administration.

Results: In the control condition, MAP and HR were 96.5 ± 2.0 mmHg and 74.9 ± 4.0 b/min, respectively, while absolute MSNA values amounted to 59.4 ± 4.2 bs/min and VC of MSNA was 5.3 ± 2.1%. Benazepril caused slight and not significant MAP and HR decreases (−5.8 ± 2.3 mmHg and −3.3 ± 1.1. b/min), which were accompanied by a marked and significant ($p < 0.01$) reduction in absolute MSNA values (−28.4 ± 3.1%) and by a significant increase ($p < 0.05$) in MSNA-VC (+41.2 ± 5.0%). In contrast amlodipine, although causing similar MAP and HR effects did not significantly affect absolute MSNA values (−4.3 ± 3%) and VC (+5.3 ± 4%).

Conclusions: These data provide evidence that the impaired MSNA variability characterizing CHF can be reversed by drug treatment. They also show, however, that only drugs, such as ACEI, capable to exert sympathoinhibitory effects, allow to improve the abnormal pattern of sympathetic nerve traffic oscillation.

334 Acute effects of intravenous enalaprilat and perindoprilat in patients with ischaemic heart disease

C. Zeitz, D.J. Campbell[1], J.D. Horowitz[2]. *Antwerp, Belgium; [1]St Vincent's Institute of Med Research, Melbourne[2]North Western Adelaide Health Service, University of Adelaide, Adelaide, Australia*

The relative contribution of kinin and angiotensin peptides to the intracardiac effects of angiotensin converting enzyme (ACE) inhibitors and their cardioprotective and anti-ischaemic properties remain controversial. We investigated the acute effects of perindoprilat (P) and enalaprilat (E) on coronary haemodynamics and metabolism, and levels of angiotensin (A), and bradykinin (BK) peptides, in 22 patients undergoing non-emergent cardiac catheterisation for the investigation of chest pain. A coronary sinus (CS) catheter was positioned to enable atrial pacing, determination of CS flow and serial sampling of CS blood. All measures were performed both at rest and during pacing induced tachycardia (at 60.5 ± 1.4% of baseline cycle length). Patients received either P 1.25 mg or E 2.5 mg, in a non-randomised, unblinded fashion, as a rapid intravenous bolus injection. Response to tachycardia (T) induction was re-examined 14 ± 1 minutes following drug administration.

Results: Both P and E abruptly and virtually completely suppressed serum ACE activity, the effects on A and BK peptides, just prior to T induction, being displayed below. T was associated with a 35 ± 14 and 44 ± 11% increase in CS flow pre and post P respectively and 58 ± 17 and 26 ± 9% increase pre and post E respectively ($p < 0.05$ for P vs E effect). P reduced myocardial lactate production and increased oxygen extraction during T, whereas E did not ($p < 0.05$ for P vs E effect).

Results: Peptide levels

ΔAII/AI	−0.6 ± 0.2*	−1.1 ± 0.7	−2.7 ± 1.1*	−1.3 ± 0.8*
ΔBK-1-9 (fmol/ml)	2.9 ± 1.6	−2.3 ± 1.1*	2.0 ± 0.2*	−2.6 ± 3.7
ΔBK-1-7 (fmol/ml)	0.7 ± 1.0	−6.7 ± 3.4	0.7 ± 0.7	−2.1 ± 1.1
ΔBK-1-7/BK-1-9	−1.9 ± 1.9	−0.6 ± 0.2*	−3.0 ± 0.9*	−0.3 ± 0.3

*$p < 0.05$

Conclusions: Despite similar inhibition of plasma ACE activity, acute administration of P, in contrast to E, exerted greater effects on transcardiac BK peptide levels. Acute effects of ACE inhibitors may depend on extent of inhibition of intracardiac ACE activity.

UPDATE ON TREATMENT OF HEART FAILURE

335 Antithrombotic therapy is associated with better survival in patients with severe heart failure

M. Echemann, F. Zannad, S. Briancon[1], F. Alla[1], J.M. Virion, Y. Juilliere[2], J.P. Villemot[3]. *CIC-INSERM, CHU Nancy, Dommartin-les-Toul; [1]Epidemiology Unit, CHU Nancy, Nancy[2]Cardiology Dept, CHU Nancy, Nancy[3]Cardiology departments, CHU Nancy and Lorraine hospitals, Nancy, France*

Background: The effects of long term antiplatelet or anticoagulant therapy on survival in patients with congestive heart failure (CHF) have not been investigated in prospective controlled trials. Moreover, it has been suggested that the benefit form ACE inhibitor therapy may be decreased in patients concomitantly treated with aspirin. The aim of this work was to identify the interaction between cardiovascular drug therapy, with special reference to antithrombotic agents, and survival, in patients with advanced CHF.

Methods: The observational prospective community based study, EPICAL (EPidémiologie de l'Insuffisance Cardiaque Avancée en Lorraine) has identified 417 patients with advanced CHF. Inclusion criteria were: age 20–80 years, at least one hospitalization for CHF with NYHA III/IV, hypotension and/or peripheral and/or pulmonary oedema and ejection fraction < 30%. Average follow up was 18 months. Cardiovascular drugs used at hospital discharge were tested in a multivariate Cox model adjusted for other known predictive factors (clinical and biological baseline characteristics). Association between variables and survival was expressed as RR (relative risk of death) and corresponding 95% CI (confidence interval).

Results: ACE inhibitors were used in 312 pts (75%), nitrates in 170 (41%), aspirin in 129 (31%) and oral anticoagulants in 128 (28%). Duration of disease, history of renal failure and/or serum creatinine>180 mmol/d, low serum sodium, serious comorbidity and age above 65 were independently associated with a lower survival. Use of nitrates (RR = 0.6, 95% CI = 0.5–0.7), aspirin (RR = 0.5 65% CI = 0.4–0.7) and oral anticoagulants (RR = 0.5, 95% CI = 0.4–0.7) were independently associated with better survival. Interaction between aspirin and the ACE inhibitor therapy was not significative.

Conclusion: Aspirin or oral anticoagulant therapy was associated with better long term survival (death risk was decreased twice) in patients with advanced CHF. These results support the conduct of a clinical trial investigating the effects of long term antithrombotic therapy in patients with heart failure.

336 Binding properties of β-adrenoceptor antagonists used in heart failure at recombinant β1, β2 and β3-adrenoceptors

P. Schnabel, C. Maack, F. Mies, M. Böhm. *Klinik III für Innere Medizin der Universität zu Köln, Cologne, Germany*

A large body of evidence indicates a benficial effect of β-adrenoceptor (β-AR) antagonists on symptoms and survival of patients with coronary heart disease and heart failure. Human myocardium contains at least four distinct β-AR subtypes, three of which have been cloned from different tissues. β1- and β2-AR are well characterized and stimulate adenylyl cyclase (AC) via stimulatory Gs proteins. β3-AR couple to inhibitory Gi proteins and thus inhibit cAMP formation by AC. The identity of a fourth β-AR subpopulation is not yet thoroughly characterized.

The present study investigates the binding properties of the widely used β-AR antagonists metoprolol (M), atenolol (A), bisoprolol (B) and carvedilol (C) at β1-, β2- and β3-AR, respectively. For this purpose, COS-7 cells were transfected with the cDNAs of the respective β-AR and radioligand binding experiments using [^{125}I]cyanopindolol were performed in membrane preparations of transfected cells. The table includes Ki-values in nM.

β-AR antagonist	β1-AR	β2-AR	β3-AR
Metoprolol (M)	69 ± 26	286 ± 73	331 ± 83
Atenolol (A)	556 ± 168	3052 ± 1348	3168 ± 772
Bisoprolol (B)	15.6 ± 2.7	235 ± 73	484 ± 198
Carvedilol (C)	0.3 ± 0.1	0.3 ± 0.1	0.3 ± 0.1

These data suggest that carvedilol is nonselective for any β-AR, while A and M exhibit a 5-fold selectivity for β1 versus β2- and β3-AR. B is 15-fold selective for β1 versus β2- and 31-fold selective for β1- versus β3-AR.

In conclusion, binding properties of β-AR antagonists on distinct β-AR differ and have to be taken into account with respect to therapeutic and adverse effects of these drugs.

337 Effect of endothelin on myocardial fibrosis in response to chronic administration of angiotensin II or aldosterone

F.J.A. Ramires, Y. Sun[1], C. Mady, J.A.F. Ramires, K.T. Weber[1]. *Heart Institute (InCor), University of São Paulo-Medical School, São Paulo, Brazil[1] Internal Medicine, University of Missouri-Columbia, Columbia, USA*

Background: Elevations of circulating angiotensin II (AII) and/or aldosterone (Ald) leads to myocardial fibrosis. Several studies have demonstrated that AII and Ald may stimulate endothelin (ET) expression while some experiments suggest ET may stimulate AII and Ald production. Other studies demonstrated ET, per se, is responsible for increased collagen synthesis. Objective: We hypothesized that ET could contribute to cardiac fibrosis through a complex mechanism involving AII or Ald.

Methods: We used bosentan (B), an endothelin ET_A and ET_B receptor antagonist, to treat Sprague-Dawley rats. Five groups were studied (14 rats in each group): 1) untreated age-sex matched controls; 2) intact rats receiving AII (75 ng/min subcutaneous); 3) intact rats receiving AII and B (100 mg/kg/day po); 4) uninephrectomized rats receiving Ald (0.75 μg/h subcutaneous) and high salt diet; 5) uninephrectomized rats receiving Ald plus high salt diet and B. Cross sections of the heart were stained with collagen specific picrosirius red and videodensitometry was then used to quantify the interstitial and perivascular collagen volume fraction (ICVF, PCVF) of the right and left ventricles (RV, LV).

Results: Table below (**p < 0.05 vs. Control and *p < 0.05 vs. Ald or AII).

Table

		Cont	AII	AII + B	Ald	Ald + B
ICVF (%)	LV	0.61	1.16**	0.70*	1.32**	0.80*
	RV	0.80	1.92**	1.33*	3.50**	2.23*
PCVF (%)	LV	1.20	5.35**	0.96*	3.63**	1.50*
	RV	1.14	4.40**	1.00*	1.71**	1.51*

Conclusion: Bosentan prevents fibrosis in both the normotensive, nonhypertrophied right ventricle and in the hypertensive, hypertrophied left ventricle. These findings suggest that endothelin plays an important role in fibrous tissue formation stimulated by AII or Ald.

338 Intra-aortic balloon counterpulsation in patients with cardiogenic shock complicating acute myocardial infarction – duration of shock to cardiac assist is an independent predictor of short-term outcome

K.H. Scholz, S. Ragab, S. Vonhof, T. Schröder[1]. *Department of Cardiology, Center for Internal Medicine, University of Göttingen; [1]Department of Medical Informatics, University of Göttingen/Department of Cardiothoracic Surgery, Heart Center Lahr, Germany*

Aims. The aim of this study was to identify clinical and procedural variables as predictors of survival in patients with cardiogenic shock complicating acute myocardial infarction supported by intraaortic balloon counterpulsation (IABP).

Methods and results. Out of 427 consecutive patients treated with counterpulsation between 1977 and 1996 at our catheterization laboratory and/or medical intensive care unit, we analyzed all 286 patients presenting with cardiogenic shock related to acute myocardial infarction. Mean duration of shock before IABP-insertion was: 9.2 ± 18.7 hours (range: 0.5 to 28 hours). Early reperfusion-procedures (thrombolysis; angioplasty; coronary artery bypass grafting) were performed in 209 patients (73%) with successfull revascularization in 149 patients (71.3%; TIMI II or III-flow). Another 13 patients had spontaneous reperfusion with open infarct-related artery at the time of IABP-placement.

In hospital mortality was 56.3% (161/286) in the total group of shock-patients, but was significantly decreased in patients in whom counterpulsation was initiated within 4 hours after onset of shock-symptoms (47.9% vs. 67.8%; P < 0.001).)

Multivariate logistic regression analysis identified early IABP-support with duration of shock to IABP-treatment of ≤4 hours (odds ratio 0.3), hyperlipidemia (odds ratio 0.3), nicotine use (odds ratio 0.4), and early revascularization with open infarct related artery within 4 hours after onset of shock (odds ratio 0.4) as independent predictors of survival. Mortality was independently elevated in patients with bundle branch block (OR 2.7), CABG-patients with graft-occlusion (OR 2.5) and in patients resuscitated before insertion of IABP (OR 2.0).

When considering patients with reopened infarct-related artery (162 patients), mortality was 39.6% in patients with duration of shock to IABP-treatment ≤ 4 hours and 62.5% in patients with duration of shock > 4 hours (42/106 vs. 35/56 pts; P < 0.01). Patients with persistent coronary occlusion (124 patients) as well had lower mortality when counterpulsation had been initiated within 4 hours (62.7% vs. 72.3%; not significant).

Conclusion. Early treatment with both revascularization and IABP-support is the most effective therapy in cardiogenic shock complicating acute myocardial infarction. In these patients, early IABP-support is an independent prognostic factor and, per se, leads to a decrease in mortality.

339 Progressive cardiac dysfunction and effects of growth hormone on cardiac function and myocardial gene expression in genetic murine dilated cardiomyopathy

M. Hongo, T. Ryoke[1], K.R. Chien[2], J. Ross Jr.[2]. *The First Department of Internal Medicine, Shinshu University School of Medicine, Matsumoto; [1]the Second Department of Internal Medicine, Yamaguchi University School of Medicine, Ube, Japan; [2]Division of Cardiology, University of California San Diego CA, USA*

Recombinant human growth hormone (rhGH) after myocardial infarction in rats has beneficial effects on cardiac function, and physiological rather than pathological hypertrophy has been suggested as a possible mechanism for this. Disruption of the muscle LIM protein (MLP), an essential regulator of myogenesis, gene in mice is associated with dilated cardiomyopathy (DCM) closely similar to human DCM. However, the effects of GH on cardiomyopathic heart are unknown. The present study was designed to determine whether cardiac dysfunction in the MLP knockout (KO) mice was progressive and to assess the effects of GH on cardiac function and myocardial gene expression in these mice. Serial echocardiographic studies were performed in 8 week old MLP KO mice (n = 31). Most of these animals exhibited increasing left ventricular (LV) chamber size and/or decreasing LV systolic function during 5 to 9 month follow-up period. Twenty-two animals showing both LV dilatation and reduced LV systolic function were randomized to vehicle (Control, n = 10) or rhGH (8 mg/kg, bid, SC) (GH group, n = 12) for 2 weeks. In the GH group, LV % fractional shortening and wall thickness were significantly increased, the LV dP/dt max was elevated, and relaxation (tau) was improved. The LV expression of many genes was altered in the MLP KO mice compared to the wild type animals, and GH reduced elevated mRNA levels for atrial and brain natriuretic peptides (p < 0.05 for each). Thus, the cardiomyopathy of the MLP KO mice was associated with progressive LV dilatation and dysfunction, and short-term rhGH treatment improved LV function and reduced elavated LV mRNA expression of members of the embryonic gene program related to pathological hypertrophy in this genetic murine DCM.

340 Bioengineered grafts to repair the infarcted myocardium

J. Leor, S. Aboulafia-Etzion, L. Shapiro[1], I. Barbash, A. Battler, Y. Granot, S. Cohen[1]. *Cardiology Dept, Ben-Gurion University, Beer-Sheva; [1]Unit of Biotechnology, Ben-Gurion University, Beer Sheva, Israel*

The persistent shortage in donor hearts stimulates the search for alternative strategies to treat end-stage heart failure. Tissue engineering is a promising strategy that offers the potential to create replacement tissues from autologous cells and three-dimensional polymeric scaffolds. We present a novel approach to tissue-engineered "myocardial tissue".

Methods and Results: We developed a method to grow cardiomyocytes and fibroblasts in three-dimensional compatible alginate scaffolds. The scaffolds are engineered to be highly porous to accommodate a large number of cells, and to be biodegradable. The alginate scaffold temporarily provides the biomechanical and structural characteristics for the replacement of the infarcted myocardium until the engrafted cells produce their own extracellular matrix. Fetal cardiomyocytes were seeded into these novel alginate scaffolds. The cells were cultured for 7 d to verify viability and morphology. The cellular constructs (10x5 mm, dxh) were surgically implanted into myocardial scar of rats (1–3 for each rat), 7 days after myocardial infarction. Two months later, the grafts were studied histologically. The engineered grafts consisted of confluent cell layer mixed with collagen fibers. The specimens showed almost complete disappearance of the scaffold polymer. Prominent blood vessels grew into the tissue-engineered graft from the surrounding coronary network. The overall appearance of the graft suggested integration into the host.

Conclusions: Cardiac cells can grow in polymeric scaffolds. The cells form a viable graft tissue, survive at least 2 months in the infarcted myocardium and stimulate neovascularization. This bioengineered tissue may be used for regeneration and healing of the infarcted myocardium. It can be used for attenuation of infarct expansion and left ventricular dilatation, for prevention of heart failure progression and to allow cell-based gene therapy into the infarcted myocardium.

CARDIOGENIC SHOCK: INTERVENTIONAL THERAPY

347 Primary stenting of left main coronary artery improves immediate and late outcome in patients admitted for acute myocardial infarction with cardiogenic shock

J. Brunet, F. Leclercq, J.P. Bertinchant, J. Nigond, J.L. Pasquier, P. Messner-Pellenc, R. Grolleau. *Department of Cardiology, University Hospital of Montpellier-Nîmes, France*

Objectives: The purpose of this retrospective study was to investigate immediate and late outcome in patients (pts) with AMI and cardiogenic shock (CS) due to acute left main coronary artery (LMCA) occlusion or critical narrowing who underwent LMCA primary stenting compared to pts treated with LMCA conventional PTCA.

Background: In AMI, occlusion of LMCA is a rare angiographic finding resulting most often in CS or sudden death. Only few data are available about LMCA stenting in AMI with CS and acute LMCA occlusion.

Methods: From 08/88 to 08/98, we reviewed 17 consecutive pts (13 men, mean age 58 yrs) admitted for AMI with CS and occlusion (TIMI 0) (n = 14) or critical narrowing (TIMI 1) (n = 3) of LMCA. From 08/88 to 01/95, PTCA was performed in 9 pts, referred for primary (n = 5) or rescue PTCA (n = 4) after failed thrombolysis. From 01/95 to 08/98, primary stenting was performed in 8 pts (6 unprotected and 2 protected LMCA). Time delay between onset symptoms and procedure was 4 ± 1.3 hrs.

Results: Angiographic success was achieved in 14 pts, providing 2 procedural death and 1 emergency CABG. Clinical outcome was available in all pts (mean follow-up 2 yrs, range 1 to 10). Table shows immediate and late clinical events in conventional PTCA and stent groups. Overall, 6/17 pts (35%) were alive and 3/6 (50%) surviving pts were event-free.

	PTCA Group (n = 9)	Stent Group (n = 8)
Procedural success.	6 (68%)	8 (100%)
In-hospital mortality	7 (78%)	3 (37%)
2-year follow up		
Mortality	1	–
Repeat PTCA	–	1
CABG	–	1
Transplantation	1	–
Overall mortality	8 (89%)	3 (37%)

Conclusion: Primary stenting is an effective treatment for AMI with CS due to acute occlusion or critical narrowing of LMCA and improves immediate and long term survival in these critically ill patients.

348 Coronary stenting in acute myocardial infarction with cardiogenic shock. Should we dilate also the non-culprit lesions?

T. Lefèvre, N. Guillard, M.-C. Morice, Y. Louvard, P. Dumas, C. Loubeyre, D. Drouet, B. Abry, J.-F. Angellier, J.-F. Vaxelaire, D. Villemant, J.J. Lanore. *Institut Cardiovasculaire Paris Sud, Massy, Quincy, Antony, France*

Background. Cardiogenic shock in acute MI remains associated with a high in-hospital mortality even after successful PTCA, stenting and IABP. In pts with multivessel disease, shock may be related not only to the culprit lesion but also to other severe lesions with no compensation of the non-infarct territory.

Methods. For this reason, we decided to evaluate in those pts a new strategy of multivessel PTCA with coronary stenting (Multivessel) and compare this strategy to the reference one i.e. treatment of the culprit vessel only (Culprit). The 2 strategies were not randomized but left to the operator's decision.

Results. Out of 884 AMI pts admitted directly to the Cathlab within 24 hours (1995–1998), 112 (12.9%) had cardiogenic shock. The main characteristics and results of the 2 shock groups are summarized below:

	Culprit	Multivessel
Patients (n)	89	23
Age (years)	71.9 ± 14.2	62.0 ± 13.6
Onset to admission (min;)	328 ± 237	509 ± 469
CPR before admission (%)	19	39
Triple vessel disease (%)	33	70
Left main disease (%)	22	23
Procedural success (%)	89	96
Coronary stenting (%)	83	96
IABP (%)	69	91
In-hospital death (%)	51	35

Conclusion. Coronary stenting in AMI with cardiogenic shock is feasible in the majority of cases. Procedural success rate is acceptable but mortality remains high. PTCA and stenting of other major vessels does not seem to increase the risk when performed by experienced operators and may be of particular interest in selected pts. This strategy should be assessed in a randomized trial.

349 Transport to primary PTCA in acute myocardial infarction complicated by acute heart failure. Results from the Prague study (national multicenter randomized study)

F. Bednář, P. Widimský, L. Groch, M. Želízko, M. Aschermann. *On behalf of the PRAGUE Study Group investigators; Cardiocenter Vinohrady Prague, University Hospital St. Anne Brno, IKEM Prague; VFN Prague, Czech Republic; 16 community hospitals*

The aim of the study was to prove the safety of interhospital transport for primary PTCA in patients with acute myocardial infarction complicated by acute heart failure. Their prognosis was compared with a group treated by thrombolysis in the community hospital.

In total, 259 patients were randomised into 3 groups: A (thrombolysis in the community hospital, no transport), B (thrombolysis during transport), C (transport to primary PTCA without thrombolysis)

Results:

	Group A	Group B	Group C
n =	87	86	86
Pts. with Killip II–IV on admission, n =	22	15	23
Mortality during transport or 30′ after	N.A.	0	0
30-days mortality of pts. Killip II–IV	36%	20%	9%

Conclusion: The transport of patients with acute myocardial infarction complicated by acute heart failure is safe and primary PTCA after transport seems to improve their mortality prognosis.

350 Should we emergently revascularize occluded coronaries for cardiogenic shock? An international randomized trial of emergency PTCA/CABG: results of the SHOCK trial

J. Col[1], J.G. Webb, L.A. Sleeper, J.D. Talley, C.E. Buller, H.D. White, R. Steingart, S. Chiu Wong, A.K. Jacobs, J.N. Slater, D. Miller, M. Menegus, J. Boland, V. Dzavik, K. Baran, R. Forman, S. Sharma, M. Porway, P. Aylward, A. Moreyra, J. Dens, E. Godfrey, S. McKinlay, T. Sanborn, M. Picard, T. Lejemtel, J.S. Hochman[2]. *For the SHOCK Investigators; [1]St. Luc Hospital, University of Louvain, Leuven, Belgium; [2]St Luke's Roosevelt Hospital Center, Columbia University, New York NY, USA*

The NHLBI funded SHOCK Trial was testing the hypothesis that, in patients (pts) with cardiogenic shock (CS) due to acute myocardial infarction (MI), a direct invasive strategy with early revascularization (ERV) reduces 30-day Mortality by an absolute 20% when compared to initial medical stabilization (IMS), including Thrombolysis, IABP, and possible revascularization after 48 hours. Thirty centers randomized 302 pts from 4/93–11/98 among 1492 pts with suspected CS. Non-randomized pts failed to meet strict CS criteria (43%), had clinical exclusion (45%), were outside time window (5%), or were eligible but not randomized (7%). Coronary angiograms pre and post angioplasty, and 2D echocardiograms were analyzed at core facilities. Trial demography: Mean age was 66 ± 10 years, 32% were women, 33% had prior MI, 46% prior hypertension, and 31% diabetes. Index MI was anterior in 60% with diagnosis of CS early after MI onset (median 5.6 hours). The hemodynamic profile at randomization was: pulmonary capillary wedge pr. 24 ± 7 mmHg, Cardiac Index 1.8 ± 0.6 l/min/m2 often recorded on support measures, systolic BP 88 ± 20 mmHg. Thrombolytic was administrated in 56%, IABP was utilized in 86%, ventilator in 83% and 55% of pts were transferred to tertiary care SHOCK center. The crossover rate from IMS to ERV was very low (<4%). Median times to PTCA and CABG in the ERV group were 0.9 and 3.0 hours after randomization, respectively.

Final analysis of the primary endpoint, 30-day all cause mortality will be presented for the two trial arms.

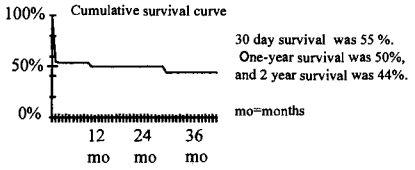
351 Long-term survival after invasive treatment of cardiogenic shock

G.K. Olivecrona, H. Öhlin, T. Molund, M. Göthberg, P. Magnusson, A. Lundin[1], B. Olsson. *Department of Cardiology, University Hospital, Lund; [1]Department of Radiology, University Hospital, Lund, Sweden*

Patients with acute myocardial infarction (AMI) and cardiogenic shock have a poor prognosis with only limited benefit on mortality rates by thrombolytic therapy. Treatment with Emergency PTCA or CABG seems to improve outcome. Information of the long term survival of these patients is scarce.

Methods: Patients were deemed to have cardiogenic shock if the systolic blood pressure was less than 80 mmHg without inotropic support, or 90 mmHg with inotropic support, and clinical signs of cardiogenic shock were present (oliguria/anuria, reduced peripheral circulation). In a consecutive series of 47 patients (mean age 64 years) with cardiogenic shock caused by AMI (not due to mechanical causes) treated with PTCA and/or CABG during 1995–1998 we analysed the long term survival. All patients were included on the "intention to treat" basis. Mean follow up time was 22 months.

Results: 4 patients died prior to treatment. 43 patients were treated with PTCA. 4 patients were treated with initial PTCA and then immediately with CABG. 32 patients were treated with IABP.



In **conclusion,** Patients with cardiogenic shock due to AMI have high initial rates of mortality despite treatment with PTCA and/or CABG, but those who survive the first thirty days seem to have a good long term outcome.

352 Long-term survival of patients undergoing coronary stent placement in cardiogenic shock after acute myocardial infarction

J. Pache, J. Dirschinger, A. Kastrati, H. Schühlen, J. Mehili, F.-J. Neumann, A. Schömig. *1. Med. Klinik rechts der Isar; Deutsches Herzzentrum, Technische Universität, Munich, Germany*

Background: Myocardial infarction (MI) complicated by cardiogenic shock is asscociated with a very high mortality. Previous studies have shown the advantages of reperfusion strategies in these patients. Comprehensive studies on the role of coronary stenting are not available.

Methods: Starting in January 1995, coronary stent placement has been the primary goal in the treatment of these patients referred to our institution. This intention-to-treat analysis provides a complete one-year clinical follow-up of all patients with cardiogenic shock referred to us after January 95.

Results: Of 108 patients admitted to our institution, one patient was treated conservatively, 107 underwent coranary angioplasty and 100 were treated with additional stent placement. These procedures were successful in 96.3% During the first 30 days, 38.9% died, 2.8% had a repeat nonfatal MI, and 2.8% needed a repeat intervention (overall adverse event rate 41.7%). After one year, 45.4% had died, 4.6% had a repeat nonfatal MI, and 8.3% required a repeat intervention (overall adverse event rate 51.9%).

Conclusions: This analysis suggest that coronary stent placement in myocardial infarction complicated by cardiogenic shock is feasible and can be achieved with a high primary success rate. Major adverse events occur mainly during the first 30 days. Patients surviving this early critical phase experience a very favorable longterm follow-up.

DIRECT ANGIOPLASTY: INTERNATIONAL EXPERIENCE

353 Twelve-month follow-up of the Stent PAMI trial

M.-C. Morice, C. Grines, M. Eijgelshoven, G.A. van Es, G. Stone, L. Mattos, E. Garcia, O. Madonna, D. Cox, F. Kiemeney, W. Van der Giessen. *On behalf of the Stent PAMI investigators; Institut Cardiovasculaire Paris Sud, Antony, France*

The Stent PAMI trial randomized 900 pts with AMI < 12 hours at 62 centers worldwide to either primary PTCA with balloon alone or elective stenting with heparin coated Palmaz Schatz stent. Primary endpoint was combined death, recurrent MI, disabling stroke or ischemia driven target vessel revascularization at 6 months (MACE). Mace at 12 months was a secondary endpoint as well as restenosis rate by QCA analysis on a 6-month angio.

Results: Baseline demographics were well matched in stent (n = 452) and PTCA (n = 448) arms except for age (60.9 stent group vs 59.2 balloon group, p = 0.05). A heparin-coated stent was deployed in 97.6% of cases and a bail-out stent was necessary for 67 (15.0%) pts. Acute angiographic success was similar between stent and PTCA group (99.8% vs 99.1%) but minimal lumen diameter post procedure was larger in the stent group (2.56 vs 2.12 mm, p < 0.0001). At 30 days outcome was similar in the two groups except for ischemic target vessel revascularization favoring the stent (1.3% vs 3.8%, p = 0.02) but at 6-month follow-up occurrence of MACE was lower (12.6% in the stent group, 20.1% in the balloon group, p < 0.01) 12-month follow-up is as follows:

	Stent%	Balloon%	p value
Death	5.5	3.1	NS
Reinfarction	2.9	2.7	NS
Disabling stroke	0.4	0.4	NS
Ischemic TVR	10.6	21	<0.0001
MACE	16.8	24.8	<0.01

In conclusion, primary stenting with heparin-coated stent achieved a superior clinical outcome as compared to balloon angioplasty with bail-out stenting at 6-month-follow-up. This superiority remains at 12 months.

354 In-hospital mortality of 865 patients with ptca for myocardial infarction complicated by cardiogenic shock. Results of the PTCA-registry of the ALKK

U. Zeymer, A. Vogt, W. Niederer, C. Pfafferott, K.W. Heinrich, W. Merx, M. Gottwik, K.-L. Neuhaus. *For ALKK Study Group; Medizinische Klinik II, Klinikum Kassel, Germany*

This study reports on the results of PTCA within 24 hours after onset of symptoms in 865 consecutive patients with acute myocardial infarction (AMI) complicated by cardiogenic shock.

Between July 1994 and October 1998 865 consecutive patients with cardiogenic shock were treated in 62 centres participating in the direct PTCA in AMI registry of the ALKK. Mean Age was 63.6 ± 11.8 yrs and 68.1% were male. The time from start of symptoms to PTCA was 284 ± 271 min and 25.8% received thrombolysis before PTCA. One-, two- and three-vessel disease was observed in 36%, 27% and 37% of the patients, respectively. A patent infarct vessel after PTCA was observed in 86% of the patients, with TIMI 3 flow in 76.5% and TIMI 2 flow in 9.5%. The total in-hospital mortality was 49.4% and was highest in the group with TIMI 0/1 flow (80.4%), somewhat lower in patients with TIMI 2 flow (64.6%) and lowest in the group with TIMI 3 flow (40.4%).

Mortality in the 335 patients with additional stent implantation was 45.1%, compared to 52.5% in patients without stent (p = 0.051). Of note, mortality in patients with TIMI 3 flow was similar (40.6 vs. 40.1) in the groups with and without stent implantation.

An intraaortic balloon pump was inserted in 94 (10.9%) of the patients, of these patients 58 (61.7%) died. An acute bypass sugery was done in 29 patients, the in-hospital mortality in this group was 38%.

Conclusion: In-hospital mortality in patients with AMI complicated by cardiogenic shock remains high, even with direct PTCA. Outcome is dependent of TIMI flow after the intervention. Stent implantation in patients with TIMI 3 flow does not appear to improve prognosis.

355 Improving survival in acute myocardial infarction treated with primary percutaneous coronary intervention: the Mayo Clinic experience

J.L. Velianou, N.M. Caplice, S.H. Wilson, D.E. Grill, G.S. Reeder, D.R. Holmes Jr, M.R. Bell. *Cardiovascular Diseases Dept., Mayo Clinic, Rochester MN, USA*

Background: The approach to treatment of acute myocardial infarction (AMI) by catheter-based techniques has evolved over recent years. Improvements in balloon and stent technology, and technical expertise have occurred. In addition, newer adjuvant antiplatelet therapies are now widely utilized. The totality of impact of these factors on outcomes has not been clearly defined.

Methods: We analyzed our PTCA registry database and identified all patients (n = 1066) who underwent primary PTCA (no thrombolytics) within 24 hours of AMI at Mayo Clinic, from 1991 to 1997 and characterized the clinical factors, procedural changes and subsequent results.

Results: The number of patients treated for AMI by primary PTCA increased from 118 in 1991 to 192 in 1997. Overall baseline clinical and angiographic characteristics were similar over the time period studied. Intracoronary stent use increased from 1991 to 1997 (1.7% vs. 62.5%, $p < 0.05$). This coincided with an increase in ticlopidine use from 1994 to 1997 (3.4% vs. 60.9%, $p < 0.05$) and abciximab use from 1995 to 1997 (2.9% vs. 63.0%, $p < 0.05$). An increase in beta-blocker (54.2% vs. 74.0%, $p < 0.05$) and ACE-inhibitor (27.7% vs. 39.1%, $p < 0.05$) use occurred with a decrease in calcium channel antagonist use (29.7% vs. 8.3%, $p < 0.05$) on discharge. Overall from 1991 to 1997, there was an increase in successful procedures (78.0% to 90.1%, $p < 0.05$) and successful lesion dilatation (83.6% to 95.1%, $p < 0.05$) with a decrease in emergency CABG (3.4% to 0.5%, $p < 0.05$), in-hospital mortality (9.3% to 4.7%,$p < 0.05$), and 1-year mortality (13.6% to 8.9%, $p < 0.05$). The incidence of stroke was very low.

Conclusions: The success rates, hospital survival and long-term survival have improved dramatically for patients with AMI treated with primary PTCA. These improvements may reflect a combination of increasing operator experience, improvement in equipment, increased use of stents, better antiplatelet therapies, and increasing use of beta-blockers and ACE-inhibitors.

356 Thrombolysis vs. PTCA vs. both in patients with acute myocardial infarction (Prague trial): narography findings and PTCA results

L. Groch, P. Widimsky, M. Aschermann, M. Zelizko, F. Bednar, O. Hlinomaz. *Interventional Cardiology Dept., St. Anne's Univ Hosp, Brno; Univ. Hosp. Kralovske Vinohrady, Prague; Univ. Hosp. Karlovonam, Prague, IKEM, Prague, Czech Republic*

The Prague trial compares the effect of 3 treatment strategies in 240 patients with acute myocardial infarction (AMI) admitted to the hospitals without PTCA centre: thrombolysis in the general hospital (group A); thrombolysis + immediate transport to the PTCA centre (group B); bolus 10,000 U of Heparin + Aspegic 500 mg i.v. + immediate transport for direct PTCA (group C).

Coronarography and PTCA results:

	Group B	Group C
Number of pts	79	80
IRA LAD	62.5%	59.1%
RCA	37.4%	30.3%
RCx	3.1%	13.6%
TIMI flow before PTCA 0+I	58.37%	66.7%
II+III	41.8%	33.3%
TIMI flow after PTCA 0+I	5.2%	5.4%
II+III	94.7%	94.5%
No of stents per pts	0.8 (0–2)	0.8 (0–2)
30 days mortality (group A 14.5%)	16.6%	8.4%
Reinfarction	9.7%	0%
Stroke in 30 days	4.1%	0%

IRA = infarction related artery.

Preliminary results: We conclude, that the administration of Heparin 10,000 U + Aspegic 500 mg i.v. is very effective before direct PTCA. This medication reopened the IRA only 8.5% less frequently (33.3% v.s. 41.8%)in comparison with the group of patients treated with streptokinasis up to one hour after admission. Direct PTCA (group C) seems to be the optimal treatment strategy for AMI (primary success 94.5%), if the transport is not longer than 1 hour.

357 Primary angioplasty versus thrombolysis in acute myocardial infarction: long-term follow-up

J.P. Ottervanger, A. Liem, A.W.J. van't Hof, H. Suryapranata, J.C.A. Hoorntje, M.J. de Boer, F. Zijlstra. *Cardiology Dept., Isala Clinics – De Weezenlanden, Zwolle, Netherlands*

Background: Several studies demonstrate a better outcome after primary angioplasty, compared to thrombolysis for acute myocardial infarction. However, until now only short-term follow-up has been presented.

Design: Long-term follow-up of a randomised trial of primary angioplasty compared to thrombolysis.

Patients and Methods: 395 patients with acute myocardial infarction were randomised to either primary angioplasty or thrombolytic therapy. Primary end points were death or recurrent myocardial infarction.

Results: Median follow-up period was 70 months in the primary angioplasty group and 67 months in the thrombolysis group. Of the 194 patients treated with angioplasty, during the follow-up period 27 patients died (14%), compared to 47 of the 201 patients (23%) treated with thrombolysis ($p < 0.05$). Adjusted for age, gender, Multi Vessel Disease (MVD) and Left Ventricular Ejection Fraction (LVEF), patients treated with thrombolysis had a relative risk of long-term mortality of 1.3 (95% CI 0.78 – 2.30) compared to those treated with primary angioplasty. Recurrent myocardial infarction during the follow-up period was observed in 12 patients (6%) treated with primary angioplasty and 44 patients (22%) treated with thrombolysis ($p < 0.05$). Adjusted for differences in age, gender, MVD and LVEF, those treated with thrombolysis had a relative risk of 2.3 (95% CI 1.5 – 3.5) on either death or recurrent infarction compared to those treated with primary angioplasty.

Conclusions: Our results show a beneficial effect of primary angioplasty on mortality and recurrent infarction, not only after short-term but also after long-term follow-up.

358 Predictors of poor outcome in a non-selected population of patients with acute myocardial infarction treated with primary angioplasty

E. García, R. Moreno, J. Soriano, M. Abeytua, E. López de Sá, J. Elízaga, J. Botas, J.F. Portales, J.R. Rey, J. Acosta, R. Rubio, J.L. López-Sendón, J.L. Delcán. *Department of Cardiology, Hospital Gregorio Marañón, Madrid, Spain*

The objective of this study was to identify clinical and angiographic predictors of in-hospital mortality in a non-selected population of patients with AMI treated with primary PTCA.

Methods: The study population is constituted by 713 patients (64 ± 13 yrs, 80% male) with AMI treated with PTCA within the first 12 hours after the onset of symptoms. A univariate and multivariate analysis were performed considering multiple clinical and angiographic variables, in order to identify predictors of in-hospital death.

Results: The mortality rate was 13.9% in the entire population and 7.6% after excluding patients in cardiogenic shock (3.2%, 18.2%, 25.0% and 69.4% in patients in Killip class I, II, III and IV). The following characteristics were associated with a higher in-hospital mortality in the univariate analysis: >65 years (19.9% vs. 8.5%, $p < 0.0001$), female gender (20.1% vs. 12.1%, $p = 0.0170$), multivessel disease (21.5% vs. 5.3%, $p < 0.0001$), angiographic unsuccessful result (49.0% vs. 10.7%, $p < 0.0001$), proximal vessel occlusion (17.6% vs. 7.4%, $p = 0.0001$), Killip class III–IV (52.6% vs. 5.0%, $p < 0.0001$), anterior location or left bundle branch block (17.1% vs. 7.8%, $p = 0.0004$), non smoking (20.9% vs. 8.9%, $p < 0.0001$), absence of hypercholesterolemia (17.4% vs. 7.5%, $p = 0.0001$), diabetes mellitus (20.9% vs. 11.8%, $p = 0.0048$) and hypertension (16.3% vs. 10.9%, $p = 0.0371$). The following were independent risk factors of in-hospital mortality in the multivariate analysis: angiographic unsuccessful result (OR 4.3; $p = 0.0012$), multivessel disease (OR 2.9; $p = 0.0025$), Killip class III–IV (OR 11.3; $p < 0.0001$), anterior location of left bundle branch block (OR 2.6; $p = 0.0208$) and absence of hypercholesterolemia (OR 2.2; $p = 0.0453$).

Conclusion: The presence of multivessel disease, an angiographic unsuccessful result, anterior location or left bundle branch block and absence of hypercholesterolemia are associated with a higher in-hospital mortality after primary angioplasty for acute myocardial infarction.

MYOCARDIAL CONTRAST ECHOCARDIOGRAPHY: PERFUSION AND REPERFUSION

359 Does colour-blooming limitate assessment of myocardial perfusion using harmonic power Doppler?

C. Lentz, K. Tiemann, J. Köster, T. Schlosser, J. Goenechea, H. Becher. *Cardiology Dept, University of Bonn, Bonn, Germany*

Background: It has been shown that visualisation of myocardial perfusion (MP) is feasible using Harmonic-Power Doppler Imaging (H-PDI) in combination with modern intravenous ultrasound contrast agents. However, it is unknown whether low intensity signals in the subendocardial myocardium are due to blooming from the high intensity signals in the cavity or reflect real perfusion.

Objective: to evaluate in a pulsatile flow phantom, whether and at which distance low intensity signals in small vessels could be visualized next to a cavity with high intensity contrast signals.

Methods: 10 small silicon tubes (diam. 0.5 mm) were fixed close to a perfused balloon (diam. 1.7 cm) at various distances (0.25–9.25 mm). Single or simultaneous perfusion of the tubes and the balloon was performed using 3 ml of the ultrasound contrast agent SH-U 563 A (Schering AG, Berlin, Germany). The recordings were performed by means of an ATL HDI-5000 ultrasound system (ATL, Bothell, WA, USA) in the intermittent Harmonic-Power-Doppler-mode (HPD) at variable receive gain (60%, 71% and 81%). The lateral and axial diameter of the tubes and of the balloon as well as their mean signal-intensity was measured off-line using a new developed imaging software.

Results: The diameter of the ballon was overestimated using the H-PDI recordings: 1.7 mm (9.9%; SD = ± 1.6%) for the highest gain setting and 0.35 mm (2%; SD = ± 1.2%)for the lowest receive-gain setting. Tubes 1.25 mm and more distant from the balloon could be delineated with all receive-gain settings.

Conclusions: Only the immediate border area of about 1 mm between a cavity with high intensity signals and a adjacant tissue with small vessels is influenced by blooming with adequate gain setting. Outside this area H-PDI signals represent real intramyocardial contrast.

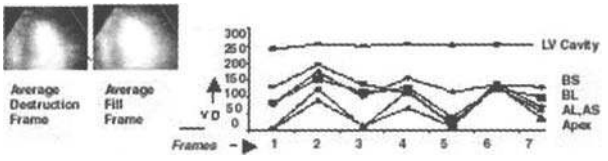
360 Triggered multiple-frame loss of correlation Doppler energy imaging produces non-uniform microbubble destruction: a quantitative videointensity analysis

T.J. Kolias, E. Avelar, T.J. Lewandowski, T. Thigpen[1], K. Bradsher, L. Cermak, W.F. Armstrong, M. Vannan. *Cardiology Dept, University of Michigan, Ann Arbor MI; [1]Acuson Corporation, Mountain View CA, USA*

Background: Loss of correlation (LOC) at high mechanical indices (MI) causes microbubble destruction. Doppler Energy imaging detects the consequent acoustic emission. We combined this method with rapid multiple-frame triggering (MFT) to delineate myocardial opacification in patients (pts) with no previous history of myocardial infarction.

Methods: An apical 4-chamber view was obtained in 8 pts using an Acuson Sequoia system. IV infusion of 3 mL of Optison at a rate of 0.5 mL/minute was used. MFT was performed at 1:4 cardiac cycles with an average frame interval of 40 msec. Data were analyzed by video densitometry (VD) using background-subtraction (averaged fill frames minus averaged destruction frames) in five regions of interest (ROI) located in the basal septum (BS), apical septum (AS), apex, apical lateral wall (AL), and basal lateral wall (BL).

Results: The difference in VD between the averaged fill frames and destruction frames was greatest in the apex (up to 90%, SD 2%). Differences in other proximal field ROIs were: AS (up to 48%, SD 5%) and AL (up to 35%, SD 46%). Changes in distal field ROIs were: BS (up to 35%, SD 20%) and BL (up to 42%,SD 29%). In the LV cavity the difference was up to 15%, SD 3%. An example is shown below (figure). Thus, the proximal field showed efficient and reproducible effect of MFT. Substantial changes in the distal field were offset by large variations.



Conclusions: Rapid MFT combined with Doppler Energy LOC imaging produces efficient but non-uniform microbubble destruction across the imaging field. This has implications for interpretation of myocardial perfusion patterns when using this MCE technique.

361 Viable myocardium can be detected by harmonic power doppler imaging in combination with SHU 563A, a new air-filled contrast agent: a contrast echocardiographic study in a canine model of acute coronary occlusion and reperfusion

C. Teupe, M. Takeuchi, J. Yao, M. Sheahan, N. Pandian. *Tufts, New England Medical Center, Boston MA, USA*

To assess whether harmonic power Doppler [HPD] imaging in conjunction with the transvenous contrast agent SHU 563A would be useful in detecting stunned but viable myocardium, we created 2–3 hr coronary occlusion [CO] followed by reperfusion [REP] in 10 dogs. Besides continuous imaging for wall motion analysis, we employed HPD in triggered mode to assess myocardial perfusion during CO and REP. TTC staining was performed postmortem to determine the presence and size of infarction. Wall motion abnormalities (WMA), perfusion defects and TTC data were compared to each other.

Results: All 10 dogs showed WMA during CO. In 8/10 HPD detected perfusion defects. The concordance rate (by segmental analysis) between WMA and perfusion defect was 86%. After REP, the extent of WMA (%LV slice) was larger than the area of perfusion defect (% slice) (WMA 30 ± 13% vs. PD 9 ± 8%, $p < 0.01$). Eventual infarct size was only 6 ± 7%. Thus, the extent of WMA was greater than the size of perfusion defect and eventual infarct indicating the presence of stunned, but viable myocardium.

Conclusion: HPD imaging in conjunction with agent SHU 563A can demonstrate the efficacy of reperfusion, identify necrotic regions and aid in the recognition of stunned but viable myocardium. This approach could be useful clinically in patients with acute myocardial infarction undergoing reperfusion therapy.

362 Assessment of myocardial reperfusion after acute myocardial infarction using harmonic power Doppler and Levovist®: intravenous versus intracoronary contrast injection

L. Agati, S. Funaro, G. Veneroso, A. Lamberti, C. Altieri, F. Bilotta, G. Benedetti, S. De Castro, C. Autore, F. Fedele. *Department of Cardiology "La Sapienza" University of Rome, Italy*

Myocardial contrast echocardiography (MCE) (intracoronary application) has emerged as accurate method to detect "no-reflow phenomenon" after acute myocardial infarction (AMI). In order to investigate the diagnostic value of harmonic power Doppler (HPD) after intravenous infusion of Levovist®, both intracoronary (IC) and intravenous (IV) contrast injections were performed in a group of patients with AMI.

Methods: Seventeen patients (mean age 50 ± 10) underwent MCE using HPD (HP Sonos 5500, ATL HDI 5000) with Levovist® (400 mg/ml, intravenous pump infusion, trigger intervals 1:4) and sonicated albumin (0.5–1, ml intracoronary bolus) within 7 days after their first AMI successfully reperfused (within 6 h from symptoms onset) by primary PTCA or IV r-TPA. Myocardial perfusion was assessed as present or absent using a 12 segment model (4-2-chamber apical views). A wall motion analysis was performed in the corresponding segments.

Results: Of a total of 204 segments, 37 were not analyzed after IVMCE and 43 after ICMCE because of artifacts. ICMCE showed perfusion defect in 31 segments (19%), whereas IVMCE in 33 (19%) with a concordance of 71% for the detection of no-reflow segments. Concordance in anteroseptal segments was 78%, and inferoseptal segments 66%. Using ICMCE as the standard, IVMCE had a sensitivity of 71% and a specificity of 92% for diagnosing contrast deficits. The extent of no-reflow after IVMCE was 18 ± 19 and after ICMCE was 21 ± 17 (ns). A perfusion defect was observed in 38% of akinetic segments and in 72% of dyskinetic segments with both methods.

Conclusion: IVMCE with Levovist® reliably identifies no-reflow phenomenon after successful reperfusion especially in anteroseptal AMI.

363 Contrast echocardiographic evaluation of myocardial salvage after reperfusion therapy in acute myocardial infarction

C. Firschke, R. Blasini, J. Patiga, U. Schricke, S. Martinoff, M. Reeg, M. Schwaiger, A. Schömig. *Deutsches Herzzentrum; 1. Medizinische Klinik der Technischen Universität München, Munich, Germany*

In the experimental setting, venous myocardial contrast echocardiography (VMCE) has been shown to accurately delineate risk area during coronary occlusion and infarct size after reperfusion. We therefore hypothesized that in patients with acute myocardial infarction (AMI), myocardial salvage after reperfusion therapy can be assessed using this technique.

15 patients with AMI underwent both rest Tc 99m Sestamibi SPECT imaging (SI; pre reperfusion injection, post reperfusion imaging) and VMCE (venous infusion of Optison, intermittent harmonic imaging, off-line digital image processing with background subtraction, grey scale expansion and color coding) before reperfusion therapy (stenting n = 12, PTCA n = 3). SI, VMCE and coronary angiography follow up was performed after 14 days. Vertical and horizontal long axis views (SI) were compared with 4- and 2- chamber views (VMCE) respectively. Separate observers determined the localization of perfusion defects on SI and VMCE pre-reperfusion and categorized pre- and post-reperfusion images as demonstrating complete (2), partial (1) or no (0) myocardial reperfusion.

14/15 infarct related arteries (LAD n = 7, LCX n = 4, RCA n = 4) could be revascularized without residual stenosis (TIMI III flow). All patients had identical angiographic results at 14 days follow up. On SI, initial perfusion defect localization was anterior (n = 7), inferior (n = 5) and lateral (n = 3). Myocardial reperfusion was categorized as 2 (n = 7), as 1 (n = 5) and as 0 (n = 3). On VMCE, in 14/15 patients initial perfusion defects were localized in concordance with SI; myocardial salvage was categorized in concordance with SI in all patients.

We therefore conclude, that VMCE is a promising clinical tool for the evaluation of myocardial salvage achieved by reperfusion therapy in patients with AMI.

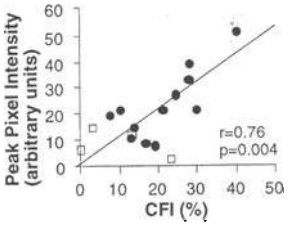
364 Demonstration of collateral-derived myocardial perfusion using quantitative myocardial contrast echocardiography

S.F. de Marchi, M. Billinger, M. Fleisch, B. Meier, C. Seiler. *Cardiology, University Hospital, Berne, Switzerland*

Background: Coronary collaterals supply myocardium at risk for infarction. In humans, this blood supply has never been assessed quantitatively at the perfusion level using contrast echocardiography.

Methods: In 16 patients (pts) undergoing coronary angioplasty, a collateral flow index (CFI) was determined using intracoronary wedge pressure measurements distal to the stenosis to be dilated. During ballon occlusion, echo contrast (Levovist®, Schering) was injected directly into the contralateral coronary arteries. Transthoracic echocardiography in the view best visualizing the myocardial area at risk was performed using harmonic imaging with high dynamic range. Pixel intensities (PI, units 0–255) were measured placing a hand-traced region of interest within the area at risk. Perfusion parameters were obtained from a fitted gamma-variate curve.

Results: The mean CFI was 18 ± 11%. The size of the regions of interest was 727 ± 193 pixels. In 12 pts, a significant background-subtracted peak of the gamma curve (peak) was observed (defined as peak > mean background + 2× standard deviation of background). Background-subtracted peak pixel intensity was linearly related to CFI in all pts (r = 0.68, p < 0.004.) and in the subgroup with significant peak (r = 0.76, p = 0.004).



Conclusions: A collateral-derived perfusion of a myocardial area at risk for infarction can be demonstrated using contralateral intracoronary echo contrast injections. The peak echo contrast effect is directly related to the magnitude of collateral flow.

IMAGING IN ISCHAEMIC HEART FAILURE

365 Tc-99m sestamibi and Thallium-201 retention in failing human hearts excised at transplantation

R. De Maria, L. Ruffini, J. Campolo, E. Vitali[1], E. Gronda[1], A. Pellegrini[1], G. Baroldi, A. Pezzano[1], O. Parodi. *CNR Clinical Physiology Institute, Milan; [1] Cardiology and Vascular Surgery Dept, Niguarda Hospital, Milan, Italy*

Different mechanisms underlie cellular retention of Tc-99m-sestamibi (MIBI) and Thallium-201 by the myocardium: Thallium-201 enters the myocell via the Na^+/K^+ ATPase, while MIBI is sequestered within the mitochondrial inner matrix. We evaluated the distribution of both tracers in failing human hearts with idiopathic dilated cardiomyopathy (IDC) and ischemic heart disease (IHD) excised at transplantation, in order to assess differences in tracer uptakes as a possible expression of distinct disease mechanisms.

Methods: Six transplant candidates, 3 IDC and 3 IHD, mean age 59 ± 3 yrs, mean LVEF 18 ± 3% were injected with MIBI 15 mCi and Thallium-201 1 mCi, 1 and 3 hours before surgery, respectively. One cm-thick slices from the excised heart were imaged on a gammacamera immediately after surgery and 30 hours afterwards, to allow radioisotope cross-talk correction. MIBI and Thallium-201 retention from 16 automatically defined regions were expressed as percent of each tracer maximum regional activity. Myocardial fibrosis was assessed in samples from the same regions as percent of histologic slide area.

Results: Out of 96 myocardial segments, 75 (29 IHD, 46 IDC) showed normal uptake (>75%) of both tracers and <5% myocardial fibrosis. MIBI activity averaged 87 ± 8% in IHD vs 89 ± 8% in IDC (ns), mean Thallium-201 activity was 86 ± 10% in IHD vs 91 ± 5% in IDC (p = 0.002); mean differential activity (Thallium-201 minus MIBI) was −1 ± 7 in IHD vs 3 ± 8 in IDC (p = 0.02). Furthermore Thallium-201 and MIBI activities were linearly related in IHD (r = 0.71, p = 0.0001) but not in IDC (r = 0.25, p = 0.08).

In conclusion, a different myocardial handling of Thallium-201 and MIBI is observed in failing hearts of IDC vs IHD; this behaviour might express either increased regional Na^+/K^+ ATPase activity or altered mitochondrial function in the failing IDC heart.

366 The magnitude of improvement of LVEF post-revascularization is determined by the extent of viable tissue

J.J. Bax, D. Poldermans, F.C. Visser, J.H. Cornel, P.M. Fioretti, A. Elhendy, C.A. Visser. *Leiden; Amsterdam; Rotterdam; Alkmaar, Netherlands; Udine, Italy*

The extent of viable myocardium, needed to result in improvement of *global* LV function is unknown. We assessed the relation between the extent of viable tissue (and scar tissue) and the magnitude of improvement of LVEF post-revascularization (post-REV).

Methods: Patients (n = 32) were studied with FDG SPECT and early thallium-201 SPECT (to assess perfusion). Data were analyzed using polar maps (13-segment model). Dysfunctional segments showing normal perfusion or mismatch were considered viable. LVEF was assessed before and 3 months post-REV. Improvement of LVEF > 5% was considered significant. The optimal cutoff level (number of viable segments) to establish improvement of LVEF post-REV was determined by ROC curve analysis.

Results: A significant relation existed between the number of viable segments on FDG SPECT and the magnitude of improvement of LVEF post-REV: y = 1.5* × −0.98 (r = 0–.70, P < 0.01). No relation existed between the extent of scar tissue and the change in LVEF. ROC curve analysis results to predict significant improvement of LVEF post-REV:

Viable segments	Sensitivity (%)	Specificity (%)
≥2	100	63
≥3	94	81
≥4	75	88
≥5	44	94

Conclusion: the extent of viable tissue is closely related to the magnitude of improvement of LVEF post-REV. Considering an improvement in LVEF > 5% significant, optimal sensitivity and specificity were obtained when ≥ 3 segments were viable on SPECT.

367 Relationship between global left ventricular function and incidence of ischaemia in viable, dysfunctioning myocardium

C. Marini, A. Gimelli, C. Marcassa[1], A. Cuocolo[2], G. Sambuceti, P. Marzullo. *CNR Institute of Clinical Physiology, Pisa; [1]Cardiologia, Centro Medico Veruno, Veruno[2]Cattedra di Medicina Nucleare, Universita di Napoli, Naples, Italy*

In patients with coronary artery disease, the progression of left ventricular (LV) dysfunction is often associated with the reduction of anginal symptoms. However, it is still to be defined whether this phenomenon actually parallels a reduction of stress-induced ischemia. This study aimed to assess the prevalence of ischemia, defined as reversibility of stress perfusion defects, in patients with significant impairment of LV function. Thallium-201 stress reinjection scintigraphy was performed in 124 patients (112 male, mean age 60 ± 9 years) with angiographically documented CAD, mean ejection fraction 0.33 ± 0.09 and previous myocardial infarction. Out of 990 segments supplied by a stenotic coronary artery 763 (77%) were scored viable. Stress (exercise or dipyridamole) imaging showed reversible defects indicative of transient ischemia in only 189 (25%) of the viable segments. To explore the relationship between incidence of ischemia and degree of dysfunction, patients were divided into two groups (with (n = 39) or without (n = 85) severe functional impairment (LVEF < 0.26). Compared with the remaining 85, the 39 patients with severe functional impairment showed a higher prevalence of NYHA III-IV dyspnea (60% vs 40%, $p < 0.05$), a lower prevalence of angina (31% vs 69%, $p < 0.05$) and a lower prevalence of ischemia in the dysfunctioning viable segments downstream from a stenotic coronary artery (18% vs 28%, $p < 0.05$). This paradoxical phenomenon was less evident when only segments with normal wall motion, supplied by stenotic arteries were considered (18% vs 22%, respetively, ns). These data confirm that reversible ischemia is relatively uncommon in patients with advanced left ventricular dysfunction, suggesting that viability rather than reversibility should guide the choice of medical treatment or revascularization. The observed low incidence of stress ischemia correlates with the dominance of heart failure symptoms and probably reflects the efficiency of the hibernation process at higher degree of LV dysfunction.

368 Enhanced diagnostic accuracy to predict improvement of LVEF post-revascularization by sequential thallium-201 imaging and dobutamine echocardiography

J.J. Bax, J. Maddahi, D. Poldermans, A. Elhendy, J.H. Cornel, P.M. Fioretti. *Leiden; Rotterdam, Netherlands; Los Angeles CA, USA; Udine, Italy*

Tl-201 imaging and low-dose dobutamine echo (LDDE) can predict functional outcome after revascularization (REV). While Tl-201 exhibits a relatively low specificity (Spec), LDDE shows a lower sensitivity (Sens). The aim of this study was to develop an optimal testing strategy for prediction of post-REV functional outcome.

Methods: 66 patients (LVEF 33 ± 8%) underwent LDDE and Tl-201 SPECT (rest-redistribution or 4-hour delayed imaging) prior to REV. Dysfunctional segments (Segs) with Tl-201 activity ≥ 50% or with contractile reserve were considered viable. LVEF was assessed before and 3 months post-REV.

Results: ROC curve analysis showed that the optimum criteria to predict improvement (≥5%) in LVEF after REV were ≥ 6 viable dysfunctional Segs (16-Segs model) on Tl-201 and ≥ 4 Segs on LDDE. Sens and Spec for Tl-201 were 83% and 65% and for LDDE 69% and 84%. Change of Tl-201 criteria to improve Spec to 78% (≥8 Segs) yielded a low Sens of 41% and change of LDDE criteria to improve Sens to 83% (≥2 Segs) lowered Spec to 57%. To achieve optimal Sens and Spec, 2 sequential testing strategies were explored. In strategy# 1, 27/66 (41%) patients with an intermediate (58%) likelihood of viability by Tl-201 (5–8 viable Segs) underwent LDDE study. In strategy#2, 26/66 (39%) patients with an intermediate (42%) likelihood of viability by LDDE (2–4 viable Segs) underwent Tl-201 study. Sens and Spec for strategy#1 were 88% and 81% and for strategy#2 79% and 82%.

Conclusion: Sequential testing by Tl-201 and LDDE in a subgroup of patients with an intermediate likelihood of viability by either test optimizes prediction of post-REV improvement of LVEF.

369 Prognostic value of the amount of dysfunctional but viable myocardium using Tl-201/I-123 BMIPP dual SPECT in revascularized patients with left ventricular dysfunction

S. Fukuzawa, S. Ozawa, M. Inagaki, J. Sugioka, K. Shimada. *Division of Cardiology, Funabashi Municipal Medical Center, Chiba, Japan*

The aim of this study was to assess the prognostic value of the amount of dysfunctional but viable myocardium in revascularized patients with severe left ventricular dysfunction using Tl-201/I-123 BMIPP dual SPECT. 76 patients with LVEF < 40% underwent dual SPECT. They were revascularized using euther CABG or PTCA and entered this study. To quantify the amount of dysfunctional but viable myocardium, both tracers uptake were scored using a 4-point system in 18-segment model. Dysfunctional but viable myocardium were defined if they exhibited the mismatch segment by at least one grade with dual SPECT images. The patients were followed up for a mean period 32 months for cardiac mortality and nonfatal cardiac events. Standard folloe-up of left ventriculography was performed 6 to 12 months after revascularization. 32 patients exhibited a large amount of dysfunctional but viable myocardium (>6 segments, group A), 28 patients had a small amount of dysfunctional but viable myocardium (2 to 6 segmaents, group B) and 16 patients were found to have irreversible damage to the myocardium (group C). Similar prerevascularization LVEF of 35 ± 5%, 34 ± 8%, 36 ± 6%, in group A, B, and C increased to 46 ± 6% ($p < 0.01$), to 40 ± 6% ($p < 0.05$), and to 36 ± 8% (n.s), respectively after revascularization. The greatest functional improvement after revascularization of group A was accompanied by a loe rate of cardiac events during follow-up and better cardiac event free survival as judged by the Kaplan-Meier survival cuirve ($p < 0.05$, vs group Band C).

In revascularized patients wuth severe LV dysfunction, the presence of a large amount of dysfunctional but viable myocardium evaluated by Tl-201/I-123 BMIPP dual SPECT identifies patients with the best prognosis.

370 Skeletal muscle I-123-metaiodobenzylguanidine scintigraphy in patients with chronic heart failure

I. Kohara, Y. Kimura, K. Hatada, R. Yuyama, J. Watanabe, S. Hamada, Y. Suga[1], T. Iwasaka. *Cardiovascular Center, Kansai Medical University, Osaka; [1]Radiology Dept, Kansai Medical University, Osaka, Japan*

To determine the abnormality of the systemic autonomic nervous system caused by the chronic heart failure(HF), we assessed 123 I-metaiodobenzylguanidine (MIBG) uptake in femoral muscle.

Methods: Sixteen HF patients without diabetes (13 men and 3 women, mean age 64 ± 14 years, mean LV ejection fraction 40 ± 14%, NYHA classification... I:2, II: 8, III: 3, IV: 4) and seven healthy control subjects (5 men and 2 women, mean age 59 ± 4 years) underwent whole body scintigraphy immediately after injection of 123 I-MIBG (111 MB), and measured the planar imaging of femoral muscle 20 minutes and 4 hours after injection. After femoral muscle scanning, myocardial scintigraphy was performed, and calculated the H/M ratio-early (H/M-E) and H/M ratio-delay (H/M-D). Then, mean counts in a region of interest (ROI) surrounding the both femoral muscle was calculated 20 minutes and 4 hours after injection (FM-E, FM-D), and further, total ROI counts was expressed as a percentage of whole body counts (%FM-E,%FM-D).

Results: There was no correlation between LV ejection fraction and FM-E, FM-D, while FM-E correlated positively to H/M-E ($r = 0.56$), H/M-D ($r = 0.50$), and FM-D correlated positively to H/M-E ($r = 0.68$), H/M-D ($r = 0.64$). HF patients had lower uptake than the control group in FM-D ($p < 0.01$). Similarly, percentage of the whole body counts in HF patients was significantly lower than that in control group (%FM-E: 2.4 ± 0.5% vs 3.7 ± 1.3%, $p < 0.005$ %FM-D: 2.3 ± 0.5% vs 4.1 ± 1.3%, $p = 0.0003$).

Conclusion: Compared with the control group, HF patients had lower uptake of 123 I-MIBG in skeletal muscle, and uptake in skeletal muscle and myocardium correlated closely in patients with HF. These results suggest that patients with chronic heart failure had the abnormality of the autonomic nervous system not only myocardium but also skeletal muscle.

COMPUTER DEMONSTRATIONS

D386 Low-cost computer system for analysis of digital diagnostic coronary angiograms in view of coronary flow measurements

B. Górecka, Z. Dzielińska, M. Dąbrowski, W. Rużyłło. *National Institute of Cardiology, Warsaw, Poland*

Absolute coronary flow and coronary flow reserve measurements are useful for determining the functional status of coronary artery. Until recently these measurements have required an invasive techniques but in the last years some noninvasive methods like e.g. MRI are used for the assessment of coronary flow. Presented method utilises the dynamics of coronary angiograms and is based on the analysis of mean brightness curve constructed for these parts of image which present whole coronary artery or its part in motion – Mean Brightness Method (MBM). The contractual measure of blood flow – Coronary Flow Index (CFI) is percent change of mean brightness of coronary artery in unit of time (%/cycle, %/sec).

System software enables review and analysis of digital coronary images in DICOM standard from CD-R as well as from cinefilm after digitisation via cinefilm projector, video camera and framegrabber into 512 × 512 × 8 matrix. Images, digitised from cinefilm can be next archive in DICOM standard for further review and analysis. The possible speed of dynamic reviewing is from 0.5 to 30 frames per sec (in loop; forward and reverse). In view of coronary flow assessment software defines cardiac cycles, generates subtracted images of coronary arteries, normalised mean brightness curves and calculates CFI.

System software enables off-line analysis of conventional coronary angiograms, is user-friendly, requires typical PC hardware (optimal parameters: processor Pentium ≥ 350 MHz, RAM ≥ 128 MB), environments supported include Windows95, Windows98, WindowsNT.

MBM and CFI were validated with positive result in group of patients with angiographically normal coronary arteries and in patients undergoing PTCA procedure by comparing with intracoronary Doppler measurements.

In conclusion: System provides accurate assessment of coronary flow by means of digital analysis of diagnostic coronary angiograms and CFI calculation; thereby might be a promising alternative to invasive coronary flow measurements.

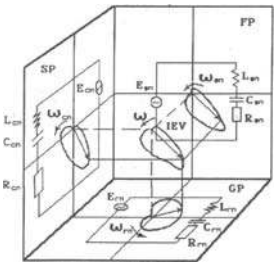
D387 Heart vectorcardiographical monitoring and arterial hypertension: new clinico-electrocardiologic aspects

P.I. Romanchuk[1], A.N. Volobuev[2]. [1]*Center of Arterial Hypertension and New Diagnostic Methods;* [2]*Department of Biophysics of Samara State Medical University, Samara, Russian Federation*

Purpose: To design simultaneous computer analysis of linear and phase electrocardiography (ECG) and integrated vectorcardiography (VCG) for monitoring of electrical remodeling (MER) of left ventricular (LV) of the heart in patients with arterial hypertension (AH).

Patients and methods: 34 healthy volunteers (17 men and 17 women) and 170 patients (85 men and 85 women) with mild AH were examined. VCG computer MER LV of hearts were carried out according to the following scheme: on admission (before treatment); after 21 days of hospitalization; on follow-up visits to the out-patient department every 3rd month within one year.

The designed spatial – volumetric 3D biophysical model of dipole electric generator of the heart is a new fundamental aspect of VCG monitoring (fig.).



New monitored ECG parameters are the following: R duration on isoelectric line, average electrosystole Q-factor of "electrical heart", de- and repolarization Q-factors.

Conclusion: Simultaneous spatial-volumetric analysis of VCG and ECG with introduction of new standard controlled parameters is fundamental modern computer technique in electrocardiology for MER LV of the heart, optimal treatment and forecast in patients with hypertension.

PEPTIDES IN VASOMOTION AND VENTRICULAR FUNCTION

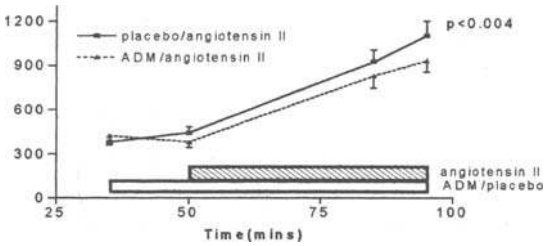
P388 Adrenomedullin selectively inhibits angiotensin II stimulated aldosterone production in healthy humans

M.C. Petrie[1], C. Hillier[2], J.J. Morton[1], J.J.V. McMurray[1]. [1]*MRC CRI in Heart Failure, University of Glasgow;* [2]*Caledonian University, Glasgow, UK*

Background: Adrenomedullin (ADM) inhibits angiotensin II (AII) stimulated aldosterone production *in vitro* in experimental animals. We investigated the effect of ADM on AII and adrenocorticotrophic hormone (ACTH) stimulated aldosterone production *in vivo* in healthy humans.

Methods: 7 volunteers were studied in a quiet, temperature controlled laboratory. After 35 minutes, an infusion (placebo or ADM [3 pmol/kg/min]) was given over 60 minutes. 15 minutes after starting this first infusion, AII (10 pg/kg/min) was co-infused and continued for 45 minutes.

Results: ADM caused a small but highly significant inhibition of AII stimulated aldosterone production ($p < 0.004$). ADM did not inhibit ACTH stimulated aldosterone or cortisol release. Data are presented as mean ± SEM.



Conclusion: ADM selectively inhibits angiotensin II stimulated aldosterone production. ADM may be an important regulator of the renin angiotensin aldosterone system in health and disease.

P389 Endothelin-1-induced ventricular arrhythmias are effectively suppressed by LU135.252, the selective endothelin A-receptor antagonist

T. Szabo, L. Geller, M. Raschack[1], L. Fazekas, O. Kiss, A. Juhasz-Nagy, B. Merkely. *Dept. of Cardiovascular Surgery, Semmelweis Medical University, Budapest, Hungary;* [1]*Knoll AG, Ludwigshafen, Germany*

Background: Endothelin-1 (ET-1) is the most potent vasoconstrictor peptide, which may have a direct arrhythmogenic effect, as well. The aim of our study was to investigate the role of the selective ET_A-receptor antagonist LU135.252 (LU) in protecting the heart from ET-1 induced ventricular arrhythmias.

Methods: Eighteen Na-pentobarbital anesthetized open-chest mongrel dogs were divided into two groups. In group A (n = 10) a bolus injection of 5 mg/kg LU was administered intravenously. The 30 min intracoronary (i.c.) ET-1 infusion was started 20 min after the LU bolus at a rate of 3 pmol/kg/min. In group B (n = 8) the 30 min ic. ET-1 was administered at a rate of 2 pmol/kg/min. Left anterior descending coronary artery flow (CBF), cardiac output (CO), ECG and arterial blood pressure (BP) were monitored. Two monophasic action potential (MAP) catheters were placed onto the left ventricular epicardium (LVEPI) and into the right ventricular endocardium (RVENDO) to follow electrophysiologic changes.

Results: Neither BP (0 min vs. 30 min: group A: 99 ± 4 vs. 90 ± 5 Hgmm; group B: 109 ± 7 vs. 105 ± 7 Hgmm), nor CO (0 min vs. 30 min: group A: 3.5 ± 0.7 vs. 3.2 ± 0.8 l/min; group B: 3.7 ± 0.3 vs. 3.1 ± 0.8 l/min) changed significantly, whereas a significant decrease was observed in CBF (DCBF30MIN: group A: 28 ± 2%, $p < 0.05$; group B: 35 ± 2% $p < 0.05$).

In group A ventricular fibrillation (VF) occurred once. Ventricular premature contractions and short, non-sustained ventricular tachycardic (VT) episodes were observed in 7 cases. Two animals exhibited sustained VT, moreover six died of VF in group B. The changes of MAP duration 90% (MAPD90) are presented in Table 1.

Table 1

Change of MAPD90	Control	ET 0 min	ET 30 min	p
Group A				
LVEPI	263 ± 7 ms	241 ± 11 ms	260 ± 14 ms	NS
RVENDO	242 ± 6 ms	233 ± 5 ms	239 ± 8 ms	NS
Group B				
LVEPI	190 ± 3 ms	188 ± 5 ms	208 ± 8 ms *	* <0.05
RVENDO	187 ± 6 ms	189 ± 5 ms	207 ± 10 ms *	* <0.05

Conclusion: Our results suggest, that a single bolus injection of LU effectively protects the heart from ET-1 induced malignant ventricular arrhythmias, but only partly inhibits ET-1 mediated vasoconstriction.

P390 Analogies of human and swine endothelin receptors in ventricular cardiomyocytes

S. Vanni, P.A. Modesti, R. Paniccia, I. Bertolozzi, G. Polidori, A. Perna[1], G.G. Neri Serneri. *Clinica Medica Generale e Cardiologia, University of Florence, Florence; [1]Cardiac and Experimental Surgery, University of Florence, Florence, Italy*

Studies are in progress to use pigs for cardiac xenotransplantation and endothelin-1 (ET-1) is potentially involved in graft rejection. The present study aimed to compare ET-1 receptor characteristics between human and swine cardiomyocytes. [125I]-ET-1 binding studies were performed with freshly isolated cardiomyocytes obtained by enzymatic digestion from left ventricles of five healthy donors, whose hearts were *not* suitable for transplatation for non cardiac reasons, and of five adult farm pigs. ETA (PD-155080) and ETB (BQ-788) selective and *non*-selective (PD-145080) receptor antagonists were used to characterize ET-1 receptor subtypes. In situ hybridization studies with specific cDNA probes (ETA, American Type Culture Collection, ATCC 105194 and ETB, ATCC 1250426) investigated the "ex vivo" cell distribution of mRNA for ETA and ETB receptors in left ventricular sections.

In both human and swine hearts [125I]-ET-1 binding reached equilibrium in about 120 min (Kobs = 0.051 and 0.049 min^{-1} respectively) and was only partially displaceable by the addition of a large excess of ET-1. In equilibrium binding studies [125I]-ET-1 had a Kd of 0.43 ± 0.08 and of 0.24 ± 0.09 nM and maximum binding (Bmax) of 42.8 ± 6.6 and of 38.5 ± 9.2 fmol/mg protein for human and swine respectively. ETA and ETB receptors are both represented in human and swine cardiomyocytes with a 85:15 ratio as indicated by the biphasic pattern of competition of both PD-155080 and BQ-788. In situ hybridization studies confirmed the prevalence of ETA at mRNA level both in human and swine left ventricular myocytes. These results showed that ET-1 binds with high affinity and poor reversibility to specific receptors, in both human and swine isolated ventricular cardiomyocytes, without significant species differences.

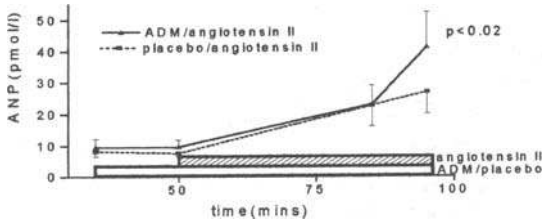
P391 Adrenomedullin and atrial natriuretic peptide interaction in humans

M.C. Petrie[1], C. Hillier[2], J.J. Morton, J.J.V. McMurray[1]. *[1]MRC CRI in Heart Failure University of Glasgow; [2]Caledonian University, Glasgow, UK*

Background: Adrenomedullin (ADM) and atrial natriuretic peptide (ANP) appear to interact. In experimental heart failure infusion of ADM results in increased ANP concentrations. Conversely, systemic infusion of ANP in healthy humans increases ADM concentrations. We have investigated the effect of ADM on angiotensin II (AII) stimulated ANP in healthy humans.

Methods: 7 volunteers were studied in a quiet, temperature controlled laboratory. After 35 minutes, an infusion (placebo or ADM [3 pmol/kg/min]) was given over 60 minutes. 15 minutes after starting this first infusion, AII (10 pg/kg/min) was co-infused and continued for 45 minutes. Plasma ANP was measured at 35 (baseline), 50, 85, 95 and 105 minutes.

Results: ADM significantly augmented AII stimulated ANP production ($p < 0.02$). Data are presented as mean ± SEM.



Conclusion: Despite its vasodilator and natriuretic action, ADM significantly augmented AII-stimulated ANP concentrations in healthy humans in this study. This provides further evidence of a synergistic interaction between ADM and ANP.

P392 Omapatrilat, a vasopeptidase inhibitor, enhances baroreflex gain in spontaneously hypertensive rats

S.T. Zhu, Y.F. Chen, S. Oparil, D.A. Calhoun. *Vascular Biology and Hypertension Program, University of Alabama at Birmingham, Birmingham AL, USA*

This study sought to determine the effects of omapatrilat on basal sympathetic nervous system activity and baroreflex function in conscious spontaneously hypertensive rats (SHR) and control normotensive Wistar-Kyoto (WKY) and Sprague-Dawley (SD) rats. Omapatrilat, a vasopeptidase inhibitor, is a single molecule that inhibits neutral endopeptidase (NEP) and ACE.

Methods: Recording electrodes were surgically secured to the lumbar nerve. After 24 hr, reflex changes in lumbar sympathetic nerve activity (LSNA) that occurred during phenylephrine- and nitroprusside-induced increases or decreases in blood pressure were measured both before and during omapatrilat exposure.

Results: Baseline mean arterial pressure (MAP) was 97 ± 4 (SD, n = 6), 101 ± 3 (WKY, n = 7), and 122 ± 2 (SHR, n = 7) mm Hg, and heart rate was 428 ± 22 (SD), 356 ± 13 (WKY), and 409 ± 25 (SHR) bpm. Table shows logistic curve-fitting values in LSNA during omapatrilat exposure (mean ± SE).

		Minimum SNA	Midpoint MAP	Maximal slope (gain)
SD	Pretherapy	23 ± 6	104 ± 2	−1.29 ± 0.10
(n = 6)	Omapatrilat	21 ± 9	85 ± 3*	−1.34 ± 0.14
WKY	Pretherapy	22 ± 5	99 ± 4	−1.54 ± 0.10
(n = 7)	Omapatrilat	19 ± 5	92 ± 3	−1.69 ± 0.20
SHR	Pretherapy	27 ± 4	124 ± 3††	−1.06 ± 0.14
(n = 7)	Omapatrilat	17 ± 4	99 ± 3*†	−1.37 ± 0.11*

*$p < 0.05$ vs pretherapy; †$p < 0.05$ vs SD rats; SNA = sympathetic nerve activity; Midpoint MAP = MAP at baroreflex curve midpoint; Maximum slope = maximal slope of the baroreflex curve.

In conclusion, therapy with omapatrilat significantly increased baroreflex gain in SHR but not in SD rats, which may contribute to its antihypertensive activity. Further study is needed to assess the relative contributions of ACE vs NEP inhibitory pathways to this response.

P393 Increasing secretion of A-type natriuretic peptide induced by annexin V in the primary culture of atrial cardiocytes

K. Taniguchi, H. Mifune[1], A. Taniuchi, H. Wakuri, K. Mutoh, S. Suzuki[2], K. Taniguchi[3]. *Department of Veterinary Anatomy, Kitasato University, Towada; [1]Institute of Animal Experiment, Kurume University, Kurume[2]Institute of Laboratory Animal Science, Kagoshima University, Kagoshima[3]Department of Veterinary Anatomy, Iwate University, Morioka, Japan*

Annexin V is one of the proteins binding phospholipid calcium-ion dependently, and reported to be distributed in both the myocytes and non-myocytes of the rat heart. On the other hand, A-type (atrial) natriuretic peptide (ANP) and endothelin (ET) which are secreted by atrial myocytes and by such non-myocytes as vascular endothelial cells, respectively, have been reported to play essential roles in the control of local circulation of the heart. However, the functional significance between annexin V and those peptides still remains unknown. We, therefore, aimed to examine whether annexin V is associated with the secretion of ANP and ET in the context of the control of local circulation of the heart.

Methods: Atrial cardiocytes were dissociated from neonatal Wistar rats 5 days of age, and processed for the primary-culture. Cultured cells were divided into 2 groups as follows: (Group1) Human recombinant annexin V (rAxV) at 1 to 1,000 ng/ml or anti-annexin V antiserum (anti-AxV) were administered into the culture medium at 2 days after the dissociation, (Group 2) Anti-ET antiserum or cytosine b-D-arabino-furanoside were applied to the medium to block the function of ET, or to prevent the proliferation of *non*-myocytes, respectively, prior to the administration of rAxV as in group 1. In both groups, the amounts of ANP secreted into the culture medium were measured by radioimmunoassay at 0 to 48 hr after the administration of rAxV. In addition, ANP-immunopositive areas were examined immunohistochemically, measured morphometrically and analyzed statistically in the cultured cells.

Results: The administration of rAxV increased the secretion of ANP dose-dependently, but that of anti-AxV induced no difference in the amount of ANP secretion in group 1. In group 2, however, the administration of rAxV caused no change in the amount of secreted ANP. These results suggest that rAxV induce the increase of ANP secretion in the close relationship with non-myocytes. Immunohistochemical studies revealed that the amount of intracellular ANP was maintained at constant level, suggesting that the ANP synthesis was accelerated when the secretion of ANP was increased by the administration of rAxV to result in the constant amount of intracellular ANP.

Conclusion: Since annexin V was reported to be secreted from cultured fibroblasts, the present results suggest that annexin V is synthesized in the myocytes and/or in non-myocytes, secreted into extracellular space, and increases the synthesis and secretion of ANP from the myocytes under the influence of ET by autocrine or paracrine manner.

P394 Efficient transcription of human angiotensin II type 2 receptor gene depends on intronic sequence elements

C. Warnecke, T. Willich, J. Holzmeister, E. Fleck, V. Regitz-Zagrosek. *Int. Med./Cardiology, Charité, Campus Virchow Clinic, Humboldt University Berlin; Deutsches Herzzentrum Berlin, Germany*

The angiotensin II receptor type 2 (AT2) is the predominant angiotensin II (Ang II) receptor in the human heart. AT2 probably mediates anti-proliferative and anti-hypertensive Ang II effects and its expression is upregulated in cardiac and vascular remodeling. We therefore analyzed the mechanisms that regulate the transcription of the human AT2 (hAT2) gene. For this purpose, we functionally characterized the hAT2 promoter using luciferase reporter gene assays in PC12W cells and Electrophoretic mobility shift assays. The downstream region of the hAT2 gene (exon 1 and 2, intron 1 and 2) was included into the analysis, since this region may also comprise *cis*-active DNA elements.

The hAT2 promoter region from −1417 through +100 exhibited only weak promoter activity in PC12W cells. Inclusion of the 152-bp intron 1 of the hAT2 gene in a luciferase construct containing the hAT2 core promoter (−271/+100) increased reporter gene expression 6.7 ± 1.65-fold (n = 4; p < 01). When intron 1, exon 2, and the 1.2-kb intron 2 were integrated in the promoter construct, luciferase activity was increased 11.6 ± 1.7-fold (n = 4; p < 0.01). In contrast, fusion of the spliced 5′untranslated regions of the hAT2 cDNAs to the promoter did not alter luciferase expression, which indicated that intronic sequence elements were responsible for the observed effect. Mapping of intron 1 revealed a 12-bp region, which mediated the increase in promoter activity. In gelshift assays, we identified PC12W cell nuclear proteins binding to the 12-bp sequence. Further reporter gene assays showed that intron 1 is *by itself* able to direct luciferase expression. This suggests that intron 1 may function as an alternative promoter perhaps under specific (patho)physiological circumstances.

In conclusion, intronic sequence elements are necessary for efficient hAT2 gene expression. In particular, the first intron represents a region with high regulatory potency.

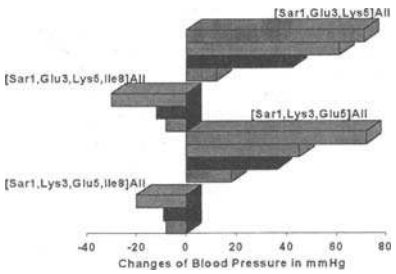
STRUCTURE AND FUNCTION OF VESSEL'S WALL

P395 The biological activity of amide linked angiotensin II cyclic analogues confirms the ring clustering and charge relay bioactive conformation of all

D.V. Vlahakos[1], E.K. Iliodromitis[1], E. Bofilis[1], K.P. Marathias[1], L. Poleyava[2], J. Matsoukas[3], P. Roumelioti[3], D.Th. Kremastinos[1]. *[1]2nd Dept of Cardiology, Onassis Cardiac Surgery Center, Athens; [3]Dept of Chemistry, University of Patras, Patras, Greece; [2]Latvian Institute of Organic Synthesis, , Latvia*

We have recently suggested that Tyr-Ile-His bend, a His-Pro trans amide bond configuration and a side chain aromatic ring cluster of the key aminoacids Tyr, His, Phe are important characteristics in the bioactive conformation of AII (J Biol Chem 269: 5303; 1994, J Med Chem 38: 4660; 1995).

Methods: To test this hypothesis novel amide linked AII-cyclic analogues with the Tyr, His, Phe ring cluster, [Sar^1, Glu^3, Lys^5] – AII and [Sar^1, Lys^3, Glu^5] – AII or without this important conformational property [Sar^1, Glu^3, Lys^5, Ile^8] – AII and [Sar^1, Lys^3, Glu^5, Ile^8] AII, were designed and synthesized by connecting the Lys amino and Glu carboxyl groups at positions 3 and 5. These analogues were then tested and compared for biological activity with the parent molecule (AII) in anesthetized rabbits under continuous blood pressure monitoring and the results are summarized in the following Figure.



Conclusion: The dose-dependent agonistic or antagonistic activity of the synthesized cyclic AII-analogues is associated with their conformational properties, as proposed in our model and provides further evidence on the importance of the charge relay system and ring clustering for AII to exert its biological activity.

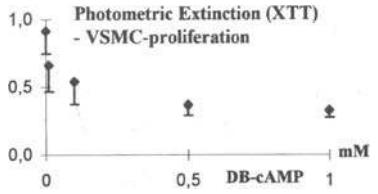
P396 Inhibiton of human vascular smooth muscle cell proliferation by cyclic-adenosine monophosphate and cylcic guanosine monophosphate – an in vitro comparison of anti-proliferative signal-transduction

A. Sasse, S. Kell, J. vom Dahl, P. Hanrath. *Department of Cardiology, University Clinic RWTH Aachen, Germany*

Background: Intracellular signal transduction of multiple receptors and substances in vascular smooth muscle cells (VSMC) are mediated through the activation of adenosine-and guanosine-cyclases resulting in an increase of cellular cyclic adenosine-monophosphate (cAMP) or cyclic guanosine monophosphate (cGMP). This signal transduction is also involved in the regulation of cellular proliferation and the activation of protein kinases.

Methods: VSMC were cultivated by explantation from human iliac artery and aorta. Proliferation was assessed by determination of bromodeoxyuridine (pyrimidine analogue) incorporation in DNA (BrdU), by cell number and through a terazolium-formazan assay measuring mitochondrial dehydrogenase activity (XTT).

Results: The cyclic monophosphate analogues 8-Br-cGMP and Dibutyryl-cAMP (DB-cAMP) as well as the phosphodiesterase inhibitor isobutyl-methyl-xanthine (IBMX) were incubated over different periods of time with proliferating human VSMC. DB-cAMP decreased growth to 35.6% (1.0 mM, p < 0.001), 8-Br-cGMP to 49.1% (1.0 mM, p < 0.001) and IBMX to 34.2% (1.0 mM, p < 0.001). Results from other methods (BrdU, cell count) parallel the given results.



Conclusion: Cyclic monophosphates show a time- and dose-dependent growth inhibitory effect on human VSMC in vitro, while cAMP is more effective than cGMP. This common pathway of receptor-mediated signal transduction might allow the treatment of hyperproliferative VSMC reactions in processes such as postinterventional restenosis and post-transplant vasculopathy.

P397 Homocysteine induces tissue inhibitor of metalloproteinase-1 expression in vascular smooth muscle cells

J.A. Rodríguez, M.A. Avila[1], L. Torres[1], E.R. García-Trevijano[1], M.V. Carretero[1], R. Arias, E. Eguinoa, J.M. Mato, D. Martínez-Caro. *Dept. of Cardiology, Faculty of Medicine, University of Navarra, Pamplona; [1]Dept. of Internal Medicine, Faculty of Medicine, University of Navarra, Pamplona, Spain*

Abnormally high levels of plasma homocysteine (HCys) have been associated with an increased risk of cardiovascular disease, although the mechanism of action is not known yet. Vascular smooth muscle cells (VSMC) have a key role in the atherosclerotic process and could be a potential target for HCys action. This study was performed to look for genes whose expression could be specifically changed by HCys in VSMC.

Primary cultures of VSMC, established from human mammary artery (h-VSMC and porcine aorta (p-VSMC), were treated or not with HCys (100 μM) and their RNA extracted. Differential display technique was used, and bands corresponding to differentially expressed genes were identified by cloning and sequencing. The specificity of the induction was confirmed by *northern blot*, with RNAs from h-VSMC and p-VSMC, treated or not with HCys.

Differential display showed a 0.9 Kb band with higher expression in h-VSMC treated with HCys. After cloning and sequencing, the fragment was identified as tissue inhibitor of metalloproteinases-1 (TIMP-1). HCys treatment induced an increase in the expression of proliferating cell nuclear antigen in quiescent VSMC. A dose-dependent increase in TIMP-1 mRNA expression after HCys treatment was observed in h-VSMC and p-VSMC.

Homocysteine induces specifically the expression of TIMP-1 invascular smooth muscle cells through an unknown mechanism. TIMP-1 induction, causing collagen and extracellular matrix accumulation, could be the key to the better understanding of the mechanisms responsible for the action of HCys as cardiovascular risk factor.

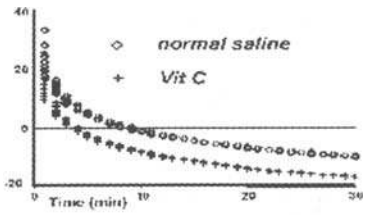
P398 Vitamin C reduces oxidative stress induced by maximal exercise and improves arterial distensibility in healthy subjects

K.K. Naka, J. Goodfellow, G.R. Ellis, R. Anderson, S. Jackson[1], F. Dunstan[2], M.P. Frenneaux. *Department of Cardiology, Univ. of Wales College of Medicine, Cardiff; [1]Department of Medical Microbiology, Univ. of Wales College of Medicine, Cardiff [2]Department of Medical Statistics, Univ. of Wales College of Medicine, Cardiff, UK*

Maximal exercise induces oxidative stress. We hypothesised that this may reduce large artery distensibility (via reduced NO bio-availability) with potential adverse effects on cardiovascular efficiency – changes that may be prevented by the free radical scavenger Vitamin C (Vit C).

Methods: 8 healthy male volunteers performed exhaustive bicycle exercise on 2 occasions, randomly assigned to either intravenous Vit C (2 g) or normal saline (placebo). For 15 minutes pre and 30 minutes post exercise we measured 1) pulse wave velocity (PWV, inversely related to arterial distensibility) in the upper limb using oscillometry (QVLTM, SciMed, UK) from transit times of pressure waveforms between 2 cuffs for 15 seconds every minute and 2) blood pressure (BP – Finapres, Ohmeda) continuously. Lipid-derived free radicals (FR) were measured ex vivo pre and post exercise by electron paramagnetic resonance spectroscopy.

Results: PWV was increased immediately after exercise but fell below baseline levels by 10 minutes following placebo, describing a curve as shown in the figure. Vit C shifted the curve downwards (mean difference ± SEM, 10 ± 3.5%, 95% CI: 1.9–18.2, p = 0.02) without changing BP pre, during or post exercise compared to placebo. FR increased after exercise with placebo (50 ± 17% rise, p < 0.05) and Vit C abolished this increase.



% changes in PWV cf. rest.

Conclusions: Arterial distensibility is transiently reduced following maximal exercise and increases later in the recovery period. Pre-treatment with Vitamin C reduces the exercise-induced oxidative stress and improves arterial distensibility. In cardiovascular disease states where oxidative stress is increased, these adverse effects seen in health may be exaggerated, suggesting a potentially important role for antioxidant therapy.

P399 The insertion/deletion polymorphism within the angiotensin converting enzyme and reactivity of isolated resistance arteries

R. Steeds, L. O'Toole, K. English, A. Morice[1], K.S. Channer. *Cardiology Dept, Royal Hallamshire Hospital, Sheffield; [1]Department of Medicine, University of Hull, Hull, UK*

An insertion-deletion polymorphism within the angiotensin converting enzyme (ACE) gene is associated with a 26% increase in risk of myocardial infarction. The aim of this was to determine whether the ACE polymorphism produced function differences in local resistance arterial reactivity.

Method: 242 resistance arterioles were excised from the margin of colonic specimens resected for adencarcinoma from 70 patients (mean age 64 ± 2 years). Vessels were loaded onto a small vessel wire myograph at a resting tension equivalent to 100 mgHg mean arterial pressure. Vessel viability was assessed by contraction >0.5 mN mm to KCl (100 mM) and >50% relaxation to acetylcholine (0.1 μM). The ACE I/D polymorphism was assayed by PCR amplification.

Results: 27 subjects were DD, 28 ID, and 15 II. Vessel contraction to angiotensin I (0.1 nM–0.1 μM) was not altered by ACE genotype (Emax DD 4.4 ± 0.6 mN/mm: ID/II 4.4 ± 0.7 mN/mm, p = 0.99). Contraction to angiotensin II (0.1 nM–0.1 μM) did not depend upon genotype (Emax DD 4.5 ± 0.5 mN/mm, p = 0.66). In order to exclude the possibility that non-ACE conversion of A I in the isolated arteries was concealing a difference between ACE polymorphisms, contraction to the ACE-specific substrate, proline10 angiotensin I (1 nM–0.1 μM) was assessed. No difference was seen (Emax DD 2.6 ± 0.3 mN/mm; Emax ID/II 2.1 ± 0.3 mN/mm, p = 0.21). Specificity of proline10 A I for ACE confirmed by abolition of contraction in the presence of the inhibitor captopril 1 mmol/L (2.04 ± 0.3 mN/mm v 0.007 ± 0.12 mN/mm, p = 0.0001). Chymostatin-sensitive A II generating enzyme was not found to be an important ACE-independent source of A II in the arteries used, since chymostatin did not reduce maximum contraction to A I (Emax 2.1 ± 0.3 mN/mm v 1.8 ± 0.4 mN/mm, p = 0.5). As expected ACE genotype was a predictor of serum ACE levels, with the highest occurring in association with the D allele. However, there was no correlation between the serum level of ACE and the EC50 for A I (r = 0.08, p > 0.2), A II (r = 0.08, p > 0.2), nor proline10 A I (r = 0.09, p > 0.2).

Conclusion: The I/D polymorphism within the ACE gene is not associated with a difference in arterial contractility despite differences in level of serum ACE. No difference in contractility is found even after exclusion of non-ACE conversion of AI.

P400 The importance of endocardial endothelium on the effects of db-cAMP on the calcium content in the isolated right ventricle of rat heart

M. Nešić[1], V. Vujičić[2], K. Gobčević[1], D. Pavlović[2], A. Nešić-Dorevska[3], V. Janković[1], M. Pavlović[1]. *[1]Faculty of Medicine, Belgrade; [2]Clinical Center of Serbia, Belgrade; [3]"Hemofarm" Concern, Vršac, Yugoslavia*

The specific functional morphological features of the endocardial endothelium suggest the possibility that this adjustable physicochemical barrier may selectively regulate the exchange of substances and ions

Methods: Experiments were performed on the isolated right ventricle of the rat heart with the intact and without endocardial endothelium. Endocardial endothelium was damaged by brief immersion of right ventricle in 1% dilute detergent solution of Triton X-100 in Krebs-Ringer. Immediately after preparation, the ventricle was suspended in a bath for isolated organs with Tyrode's solution that was bubbled with 95% O_2/5% CO_2. Contractions were induced with square wave impulses of twice the diastolic threshold and a duration of 5 ms at a frequency of 1 Hz. After the stabilization period db-cAMP (Sigma, USA) in a concentration of 3×10^{-4} moll/l, was added into the bath and contractions were registrated for another 30 minutes. After that, the ventricle was removed from the bath and the lower part of the ventricle was taken, minced and dried at 105°C to constant weight, and then the tissue was extracted. Calcium was determined by the atomic absorber, from the appropriate dilutions of the extracted tissue,

Results: The obtained results show that the control values of the calcium content in the myocardium of the right ventricle with the intact endocardial endothelium was 35 mmoll/l while in the myocardium without endocardial endothelium it was 125 mmoll/l. Db-cAMP, in the applied concentration, in the experimental group, in the presence of endocardial endothelium caused mild increase (39 mmoll/l, p > 0.05), but in the group without endocardial endothelium significant decrease (54 mmoll/l, p < 0.05) of the content of myocardial calcium, in comparison with the control group.

Conclusion: The effects of db-cAMP on the content of myocardial calcium are different depending on the presence of endocardial endothelium.

P401 Calcitonin gene-related peptide-induced vasodilation does not depend on the activation of potassium channels in man

L.M.A.B. Van Bortel[1], J.N.J.M. de Hoon[1], P. Pickkers[2], P. Smits[2], H.A.J. Struijker-Boudier[1]. *[1]Dept. of Pharmacology, Maastricht University, Maastricht; [2]Depts. of General Internal Medicine and Pharmacology, University Hospital Nijmegen, Nijmegen, Netherlands*

Aims: *In vitro* experiments suggest that potassium channels (K-channels) contribute to CGRP-induced vasodilation. It was investigated in man whether ATP sensitive K-channels (K_{ATP}-channels) or calcium sensitive K-channels (K_{Ca}-channels) are involved in the vasodilation induced by CGRP.

Methods: Venous occlusion plethysmography was used to measure the forearm blood flow (FBF) response to increasing infusion rates of CGRP (3-10-30 ng/min/dl forearm) into the brachial artery of 24 healthy subjects. Dose-response curves were constructed before and during the co-infusion of placebo (NaCl 0.9%, n = 8), the K_{ATP}-channel blocker glibenclamide (2 μg/min/dl forearm, n = 8) and the K_{Ca}-channel blocker tetra-ethyl-ammonium chloride (TEA, 0.1 mg/min/dl forearm, n = 8). Forearm vascular resistance (FVR) was calculated (FVR = mean arterial pressure/FBF) and presented as percentage change from baseline in FVR (ΔFVR). Dose-response curves were compared using ANOVA with repeated measures and Wilcoxon's matched-pairs signed-rank tests. Data are presented as mean ± SEM.

Results: CGRP (n = 24) increased FBF from 2.4 ± 0.2 at baseline to 4.9 ± 0.4, 8.0 ± 0.7 and 12.2 ± 1.1 ml/min/dl forearm, respectively (p < 0.001). ΔFVR during the first co-infusion of CGRP and placebo (−51 ± 4, −66 ± 5 and −75 ± 5%) did not differ from ΔFVR during the second co-infusion of CGRP and placebo (−43 ± 5, −68 ± 4 and −80 ± 3%). ΔFVR during co-infusion of CGRP with glibenclamide (−36 ± 3, −61 ± 3 and −81 ± 2%) or TEA (−37 ± 2, −64 ± 3, −82 ± 2%) was comparable to ΔFVR during CGRP with placebo.

Conclusions: The intra-brachial infusion of CGRP results in a dose-dependent and repeatable increase in FBF. In contrast to *in vitro* experiments, CGRP-induced vasodilation *in vivo* seems not to be mediated by ATP sensitive or calcium sensitive potassium channels in man.

P402 Abnormal vascular function in patients with pre-dialysis renal failure

J. Thambyrajah, M.J. Landray[1], F.J. McGlynn[1], H.J. Nield[1], D.C. Wheeler[1], J.N. Townend[1]. *Division of Medical Sciences, University of Birmingham, Birmingham; [1]Division of Medical Sciences, University of Birmingham, Birmingham, UK*

Patients with chronic renal failure (CRF) are at 10- to 20-fold increased risk of cardiac death and mortality when compared to matched non-uraemic controls. Endothelial dysfunction plays a key early role in the development of atherosclerotic vascular disease (AVD). The vascular response to nitrates, independent of the endothelium, is also abnormal in patients with atheroma.

Methods: We studied 80 patients (mean ± SD age 61.9 ± 12.2 years, 58 men) with non-diabetic renal failure (serum creatinine, SCr, range 136 to 747 umol/L) and 26 healthy age and sex-matched controls (mean ± SD age 59.9 ± 14.0 years, 17 men). Endothelial function was assessed using high-resolution ultrasonography to measure flow-mediated endothelium-dependent dilatation (EDD,% change) of the brachial artery following reactive hyperaemia. Endothelial independent dilatation (EID,% change) was also assessed following sublingual glyceryl trinitrate. The patients were divided into those with and without clinically apparent AVD.

Results: Although CRF patients had significantly impaired EDD compared to controls, there was no difference between CRF patients with and without AVD. Within the CRF group, EDD was not significantly different in patients in the upper and lower quartiles of calculated GFR (2.8 ± 2.6% v 3.5 ± 3.7%). EID was also reduced in CRF suggesting impaired smooth muscle response to nitric oxide.

Results

	Control	CRF No AVD	CRF Overt AVD	All CRF
N	26	51	29	80
SCr (umol/L)	97 ± 12	279 ± 124	273 ± 130	277 ± 125
GFR (ml/min)	77 ± 21	31 ± 15	30 ± 12	31 ± 14
EDD (%)	6.7 ± 2.8	3.5 ± 3.1***	1.9 ± 2.8***	2.9 ± 3.1***
EID (%)	14.8 ± 4.8	11.0 ± 4.5**	10.3 ± 4.7**	10.8 ± 4.5***

mean ± sd ** $p < 0.01$ *** $p < 0.001$ vs. controls

Conclusions: Vascular function is abnormal in CRF, even in patients with biochemically mild renal insufficiency and patients without AVD, suggesting that subclinical AVD is present early in the development of renal failure.

P403 Angiotensin II increases superoxide production in human internal mammary artery but not saphenous vein

C. Berry, C.A. Hamilton, A.F. Dominiczak, J.J.V. McMurray. *MRC CRI in Heart Failure, University of Glasgow and Department of Medicine, Western Infirmary, Glasgow, UK*

Purpose of study: In experimental animals angiotensin II (AII) exerts some of its vascular actions by stimulating NAD(P)H oxidase mediated superoxide ($^{\bullet}O_2^-$) production. We have determined whether AII increases $^{\bullet}O_2^-$ production in human blood vessels.

Methods: Human internal mammary artery (IMA) and saphenous vein (SV) were obtained during coronary artery bypass surgery. They were divided into 0.5–1 cm segments and incubated at 37 °C in hepes buffer in the absence (control (CTRL)) and presence of AII (10^{-6} M, 10^{-9} M, 10^{-12} M) for 4 hours and for different time periods (15 mins, 1 and 4 hours) with AII 10^{-6} M. Norepinephrine (NE) was used as a positive control. $^{\bullet}O_2^-$ production was quantified using lucigenin chemiluminescence in a liquid scintillation counter.

Results: Mean ± SEM superoxide production (pmol/mg/min)

	IMA (n = 29)		IMA (n = 11)		IMA (n = 14)
CTRL	927 ± 114	CTRL	1360 ± 293	CTRL	1550 ± 346
AII	1591 ± 210	AII	2285 ± 502	AII	2060 ± 384
10^{-6} M	$p < 0.002$	10^{-9} M	$p < 0.0065$	10^{-12} M	$p < 0.1$

Time	15 min (n = 11)	1 hour (n = 10)	4 hour (n = 29)
CTRL	1173 ± 239	1331 ± 232	927 ± 114
AII	918 ± 170	2572 ± 708	1591 ± 210
10^{-6} M	$p < 0.2$	$p < 0.05$	$p < 0.002$

There was no increase in $^{\bullet}O_2^-$ production in either SV (n = 8) incubated with AII 10^{-6} M, or IMA (n = 8) incubated with NE 10^{-6} M for 4 hours.

Conclusion: These results show, for the first time in human arteries, that AII increases $^{\bullet}O_2^-$ production. Diseases states associated with increased AII production, such as heart failure, may be associated with increased free radical production and vascular oxidative stress.

P404 Impact of medium-term balloon inflation during active coronary perfusion on endothelial morphology and endothelin-1 metabolism

Jörg M. Strotmann[1], Michael Kirchengast[2], Alfred Hahn[2], Carl-Erik Dempfle[3], Wolfram Voelker[1]. *[1]Department of Cardiology; [3]Hemostasiology, Klinikum Mannheim, University of Heidelberg; [2]Knoll AG, Preclinical Cardiology Ludwigshafen, Germany*

Background: Coronary restenosis after PTCA plays a crucial role in clinical routine. One candidate for the induction of restenosis is endothelin 1 (ET1) with subsequent proliferation of coronary media and intima. This study evaluated the impact of low pressure balloon inflation on coronary morphology and ET1-metabolism.

Methods: In 12 landrace pigs a perfusion balloon-catheter (2.5 mm diameter) was introduced in the left anterior descending coronary artery (LAD) and inflated with 1.2 bar. After active perfusion over 30 min. the balloon was withdrawn. Pre, during and 30 min. after the end of perfusion blood samples were taken from the ascending aorta and the great cardiac vein. After 3 months the pigs were sacrificed and the LAD segments with prior contact to the balloons (LADB) and a reference segment, taken from the right coronary artery (RCA), were analysed with a selective ET1-PCR for ET1-mRNA expression. From the histologic samples the area of coronary media and intima/neointima was assessed.

Results: In 8 pigs intimal proliferation in the LADB could be detected (0.1 ± 0.06 mm^2 vs 0 mm^2; $p < 0.0004$ compared to RCA), the media/lumen-area ratio remained unaltered in those segments. There was no difference between ET1 concentration in the great cardiac vein and the aortic root pre, during and after 30 min. of perfusion. ET1-PCR (light-cycler) showed no significant difference in mRNA transcript-level between LADB and RCA.

Conclusion: Low pressure balloon inflation can induce coronary intima-proliferation without evidence of increased ET1-metabolism. However, the clinical relevance of this finding is uncertain.

P405 Hypoxia induces heat shock protein expression in human coronary artery bypass grafts

A. Lercher, S. Dirnhofer[1], J. Bonatti[2], S.B.C. Watzka[2], B. Puschendorf, J. Mair[3]. *Med. Chemistry and Biochemistry, Innsbruck; [1]Pathology Dept, Innsbruck[2]Cardiac Surgery Dept, Innsbruck[3]Cardiology, Innsbruck, Austria*

Background: Heat Shock Proteins (HSPs), present in the vascular wall, are molecular chaperones which are essential for cell survival. Heat shock and hypoxia markedly increase the expression of several HSPs, especially the inducible Hsp70 isoforms. In our study, we investigated whether HSPs are in principle inducible in human coronary artery bypass grafts.

Method: We used remnants of the saphenous vein (SV) and the internal mammary artery (IMA) from 29 patients undergoing coronary artery bypass surgery. Each vessel was devided into segments, one for control conditions at 37°C (5% CO_2/95% air), the remaining ones for thermal (30 min at 42°C) or hypoxic treatment (6 h oxygen deprivation with nitrogen). The expression of Hsp60, Hsp72 and Hsp73 was investigated by immunohistochemistry and western-blot analysis.

Results: Immunohistochemically, segments of the SV undergoing a 30 minutes heat shock at 42°C showed significantly increased expression of Hsp72 in the intima ($p = 0.0354$) and Hsp73 in the media ($p = 0.0033$). In the IMA, Hsp72 and Hsp73 were both expressed in the intima at significantly higher levels ($p = 0.0416$ each). The results were further confirmed by western-blot analysis in a representative vein (7.5fold increase of Hsp72 and a 2.3fold increase of Hsp73 expression). A 6 hour oxygen deprivation resulted in elevated levels of Hsp60 (media: $p = 0.0478$), Hsp73 (intima: $p = 0.0294$) and Hsp72 (intima: $p = 0.0002$ and media: $p = 0.0038$) in the SV (western-blot analysis of Hsp72: 2fold, 1.5fold and 3.5fold increased, on average 2.3fold). Hypoxia enhanced Hsp73 expression in the intima of the IMA ($p = 0.0478$).

Conclusion: Our results clearly demonstrate that hypoxia strongly increases HSPs expression in human coronary artery bypass grafts. The marked increase of the inducible form of the Hsp70 family in the saphenous vein was most striking. Heat treatment was an effective inducer of Hsp72 and Hsp73 expression in both, saphenous vein and internal mammary artery.

P406 Homocysteine-induced endothelial superoxide anion production is associated with upregulation of superoxide dismutase activity

D. Lang, M.B. Kredan, S. Moat[1], H.J. Powers[1], M.J. Lewis. *Pharmacol., Therapeutics & Toxycology, Wales University College of Medicine, Cardiff; [1]Child Health Dept, Sheffield's Children Hospital, Sheffield, UK*

Elevated plasma levels of homocysteine (HC) are associated with endothelial dysfunction, the induction of oxidative stress by HC having been postulated as a causative mechanism in this process. We have therefore studied the effect of HC on cultured porcine aortic endothelial cell (PAE) superoxide anion (O_2^-) production as a marker of oxidative stress, and the ability of the PAE to control their natural anti-oxidant defences in response to this pathological insult.

Methods: Confluent PAE monolayers (first passage) were incubated at 37°C for 24, 48 and 72 hours in the absence or presence of HC (1 mM), fresh HC being added to the appropriate cells every 24 hours. Following incubation, some cells were trypsin (0.05% w/v)-digested and harvested for the measurement of O_2^- production by lucigenin-chemiluminescence in the presence of triton X-100. The integral of each response represents the total O_2^- produced and is expressed as mV.s/million cells. Superoxide dismutase (SOD) activity was then measured spectrophotometrically in lysates from the rest of the cells using a method based on the ability of the enzyme to inhibit the auto-oxidation of pyrogallol. All data is expressed as mean ± s.e.m. and n = 5 or greater.

Results: In the absence of HC, baseline O_2^- production did not alter with time (19.4 ± 2.2, 19.2 ± 2.3 & 16.7 ± 0.7 mV.s/million cells after 24, 48 and 72 hours respectively). Exposure to HC resulted in a significant ($p < 0.001$) increase in O_2^- production after 24 hours (65.8 ± 4.0 mV.s/million cells), which although still significant ($p < 0.001$) declined after 48 hours (42.0 ± 2.3 mV.s/million cells). After 72 hours, even in the presence of HC, O_2^- production returned to baseline levels (18.9 ± 1.6 mV.s/million cells). Again, in the absence of HC, baseline SOD activity did not alter with time (3.4 ± 0.7, 4.0 ± 0.8 & 2.7 ± 0.4 U/mg protein after 24, 48 and 72 hours respectively). However, SOD activity was significantly elevated ($p < 0.001$) following exposure to HC for 72 hours (8.9 ± 1.3 U/mg protein).

In conclusion, these data demonstrate that exposure to HC induces significant, and time-dependent increases in endothelial O_2^- production that are accompanied by an increase in SOD activity. Endothelial cells are therefore capable of acutely upregulating their natural antioxidant defences in response to the induction of oxidative stress.

P407 Has transforming growth factor beta I cytoprotective properties in heavy smokers with intact endothelial function?

C. Schmidt-Lucke, D. Reinhold, M. Prinzen, A. Kollmann, B. Mlasowsky, S. Ansorge, H.U. Klein, J.A. Schmidt-Lucke. *Departement for Cardiology, Angiology and Pulmology, Institute for Experimental Medicine, University of Magdeburg, Germany*

Some patients do not exhibit atherosclerosis despite cardiovascular risk factors. An effect of transforming growth factor beta 1 (TGF-β1) on endothelial NO-synthase (eNOS) and in the development of atherosclerosis has been suggested. In the present study, we used our new human in-vivo model to assess NO-mediated endothelial function (EF) of lower extremities, a vascular bed more relevant to atherosclerosis than the commonly examined forearm vessels.

In 44 clinically healthy individuals (21 to 59 years), 20 smokers and 24 controls, matched for age and sex, EF was assessed by reactive hyperaemia (peak flow (PF) and late hyperaemic reaction (LHR)) with venous occlusion plethysmography (VOP) (in ml/100 ml tissue/min), and by intraarterial stimulation with the endothelium-dependent NO-stimulator acetylcholine (A). Concentrations of TGF-β1 were measured from citrate plasma with an ELISA taken from the femoral vein.

Overall, smokers showed a 32% lower PF in VOP in response to A (10.8 vs. 15.9, $p < 0.05$), as well as 58% lower LHR (2.8 vs. 4.8, $p < 0.05$). A decline of PF with age was seen in controls ($r = -0.5$, $p < 0.05$). The *older* subgroup (>45 years) of smokers presented with nearly double high PF (14.9 vs. 8.4, $p < 0.05$) than age-matched controls, and with a higher LHR than younger smokers (6.2 vs. 2.1, $p < 0.01$). Even a positive correlation between pack-years and LHR was found ($r = 0.62$, $p < 0.005$). Similar TGF-β1 concentrations were found comparing all smokers and controls (3.2 vs. 2.5 ng/ml). However, smokers with preserved EF showed higher TGF-β1 than those with impaired EF (3.7 vs. 1.2 ng/ml, $p < 0.0005$). There was even a strong correlation of TGF with EF in smokers ($r = 0.77$, $p < 0.0005$), but not in controls. TGF-β1 did not correlate with age in either group.

Our new method confirmed age- and risk factor-related endothelial dysfunction. Stringent inclusion criteria promoted a selection of a subgroup of smokers with an unexpectedly intact endothelium, superior to age- and sex-matched controls as to younger smokers. A strong correlation of TGF-β1 with endothelial function was found only in smokers, suggesting this cytokine to actively maintain normal physiological function of endothelial cells. Since control individuals lack this correlation, a *direct* influence of TGF-β1 on availability of NO under physiological conditions seems unlikely. Identification of individuals with intact endothelium despite risk factors provides a new approach of our understanding of atherosclerosis.

P408 Homocysteine-induced endothelial superoxide anion production is inhibited by tetrahydrobiopterin and folate

M.B. Kredan, D. Lang, M.J. Lewis. *Pharmacol., Therapeutics & Toxycology, Wales University College of Medicine, Cardiff, UK*

Increased oxidative stress and the inactivation of nitric oxide (NO) have been postulated as causative mechanisms in homocysteine (HC)-induced endothelial dysfunction. A reduction in essential co-factors for NO synthesis secondary to the induction of oxidative stress may lead to impaired NO activity. We have therefore studied the effect of co-factor supplementation on HC-induced superoxide anion (O_2^-) production by cultured porcine aortic endothelial cells (PAE).

Methods: PAE were incubated at 37°C for 24 hours in the absence or presence of either HC, cysteine (CYS) or glutathione (GT, all 1 mM) or HC with either tetrahydrobiopterin (BH4, 0.5 mM, an essential co-factor for NO production), methyltetrahydrofolate (MTHF, 0.5 mM, the active circulating form of folate, also involved in intracellular BH4 regeneration) or folic acid (FA, 0.5 mM, involved in HC metabolism). Following incubation, the cells were trypsin (0.05% w/v)-digested and then harvested for the measurement of O_2^- production by lucigenin-chemiluminescence in the presence of 1% (v/v) triton X-100. The integral of each response represents the total O_2^- produced and is expressed as mV.s/million cells, and all data is expressed as mean ± s.e.m., n = 8 or greater.

Results: In the absence of any intervention, baseline O_2^- production was 21.0 ± 2.4 mV.s/million cells. This level was unaffected by incubation with either CYS or GT. However, exposure to HC resulted in a significant ($p < 0.001$) increase in O_2^- production (53.4 ± 2.9 mV.s/million cells). Furthermore, this HC-induced increase in O_2^- production was completely inhibited ($p < 0.001$) by BH4, MTHF and FA (15.8 ± 1.6, 24.2 ± 3.3 and 17.5 ± 1.0 mV.s/million cells respectively)

In conclusion, these data demonstrate that (a) HC-induced increases in O_2^- production are not a non-specific effect of thiol-containing compounds and (b) addition of BH4, MTHF and FA inhibits the HC-induced effect. This inhibition may be a direct antioxidant effect or may involve augmented NO production due to the increased availability of NO synthase co-factors, eg. BH4 itself.

P409 Chronic renal failure impairs endothelial cell viability and enhances proliferation

R. Chana, J. Thambyrajah[1], M.J. Landray[1], J.N. Townend[1], D.C. Wheeler. *Department of Nephrology, University Hospital NHS Trust, Birmingham; [1]Division of Medical Sciences, University of Birmingham, Birmingham, UK*

Patients with chronic renal failure are more likely to develop atherosclerosis when compared to age and sex matched controls. Endothelial injury is thought to represent one of the earliest stages in the development of atherosclerosis. These experiments were designed to determine whether uraemia may contribute directly to vascular damage.

Fresh serum was collected from 36 patients with pre-dialysis chronic renal failure and 36 healthy controls. Serum samples were heated to inactivate complement and added to sub-confluent human umbilical vein endothelial cells grown in multiwell plates. Cell viability was assessed by estimating the capacity of endothelial mitochondria to metabolise a tetrazolium salt to a blue formazan product, the development of which was measured by spectrophotometry. Incorporation of tritiated thymidine into nuclear DNA was used to estimate cell proliferation rate. The results shown below represent cells grown in 20% human serum and are expressed as a percentage of values obtained under standard growth conditions (20% foetal calf serum).

Results

	Controls	Renal failure	Significance
Patient age	60.0 (33.5–68.5)	56.0 (48.5–62.5)	NS*
Sex (M:F)	20:16	17:19	NS**
Viability (%)	79.9 (66.2–87.7)	66.2 (62.8–76.5)	0.006*
Proliferation (%)	197.0 (168.5–216.0)	222.2 (209.3–261.7)	0.001*

median (inter-quartile range) * Kruskal-Wallis ** Chi-squared

When compared to serum from normal controls, uraemic serum was more toxic to endothelial cells and stimulated a greater increase in the rate of cell division. These data suggest that in patients with chronic renal failure, the endothelium may be more vulnerable to injury and responds by cellular proliferation. This process may result from exposure to circulating uraemic toxins and could directly contribute to the development of premature vascular disease.

P410 Plasminogen activator and plasminogen activator inhibitor expression in vascular culture

Qamar Javed, Elizabeth L. Spring, David P. de Bono. *Division of Cardiology, University of Leicester, Clinical Sciences Wing, Glenfield General Hospital, Leicester, UK*

We have studied the expression of tissue-type plasminogen activator (t-PA) and its inhibitor (PAI-1), which regulate fibrinolysis and are relevant to the process of tissue remodelling, in organ cultures of human saphenous vein (HSV) and coronary endarterectomy tissue (CEA).

Methods: HSV and CEA samples were obtained from patients undergoing coronary artery surgery, and cultured for up to 14 days. The expression of t-PA and PAI-1 in tissue cultures was investigated using immunohistochemical, biochemical (Elisa; Western blotting) and molecular (RT-PCR) techniques.

Results: Immunostaining showed basal levels of t-PA in preculture controls. t-PA antigen expression increased in vascular cultures. PAI-1 immunostaining was intense in controls but declined in postculture tissue. Immunoblotting of vascular extracts revealed an up-regulation of t-PA and a down-regulation of PAI-1 antigen expression in HSV culture confirming the findings from the immunohistochemical study. RT-PCR demonstrated that the relative amounts of mRNA encoding t-PA increased ($P < 0.05$) while PAI-1 decreased ($P < 0.05$) in 10 days postculture tissue.

Conclusion: Local expression of t-PA is up-regulated while that of PAI-1 down-regulated during SMC proliferation in tissue culture. A down-regulation of PAI-1 mRNA is in contrast to the situation in complex human atheroma. We suggest that this crucial difference may be due to the inflammatory cells in the vessel wall.

P411 Isolation of Chlamydia pneumoniae-specific T lymphocytes from atheromatous plaque

A.J. Curry, I. Portig, J.C. Goodall, P. Kirkpatrick[1], J.S.H. Gaston. *Medicine Dept, Addenbrooke's Hospital, Cambridge; [1]Neurosurgery Dept, Addenbrooke's Hospital, Cambridge, UK*

Chlamydia pneumoniae (Cpn) infection has been implicated in the pathogenesis of atheroma, but its role is unclear. Since atheroma plaques contain activated T cells, we have determined whether any of these cells have specificity for Cpn.

Methods: T cell lines were generated from plaque material from 14 carotid endarterectomy patients. T cell lines were readily established by culture with IL-2 and either recall antigens or PHA; IL-2 alone was not sufficient.

Results: Although PHA was more effective than recall antigens ($p < 0.05$) in establishing T cell lines from plaques, each of three recall antigens – tetanus toxin (TT), PPD and Chlamydia trachomatis (Ct, used as a source of chlamydial antigens) was equally effective. When the specificity of the T cell lines was examined in proliferation assays, PPD-specific lines predominated in cultures initially stimulated with PHA. In cultures initially stimulated with PPD or TT, the frequency of TT- or PPD-responsive lines was similar, whereas Ct-responsive lines were less common ($p < 0.05$). Conversely, initial stimulation with Ct resulted in predominantly Ct-specific lines ($p < 0.05$). Ct-responsive lines were expanded and further characterized by stimulation with recombinant Cpn or Ct antigens, including OMP-2 and hsp60. Several lines responded to one or more of these antigens.

Conclusions: The atheromatous plaque contains memory T lymphocytes with various specificities, including C. pneumoniae. Whether Cpn-specific T cells are present at higher frequency in plaques than in PB, and whether they show evidence of activation by Cpn in the plaque remains to be investigated.

P412 Dehydroepiandrosterone relaxes rabbit coronary arteries by a calcium antagonistic mechanism

G. Figtree. *Cardiac Medicine, National Heart and Lung Institute, London, UK*

Epidemiological studies demonstrate an inverse association between levels of DHEA (3-b hydroxy-5-androsten-17-one) and cardiovascular mortality in men, but not in women. The effects of DHEA on the coronary vasculature is unknown, therefore we investigated the effect of DHEA on rabbit coronary arteries in vitro. Epicardial coronary arterial rings of male and female rabbits were suspended in organ baths for measurement of changes in isometric tension. DHEA (3, 10, 30 mM) induced significant relaxation of coronary arterial rings precontracted with K^+ (30 mM) in a dose-dependent manner (mean ± SEM; 24.6 ± 3.6, 47.0 ± 3.9, and 86.1 ± 4.2% respectively, $P < 0.001$) compared with control (3.2 ± 1.5, 4.2 ± 1.5, 5.1 ± 1.5; n = 11). Relaxation to DHEA at lower concentrations (0.3, 1 mM) was not significant. There were no differences between arteries from male or female rabbits (n = 10; $P > 0.05$), or between rings with or without endothelium (n = 8–12; $P > 0.05$). L-NAME (n = 10), ICI 182,780 (a specific estrogen receptor antagonist n = 6) and barium chloride (n = 7) did not affect DHEA-induced relaxation compared with control rings with an intact endothelium (n = 8; $P > 0.05$). Calcium concentration-dependent contraction curves (4, 3.5, 3, 2.5 and 2 – log M calcium) in K^+ depolarization medium were shifted to the right after incubation with DHEA (10 mM) (8.9 ± 5.2, 21.6 ± 6.7, 48.0 ± 5.1*, 79.5 ± 4.3** and 99.9 ± 2.6% contraction respectively; *$P < 0.05$; **$P < 0.01$) compared to control (10.7 ± 2.9, 35.0 ± 4.9, 66.2 ± 3.1, 86.2 ± 6.4 and 100 ± 0.0% contraction respectively). Maximal contraction was not reduced however. We have demonstrated that DHEA induces significant relaxation in isolated rabbit coronary arteries independent of the endothelium and nitric oxide. Potassium channels are unlikely to be involved.

ADULT CARDIOVASCULAR PATHOLOGY

P413 Effect of intracellular acidification on free intracellular Mg^{2+}: an ETH 7025-Mg^{2+}-ion-selective microelectrode study on guinea pig papillary muscle

H. Köppel[1], R. Gasser[1], W. Klein[1], U. Schaller[2], U. Spichiger[2]. *[1]Experimental Cardiology, University of Graz, Austria; [2]Dept. Organic Chemistry, ETH Zurich, Switzerland*

The assessment of free, ionised, intracellular Mg^{2+} ($(Mg^{2+})_i$) in myocardial tissue is problematic and its metabolism has not been well understood as yet. This, for example, makes the design of trials on therapeutic use of Mg (e.g. LIMIT II and ISIS 4) difficult and the interpretation of conflicting results almost impossible.

Here, we assess the effect of changing intracellular pH (pH_i; measured with pH-selective microelectrodes) on cytoplasmic $(Mg^{2+})_i$ using a newly designed Mg^{2+}-selective microelectrode with the neutral carrier ETH 7025) and measure $(Mg^{2+})_i$ in isolated resting guinea pig papillary muscle (Tyrode, pH 7.4, 36°C; for details of method see our earlier work – J Physiol 431, 713–41, 1990 and Pflügers Arch 423, 338–42, 1993).

We find that changing extracellular pH for 15 minutes from 7.4 to 6.4 leads to a change of intracellular pH from 7.19 ± 0.03 to 6.81 ± 0.06 (n = 7; ± SEM for all exp.). This change of pH_i leads to a small, but detectable rise in $(Mg^{2+})_i$ by a maximum amount of 0.19 ± 0.06 mM from an initial value of 0.73 ± 0.08 mM after approximately 7 minutes, followed by a slow decrease of $(Mg^{2+})_i$ to almost normal. This would amount to a liberation of 1.5% of the cells total Mg content, assuming that $(Mg^{2+})_i$ constitutes 1/17 of the cells total Mg (J Physiol 224, 121–39, 1972).

In summary, we find that intracellular acidification liberates $(Mg^{2+})_i$ from intracellular binding sites. The transient nature of the observed $(Mg^{2+})_i$ rise further suggests, that the levels of cytoplasmic $(Mg^{2+})_i$ are well regulated and even small changes in $(Mg^{2+})_i$ are adjusted within short time.

P414 Decreased expression of insulin-like growth factor-I is associated with apoptosis of vascular smooth muscle cells in the human atheromatous plaque

Y. Okura, M. Brink, A. Kalangos, P. Delafontaine. *Division of Cardiology, Hopital Cantonal de Geneve, Geneva, Switzerland*

Insulin-like growth factor-I (IGF-I) plays an important role in survival of vascular smooth muscle cells (VSMCs) as well as in cell cycle progression and in migration of VSMCs.

Methods: In order to determine whether the specific localization of IGF-I is related to the localization of apoptotic cells in human aortic atherosclerotic lesions, IGF-I was determined using both immunocytochemical techniques and in situ hybridization. Alpha-smooth muscle (SM) actin, vimentin (a marker of dedifferentiated cells), and apoptotic cells were detected immunocytochemically or by the TUNEL assay.

Results: Microscopic analysis revealed that the expression of IGF-I was significantly lower in the intima just adjacent to the lipid pool, including the shoulder part of the plaque, as compared to the fibrous cap of the atheromatous plaque or the medial layer, which is compatible with the findings of in situ hybridization.

Comparison of the IGF-I labeling pattern with immunostaining for alpha-SM actin and vimentin showed that the intima close to the lipid pool contains areas characterized by poor or absent expression of IGF-I regardless of positive staining for alpha-SM actin and vimentin. In parallel serial sections, the TUNEL assay detected the presence of apoptotic cells in the regions with poor expression of IGF-I.

In conclusion, since IGF-I is a potent survival factor for VSMCs, its absence in areas close to the lipid pool and particularly in the shoulder region might be associated with apoptotic changes and predispose these regions to fissuring and plaque rupture.

P415 Differential development of hypoxia-induced pulmonary hypertension and right ventricular hypertrophy in transgenic mice with various deficiencies in the plasminogen/plasmin system

Marcel Levi[1,2], Lieve Moons[1], An Bouché[1], Desiré Collen[1], Peter Carmeliet[1]. *[1]Center for Transgene Technology and Gene Therapy, Flanders Interuniversity Institute for Biotechnology, KU Leuven, Leuven, Belgium; [2]Department of Vascular Medicine, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

Background & Aim: Hypoxia results in the development of pulmonary hypertension and right heart failure. The precise molecular mechanisms involved in the pathogenesis of hypoxia-induced pulmonary vascular remodeling are unknown, but several observations point to a potentially important role of the plasminogen system. Aim of this study was to investigate the development of pulmonary hypertension and vascular remodeling in mice with targeted disruption of genes of the plasminogen system.

Methods: Mice with a deficiency of tissue-type plasminogen activator (t-PA$^{-/-}$), urokinase-type plasminogen activator (u-PA$^{-/-}$), u-PA receptor (u-PAR$^{-/-}$), or plasminogen (plg$^{-/-}$), and wild-type (WT) mice were subjected to hypoxia (FiO_2 10%), whereas for each group control mice were kept under similar but normoxic conditions. Adult and neonate mice were placed under hypoxia for 28 and 10 days, respectively.

Main results: Hypoxia caused a significant 2.5-fold rise in right ventricular (RV) pressure in WT mice, associated with a 1.8-fold increase in RV weight. Deficiency of u-PA completely prevented this increase in RV pressure and hypertrophy, whereas t-PA$^{-/-}$ mice showed changes that were comparable with WT mice. Plg-deficient mice did also not develop pulmonary hypertension and RV hypertrophy and u-PAR$^{-/-}$ mice showed an intermediate reponse, indicating that the u-PA effect is in part mediated by the u-PA receptor. Histological analysis revealed that hypoxia induced an increase in smooth muscle cells within distal arterial walls and loss of peripheral vascular density in the lungs of WT mice, as evidenced by a 2-fold increase in the ratio of media thickness over vascular diameter and a 54% reduction in arteries per 100 alveoli. In u-PA$^{-/-}$ and plg$^{-/-}$ mice this vascular remodeling was completely blunted.

Conclusion: In the development of pulmonary hypertension, RV hypertrophy and pulmonary vascular remodeling, u-PA appears to play a pivotal role. Plg$^{-/-}$ mice showed a similar lack of response to hypoxia, suggesting that in the development of these changes u-PA acts by conversion of plasminogen to plasmin. The essential role of the plasminogen/plasmin system as a mediator of the adaptive response to chronic hypoxia and in the occurrence of hypoxic pulmonary vascular disease might be a point of impact for eventual future, novel therapeutic strategies.

EXCITATION–CONTRACTION COUPLING

P416 Effects of isoproterenol in phospholamban-deficient mouse hearts with altered thyroid states

E. Kiss, A.G. Brittsan[1], I.L. Grupp[1], E.G. Kranias[1]. *2nd Department of Medicine, Szent-Gyorgyi Medical University, Szeged, Hungary; [1]Pharmacology and Cell Biophysics, University of Cincinnati, Cincinnati, USA*

The aim of the present study was to determine the effects of beta-adrenergic stimulation in phospholamban-deficient (PLB-KO) mouse hearts with altered thyroid conditons. Examination of the beta-myosin heavy chain protein expression revealed similar increases in hypothyroid wild-type (WT) and PLB-KO hearts, while the alpha-myosin heavy chain levels were downregulated in both WT and PLB-KO hypothyroid hearts, as compared to their respective euthyroid controls. Quantitative immunoblot analysis of the cardiac SR Ca-ATPase tissue levels revealed significant increases in hyperthyroidism and decreases in hypothyroidism compared with euthyroidism, and these changes were similar between PLB-KO and WT hearts. An opposite trend was observed for PLB expression levels in the WT group, which were depressed (69%) in hyperthyroid hearts but increased (133%) in hypothyroid hearts. To examine whether the observed changes in SR calcium handling proteins were reflected in altered cardiac function, contractile parameters were assessed in isolated work-performing hearts. Hypothyroidism was associated with significantly depressed basal contractile parameters in both WT and PLB-KO hearts, when compared to their respective euthyroid controls. Increased basal contractile function was observed in the hyperthyroid WT hearts, while no further enhancement in the contractile parameters of the hyperdynamic PLB-KO hearts was noted in the hyperthyroid condition. During isoproterenol stimulation of WT hearts, the responses in the rates of contraction and relaxation were highest in the hypothyroid group, followed by the euthyroid and lastly by the hyperthyroid groups. Furthermore, there was a close linear correlation between the magnitude of the contractile parameter responses and the PLB/SERCA ratios in these WT hearts. However, the PLB-KO hypothyroid, euthyroid and hyperthyroid hearts did not exhibit significant responses to isoproterenol. Since the changes in SERCA, alpha- and beta-myosin heavy chains were similar in PLB-KO and WT hearts, under various thyroid conditions, the lack of isoproterenol response appeared to be due to ablation of PLB in the PLB-KO hearts. These findings suggest that PLB is an important regulator in the heart's responses to beta-adrenergic stimulation not only in the euthyroid myocardium, but also under various thyroid states.

P417 Functional difference of K_{ATP}-channels in young and adult rabbit hearts

C.A. Schumacher, A. Baartscheer, J.W.T. Fiolet. *Department of Clinical and Experimental Cardiology, Cardiovascular Research Institute Amsterdam; Academic Medical Centre, University of Amsterdam; The Interuniversity Cardiology Institute of the Netherlands, Amsterdam, Netherlands*

Objective: Age dependent differences in conductance and density of K_{ATP} channels have been demonstrated. We previously found that the K_{ATP}-channel opener cromakalim, at concentrations not causing action potential shortening, caused significant SR calcium depletion in ventricular myocytes of adult rabbits, suggesting presence of K_{ATP}-channels in the SR membrane. The aim of the present study was to investigate whether there is also age dependency of K_{ATP}-channel opening on SR calcium content.

Methods: Calcium transients and SR calcium content were measured in indo-1 loaded electrically stimulated (2 Hz) ventricular myocytes from young (7 weeks old, mean body weight 1.8 kg, 11 cells from 3 rabbits) and adult (>14 weeks old, mean body weight 3.0 kg, 16 cells from 6 rabbits) rabbits (37°C). SR calcium content was estimated from the change of cytosolic calcium following rapid cooling (RC) to 1°C. Each myocyte was stimulated for 5 minutes, subjected to RC, allowed to recover from RC for 5 minutes, subsequently treated with cromakalim (10 μM) during 5 minutes and again subjected to RC.

Results: Control transient amplitudes were not significantly different between groups. 10 μM cromakalim did not shorten action potentials. Calcium transient amplitude as well as SR calcium content were significantly reduced by cromakalim in adult, but not in young rabbits as shown in the table (all data expressed as % of control transient amplitude, mean ± SEM).

	Control RC	Recovery amplitude	Cromakalim amplitude	Cromakalim RC
Young (n = 11)	292 ± 25	106 ± 6	85 ± 5	259 ± 29
Adult (n = 16)	245 ± 15	97 ± 6	59 ± 3#§	131 ± 11#§

#p < 0.0001 adult versus young; §p < 0.0001 cromakalim versus control

Conclusion: Cromakalim, at a concentration not causing action potential shortening, substantially reduces calcium transients and SR calcium content in adult, but not in young rabbits. This suggests late expression of SR-specific K_{ATP}-channels.

P418 S100A1 increases intracellular Ca^{2+} transients of cultured neonatal cardiomyocytes as a paracrine factor

M. Reppel[1], M. Börries[1], C.W. Heizmann[2], A. Remppis[1], H.A. Katus[1]. *Medizinische Klinik II; [1]Medizinische Universität zu Lübeck, Germany; [2]Klinische Chemie und Biochemie, Kinderspital, Universität Zurich, Switzerland*

S100A1 is a new regulatory protein of myocardial contractility increasing contraction and relaxation velocity as well as cell shortening in adult rat cardiomyocytes. Since S100 proteins have also been described as paracrine factors being involved in cell differentiation, it was the aim of this study to determine the effects of S100A1 as a culture medium additive on intracellular Ca^{2+} transients in cultured rat neonatal cardiomyocytes.

Recombinant S100A1 protein (2 μM) was added to culture medium every other day. On Day 5 and day 7 cells were loaded with FURA2PE3AM and intracellular Ca^{2+} transients measured under electric field stimulation (0.5–1 Hz). With S100A1 we observed a significantly increased velocity of cytosolic Ca^{2+} elimination ($-\Delta c/\Delta t$ +20%; $p < 0.015$) on day 5 compared to controls. Additionally, on day 7 there was a significant increase of systolic SR Ca^{2+} release ($+\Delta c/\Delta t$; +30%; $p < 0.01$) as compared to control cells.

These data show for the first time that recombinant S100A1 protein acts as a paracrine factor evoking similar effects on intracellular Ca^{2+} transients as seen after adenoviral overexpression of this Ca^{2+} binding protein. Since S100A1 is being expressed in embryogenesis as early as on day 9 our findings imply that S100A1 might represent a differentiation factor in foetal cardiogenesis.

P419 Regional dependent differences in the activity of the Na^+/Ca^{2+}-exchanger in human non-failing myocardium

H. Diedrichs, J. Müller-Ehmsen[1], C. Zobel, A.A. Mc Donough[1], R.H.G. Schwinger. *Klinik III für Innere Medizin der Universität zu Cologne, Germany; [1]Department of Physiology and Biophysics, University of Southern California, Los Angeles CA, USA*

To test the hypothesis that the contribution of the Na^+/Ca^{2+}-exchanger (NCX) to the intracellular Ca^{2+}-homeostasis in human cardiomyocytes is different in atrial versus ventricular myocardium, we investigated the regional pattern of protein expression by immunoblot and the time dependent (1–60 s) and Ca^{2+}-dependent (0.3–1000 μM) activity by Na^+-dependent vesicular Ca^{2+}-uptake of the NCX in 14 human nonfailing hearts. The protein expression of the NCX was significantly lower in left atrial (LA) compared to left ventricular myocardium (LV) (0.5 ± 0.1 vs. 1.0 ± 0.2). This was paralleled by a reduced NCX-activity in myocardial vesicles from LA ($t_{1/2}$ 7.9 ± 1.5 vs. 2.5 ± 0.3 s). When measuring the NCX activity at different Ca^{2+}-concentrations (t = 3 s), we found a reduced maximal activity of the NCX in LA (0.78 vs. 1.02 nmol/mg protein * 3 s) and a reduced affinity of the NCX towards Ca^{2+} (K1/2 67μmol/l vs. 45 μmol/l).

These data indicate that the protein abundance and maximal activity of the NCX in left atria is reduced as compared to left ventricle. Interestingly, also the affinity of the NCX towards C^{2+} is reduced in left atria, indicating that structural or functional differences of the NCX are present. It is concluded, that the contribution of the NCX to the intracellular Na^+ and Ca^{2+}-homeostasis is different in atrial and ventricular myocardium.

P420 Contractile remodelling in human atrial fibrillation: lack of response to Bay K 8644

U. Schotten, I. Sabatschus, M. Vogel, C. Stellbrink, F. Schoendube, P. Hanrath, M. Allessie. *Dept. of Cardiology and Dept. of Thoracic- and Cardiovascular Surgery, University Hospital Aachen, Germany; Dept. of Physiology, Cardiovascular Research Institute Maastricht, Netherlands*

Background: After the cessation of atrial fibrillation (AF) the mechanical function of the atria is reduced (contractile remodeling). Altered intracellular Ca^{2+} handling and myolysis have been proposed to underlie this phenomenon.

Methods: We studied the positive inotropic effect of Ca^{2+}, the L-type Ca^{2+} channel agonist Bay K 8644 and isoprenaline (Iso) on thin isolated trabeculae of right atrial appendages of patients undergoing mitral valve repair. 11 patients were in sinus rhythm (SR), whereas 10 had developed chronic (≥6 month) AF. Force of contraction was measured under isometric conditions at a stimulation frequency of 1 Hz at 37°C (baseline conditions).

Results:

	Mean force of contraction (mN/mm²) ± SEM			
	baseline	Ca^{2+} 12 mM	Bay K 8644 10 μM	Iso 1 μM
SR n = 11	3.1 ± 0.3	7.4 ± 0.5#	7.3 ± 0.1#	7.5 ± 0.7#
AF n = 10	0.6 ± 0.1*	6.7 ± 0.7#	0.7 ± 0.1*	4.6 ± 0.6#*

*: $p < 0.05$ AF versus SR, #: $p < 0.05$ versus baseline.

Conclusions: 1) Since the maximal achievable force of contraction at a high extracellular Ca^{2+} concentration was only slightly smaller in AF patients myolysis is not the prevailing mechanism of contractile remodeling in AF patients. 2) The lack of response to Bay K 8644 in AF patients suggests either a downregulation or an altered function of the L-type Ca^{2+} channel. 3) The reduced β-adrenergic responsiveness in atrial myocardium of AF patients might be explained by altered expression or function of the L-type Ca^{2+}-channel.

P421 Synchronization of rigor contracture in end-to-end connected cardiomyocites

S. Lane, M. Ruiz-Meana, D. Garcia-Dorado, Y. Puigfel, J. Soler-Soler. *Laboratori B, Cardiologia, Hospital Vall d'Hebron, Barcelona, Spain*

During myocardial ischemia or anoxia, depletion of ATP to critical levels results in rigor contracture, followed by Ca^{2+} rise and progression of cell injury. In situ cardiomyocytes are efficiently connected to each other through specialized connections including gap junctions that communicate the cytoplasm of adjacent cells. Although cytosolic changes associated to energy depletion including acidosis and Ca^{2+} rise, have been described to produce uncoupling, some of these changes, specially Ca^{2+} rise occur only after rigor onset. The purpose of this study was to investigate whether cell-to-cell communication may allow synchronization of the onset of rigor contracture in cardiomyocytes. The time to onset of rigor shortening, its time course, and the changes in the cytosolic Ca^{2+} (fura2) and Na^+ (SBFI) concentrations were analyzed in isolated adult rat cardiomyocytes submitted to simulated anoxia (metabolic inhibition 2 mM NaCN at extracellular (pHo) of 7.4) or ischemia (pHo = 6.4). The changes observed in end-to-end connected cell pairs resulting from incomplete dissociation were compared with those observed in pairs of non-connected cells. The experiments were performed at 37°C on the stage of an inverted microscope connected to a ratiofluorescence image system. Rigor contracture appeared after 20.4 ± 1 min of energy depletion at pH 6.4, and after 15.3 ± 1.3 min at pH 7.4, without differences between connected and separated cells, and resulted in a homogeneous reduction of cell length of 28.6 ± 1%. The onset of rigor contracture in non-connected cell pairs was asynchronous, with a mean difference of 180 ± 174 sec at pH = 7.4, and 306 ± 66 sec at pH = 6.4. However, there was a marked synchronization in the onset of rigor in connected cell pairs, with a mean difference of 6.4 ± 1.4 sec and 9.8 ± 4.2 sec at pH 7.4 and 6.4 respectively ($p < 0.001$ respect the corresponding values in non-connected cell pairs), and an excellent correlation between the time of onset in the 2 cells ($r = 0.99$ and $r = 0.99$ respectively at pH 7.4 and 6.4). Ca^{2+} rise occurred after rigor onset in all cells, and was virtually identical in connected cells but largely variable in separated cells. Na^+ rise preceded rigor onset, and its time course was also superimposable in connected cells and largely variable in separated cells. It is concluded that intercellular communication synchronizes the progression of ischemic injury in adjacent cardiomyocytes, even in the presence of acidosis.

P422 Role of FKBP12.6 in excitation-contraction coupling in rabbit ventricular myocytes

J. Prestle, A. Janssen, S.E. Lehnart, O. Zeitz, P.M.L. Janssen, G. Hasenfuss. *Dept. Cardiology and Pneumology, Georg-August-University Goettingen, Goettingen, Germany*

The cardiac ryanodine receptor (RyR2) is tightly associated with the FK-506 binding protein FKBP12.6. However, the function of FKBP12.6 in excitation-contraction coupling (E-C coupling) processes in cardiomyocytes is poorly understood.

We used adenovirus-mediated gene transfer to overexpress the human FKBP12.6 gene (Ad-FKBP12.6) together with green fluorescent protein (GFP) as a reporter gene in isolated rabbit ventricular myocytes.

Contractile function of Ad-FKBP12.6 infected myocytes was analysed by a video edge detection-system after 24 h (weak expression of the transgene) and 48 h (strong expression of the transgene) and compared with control (Ad-GFP) infected myocytes. The data are summarised in the following table.

	24 h		48 h	
	Ad-GFP	Ad-FKBP12.6	Ad-GFP	Ad-FKBP12.6
Fractional shortening (%)	4.2 ± 0.2 (*P = 0.07 *vs.* Ad-GFP)	4.8 ± 0.2* (*P = 0.07 *vs.* Ad-GFP)	3.6 ± 0.1 (*P < 0.01 *vs.* Ad-GFP)	4.3 ± 0.1* (*P < 0.01 *vs.* Ad-GFP)

Stimulation frequency 2 Hz; [Ca^{2+}] 1.8 mM; Ad-GFP, n = 48; Ad-FKBP12.6, n = 58.

At 48 h post transfection, myocyte shortening was significantly increased by 18% in FKBP12.6 overexpressing cells as compared with control transfected myocytes. This study demonstrates a direct role of FKBP12.6 in E-C coupling in cardiac myocytes.

P423 Interruption of the positive sarcoplasmic reticulum load-frequency relationship in guinea pig cardiac myocytes occurs prior to demonstrable spontaneous calcium release

R. Egdell, K.T. MacLeod. *National Heart & Lung Institute, Cardiac Medicine, London, UK*

Myocardial tissue of most mammalian species, including human, demonstrates a positive force-frequency relationship, meaning that developed force (or cell shortening, or sarcoplasmic reticulum (SR) load in isolated cells) increases as stimulation frequency increases. However as one reaches high stimulation frequencies, or under other conditions which increase intracellular calcium levels, developed force may start to decrease. At about this point aftercontractions (ACs), caused by spontaneous release of calcium from the SR, are frequently noted, and it has been hypothesized that the decline in systolic mechanical function is the direct result of ACs. We investigated this relationship further by direct measurement of SR load in isolated guinea pig left ventricular myocytes following drive trains. Cells were impaled with microelectrodes and subjected to rapid application of caffeine under voltage clamp conditions, following conditioning drive trains but before the onset of ACs. The resulting inward charge movement was used to calculate SR load. Cell shortening during the final stimulus of the drive train and delay from caffeine application to the onset of an inward current were also recorded, as surrogate measures of SR load. Measurements were taken after drive trains of 0.2 Hz, 0.5 Hz, at threshold frequency for ACs, and at maximal frequency. Directly measured SR loads, normalized to load at 0.2 Hz, were as follows (mean ± SEM (n)): 0.5 Hz, 1.5 ± 0.3 (14)*; threshold frequency, 1.1 ± 0.2 (12); maximal frequency, 1.5 ± 0.1 (19)* (*$p < 0.05$). The other two surrogate measures of SR load yielded identical "N shaped" curves, with a decline in load at threshold frequency. Cell edge detection records indicated that there had been no ACs during the drive train or prior to the caffeine application, and further experiments using caffeine applications at different times following the final stimulus showed no decline in SR load between drive train and AC. We therefore conclude that the positive load-frequency relationship is interrupted at frequencies which lead to ACs before there has been any evidence of spontaneous SR release.

P424 Ca^{2+} handling and sarcoplasmic reticulum Ca^{2+} content in isolated human atrial myocardium

L.S. Maier, P. Barckhausen, G. Hasenfuss, B. Pieske. *Abt. Kardiologie und Pneumologie, Zentrum Innere Medizin, Göttingen, Germany*

Nonfailing human ventricular myocardium is characterized by a frequency-dependent increase in twitch force (positive force-frequency relation) and a rest-dependent increase in twitch force (post-rest potentiation). This physiological behavior is paralleled by increases in intracellular Ca^{2+}-transients due to increases in sarcoplasmic reticulum (SR) Ca^{2+}-content. Whether human atrial myocardium shows a similar behavior is unknown.

Methods: Isolated muscle strips from human atria (n = 10), electrical stimulation, isometric contractions, 37°C. Increase in stimulation rates (0.25–3 Hz), rest-intervals (1–240 s). SR Ca^{2+}-content was measured by rapid cooling contractures (RCCs) as index for SR Ca^{2+}-content. To test for the relative contribution of SR Ca^{2+}-ATPase vs. Na^+/Ca^{2+}-exchange to cytosolic Ca^{2+} elimination we used paired RCCs: After brief rewarming after RCC1 a second RCC (RCC2) tests for the amount of Ca^{2+} taken up by the SR at the end of RCC1. In another set of experiments, intracellular Ca^{2+}-transients were measured with the Aequorin-method.

Results: In atrial human myocardium, twitch force frequency-dependently increased by 157 ± 38% (3 vs. 0.25 Hz; $p < 0.05$) which is paralleled by an increase in SR Ca^{2+}-content by 44 ± 14% ($p < 0.05$). Intracellular Ca^{2+}-transients increased by 80 ± 17% ($p < 0.05$). With increasing stimulation frequency RCC2/RCC1 increased from 41 ± 7 at 0.25 Hz to 57 ± 7% at 3 Hz ($p < 0.05$). When increasing rest intervals, post-rest twitch force decreased by 68 ± 5% and SR Ca^{2+}-content by 49 ± 10% ($p < 0.05$).

Conclusions: In atrial human myocardium, the positive force-frequency relation is due to increased intracellular Ca^{2+}-transients and SR Ca^{2+}-content. The SR Ca^{2+}-ATPase competes more effectively with Na^+/Ca^{2+}-exchange at increasing stimulation frequencies. In contrast, at long rest intervals SR Ca^{2+}-content decreases resulting in the post-rest decay of twitch force.

P425 Total calcium handling assessed from mechanoenergetics in a beating left ventricle: integrative analysis

J. Araki, S. Mohri, J. Shimizu, T. Imaoka, G. Iribe, S. Suzuki, T. Mikane, T. Ohe, M. Hirakawa, H. Suga. *Depts of Physiol II, Cardiovasc Med, and Anesthesiol & Resuscitol, Okayama Univ Med Sch, Okayama, Japan*

Purpose: We aimed to assess total Ca handling in excitation-contraction coupling (ECC) in a beating left ventricle (LV). To this end, we have developed a new integrative analysis method. The method utilizes the internal Ca recirculation fraction (RF) and O_2 cost of contractility (Emax).

Methods: We obtained RF from the time constant (t_c) of the exponential decay component of the postextrasystolic potentiation. We obtained the O_2 cost of Emax from LV O_2 consumption (Vo_2) at different Emax levels. Our equation calculated the unknown total Ca handling, futile Ca cycling and Ca reactivity of Emax from the measured RF and Vo_2 for ECC.

Results: The representative results in canine cross-circulated LVs are listed below. The calculated total Ca handling fell between 31 and 111 μmol/kg. This range is comparable to the literature data obtained by in vitro biochemical methods using excised myocardium. These total Ca values are two order of magnitude higher than the well-known Ca transient (free Ca concentration) values obtained by Ca indicators.

Measured cardiac mechanoenergetics and the calculated Ca handling parameters

Treatment	Measured				Calculated

(#: assumed to be zero in control. *: assumed to be unchanged from control)

Conclusion: The present method for the first time has enabled assessment of major parameters of ECC Ca handling in a beating LV. These data had not been available by any conventional methods. Our integrative analysis method may be useful to better understanding of the pathophysiology of total Ca handling in a beating heart.

P426 The effects of changes in pHi on cell contraction, Ca transients and the Ca sensitivity of myofilaments in rat ventricular myocytes: study with dual-loading method of indo-1 and SNARF-1

H. Terada, W. Liu[1], S. Sugiyama[1], N. Nomura[1], H. Satoh[1], H. Hayashi[2]. *Internal Medicine III, [1]Internal Medicine, III, [2]Photon Medical Research Center, Hamamatsu Univ., School of Med., Hamamatsu, Japan*

The objectives of this study were to develop the method to measure Ca transients (CaT), pHi and cell length simultaneously, and to examine the effects of pHi on CaT, cell contraction and the Ca sensitivity of myofilaments.

Method: In order to measure $[Ca]_i$ and pHi, microscopic fluorescent measurements were carried out in isolated rat ventricular myocytes dual-loaded with indo-1/AM (10 μM) and SNARF-1/AM (5 μM). Cell length was measured from the bright-field image. Intracellular acidosis or alkalosis were induced by propionate (20 mM) or NH_4 < Cl (15 mM), respectively.

Result: The method was validated since there was no interaction between each indicator and in vivo calibration curves of Ca and pH from dual- and single-loaded myocytes were not different. The amplitude of twitch cell shortening and CaT, and pHi in control myocytes were 5.0 ± 0.7 μm, 468.8 ± 42.6 nM, and 7.27 ± 0.07, respectively. NH_4Cl induced an intracellular alkalosis (pHi 7.66 ± 0.08) and significantly increased the twitch cell shortening (10.5 ± 1.3 μm) without a change in the amplitude of CaT (377.0 ± 70.2 μM). Propionate induced an intracellular acidosis (pHi 6.89 ± 0.08) and significantly decreased the twitch cell shortening (2.1 ± 0.6 μm) without a change in the amplitude of CaT (471.9 ± 90.4 μm). The effects of pHi on the Ca sensitivity of myofilaments were assessed with phase-plane analysis of cell length and $[Ca]_i$. Propionate or NH_4Cl shifted the trajectories to the rightward or to the leftward, respectively. The shift of the trajectories by intracellular alkalosis was larger than that by acidosis. The ratios of% changes in twitch cell shortening to% changes in CaT (CS/CaT:1.0 in control) were calculated to estimate the Ca sensitivity of myofilaments. Propionate decreased the CS/CaT (0.48 ± 0.06) whereas NH_4Cl increased the CS/CaT (2.97 ± 0.56). In order to compare the relative influence of intracellular acidosis and alkalosis to the Ca sensitivity of myofilaments, CS/CaT was divided by the change of pHi in each individual myocyte (CS/CaT/delta-pHi:an index reflecting the change in the Ca sensitivity by unit change in pHi). CS/CaT/delta-pHi in myocytes exposed to NH_4Cl was significantly larger than the index in myocytes exposed to propionate (8.1 ± 1.5 vs 1.8 ± 0.4).

Conclusion: CaT, pHi and cell length could be simultaneously measured with dual-loading method of indo-1 and SNARF-1. Intracellular acidosis decreased the Ca sensitivity of myofilaments while alkalosis increased the Ca sensitivity of myofilaments. The relative influence of changes in pHi to the Ca sensitivity of myofilaments was larger in intracellular alkalosis.

P427 Soluble mediator released from postischaemic reperfused rat hearts reduce Ca^{2+} transient and contractility by blocking the L-type Ca^{2+} channel

V. Stangl, P. Bramlage, A. Jarrin, A. Staudt, G. Baumann, J.-U. Borschke[1], G. Isenberg[1], S.B. Felix. *Kardiologie, Campus Mitte, Charité, Humboldt-Universität, Berlin[1] Institut für Physiologie, Universität Halle, Halle, Germany*

We have recently reported that after myocardial ischemia (IS) during reperfusion (R) a cardiodepressant mediator is released from isolated hearts. The mediator is very small (<1 kD), soluble, stable up to 24 hours and not a protein. Aim of the present study was to elucidate mechanisms of the cardiodepressant effect.

Methods: After 10 min global ischemia of isolated rat hearts the coronary effluent was collected during the first 30 sec of reperfusion and was diluted with experimental buffer 1:2, 1:4, 1:8, and 1:16. This effluent induced a concentration-dependent reduction in cytosolic Ca^{2+} transients and cell shortening in field stimulated isolated rat ventricular myocytes loaded with Fluo-3-AM. At a dilution of 1: 4, the effluent caused a 46% reduction of cell shortening and a 26% reduction of cytosolic Ca^{2+} transients. To elucidate the underlying mechamism, we investigated the effect of the postischemic effluent on L-type Ca^{2+} channel current. In voltage-clamped myocytes, the effluent (dilution 1:4) reduced the peak L-type Ca^{2+} current by 54%: an effect resulting from reduced maximal conductance, and not from changes in voltage- and time-dependent gating. When undiluted, the effluent completely blocked contractions, Ca^{2+} transients and Ca^{2+} currents.

Conclusion: Cardiodepressant mediators released from isolated hearts after ischemia during reperfusion reduce Ca^{2+} transients and cell contractions via a block of L-type Ca^{2+} channels.

P428 Blunted positive inotropic response to endothelin-1 in rabbit ventricular myocytes overexpressing protein kinase Cε

J. Prestle, S. Baudet[1], P.M.L. Janssen, J. Weisser, A. Janssen, B. Pieske, G. Hasenfuss. *Dept. Cardiology and Pneumology, Georg-August-University Goettingen, Goettingen; [1]Dept. Cardiology and Angiology, University Freiburg, Freiburg, Germany*

Protein kinase C (PKC) is discussed to be involved in e-c coupling processes in cardiomyocytes. By means of adenovirus-mediated gene transfer we overexpressed PKCε in rabbit ventricular myocytes. Infection of isolated myocytes with increasing virus titers resulted in a dose-dependent increase in PKCε protein expression accompanied by a >20-fold increase in basal PKCε kinase activity at a multiplicity of infection of 100.

Contractile behaviour of PKCε overexpressing myocytes was analysed by a video edge detection-system 48 h post transfection. As compared with control (Ad-LacZ) infected myocytes, basal fractional shortening increased significantly by 21% in Ad-PKCε transfected myocytes. Interestingly, the positive inotropic effect of endothelin-1 (ET-1) was completely abolished in Ad-PKCε transfected myocytes. The data are shown in the following table.

	Ad-LacZ	ET-1	Ad-PKCε	ET-1
Fractional shortening (%)	1.9 ± 0.8 ($^*P < 0.05$)	$2.9 \pm 0.4^*$	$2.3 \pm 0.8^*$ ($^*P < 0.05$ *vs.* Ad-LacZ)	2.3 ± 1.0 ($^*P < 0.05$ *vs.* Ad-LacZ)

1 Hz; $[Ca^{2+}]$ 2 mM; Ad-LacZ, n = 29; Ad-PKCε, n = 36; [ET-1] 10^{-9} M.

Myocyte shortening in response to Angiotensin II was unchanged in Ad-PKCε *vs.* Ad-LacZ infected myocytes.

These data demonstrate a direct involvement of PKCε in ET-1 signal transduction pathway.

P429 Contracting human myocardium in multi-day cell culture

P.M.L. Janssen, S.E. Lehnart, G. Hasenfuss. *Cardiology Dept, University Clinic Göttingen, Göttingen, Germany*

Functional studies of many different human cell types have been successfully conducted under in vitro conditions. Despite many efforts, it has not been possible to develop either a stable human or animal cardiac myocyte cell line or a human primary culture in which contractile functionality can unambiguously be studied over several days. We hypothesize that by mimicking the in vivo situation in an in vitro environment we can preserve viability and function of human myocardial preparations over several days. From explanted hearts of patients undergoing cardiac transplantation, small (average diameter < 0.5 mm) multicellular myocardial preparations (n = 11) were dissected. Preparations were mounted in a custom build, sterile muscle chamber, in a modified culture medium containing 1.75 mM Ca^{2+}, pH of 7.4 and 37° C. Muscles were stimulated at 0.5 or 1 Hz and were kept contracting isometrically for at least 48 hours and up to 6 days. Our data show that contractile function of human myocardial tissue can be preserved over several days, allowing for continuous measurements of myocardial function ex vivo; active force development after 48 hours was 11.4 ± 2.8 mN/mm^2 and had not changed significantly from the initial value of 10.6 ± 1.2 mN/mm^2 at t = 0. Diastolic tension also remained unchanged, from 0.9 ± 0.1 mN/mm^2 at the start of the experiment to 1.0 ± 0.1 mN/mm^2 after 48 hours. After at least 48 hours, the contractile response to stimulation with 1 μM Isoproterenol was clearly present: developed force increased to 631 ± 146% of control values, while half-relaxation time declined to 57 ± 6% of control (n = 7). This implies that not only the entire signal transduction cascade including beta-receptors, protein kinases and cAMP are functionally preserved, but also demonstrates the presence of cardiac reserve in these preparations. After 2–6 days of continuous contractions the cultured preparations still behave similar to the in vivo situation, while also regulatory physiological (like post-rest potentiation and force-frequency relationship) and pharmacological responses are well preserved. This technique now allows studying regulation of contractile function of human myocardium in vitro and can be used in a variety of research areas because correlation between changes in protein expression (including application of gene-transfer) and consequent changes in function can now be directly examined.

P430 Inositol 1,4,5-trisphosphate receptors in cardiac myocytes: isoform expression, subcellular localisation and physiological function

M. Laine, M.D. Bootman, M.J. Berridge, P. Lipp. *Cambridge, UK*

Increased intracellular Ca^{2+} levels have been suggested to mediate cardiac hypertrophy, but the mechanism of this Ca^{2+} increase is not established. Many cardiovascular hormones inducing hypertrophy, such as angiotensin-II (AT-II) and endothelin (ET), are coupled to the inositol 1,4,5-trisphosphate Ca^{2+} release channels (InsP3R). We therefore investigated the isoform specific expression and subcellular localisation of InsP3Rs in rat heart. The hormonal modification of Ca^{2+} release from sarcoplasmic reticulum was examined by real-time confocal imaging with the Ca^{2+} indicator fluo-3.

Ratiometric PCR analysis indicated that isolated ventricular and atrial myocytes almost exclusively expressed InsP3R type II mRNA, while aortic endothelial cells and Purkinje fibres mainly contained type I mRNA. [^{3}H]InsP3 binding and Western blot analysis showed that atrial myocytes expressed 5-fold higher levels of InsP3R protein than ventricular myocytes. These findings were substantiated by a higher InsP3-induced Ca^{2+} release in permeabilised atrial as compared to ventricular myocytes. Probing of Purkinje fibres with isoform specific antibodies against InsP3Rs showed a strong positive staining for InsP3R type I. Ventricular and atrial myocytes stained mostly with InsP3R type II antibodies in the perinuclear region. In the atrial cells additional InsP3R type II was found as a punctated staining pattern in the sub-sarcolemmal region. Double labelling of atrial myocytes for InsP3Rs and RyRs revealed a co-localisation of these two Ca^{2+} release channels. Stimulation of atrial myocytes, but not ventiricular myocytes, with InsP3-mobilising agonists (ET, AT-II and phenylephrine), increased the frequency of Ca^{2+} sparks in the sub-sarcolemmal and perinuclear region. Sparks frequently triggered waves generating action potentials. After inhibiting RyRs with a high concentration of ryanodine (100 mM), we observed very small (~30 nM) and brief (lifetime ~66 ms) Ca^{2+} release signals most likely originating from single or a few InsP3Rs. Inhibition of InsP3Rs with xestospongin C (10 mM) suppressed any effect of hormonal stimulation.

This study revealed the potent role of InsP3-generating hormones in regulating Ca^{2+} signalling in cardiac myocytes. InsP3Rs were able to trigger Ca^{2+} sparks by activating co-localised RyRs. The sparks induced Ca^{2+} waves generating spontaneous electrical activity. The localisation of InsP3Rs in the perinuclear area suggests an involvement of these channels in the regulation of gene expression.

P431 Acute ischaemic asynchronic segmental motion: is this passive motion or active contraction? A segmental velocity versus strain and strain rate imaging study

T. Kukulski, I. De Scheerder, F. Jamal, M. Szilard, X. Liu, J. D'hooge, B. Bijnens, G.R. Sutherland. *Department of Cardiology, University Hospital Gasthuisberg, Leuven, Belgium*

Implanted microcrystals have shown segmental diastolic thickening to occur in acute ischemia in open chest animals. This phenomenon has been linked to viability. Diastolic thickening can now be produced in an animal model using PTCA circumflex occlusion.

Aim of the study: To determine whether this thickening represents a passive event or active contraction, segment motion was analysed pre during and post PTCA occlusion by a combination of M mode, Doppler Myocardial Imaging (DMI) and Strain (S) and Strain Rate (SR) parameters

Methods: Radial S and SR' values were calculated for ischemic segments (LV short axis view) for a 20 sec PTCA circumflex occlusion in 7 consecutive closed chest pigs. S, SR and DMI velocity data were collected (178 fps) and compared to wall thickening M-mode and segmental DMI velocity data for the ischemic segment (posterior basal). Peak values, integrals and time duration of both velocity (Vel) and strain rate (SR) curves were computed for both systolic (I) (pre, during, and post occlusion) and diastolic (II) wall thickening phases (during occlusion). Mitral valve opening (MVO) was used as a reference to monitor changes in global diastolic function.

Results: Ischemic segment diastolic thickening consistently occurred after a 20 sec occlusion. Peak systolic thickening (motion I) was 0.55 ± 0.09 cm and preceded mitral valve opening by 140 ± 36 ms (240 ± 34 ms after onset of QRS) while the peak thickening (0.66 ± 0.1 cm) of motion II occurred 26 ± 22 ms after MVO (407 ± 40 ms after onset of QRS). For velocity and atrain parameters see table.

	Baseline Motion I	Occlusion Motion I	Occlusion Motion II	Occlusion p I vs II	Recovery Motion I
Peak Vel (cm/s)	5.24 ± 1.33	4.22 ± 0.91	2.31 ± 1.11	p = 0.007	5.12 ± 0.92
Vel Integr	0.64 ± 0.25	0.43 ± 0.16	0.13 ± 0.01	ns	0.58 ± 0.19
Peak SR (Hz)	2.96 ± 0.36	1.88 ± 0.55	2.78 ± 1.03	p = 0.04	2.61 ± 0.48
Strain	0.37 ± 0.08	0.21 ± 0.09	0.15 ± 0.04	p = ns	0.35 ± 0.14
Duration (ms)	246 ± 35	193 ± 39	84 ± 16	p < 0.001	248 ± 45

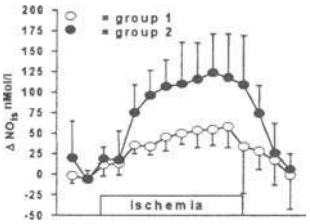
Conclusions: Diastolic thickening had peak SR's similar to systolic SR's pre ischemia but low strain values. As segmental SR's better reflect contractile function than S values this gives added evidence that diastolic thickening is active contraction and not a passive event.

INFLAMMATION AND CYTOKINES

P432 Increase in the interstitial nitric oxide concentration during myocardial ischaemia

H. Post, R. Schulz, C. Martin, A. Jalowy, H. Dörge, M. Behrends, G. Heusch. *Department of Pathophysiology, University of Essen, Germany Medical School*

In dogs, the coronary venous concentration of nitric oxide (NO) metabolites is increased during acute myocardial ischemia. However, it is the interstitial, not the intravascular NO concentration that impacts on cardiomyocyte function. We therefore tested whether or not the interstitial NO concentration (NO_{is}) increases during myocardial ischemia in 14 enflurane-anaesthetized swine. The LAD coronary artery was cannulated and perfused from an extracorporeal circuit. Microdialysis probes were implanted into the anterior wall and perfused with oxyhemoglobin. After control measurements, 90 minutes ischemia were followed by 120 min reperfusion. At the beginning of ischemia, coronary arterial flow was reduced to decrease a work index of the anterior wall (sonomicrometry and micromanometry) by 50% in group 1 (n = 4) and 90% in group 2 (n = 10). Microdialysis samples were obtained in 10 min intervals, and NO_{is} was derived from the conversion of oxy- to methemoglobin, as assessed by spectrophotometry. Transmural blood flow (microspheres) was reduced from 1.06 ± 0.25 (SD) to 0.45 ± 0.11 ml/min/g in group 1 and from 0.91 ± 0.26 to 0.13 ± 0.07 ml/min/g in group 2. After 120 min reperfusion, the myocardium was completely viable in group 1, whereas in group 2 infarct size was 15.7 ± 10.8% of the area at risk (TTC). During 90 min ischemia, NO_{is} was increased by 42 ± 14 nMol/l in group 1 and by 96 ± 33 nMol/l in group 2.



Since superoxide radicals can also induce conversion of oxy- to methemoglobin, in a subset of experiments (n = 4) an additional microdialysis probe was perfused with oxyhemoglobin plus superoxide dismutase solution. Addition of superoxide dismutase to oxyhemoglobin did not decrease the measured concentrations of NO_{is}.

P433 Increased tumour necrosis factor in canine model of reversible myocardial ischaemia: relation to the extend of ischaemia

B. Stojnic[1], S. Tisma[2], D. Djurdjevic[3], N. Pejnovic[3], B. Ciric[1], D. Vojvodic[3], M. Prcovic[1]. [1]*Department of Cardiology;* [2]*Department of Cardiac Surgery;* [3]*Institute for Experimental Medical Research, Military Medical Academy, Belgrade, Yugoslavia*

Tumor necrosis factor (TNF) is increased in acute myocardial infarction. The purpose of this study was to estimate whether TNF is elevated during shorter periods of ischaemia followed by reperfusion and to investigate its relation to the extend of ischaemia.

Methods: Eleven dogs underwent 15 min of left anterior descending coronary occlusion followed by reperfusion. Cardiac TNF was determinated at baseline, at 15 min of ischaemia and after 10 min of reperfusion. TNF was detected on L 929 TNF sensitive cell line (bioassay). Two dimensional echocardiography (short axis view) was used to analyzed left ventricular function. Risk area (RA) (ischaemic) was expressed in % of total short axis area.

Results: TNF was 944 ± 290 pg/ml at baseline, increased during ischaemia to 1376 ± 470 pg/ml and further more during reperfusion 1548 ± 635 pg/ml (p < 0.05). TNF during ischemia-reperfusion was slightly lower in cases (n = 6) with RA less than 25% in comparison to those with RA greather than 25% (n = 5). It was 1275 ± 462 v 1492 ± 574 pg/ml (NS) in ischaemia and 1482 ± 578 v 1635 ± 623 pg/ml (NS) during reperfusion.

In conclusion, this study shows that the release of TNF during ischaemia-reperfusion is present even in short and reversible ischaemia and tend to be related to the ischaemic deterioration in myocardial mechanical performance.

P434 Interleukin-1 in cardiodepressant concentration suppresses arrhythmias provoked by α-adrenoceptor stimulation

F. Schlegel, K. Werdan, U. Müller-Werdan. *Department of Medicine III, University of Halle-Wittenberg, Germany*

In severe heart failure and systemic inflammatory response syndromes elevated blood levels of interleukin-1β (IL-1β) have been reported. Several mechanisms of an IL-1-mediated cardiodepression have been proposed, including the induction of an inducible nitric oxide (NO) synthase. Conflicting results have been reported regarding the potential of IL-1 to induce or suppress arrhythmias. Thus we investigated the antiarrhythmic and cardiodepressant potential of IL-1β in neonatal rat cardiomyocytes (CM).

Methods: CM were incubated for up to 24 h in the absence or presence of IL-1β (100 U/ml) in serum-free medium. Production of NO was assessed by a NO-sensitive microelectrode and the Griess reaction. CM were electrically triggered at constant pace, contractions were monitored continously.

Results: Il-1β (24 h) did not alter morphological appearance of the cells, but resulted in a significant increase in the contents of NO, nitrite and lactate (indicative of altered energy metabolism) in the culture supernatants, which was suppressed by simultaneous administration of dexamethasone (Dex.) (0.1 μM). A lacking response in pulsation amplitude of the IL-1β treated CM to isoproterenol (control: n = 20, 148% ± 20 *versus* IL-1β: n = 27, 103% ± 3*, p < 0.05) was preserved, if Dex. was added (control: n = 21, 131% ± 10 *versus* IL-1β: n = 27, 130% ± 8). Arrhythmias were regularly elicited in controls upon α-adrenoceptor-stimulation (16/17), even if the duration of the electrical pulse was increased to keep the cells in pace. In contrast, recordings of IL-1β-treated CM (n = 11) did not display beating irregularity. If, however, Dex. was added to the incubation medium, arrhythmias occurred both in the groups without IL-1β (9/11) and with IL-1β (9/10).

Conclusion: A potentially beneficial antiarrhythmic effect of IL-1β may accompany its cardiodepressant action *in vivo*.

P435 Time course of nitric oxide release during myocardial ischaemia and reperfusion

A.M. Prasan, H.C.K. McCarron, Y. Zhang, R.W. Jeremy. *Department of Medicine, University of Sydney, Sydney, Australia*

Background: Nitric oxide (NO) is widely considered to be protective against myocardial ischaemia/reperfusion (I/R) injury, leading to suggestions that NO supplementation is a desirable therapeutic goal.

Methods: Isolated rabbit hearts (n = 6) were perfused at 37°C with Krebs-Henseleit solution. A quartz electrode (30 μm), coated with porphyrin and nafion was advanced into the coronary sinus. The electrode system (Bio-logic) was specific for NO and was calibrated using saturated NO solution (1 pA current change equated to 1 nM [NO] change). Reference and counter electrodes were inserted into the right atrium and organ bath, respectively, and continuous [NO] measurements were made each 500 ms by differential amperometry. After 10 minutes control perfusion, normothermic low-flow global ischaemia (1–3 ml/min) was imposed for 60 mins, followed by 60 mins reperfusion at mean perfusion pressure 80 mmHg.

Results: Left ventricular developed pressure was 82 ± 14 mmHg before ischaemia and 55 ± 16 mmHg after 60 minutes reflow ($p < 0.01$). There was an early increase in NO release from the myocardium (peak at 13 ± 4 minutes after onset of ischaemia, peak current = 3.06 ± 0.47 nA vs basal current = 2.54 ± 0.36 nA, $p < 0.01$) which declined during later ischaemia and decreased further during reperfusion (table).

Change in NO concentration with time

	Ischaemia			Reperfusion	
Time	Peak	30 mins	60 mins	5 mins	30 mins
d[NO] (nM)	513 ± 159	282 ± 82*	146 ± 86**	159 ± 112**	−56 ± 69**

Mean ± sem, d[NO] = Change in [NO] relative to baseline. **p < 0.01, *p < 0.05 vs peak [NO]

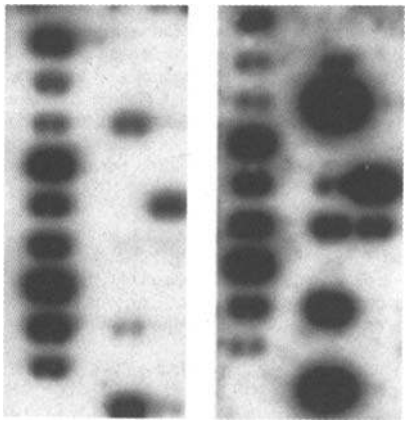
Conclusion: The net increase in NO release for ischaemic myocardium does not support the hypothesis of NO deficiency during ischaemia. Reduced NO release during reperfusion is more likely due to oxygen free radical scavenging than impaired synthesis of NO.

P436 cDNA arrays provide new insights into the cytokine pattern of chemokine-stimulated monocytes

E. Katzer, O. Renner, I. Buschmann, E. Deindl, M. Heil, M. Clauss, I. Hoefer, N. van Royen, W. Klein[1], W. Schaper. *Experimental Cardiology Dept, Max-Planck-Institute, Bad Nauheim, Germany; [1]Dept. for Cardiology, University of Graz, Graz, Austria*

Introduction: The invasion of monocytes into proliferating collateral arteries is a key-event during early arteriogenesis. After maturation these macrophages create an inflammatory environement by producing several growth factors, chemokines etc.. To elucidate this complex biological cascade Human cDNA-Arrays were used to analyze the simultaneous expression-pattern of monocytes after treatment with CC-chemokines.

Methods: Monocytes were isolated from buffy-coats by density-gradient centrifugation. Cells were further isolated by elutriation. The final cell-supension contained >90% of monocytes. Monocyte-stimulation was done for 6 and 12 hours with MCP-1 (200 ng/ml). Total-RNA was isolated, revers transcribed and radioactive labelled. The probes were hybridized to Cytokine/Receptor cDNA-Arrays. Signal evaluation was done by phosphorimaging. Verification was done via RT-PCR and Northern-Blot-Analysis. To our knowledge this is the first monocyte gene-expression study analyzing the simultaneous expression-pattern of 266 genes at m-RNA level after chemokine-stimulation.



Results: MCP-1 stimulation of isolated human monocytes leads to a specific pro-inflammatory and angiogenic expression-pattern of several proteins and their receptors. TNF-alpha, VEGF and MIP-alpha are significantly upregulated as compared to control while the housekeeping genes show an unchanged pattern (left row of cDNAs) (figure)

These factors are a prerequisit for tissue remodelling and vessel growth, confirming our data with CC-chemokines in vivo.

P437 Peripheral benzodiazepine receptors expression on leukocytes in patients with ischaemic heart disease

C. Falcone, C. Auguadro, I. Mazzucchelli[1], A. Serio, M. Vezzoli[1], A. Mazzone[1]. *Cardiology Dept, Policlinico San Matteo, Pavia; [1]Internal Medicine and Nephrology Dept, Policlinico San Matteo, Pavia, Italy*

Background: The opioids are involved in the endogenous pain-modulating system and differences in endogenous opiate levels between symptomatic and asymptomatic patients during episodes of myocardial ischemia have been reported.

Objectives: The purpose of this study was to assess the benzodiazepine receptors expression in leukocytes of patients (pts) with ischemic heart disease.

Methods: The study population consisted of 57 male patients with reproducible exercise-induced myocardial ischemia. The presence of a unique behaviour in the anginal pain perception both during exercise-induced ischemia and during daily life was the most important inclusion criterion. In all the enrolled patients venous blood samples were taken to evaluate the expression of peripheral benzodiazepine receptors by means of flow cytometry. The study cohort was classified into two groups: Group 1 (G1) 24 pts referring anginal pain both at home and during exercise stress test; Group 2 (G2) included 33 pts asymptomatic both during daily life and during exercise-induced ischemia. Results were expressed as mean ± SD. The tMann-Whitney analysis was used to investigate differences among the two different groups.

Results: In patients with silent ischemia (G2) the pBZRs expression resulted significantly higher than in the symptomatic patients (G1) in all types of leukocytes. The pBZr expression on lymphocytes of asymptomatic patients was 2.0 ± 0.4 × 10^{-5} sites per cell and on the same type of cells of the symptomatic group it was 1.2 ± 0.4 × 10^{-5} sites per cell, $p < 0.005$. The pBZRs expression on granulocytes was 7.22 ± 0.8 × 10^{-5} sites per cell in G2 pts and it was 4.25 ± 0.9 × 10^{-5} sites in G1 pts ($p < 0.001$). A similar increase of pBZRs expression on monocytes of asymptomatic patients compared to that of symptomatic patients was demonstrated (G2 = 13.4 ± 0.9 × 10^{-5} sites per cell, G1 = 8.0 ± 0.5 × 10^{-5} sites per cell, $p < 0.001$)

Conclusions: An increase in peripheral benzodiazepine receptors on leukocites was documented in pts with silent ischemia in comparison to the symptomatic ones. These results suggest an involvement of the pBZRs in anginal pain perception.

FAILING MYOCARDIUM

P438 Adrenoreceptor sensitivity and contractile function in failing human myocardium

S. Leslie, S.M. Cobbe[1], D.J. Webb[2], M. Denvir. *Cardiology Dept, University of Edinburgh, Edinburgh; [1]Cardiology Dept, Glasgow Royal Infirmary, Glasgow [2]Medicine Dept, University of Edinburgh, Edinburgh, UK*

Adrenoreceptor down-regulation and altered calcium regulation are important cellular abnormalities observed in failing myocardium. We have explored the relation between these two abnormalities in electrically stimulated isolated cardiac muscle strips from the right ventricles of patients with heart failure (n = 8) prior to cardiac transplantation. Right atrial strips from patients with ischaemic heart disease (n = 7) but no evidence of heart failure were used as controls. Small muscle strips (0.3–0.5 mm diameter) were mounted for measurement of isometric tension, stretched to Lmax and stabilised for 60 minutes. Force frequency response was diminished or negative in all failing strips but had a positive relationship in all non-failing atrial strips (23 ± 3.8% vs −10.8 ± 4.6% at 100 min^{-1}, P = 0.02). Post-rest responses (30–180 seconds) were reduced in failing muscle strips compared with non-failing strips (13.7 ± 6.2% vs 37.2 ± 12.9% increase after 180 s rest, P = 0.03). Responsiveness to isoprenaline was assessed and dose-response curves constructed for individual muscle strips. EC50 (isoprenaline) correlated with the force frequency response as assessed by the change in force between maximum and minimum stimulation frequencies (r = 0.61, P = 0.04) and demonstrated a weak relation with post rest responses (r = 0.32, P = 0.29). Isoprenaline re-established a positive force frequency response in 3 of 9 (n = 7 hearts) failing preparations, all of which had EC50s close to those of normal atrial strips. Isoprenaline had no significant effect on post-rest responses in failing myocardium but significantly increased post-rest contractures in non-failing strips. These results suggest a close relation between adrenoreceptor down-regulation and abnormal mechanical properties of failing myocardium. Contractile dysfunction in heart failure may therefore be secondary to changes in adrenoreceptor responses and not due to intrinsic alterations in calcium cycling.

P439 Effects of adrenomedullin on contractile function in isolated rat, rabbit and human cardiomyocytes

J. Weisser, E. Dieterich, B. Pieske. *Abt. f. Kardiologie und Pneumologie, Zentrum Innere Medizin, Göttingen, Germany*

Adrenomedullin (ADM) is an endogenous vasoactive peptide. Positive inotropic effects of ADM have been shown in rat hearts. In patients with heart failure, ADM plasma levels are elevated. Therefore, we investigated the influence of ADM on isolated human, rat and rabbit myocytes.

Methods: A: Isolation of ventricular myocytes from endstage failing human hearts (n = 6) by enzymatic digestion (Protease 0.5 mg/ml; Collagenase 1 mg/ml). B: Isolation of rat and rabbit ventricular myocytes (n = 8, n = 7 hearts) by enzymatic digestion (Collagenase 1 mg/ml, Langendorff-perfusion). Electrical stimulation (0.5 Hz), registration of fractional shortening (FS) and relaxation characteristics by video-edge-detection. ADM-concentration-response- curves (10^{-10}–10^{-7} M).

Results: In end-stage failing human myocytes, ADM did not increase FS, (108 ± 27% at 10^{-8} M and 96 ± 29% at 10^{-7} M, compared to control). Time to peak shortening (TPS) increased slightly from 365 ± 34 to 397 ± 47 ms, n.s.. Relaxation time (RT50%) did not change (174 ± 73 ms at 10^{-7} M vs. 187 ± 35 ms). In contrast, ADM increased FS in rat myocytes to maximal 172 ± 31% (at 10^{-8} M) compared to control ($p < 0.05$). TPS increased from 76 ± 3 ms to 94 ± 15 ms and RT50% increased from 22 ± 2 ms to 44 ± 7 ms ($p < 0.05$). Increasing ADM to 10^{-7} M led to development of arrhythmias. In rabbit myocytes, ADM decreased FS to 72 ± 13%, compared to control, $p < 0.05$. TPS increased from 175 ± 23 to 225 ± 38 ms and RT50% from 61 ± 11 to 79 ± 21 ms ($p < 0.05$).

Conclusions: In human failing myocytes, ADM did not affect contractile function. In contrast, an increase in contractility, associated with increased contraction and relaxation times, could be observed in rat myocytes. In rabbit myocytes, ADM decreased contractility. At higher concentrations, ADM induced arrhythmias in all species. The functional effects of ADM are species-dependent and deserve further investigation.

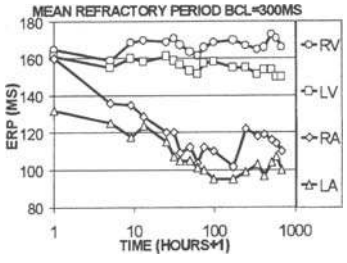
P440 Tachycardia-induced electrical and structural remodelling. Differences between atria and ventricles

B.A. Schoonderwoerd, I.C. Van Gelder, E. Schelhaas, B. Hooft van Huysduynen, R.G. Tieleman, K. Bel, J.G. Grandjean, H.J.G.M. Crijns. *Thoraxcenter, University Hospital Groningen, Netherlands*

Background It is well known that chronic atrial tachycardia causes atrial and ventricular dilatation and atrial electrical remodelling, characterised by shortening of atrial refractory periods (AERP) and loss of physiological adaptation of AERP to rate. However, to date the nature and time course of changes in ventricular refractory periods (VERP) caused by chronic rapid rates and their relation to mechanical changes are to be established.

Methods After being instrumented with epicardial electrodes on both atria and both ventricles and piezoelectric transducers on the right atrium (RA) and left ventricle (LV), five goats were subjected to four weeks of rapid atrioventricular (AV) sequential pacing with a rate of 240 bpm. AV pacing was only interrupted for measurement of left and right AERP and VERP at three basic cycle lengths (BCL) of 400 ms, 300 ms and 200 ms and measurement of RA and LV endsystolic (ES) and enddiastolic (ED) diameters during sinus rhythm.

Results Left and right AERP decreased at all BCL, reaching minimum values after 168 hours. In contrast, left and right VERP did not change at any BCL during four weeks of rapid AV pacing. RA and LV diameters increased progressively to 139%/144% and 120%/116% of baseline, respectively (ED/ES).



Conclusions This study demonstrates a difference between the atria and ventricles with respect to tachycardia induced electrical remodelling and a discrepancy between tachycardia induced ventricular electrophysiological and mechanical changes.

P441 Regulation and localisation of endothelin receptors, ET-1 peptide, and ECE in non-failing and end-stage failing human hearts

B. Beyermann, R. Deres, B.M. Loeffler[1], V. Breu[1], B. Pieske. *Cardiology and Pneumology Dept, Zentrum Innere Medizin, Göttingen, Germany[1] F. Hoffmann-La Roche Ltd,, Pharma Division, Preclinical Research, Basel, Switzerland*

The purpose of this study was to characterise endothelin (ET) receptors, ET-1 peptide and Endothelin-converting-enzyme (ECE) in human ventricular myocardium from non-failing (NF; n = 5) and endstage failing hearts with ischemic (ICM, n = 5) or dilative (DCM; n = 7) cardiomyopathy.

Methods: Radioligand competition binding in microsomal membranes from human myocardium using [125 I] ET-1 as labelled ligand and ET-1, ET-3 and the selective ETA subtype antagonist BQ123 as unlabelled ligands. ET-1 peptide content was assessed by radioimmunoassay. Localisation of ET-1 peptide and ECE by immunohistochemistry

Results: In nonfailing myocardium, endothelin receptor density was 67 ± 14 fmoles/mg protein. Subtype receptor analysis showed 59 ± 4% ETA and 41 ± 4% ETB receptors and no significant difference between left and right ventricles was observed. In ICM, the overall receptor density was decreased to 45 ± 6 fmoles/mg protein, but the relative proportions of receptor subtypes remained similar (64 ± 3% ETA and 36 ± 3% ETB). In DCM, ET-receptor density was significantly increased to 105 ± 18 fmoles/mg protein. This resulted from a selective increase in ETA receptor density to 73 ± 10 fmoles/mg protein with no change in ETB receptor density. ET-1 content was 4530 ± 800 pg/mg protein in NF, and increased significantly to 11800 ± 2600 in ICM and to 13800 ± 1880 pg/mg protein in DCM. Semiquantitative optical analysis revealed enhanced ET-1 and ECE staining in ICM and DCM as compared to nonfailing myocardium. ET-1 and ECE were expressed in endothelial cells, smooth muscle cells and cardiac myocytes, but little in connective tissue. Increased ET-1 staining in ICM and DCM resulted from overexpression in myocytes.

Conclusion: Activation of the ET-system in human heart failure is associated with altered endothelin receptor, ET-1 peptide and ECE-expression on the level of the myocardium. While differences in ETA-receptor regulation may exist between ICM and DCM, ET-1 is increased similarily in both types of disease.

P442 Cardioprotective effects of carvedilol in a rat model for adriamycin-induced cardiomyopathy

K. Teraoka, M. Hirano[1], Y. Nagai, A. Yamashina. *The 2nd Dept. of Internal Medicine, Tokyo Medical University, Tokyo; [1]The 2nd Dept. of Internal medicine, Tokyo Medical University, Tokyo, Japan*

Objective: To investigate macrobiotic and cardioprotective effects of carvedilol in a rat model for adriamycin-induced cardiomyopathy.

Methods: Male Wistar rats aged 8 weeks were used for this study. A rat model for adriamycin-induced cardiomyopathy was developed by intraperitoneal administration of adriamycin at a dose of 1 mg/kg (as a 10 mg/ml solution) repeated 15 times (to a total dose of 15 mg/kg) within a period of 3 weeks. From 2 weeks after the start of administration period, 49 animals assigned to the carvedilol administration group (Group C) were given diet containing 3.44 mg/kg carvedilol while 53 animals of the no-treatment group (Group N) were given control diet containing no drug. After the end of the administration period, follow-up observation was conducted for 12 weeks. Echocardiogram was obtained 4, 8 and 12 weeks after the end of adriamycin administration, as well as before starting the inducer administration, to investigate changes in heart volume and cardiac function. At the end of the follow-up period, all surviving animals were sacrificed for histo-pathological examination.

Results: 1) Mortality in Group C, 14.3% (7/49), was significantly lower than that in Group N, 35.8% (19/53) (Log-Rank test ($p = 0.04$)). 2) Starting from a baseline value of 85 ± 5.3%, difference in ejection fraction (EF) observed between Groups C and N became evident with time after the end of adriamycin administration: Week 4, 79.6 ± 5.5% for Group C vs. 74.3 ± 7.9% for Group N ($P = 0.03$); Week 8, 75.2 ± 8.4% for Group C vs. 67.9 ± 9.1% for Group N ($P = 0.03$); and Week 12, 73.4 ± 8.6% for Group C vs. 62.3 ± 8.5% for Group N ($P = 0.0003$). This indicates that carvedilol significantly improved cardiac functional impairment, especially 12 weeks after the end of adriamycin administration. 3) Fibrogenesis around microarteries within cardiac muscle tissue, interstitial fibrinogenesis and adria cells were observed in both groups, but these myopathic changes were apparently milder in Group C than in Group N.

Conclusion: Carvedilol significantly diminished mortality of heart failure and significantly improved cardiac functional impairment in a rat model for adriamycin-induced cardiomyopathy.

P443 Adrenomedullin does not improve contractility and decreases intracellular Ca^{2+} transients in human non-failing and failing myocardium

J. Weisser, E. Dieterich, P. Barckhausen, B. Pieske. *Abt. f. Kardiologie und Pneumologie, Zentrum Innere Medizin, Göttingen, Germany*

In patients with heart failure, plasma levels of the endogenous vasoactive peptide Adrenomedullin (ADM) are elevated. Positive inotropic effects of ADM have been shown in rat myocardium. However, functional effects of ADM in human myocardium remain to be established. We investigated the effects of ADM on contractile function and intracellular Ca^{2+} transients (aequorin method) in human nonfailing and end-stage failing myocardium.

Methods: A: Isolation of ventricular myocytes from failing human hearts (n = 7); enzymatic digestion, Collagenase 1 mg/ml via perfusion of a left ventricular arterial branch. Electrical stimulation (0.5 Hz) and registration of fractional shortening (FS) and relaxation characteristics by video-edge-detection. B: Preparation of left ventricular muscle strips from the same hearts, and from 3 nonfailing hearts, isometric contractions at Lmax, electrical stimulation. Macroinjection of the photoprotein aequorin. Registration of isometric force (IF) and intracellular Ca^{2+} transients with ADM (10^{-9}–10^{-7} M) or increasing $[Ca^{2+}]_o$ (1.5–7.2 mM).

Results: ADM did not affect FS in isolated myocytes (91 ± 10% at 10^{-9} M and 102 ± 14% at 10^{-7} M, vs. control = 100%). Time to peak shortening (TPS) and relaxation time (RT50%) increased slightly (297 ± 33 to 354 ± 45 ms; 147 ± 28 to 178 ± 38 ms at 10^{-7} M, respectively, n.s.). However, arrhythmias were induced by ADM at 10^{-7} M. Increasing $[Ca^{2+}]_o$ to 5.6 mM in the same myocytes led to an increase in FS to 228 ± 45% ($p < 0.05$ vs. control). In muscle strip preparation from the same hearts, ADM decreased IF to 88 ± 4 at 10^{-9} M and 89 ± 5% at 10^{-7} M (n.s. vs. control). Aequorin light emission decreased to 73 ± 7% at 10^{-7} M ($p < 0.05$ vs. control). In nonfailing myocardium, ADM did not increase IF and slightly decreased Ca^{2+} transients to 89 ± 12%, (n.s. vs. control). Increasing $[Ca^{2+}]_o$ to 5.6 mM increased IF to 266 ± 55%, and aequorin light emission to 258 ± 42% ($p < 0.05$ vs. control) in the muscle strips.

Conclusions: In contrast to rat hearts, ADM does not increase contractility in human venticular failing and nonfailing myocardium. The small negative inotropic effect of ADM was related to a parallel decline in intracellular Ca^{2+} transients. Functional effects of ADM in heart failure patients may primarily result from vasodilatory activities of this peptide.

P444 Genetic analysis of a new form of autosomal dominant dilated cardiomyopathy

G. Bonne[1], S. Varnous[1], M.R. Di Barletta[3], A. Muchir[1], H.-M. Bécane[2], E.-H. Hammouda[2], L. Merlini[4], F. Muntoni[5], C.R. Greenberg[6], J.-A. Urtizberea[2], D. Duboc[1,2], D. Toniolo[3], M. Fardeau[1,2], K. Schwartz[1]. *[1]INSERM UR523; [2]Institut de Myologie, GH Pitié-Salpétrie-Paris, France; [3]Institute of Genetic, Biochemistry and Evolution, CNR-Pavia; [4]Istituto Ortopedico Rizzoli, Neuromuscular Laboratory, Bologna, Italy; [5]Department of Paediatrics, Hammersmith Hospital, Imperial College School of Medicine, London, UK; [6]Health Science Center, Winnipeg, MB, Canada*

Emery-Dreifuss muscular dystrophy (EDMD) is characterized by early contractures of elbows and Achilles tendons, slowly progressive muscle wasting and weakness and an adult onset of cardiac conduction defect, ventricular dysrhythmias with an evolution to severe cardiomyopathy that is life threatening. Two modes of inheritance exist, X-linked and autosomal dominant. Mutations in the *EMD* gene encoding emerin are responsible for the X-linked form.

We have studied a large French family with the autosomal form of EDMD (EDMD-AD). In this family, 17 members were affected, 5 presented both cardiac and skeletal muscle involvement and interestingly 12 members presented exclusively cardiac manifestations.

We have mapped EDMD-AD locus in this pedigree to a 8-cM interval on chromosome 1q11–q23, and found that four other small families were potentially linked to this locus. This region contains the lamin A/C gene (*LMNA*), a candidate gene encoding two proteins of the nuclear lamina, lamins A and C originated through alternative splicing. We identified four mutations in *LMNA* that co-segregate with the disease phenotype in the five families: a non-sense mutation and three missense mutations.

These results are the first to identify mutations in a component of the nuclear lamina as a cause of inherited cardiac and skeletal muscle disorder. Further analysis of phenotype/genotype relationship will help to clarify the variability of the phenotype observed in the large pedigree.

P445 Left ventricular remodelling in chronic heart failure: relevance to changes in exercise performance

V. Florea, M. Henein[1], S. Anker[1], D. Francis[1], J. Chambers[1], D.G. Gibson[1], A.J.S. Coats[1]. *Chisinau, Moldavia; [1]Cardiac Medicine, National Heart and Lung Institute, London, UK*

Objective: In recent years, emphasis has begun to shift from functional to structural changes (referred to as remodelling) that occur in the failing heart. The impact of ventricular structural changes on clinical course and exercise performance remains to be elucidated. This study sought to determine whether changes in left ventricular structure with emphasis on left ventricular size, mass and geometry over time were related to changes in exercise capacity in patients with chronic heart failure (CHF).

Methods: Sixty-two patients with CHF (58 men; mean [± SD] age 60 ± 10 years) underwent echocardiographic examination and treadmill cardiopulmonary exercise testing at baseline and after median of 14 months (at baseline: mean left ventricular fractional shortening (LVFS) 16 ± 8%, mean peak oxygen consumption (VO_2) 18 ± 6 ml/kg/min).

Results: Changes in peak VO_2 per year were significantly related to changes per year in measurements of left ventricular size ($r = -0.48$, $p < 0.001$ for end-diastolic diameter and $r = -0.55$, $p < 0.001$ for end-systolic diameter), mass ($r = -0.44$, $p < 0.001$) and relative wall thickness ($r = 0.40$, $p < 0.01$) but did not correlate with changes over time in LVFS ($r = 0.28$, $p = 0.032$). Stronger relationships were found between changes in the ventilatory responce to exercise (VE/VCO_2) and those of left ventricular cavity dimensions ($r = 0.62$, $p < 0.001$ for end-diastolic diameter and $r = 0.57$, $p < 0.001$ for end-systolic diameter) and mass ($r = 0.71$, $p < 0.001$).

Conclusions: Changes over time in objective measures of left ventricular dimensions, mass and relative wall thickness in patients with CHF are significantly related to changes in exercise capacity and respiratory efficiency.

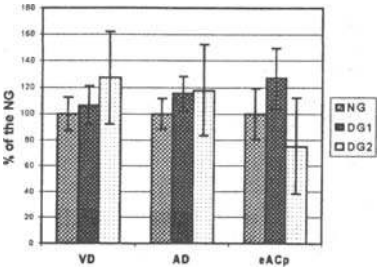
P446 Effective atrial contribution in sequentially paced patients with impaired ventricular function

J. Kvasnička, M. Měšťan, V. Rozsíval, M. Tauchman, J. Jandík, I. Gajdošová. *Department of Internal Medicine, Charles University Faculty of Medicine, Hradec Králové, Czech Republic*

Objective: To assess the effective atrial contribution (eACp) to the ventricular contraction in sequentially paced patients (pts) with various degrees of left ventricular dysfunction.

Methods: Thirty pts with implanted Physios DDD pacemaker were examined. Pressure in the ascending aorta was measured by the Millar catheter. The pressure signal was digitized and the data were accepted only if the defined criteria of the signal stability were met. Switching-off the atrial stimulus at AV intervals of 50, 100, 150, 200 and 250 ms from the DDI into the VVI mode during quiet expiration induced a drop in the pressure-pulse amplitude, which was expressed in per cent of the amplitude of the preceding beat. By definition, the maximal drop indicated the optimal AV interval and quantified the eACp. Ejection fraction (EF) was measured by radionuclids, left atrial (AD) and ventricular (VD) dimensions by ultrasound. Pts were divided into 3 groups according to their EF. NG included 10 pts with a normal values (>55%), DG1 9 pts with $50 < EF \leq 55\%$ and DG2 11 pts with $EF \leq 50\%$.

Results: There was a trend for the eACp and the atrial dimension to be higher in DG1 than in NG (mean 51.1 ± 13.8 v. 40.4 ± 14.0 and 22.5 ± 2.5 v. 19.5 ± 2.9 respectively). In DG2, the atrial dimension was similar as in DG1 (mean 22.9 ± 4.4 v. 22.5 ± 2.5) while the eACp was significantly ($p = 0.012$) lower (mean 51.1 ± 13.9 v. 30.4 ± 14.9). There was a significant association of the eACp and EF ($r = 0.554$, $p = 0.011$) in pts with the $EF \leq 55\%$. In the same pts, no significant correlation was found for the eACp and the left atrial dimension ($r = 0.28$, $p = 0.23$).



Conclusions: In sequentially paced pts with slightly decreased left ventricular EF the augmented atrial pump function compensates for ventricular dysfunction. In severe ventricular dysfunction the atrial pump function is significantly depressed.

MYOCARDIAL PROTECTION

P447 Sodium/hydrogen exchange inhibitor HOE 642 attenuates myocardial reperfusion injury in rabbits by inhibition of polymorphonuclear leukocyte–endothelium interaction

M. Buerke, H. Mahn, S. Lindemann, H.J. Rupprecht, J. Meyer, H. Darius. *II. Department of Medicine, Johannes Gutenberg-University, Mainz, Germany*

Myocardial reperfusion injury has been to neutrophil released mediators like oxygen derived radicals loss of endogenous nitric oxide and increased neutrophil adherence.

We studied the effect of the sodium/hydrogen exchange inhibitor HOE 642 in vivo in a rabbit myocardial reperfusion injury model (60 minutes ischemia followed by 3 hours reperfusion). HOE 642 (1 mg/kg) or its vehicle were injected 5 minutes prior to reperfusion. Myocardial injury following HOE 642 treatment was significantly reduced compared to vehicle treated animals (13% ± 3.1% vs 22.6% ± 2.5% necrosis related to ischemic myocardium, $p < 0.05$). Plasma creatine kinase (CK) activity, another marker for myocardial injury increased from 1.5 ± 0.2 IU/g protein at baseline to 21.3 ± 3.3 IU/g protein following 3 hours of reperfusion in the vehicle group. Administration of HOE642 significantly decreased plasma CK release throughout the reperfusion period (13.8 ± 1.5 IU/g protein, $p < 0.05$). In the necrotic zone myeloperoxidase (MPO) activity, a marker for polymorphonuclear leukocyte (PMN) accumulation, was significantly decreased in HOE 642 treated animals compared to the vehicle group ($p < 0.01$). Histologic analysis of ischemic reperfused myocardium of vehicle treated animals showed 85 ± 12 PMN/mm^2. HOE 642 treatment resulted in a significant reduction of neutrophil accumulation in the reperfused myocardium (24 ± 9 PMN/mm^2, $p < 0.001$). *In vitro* adhesion assays demonstrated reduced PMN adherence to ischemic-reperfused coronary arteries in HOE 642 treated animals. Further, HOE642 significantly reduced PMN adherence to thrombin activated vascular endothelium.

Thus, blocking of sodium hydrogen exchange pump with HOE 642 appears to be an effective mean to preserve ischemic myocardium from injury following reperfusion. The cardioprotective effect appears to be at least in part due to reduced PMN adhesion and infiltration with subsequent diminished myocardial necrosis.

P448 Anaplerotic carboxylation of pyruvate in the in vivo swine heart

W.C. Stanley, A.R. Panchal, B. Comte[1], H. Brunengraber[1]. *Dept. of Physiology and Biophysics, Case Western Reserve University, Cleveland OH; [1]Dept of Nutrition, Case Western Reserve University, Cleveland OH, USA*

It has been suggested that optimal mitochondrial function requires a constant rate of pyruvate carboxylation to provide anaplerotic substrate for the citric acid cycle (CAC). The use of [U-^{13}C]pyruvate tracer was recently introduced in the isolated heart to measure the contribution of pyruvate carboxylation and decarboxylation to the synthesis of citrate in the CAC (Comte et al. J Biol Chem 272:26125, 1997). Comparison of triply labeled and doubly labeled isotopomers of citrate by gas liquid chromatography-mass spectrometry (GCMS) analysis enables one to calculate the relative rate of entry of pyruvate into the CAC through pyruvate carboxylation (via malic enzyme and/or pyruvate carboxylase) and decarboxylation (via pyruvate dehydrogenase(PDH)) pathways. In this study we measured these rates in the anterior free wall of intact anesthetized open chest domestic swine (n = 6). [U-^{13}C] pyruvate was infused into the left anterior descending coronary artery for one hour via an extracorporeal perfusion circuit. Constant values in LAD arterial blood were reached after 5 min of pyruvate infusion for both [U-^{13}C]pyruvate enrichment (80%) and concentration (0.8 mM). At the end of the protocol a myocardial biopsy was taken from the LAD bed and freeze clamped. GCMS analysis was performed on the tissue for the enrichment of [U-^{13}C]pyruvate and isotopomers of citrate. After correction for recycling of carbon in the CAC, the relative rates of citrate formation from pyruvate decarboxylation and carboxylation were calculation from the doubly and triply labeled isotopomers of citrate, and the tissue enrichment of triply labeled pyruvate. Pyruvate decarboxylation accounted for 55 ± 13% of citrate formation and carboxylation for 2.3 ± 1.1%, with the balance (42 ± 12%) presumably coming from lipid oxidation. We investigated this further by performing the same studies in the presence of an intracoronary infusion of octanoate (1 mM in LAD blood) to inhibit the flux of pyruvate through PDH. This resulted in profound inhibition of pyruvate decarboxylation (3.9 ± 2.8% of citrate formation) without any effected on pyruvate carboxylation (1.8 ± 0.7% of citrate formation). In conclusion, this is the first study to measure the contribution of pyruvate carboxylation to the Krebs cycle in vivo, and demonstrate that it accounts of approximately 2% of the Krebs cycle flux in the intact working swine heart. Furthermore, we have shown that this rate is constant when flux through PDH is inhibited by >90%. The physiological importance of this anaplerosis could be related to the cardioprotective effects of pyruvate.

P449 Acute and chronic treatment with the NHE-1 inhibitor cariporide – influence on infarct size in rabbits with hypercholesterolaemia

O. Jung, B.A. Schölkens, W. Jung, H.J. Lang, W. Linz. *Hoechst Marion Roussel, DG Cardiovascular Diseases, H 813, D-65926 Frankfurt/Main, Germany*

Hypercholesterolemia is a major risk factor associated with increased atherosclerotic diseases. In rabbits fed with an atherogenic diet we looked on infarct size and the cardioprotective effect of the NHE-1 inhibitor cariporide under these conditions.

Methods: White New Zealand rabbits were fed with atherogenic diet over 4 weeks (0.25% cholesterol and 3% coconut-oil) or with normal diet and randomized in 3 groups (n = 7/group): placebo, cariporide acute (0.3 mg/kg 10 min before occlusion of LAD) and cariporide chronic (4 weeks 0.1% in chow = 100% blockade of the NHE-1). Thereafter, the animals were subjected to a 30 min occlusion of the LAD, followed by 2-h reperfusion. The left ventricle was stained with triphenyl-tetrazolium chloride and the infarct size expressed as a percentage of area at risk.

Results: In cholesterol fed rabbits infarct size was significantly increased when compared with normal diet animals (63 ± 3% vs 41 ± 3%). Acute cariporide treament halved infarct size in normal diet rabbits to 16% ± 3% (−61%) as well as in atherogenic diet rabbits to 22 ± 3% (−65%). Chronic treatment with cariporide also reduced infarct size significantly: normal diet 19 ± 2% (−53%), atherogenic diet 32 ± 3% (−49%).

Conclusion: Acute and chronic treatment with the NHE-1 inhibitor cariporide significantly reduced infarct size in normal rabbits but also in rabbits with hypercholesterolemia.

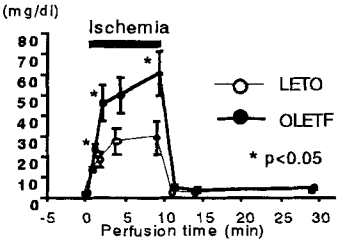
P450 Ischaemic tolerance is attenuated in the spontaneously diabetic Otsuka Long-Evans Tokushima Fatty rats

R. Anzawa, S. Seki, K. Horikoshi, T. Onodera, M. Taniguchi, S. Mochizuki. *Division of Cardiovascualr Research, Department of Internal Medicine 4, Jikei University School of Medicine, Tokyo, Japan*

Previous studies have demonstrated that heart from streptozotocin-induced diabetes mellitus are less susceptible to ischemia and reperfusion injury. However, ischemic tolerance of spontaneously diabetic heart is largely unknown. The aim of this study is to put these past findings in context with spontaneously diabetic, insulin resistant rat heart.

Methods: Male Otsuka Long-Evans Tokushima Fatty (OLETF) strain of 4 and 8 months old and respective age matched non-diabetic Long-Evans Tokushima Otsuka (LETO) rats were used. The hearts from these 4 groups were perfused by the working heart mode with Krebs-Henseleit bicarbonate buffer. Whole heart ischemia was induced by use of one-way ball valve with 300 bpm pacing. Following 10 min of ischemia, the hearts were reperfused for 20 min without pacing. Cardiac output (CO) and left ventricular pressure (LVP) were monitored. Coronary effluent was collected and lactate, pyruvate and H^+ were measured.

Results: At age of 4 months, OLETF showed a slight increase in body weight, while there were no differences in blood glucose level and postischemic recovery of cardiac function between these strains. At 8 months old, however, body weight (518.8 ± 16.1 vs 433.8 ± 16.0 g, $p < 0.05$), HbA1c (3.62 ± 0.14 vs 2.72 ± 0.28%, $p < 0.05$), and blood glucose level during OGTT (60 min; 315.8 ± 22.3 vs 153.6 ± 7.8 mg/dl, $p < 0.01$) were significantly higher in OLETF compared with those in LETO. Recovery of cardiac work (CO × LVP) on reperfusion was significantly lower in OLETF than that in LETO (10 min; 1561.2 ± 453.7 vs 3645.6 ± 834.9 ml · mmHg/min, $p < 0.05$). Lactate level in coronary effluent during ischemia was significantly higher in OLETF compared with that in LETO (Figure).



Conclusion: Hearts from spontaneously diabetic OLETF rat (of 8 months old) are shown to be more susceptible to ischemic insult which is different from that seen in streptozotocin-induced diabetic heart. Mechanism is unknown, but significantly lower level of lactate may be involved.

P451 Enhanced endogenous adenosine production protects the heart after transplantation

R.T. Smolenski, O. Raisky, K.K. Kalsi, J. Jayakumar, M.H. Yacoub. *Heart Science Centre, Imperial College, Harefield Hospital, Harefield, UK*

Increase in endogenous adenosine (Ado) production could protect the heart after transplantation due to potent antiplatelet, antiinflammatory and immunosuppressive effects of Ado. We aimed to optimise the procedure to increase endogenous Ado production by combined application of Ado metabolism inhibitors and nucleotide precursors using isolated cardiac cells and to evaluate this intervention in a protocol mimicking conditions of cardiac preservation for transplantation.

Methods: Isolated rat heart capillary endothelial cells and cardiomyocytes were incubated with various combinations and different concentrations of: Ado deaminase inhibitor – erythro-9(2-hydroxy-3-nonyl)adenine (EHNA), Ado kinase inhibitors – 5′-iodotubercidin (ITu) or 5′-aminoadenosine (AA) and nucleotide precursors – adenine (A) or ribose (R). The optimal combination and concentrations were established to maximise Ado production and cellular ATP content. Cardioprotective effects were then evaluated using heterotopic rat heart transplanation model. Donor hearts were collected, infused with St.Thomas' No. 1 cardioplegic solution and subjected to 4 h of storage at 4°C followed by heterotopic abdominal transplantation. The solution containing EHNA/AA/A/R was infused 10 min before reperfusion of transplanted heart into one group of recipient rats (T, n = 8) while vehicle was infused in control group (C, n = 8). Hearts were than collected after 24 h and mechanical function was evaluated in Langendorff perfusion system using balloon inserted into the left ventricle.

Results: Ado content increased in the incubation medium of both the endothelial cells and cardiomyocytes incubated with Ado kinase and Ado deaminase inhibitors, but addition of A (endothelial cells) or A with R (cardiomyocytes) was necessary to protect cellular ATP pool. Cardiac function was markedly improved in group T: +dP/dt was 2658 ± 195 and 3801 ± 216 mmHg/s, −dP/dt was −2465 ± 189 and −3415 ± 290 mmHg/s and maximum developed pressure was 87.0 ± 6.8 and 118.1 ± 8.2 mmHg in C and T respectively. Left ventricular static compliance was also improved in T as indicated by balloon volume – end diastolic pressure relation.

In conclusion: Inhibition of Ado kinase and Ado deaminase together with supply of adenine and ribose is effective procedure to increase endogenous Ado production in heart cells and to protect hearts from injury following prolonged cold storage during transplantation.

P452 Time-dependent changes of cardiac gene transcription levels of angiotensin II receptors after myocardial infarction: effects of ramipril treatment

Y.C. Zhu, Y.Z. Zhu, D.Z. Tian, J. Li, T. Unger[1], T. Yao. *Dept. of Physiology, Shanghai Medical University, Shanghai, China; [1]Dept. of Pharmacology, University of Kiel, Kiel, Germany*

Aim: To study the early changes of cardiac angiotensin (Ang) II receptor gene transcription after myocardial infarction (MI) in rats chronically treated with the angiotensin converting enzyme (ACE) inhibitor ramipril.

Methods: MI was induced by left anterior descending coronary artery ligation in rats and sham-operated rats were used as control. Rats were treated daily with ramipril (1 mg kg^{-1}) or water, initiated 1 week before surgery. Quantitative RT-PCR was applied to determine the Ang II receptor AT1, AT2 receptor gene mRNA levels in the non-infarcted myocardium. Hymodynamic parameters such as mean blood pressure (MBP), left ventricular end-diastolic pressure (LVEDP), left ventricular systolic pressure (LVSP), left ventricular contractility (LV dp/dtmax) were measured by arterial and intraventricular catheterization at 3 h, 1 d, 3 d, and 7 d after operation.

Results: AT1 and AT2 mRNA levels increased time point dependently in the cardiac septum after MI reaching a peak on day 1. There was no significant difference of the myocardial AT1 and AT2 receptor mRNA levels between the ramipril-treated- and water-treated rats after MI. LVEDP increased 1 d after MI and myocardial contractile function decreased at 3 h, 1 d, 3 d, and 7 d after MI. Ramipril significantly lowered LVEDP at 1 d and 3 d after MI, and improved myocardial contractility at the 7 d after MI.

Conclusion: The AT1 and AT2 receptor gene transcription in the non-infarcted myocardium was associated with the process of cardiac remodeling after MI but not affected by ACE inhibition.

P453 Urocortin protection of cardiac myocytes from lethal ischaemia is mediated by MAP-kinase

B.K. Brar, A.K. Jonassen, A. Stephanou, K.M. Lawrence, G. Santilli[1], R.A. Knight[1], D.S. Latchman. *Dept of Molecular Pathology, Windeyer Institute of Medical Sciences, UCL; [1]Dept of Cystic Fibrosis, National Heart and Lung Institute, Imperial College London, UK*

Urocortin (UCN), a peptide related to CRH, protects neonatal cardiac myocytes from lethal ischaemic injury UCN is expressed predominantly in tissues of the CNS, however is found in cardiac muscle. UCN binds with high affinity to the CRH-R2b receptor which has specific expression in the heart. In this study we show that UCN blocks ischaemic induced cardiacmyocyte death in vitro and ex vivo when administered prior to the lethal stress and during reoxygenation and investigate the role of the MAP-kinase (p42/44 ERK-1/2) pathway in this mechanism.

Methods: Immunoblot analysis using anti UCN anti-body was used to detect the expression of UCN peptide in primary cardiomyocytes isolated from 2-day old neonatal rats. These cells were subjected to simulated ischaemia in ischaemic buffer (IB) and placed in an atmospheric chamber of 5% CO_2 and 95% argon at 37°C for 6 hrs. UCN (10-8 M) was added to the cells prior to this stress and in 2 hrs of reoxygenation. Cell death was assessed by TUNEL, Trypan blue, FACS and annexin-V labelling. To explore the potential down stream pathways responsible for this effect, immunoblot analysis using anti-active p42/44 anti-body was used to investigate ER-2 phosphorylation by UCN. A MAP kinase 1 (MEK) dominant negative mutant cDNA (MEK-1 DN) transfected by calcium phosphate co-precipitation into cardiomyocytes, was used to investigate the cell survival effect of UCN. PD098059 is capable of blocking the activation of the MEK-1, ERK1/2 (p42/44) cascade and was added to the cells 10 min prior to the incubations with UCN, similarly with the PKC inhibitor H7. Ex-vivo ischaemia/reperfusion studies were performed on isolated rat hearts using the Langerdoff perfusion apparatus. Following 20 min stabilisation, all hearts underwent 35 min regional ischaemia followed by 120 min reperfusion. UCN (10-8 M) was perfused on the heart 30 min before or for 30 min during reperfusion. Infarct size (I) was determined using TTC staining, the risk zone (R) with fluorescent microspheres and the % I/R was calculated.

Results: UCN peptide expression levels decrease following ischaemia and further during reoxygenation suggesting release of the peptide. UCN causes rapid phosphorylation of LRK1/2 (p42/44) and protects cardiac myocytes from ischaemic injury when added prior to this stress and in reoxygenation. MEK-1 DN, PD098059 and H7 block the survival effect of UCN, indicating the requirement of a MAP kinase, PKC pathway. UCN protects the intact rat heart from simulated ischaemia/reperfusion

Conclusion: UCN peptide is expressed by cardiac cells and administration of exogenous UCN inhibits ischaemia/reperfusion induced cell death via a ERK1/2 (p42/44) pathway. Hence UCN is a potential novel therapeutic peptide against ischaemia/reperfusion injury.

P454 Pretreatment with inhibitors of KATP channels or PKC abolished the cardioprotective effects of the EP3-receptor agonist TEI-3356 in a model of myocardial injury in the rat

K. Zacharowski, A. Olbrich, C. Thiemermann. *William Harvey Research Institute, London, UK*

Introduction: The cardioprotective effects of E-type prostaglandins have been attributed to vasodilatation, inhibition of platelet and neutrophil function (all due to activation of EP2-receptors) and a 'cytoprotective effect', the mechanism of which is still unknown. We have recently reported that the prostanoid-derivatives, ONO-AE-248, GR 63799X and M&B 28767 reduce myocardial injury in the rat.

Objective: This study investigated the effects of the prostanoid EP3-receptor agonist TEI-3356 on the infarct size caused by regional myocardial ischaemia and reperfusion in the rat. In addition, we have also elucidated the role of protein kinase C (PKC) and ATP-sensitive potassium (KATP) channels in the cardioprotective effects of TEI-3356.

Methods: Male Wistar rats (240–350 g) were anaesthetised, tracheotomised and ventilated. The jugular vein and carotid artery were cannulated to administer drugs and to measure mean arterial blood pressure, respectively. The chest was opened by a left-side thoracotomy and an atraumatic needle was placed around the left anterior descending coronary artery (LAD). After 30 min of recovery, the rats were subjected to 25 min occlusion of the LAD followed by 2 h of reperfusion. At the end of the experiments, the LAD was re-occluded and 1 ml of Evans Blue dye (2% w/v) was i.v. injected to determine the perfused and the non-perfused (area at risk, AR) myocardium. Infarct size (IS) was determined by using p-nitro-blue tetrazolium. All drugs used in this study were i.v. administrated 10 min prior LAD-occlusion.

Results: The mean values for the AR ranged from 46 ± 2% to 54 ± 3% ($p > 0.05$). Treatment of rats with TEI-3356 (1 μg/kg/min) resulted in a significant reduction in IS from 60 ± 3% (control, n = 12) to 36 ± 3% (n = 8; $p < 0.05$) of the AR. The reductions in IS caused by TEI-3356 was not due to a reduction in blood pressure. Pretreatment of rats with either 5-hydroxydecanoate (5-HD, 5 mg/kg, inhibitor of KATP-channels), staurosporine or chelerythrine (Stau, 1 μg/kg, or Chel, 0.7 mg/kg, inhibitors of PKC) attenuated the cardioprotective effects of TEI-3356. However, 5-HD, Stau or Chel did not affect IS ($p > 0.05$). In sham-operated animals, none of the drugs used had any affect on any of the parameters measured.

Conclusions: Thus, activation of the EP3 receptor leads to protection of the heart against ischaemia-reperfusion injury. The cardioprotective effect of TEI-3356 may involve the activation of PKC and the opening of KATP-channels.

P455 Initial report of AMP579 delivery for myocardial infarction reduction (ADMIRE)

S. Kopecky, M. Midei[1], M. Kellett[2], J. Butler[3], G. Fromell[4], A.E. Holland, D. Lester[4], D. Tipping[4], R. Gibbons, S. Lee[5]. *Cardiovascular Disease Dept, Mayo Clinic, Rochester MN; [1]for the ADMIRE Investigators, Powson MD[2]for the ADMIRE Investigators, Portland ME[3]for the ADMIRE Investigators, Fort Meyers FL[4]Collegeville PA[5]Washington D.C., USA*

Introduction: AMP579 is a mixed adenosine agonist with both A1 and A2a effects which has been found to have myocardial protectant properties in animal models of acute MI.

Methods: The ADMIRE Study evaluated AMP579 in a double-blind multicenter placebo controlled trial of 321 patients with acute ST elevation anterior or non-anterior MI undergoing primary PTCA within 6 hours of the onset of symptoms. Patients were randomized to either placebo (P) vs 15 mcg/kg, 30 mcg/kg or 60 mcg/kg continuous infusion over six hours. The primary endpoint was final myocardial infarct size measured by sestamibi scanning at 120 to 216 hours post-PTCA. Secondary endpoints were: 1)myocardial salvage (%LV) and salvage index at 120 to 216 hours in a subset of patients with a baseline sestamibi scan; 2)ejection fraction and heart failure at 4–6 weeks; 3)duration of hospitalization; and 4) cardiac events at 4 weeks and 6 months.

Results: In all treatment groups combined the median final MI size was 10.0% without a significant difference between the P and AMP groups. There was however a trend in final MI size in the anterior MI subgroup receiving P vs. AMP 30 vs. 60 mcg/kg (18.3% vs. 14.0% vs. 13.5%, respectively). In addition, there was a trend towards increased myocardial salvage in the anterior MI group with scans both at baseline and at day 5–9 (Table).

There were no significant differences between treatment groups in the incidence of hypotension, hemorrhage, non-cardiac adverse events or mortality related to treatment.

Treatment Trends

Treatment	P	AMP 15 mcg/kg	AMP 30 mcg/kg	AMP 60 mcg/kg
No. Patients	9	11	14	11
Myocardial Salvage (%LV)				
Median	17.0	27.0	30.0	42.0
(25, 75 percentile)	(12.36)	(1.36)	(5, 45)	(18.54)

Conclusion: 1) AMP579 is safe in acute MI at the doses tested; 2) Although there was no significant difference in the primary endpoint, there was a trend towards smaller infarct size and greater myocardial salvage in patients with anterior MIs treated with the two higher dose groups of AMP579 compared to placebo.

P456 Factors improving survival of Sarcoglycan deficient myotubes subjected to cyclic stretch

M. Sampaolesi, T. Yoshida, Y. Iwata, H. Hanada, M. Shigekawa. *Molecular Physiology Dept., NCVC, Osaka, Japan*

Sarcoglycans (SGs), which are the muscle specific components of the dystrophin-associated protein, are essential for the normal function of myocytes. Mutations or deficiencies of sarcoglycan proteins cause severe cardiac and skeletal myopathies in humans and animal models such as cardiomyopathic hamster.

To investigate how the lack of SGs can produce dystrophic phenotype in myocytes, we used both L6 cell line and skeletal muscle primary cultures, from which SGs were depleted by specific SGs antisense oligonucleotide (ASODN) treatment. In SGs-deficient myotubes subjected to cyclic tension at 6 cycle/min of up to 20% elongation for 1 hour using Flexercell Strain Unit, a marked increase in creatine phosphokinase (CPK) release was observed compared to the control. The confocal microscopic images showed a normal distribution of actin in SGs deficient myotubes and comparable gross morphology to the control before and after stretching. However, dystrophin immunostaining was markedly reduced in SG-deficient myotubes subjected to stretching compared to the control. Nifedipine or Tranilast medium supplementation or intracellular loading of BAPTA were able to reduce the stretch-induced CPK release. In contrast, an increase of extracellular Ca++ concentration enhanced the stretch-induced CPK release in ASODN-treated L6 myotubes. We also evaluated the effects of immunosuppressive drugs and Na/H exchanger inhibitors on CPK release from SG-deficient myotubes. We found that FK506, HOE-694 effectively reduced CPK release from SG-deficient myotubes subjected to stretching. These results suggest that the lack of SGs causes cell damage by making the cell membrane weaker to applied mechanical strain; a change in Ca++ or pH homeostasis appear to be involved in the stretch-induced damage of SG-deficient myotubes.

P457 Ischaemic preconditioning attenuates nf-kb activation and gene expression of inflammatory cytokines in ischaemia-reperfused rat heart

G. Hiasa, M. Hamada, S. Ikeda, O. Sasaki, T. Ohtsuka, H. Hashida, M. Suzuki, Y. Hara, Y. Shigematsu, K. Hiwada. *Ehime University, Ehime, Japan*

Background: Repetitive brief episode of ischemia and reperfusion make the myocardium more tolerant to the subsequent prolonged ischemia. The cardioprotective effect of this phenomenon is known as ischemic preconditioning. However, the exact molecular mechanisms for ischemic preconditioning remain unknown. NF-κB plays a pivotal role in the regulation of immune and inflammatory responses via the gene expressions of such inflammatory cytokines and adhesive molecules as IL-1, IL-6, TNF-α, and ICAM-1. The aim of this study is to investigate the effects of ischemic preconditioning on the expression of cardiac NF-κB and inflammatory cytokines in ischemia-reperfused (I/R) rat model.

Methods: Rats undergoing ischemic preconditioning (IP group n = 6) and controls (C group n = 6) were subjected to 30 min of left coronary artery occlusion followed by 3 hours of reperfusion. Ischemic preconditioning was achieved four 5-min cycles of ischemia, each followed by 10 min of reperfusion. Risk area was determined by injection of Evan's blue and infarct size was measured by triphenyl tetrazolium chloride method. The nuclear DNA binding activity of NF-κB was evaluated by electrophoretic mobility shift assays (EMSA). The mRNA levels of TNF-α, IL-1 β, and IL-6 were measured by semi-quantitative RT-PCR. The localization of activated NF-κB was evaluated by immunohistochemical method using anti-p65 NF-κB polyclonal antibody.

Results: Infarct size was significantly reduced in IP group as compared with C group. The DNA binding activity of NF-κB was also significantly reduced in IP group. The immunohistochemical method revealed that NF-κB immunopositivities were mainly localized in the infiltrated imflammatory cells and cardiomyocytes in infarct zone. In contrast, the percentage of immunopositive cells was decreased in IP group. The semi-quantitative RT-PCR revealed that the mRNA levels of IL-6 and TNF-α were also significantly downregulated in IP group as compared with C group.

Conclusion: These data suggest that (1) the induction of inflammatory cytokines and NF-κB plays an important role in I/R injury and that (2) the attenuated gene expressions of these inflammatory cytokines may contribute to the infarct size reduction via NF-κB downregulation by ischemic preconditioning in this model.

P458 Stimulation of glucose oxidation during reperfusion is mediated by calcium-dependent activation of pyruvate dehydrogenase

Jérôme Terrand, Nathalie Rosenblatt, Irène Papageorgiou, René Lerch. *Cardiology Center, University Hospital, Geneva, Switzerland*

We have previously observed that oxidation of glucose is enhanced early during reperfusion following prolonged ischemia. To determine the role of activation of pyruvate dehydrogenase (PDH), a mitochondrial key enzyme of glucose oxidation, isovolumically beating isolated rat hearts, perfused with erythrocyte-enriched Krebs-Henseleit buffer (8 mM glucose, 0.4 mM palmitate, 70 mU/l insulin), were subjected to 20 or 35 min of no flow ischemia followed by 60 min of reperfusion. Myocardial activity of PDH was mesured by the method of J.G. MacCormack and R.M. Denton (Meth. Enzymol. 174, 95. 1989). Ruthenium red (RR) was added to the perfusate (6 μM) to inhib mitochondrial calcium uptake.

Results: Hearts subjected to 20 minutes of ischemia exhibited complete recovery of left ventricular pressure development (LVDP: 81 mmHg). In contrast, after 35 minutes of ischemia, recovery of LVDP was poor (30 mmHg; $p < 0.001$) compared to control.

	Glucose oxidation (nmole min^{-1} g w w^{-1})				% of PDH activation			
Ischemia:	control	20 min	35 min	35 min + RR	control	20 min	35 min	35 min + RR
Reperfusion + 5 min	18 ± 3	24 ± 5	$112 \pm 19^{**}$	$42 \pm 3^{+}$	13.3 ± 3	$38 \pm 4^{*}$	$73 \pm 2^{**}$	$15 \pm 3^{+}$
Reperfusion + 60 min	20 ± 8	10 ± 1	52 ± 16	45 ± 12	15 ± 2	12 ± 3	$50.2 \pm 2^{**}$	13 ± 4

$^{*}p < 0.05$; $^{**}p < 0.001$ versus control; $^{+}p < 0.05$ versus 35 min

Conclusion: The results indicate that glucose oxidation and activity of PDH increase during reperfusion depending on the severity of ischemia injury. Activation of PDH seems to be mediated by myocyte calcium overload.

CARDIAC HYPERTROPHY

P459 Activation of the transcription factor NF-κB and expression of cyclooxygenase-2 in angiotensin II-stimulated cardiac fibroblasts

N. Scheuren, W. Schorb, M. Jakobs, S. Staufenberger, U. Gergs, G. Ertl. *2nd Medical Clinic, Faculty of Medicine Mannheim, University of Heidelberg, Germany*

Increasing evidence suggests that angiotensin II, one of the most important mediators of cardiac hypertrophy and fibrosis, may act as a direct growth factor for the heart. However, direct effects of angiotensin II on cardiac cells have not been well characterized. Angiotensin II may exert its effects by inducing inflammatory mediators. Because transcription factor NF-κB is crucial in activating the transcription of genes coding for inflammatory mediators, we examined the activation of transcription factor NF-κB and expression of NF-κB-dependent COX-2 after angiotensin II stimulation in adult rat cardiac fibroblasts.

Methods: The effects of angiotensin II and AT_1- and AT_2-receptor antagonists on modulation of transcription factor NF-κB were examined with electrophoretic mobility-shift assays and confocal immunofluorescence experiments. COX-2 expression was analyzed by RT-PCR and Western blotting.

Results: Angiotensin II (10^{-6} M) increased NF-κB (p50/p65) DNA binding activities in rat cardiac fibroblasts and induced COX-2 expression. AT_1- but not AT_2-receptor-antagonists (10^{-6} M) inhibited NF-κB activation and nuclear translocation of NF-κB as well as COX-2 expression (n = 6).

In conclusion our data raise the possibility that the NF-κB signal-transduction pathway may contribute significantly to myocardial inflammation, injury, and fibrosis.

P460 Coordinated upregulation of left ventricular TGFβ, collagen and fibronectin mRNA in aortic stenosis

J. Fielitz[1], S. Hein[2], E.P. Bauer[2], B. Hannack[1], J. Schaper[3], E. Fleck[1], V. Regitz-Zagrosek[1]. *[1]Dept. Internal Med, Cardiology, Virchow-Klinikum, Charite, Humboldt University; German Heart Institute Berlin; [2]Kerckhoff Klinik, Heart, Thoracic and Vascular Surgery; [3]Max Planck Institute, Exp. Cardiology, Bad Nauheim, Germany*

The activation of the renin angiotensin system (RAS) has been associated with increased myocardial fibrosis in heart failure and in pressure overloaded hearts. Growth factors like TGFβ are probably also involved in this process. Our aim was to investigate whether the ACE mRNA together with TGFβ, collagen (col) I, col III, and fibronectin (fn) mRNA is increased in pressure-overloaded human hearts.

We investigated human left ventricular myocardium which was harvested from patients undergoing aortic valve replacement due to aortic stenosis (AS, n = 16). Probes from non-transplanted donor-hearts and pts with mitral valve disease were used as controls (n = 7). For mRNA quantitation, we used an externally standardized RT-PCR-HPLC system. GAPDH and PDH mRNAs were used as external reference genes.

We measured a significant increase of ACE (157%), col I (230%), col III (192%), fn (254%) and TGFβ (167% of control) mRNA content in AS.

Group	ACE	Col I	Col III	fn	TGFβ
Control	1.08 ± 0.5**	0.1 ± 0.07*	0.12 ± 0.06*	0.13 ± 0.9*	3.0 ± 0.7*
AS	1.7 ± 0.3	0.23 ± 0.11	0.23 ± 0.11	0.33 ± 0.19	5.0 ± 1.9

*p < 0.007 or **p < 0.03 compared with AS

A highly significant correlation existed between the expression of coll, III and fn (col I vs. col III: r = 0.91, p < 0.001, col III vs. fn: r = 0.91, p < 0.001, col I vs. fn: r = 0.91, p < 0.001) although these genes are located on different chromosomes. A significant correlation was also observed between TGFβ and coll (r = 0.37, p < 0.05) and fn (r = 0.41, p < 0.02) but not with ACE.

Pressure overload induces the coordinated upregulation of collagen I, III and fibronectin in the human myocardium. ACE and TGFβ are probably involved in this process.

P461 Alterations in right ventricular remodelling and regional function in primary versus thromboembolic pulmonary hypertension using magnetic resonance imaging

V.A. Ferrari, L. Axel[1], K.Y. Wang, Z. Fayad[1], B. Cheney, T. Plappert, M. St John Sutton. *Div. of Cardiovascular Medicine, University of Pennsylvania Med. Ctr., Philadelphia PA; [1]Dept. of Radiology, Univ. of Pennsylvania, Philadelphia PA, USA*

Pulmonary hypertension (PH) causes adaptive remodeling of the right ventricle (RV), often leading to RV failure. Magnetic resonance imaging (MRI) with tissue tagging (MRTT) enables an integrated evaluation of RV structure and regional intramural function. To characterize the ventricular response and the remodeling process in primary PH (PPH) vs. thromboembolic PH (TPH) under similar loading conditions, MRI studies were performed on a 1.5 T MR scanner (Signa, GEMS) using a fast breath-hold sequence and 2D MRTT.

Methods: Six patients with PPH (mean age 47, 4 female) were compared to seven patients with TPH (mean age 43, 4 female). Pulmonary artery (PA) systolic pressure was similar in PPH and TPH (80 ± 11 vs. 75 ± 10 mmHg, p = NS). Short axis images were acquired from the PA to the RV apex using 6 mm slices. Global RV parameters of end diastolic volume (EDV, in ml), mass (M, in g), mass-to-volume ratio (M:V), and ejection fraction (EF, in%) were measured by modified Simpson's method. RV free wall thickness (RVWT, in mm) was measured at the mid-ventricular level. Regional RV systolic function was measured at 3 short axis locations (Basal Inflow, Mid-Ventricle, Apex). Regional 2D strain parameters E1 (comparable to wall thickening) and E2 (comparable to circumferential shortening) were measured and pooled by location.

Results: RV EDV was greater in TPH (110 ± 21 vs. 82 ± 17, p < 0.05), while RV M was similar (p = NS). RV M:V was greater in PPH (1.7 vs. 1.3, p < 0.05), and RVWT was greater in PPH (10 ± 2 vs. 7 ± 2, p < 0.05). RV EF was depressed in both groups, but was greater in PPH (28 ± 3% vs. 20 ± 4%, p < 0.05). E1 was similar in the two groups at all locations (p = NS). E2 was greater in the Basal Inflow and Mid-Ventricular regions in PPH vs. TPH (−0.125 vs. −0.101, p < 0.05).

Conclusion: MRI and MRTT permit characterization of 2 distinct global and regional remodeling patterns in PH, with differing impacts on RV contractile function despite similar loading conditions. These data may provide new insights into the mechanisms and prognosis of RV failure in PH.

P462 Chronic effects of p70S6-kinase-inhibitor rapamycin on left ventricular function, heart morphology and vascular reactivity in rats

K. Hu, J. Bauersachs, P. Gaudron[1], A. Simm[2], R. Kaiser, H. Han, G. Ertl. *Medizinische Universitätsklinik Würzburg; [1]II. Medizinische Universitätsklinik, Klinikum Mannheim, Universität Heidelberg, Mannheim; [2]Biozentrum, Universität Würzburg, Germany*

Rapamycin (R) inhibits angiotensin II induced cardiomyocyte hypertrophy by p70S6 kinase inactivation in vitro. The effects of R in vivo are unclear. We treated rats with R (0.5 mg/kg/day, R0.5 or 2.0 mg/kg/day, R2.0) or placebo (P) per gavage for 8 weeks. Mean arterial pressure (MAP), cardiac index (CI) were measured by Millar-tip catheter and electromagnetic flowmeter, respectively and total peripheral resistance index (TPRI, mmHg/ml/min/kg) calculated. After hemodynamic measurements, hearts were excised, weighed and analyzed morphometrically. The phenylephrine (PE) induced vasoconstriction as well as acetylcholine (Ach) and nitroprussid (SNP) induced relaxation were studied in aortic ring in vitro. Results are shown below:

	P (n = 10)	R0.5 (n = 10)	R2.0 (n = 10)
MAP (mmHg)	109 ± 4	120 ± 3	135 ± 6*
TPRI	0.28 ± 0.02	0.37 ± 0.02*	0.39 ± 0.02*
CI (ml/min/kg)	308 ± 9*	268 ± 17	258 ± 17*
LV weight (mg/g)	2.26 ± 0.07	2.39 ± 0.05	2.55 ± 0.06*
RV weight (mg/g)	0.58 ± 0.03	0.66 ± 0.03	0.70 ± 0.04*
LV cavity area (mm^2)	41 ± 2	37 ± 2	32 ± 2*
LV wall thickness (mm)	1.47 ± 0.08	1.68 ± 0.09	1.91 ± 0.10*
LV myocyte CSA (μm^2)	181 ± 17	188 ± 22	230 ± 25
PE, Kmax (% KCl)	155 ± 8	174 ± 16	212 ± 10*
Ach, EC50 (−logM)	6.71 ± 0.05	6.70 ± 0.08	6.39 ± 0.06*
SNP, EC50 (−logM)	8.6 ± 0.10	8.5 ± 0.12	7.9 ± 0.09*

(mean ± sem; *p < 0.05 vs. P; CSA, cross section area; Kmax, maximal contraction)

Thus, Rapamycin induced dose-dependent hypertension, LV hypertrophy in vivo and vascular dysfunction with increased constriction and reduced response to vasodilator stimuli.

P463 Physiological left ventricular hypertrophy induced by voluntary exercise in rat hearts

Yoko Eto, Teruhiko Aoyagi, Katsunori Yonekura, Makoto Sonoda, Naoto Arai, Masataka Sata, Hiroshi Yamashita, Akihiro Matsumoto, Ikuo Yokoyama, Seiryo Sugiura. *The Cardiovascular Medicine, Faculty of Medicine, University of Tokyo, Japan*

Introduction: Exercise training has been demonstrated to induce physiological cardiac hypertrophy with normal or enhanced cardiac performance. Pathological cardiac hypertrophy caused by clinical disorders such as valvular heart disease and hypertension eventually results in congestive heart failure. Difference between exercise-induced hypertrophy and pathological hypertrophy is not clear. Recently, calcineurin was shown to be involved in pathological hypertrophy. Whether calcineurin participates in exercise-induced cardiac hypertrophy is unknown. The purposes of this study were 1) to assess mechanical performance of rat hearts with the exercise-induced hypertrophy; 2) to determine whether calcineurin plays a role in the exercise-induced hypertrophy. Previous animal studies of exercise training used short and intense exercise such as forced treadmill running and swimming. These types of exercise may not be physiological with excessive stress inducing unfavorable neurohumoral responses. Therefore, we rather elevated a baseline physical activity level of rats in the environment allowing them to exercise voluntarily.

Methods: 7 week-old male Wistar rats were assigned to either 10 weeks of voluntary exercise training program (Ex) or sedentary condition (Sed). Ex rats ran at their favorite time, with speed and duration of their choice in our specially manufactured cages with a controlled running wheel and distance counter. We did echocardiography, histologic examination, and evaluation of myocardial calcineurin level by Western blotting.

Results: Ex rats ran 2.0 ± 0.7 km a day. Exercise increased left ventricular (LV) weights per body weights by 12% ($p < 0.05$). There was a positive correlation between LV weights and running distance ($r = 0.73$, $p < 0.05$). No obvious fibrotic change was induced by the exercise. LV myocyte width was 22.7 ± 1.2 mm in Ex rats and 19.3 ± 1.4 mm in Sed rats (statistically not significant). Exercise increased LV diastolic dimension (7.8 ± 0.3 in Ex rats vs. 6.9 ± 0.3 mm in Sed rats, $p < 0.05$) and stroke volume (0.20 ± 0.02 vs. 0.18 ± 0.02 ml, $p < 0.05$). Protein level of calcineurin did not significantly differ between the two groups.

Conclusion: Voluntary exercise induced LV hypertrophy without impairment in mechanical performance. Increased LV diastolic dimension without significant change in myocyte width may correspond to eccentric hypertrophy observed in athlete hearts. Protein level of calcineurin was not affected by the voluntary exercise. These findings may distinguish physiological hypertrophy in the voluntary-trained rats from pathological hypertrophy.

P464 Transgenic mice with cardiac specific overexpression of the β1-adrenergic receptor

S. Engelhardt, L. Hein, M.J. Lohse. *Institute of Pharmacology and Toxicology, University of Würzburg, Würzburg, Germany*

The heart expresses both β1- and β2-adrenergic receptors which mediate the stimulation of heart rate and contractility by catecholamines. To study the function of the predominant β1-subtype we have overexpressed it in transgenic mice under the control of the heart-specific α-myosin heavy chain promoter. Two independent lines were identified by Southern blotting and receptor density was determined by radioligand binding. Transgene expression was age-dependent with 5-fold and 15-fold overexpression at six weeks of age. *In vitro* experiments determining the spontaneous frequency of isolated atria in response to agonist stimulation revealed a shift of the concentration-response curve to the left. This effect was more pronounced in the line with 15-fold overexpression. *In vivo* basal heart rate and contractility were higher in both transgenic lines at young age (12 weeks) but a pronounced decrease of contractility was observed in the line with high overexpression with increasing age. Pathological examination revealed age-dependent progressive myocyte hypertrophy. At 35 weeks of age there was an increase in myocyte cross-sectional areas of 252 ± 20% in transgenic mice as compared to wild-type littermates. We conclude that modest overexpression of β1-adrenergic receptors in the heart results in increased responsiveness to catecholamines, but that higher levels of these receptors are ultimately detrimental.

P465 Endothelin-1-induced increases in coronary microvascular endothelial superoxide anion production: a possible role in left ventricular hypertrophy?

S.I. Mosfer, D. Lang, M.J. Lewis. *Pharmacol., Therapeutics & Toxycology, Wales University College of Medicine, Cardiff, UK*

Elevated plasma angiotensin II (ang II) levels in guinea pigs with left ventricular hypertrophy (LVH) are associated with activation of NAD(P)H oxidase-induced superoxide (O_2^-) generation from coronary microvascular endothelial cells (CMVE), and subsequent endothelial dysfunction. Ang II has also been shown to modulate the release of endothelin-1 (ET-1) from endothelial cells. We have therefore studied the possible role of ET-1 in LVH and endothelial dysfunction.

Methods: In the present study we measured plasma levels of ET-1 by radioimmunoassay in a guinea pig supra-renal aortic-banded, pressure overload model of LVH. Subsequently, CMVE (isolated from normal guinea pigs) were cultured for 14 days (including one passage) and lucigenin-chemiluminescence used to measure ET-1-induced changes in CMVE NADH/NADPH-dependent O_2^- production following cell lysis. The integral for the first 10 minutes of the reaction represents the total O_2^- produced over this time, and was normalised to CMVE lysate protein content.

Results: Plasma ET-1 levels were unaltered in sham-operated animals compared to normals (21.9 ± 2.5 cf. 25.4 ± 1.4 pg/ml respectively), but were significantly ($p < 0.05$) elevated in aortic-banded animals (31.7 ± 1.9 pg/ml). In control CMVE, NADH and NADPH oxidase activity was 1097.9 ± 105.5 & 273.1 ± 24.7 V.s/mg protein respectively. NADH oxidase activity was significantly ($p < 0.01$) increased (1540.2 ± 121.2 V.s/mg protein) by incubation with ET-1 (1 nM for 9 hours), but NADPH oxidase activity (280.8 ± 30.8 V.s/mg protein) was unaltered. This ET-1 induced increase in NADH oxidase activity was significantly ($p < 0.05$) inhibited (1050.8 ± 104.2 V.s/mg protein) by the ETA receptor antagonist BQ123 (1 μM for 9 hours).

In conclusion, these data demonstrate that (a) plasma levels of ET-1 are elevated in our model of LVH and (b) ET-1 stimulates increased O_2^- production by CMVE. ET-1 may therefore play a role in the endothelial dysfunction associated with LVH.

P466 Induction of BNP expression in human atrial myocardium by diastolic stretch

D. Radicke, S. Wiese, T. Breyer, S. Schmidt-Schweda, A. Dragu, T. Burkard, Ch.J.F. Holubarsch. *University of Freiburg, Germany, Dept. Cardiology & Angiology*

Recently, BNP has been described as an "emergency hormone" which is quickly and markedly expressed in isolated neonatal rat myocytes under a variety of conditions. Using the published sequence of human BNP, we synthetized a cDNA-probe and studied gene-expression of BNP (total RNA, northern-blots) in right atrial muscle preparations obtained from patients undergoing aorto-coronary bypass surgery without any clinical signs of congestive heart failure. N = 20 muscle preparations were mounted in an isometric myograph, stimulated at 60 beats per minute at an experimental temperature of 37°C, and stretched to l_{max}, the muscle length at which maximum systolic force is developed. Half of the preparations were overstretched to 120% of l_{max}, increasing diastolic tension exponentially and decreasing systolic tension significantly. Gene expression of BNP was determined at 1, 2, 4 and 8 hours after start of overstretch. Gene expression of BNP was found to be linearly related to the time of diastolic overstretch: $y = 1.21 + 0.62t$, when y represents the relative increase in mRNA of BNP and t the time of diastolic overstretch. In control experiments without diastolic overstretch, no increase in BNP-mRNA was found. The stretch-induced increase in BNP-expression was suppressed by preincubation with losartan (10^{-6} M). In conclusion, BNP, an "emergency hormone" for hemodynamic overload, is increasingly expressed by diastolic overstretch in human cardiac muscle obtained from right atria of patients without heart failure, an effect which is mainly mediated by angiotensin II.

P467 Midwall myocardial shortening in athletic left ventricular hypertrophy

J. Mayet, B. Wasan, B. Ariff[1], N. Chapman[1], M. Shahi, S. Thom[1], R.A. Foale. *Cardiology Dept., St Mary's Hospital, London; [1]Peart-Rose Clinic, St Mary's Hospital, London, UK*

Patients with pathological LVH have depressed midwall systolic shortening (MS)in spite of normal indices of left ventricular chamber function. Whether MS is depressed in physiological hypertrophy is unknown. In order to assess the effects of LVH induced by physical exercise on midwall left ventricular function 12 professional football players and 15 athletes recruited from the British Olympic Medical Centre were divided into those with concentric hypertrophy (group 1) and those with eccentric hypertrophy (group 2). Systolic left ventricular function was assessed at the midwall and endocardium using echocardiography and compared with 15 age and sex matched normal control subjects (group 3). Left ventricular mass index was significantly greater than controls in both athletic groups (Group 1 155 ± 5.8*, group 2 141 ± 11.1*, group 3 101 ± 5.8 g/m^2; *$p < 0.01$ compared with group 3). Left ventricular systolic function assessed at the endocardium was similar among all three groups (Ejection fraction; group 1, 63.7 ± 1.66; group 2, 66.8 ± 1.44; group 3, 66.2 ± 2.38%. Endocardial fractional shortening; group 1, 35.1 ± 1.25; group 2, 37.6 ± 1.13; group 3, 37.1 ± 1.71%). Additionally, MS was also similar among the three groups (MS; group 1, 21.2 ± 0.96; group 2, 21.9 ± 0.86; group 3, 21.9 ± 1.31%).

In contrast to patients with pathological LVH, subjects with physiological left ventricular hypertrophy due to exercise have a normal MS. There was no discrepancy between midwall and endocardial shortening in athletes with either eccentric or concentric hypertrophy compared with normal controls. This finding is reassuring but does imply that cardiac geometric changes alone cannot explain the discrepancy between midwall and endocardial systolic function in pathological LVH.

P468 Enhanced expression of cardiac adenosine A1-receptor in rats with pressure-overload left ventricular hypertrophy

S. Perlini, P. Vandoni[1], B. Arosio[2], D. Santambrogio[2], L. Parmeggiani[2], G. Annoni[2], E. Chung[3], T.E. Meyer[4], A.U. Ferrari[1]. *Clinica Medica 1, IRCCS San Matteo, Univ. Pavia, Pavia; [1]Clinica Medica Generale, Centro Fisiologia Clin e Ipertensione, Milan[2]Cattedra Geriatria, Univ. Milan, Milan, Italy[3]Div. of Cardiology, Univ. Massachusetts, Worcester MA[4]Div. of Cardiology, Univ of Massachusetts,, Worcester MA, USA*

Myocardial adenosine (Ado) is increased in the compensated stages of pressure-overload hypertrophy (POH). In this setting, which is characterized by increased cardiac adrenergic stimulation, this may represent an important cardioprotective mechanism due to the known antiadrenergic properties of Ado. However, the ultimate effect of Ado will depend on the behaviour of the myocardial receptor that mediates the response, i.e. the Ado A1-receptor. We therefore examined whether left ventricular (LV) Ado A1-R gene expression is modified in the early stages of POH.

Methods: Sprague-Dawley rats aged 6 weeks were subjected to abdominal aortic banding (B) or sham operation (S). One and two weeks (wk) later, left ventricular systolic pressure (LVP, mmHg, transcarotid catheter) was measured under ketamine anesthesia. LV weight (LVw, mg/100 g body weight) was obtained post-mortem. A1-R mRNA expression (densitometric units) was measured in tissue fragments from the LV, the right ventricle (RV) and the aortic arch (AoA) by reverse transcription polimerase chain reaction, the data being normalized for the reference gene GAPDH. LV atrial natriuretic peptide (ANP) mRNA expression was also measured.

Results:

	n	LVP	LVw	LV ANP	LV A1-R	RV A1-R
S-wk1	10	108 ± 10	2.05 ± 0.03	0.13 ± 0.06	1.42 ± 0.14	0.99 ± 0.13
B-wk1	11	142 ± 13*	2.93 ± 0.17*	0.89 ± 0.14*	1.73 ± 0.18*	1.26 ± 0.14
S-wk2	10	110 ± 11	2.09 ± 0.05	0.11 ± 0.03	1.75 ± 0.09	n.a.
B-wk2	12	153 ± 14*	3.12 ± 0.19*	0.47 ± 0.11*§	3.01 ± 0.47*§	n.a.

Means ± SEM; *$p < 0.05$ vs respective sham; §$p < 0.05$ vs wk 1. No significant intergroup differences in AoA A1-R were observed.

In conclusion, gene expression of LV, but not aortic, Ado A1-receptor is markedly enhanced since the early stages of POH, further supporting the notion that activation of this "antiadrenergic" receptor may represent a cardioprotective mechanism in the adaptation to pressure overload.

P469 The effect of growth hormone and insulin-like growth factor-I on isolated rat cardiomyocytes

P. Schnabel, F. Mies, M. Geisler, M. Böhm. *Klinik III für Innere Medizin der Universität zu Köln, Cologne, Germany*

Cardiac hypertrophy is a mechanism of adaptation to increased workload of the heart. Initially, it reduces wall stress and increases cardiac output. However, hypertrophy is a predictor of heart failure and associated with a bad prognosis. However, recent studies suggested a clinical benefit of the hypertrophy-inducing hormones growth hormone (GH) and/or its effector molecule insulin-like growth factor-I (IGF-I) in heart failure.

In order to characterize the signal transduction of GH and IGF-I, rat cardiomyocytes (CM) were incubated with GH (100 nM) and IGF-I (100 nM), respectively. The expression of immediate early genes such as c-myc, c-fos and c-jun as well as of phospholipase C (PLC)-isozymes and of GAPDH were determined by RT-PCR.

Both GH and IGF-I resulted in an increase of expression of c-myc, c-fos and c-jun. Expression of PLCβ3 was also increased by GH and IGF-I. The induction of immediate early genes by GH was not abolished by preincubation od CM with the IGF-I receptor antagonist IGF-I anolog. The early growth response of CM to IGF-I was abolished by preincubation with wortmannin (25 nM), an inhibitor of phosphoinositide-3-kinase (PI3K), and rapamycin, an inhibitor of the p70 S6-kinase (p70^{S6K}) pathway. Moreover, preincubation of CM with antisense oligonucleotides (AO; 5 μM) directed against PLCβ3 abolished the induction of immediate early genes, while the corresponding sense oligonucleotides (SO) had no effect.

In conclusion, the data suggest that the induction of immediate early genes by IGF-I requires PI3K and p70 S6K activity and the expression of PLCβ3. The induction of immediate early genes by GH involves a signalling mechanism beyond IGF-I.

P470 Left ventricular hypertrophy and myocardial damage in response to aortic banding differ between male and female rats

R. Maestri, R. Pacchiana, D. Corradi, E. Cigola, M. Monica, N. Bertani, G. Graiani, F. Quaini, G. Olivetti. *Pathology Dept., University Medical School of Parma, Parma, Italy*

Several lines of evidences demonstrate that incidence and behavior of cardiovascular diseases are gender related and females (F) have distinct advantages over males (M). To test whether myocardial response to an increased afterload may differ in time and magnitude between sexes supraventricular aortic banding was obtained with a calibrated ring to reduce the aortic diameter by 30%. M(n = 72) and F(n = 72) rats were sacrificed 2, 4, 6, 10, 15 and 90 days after surgery. Control animals matched for age and body weight (bw) were submitted to a sham operation (SO)(M = 41,F = 53) in which the aorta was not constricted. Following measurement of intraventricular pressure by puncturing the left ventricular (LV) chamber with a needle connected to a fluid filllled transducer, hearts were arrested with cadmium chloride, the weight of the ventricles determined and replacement myocardial fibrosis morphometrically measured on paraffin embedded tissue. LV pressure increased to 273 ± 17 mmHg in M and 257 ± 35 mmHg in F 2 days after surgery and remained elevated until 90 days without evidences of LV dysfunction and differences between sexes. In comparison with SO, LV weight in F rats increased 18% ($p < 0.05$) at 2 days and progressively with time reaching a 56% ($p < 0.005$) increase at 90 days. In contrast, in M the hypertrophic response of LV was 18% ($p < 0.01$) at 6 days and only 46% ($p < 0.005$) at 90 days. During the entire experiment bw was not affected by the surgical procedure so that the changes in LV weight to bw were similar to those found at ventricular level. Aortic banding did not affect RV weights although at 90 days a 20% (ns) increase was seen in both M and F rats. Myocardial damage characterized by reparative tissue at the early stages and fibrotic tissue in the later intervals was limited to LV and was already present at 2 days after surgery. Quantitatively, in F rats the amount of tissue damage increased more than 2-fold from 69 ± 38 mm^3 at 2 days to 144 ± 58 mm^3 at 90 days whereas in the same interval in M LV a 4.5-fold increase was seen from 51 ± 23 mm^3 to 230 ± 82 mm^3. In conclusion, acute aortic banding in rats induces LV hypertrophy and myocardial damage progressively increasing with time in both sexes. However, in F rats LV hypertrophy takes place earlier, is greater than in M rats and is accompanied by less amount of damage. The attenuated myocardial growth of LV in M rats may be the consequence of the larger amount of scarred tissue. Thus, the growth reserve capacity of the LV in response to stressful conditions in M is significantly lower than in F rats.

P471 Identification of a silencer element in the 5.1 kb rat atrial natriuretic peptide promoter in acute and chronic pressure overload

B. Mayer, P. Kempt, T. Cornelius, H. Hupf, C. Hengstenberg, S.R. Holmer, G.A.J. Riegger, H. Schunkert. *Klinik für Innere Medizin II, Universität Regensburg, Regensburg, Germany*

Upregulation of left ventricular atrial natriuretic peptide (ANP) is a conserved marker of cardiac hypertrophy. In the present study we investigated the activity of the 3.6 kb promoter region of the rat ANP gene and characterized an additional 1.5 kb fragment upstream of the 3.6 kb fragment in chronic and acute pressure overload.

Design and Methods: The upstream 5′ flanking site of the previously cloned 3.6 kb ANP promoter was extended by 1.5 kb using the promoter walker method. The newly cloned 1.5 kb fragment shows no homologies with any known sequence (EMBL). Promoter-reporter gene (luciferase) constructs carrying the 3.6 kb fragment or different sections of the newly cloned 1.5 kb upstream sequence together with the 3.6 kb fragment, were transfected (lipofection) into rat left ventricles (LV) after 8 weeks of supraaortal banding. Luciferase activity was measured in LV tissue 3 days after transfection. Similarly, promoter constructs were transfected into normal rat hearts 3 days prios to acute wall stress (isovolumetric balloon in the Langendorff apparatus for 2 hours) before assessment of luciferase activity (n = 5).

Results: In vivo transfection of the construct carrying the previously cloned 3.6 kb promoter revealed a significant 2.2-fold ($p < 0.05$) and 40-fold ($p < 0.01$) upregulation of luciferase activity after chronic and acute stimulation, respectively. Upstream extension of the 3.6 kb promoter by the newly cloned DNA stretch (0.6 or 1.5 kb) resulted in a substantial 50% or 90% loss of luciferase activity in chronic hypertrophy or after acute wall stress, respectively ($p < 0.05$ vs. 3.6 kb fragment).

In conclusion, acute and chronic wall stress activate the 3.6 kb ANP promoter. However, the physiological relevance of this promoter section may be overestimated since a dominant silencer in the newly cloned upstream promoter inhibits the response of the promoter to both acute and chronic wall stress. Specifically, an inhibitory element was located 3388 to 4225 bp upstream of the ANP transcription start site that that may have important functional implications for the in vivo regulation of ANP.

P472 In compensated human cardiac hypertrophy relaxation velocity correlates with myocardial SERCA 2a levels

U. Schotten, M. van Helden, M. Hense, F. Schoendube, P. Hanrath. *Dept. of Cardiology and Dept. of Thoracic- and Cardiovascular Surgery, University Hospital Aachen, Germany*

Background: Reduced activity of the sarcoplasmic reticulum (SR) Ca^{2+}-ATPase (SERCA) contributes to alterations of intracellular Ca^{2+} handling and contractile behavior in human failing myocardium. In compensated cardiac hypertrophy relaxation impairment precedes the development of reduced systolic pump function but alterations of the SR Ca^{2+} transport proteins are not yet established.

Methods: We studied the diastolic contractile properties and the myocardial SR Ca^{2+} ATPase (SERCA) protein expression in septal myocardium from patients with hypertrophic obstructive cardiomyopathy (HOCM, n = 7) or aortic valve stenosis (AoSt, n = 8) and in nonfailing myocardium (NF) of 4 organ donors. Force of contraction of thin isolated muscle preparations was measured under isometric conditions at a stimulation frequency of 0.5 Hz and 37°C. SERCA protein expression was determined by Western blot analysis.

Results: Mean relaxation velocity (−dT/dt) and mean SERCA protein expression (1000 cpm/mg protein) ± SEM.

	NF	HOCM	AoSt
−dT/dt (mN/mm²/s)	12.4 ± 1.1	6.6 ± 1.2*	6.7 ± 0.9*
SERCA (10^3 cpm/mg protein)	72.5 ± 5.8	45.1 ± 2.2*	46.1 ± 2.1*

*: $p < 0.05$ versus NF.

Within all patients with cardiac hypertrophy there was a significant correlation between −dT/dt and SERCA expression ($r = 0.69$, $p = 0.004$).

Conclusion: The results support the hypothesis that reduced SERCA protein expression contributes to the relaxation impairment in compensated cardiac hypertrophy before pump failure due to progressive dilation of the left ventricle develops.

P473 Translocation of annexin V in cardiac cells during calcium overload

Y. Horikawa, N. Kaneko, F. Chiwaki, R. Matsuda[1], K. Shimamoto[2]. *First Internal Medicine, Dokkyo University School of Medicine, Tochigi; [1]Anatomy, Tokyo Women's Medical University, Tokyo; [2]Cardiology, Aoyama Hospital, Tokyo, Japan*

Annexin V (An V) has the ability to bind to membranes in a Ca^{2+} dependent manner. However, the function of An V requires further clarification. We had reported that An V moves from cytosol to the cell membrane during ischemia and reperfusion and that An V may play a role of cardiac cell injury. However several papers reported recently that An V had already bound to cell membranes in the physiological state.

It is our aim to show that An V is in cytosol in the physiological state and that An V translocates to the cell membrane during calcium overload.

The trabecule of the rat right ventricle was permeabilized by alpha-toxin. They were then incubated in a Ca^{2+} buffered solution (pCa 6.3, 6.0, 5.6, or 4.5) containing 30 mM Pipes, 5 mM Mg-ATP, 10 mM creatine phosphate, $MgCl_2$ calculated to 2 mM Mg^{2+}, 10 mM total EGTA and Ca-EGTA/EGTA calculated for the desired pCa. Another group was incubated in pCa 6.3 for 30 min after it was exposed to pCa 4.5 for 30 min.

At the end of incubation, muscles were homogenized and centrifuged at 48,000 × g at 4°C for 30 min. The pellets were suspended in the same buffer but containing 1% Triton-X-100 and centrifuged at 48,000 × g. Annexin V was stained with polyclonal antibody in the western blot method.

The staining of annexin V was strongly pronounced in a cytosolic fraction in pCa 6.3, which means the physiologic state. An V was both in the membrane fraction and in the cytosolic fraction in pCa 6.0, and An V was also strongly stained in the membrane fraction in pCa 5.6 and 4.5, which indicates Ca overload. In the muscles exposed in pCa 6.3 after pCa4.5, An V was found in both the cytosol and membrane.

This result shows that annexin V is present in cytosol under the physiological Ca^{2+} concentration and translocates to the cell membrane in response to the rise in intracellular Ca^{2+} and that this binding is reversible. It should be suspected that An V may play a role of cardiac cell injury.

PULMONARY CIRCULATION

P474 Modulation by nitric oxide of the endothelin B receptor mediating pulmonary hypertension in the guinea pig

P. Del Basso, R. Calabrese, L. Argiolas. *Pharmacology Dept, Istituto Superiore di Sanita, Rome, Italy*

The endothelins (ETs) play a significant role in pathophysiology of pulmonary disorders, notably of pulmonary hypertension. Since the diverse effects of ETs are mediated via distinct receptor subtypes, aims of the present study were a) to characterize which receptors are involved in the potent pulmonary hypertensive effect of ETs and b) to verify whether endogenous production of nitric oxide (NO) may modulate such hypertension.

Methods: The work was performed on the heart-lung preparation of guinea pig (HLP) perfused with homologous blood, according to the previous described method (Argiolas et al., Br. J. Pharmacol. 114: 203–9, 1995).

Results: Bolus injections (12.5–400 ng) of ET-1 and of the ET B selective agonist, ET-3,into the venous cannula of the HLPs produced a dose-dependent increase of pulmonary arterial pressure (PAP) and pulmonary vascular resistance (PVR, calculated as PAP-LAP/CO). Adding to the perfusing blood the selective ET B receptor antagonist BQ 788 (0.0001 mM) the pulmonary hypertensive effects elicited by both ET-1 and ET-3 were almost completely abolished. In addition, the dose-response curves elicited by ET-3 for PAP and PVR were significantly shifted to the left by the presence of the NO synthase inhibitor, L-Nw-Nitro-L-Arginine (L-NNA, 0.2 mM).

In conclusion, our data on HLPs of guinea pigs indicate that the pulmonary hypertensive effects of endothelins are mainly mediated via stimulation of ET B receptor subtype. Moreover, it is suggested that generation of NO attenuates these hypertensive effects, thus contributing to the overall pulmonary hypertension induced by ETs.

P475 Intensive short-term observation for clinically stable patients with acute pulmonary embolism and right ventricular dysfunction

S. Grifoni, I. Olivotto, A. Camaiti, P. Cecchini, F. Pieralli, A. Conti, G. Santoro[1], G. Berni. *Emergency Department, [1]Cardiologia 2 San Luca, Azienda Ospedaliera Careggi, Florence, Italy*

Background: Optimal treatment for patients with pulmonary embolism (PE) presenting with acute right ventricular dysfunction (RVD) but no evidence of shock is still under debate. While some advocate extensive use of thrombolysis, conservative treatment strategies based on the initial clinical course may represent a viable alternative to identify patients at higher risk and reduce treatment-related complications. We report our experience with intensive short-term observation of clinically stable patients with acute PE and RVD.

Methods: Among 223 consecutive patients with PE (diagnosed by by lung scintigraphy, spiral CT scan, and/or pulmonary angiogram), 89 (40%; age 69 ± 15 years; female 64%), were normotensive or moderately hypotensive on presentation (but not in shock), and had echocardiographic evidence of RVD, defined as RV dilatation (end-diastolic dimension > 30 mm or right/left ventricular ratio > 1 in 4-chamber view), and/or paradox septal systolic motion, in the absence of RV hypertrophy. These patients were observed for >24 hours in our Chest Pain Unit, with continuous monitoring of blood pressure, pulse oxymetry and ECG, and serial heart and venous ultrasound scans. The decision of instituting "rescue" thrombolysis was based on the clinical course and associated conditions of each patient.

Results: Of the 89 study patients, the majority (n = 75; 84%) had an uneventful clinical course and were discharged: all were treated with i.v. heparin except 5 who received temporary vena cava filter and urokinase infusion for proximal floating venous thrombosis. Two additional patients remained stable but later died of cancer. The remaining 12 (13%, age 70 ± 15 years) experienced clinical deterioration due to PE (worsening dyspnea and/or hypotension leading to shock) <48 hours after admission. Of these, 7 patients (age 66 ± 17 years, range 34–85) were immediately treated with "rescue" thrombolysis with urokinase (n = 5) or rtPA (n = 2): all recovered and were successfully discharged. In the remaining 5 patients (age 76 ± 11 years, range 62–87), thrombolysis was withheld because of very recent surgery (1 patient, who died of PE), or advanced cancer (4 patients, 3 of whom died of PE). Therefore, total acute mortality for PE in the study group was 4.5%, with all deaths but 1 occurring in terminally ill patients.

Conclusions: Intensive short-term observation represents a valid management strategy for patients with PE and RVD who are clinically stable on presentation, allowing timely and selective use of "rescue" thrombolysis to suitable candidates and minimising treatment-related complications.

P476 Prognostic indicators in scleroderma-associated pulmonary hypertension

J. Coghlan, B. Colerio[1], C. House, D. Abrahams[1], C. Black[1]. *Cardiology, Royal Free Hospital, London; [1]Academic Rheumatology Dept, Royal Free Hospital, London, UK*

Scleroderma associated pulmonary hypertension (SSc-PHT) and primary pulmonary hypertension (PPH) are distinct conditions. Continuous prostacycline therapy may induce dramatic reductions of pulmonary artery pressure (PAP) in PPH and is prognostically beneficial. PAP rarely falls significantly in SSc-PHT during chronic prostacycline therapy and prognostic benefit has not been shown to date. Right atrial pressure (RAp), cardiac index (CI), mixed venous oxygen (SVO_2), and response during vasodilator challenge are prognostic markers in PPH. Appropriate prognostic indicators for SSc-PHT are not known.

We have performed vasodilator challenges in and followed 35 patients with SSc-PHT over the past 26 months, 29 are female, mean age is 64. 13 patients have died after a mean follow up of 39 weeks, survivors have been followed for an average of 36 weeks. Survivors had a lower right atrial pressure, higher cardiac index and lower baseline pulmonary vascular resistance (PVR), than non-survivors. 10/14 non-survivors had a baseline PVR > 850 dynes cm^{-5}, versus 5/21 survivors. But preserved vasodilator reserve has no influence on survival (see table).

Baseline Haemodynamic Data

	PVR (dynes cm^{-5})	RA (mmHg)	CI (l/min/m^2)	SVO_2 (%)	Fall PVR (%)
Non-survivors	1247 ± 676	11 ± 6.4	1.94 ± 0.6	60 ± 12	38 ± 13
Survivors	661 ± 390	6.8 ± 4.4	2.4 ± 0.6	65 ± 9	35 ± 15
p Value	<0.003	<0.03	<0.03	=0.16	=0.5

Data as Mean+SD, statistics: unpaired T test

Catheterisation was repeated between 4 & 6 months in 14 patients of whom 7 subsequently died. A fall in mixed venous oxygen despite treatment was the most powerful predictor of subsequent death (−19 + 18% v +1 + 6% p < 0.02).

Right ventricular failure develops at relatively low pulmonary pressures in SSc-PHT. PVR in excess of 850 dynes cm^{-5} and progressive fall in mixed venous oxygen appear suitable markers for poor prognosis in this population.

P477 Effects of pulmonary hypertension on right ventricular function in the newborn lamb

M. de Vroomen[1,2], P. Steendijk[1], R.H. Lopes Cardozo[2], F. van Bel[2,3], J. Baan[1]. *Departments of [1]Cardiology; [2]Pediatrics, Leiden University Medical Center; [3]Department of Neonatology, Wilhelmina Children's Hospital, Utrecht, Netherlands*

Severe respiratory diseases of the newborn are often accompanied by pulmonary hypertension causing an increased afterload of the right ventricle (RV). To determine the effects of this increased afterload on RV function, we examined RV function before, during and after partial balloon occlusion of the pulmonary artery, in nine newborn lambs. RV function was quantified by indices derived from RV pressure-volume relations, obtained by a combined pressure-conductance catheter during inferior vena cava occlusion.

Results: An almost 2-fold increase of end-systolic RV pressure (Pes) was applied during 4 hours. Cardiac output (CO) and stroke volume (SV) were maintained while end-diastolic volume (Ved) did not change significantly during this period. RV systolic function improved significantly; the end-systolic pressure-volume relation (ESPVR) shifted leftward, indicated by a significantly decreased volume intercept at a pressure of 25 mmHg (V-25), and an increased slope (Ees).

	Pes (mmHg)	V-25 (ml)	Ees (mmHg/ml)	CO (ml/min)	SV (ml)	Ved (ml)
Before	21.9 ± 1.6	4.96 ± 0.71	3.84 ± 0.64	0.74 ± 0.08	4.30 ± 0.40	7.95 ± 1.32

* = $p < 0.05$, compared to 'Before'

Conclusion: In this newborn model, maintenance of CO during increased RV afterload is *not* obtained by an increased end-diastolic volume (Frank Starling mechanism). Instead, the RV maintains its output by improving systolic function, known as homeometric autoregulation.

P478 Right and left diastolic ventricular dysfunction in primary pulmonary hypertension: an echocardiographic and radionuclide study

C. Selton-Suty, F. Chabot, P. Houplon, N. Delorme, P.Y. Marie, J.M. Polu, Y. Juillière. *Cardiology and Pneumology, CHU Nancy-Brabois, Nancy, France*

Primary pulmonary hypertension (PPH) induces RV systolic dysfunction but few data exist regarding RV and LV diastolic function. To assess both RV and LV diastolic functions in PPH, we compared 12 normal pts (gr 1: 6 M/6 F, 40 ± 15 yrs) to 22 pts (gr 2: 5 M/17 F, 51 ± 14 yrs, ns for sex and age) with PPH. Radionuclide determination of RV and LV peak filling rate (PFR) and EF, and echocardiographic measurements of pulsed wave Doppler indexes of RV and LV diastolic function (E max and A max) were performed. We also recorded RV and LV inflow by colour M-mode to assess RV and LV flow propagation velocity (FPV).

Results:

		Group 1	Group 2	p value
LV function:	LV EF (%)	68 ± 9	61 ± 12	ns
	Mitral E (m/s)	0.78 ± 0.21	0.57 ± 0.25	0.02
	Mitral A (m/s)	0.63 ± 0.21	0.67 ± 0.10	ns
	Mitral E/A	1.32 ± 0.48	0.74 ± 0.22	0.001
	LV FPV (cm/s)	72.7 ± 20.2	45.4 ± 18.8	0.003
	LV PFR	4.1 ± 0.9	2.3 ± 0.7	0.003
RV function:	RV EF (%)	58 ± 6	33 ± 10	0.0001
	Tricuspid E (m/s)	0.57 ± 0.21	0.58 ± 0.29	ns
	Tricuspid A (m/s)	0.44 ± 0.24	0.61 ± 0.13	0.03
	Tricuspid E/A	1.41 ± 0.44	0.80 ± 0.38	0.002
	RV FPV (cm/s)	42.0 ± 11.5	31.9 ± 8.0	0.02
	RV PFR	2.5 ± 0.5	1.7 ± 1.0	0.05

Both systolic and diastolic RV functions are severely depressed in primary pulmonary hypertension. Additional LV diastolic dysfunction exists and might be attributable to RV pressure overload causing leftward ventricular septal shift, thereby impairing LV filling.

P479 Prevalence of heart valve abnormalities in patients with pulmonary hypertension associated with intake of the appetite-suppressant drug menocil (aminorex)

Shahrzad Rezaie-Majd[1], Reinhard Horvat[3], Meinhard Kneussl[2], Irene Lang[1]. *[1]Department of Cardiology; [2]Pulmology; [3]Pathology, University of Vienna, Austria*

Recent reports have revealed an increased prevalence of mitral and aortic valve fibrosis and valvular incompetence in patients on the appetite suppressant drugs fenfluramine and phentermine (*fen-phen*). To test the hypothesis that pulmonary hypertension may be driven by a serotonin-dependent mechanism leading to carcinoid-like changes of the valve apparatus, we reviewed the autopsy reports, charts and echocardiograms of 137 patients newly diagnosed with primary pulmonary hypertension (PPH) in Austria between 1967 and 1985. Three patients had been on phentermine and three on preludin and were excluded from the analysis. Time to death was 132 months (13–348) for Menocil-PPH patients. In 58 patients a sufficient description of valvular morphology was available through autopsy reports. Six patients are alive and were examined by echocardiography.

Diagnosis	n	BMI (body mass index)	Mean PAP at diagnosis (mmHg)	PVR (dynes sec cm^{-5})
CTEPH	10	21.9 ± 3.5	52.6 ± 19.2	854 ± 523.6
Menocil PPH	60	30.3 ± 6.5	53.7 ± 18.5	528 ± 103.6
PPH	55	23.7 ± 4.2	64.1 ± 24	865.9 ± 176.8

Anoretic drug intake (months)	Valve condition (aortic [AV] and mitral valve [MV])
0	3 normal, 1 thickened MV
6–91	18 normal, 1 thickened MV, 4 thickened AV + MV
0	29 normal, 1 thickened MV + AV, 1 calcified MV

In two Menocil patients descriptions of extensive whitish thickenings of MV and AV and the right ventricular myocardium were found (time to death 48 months). Although the number of patients is small, and the analysis focused on patients with pulmonary hypertension, there is evidence of the kind of valvular pathology recently observed in patients on *fen-phen*.

P480 Determinants of pulmonary arterial wall morphology in patients undergoing the Ross operation (pulmonary autograft)

E.J. Birks, A. O'Halloran, M.H. Yacoub. *NHLI at Imperial College of Science, Technology & Medicine, London, UK*

Background: Following pulmonary autograft replacement of the aortic valve and root the pulmonary arterial wall is subjected to substantially higher pressures. There is concern about the progress of dilatation of the pulmonary arterial wall in patients due to the different morphology of that vessel compared to the aorta. In an attempt to clarify this issue we have examined the structure of the pulmonary artery (PA) wall and aorta in 18 patients undergoing the Ross operation at our institution and compared it to the structure of 8 organ donors.

Methods: *Autograft series:* Ages varied from 6–60 yrs, mean 36.1 yrs. Fourteen were male, 4 were female. The disease was endocarditis (4), aortic stenosis (7), aortic regurgitation (4), mixed aortic valve disease (2), previous VSD and aortic valve repair (1). The preoperative PA pressure was estimated to be normal in 14, slightly elevated in 2, moderately elevated in 1 and severely elevated in 1. The degree of pre operative aortic regurgitation was none in 3, mild in 4, moderate in 3 and severe in 8. *Donor series:* Ages varied from 29–65 yrs, mean 52 yrs. Three were male, 5 were female. Samples were taken from the anterior wall of the PA and aorta at operation. Media thickness was measured in each aorta and PA. Immunocytochemistry was performed using the primary antibodies Collagen I and III and sections were stained with Elastic von Gieson to measure the elastic fibre distribution. Distribution of staining was measured using image analysis. The fragmentation of the elastic fibres in the PA media was graded from 1 (no/little fragmentation) to 4 (severe).

Results: The aortic media was thicker than the PA media in both patient and donor populations. In the autograft series Collagens I and III showed more order in the aorta than in the PA, but were distributed similarly in both. The elastic fibre in all aortas showed little or no variation, whereas in PAs there was considerable variation in fragmentation. Fragmentation did not correlate with patient age, sex, primary diagnosis, symptom duration or pre operative degree of aortic regurgitation, but patients with higher pre operative PA pressures had lower fragmentation scores. To date there has been no correlation between PA structural parameters and subsequent regurgitation of the autograft.

Conclusions: In conclusion detailed PA wall composition is different from that of the aortic wall in our patients undergoing the autograft operation. There is wide variation in PA structure within our patients receiving autografts and these changes appear to be influenced by PA pressure. The implications of these findings on the long-term function of the autograft requires further evaluation.

P481 Prevalence of pulmonary hypertension in liver transplant recipients

N. Galiè[1], A. Manes[1], L. Cecilioni[4], B. Begliomini[2], C. Morelli[4], E. Jovine[3], G. Martinelli[2], A. Cavallari[3], A. Branzi[1]. *Institutes of [1]Cardiology; [2]Anesthesiology; [3]General Surgery; [4]Gastroenterology, University of Bologna, Italy*

Pulmonary hypertension (PH) defined as mean pulmonary artery pressure (PAP) > 25 mmHg at rest is a well recognised complication in patients with portal hypertension. In this setting, PH is considered to be due to the increase of cardiac output (hyperdynamic state) and/or to the increase of pulmonary vascular resistance.

Methods: to characterize pulmonary hemodynamics, a group of 352 liver transplant recipients underwent right heart catheterization with Swan-Ganz catheter after the induction of anesthesia and before skin incision for liver transplantation. 233 were males and 119 females, mean age was 46 ± 12 years. 202 (57%) patients had post-hepatitic cirrhosis, 30 (8.5%) had alchoolic cirrhosis, 27 (7.6%) had primary biliary cirrhosis and 93 (26%) had other conditions leading to liver transplantation.

Results: right atrial pressure (RAP), PAP, cardiac index (CI), pulmonary wedge pressure (PWP), pulmonary (PVR) and systemic vascular resistance (SVR) were as follows:

RAP mmHg	PAP mmHg	PWP mmHg	CI l/min/m2	PVR UR	SVR UR
8 ± 4	17 ± 6	9 ± 4	4.6 ± 1.6	1.1 ± 0.7	9.2 ± 3.8

PH was detected in 21 (6%) patients. In 9 (2.5%) of them an increase of PVR (PVR > 2 RU) was also present. An hyperdynamic state (CI > 3.5 l/min) was detected in 276 (78%) patients. RAP was increased (>7 mmHg) in 191 (54%) patients. In patients without PH, PAP correlated with RAP ($r = 0.65$, $p < 0.0001$) and PWP ($r = 0.62$, $p < 0.0001$) but not with CI. In patients with PH no correlations between PAP, filling pressures and CI were found.

Conclusions: 1) PH is present in a small percentage of candidates to liver transplantation; 2) hyperdynamic circulation is the most frequent hemodynamic condition; 3) in patients without PH, PAP is correlated with the filling pressures of the ventricles; 4) in patients with PH the increase of PAP is not related to hyperdynamic state and/or to filling pressures.

P482 Pulmonary arterial elasticity in the clinical practice

K. Karlocai, Z.S. Visontai[1], B. Mersich[1], G. Kovacs[1], G. Jokkel[1], M. Kollai[1]. *Cardiology, National Koranyi Institution, Budapest; [1]2nd Institute of Physiology, Semmelweis Medical University, Budapest, Hungary*

Since the introduction of sonographic techniques, the distensibility of the large elastic vessels can be studied under clinical conditions. The elastic behavior of the systemic large arteries has been well documented but less information is available about the pulmonary vessels. The aim of the present study was to determine the elasticity of the pulmonary artery, namely its pressure-diameter relationship and to investigate the effect of age on elastic parameters in humans.

Healthy volunteers (n = 7, 23 ± 3 years) and patients (n = 8, 55 ± 14 years) of our department of cardiology were studied. The pressure in the main left branch of the pulmonary artery was measured at right heart catheterization, while the diameter and its change with the pulse were measured simultaneously by ultrasound (3.5 MHz) from suprasternal position at rest and during light exercise. Dynamic distensibility (D_{dyn}) was determined using the pulse pressure, while the static distensibility (D_{stat}) was determined during exercise. Data are given as mean ± 1 SD.

We found that the end-diastolic diameter of the pulmonary artery was greater in older (>35 years) than in younger (<35 years) subjects (1.30 ± 0.18 vs 0.91 ± 0.09 cm; $p < 0.05$). In younger subjects D_{dyn} of the pulmonary artery was higher than of the systematic elastic arteries (normal range: 5–15 × 10^{-3} $mmHg^{-1}$). During exercise the pressure-diameter relationship shifted upwards, resulting in a further increased value of D_{stat} (39 ± 27 × 10^{-3} $mmHg^{-1}$). In older subjects D_{dyn} was considerably less (14 ± 11 × $10^{minus;3}$ $mmHg^{-1}$), and the pressure-diameter relationship shifted to the right, often indicating complete lack of D_{stat}.

It is concluded that pulmonary elasticity can be determined by ultrasound and that the age-related decrease of pulmonary distensibility is greater than that of systematic elastic arteries.

P483 Use of an echo-enhancer agent for the estimation of pulmonary artey pressure by Doppler echocardiography in patients with chronic obstructive pulmonary disease

X. Borras, F. Carreras, R. Leta, X. Güell, V. Plaza[1], J. Rubio[1], J. Sanchis[1], G. Pons-Llado. *Cardiology Dept, Hospital Sant Pau, Barcelona; [1]Pneumology Dept, Hospital Sant Pau, Barcelona, Spain*

Objective: to assess the added value of using an echo-enhancer agent (EEA) in the estimation of systolic pulmonary artery pressure (PAPs) by Doppler, provided the increase in the intensity of the Doppler signal of tricuspid regurgitation (TR) produced by the agent, in patients with chronic obstructive pulmonary disease (COPD).

Patients: 27 consecutive patients from the Pneumology Department were studied, all of them with COPD without clinical signs of congestive heart failure.

Methods: tricuspid valve flow was obtained by continuous wave Doppler (CWD) from a 4-chamber echocardiographic apical view. When an adequate spectral velocity curve allowing the determination of peak velocity (Vmax) was recorded, PAPs was calculated by application of the equation: PAPs = $4(Vmáx)^2 + 5$. The same procedure was repeated after the administration through a peripheral vein of a bolus of Levovist® (microparticles of galactose and palmitic acid) (2.5 g at a concentration of 200 mg/ml).

Results: In all cases but one a reliable signal of tricuspid valve flow was obtained. Basally, a Doppler signal of TR was detected in 21 patients (78%), in all cases of trivial or mild degree. The determination of Vmax and, thus, the calculation of PAPs was judged as appropriate in 14 patients (52%). After the administration of the EEA the TR Doppler signal intensity was greatly increased, allowing the calculation of PAPs in 24 cases (89%) ($p < 0.001$). Compared with the basal study, the recording of the velocity profile curve improved in 21/24 cases (88%), this allowing the measurement of Vmax with a higher degree of confidence and showing also a systematic underestimation of PAPs measurements in those 14 patients in whom PAPs could be measured both basally and after the use of the EEA (37 ± 10 vs. 51 ± 17 mm Hg, $p < 0.001$).

Conclusions: The use of an EEA in patients with COPD increases the sensitivity of CWD to detect Vmax form a Doppler signal of TR, this allowing the estimation of PAPs in 89% of cases. In those 14 patients in whom a comparison betweeen basal an enhanced determinations could be performed, a systematic underestimation of PAPs in the basal condition was observed, probably due to an unadvertedly insufficient signal intensity of the TR Doppler signal.

P484 Troponin I can predict the decision for thrombolysis in acute pulmonary embolism

F. Post, T. Voigtländer, B. Nowak, D. Peetz[1], D. Mertens, G. Hafner[1], H.-J. Rupprecht, J. Meyer. *II. Medical Clinic, University of Mainz; [1]Clinical Chemistry, University of Mainz, Germany*

Decision for thrombolysis (Lys) in acute pulmonary embolism is based on the presence of right ventricular overload (RO) and severity in clinical presentation. Troponin I (TnI) is a marker for myocardial injury which might be elevated in PE due to RO. In order to find out whether there is a correllation between the severity of PE and TnI we conducted a retrospective study on TnI in pulmonary embolism.

Method: We measured TnI levels in 46 patients with APE. The use of lys was left to the discretion of the physician in charge. For analysis patients were divided into 5 groups: (A) minor PE (PE, no RO, no systemic hypotension), (B) submassive PE (PE, RO and no systemic hypotension) and (C) massive APE (PE, RO and systemic hypotension) as well as TnI elevation (TnI+) and no TnI elevation (TnI−). The rate of lys (LR) between groups was compared.

Results: Table 1 shows results for class A-C, table 2 for TnI+ and TnI−.

Table 1

	A (n = 10)	B (n = 25)	C (n = 11)
TnI+	1	11	9
Lys	1	10	8
LR	10%	40%	72.7%

Table 2

	TnI+ (n = 21)	TnI− (n = 25)
Lys	15	4
LR	71.4%	16.0%

Of the TnI+ patients 3 did not receive lys due to contraindications. If these patients were excluded from analysis LR was be 83.3% for TnI+.

Conclusion: For the decision on use of lys in PE physicians often rely on clinical presentation and presence of RO. TnI is a good marker to select pat. that should receive lys on this basis ($p < 0.001$). It might be a useful marker for decision making of therapy in PE.

P485 Reversal by indapamide of monocrotaline-induced changes in the pulmonary circulation and in the right ventricle in the rat

W.A. Medawar, H.G. Kaspar, H.K. Ibrahim, A.U. Al-Tayeh, S.J. Nasr, M.E. El-Sabban, M.G. Nasser. *Depts. of Physiology & Internal Medicine, Pathology, Biology, and Human Morphology, Am. Univ. of Beirut, Lebanon*

This study investigated the sequence of structural and biochemical changes in the pulmonary circulation and in the right ventricle (RV) in Monocrotaline (MCT)-treated rats. The reversibility of these changes was tested using Indapamide (IND), a Ca^{2+} channel blocker with cardioprotective properties.

Methods: Pulmonary vascular lesions were initiated and sustained by one single s.c. injection of MCT 80 mg/kg. IND 0.1 m g/kg was given daily by gavage to MCT treated animals. (RV) ww, (LV) ww, lung ww/dw, total protein (TP) in mg/g RVdw and% medial thickness (MT) of pulmonary vessels were measured in controls, MCT- and (MCT + IND)-treated animals at one, two and three weeks respectively. The results are shown below.

	Control	MCT			MCT + IND		
		Week 1	Week 2	Week 3	Week 1	Week 2	Week 3
RV/LV × 10^3	282 ±7.54	289.1 ±8.5	331** ±19.6	325.8** ±10	276.32 ±11.8	291.8** ±3.83	284.4** ±3.9
LV/BW × 10^3	1.9 ±6 × 10^2	1.9 ±2 × 10^2	1.9 ±7 × 10^2	1.9 ±10^{-1}	1.9 ±8.5 × 10^2	1.9 ±8 × 10^2	1.92 ±4 × 10^2
Lung ww/dw	4.85 ±0.11	5.4** ±0.08	5.46 ±0.12	5.31** ±0.08	5.16** ±0.06	4.87++ ±0.08	4.87++ ±0.05
TP	738.7 ±26.4	685.5 ±20	520.1** ±18	619.8** ±24	639.6 ±23.24	580.5*+ ±25.2	820.7++ ±51.5
TC	47.8 ±1.67	55.6** ±0.9	58.06** ±1.2	56.32** ±1	50.92 ±1.57	53.6*+ ±0.97	51.58+ ±1.3
% MT	10.2 ±0.81	15.2** ±0.3	20.22** ±1	20.56** ±0.7	16.38** ±0.47	15.94**+ ±0.7	17.1**++ ±0.4

*$p < 0.05$, **$p < 0.01$ MCT- and (MCT + IND)-experiments compared to controls, +$p < 0.05$, ++$p < 0.01$ (MCT + IND)-compared to MCT experiments.

The results above show that MCT induced in parallel, an increase in RV/LV, lung wet/dry weight, TC and%MT. In contrast TP was reduced. IND reversed all above changes to control level except for%MT which IND only partially reversed but to a significant degree.

Conclusion: While it significantly reversed the vascular changes, (IND) completely abolished RV changes that resulted from MCT administration.

ACTIVATION OF VASCULAR SMOOTH MUSCLE: GROWTH FACTORS AND OTHER MEDIATORS

P486 Troglitazone inhibits mitogenic signaling by insulin in vascular smooth muscle cells

S. Goetze[1], X-P. Xi[2], K. Graf[1], W.P. Meehan[2], W.A. Hsueh[2], R.E. Law[2], E. Fleck[1]. *[1]Department of Medicine/Cardiology, Charite, CVK, Humboldt Universität Berlin; Deutsches Herzzentrum Berlin, 13353, Berlin, Germany; [2]University of California, Los Angeles CA; School of Medicine, Division of Endocrinology, Diabetes and Hypertension, 90095, Los Angeles CA, USA*

Troglitazone (TRO) is an oral insulin-sensitizer which improves glucose utilization by skeletal muscle and adipose tissue. In vascular smooth muscle cells (VSMC), insulin transduces a mitogenic signal that is dependent on the extracellular signal regulated kinases 1 and 2 (ERK 1/2). We examined the effects of TRO on this pathway and found that it inhibits mitogenic signaling by insulin in VSMC. Insulin (1 μmol/L) stimulated DNA synthesis, measured by BrdU-incorporation, in quiescent VSMC by 3.2-fold. Treatment with TRO (1–20 μmol/L) inhibited insulin-induced DNA synthesis in a dose-dependent manner, leading to a 72.8% inhibition at the maximal concentration. TRO at 1 and 10 μmol/L had no significant effect on insulin-stimulated ERK 1/2 activity. At 20 μmol/L, however, TRO surprisingly enhanced insulin-stimulated ERK 1/2 activity by 1.5-fold. Mitogenic signaling through the ERK 1/2 pathway involves translocation of ERKs to the nucleus, where they phosphorylate transcription factors such as Elk-1 which regulate critical growth response genes. In transfection experiments using GAL-Elk-1 chimera expression plasmids, TRO at 1–20 μmol/L inhibited insulin-stimulated, ERK 1/2-dependent Elk-1 transcription factor activity. In contrast, TRO had no effect on events in the insulin-stimulated association of PI3 kinase and IRS-1. TRO is a known ligand for the nuclear transcription factor peroxisome proliferator-activated receptor gamma (PPARγ), and may exert its antiproliferative effects through the activation of this nuclear receptor. Two other PPARγ ligands rosiglitazone (RSG) and 15-deoxy-$\Delta^{12,14}$-prostaglandin J2 also inhibited insulin-induced DNA synthesis. In summary, these data show that TRO inhibits mitogenic signaling by insulin at a point distal. of ERK 1/2 activation, potentially by a PPARγ-mediated inhibition of ERK-dependent phosphorylation and activation of nuclear transcription factors.

P487 Latent transforming growth factor-beta (TGF-β) binding proteins: a role in targeting TGF-β following arterial injury

S. Sinha, C.M. Kielty, A.M. Heagerty[1]. *Wellcome Trust Centre for ECM research, University of Manchester, Manchester; [1]Department of Medicine, University of Manchester, Manchester, UK*

Background: TGF-beta1 has a key role in wound healing and in the arterial response to injury. However, the processes governing the distribution and activity of this multifunctional cytokine in vivo remain poorly understood. LTBPs, members of the fibrillin superfamily of matrix proteins, are thought to regulate TGF-beta1 release, targeting and activation in vitro. Thus, after vascular injury, LTBPs may play an important role in controlling TGF-beta1 availability and function while also forming essential components of the extracellular matrix.

Methods and Results: We investigated the upregulation, distribution and processing of LTBP isoforms 1 and 2 and their association with TGF-beta in vivo in a porcine model of coronary artery balloon injury and ex vivo using organ cultures of injured coronary arteries (1 week post angioplasty). Using immunohistochemistry, we detected LTBP1 in the thrombus acutely after injury and upregulation of both LTBP1 and LTBP2 in the neointima and neoadventitia at 1 and 2 weeks post-angioplasty. These isoforms co-localised with TGF-beta. Immunoprecipitation from 35S-radiolabelled organ cultures confirmed an increase in the synthesis of LTBP1 and 2 in injured vessels compared to uninjured controls. Unlike LTBP2, multiple proteolytically processed forms of LTBP1 were found. Plasmin digests of matrix released newly incorporated LTBP1. On Western blotting latent TGF-beta1 was found to be associated with LTBP1 through a disulfide bond.

Conclusions: LTBPs are significantly upregulated following arterial injury. Differential processing of the isoforms implies different roles for LTBP1 and LTBP2. Association of latent TGF-beta1 and LTBP1 plus the ability to release LTBP1 from the matrix by proteolysis suggests that this isoform may control TGF-beta1 targeting and provide an extracellular reservoir of latent growth factor after coronary angioplasty.

P488 Human vascular smooth muscle cells take up aggregated LDL through the low-density lipoprotein receptor-related protein

V. Llorente, J. Martinez-Gonzalez[1], L. Badimon[1]. *Cardiovascular Laboratory, Cardiovasc.Res.Cter.IIBB/CSIC-HSCSP, Barcelona; [1]Cardiovascular Laboratory, Cardiovasc.Res.Cter-IIBB/CSIC-HSCSP, Barcelona, Spain*

One of the main events in the atherogenic cascade is the lipid deposition. The internalization of modified LDL by macrophages and vascular smooth muscle cells (VSMC) produces cholesteryl ester (CE) accumulation, the hallmark of foam cell formation. Macrophages become foam cells through the uptake of diverse modified LDLs, whereas aggregated LDL (agLDL) seems to be a key condition for lipid accumulation in VSMC. While in atherosclerotic plaque scavenger receptors are mainly expressed in macrophages, low density lipoprotein receptor-related protein (LRP) is highly associated to VSMC. The aim of this study was to analyze whether LRP mediates the uptake of agLDL by VSMC.

Methods: Cultured human VSMC were obtained from human aortas of explanted hearts at transplant operations performed at the Hospital de la Santa Creu i Sant Pau. Human LDL was aggregated by vortexing and labeled with 1,1′-dioctadecyl-3,3,3′,3′-tetramethylindocarbocyanine (DiI). Binding experiments were performed by incubating VSMC with DiI-LDL (native or ag-) at 4°C for 30 min followed by the internalization during 4 h at 37°C. Following DiI-LDL incubation, several samples were stained with anti-LRP antibodies to analyze the colocalization of DiI-LDL and LRP. The free and esterified cholesterol content of VSMC was analyzed by thin layer chromatography after 18 hours incubation with lipoproteins.

Results: The CE content of VSMC treated with 100 μg/ml of agLDL increased 70-fold over that in VSMC incubated with the same concentration of native LDL. Co-incubation of agLDL with anti-LRP antibodies decreased in a dose-dependent manner agLDL derived CE accumulation (from 20% at 12.5 μg/ml to 80% at 50 μg/ml) in VSMC. By the contrary, anti-LDL receptor antibodies did not show any effect. Lactoferrin (25 μg/ml), an agonist of low density lipoprotein receptor-related protein (LRP), strongly inhibited CE accumulation from agLDL (>85 ± 5.69%). Fluorescence microscopy analysis using agLDL labeled with DiI indicates that lactoferrin impairs agLDL binding. Confocal microscopic analysis using DiI-agLDL and antibodies against LRP indicates a colocalization of agLDL and LRP.

In conclusion: These results indicate that LRP is the receptor involved in the uptake of agLDL by human VSMC. Since LRP is highly expressed in atherosclerotic plaques and subendothelial LDL retention and aggregation are key events in atherogenesis, uptake of agLDL through LRP could have a crucial role in VSMC-lipid deposition in atherosclerotic lesions.

P489 Urokinase plasminogen activator/receptor expression precedes arterial contracture in a porcine model of coronary artery injury

K. Pels[1,2], M. Labinaz[1], H.-P. Schultheiss[2], E.R. O'Brien[1]. *[1]University of Ottawa Heart Institute, Ottawa ON, Canada; [2]Dep. of Cardiology, Benjamin Franklin Hospital, FU Berlin, Germany*

Current theories of arterial response to coronary injury highlight the role of the adventitia in arterial remodeling and the development of lumenal narrowing. Urokinase plasminogen activator and its receptor (uPA/R) are important molecular mediators of tissue remodeling through proteolytic and non-proteolytic functions. The purpose of our study was to examine the expression of uPA/R and its correlation with changes of arterial wall structure and lumenal narrowing after coronary angioplasty. Porcine coronary arteries were examined on days 3, 7, 14 and 28 after arterial injury using in situ hybridization and image analysis. Within 3–7 days after balloon injury, uPA/R mRNA was overexpressed particularly in adventitial myofibroblasts. At later time points uPA/R expression was absent. Adventitial dense connective tissue (ADCT) increased dramatically 3 days after injury, associated with an increase in external elastic lamina area (EELA) and lumenal area (LA). Later on (day 14) adventitial fibrosis occurred and EELA and LA decreased.

(mm^2)	Control	Day 3	Day 14
ADCT	0.7 ± 0.11	2.2 ± 1.65*	3.1 ± 0.89*
EELA	2.8 ± 0.70	6.6 ± 2.2*	3.3 ± 0.3
LA	1.9 ± 0.6	5.1 ± 2.1*	1.4 ± 0.3

[*$p < 0.05$ injury vs. control]

Early adventitial uPA/R expression correlates with an increase in ADCT, EELA and LA. Downregulation of uPA/R later after injury coincides with an decrease in EELA and lumenal narrowing. Adventitial contracture after coronary injury may be controlled in part by modulation of arterial wall structure through uPA/R system.

P490 Temporal modulation of negative growth regulators during development of vascular smooth muscle

L. Fan, D. Feng, K.L. March. *Krannert Institute of Cardiology, Indiana University School of Medicine, Indianapolis, USA*

Temporal control of cell cycle exit in concert with differentiation is of key importance. We have previously demonstrated that conditionally-transformed smooth muscle cells (TsT-SMC) from adult transgenic mice expressing a temperature-sensitive mutant of the SV40 T antigen (tsA58) under control of the mouse vascular SMC alpha-actin promoter exhibit increased expression of the smooth muscle marker myosin heavy chain upon TAg inactivation, in conjunction with an increase in hypo-phosphorylated RB protein. To gain further insight into the role of negative growth regulatory proteins in smooth muscle differentiation and cell cycle exit, expression of smooth muscle markers as well as growth regulators was explored in tissue and cell populations derived from these mice as a function of development. Immunostaining and co-immunoprecipitation were performed for protein presence and Tag interaction. Immunoprecipitation demonstrated interaction of TAg in aortic cells with each of the negative growth regulators pRB, p107, p130 and p53. Progressive loss of PCNA occurred from tissue obtained at embryonic day 18, to neonatal day 1, into adulthood, correlating with reduction in proliferation. This was paralleled by a small increase in p130 level, a progressive increase in apparent molecular weight of the p107 immunoreactive band, and a remarkable increase (10-fold) in the expression of pRB. Smooth muscle markers increased their expression in parallel, including myosin heavy chain 204. These data further support that the expression and function of pRB, in particular among its homologs, may play an important role in the cell cycle exit and differentiation of vascular smooth muscle during normal development of thoracic aorta.

P491 Dynamic gene expression of proprotein convertases and their putative substrate precursor proteins in rat aorta organ culture

P. Stawowy[1,3], J. Marcinkiewcz[1], K. Graf[3], M. Chrétien[1,2], E. Fleck[3], M. Marcinkiewcz[1]. *[1]Lab. of Molecular Neuroendocrinology, Clinical Research Institute of Montreal, H2W 1R7, Montreal PQ; [2]Loeb Health Research Institute, K1Y 4K9, Ottawa ON, Canada; [3]Medicine/Cardiology, Chartié, Humboldt-University Berlin and German Heart Institute Berlin, 13353 Berlin, Germany*

The involvement of growth factors (GFs) in arterial pathology (e.g. atherosclerosis) is well established. Most of these proteins require posttranslational processing by proprotein convertases (PCs), which can potentially control their activation. These enzymes include members of the family of subtilisin/kexin-like mammalian PCs with specificity to Arg↓, as well as the novel enzyme SKI-1 with specificity to Ala↓ and Thr↓ at the cleavage site. We investigated the gene expression of PCs in rat aorta, using an organ culture system (serum-free DEMEM; 0, 4 and 24 h), which maintains cell-cell/cell-matrix interactions. Induction of cell proliferation and organ viability was assessed by PCNA immunoblotting, demonstrating the increase over time. Furthermore, PCNA immunostaining was localized to vascular smooth muscle cells (VSMCs) of aorta cultured for 24 h. As demonstrated by western blot analysis, PC5 isoform A and PC7 were present in tissue extracts, whereas shed PC5 isoform B was detected at 4 h (peak) and 24 h in culture medium (CM). PC7 was not found in CM. SKI-1 was found only after 24 h in tissue extracts and CM. Furin was detected at all time points and could not be found in CM. Other convertases, such as PC1 and PC2 were undetectable. Injury related GFs, like NGF, PDGF-A and TGF-beta 1 were released into CM and found in tissue extracts. Immunohistochemical detection of PCs was generally weak in normal arteries, mainly localizing to VSMCs at the adventitial border. In the rat aorta organ culture, PCs immunoreactivity increased and was found thoughout the medial layer in VSMCs, colocalized with proliferating VSMCs. In conclusion, this is the first report, demonstrating that several PCs are present in arteries and that their gene expression displays a dynamic course with the induction of VSMCs and their potential substrates (injury related GFs).

P492 Troglitazone inhibits all-induced ERK 1/2 nuclear translocation and activation in vascular smooth muscle cells

S. Goetze[1], X-P. Xi[2], K. Graf[1], W.A. Hsueh[2], R.E. Law[2], E. Fleck[1]. *[1]Department of Medicine/Cardiology, Charite, CVK, Humboldt Universität Berlin; Deutsches Herzzentrum Berlin, 13353 Berlin, Germany; [2]University of California, Los Angeles CA; School of Medicine, Division of Endocrinology, Diabetes and Hypertension, 90095, Los Angeles CA, USA*

Angiotensin II (AII) stimulates vascular smooth muscle cell (VSMC) proliferation and migration. These effects of AII are mediated via activation of the extracellular signal-regulated kinases 1/2 (ERK 1/2) and can be blocked by troglitazone (TRO), a novel antidiabetic agent. AII-induces ERK 1/2 activation in VSMC through the cytosolic PKCzeta → MEK → ERK pathway and the subsequent translocation of ERK into the nucleus, where ERK activates multiple transcription factors which modulate gene expression. To understand how TRO interferes with AII-induced mitogenic and chemotactic signal transduction, we examined the participating signaling events in rat aortic VSMC. We observed a significant increase in PKCzeta activity after stimulation with AII at 10 minutes and 2 hours, and a rapid and transient activation of cytosolic ERK 1/2 by AII at 10 minutes with a return to baseline levels at 2 hours. Nuclear translocation of ERK 1/2 was observed 10 minutes after stimulation with AII, with a further accumulation of total nuclear ERK 1/2 protein after 2 hours. This was accompanied by a marked increase in activated nuclear ERK 1/2. Although PKCzeta was constitutively present in the nuclear compartment and did not translocate upon stimulation with AII, we observed a significant increase in nuclear PKCzeta activity after AII treatment. TRO did not affect AII-induced activation of PKCzeta or its downstream signaling kinases ERK 1/2 in the cytosol. In contrast, AII-induced activation of PKCzeta and ERK 1/2 in the nucleus were both inhibited by TRO. Nuclear translocation of ERK 1/2 induced by AII was completely blocked by TRO. TRO, therefore, inhibits both AII-induced nuclear translocation and activity of ERK 1/2 and the nuclear activity of its upstream signaling kinase PKCzeta. Since ERK 1/2 nuclear translocation may be a critical signaling step for multiple growth factors that stimulate VSMC proliferation and migration, TRO may provide a new therapeutical approach for the prevention and treatment of atherosclerosis and restenosis.

P493 Expression of tumour necrosis factor-α and interleukine-6 in stenotic lesions of cholesterol fed rabbits after angioplasty

A. Dorszewski[1,2], G. Plenz[2], M. Deng[3], H. Robenek[2], G. Breithardt[1,2]. *[1]Department of Cardiology, Hospital of the University of Münster, Münster; [2]Institute for Arteriosclerosis Research at the University of Münster, Münster; [3]Department of Thoracic and Cardiac Surgery, Hospital of the University of Münster, Münster, Germany*

Cytokines mediate modulation of cellular functions, activation of macrophages and proliferation of smooth muscle cells (SMC) after balloon injury. They play a major role in inflammatory processes which are involved in development of restenosis and plaque rupture. Aim of our study was to investigate the expression pattern of preinflammatory cytokines-tumor necrosis factor-α (TNF-α) and interleukine-6 (IL-6) – in stenotic lesions of rabbits aortas after angioplasty.

Newzealand white rabbits (3.0–4.5 kg) received either normal chow (A; n = 4) or 1% cholesterol rich diet for 6 weeks (B; n = 3), or were treated as B and underwent balloon injury of the abdominal aorta (C; n = 5), or received the treatment as C and angiographically controlled angioplasty of stenotic lesions (PTA) was performed 6 weeks after balloon injury. 1, 10 days and 5, 12 weeks after PTA (n = 5 each point of time) specimens were gained in regions of maximum plaque formation. Morphometry, immunhistochemistry and in-situ hybridisation were performed for evaluation.

In non-treated aortas (A) TNF-α and IL-6 mRNA were only erpressed in scattered cells in the subendothelium and adventitia. Cholesterol-diet (B) led to enhanced expression of TNF-α and Il-6 subendothelially and in inner medial layers. Stenotic lesions of balloon injured aortas (C) showed high transcription activity in areas of plaque cap and basis, mainly localized next to lipidloaden foam cells, less to SMC. 1 day after PTA (D) pronounced expression of IL-6 was observed in regions of plaque rupture, shoulder and cap, inner medial layers and medial/advential transition zone. TNF-α-mRNA expression was upregulated in all vascular layers, more pronounced in the neointima and media than in the adventitia. After 5 weeks the expression pattern of TNF-α-mRNA changes leading to upregulation in regions of cap and shoulder of plaques and areas of rupture of the internal elastic lamina. IL-6-mRNA revealed similar expression pattern, but more pronounced in plaque cap and shoulder. After 12 weeks expression pattern of TNF-α and IL-6 were mainly unchanged but less intense.

Distinct expression pattern of TNF-α and IL-6 were observed in the development of stenotic lesions, and especially macrophages, endothelial cells and SMC appear to influence the signal transduction. These results demonstrate the role of ongoing inflammatory processes in modulation of cellular functions and proliferation after vascular injury and in the development of restenosis.

P494 Locally-delivered oligodeoxynucleotides to mitogen activated protein kinase downregulate target protein and inhibit neointima formation following balloon angioplasty

B. Liu, M. Fisher, P.H. Groves. *Cardiovascular Sciences Research Group, Wales Heart Research Institute, UWCM, CF4 4XN Cardiff, UK*

Vascular smooth muscle cell (VSMC) proliferation has a central role in the formation of the arterial neointima, the characteristic pathological lesion of atherosclerosis, angioplasty restenosis and saphenous vein graft failure. Mitogen activated protein kinase (MAPK) is centrally involved in the downstream transduction of growth signals from a variety of receptors and thus represents a potential target for modifying this proliferative response. We have previously shown that antisense oligodeoxynucleotides (ODN) directed against MAPK (AMK) down-regulate the target protein and inhibit proliferation of VSMC in vitro. In this study we investigated the effects of AMK on in vivo MAPK expression and neointima formation in a porcine model of angioplasty.

Methods: 11 Large White pigs (25–30 kg, female) were randomly divided into sense (n = 5) and antisense (n = 6) groups. Arterial injury was induced by high-pressure oversized balloon angioplasty in both carotids. AMK or matching sense ODN (SMK) was then introduced by liposomal transfection using a microporous delivery catheter. ODN concentration was 0.2 μM in all cases. In some animals fluorescein-labeled ODN was used to assess uptake. After 7 days, animals were sacrificed and the carotid arteries harvested. Some sections of artery were fixed for histological analysis and others frozen in liquid nitrogen for subsequent protein extraction. MAPK expression was assessed by Western blotting and neointima formation measured by computerized planimetry.

Results: Both cytoplasmic and nuclear uptake of fluorescein-labeled ODNs were noted in histological sections. Transfection of AMK resulted in a 43% decrease in MAPK expression compared with the sense ODN ($p < 0.01$; Fig. 1). This was matched by a significant reduction in both neointimal area and intimal/medial area ratio in the antisense group (Table).

	Sense (n = 5)	Antisense (n = 6)
Intimal area (mm^2)	0.043 ± 0.002	0.038 ± 0.005**
Intimal/Media ratio	0.022 ± 0.007	0.017 ± 0.008*

Data represent mean ± s.e.m. Compared with sense group, $^{**}p < 0.01$, $^{*}p < 0.05$

Figure 1. Representative Western blot showing downregulation of MAPK by antisense ODNs.

Conclusion: Antisense ODNs to MAPK down-regulated the expression of MAPK and inhibited neointima formation following porcine carotid angioplasty. The data indicate that MAPK is important in regulation of VSMC proliferation following arterial injury and suggest that its downregulation may have therapeutic potential in limiting the response to injury.

P495 Differential activation of mitogen-activated protein kinases in smooth muscle cells by angiotensin II: involvement of free radical generation via NAD(P)H-oxidase

C. Viedt, U. Soto[2], H.I. Krieger-Brauer[1], M. Werle, L. Jahn, J. Kreuzer. *Innere Medizin III; [1]Innere Medizin I, University of Heidelberg, Heidelberg; [2]Deutsches Krebsforschungszentrum, Heidelberg, Germany*

Background: The atherogenic effect of the renin-angiotensin system can be explained in part by the influence of its effector, angiotensin II (Ang II) on vascular smooth muscle cell (VSMC) growth. Previous reports have shown that Ang II can stimulate O_2^- levels from rat smooth muscle cells via NAD(P)H oxidase and there is evidence that reactive oxygen species (ROS) plays a role in the pathogenesis of atherosclerosis. We propose that Ang II atherogenicity may be mediated in part by ROS-dependent signals, activating mitogen-activated protein (MAP) kinases which are involved in proliferation and differentiation.

Methods and Results: Rat vascular SMC were stimulated with Ang II. The activities of mitogen-activated protein (MAP) kinases were measured by Western blot analysis or by immunocomplex kinase assay. Activator protein-1 (AP-1) binding was determined using an electrophoretic mobility shift assay. Treatment of rat SMC with Ang II resulted in rapid formation of ROS and activation of *extracellular signal regulated* (ERK), *c-Jun amino terminal kinase* (JNK) and p38MAPK, and their downstream effector, AP-1. Ang II-induced activation of p38MAPK, JNK and ERK1/2 was inhibited by the type 1 Ang II-receptor blocker losartan, but not by the type 2 Ang II-receptor antagonist PD123319. Interestingly, only the activation of ERK$\frac{1}{2}$, but not JNK and p38MAPK, was tyrosine kinase, PKC and MEK1/2 dependent. Ang II also induced the rapid formation of ROS, which could be inhibited by a specific antibody against the p22phox subunit of the NAD(P)H-oxidase. JNK and p38MAPK, but not ERK activation was inhibited by an antioxidant and an inhibitor of NAD(P)H-oxidase.

Conclusions: The results indicate that in vascular smooth muscle cells, Ang II activates MAPK and AP-1 through different pathways and suggest that ROS, generated by p22phox mediate Ang II-induced JNK and p38MAPK activation, which may contribute to the pathogenesis of atherosclerosis.

P496 TGF-β1, TGF-β2, and MCP-1 secretions respond to irradiation in a dose dependent manner in cultured smooth muscle cells

A.T. Nguyen, H.P. Stoll, W.L. Winkle, G.D. Hutchins, K.L. March[1]. *Indiana University, Indianapolis IN; [1]Roudebush VA Medical Center, Indianapolis IN, USA*

The TGF family of cytokines is known to influence tissue fibrosis and remodeling as well as smooth muscle cell differentiation. Adventitial or medial cells are thought to trigger the restenosis process by cytokine secretion. We used a cell culture model to study the impact of radiation on cytokine secretion and cell proliferation utilizing the positron emitter Ga-68 we proposed earlier for liquid-filled balloon brachytherapy. Bovine smooth muscle cells were plated at confluence, growth arrested at 72 hourspost plating, and subsequently irradiated with Ga-68 at doses ranging from 1 to 12 Gy. The activity was delivered into cell culture wells and exposed in contact with the bottom of the insets holding cultured cells. Dosimetry was established by irradiating GAF-chromic film under the same geometry. Irradiated cells were replated at 10000/cm^2. At multiple time points, cells were counted with Trypan blue staining and media conditioned for 4 days were assayed for TGF-beta1 (TGF-B1), -beta2 (TGF-B2), and macrophage chemotactic protein (MCP-1) by ELISA. Cytokine concentrations were normalized to cell counts.

Dose (Gy)	Cell Count (1000/cm^2)	TGF-B1	TGF-B2 (pg/1000 cells)	MCP-1
0	118 ± 1.7	37.4	5.6	33
1	92 ± 2.1	42.6	10.1	31.4
3	71 ± 0.2	49.2	15.4	4.9
6	12 ± 0.2	104	75.3	0.0
12	7 ± 0.2	130	120	0.0

ED50 was approximately 5 Gy for TGF-beta1, 6 Gy for TGF-beta2, and 2 Gy for MCP-1. Irradiated smooth muscle cells in culture show growth inhibition, upregulation of TGF-beta1/2, and downregulation of MCP-1 in a dose dependent manner. We hypothesize that the efficacy of brachytherapy is in part modulated by cytokine-mediated smooth muscle cell differentiation and macrophage chemoattraction.

P497 Effects of all-trans-retinoic acid after local delivery in the rabbit carotid artery

C. Herdeg, M. Oberhoff, A. Baumbach, A. Blattner, D.I. Axel, S. Schroeder, K.R. Karsch. *Dept. of Cardiology, Div. Of Medicine, University of Tübingen, Tübingen, Germany*

Retinoids regulate a variety of biological processes and play an important role in the homeostasis of cell differentiation and proliferation. The broad biological spectrum, however, leads to many severe side effects and limits the clinical use of retinoids. Local delivery of all-trans-retinoic acid (atRA) for the prevention of restenosis might be a way of exploiting the potent pharmacological properties of this compound while concurrently minimizing systemic side effects.

This hypothesis was tested in an experimental rabbit angioplasty model. After induction of a fibromuscular plaque in the right carotid artery of 45 New Zealand rabbits, 30 animals underwent balloon angioplasty of the preformed plaque formation. Subsequent local atRA delivery (10 ml, 10 μmol/L) with the double balloon catheter was performed in 15 animals. 10 animals were solely electrostimulated and 15 animals served as control group with balloon angioplasty only. 5 sham-operated animals received vehicle without atRA. Vessels were excised 7 days (n = 15) and 28 days (n = 20) after intervention. Immunocytochemistry with antibodies against alpha-actin, bromodeoxyuridine, macrophages collagen I, III and von Willebrand factor was performed.

Results: After local atRA delivery in vivo, the extent of stenosis increased slightly from 18.6 ± 7.7% (1 week) to 21.7 ± 8.3% 4 weeks after intervention compared to 31.8 ± 13.4% in balloon-dilated animals. Immunozytochemistry revealed an inhomogenous staining pattern after local atRA delivery in the α-actin- and BRDU-stained histologies indicating potential effects of atRA on cell proliferation and differentiation.

Conclusions: In this study, atRA was a potent inhibitor of smooth muscle cell proliferation in vivo. Local atRA delivery led to a better preservation of vessel shape and might be a promising strategy for the prevention of restenosis.

P498 Galectin-1 modifies growth of vascular smooth muscle cells

E.P. Moiseeva, Q. Javed, E.L. Spring, J.H. Baron, D.P. De Bono. *Division of Cardiology, University of Leicester, Leicester, UK*

We investigated the role of the matricellular protein galectin-1 (Gal-1), beta-galactoside-binding lectin, in smooth muscle cell (SMC) proliferation in atheroma and in SMC anchorage-dependent growth in cell culture.

Gal-1 expression in human coronary endarterectomy samples was visualized by tissue section immunostaining with anti-Gal-1 antibody. Anchorage-dependent growth of human vascular SMCs was determined by ^{3}H-thymidine incorporation. Recombinant Gal-1 fusion protein (Gal-1FP) binding to extracellular matrix (ECM) proteins was measured by ELISA. Gal-1 binding to SMCs and ECM of SMCs was estimated by the binding of 125I-labelled-Gal-1FP in cell culture.

Gal-1 is upregulated in endarterectomy samples cultured for 7 days in the presence of serum. Prominent Gal-1 staining coincided with the PCNA expression in SMCs. In cell culture Gal-1 FP increased anchorage-dependent growth of SMCs compared to cell growth on plastic or endogenous ECM (130% and 118%, $p < 0.01$ and $p < 0.05$ respectively). Gal-1 FP increased anchorage-dependent growth of SMCs on thrombospondin (TSP) (164%, $p < 0.01$) and osteopontin (OSP) (167%, $p < 0.01$), but decreased cell growth on laminin (LN, 73%, $p < 0.01$%). Gal-1 FP binding to ECM proteins was in the order: LN = cellular fibronectin > TSP > plasma fibronectin. The binding of Gal-1 FP to SMCs was fifty times stronger than to ECM, produced by these SMCs.

In conclusion, Gal-1 is upregulated during atherosclerotic SMC proliferation and modulates anchorage-dependent growth of SMC, with differing effects depending on the ECM protein substrate.

P499 Different kinetic properties of endothelin-1 binding between ETA and ETB receptor subtypes

S. Vanni, P.A. Modesti, R. Paniccia, B. Bandinelli, M. Maccherini[1], G. Sani[2], G.G. Neri Serneri. *Clinica Medica Generale e Cardiologia, University of Florence, Florence; [1]Thoracic and Cardiovascular Surgery, University of Siena, Siena[2]Department of Cardiosurgery, University of Cagliari, Cagliari, Italy*

At present several studies investigated the characteristics of endothelin-1 binding in human heart but informations about cell type distribution and kinetic properties of the two endothelin receptor subtypes are laking. Aim of the present study was to investigate cell type distribution and kinetic properties of ET-1 receptor subtypes in left ventricles obtained from 5 healthy donors whose hearts were not suitable for transplantation for non cardiac reasons. [125I]-ET-1 binding studies were performed with ETA (BMS-182874) and ETB (BQ-788) selective antagonists on both ventricular membranes and enzymatically isolated cardiomyocytes. In situ hybridization studies with specific cDNA probes (ETA ATCC 105194 and ETB, ATCC 1250426) investigated cell distribution of mRNA for ETA and ETB receptors in left ventricular sections.

In competition studies BMS-182874 selectively and competitively displaced [125I]-ET-1 (2,000 Ci/mmol) binding with about 1300 times greater affinity for ETA than ETB subtypes both on ventricular membranes and isolated myocytes. The [125I]-ET-1 specific binding revealed 42,851 ± 2,546 receptors/myocyte with a prevalent proportion of ETA receptor subtypes both on myocytes (84 ± 2%) and ventricular membranes (64 ± 2%). In situ hybridization studies revealed that mRNA for ETA receptors was expressed both on myocytes and non-myocyte cells, whereas mRNA for ETB receptors was almost exclusively expressed on fibroblasts and endothelial cells.

In kinetic experiments specific binding of ET-1 to both ventricular membranes and myocytes in the presence of specific ETA and ETB receptor antagonists showed a different time course: association and dissociation phases were significantly shorter for ETB than for ETA ($p < 0.01$) without differences in the final calculated dissociation constant as confirmed by equilibrium binding studies.

In conclusion: 1) ET-1 receptor subtypes have different cell type distribution in human left ventricle because cardiomyocytes mainly express the ETA subtype. 2) the ETA subtype showes a more delayed and stable ET-1 binding than the ETB subtype. This suggests a clearance function of ETB receptors.

P500 TNFα inhibits insulin-signaling pathways in vascular smooth muscle cells

S. Goetze[1], H. Kawano[2], Y. Kawano[2], W.A. Hsueh[2], R.E. Law[2], E. Fleck[1]. *[1]Department of Medicine/Cardiology, Charite, CVK, Humboldt Universität Berlin; Deutsches Herzzentrum Berlin, 13353 Berlin, Germany; [2]University of California, Los Angeles CA; School of Medicine, Division of Endocrinology, Diabetes and Hypertension, 90095, Los Angeles CA, USA*

Tumor necrosis factor alpha (TNFα) interferes with insulin signaling in adipose tissue and may promote insulin resistance. Insulin binding to the insulin receptor (IR) triggers its autophosphorylation, resulting in phosphorylation of Shc and the downstream activation of p42/p44 MAP-kinase (MAPK), which mediates insulin-induced proliferation in VSMC. Since insulin resistance is associated with vascular alterations, we examined the effects of TNFα on mitogenic signaling by insulin. In rat aortic VSMC, insulin (1 μmol/L, 5 min) induced rapid phosphorylation of the IR and Shc and caused a 5.3-fold increase in activated, phosphorylated MAPK at 10 min ($p < 0.05$). Insulin induces a biphasic MAPK-activation with a transient peak at 10 min and a sustained late phase after 2 h. Preincubation (30–120 min) with TNFα had no effect on insulin-induced IR-phosphorylation. In contrast, pretreatment with TNFα transiently suppressed insulin-induced MAPK-activation (94% inhibition after 30 min and 89% after 60 min preincubation, $p < 0.05$). After longer exposure to TNFα (90–120 min), MAPK-activation was restored. Insulin-induced phosphorylation of Shc was inhibited by TNFα in a similar pattern. Moreover did pretreatment with TNFα for 30 min suppress not only the early phase, but the entire biphasic MAPK response to insulin. Since mitogenic signaling by insulin in VSMC requires MAPK-activation, we examined the effect of TNFα on insulin-induced proliferation. Insulin alone induced a 3.4-fold increase in DNA synthesis, that was inhibited by 48% when TNFα was added 30 min before insulin ($p < 0.05$). TNFα alone was not mitogenic. Inhibition of MAPK with PD98059 (30 μmol/L) also inhibited insulin-stimulated proliferation (57% inhibition; $p < 0.05$). In contrast to insulin, TNFα did not inhibit PDGF-induced MAPK-activation or DNA-synthesis in VSMC. Thus, TNFα specifically interferes with insulin-induced mitogenic signaling by inhibiting the phosphorylation of Shc and the downstream activation of MAPK.

P501 Endothelin induces inflammatory activation of human vascular smooth muscle cells

M. Browatzki, R. Kranzhöfer, W. Kübler. *Department of Cardiology, University of Heidelberg, Germany*

Acute coronary syndromes are associated with increased endothelin (ET) levels in plasma and within the atherosclerotic plaque. On the other hand, such syndromes are also characterized by systemic and local (at the site of the culprit lesion) inflammation. This study tetsted the hypothesis that ET promotes vascular inflammation by induction of cytokine release from vascular smooth muscle cells (SMC).

Methods: Human vascular SMC were stimulated with ET-1. Release of the cytokine interleukin-6 (IL-6) into the culture medium was quantified by ELISA. Levels of IL-6 mRNA in SMC were determined by RT-PCR. Activation of the proinflammatory transcription factor nuclear factor-κB (NF-κB) was examined using electrophoretic mobility shift assay.

Results: ET-1 (100 pM–1 μM) stimulated concentration-dependently IL-6 release by SMC up to 689 ± 41 pg/ml at 10 nM (control 288 ± 3 pg/ml, $p < 0.05$). This ET-1 effect was blocked by the ET receptor antagonist BQ-123, but not by BQ-788 (10 μM each), suggesting that ET-induced IL-6 release is mediated by the ET-A receptor. ET-1 also increased IL-6 mRNA indicating regulation of IL-6 release at the transcriptional level. Moreover, NF-κB, which is necessary for transcription of most cytokine genes, was activated by ET-1. The antioxidant pyrrolidine dithiocarbamate (10 μM) inhibited ET-1-induced IL-6 release indicating involvement of reactive oxygen species in ET-1 signaling.

Conclusion: The data suggest that endothelin may contribute to the pathogenesis of acute coronary syndromes by inflammatory activation of vascular SMC. Thus, inhibition of endothelin may be a novel strategy for treatment of acute coronary syndromes.

P502 The renin-angiotensin system may contribute to inflammatory activation of the vessel wall during atherogenesis

R. Kranzhöfer, M. Browatzki, J. Schmidt, W. Kübler. *Department of Cardiology, University of Heidelberg, Germany*

Clinical, experimental and genetic data suggest involvement of the renin-angiotensin system (RAS) in atherogenesis. Chronic inflammation of the vessel wall mediated by cytokines is a hallmark of atherosclerosis. This study tested therefore the hypothesis that the RAS induces inflammatory signals in vascular smooth muscle cells (SMC), the most abundant cell type in atherosclerotic tissue.

Methods: Human vascular SMC were stimulated with angiotensin (ANG). Release of the cytokine interleukin-6 (IL-6) into the culture medium was quantified by ELISA. Levels of IL-6 mRNA in SMC were determined by RT-PCR. Activation of the proinflammatory transcription factor nuclear factor-κB (NF-κB) was examined using electrophoretic mobility shift assay.

Results: ANG II (10 nM-1 μM) stimulated concentration-dependently IL-6 release by SMC up to 1037 $\pm$ 63 pg/ml at 1 μM (control 423 $\pm$ 106 pg/ml, n = 3 each, $p < 0.05$). This ANG II effect was blocked by the ANG receptor antagonist losartan (1 μM), suggesting that ANG II-induced IL-6 release is mediated by the ANG-AT1 receptor subtype. ANG I similarly stimulated IL-6 release by SMC. The effect was blocked by ACE inhibitors. ANG II also increased IL-6 mRNA indicating regulation of IL-6 release at the transcriptional level. Moreover, NF-κB, which is essential for transcription of most cytokine genes, was activated by ANG II. The antioxidant PDTC (10 μM) inhibited ANG II-induced IL-6 release indicating involvement of reactive oxygen species in ANG signaling.

Conclusion: The data suggest that the RAS may contribute to atherogenesis by inflammatory activation of the vessel wall. ACE inhibitors or ANG II-receptor antagonists could exert an anti-inflammatory action on the vessel wall.

P503 Endothelin-1 and activation of mitogen-activated protein kinases in smooth muscle cells: identification of an oxygen-radical-dependent mechanism

Jörg Kreuzer, Jianwei Fei, Christiane Viedt, Martina Werle, Lisa Watson, Lothar Jahn. *Medizinische Klinik III, Universität Heidelberg, Germany*

Background: Endothelin (ET-1) has been proposed to contribute to atherogenesis and plaque rupture in coronary heart disease. Plaque progression and destabilization has been associated with the inflammatory response of vascular smooth muscle cells (SMC). Mitogen activated protein kinases (MAPK) are strong candidate signal transducers for the activation of SMC. The present study aimed to determine if ET-1 also has a direct effect on the MAPK, c-Jun amino terminal kinase (JNK) and extracellular signal regulated kinase (ERK1/2) in addition to its traditional role in vasoconstriction.

Methods and Results: Rat SMC were exposed to ET-1 over time at concentrations from 10^{-6}-10^{-10} M and MAPK activity was quantitated. Activation of both JNK and ERK were observed, with a maximum stimulation at 10^{-7} M ET-1. Both kinases were activated by ET-1 binding to a single receptor (ET-1 1A) but differed in their downstream mechanisms: only JNK activation was sensitive to the radical scavenger N-acetylcysteine and the inhibitor of NADPH oxidase, DPI, indicating a role for reactive oxygen species (ROS). The downstream MAPK effector and proinflammatory transcription factor, the AP-1 complex, was shown to comprise mainly the JNK substrate c-Jun, and AP-1 activation was maximal at 2 h after addition of ET-1 and also dependent on ROS.

Conclusion: The data indicate a differential, ET-1 dependent mechanism of MAP-Kinase activation. Whereas JNK was preferentially activated through oxygen radicals, ERK activation appeared to be independent of radical formation. Activation of MAP-kinases in SMC may be one of the underlying mechanisms of plaque destabilization by ET-1.

P504 Atorvastatin attenuates angiotensin II-induced free radical release mediated by AT1 receptor down-regulation in vascular smooth muscle cells

S. Waßmann, G. Nickenig, A.T. Bäumer, M. Böhm. *Klinik III für Innere Medizin, University of Cologne, Germany*

HMG-CoA reductase inhibitors (statins) significantly reduce lipid-induced cardiovascular mortality. There is evidence that these drugs exert direct effects on vascular cells independent of lowering cholesterol concentrations. Therefore, the effect of atorvastatin (ator) on AT1 receptor (AT1-R) gene expression, cell proliferation, and release of reactive oxygen species (ROS) in vascular smooth muscle cells (VSMC) was investigated.

Methods: Rat aortic VSMC in culture were incubated with 1–10 μmol/l atorvastatin. AT1-R mRNA was assessed by Northern analysis, AT1-R density was measured with ^{125}I-angiotensin radioligand binding assays, DNA synthesis was assessed by ^{3}H-thymidine and BrdU incorporation, and the effect on angiotensin II (ang II)-induced release of ROS was measured with DCF fluorescence lasermicroscopy.

Results: Preincubation with ator for 12 h reduced significantly the ang II-induced release of ROS (115.3 $\pm$ 23.7% vs 146.4 $\pm$ 29.9 of controls). DNA synthesis was decreased to 58.9 $\pm$ 5.0% of control levels after 24 h incubation, and ang II-induced cell proliferation was attenuated by 29.9 $\pm$ 8.7%. AT1-R mRNA expression was down-regulated to max. 53.7 $\pm$ 2.0% of controls after 4 h incubation, and AT1-R density was decreased to 59.5 $\pm$ 13.3% of controls after 24 h incubation with ator (B_{max} 1424 $\pm$ 474 vs 823 $\pm$ 235; no change in K_D). Mevalonate but not hydroxy-cholesterol inhibited AT1-R mRNA down-regulation by ator.

Conclusion: Atorvastatin attenuates ang II-mediated release of ROS and decreases ang II-induced cell proliferation. This is governed through a direct down-regulation of AT1 receptor expression by atorvastatin. Our findings demonstrate direct effects of statins on vascular cells independent of plasma cholesterol levels. Statin-caused therapeutic benefits may in part be mediated through these effects, since VSMC proliferation, free radical release, and AT1 receptor regulation play a major role in the pathogenesis of atherosclerosis.

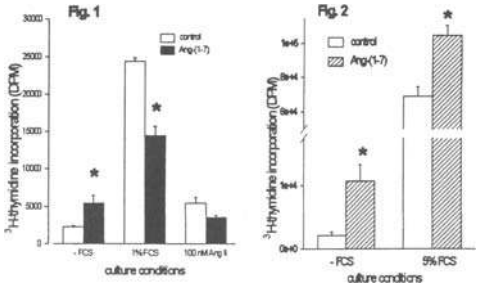
P505 Angiotensin-(1–7) changes the growth of human vascular smooth muscle and endothelial cells differentially

Anton J.M. Roks, Dieter M.M. De Cleen, Vincent F.M. Segers, J. Hendrik Buikema, Wiek H. Van Gilst. *Dept. of Clinical Pharmacology, University of Groningen, A. Deusinglaan 1, 9713 AV Groningen, Netherlands*

The renin-angiotensin system has two bio-active endproducts angiotensin II (Ang II) and angiotensin-(1–7) (Ang-(1–7)) which have opposite effects, compared to eachother. With respect to this, Ang-(1–7) inhibits vascular smooth muscle cells (VSMC) growth in animals. Its effects on human VSMC or on endothelial cells is unknown. We studied the effect of Ang-(1–7) on growth of human VSMC (HA-VSMC) and human endothelial cells (HUVEC).

Methods: HA-VSMC and HUVEC were made quiescent before each experiment. For HA-VSMC the effect of 1 μM Ang-(1–7) was studied under three circumstances: in absence of fetal calf serum (FCS), in the presence of 1% FCS, and in the presence of serum free medium with 100 nM Ang II. For HUVEC the effect of 1 μM Ang-(1–7) was studied under two conditions: in absence and in the presence of 5% FCS. Incorporation of [^{3}H]-thymidine was measured to quantify cell growth.

Results: Compared to serum free medium, 1% FCS induced a tenfold increase in [^{3}H]-thymidine incorporation in HA-VSMC and Ang II a 2.4 $\times$ increase (Fig. 1). In absence of FCS, Ang-(1–7) increased [^{3}H]-thymidine incorporation by 140% in HA-VSMC, whilst in the presence 1% FCS it inhibited growth by 40% (Fig. 1). In the presence of Ang II, growth was inhibited by 36% (Fig. 1). In HUVEC, [^{3}H]-thymidine incorporation was 32 times higher in cells grown on 5% FCS as compared to cells grown in absence of FCS (Fig. 2). In the absence of FCS, Ang-(1–7) increased [^{3}H]-thymidine incorporation in HUVEC by 400% (Fig. 2). In the presence of 5% FCS, it increased incorporation by 50% (Fig. 2).



Discussion: Ang-(1–7) can have a growth promoting as well as growth inhibiting effect in cardiovascular cells, depending on cell type and state. Thus, Ang-(1–7) may be involved in both the repair of endothelium and in angiogenesis, thereby fulfilling clinically benificial tasks.

P506 Hyperexpression and activation of stress-activated protein kinases/c-Jun NH2-terminal protein kinases (SAPK/JNK) in atherosclerotic lesions: role of LDL

Y. Hu, B. Metzler[1], H. Dietrich, Q. Xu[1]. *Institute for General and Exp. Pathol., University of Innsbruck, Innsbruck;* [1] *Institute for Biomedical Aging Res., Austrian Academy of Sciences, Innsbruck, Austria*

Hyperlipidemia alters gene expression of arterial endothelial and smooth muscle cells (SMCs) and induces atherosclerotic lesions, in which cell proliferation and apoptosis co-exist. The signal transduction pathways that mediate these responses in the vessel wall in vivo have yet to be identified. Stress-activated protein kinases (SAPK) or c-Jun NH2-terminal protein kinases (JNK) are thought to be crucial in transmitting transmembrane signals required for cell differentiation and apoptosis in vitro. In the present study, we investigated the activity, abundance and localization of SAPK/JNK in atherosclerotic lesions of cholesterol-fed rabbits. Immunohistochemical analysis revealed abundant and heterogenic distribution of SAPK/JNK, mainly localized in cell nuclei of the lesional cap and basal regions. Double-staining of the lesions demonstrated that a portion of a-actin+ SMCs contained abundant SAPK/JNK proteins. SAPK/JNK protein levels in protein extracts from atherosclerotic lesions were 2- to 3-fold higher than the vessels of chow-fed rabbits. SAPK/JNK kinase activities were elevated 3–5-fold over the normal vessel. Furthermore, LDL stimulated SAPK/JNK activation in cultured SMCs in a time- and dose-dependent manner. LDL also induced SAPK/JNK activation in vascular SMCs derived from LDL-receptor-deficient (Watanabe) rabbits. Heparin, which inhibits LDL-receptor binding, did not influence LDL-stimulated SAPK/JNK activation, indicating a LDL-receptor-independent process. Thus, SAPK/JNK persistently activated and hyperexpressed in lesions may play a key role in mediating cell differentiation and apoptosis in hypercholesterolemia-induced atherosclerosis.

P507 Urokinase induces activation and formation of Stat4 and Stat1–Stat2 complexes in human vascular smooth muscle cells

I. Dumler, A. Kopmann, K. Wagner, H. Haller, D.-C. Gulba. *Franz Volhard Clinic and Max-Delbrück Center for Molecular Medicine, Humboldt University at Berlin, Germany*

Urokinase (uPA) and its specific receptor (uPAR), act in concert to stimulate cytoplasmic signaling machinery and transcription factors responsible for cell migration and proliferation. Recently we demonstrated that uPA activates the Jak/Stat signaling in human vascular smooth muscle and endothelial cells, namely Janus kinases Jak1 and Tyk2 and signal transducer and activator of transcription Stat1. However, the important question whether other transcription factors of the Stat family, in addition to Stat1, are involved in the uPAR-related signaling has not been addressed. In this study, we demonstrate that Stat4 and Stat2, but not Stat3, Stat5 or Stat6, are rapidly activated in response to uPA. We demonstrate further using electrophoretic mobility shift assay and confocal microscopy study, that Stat4 and Stat2 rapidly and transiently translocate to the cell nuclei where they bind specifically to the regulatory DNA elements. Analysis of Stat complexes formed in response to uPA, revealed Stat2-Stat1 heterodimer which lacks p48, a DNA binding protein known to combine with Stat1-Stat2. This new uPA-induced Stat2-Stat1 heterodimer binds to interferon (IFN)-g activation site (GAS) distinct from the IFN-stimulated response element (ISRE) to which the p48 protein containing complexes generally bind. We conclude that uPA activates a specific and unusual subset of latent cytoplasmic transcription factors in human vascular smooth muscle cells that suggests a critical role of uPA in these cells. Our finding that physiological concentration of uPA induces Stat4 activation is, to our knowledge, the first indication that there is at least one more natural ligand for the Stat4 protein beyond IL-12.

P508 Nifedipine induces a pro-atherogenic effect on smooth muscle cells in culture, incubated with LDL isolated from patients with coronary diseases

M. Raicu, A. Sima, D. Toporan[1], C. Stancu, T. Protopopescu[1], A. Ioan[1], M. Simionescu. *Institute of Cellular Biology and Pathology "N. Simionescu", Bucharest;* [1] *"St. Pantelimon" Hospital, Clinic of Cardiology, Bucharest, Romania*

Our previous results have demonstrated the Nifedipine ineffectiveness in prevention of atheroma formation in atherosclerotic hamsters. The aim of this study is the investigation of the effects induced by this calcium channel blocker on lipid loading of human aortic smooth muscle cells (SMC) incubated with serum or lipoproteins (LP) isolated from coronary patients.

Methods: Blood was collected from 12 male, coronary patients hospitalised with unstable angina or stable chronic ischaemic cardiopathy, and 6 subjects had no history of cardiovascular diseases. The following plasma assays were performed: glycemia, cholesterol, triglycerides and lipid peroxides. In order to study the effect of Nifedipine, patients LP were incubated for 1–5 days with SMC in culture, with cholesterol concentrations between 25–100 μg/ml medium, in the presence or absence of 10 μM Nifedipine or 10 μM Diltiazem. Quantification of cellular proliferation was done after ^{3}H-thymidine incorporation and lipid loading of the cells was visualised by Oil Red staining and examined ultrastructurally, by electron microscopy. The effect of Nifedipine was compared with that of Diltiazem.

Results: Both calcium channel blockers studied decreased the rate of human aortic SMC proliferation in culture. At similar concentrations, Nifedipine was a stronger inhibitor of proliferation than Diltiazem. The incubation with sera or LDL isolated from patients induced proliferation and lipid loading of human aortic SMC. The anti-proliferative effect of both calcium channel blockers used was maintained under LP incubation conditions. Nifedipine did not impede the intracellular lipid accumulation and SMC transformation into foam cells, by comparison with Diltiazem, that reduced SMC lipid loading significantly.

Conclusions: Nifedipine, the first calcium channel blocker of the dihydropyridine class, has pro-atherogenic effects upon human aortic SMC in culture, as our present experiments demonstrate. The transformation of SMC into foam cells, as a result of the incubation with LP in the presence of Nifedipine, offers a good explanation – at cellular and molecular level – for the aggravation of the atherogenic process, previously reported in atherogenic animal models treated with Nifedipine. The correlation of clinical and experimental data could be essential in the adequate selection of different drugs in the treatment of coronary diseases.

P509 Cyclic AMP and cyclic GMP inhibit matrix metalloproteinase-9 expression in vascular smooth muscle cells

Shaista Hussain, Mark Bond, Andrew C. Newby. *Bristol Heart Institute, University of Bristol, Bristol, UK*

Introduction. Matrix metalloproteinases (MMPs) are a family of metal dependent endopeptidases, which play an important role in the resorption of extracellular matrixes. Activity of MMPs is essential for vascular smooth muscle cell (VSMC) migration and proliferation, for example in atherosclerosis. Second messengers cAMP and cGMP inhibit proliferation and migration in VSMC. Based on this, we investigated the influence of cyclic nucleotides on MMP expression in VSMC.

Method. Rabbit VSMCs were stimulated with combinations of the inflammatory cytokine, interleukin -1 (il-1), and growth factors, platelet derived growth factor (PDGF) or basic fibroblast growth factor (bFGF). The effects of 8-bromo cAMP or 8-bromo cGMP or agents that elevate endogenous cAMP or cGMP levels were then investigated. Gelatin zymography and northern analysis were used to quantify MMP-9 expression. Western analysis was used to quantify MMP-1 (Collagenase) and MMP-3 (Stromelysin) expression. Effects on the transcription factors, AP-1 and NF-kB, were investigated by electromobility shift assay.

Results. Gelatin zymography demonstrated that either 8-Br-cAMP or 8-Br-cGMP (50–800 μM) significantly reduced MMP-9 production in response to il-1 and PDGF by 94.5 $\pm$ 1.05% ($p = 0.0174$) and 66.4 $\pm$ 0.98% ($p = 0.0288$) respectively ($n = 3$), or bFGF (not shown). A similar effect was observed with forskolin, or 3-morphilinosydnonomine (SIN-1) plus 3-isobutyl-1 -methylxanthine (IBMX). This inhibitory effect was also replicated at the level of MMP-9 mRNA. EMSA demonstrated that cAMP and cGMP reduced il-1 and bFGF stimulated levels of NF-kB but not AP-1. Western analysis demonstrated that the cyclic nucleotides did not inhibit the il-1 and PDGF induced levels of MMP-1 or MMP-3.

Conclusion. Cyclic nucleotides selectively inhibit MMP-9 expression in VSMC by inhibiting NF-kB DNA binding. This mechanism may contribute to the inhibitory effect of cyclic nucleotides on VSMC migration and proliferation.

P510 Angiotensin II activates the JAK/STAT cascade via an NADH/NADPH-dependent mechanism

B. Schieffer, D. Hilfiker-Kleiner, H. Drexler. *Dept. of Cardiology and Angiology, Medizinische Hochschule Hannover, Hannover, Germany*

Superoxide anions generated via the NADH/NADPH-oxidase system supress the endogeneous nitric oxide (NO) bio-availability, which is involved in the generation of arterial hypertension. Angiotensin II (Ang II) is a known to stimulate the NADH/NADPH-oxidase system in-vitro and in blood vessels in a variety of models in-vivo. Moreover, Ang II was shown to stimulate growth and inflammatory processes, which involve the activation of the Jak/Stat signaling cascade. Therefore, the present study investigated (A) whether Ang II induces the Jak/Stat cascade via superoxide anions and (B) whether this activation of the Jak/Stat cascade leads to an inflammatory response. Therefore, rat aortic smooth muscel (RASM) cells were stimulated with Ang II (10^{-7} M). Superoxide anions generation was blocked with dipenyleniodonium (DPI, 100 μM) and with TIRON (0.3 mM), known inhibitors of the NADH/NADPH-oxidase system. Losartan (10^{-5} M), the Ang II typ 1 (AT1) receptor antagonist was used as control. Interleukin 6 (IL-6) synthesis and release was monitored as a marker of inflammation on RNA-level. As shown previously, Ang II stimulates the rapid phosphorylation of JAK2 and STAT1/STAT3 heterodimers via its AT1-receptor.This activation leads to an increase of IL-6 on RNA-level. DPI and Tiron abolish the activation of JAK2 and STAT1/STAT3 and subsequently the synthesis of IL-6. To elucidate which subunit of the NADPH-system may be responsible for this superoxide anion dependend activation, neutralizing antibodies to p47phox were electroporated into RASM cells. The results showed that blockade of p47phox abolished the Ang II-induced activation of the Jak/Stat cascade and the synthesis of IL-6. Immunohistochemical stainings in coronary artery sections obatined from patients undergoing heart transplantation due to ischemic heart disease revealed a tight cellular co-localization of Ang II, JAK2, STAT1/STAT3, p47phox and IL-6 at the fibrous cap of stable atherosclerotic plaques.

Thus, these results demonstrate that Ang II stimulates via superoxide anions – generated by the NADH/NADPH-oxidase system- the activation of the Jak/Stat cascade. Moreover, superoxide anions seem to be responsible for the Ang II-induced synthesis of pro-inflammtory cytokines in RASM cells. Together with the immunohistochemical results, these data are consistent with the notion that Ang II induces via superoxide anions and the activation of the Jak/Stat cascade an inflammatory response in human coronary artery plaques, which may potentially contribute to the development of an acute coronary syndrome.

P511 Protein-RNA interactions in the 3′untranslated region of the AT1 receptor mRNA. RNA binding sequence and functional characterization

G. Nickenig, F. Michaelsen, C. Müller, K. Strehlow, M.B. öhm. *Klinik III für Innere Medizin, Universität Köln, Cologne, Germany*

Background. The expression of the angiotensin AT1 receptor which plays a pivotal role in cardiovascular physiology and pathophysiology is regulated by various agonists as well as neurohumoral and metabolic stimuli predominately via posttranscriptional mechanisms. This study investigated mechanisms involved in posttranscriptional regulation.

Methods. Interactions of the AT1 receptor mRNA and polysomal proteins isolated from rat aortic vascular smooth muscle cells in culture were assessed with UV-mRNA-protein crosslink assays. The functional characterization of these protein-RNA interactions were accomplished by transfection of appropriate AT1 receptor mRNA transcripts into VSMC. DNA-mutations were accomplished with site-directed mutagenesis and exo-nuclease III-nested deletions.

Results. The AT1 receptor mRNA interacts with polysomal proteins in its very 3′end. Multiple mutational studies demonstrated that several binding proteins associated with the AT1 receptor mRNA at base 2176–2195. This fragment is in close neighborhood to the poly(A)-tail and comprises an AUUUUA hexamer and A + U rich flanking regions. Transfection decoy assays with AT1 receptor mRNA transcripts base 1864–2213 or 2175–2213 which reduce binding of polysomal proteins to the wild type AT1 receptor mRNA led to an increased basal expression of AT1 receptor mRNA.

Conclusion. A family of at least six polysomal proteins bind to the 3′untranslated region of the AT1 receptor mRNA. Especially a 50 and a 45 kDa protein bind at the region base 2175–2195 which contains an AUUUUA hexamer. Binding of proteins to this cognate sequence cause decreased turnover of the AT1 receptor mRNA. These findings establish novel molecular mechanisms involved in AT1 receptor regulation and may contribute to the understanding of general events of posttranscriptional modulation of mRNA steady state levels.

P512 Apoptosis of smooth muscle cells stimulates platelet aggregation

G. Bauriedel, R. Hutter, B. Lüderitz. *Department of Cardiology, University of Bonn, Bonn, Germany*

In acute coronary syndrome (ACS) and following angioplasty (PTCA), plaque rupture leads to the formation of thrombi. However, the spatiotemporal relation of platelet aggregation (PA) to vascular injury is incompletely understood. Apoptosis (A) of smooth muscle cells (SMCs) implicated in plaque rupture may contribute to increased thrombogenicity. To test this hypothesis, we examined *ex vivo* PA on A-SMCs in whole blood from healthy donors (D; n = 8), patients with ACS (n = 14) and after PTCA (n = 16).

Methods: Blood samples were obtained from D denying drug intake for at least one week and from patients under standard medication with ACS or post PTCA. A of SMCs was induced by ultraviolet irradiation and assessed by DNA laddering or by flowcytometric analysis. PA and release of platelet ATP were measured simultaneously using a Whole-Blood Lumi-Aggregometer (Chrono-Log Corp., Havertown, USA). PA was determined by the increase in impedance across paired electrodes in response to the aggregatory agent (Collagen, A-SMCs). ATP release was measured by luminescence after addition of the luciferin-luciferase reagent. Control aggregation curves remained nearly unchanged without PA agents; calibration standards were 5 ohm impedance change and 2 nmoles ATP. Intact SMCs did not induce either PA or ATP release (negative controls).

Results: A-SMCs were comparable to collagen in their stimulation of PA in all three groups, whereas only collagen induced significant ATP release. Notably, A-SMCs induced PA in patients with ACS or following PTCA, despite concomitant intensive anti-PA treatment. As also shown in the Table, anti-aggregatory comedication did not significantly diminish, but delay A-SMCs-induced PA ($x \pm$ S.D.).

Group	Agent	Final conc.	Time to PA	Impedance change	ATP release
D	A-SMCs	4000 cells/ml	8.7 ± 2.6 min	18 ± 2 ohms	0.1 ± 0.1 nmol
D	Collagen	2 μg/ml	1.1 ± 0.7	21 ± 3	1.3 ± 0.4
ACS	A-SMCs	4000 cells/ml	12.9 ± 4.6	15 ± 3	0.2 ± 0.2
ACS	Collagen	2 μg/ml	1.9 ± 0.5	16 ± 5	0.4 ± 0.2
PTCA	A-SMCs	4000 cells/ml	13.1 ± 3.7	16 ± 2	0.1 ± 0.1
PTCA	Collagen	2 μg/ml	1.8 ± 0.7	12 ± 3	0.3 ± 0.4

In conclusion, our data on *ex vivo* platelet aggregation demonstrate apoptosis of smooth muscle cells to be a novel potent stimulus that may play an important role in the thrombogenicity of the diseased vascular wall.

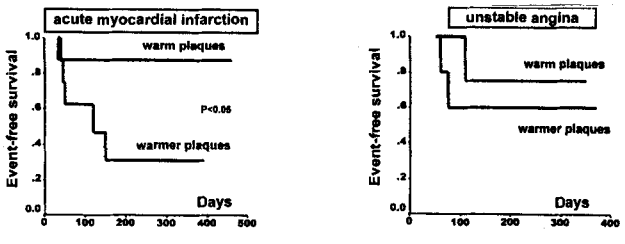
ATHEROSCLEROSIS

P513 Plaque temperature in acute ischaemic syndromes: an additional prognostic factor for long-term outcome?

C. Stefanadis, C. Vlachopoulos, L. Diamantopoulos, E. Tsiamis, E. Vavouranakis, N. Giatrakos, J. Demellis, C. Stratos, P. Toutouzas. *Hippokration Hospital, Athens Medical School, Athens, Greece*

We have shown in vivo that temperature (T) heterogeneity within coronary arteries is increased in acute ischemic syndromes (*Ann Intern Med 1998;129:1079–80*). To assess the association between T and long-term outcome, 27 patients with acute ischemic syndromes (11 unstable angina, 16 acute myocardial infarction) who underwent emergency coronary intervention were followed for a mean follow-up of 6.9 months. T was measured at the time of intervention using a catheter-based technique that was developed in our laboratory and has been previously validated.

Results: Difference of plaque T from healthy vessel wall was larger in acute myocardial infarction patients compared with unstable angina (1.44 ± 0.65 and 0.72 ± 0.40 °C respectively, P < 0.01). Within each group, event (death, re-intervention, hospitalization, symptom recurrence) -free survival was worse in patients who had plaque T difference above the median value of the each study group.



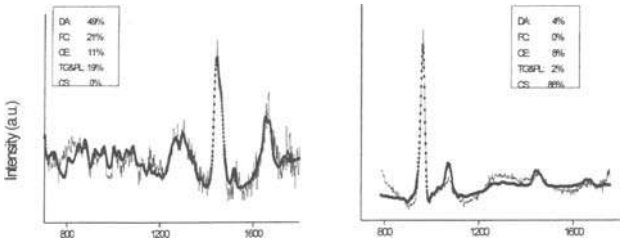
Conclusions: Increased plaque T is associated with an adverse long-term outcome after coronary interventions in acute ischemic syndromes. This new prognostic factor may identify patients that are at higher risk to develop adverse events after coronary intervention.

P514 Histopathological assessment of atherosclerotic plaques by optical fiber-based Raman spectroscopy

H.P.J. Buschman[1,2], E.T. Marple[3], M.L. Wach[3], A. van der Laarse[1], G.J. Puppels[2]. *[1]Department of Cardiology, Leiden University Medical Center; [2]Laboratory for Intensive Care Research and Optical Spectroscopy, Erasmus Medical Centre Rotterdam, Netherlands; [3]Visionex, Inc., Atlanta GA, USA*

We used Raman spectroscopy to assess the chemical composition of atherosclerosis in perfused intact human coronary artery tissue.

Methods and Results: Human coronary artery samples of 5–6 cm length (n = 6) were mounted in an *in vitro* set-up and perfused with a salt solution at ~80 mm Hg. Near infrared laser light (830 nm; 100 mW) was delivered to the tissue through the central fiber of a 5F optical fiber catheter that was inserted transluminally into the artery sample. High quality tissue Raman signals were collected by surrounding fibers in 10–60 s. The spectra were modeled with Raman spectra of the chemical components comprising the artery (Figure 1). These components were free cholesterol, cholesterol esters, calcium salts, triglycerides and phospholipids, and artery protein. A diagnostic algorithm used this information to classify the examined tissue into either non-atherosclerotic tissue, atheromatous plaque, or calcified plaque.



Conclusion: Intravascular optical fiber Raman spectroscopy can provide *in situ* histopathology, which may be used to study vascular disease in the patient *in vivo*, to predict plaque rupture and to evaluate therapeutic effects.

P515 Inducible nitric oxide synthase is upregulated in ruptured infarct-related coronary plaques

K.M. Cromheeke, J.M. Bosmans, M.M. Kockx[1], H. Bult[2], A.G. Herman[2], C.J. Vrints. *Dept. Cardiology, University Hospital, Antwerp; [1]Dept. Pathology, AZ Middelheim, Antwerp[2]Div. of Pharmacology, University of Antwerp, Antwerp, Belgium*

Objective: Inducible nitric oxide synthase (NOS II) produces high concentrations of nitric oxide, known as very cytotoxic. We investigated the presence of NOS II in coronary atherosclerotic lesions after acute myocardial infarction (AMI) and unstable angina pectoris (UA), and correlated this with the presence of signs of plaque rupture on coronary angiography and intravascular ultrasound (IVUS).

Methods: Patients (n = 22) with a recent AMI (n = 8) or with UA (Braunwald class IIb or IIIb) (n = 14) were examined with angiography and IVUS before directional atherectomy and stenting was performed. The angiographical and IVUS images were assessed for the presence of plaque rupture. The atherectomy specimens were immunohistochemically investigated and immunoreactive areas were quantified.

Results: The atherectomy specimens of patients with AMI contained more CD68 (macrophages) immunoreactivity (19.3 ± 7.1%) than the specimens of patients with UA (6.0 ± 2.7%) ($p < 0.05$). Also the NOS II immunoreactive area was higher in the AMI group (6.1 ± 2.2% versus 1.8 ± 0.8%) ($p < 0.05$). NOS II was present in the macrophages. A strong correlation between macrophages and NOS II ($r = 0.7$, $p \leq 0.01$) was found. Angiographic evidence of plaque rupture was observed in 7 of 8 patients with AMI. In the UA group the infarct-related lesion showed signs of plaque rupture in 8 of 14 patients. IVUS showed the presence of a ruptured cap covering an eccentric lipid pool in 40% of all (AMI + UA) patients. A correlation between IVUS lesion type and the presence of macrophages and NOS II was however not present.

Conclusion: We demonstrated that plaque ruptures related with AMI contain abundant macrophages with NOS II expression. Plaques of patients with UA contain less signs of inflammation. Excessive accumulation of NOS II containing macrophages can be a major factor in the final step of plaque destabilisation and rupture. However it can not be excluded that macrophages further accumulate in the fibrous caps after rupture.

P516 Pravastatin suppresses T-lymphocyte proliferation and interferon-gamma production

P. Langton, A.M.J. Shearwood, M.J. Garlepp[1], J. Hung, P.J. Thompson. *University Department of Medicine, Sir Charles Gairdner Hospital, Nedlands; [1]School of Pharmacy, Curtin University, Perth, Australia*

Hypercholesterolaemia and atherosclerosis are associated with lymphocyte mediated inflammation. We have previously shown increases in lymphocyte proliferative responses and the production of the key regulatory cytokine interferon-gamma(IFN) in the hyper-cholesterolaemic apolipoprotein E deficient (apoE−) murine model of atherosclerosis. We then sought to investigate whether lymphocyte activation in apoE− mice could be suppressed by pravastatin.

Studies were performed on splenic lymphocytes from apoE− mice and on C57Bl/6j (normal cholesterol) controls. Pravastatin or placebo was administered to the mice in their drinking water. Mitogen (conA) stimulated lymphocyte proliferation was assessed by ^{3}H-thymidine incorporation and IFN production measured by ELISA of culture supernatants. Assays were performed in the presence or absence of in vitro pravastatin (100 μM).

Compared to placebo, pravastatin significantly reduced cholesterol in apoE− mice (mean 19.5 vs 30.9 μM; $p < 0.05$) but not in C57 controls (1.7 vs 2.4 μM). Ex vivo lymphocyte proliferation was decreased in pravastatin treated mice compared to placebo (stimulation index 10.6 vs 23.5; $p = 0.02$). In both C57 and apoE− mice, in vitro pravastatin was associated with suppression of cell proliferation (39.5 vs 72.0; $p < 0.001$) and IFN production (42.1 vs 71.2 U/100 μL; $p < 0.001$).

Pravastatin is able to suppress ex vivo and in vitro mitogen stimulated lymphocyte activation. These effects raise the possibility that pravastatin may modify the atherosclerotic process by direct immunomodulatory mechanisms, in addition to cholesterol lowering.

P517 Serum glucose but not insulin modulates platelet-dependent thrombosis in patients with coronary artery disease

M. Shechter, M. Paul Labrador, C.N. Bairey Merz, S. Kaul. *Cedars-Sinai Medical Center, Los Angeles CA, USA*

Previously we demonstrated that elevated blood glucose (G) is associated with augmented platelet-dependent thrombosis (PDT). High plasma insulin (I) levels are associated with enhanced risk of CAD, however, the mechanisms are unknown. We prospectively measured PDT in 36 stable CAD patients (mean age 68 ± 9 years) on aspirin with controlled lipid levels. Porcine aortic media was exposed to flowing non-anticoagulated venous blood in an ex-vivo perfusion chamber. PDT was measured by computerized morphometry. Total plasma immunoreactive I and G levels were measured after overnight fast.

Results: Initial correlation analysis between I, G and PDT demonstrated I ($r = 0.015$, $p = 0.93$) and G ($r = 0.51$, $p = 0.002$). Patients were divided into two groups: Group A ≤ and Group B > the median I level (17 μU/ml). There were no significant differences in age, serum lipids platelet count or fibrinogen levels between the two groups. PDT was not significantly elevated in Group B vs Group A (103 ± 128 vs 84 ± 74 μm^2/mm, p = NS). PDT, however, was significantly augmented in patients with G > compared to <median (90 mg/dl) level (159 ± 141 vs 67 ± 69 μm^2/mm, $p < 0.01$).

Conclusion: Elevated G but *not* I is associated with augmented PDT in stable CAD patients with controlled lipid levels. This finding suggests that the mechanism contributing to the enhanced thrombogenic risk of CAD may be related to hyperglycemia rather than hyperinsulinemia.

P518 Morphologic modelling and histopathological classification of human coronary atherosclerosis by morphology based Raman spectroscopy

H.P.J. Buschman[1,2], J.T. Motz[2], M. Fitzmaurice[3], A. van der Laarse[1], M.S. Feld[2]. *[1]Department of Cardiology, Leiden University Medical Center, Leiden, Netherlands; [2]G.R. Harrison Spectroscopy Laboratory, Massachusetts Institute of Technology, Cambridge MA; [3]Institute of Pathology, University Hospitals Cleveland, Cleveland OH, USA*

The development of an atherosclerotic plaque in arterial intima is characterized by morphological changes, which are detected by pathologists in stained tissue sections. The changes are used to determine the state of disease of the tissue. In the present study we present a classification technique for atherosclerosis based on morphological Raman microspectroscopy.

Methods and Results: Raman spectra were collected from eight morphological structures in unstained coronary artery sections with a Raman spectroscopy system (Table 1). These morphological Raman spectra were used as basis spectra in a linear fitting model, to obtain morphological information from macroscopic coronary artery Raman spectra of unknown composition, that were subsequently classified by a pathologist into three classes (normal tissue, atheromatous tissue, and calcified tissue). The results show significant changes in all morphological structures in the different artery samples.

Table 1. Fit contribution of morphological structure to artery tissue (n = 97). The data are corrected for the calcification contribution.

Structure	Normal (n = 73)	Atheromatous (n = 10)	Calcified (n = 14)
Collagen fiber	0.26 ± 0.02	0.15 ± 0.05	0.44 ± 0.07
Cholesterol crystal	0.05 ± 0.01	0.22 ± 0.03	0.09 ± 0.03
Calcification	0.01 ± 0	0.01 ± 0.01	0.68 ± 0.09
IEL (elastin)	0.07 ± 0.01	0.10 ± 0.02	0.09 ± 0.02
Adventitial fat	0.38 ± 0.03	0.24 ± 0.03	0.29 ± 0.06
Foam cell/necrotic core	0.03 ± 0.01	0.23 ± 0.04	0.07 ± 0.03
Smooth muscle cell	0.20 ± 0.01	0.05 ± 0.02	0.02 ± 0.01

Conclusion: The pathological state of human coronary artery may be assessed by determining morphological information with Raman spectroscopy. This technique may be used for histopathological classification of atherosclerosis *in situ*, and provide a better understanding of the dynamics in the evolution of atherosclerotic lesions.

P519 Association of endotoxemia with carotid atherosclerosis and cardiovascular disease: prospective results from the Bruneck study

C.J. Wiedermann, S. Kiechl[1]. *Internal Medicine Dept., University of Innsbruck, Innsbruck; [1]Department of Neurology, University of Innsbruck, Innsbruck, Austria*

Objectives: Focus of the current study was on the significance of bacterial endotoxin, which shows a variety of pro-atherogenic properties and may occur at high concentration in the circulation of infected subjects. The possibility of an infectious risk factor in atherogenesis and cardiovascular disease has stimulated renewed research interest, but the nature of such process remains obscure.

Methods: We measured plasma endotoxin levels (LAL assay) in a random population of 516 men and women 50 to 79 years old at the 1990 baseline evaluation (Bruneck Study). Endpoints of this prospective survey were incident (early) atherosclerosis in the carotid arteries as assessed with high-resolution Duplex ultrasound (five-year follow-up rate, 98%) and incident cardiovascular disease (follow-up rate, 100%).

Results: Median endotoxin concentration amounted to 14.3 pg/mL with a range of 6.0 to 209.2 pg/mL. Subjects with levels beyond 50 pg/mL (90th percentile) faced a three-fold risk of incident atherosclerosis (OR 95% CI 2.9 [1.4–6.3]; $P < 0.01$). The risk associated with high endotoxin was most pronounced in subjects with chronic infections and in current and ex-smokers. Notably, smokers with low endotoxin levels and non-smokers did not differ in their atherosclerosis risk, whereas smokers with high levels almost invariably developed new lesions. All findings emerged as independent of vascular risk factors. Similar results were obtained for incident cardiovascular disease.

Conclusion: The current study yields first epidemiologic evidence that endotoxemia constitutes a strong risk factor of early atherogenesis in subjects with chronic or recurrent bacterial infections and a link in the association between cigarette smoking and atherosclerotic disease.

P520 Inflammation and increased oxidative stress as risk factors for atherosclerosis in chronic renal failure

T. Jogestrand, P. Stenvinkel[1], O. Heimbürger[1], U. Diczfalusy[2], L. Berglund[3]. *Department of Clinical Physiology; [1]Department of Renal Medicine; [2]Department of Clinical Chemistry, Huddinge University Hospital, Stockholm, Sweden; [3]Department of Medicine, Columbia University, New York NY, USA*

Atherosclerotic cardiovascular disease and malnutrition are widely recognized as leading causes of the increased morbidity and mortality observed in uremic patients. In chronic renal failure (CRF) increased concentration of acute phase proteins, such as C-reactive protein (CRP), has been associated with an increased mortality. The aim of present study was to assess the interactions between cardiovascular disease, inflammation, malnutrition and oxidative stress in CRF.

Methods: 109 predialysis patients (age 52 ± 1 years) with terminal CRF were studied. By using non-invasive B-mode ultrasonography the cross-sectional common carotid intima-media area was calculated and the presence or absence of carotid plaques was determined. Nutritional status was assessed by subjective global assessment (SGA), dual-energy x-ray absorptiometry, serum albumin, serum creatinine, serum urea and 24-hour urine urea excretion. The presence of an inflammatory reaction was assessed by CRP, fibrinogen and TNF-α. Lipid parameters as well as markers of oxidative stress (autoantibodies against oxidized LDL; vitamin E) were also determined.

Results: Compared to healthy controls, CRF patients had an increased mean intima-media area (18.3 ± 0.6 vs. 13.2 ± 0.7 mm^2; $p < 0.0001$) and a higher prevalence of carotid plaques (72 vs. 32%; $p = 0.001$). The prevalence of malnutrition (SGA 2–4) was 44%, and 32% of all patients had an acute phase response (CRP ≥ 10 mg/l). Malnourished patients had higher CRP levels (23 ± 3 vs. 13 ± 2 mg/l; $p < 0.01$), elevated intima-media area (20.2 ± 0.8 vs. 16.9 ± 0.7 mm^2; $p < 0.01$) and a higher prevalence of carotid plaques (90 vs. 60%; $p < 0.0001$) compared to well-nourished patients. During stepwise multivariate analysis adjusted for age and gender, vitamin E ($p < 0.05$) and CRP ($p < 0.05$) remained associated with an increased intima-media area. The presence of carotid plaques were significantly associated with age ($p < 0.001$), log oxLDL ($p < 0.01$) and small apo(a) isoform size ($p < 0.05$) in a multivariate logistic regression model.

Conclusion: The present results indicate that the rapidly developing atherosclosis in advanced chronic renal failure appears to be caused by a synergism of different mechanisms, including inflammation and oxidative stress.

P521 Recombinant human apo A-I adenoviruses lack hepatotropism after systemic injection in rabbits

Bart De Geest, Marleen Lox, Désiré Collen, Paul Holvoet. *Center for Molecular and Vascular Biology, University of Leuven, Leuven, Belgium*

Stable elevation of HDL cholesterol, induced by apo A-I gene transfer, may lead to a dramatic decrease of atherosclerotic vascular disease. Recombinant adenoviruses have been shown to be hepatotropic after gene transfer in mice. In the present study, we compared systemic infusion versus portal vein injection in New Zealand White Rabbits of human apo A-I adenoviruses containing the ubiquitously active cytomegalovirus (CMV) promoter (CMV/A-I.gA-I) or the liver-specific 256bp apo A-I promoter (A-I.gA-I.4xapoE).

Results: Ear vein injection (n = 11) and portal vein injection (n = 3) of 10^{11} p.f.u. of CMV/A-I.gA-I induced human apo A-I levels of 19 ± 3.2 mg/dl respectively 18 ± 3.0 mg/dl at day 3, 14 ± 3.8 mg/dl respectively 18 ± 6 mg/dl at day 6 and 0 ± 0 mg/dl respectively 0 ± 0 mg/dl at day 10. Human apo A-I levels after gene transfer by ear vein injection (n = 3) of 10^{11} p.f.u A-I.gA-I.4xapoE were undetectable at any time point. In contrast, portal vein infusion (n = 3) of 10^{11} p.f.u. A-I.gA-I.4xapoE resulted in human apo A-I levels of 23 ± 5 mg/dl at day 3, 40 ± 1.6 mg/dl at day 6, 41 ± 1.0 mg/dl at day 10, 7.0 ± 3.7 mg/dl at day 14 and 0 ± 0 mg/dl at day 21. Portal vein infusion with 2 × 10^{11} p.f.u A-I.gA-I.4xapoE (n = 3) induced human apo A-I levels of 38 ± 6.3 mg/dl at day 3, 65 ± 5 mg/dl at day 6, 64 ± 16 mg/dl at day 10, 15 ± 15 mg/dl at day 14 and 0 ± 0 mg/dl at day 21.

Conclusion: Successful human apo A-I gene transfer in rabbits with recombinant human apo A-I adenoviruses containing a liver-specific promoter is strictly dependent on portal vein infusion, indicating absence of hepatotropism of adenoviruses in rabbits. Because we observed human apo A-I expression for more than 6 months after gene transfer with A-I.gA-I.4xapoE in C57BL/6 mice, the rapid decline of human apo A-I levels after day 10 in rabbits suggests a cellular and/or humoral immune response against human apo A-I.

P522 A novel Ca^{2+}-independent pathway for NO synthase activation in endothelial cells via Akt-dependent phosphorylation

S. Dimmeler, I. Fleming[1], B. Fißlthaler[1], C. Hermann, R. Busse[1], A.M. Zeiher. *Dep. of Molecular Cardiology; [1]Institut for Cardiovascular Physiology, University of Frankfurt, Germany*

Fluid shear stress enhances nitric oxide (NO) production by activating the endothelial nitric oxide synthase (eNOS). The enhanced activity of eNOS is thought to be regulated by phosphorylation, although the signalling pathway involved is unclear. Since shear stress has been shown to stimulate the serine/threonin kinase Akt via the phosphoinositide-3 kinase (PI3K), we examined the contribution of the PI3K/Akt-pathway in regulation of eNOS phosphorylation and activity.

Phosphorylation of eNOS was determined by two-dimensional amino acid analysis of eNOS immunoprecipitated from ^{32}P-labelled human umbilical vein endothelial cells. The application of fluid shear stress (1 h) to endothelial cells resulted in a 2-fold increase in the serine phosphorylation of eNOS, which was abrogated by the PI3K inhibitor wortmannin (20 nM). Moreover, the shear stress-stimulated increase in cyclic GMP (186 ± 50%), which reflects eNOS activation, was also prevented by wortmannin (104 ± 23%). Furthermore, Akt directly phosphorylated eNOS in vitro. To test whether the phosphorylation of eNOS by Akt regulates eNOS activity, the two serine residues (S633 and S1177), matching the consensus sequence for Akt, were mutated into phospho-mimetic aspartic acid residues and the mutants were overexpressed in endothelial cells. The S1177D mutant revealed a 2-fold increase in enzyme activity as measured by the L-arginine assay compared to eNOS wild type (wt)-transfected cells ($p < 0.007$), whereas mutation of S633 did not affect eNOS activity. Moreover, mutation of the S1177 enhanced the sensitivity of eNOS towards calcium.

Conclusion: These results demonstrate a novel pathway for activation of the eNOS, which may have important therapeutic implications.

P523 n-3 Polyunsaturated fatty acids decrease intracellular production of reactive oxygen species and endothelial activation: a link to their anti-atherogenic and anti-inflammatory properties

Raffaele De Caterina[1,2], Martin Spiecker[1], Todd Bourcier[1], Vito La Fata[1], James K. Liao[1]. *[1]Brigham and Women's Hospital, Boston MA, USA; [2]CNR Institute of Clinical Physiology, Pisa, Italy*

We have previously shown that the n-3 polyunsaturated fatty acid (FA) docosahexaenoate (DHA) and, to a lesser extent, other unsaturated FA, inhibit the expression of adhesion molecules and chemoattractants in cultured endothelial cells after interleukin (IL)-1 stimulation, and subsequent monocyte recruitment onto endothelium. These properties were shown to be a function of the number of unsaturation in the FA carbon chain. In investigating potential mechanism(s) for these effects, we incubated increasing concentrations (5–50 μM) of DHA, or stearate and palmitate as control saturated FA, with cultured saphenous vein endothelial cells for 24–72 h, followed by IL-1 (1 ng/mL) stimulation. DHA, but not stearate inhibited VCAM-1 mRNA levels at Northern analysis. Actinomycin-D studies indicated that DHA inhibits VCAM-1 expression at a transcriptional level. In transient transfection experiments with plasmid constructs consisting of a functional −1.8 kb VCAM-1 prommoter linked to the chloramphenicol acetyl transferase (CAT) reporter gene, DHA inhibited IL-1-stimulated VCAM-1 promoter activity by 70%. Electrophoretic mobility shift assays indicated that DHA suppresses IL-1-induced nuclear factor (NF)-κB activation. Since NF-κB activation is thought to occur via the generation of reactive oxygen species, particularly H_2O_2, we assessed the EC redox state by using a permeable oxidant-sensitive probe, dichlorofluoresceine (DCF). DHA suppressed IL-1 or TNF-induced increase in DCF fluorescence in a concentration-dependent fashion. Thus, a highly unsaturated FA, known for its susceptibility to peroxidation, paradoxically decreases the intracellular generation of reactive oxygen species, possibly preventing the dismutation of superoxide to H_2O_2, in intracellular compartments critical for cytokine signal transduction. These findings indicate that n-3 FA inhibit endothelial activation via inhibition of the oxidant-sensitive transcription factor NF-κB. These "antioxidant" properties of polyunsaturated FA may be one mechanism by which they are beneficial in atherosclerosis or inflammation.

P524 Advanced glycation end-products as pro-inflammatory cytokine equivalents for vascular endothelium

G. Basta, G. Lazzerini, M. Massaro, P. Tanganelli[1], A.M. Schmidt[2], R. De Caterina. *CNR Institute of Clinical Physiology, Pisa; [1]Institute of Pathology, the University of Siena, Italy; [2]Columbia University, New York NY, USA*

Background: Advanced glycation end-products (AGEs) play a pivotal role in chronic disease such as diabetes and atherosclerosis. We investigated whether AGEs isolated *ex vivo* from patients or produced *in vitro* affect endothelial activation, and assessed some of the mechanisms involved. We also tested the co-expression of AGEs and products of endothelial activation in human inflammatory tissues.

Methods: AGEs were affinity-purified from plasma of uremic patients or prepared by incubating serum albumin in buffered saline with ribose at 37°C for 4 weeks, and characterized by fluorimetry and binding by specific antibodies. The expression of endothelial leukocyte adhesion molecules (VCAM-1, ICAM-1, E-selectin) and constitutive endothelial antigens were assessed by cell surface EIA and flow cytometry on cultured saphenous vein endothelial cells. Monocytoid cell or neutrophil adhesion to endotheliums was assessed by rotational adhesion assays. Specific mRNA levels were evaluated by Northern analysis.

Results: AGEs from both sources induced a concentration-dependent increase in expression of all adhesion molecules assayed, and monocytoid cell and neutrophil adhesion, which were completely and specifically blocked by anti-RAGE IgG. Northern analysis indicated a concomitant increase in adhesion molecule mRNA levels, which again was completely blocked by anti-RAGE IgG. Inflammatory tissues from rheumatoid synovia co-expressed adhesion molecules, AGEs and RAGE.

Conclusions: AGEs induce a generalized state of endothelial activation, which may contribute to inflammatory vascular changes also occurring in non-diabetic conditions.

P525 Extracellular matrix remodelling in diabetic vascular injury

M. Karim, F. Meng, Y.T. Zhou[1]. *Cardiology Dept, Dallas VA Medical Center, Dallas TX; [1]Endocrinology Dept, University of Texas Southwestern, Dallas TX, USA*

Diabetes mellitus is associated with excess atherosclerotic vascular fibrosis. Mechanisms leading to interstitial remodelling following angioplasty are not known.

Methods. NZ white rabbits (n = 12) were injected with a single IV dose of alloxan monohydrate (100 mg/kg), to induce chemical-diabetes. Four weeks later, diabetic animals and another group of control, non-diabetic rabbits (n = 10) underwent atherogenic diet and barotrauma injury in the right iliac artery. Left iliac was sham operated. All rabbits were sacrificed after 40 days of injury and vessels analyzed by RT-PCR (messenger RNA), biochemical (proteins, hydroxyproline, DNA), and computerized histomorphometric measurements (H&E, picrosirius red staining).

Results. Serum glucose was 200–400 mg/100 ml in the diabetic rabbits, accompanied by a 3–6 times higher conc. of triglyceride and total cholesterol level compared to non-diabetics ($p \leq 0.001$). A substantial increase in both procollagen type I (2 folds higher) and TGFb1 (5 folds higher) gene expression ($p < 0.001$) was associated with a moderate rise in vascular fibrillar collagen conc. (~31%), and a 15% reduction in cross-sectional area in the diabetic injured arteries. Matrix degradative enzyme mRNA (collagenase 1, and 9) were quantitated 3 times higher ($p \leq 0.01$) in diabetes. AT1 Ang II receptor mRNA was also 2 times higher in diabetic rabbits.

Conclusions. We conclude that a major up-regulation in levels of vascular TGFb1 is associated with enhanced remodelling and expansion of extracellular matrix leading to interstitial vascular fibrosis in diabetes mellitus.

P526 Evidence for cyclooxygenase-2-dependent prostacyclin production in atherosclerosis

D. Kearney, O. Belton, D. Byrne[1], A. Leahy[1], D. Fitzgerald. *Clinical Pharmacology Dept, Royal College of Surgeons in Ireland, Dublin; [1]Department of Vascular Surgery, Beaumont Hospital, Dublin, Ireland*

©Prostaglandins (PGs) play a major role in the regulation of platelet and vascular function. Ischaemia reperfusion injury, seen in patients undergoing revascularisation surgery, causes a rise in PG production. We examined the generation of PGs in 35 patients undergoing vascular surgery, using assays for the analysis of the principle endothelial product prostacyclin (PGI2) and the principle platelet product thromboxane A2 (TxA2). We hypothesised that selective cyclooxygenase-2 (COX-2) inhibition would significantly reduce the post-operative rise in PG production.

Previous work in our laboratory, using balloon angioplasty in rat carotid arteries, has demonstrated COX-2 expression in neo-intimal tissue. We have also shown that COX-2 expression is present in human atherosclerotic plaque, localised to the vascular smooth muscle cells, in endarterectomised patients.

Methods: In this study, patients undergoing revascularisation surgery for aortic or peripheral vascular disease were randomised to receive: i) no treatment ii) aspirin alone iii) nimesulide (a selective COX-2 inhibitor) alone or iv) aspirin and nimesulide. The stable urinary metabolites of PGI2, 2,3 dinor-6-keto PGF1alpha (PGI-M) and thromboxane A2, 11-dehydro thromboxane B2 (Tx-M) were measured using mass spectrometry. Measurements were made pre-operatively and for up to 48 hours post-op.

Results: Patients on nimesulide alone or in combination with aspirin showed a marked reduction in post-op production of PGI-M relative to those on no treatment [334 ± 107 to 2029 ± 818 for nimesulide alone and 139 ± 41 to 1013 ± 307 for nimesulide+aspirin vs 738 ± 246 to 4299 ± 1566, $p < 0.05$]. Patients on aspirin showed a marked reduction in Tx-M post-op compared to those on no treatment or on nimesulide alone [1093 ± 342 to 4178 ± 1169 vs 3566 ± 764 to 22760 ± 12197 for no treatment and 2501 ± 694 to 15365 ± 7996 for nimesulide alone, $p < 0.01$]. Nimesulide alone had little effect on Tx-M production [$p > 0.5$]. All results are expressed as pg/mg creatinine, mean values ± s.e.m.

Conclusion: These results indicate that in patients with widespread atherosclerotic disease, the rise in TxA2 formation after revascularisation surgery is primarily COX-1 dependent. The rise in PGI2 production, however, shows significant COX-2 dependency. As PGI2 is a potent vasodilator and inhibitor of platelet aggregation, the use of selective COX-2 inhibition in patients with atherosclerotic disease may expose these patients to the potentially harmful effects of unopposed TxA2 production.

P527 Hyperhomocysteinaemia and progression of coronary atherosclerosis

F.F. Willems[1], W. Jukema[2], A.H. Zwinderman[2], G.H.J. Boers[3], A.J. van Boven[4], J. Lindemans[5], A.V.G. Bruschke[2], P.P.H.M. Delnoy[1], W.R.M. Aengevaeren[1], H.J. Blom[5], F.W.A. Verheugt[1]. *[1]Heartcenter; Departments of [3]Internal Medicine; [5]Laboratory of Pediatrics and Neurology, University Hospital Nijmegen; [2]University Hospital Leiden; [4]University Hospital Groningen; [5]University Hospital Rotterdam; Interuniversity Cardiology Institute of the Netherlands, , Netherlands*

Background: Hyperhomocysteinemia (HHCY) is an independent risk factor for the development of coronary artery disease (CAD) although the mechanisms responsible for the atherogenic or thrombogenic effects of homocysteine (HCY) have not yet been determined. Aim of this study was to evaluate the effect of HHCY on angiographic progression of coronary atherosclerosis.

Methods: To assess the effects of HHCY on progression of coronary atherosclerosis, HCY was determined after an overnight fast in 216 male patients who participated in the placebo group of the Regression Growth Evaluation Statin Study (REGRESS). These patients had normal to mildly elevated total cholesterol and were scheduled for coronary arteriography. Two years after enrollment a second coronary arteriography was performed. Progression of coronary atherosclerosis was assessed by quantitative coronary angiography (QCA). Progression was expressed as a decrease in average Mean Segment Diameter (MSD) and average Minimum Obstruction Diameter (MOD) of all available coronary segments.

Results:

HCY μmol/l	Changes MSD/SD	Change MOD/SD
<11.2	−0.0618 mm 0.1876 (ns)	−0.0703 mm 0.1605 (ns)
11.2–13.1	−0.1283 mm 0.2145 (ns)	−0.1390 mm 0.2278 (ns)
13.1–15.4	−0.1385 mm 0.2344 (ns)	−0.1514 mm 0.2610 (ns)
>15.4	−0.1261 mm 0.1963 (ns)	−0.1122 mm 0.2016 (ns)

Conclusion: There is no significant correlation between HCY levels and decrease of MSD and MOD, suggesting that the mechanism responsible for the reported higher mortality of patients with HHCY and CAD is not the progression of atherosclerosis.

P528 Vastatins compete with norepinephrine for the alpha receptor in aorta

M.J. Crespo[1], P.I. Altieri[2], N. Escobales[2]. *[1]Department of Pharmacology; [2]Department of Physiology, University of Puerto Rico, School of Medicine, San Juan, Puerto Rico*

Previous studies from our laboratory have shown that vastatins, in particular simvastatin (SV), inhibit the contraction of aortic rings by Angiotensin II and Norepinephrine (NE). These effects of SV appears to be due to depletion of $InsP_3$- sensitive Ca^{+2} pools because the drug releases CA^{+2} from these stores in a manner similar to that of thapsigargin, a SERCA type Ca^{+2} pump inhibitor. An additional mechanism by which vastatins could inhibit the contraction of aortic rings by various agonists could involve an interaction with receptors on the cell surface because pravastatin (20 uM), a vastatin that does not affect aortic ring contractility, displaces NE-concentration response curve to the right. The latter effect suggest a competition between the drug and NE for receptor binding. To evaluate this point further, NE concentration-response curves (10^{-10} to 10^{-5}) were performed in the presence and absence of 5 uM vastatins. From these studies EC_{50} values were obtained and the results areas follows (nM): None = 1:01 ± 0.3, Simvastatin 11.1 ± 1.6 ($P < 0.05$), Lovastatin (LV) = 15.6 ± 2.7 ($p < 0.05$), Mevastatin (MV) = 10.1 ± 3.3 ($P < 0.05$) and Pravastatin = 0.78 ± 0.2 (N.S.). These data suggest that (5 uM) SV, LV, and MV, but not PV, compete with NE for receptor binding. SV was the only drug that in addition to induce a right shift in NE-concentration response curves, significantly reduces the maximal contraction by this agonist (29%, $P < 0.05$). Altogether these results indicate that vastatins could affect the NE-induced contraction by two different mechanisms: 1) by affecting intracellular Ca^{+2} release, and 2) by competing with NE at the alpha-receptor. SV (uM) possesses both of these effects whereas at similar concentrations LV, and MV, display only the alpha-receptor antagonism.

P529 Statin-sensitive dysregulated at1 receptor function and density in hypercholesterolaemic men

G. Nickenig, A.T. Bäumer, Y. Temur, D. Kebben, F. Jockenhövel[1], M. Böhm. *Klinik III für Innere Medizin; [1]Klinik II für Innere Medizin, Universität Köln, Cologne, Germany*

Background: Hypercholesterolemia causes a significant up-regulation of vascular AT1 receptor expression in cell culture and animal models and is a well established risk factor for cardiovascular disease. The presented studies were undertaken to examine AT1 receptor overexpression in hypercholesterolemic men and therapeutic interventions thereof by HMG-CoA-reductase inhibitors (statins).

Methods: Effects of AT1 receptor activation were measured by assessing the blood pressure following infusion of angiotensin II in normo-(cholesterol 181 ± 11 mg/dl, low density lipoprotein 100 ± 7 mg/dl) and hypercholesterolemic (cholesterol 294 ± 10 mg/dl, low density lipoprotein 215 ± 9 mg/dl) men (n = 19/20). AT1 receptor expression was assessed in the same population on isolated platelets. In addition, patients were investigated before and after cholesterol-lowering therapy with statins.

Results: Hypercholesterolemia led to a significant increase of angiotensin II-induced blood pressure elevation. In contrast, norephinephrine-caused blood pressure enhancement was similar in normo- and hypercholesterolemic individuals. AT1 receptor expression was significantly enhanced in hypercholesterolemic individuals (B_{max} = 5.2 ± 1.2 fmol/mg protein) compared to normocholesterolemic men (B_{max} = 2.1 ± 0.2 fmol/mg protein). Cholesterol-lowering treatment with statins reversed the elevated blood pressure response to angiotensin II infusion and remarkably down-regulated AT1 receptor density

Conclusions: Hypercholesterolemia induces AT1 receptor overexpression and enhances biological effects of angiotensin II in men. These findings provide novel insights in the pathogenesis of hypertension and atherosclerosis and may initiate rational and new therapeutic concepts which could potentially prevent complications under these conditions. In addition, statin-caused modulation of AT1 receptor expression may be involved in beneficial therapeutic effects irrespective of plasma cholesterol-lowering.

P530 Oestrogen decreases angiotensin II mediated free radical production in vascular smooth muscle cells via AT1 receptor modulation

A.T. Bäumer, G. Nickenig, K. Strehlow, S. Waßmann, H. Sauer[1], M. Böhm. *Klinik III für Innere Medizin; [1]Zentrum für Physiologie und Pathophysiologie, Universität zu Köln, Cologne, Germany*

In postmenopausal women, hormone replacement therapy influences lipid metabolism and potentially exerts direct effects on vascular cells. In order to elucidate those effects of estrogen on vascular smooth muscle cells (VSMC), angiotensin II mediated reactive oxygen species (ROS) production and AT 1 receptor (AT1) expression were investigated in the presence of 17β-estradiol (E_2) in VSMC.

Methods: In female rat VSMC, intracellular ROS levels were measured by confocal laserscanning microscopy using the fluorescent probe H_2DCF-DA. AT1 expression was determined by Northern analysis, and radioligand binding studies with ^{125}I-angiotensin II.

Results: After 3 h, angiotensin II caused significantly increased intracellular ROS levels in VSMC. 12 h pre-treatment with 1 μmol/l E_2 decreased the angiotensin II mediated ROS production ($p < 0.05$). E_2 led to a dose and time dependent downregulation of AT1 with a maximum of 40 ± 6% at 4 h treatment with 1 μmol/l E_2 ($p < 0.05$). In accordance, AT1 receptor density was decreased to 58 ± 4% after 12 h. Incubation of VSCM with the stereoisomeric 17 α-estradiol (1 μmol/l) or the estrogen receptor antagonist tamoxifen (1 μmol/l) did not influence AT1 mRNA expression, but tamoxifen completely prevented E_2 induced AT1 modulation ($p < 0.05$ vs. E_2 alone). Experiments performed under transcriptional blockage showed that E_2-induced AT1 downregulation was mediated through destabilsation of AT1 mRNA.

Conclusion: AT1 receptor activation is one major pathway leading to ROS release in the vessel wall. This free radical release is inhibited through estrogen-induced AT1 receptor downregulation via posttranscriptional mechanisms. These data may explain the role of estrogen in the pathophysiology of atherosclerosis and hypertension because oxygen derived free radicals and the local RAS of the vascular wall are important for the pathohysiology of both diseases.

P531 An in vitro study on the antioxidant capacity of statins

F. Franzoni, F. Regoli[1], F. Galetta[2], D. Taccola, F. Cinotti, C. Giusti. *Internal Medicine Dept, Pisa University, Pisa; [1]Biology and Genetics Dept, Ancona University, Ancona[2]Dept. of Internal Med., Pisa University, Pisa, Italy*

The remarkable results achieved by statins on the various end-points (stroke, total and cardiovascular mortality rate) have lead to the theory whereby these drugs may have a 'stabilising' mechanism on the atherosclerotic plaque, independent of reduced blood cholesterol levels, which are involved, however, in the progression of the disease.

Purpose: The purpose of this study was to assess the total antioxidant capacity of four known statins: Atorvastatin, Simvastatin, Pravastatin and Fluvastatin.

Methods: The total antioxidant capacity of Atorvastatin, Simvastatin, Pravastatin and Fluvastatin was calculated. The efficiency of these molecules as free radical scavengers was compared against peroxyl and hydroxyl radicals obtained through thermal decomposition of an azo-bis precursor and a modified Fenton reaction, respectively, measured by gas-chromatography. The results achieved with the drugs under analysis were expressed in TOSC (Total Oxyradical Scavenger Capacity) units and compared with the specific TOSC value per mg of certain classical antioxidants such as glutathione, ascorbic acid, uric acid and Trolox (the hydrosoluble analogue of Vitamin E).

Results: All the drugs analysed showed a good total antioxidant capacity towards the reactive oxygen species. In particular, Atorvastatin and Simvastatin proved to be exceptional scavengers of hydroxyl radicals with specific TOSC values of 2296 and 3375, respectively (TOSC/mg of tablet at 148 and 337, respectively), greater than that shown by Pravastatin (TOSC/mg active principle = 931; TOSC/mg of tablet = 45), by Fluvastatin (TOSC/mg of active principle = 875; TOSC/mg of tablet = 89) and by the classical antioxidants such as reduced glutathione (TOSC = 358), uric acid (TOSC = 1249) and Trolox (TOSC = 759) used as controls.

Conclusion: Atorvastatin and Simvastatin show a high capacity in neutralising OH−. Their TOSC values (referring to the active principle alone) are not only the highest among the various drugs analysed but are also higher than that of classical antioxidants (Glutathione, Uric Acid and Trolox).

P532 Inhibition of nuclear factor-κB-binding activity by hormone replacement therapy in vivo

P.B. Salbach[1], B. Salbach[3], A. Bierhaus[2], T. von Holst[3], P.P. Nawroth[2], W. Kübler[1]. *Departments of [1]Cardiology; [2]Endocrinology; [3]Gynaecology, University of Heidelberg, Heidelberg, Germany*

Hormone replacement therapy (HRT) in postmenopausal women is associated with a reduced risk for cardiovascular disease. A well documented antioxidant capacity of estradiol may be partially responsible for this beneficial effect. Because increased expression of the oxidative stress sensitive transcription factor nuclear factor$_\kappa$-B (NF-$_\kappa$B) is closely linked to development of cardiovascular disease, we studied the effect of HRT on NF-$_\kappa$B activity in vivo as well as on levels of NF-$_\kappa$B dependent markers of endothelial dysfunction.

Methods: To determine the NF-$_\kappa$B activity in vivo a Electrophoretic Mobility Shift Assay (EMSA) based detection system in ex vivo isolated blood mononuclear cells (PBMC) was used in 20 postmenopausal women before and after 6 weeks under HRT. Seum levels of lipidhydroperoxides (Lpx), as well as levels of soluble adhesion molecules vascular cell adhesion molecule-1 (sVCAM-1) and sE-selectin were measured by ELISA and lipidhydroperoxides were measured by an colorimetric method.

Results: After 6 weeks therapy NF-$_\kappa$B binding activity was reduced by 41% ($p < 0.001$). This was paralleled by reductions in serum lipid hydroperoxides (−19.69%; $p < 0.0081$) as a marker of oxidative stress and decreases in levels of NF$_\kappa$-B controlled sVCAM-1 (−15.48%, $p < 0.0002$) and E-selectin (−18.49%, $p < 0.0009$).

Conclusions: The present results indicate that estrogen replacement therapy inhibits transcription factor NF-$_\kappa$B activity in vivo. This may represent a novel mechanism for the vasoprotective effects of HRT.

P533 Intramuscular administration of oestrogen induces collateral artery augmentation in a rabbit model of chronic limb ischaemia

Z.S. Kyriakides, P. Petinakis, L. Kaklamanis, E. Sbarouni, D. Iliopoulos, N. Kostomitsopoulos, P. Karayannakos, D.Th. Kremastinos. *Laboratory of Experimental Surgery, School of Medicine and Onassis Cardiac Centre, Athens, Greece*

We tested the hypothesis that estrogen (Estr) can induce collateral artery augmentation in a rabbit model of chronic limb ischemia (I).

Methods: I was induced in the hindlimb of 16 oophorectomised New Zealand White rabbits by excision of the femoral artery. Ten days (D) after the induction of I (D 0), they were randomized into 3 groups according to the intramuscular treatment in the I limb: controls (n = 4) receiving saline at D 0; Estr 1 group (n = 6) receiving estradiol valerate, modified release (EVMR) 1 mg/kg at D 0; and Estr 2 group (n = 6) receiving EVMR 1 mg/kg at D 0 and D 15. Revascularization in the I limb was evaluated by calf blood pressure measurement and expressed as I/normal limb ratio (BPR), and capillary (Cap) density to muscle fiber ratio, after examination of light microscopic sections taken from the abductor muscle of the I limb at the time of death (D 30).

Results:

Mean ± SD	Controls	Estr 1	Estr 2
Cap/Muscle	0.83 ± 0.06	1.08 ± 0.14*	1.01 ± 0.14*
Calf BPR, D 30	0.37 ± 0.02	0.52 ± 0.11	0.65 ± 0.14*#
βEst D 15, pg/ml	13 ± 4	19 ± 1*	18 ± 3*
βEst D 30, pg/ml	8 ± 1	11 ± 2	27 ± 12*#

*$p < 05$ vs control; #: $p < 0.05$ vs Estr 1; βEst: 17-β-estradiol plasma levels.

Conclusion: Administration of Estr augments limb perfusion and is accompanied by evidence of increased collateral formation in I rabbit hind limbs. This study thus supports the hypothesis that administration of Estr to stimulate angiogenesis may represent a new therapeutic modality in the management of arterial insufficiency.

P534 C-reactive protein and atherogenesis – C-reactive protein is chemotactic for monocytes in vitro and its accumulation in the arterial intima precedes monocyte infiltration in early atherogenesis

J. Torzewski, C. Riest, M. Bienek, Z. Kaya, W. Koenig, V. Hombach, M. Torzewski. *University of Ulm, Internal Medicine II-Cardiology Ulm; University of Regensburg, Clinical Chemistry and Laboratory Medicine Regensburg, Germany*

There are several arguments suggesting that C-reactive protein may be intimately involved in atherosclerotic lesion formation. Thus, C-reactive protein aggregates lipid particles, for example LDL and VLDL. Furthermore, CRP interacts with specific receptors on inflammatory cells and activates the complement system via the classical pathway.

CRP has repeatedly been demonstrated to be present in advanced atherosclerotic lesions of humans. Recently, it has been demonstrated in early atherosclerotic lesions of humans for the first time and shown to colocalize with the terminal membrane attack complex of human complement suggesting that CRP may be the major complement activating molecule in atherosclerotic lesions.

In this study we have investigated the effects of purified human CRP on the chemotaxis of freshly isolated human blood monocytes in a modified Boyden microchemotaxis chamber. Additionally, we have stained the earliest stages of atherogenesis, so called insudative areas, in human coronary arteries by means of immunohistochemistry with monoclonal anti-CRP- and anti-CD68-antibodies in order to investigate whether CRP-deposition in the arterial wall precedes monocyte infiltration in atherogenesis.

Purified human CRP is chemotactic for human blood monocytes in a modified Boyden microchemotaxis chamber. The effect is CRP-dose-dependant and the maximum chemotactic response is observed at a CRP-concentration of 40 μg/ml. Higher CRP-concentrations result in a decrease of chemotactic activity. Checkerboard-analysis revealed that the effect is truely chemotactic rather than chemokinetic. CRP deposits in the arterial intima of human coronary arteries in the earliest stages of human atherogenesis preceding monocyte infiltration.

We conclude that CRP may be centrally involved in human atherogenesis. In addition to lipid aggregation and complement activation in the arterial wall, CRP may be one of the major chemoattractants for human blood monocytes in early atherogenesis.

P535 Coronary artery expression of $VEGF_{165}$ after balloon angioplasty correlates with vasa vasorum angiogenesis: potential role in arterial remodelling

K. Pels[1,2], M. Labinaz[1], Harvey Miller[1], H.-P. Schultheiss[2], E.R. O'Brien[1]. *[1]University of Ottawa Heart Institute, Ottawa ON, Canada; [2]Dep. of Cardiology, Benjamin Franklin Hospital, FU Berlin, Germany*

Vascular endothelial growth factor (VEGF) is an endothelial cell (EC) specific mitogen that induces angiogenesis in response to myocardial ischemia. We have recently demonstrated that regression of adventitial vasa vasorum after porcine coronary balloon injury parallels arterial lumenal narrowing. Therefore, in balloon injured porcine coronary arteries we sought to determine 1) changes in adventitial microvessel number (MVN) using image analysis and 2) VEGF expression. Pigs were sacrificed 60 min and 3, 7, 14 days after injury. Most abundant VEGF protein expression was immunodetected in the adventitia at early time points (60 min, 3 and 7 days) after arterial injury. Non-injured arteries (as well as the intima or media of all injured arteries) did not express VEGF protein. Using RT-PCR only the transcript corresponding to the 165 amino acid form of VEGF was identified. Adventitial angiogenesis occurred early in response to arterial injury, indicated by EC labeling index (EC LI) and MVN which were highest on days 3 and 7 respectively.

	Control	1 Hour	Day 3	Day 7	Day 14
EC LI	<1%	N/A	12–15%	3–16%	0–10%
MVN	16 ± 4	<5	38 ± 6*	39 ± 5*	28 ± 5

[*$p < 0.05$ injury vs. control]

VEGF165 expression after coronary angioplasty correlates with the angiogenesis of vasa vasorum and may be an important component of arterial repair, possibly by modulation of arterial remodeling.

P536 Vascular endothelial growth factor-induced chemotaxis of monocytes is attenuated in patients with diabetes mellitus: A potential predictor for the individual angiogenic response

Johannes Waltenberger, Juliane Lange, Andrea Kranz. *Dept. of Internal MedicineII, Ulm University Medical Center, Ulm, Germany*

Vascular endothelial growth factor-A (VEGF) is a potent angiogenic growth factor. In vitro, VEGF is acting on endothelial cells as well as on monocytes, two cell types participating in the angiogenic process *in vivo*. So far, it has not been possible to identify and assess differences in the individual angiogenic response.

We report about a chemotaxis assay using isolated monocytes from individual patients and from healthy volunteers, who served as normal and age-matched controls. The chemotactic response of individual monocyte preparations to VEGF (mediated via Flt-1, the VEGF-receptor 1) was quantitatively assessed using a modified Boyden chamber. While the migration of monocytes from healthy volunteers (n = 14; age 56.4 ± 4.0 years) could be significantly stimulated with VEGF (1.0 μM) to 148.4 [136; 170]% of the control value, monocytes from diabetic patients (n = 16; 68.3 ± 10.4 years; median HbA1c 8.5%) could not be stimulated with VEGF in this assay (91.1 [83; 98]% of unstimulated control; $p \ll 0.0001$). In contrast, the response of monocytes to the chemoattractant fMLP remained intact in diabetc patients (304% versus 235% in control group). The VEGF-inducible kinase activity of Flt-1 remained fully intact in monocytes from diabetic patients as assessed by in vitro kinase assays.

In conclusion, the cellular response of monocytes to VEGF is attenuated in diabetic patients, based on a signal transduction defect. Therefore, we predict that the use of VEGF for the therapeutic stimulation of angiogenesis should give better results in patients not suffering from diabetes mellitus.

P537 Augmentation of plasminogen activator inhibitor type-1 in adipocytes by glucose: implications for diminished fibrinolysis in obese insulin-resistant subjects

T. Sakamoto, B.E. Sobel[1], S. Fujii[1]. *Cardiovascular Medicine Dept., Kumamoto University Hospital, Kumamoto, Japan; [1]Medicine Dept., University of Vermont, Burlington VT, USA*

Background: Vasculopathy is accelerated in type II diabetes mellitus (DM). Mechanism(s) responsible have not yet been completely elucidated. We have shown previously that plasminogen activator inhibitor type-1 (PAI-1) in blood, the primary physiological inhibitor of tissue-type or urokinase-type plasminogen activator, is increased in non-insulin dependent DM (NIDDM) accounting for an unfavorable shift in the balance between thrombosis and fibrinolysis. Adipose tissue PAI-1 is a source of circulating PAI-1.

Methods: To determine whether the concentration of glucose and insulin consistent with the hyperglycemia and hyperinsulinemia seen in NIDDM can increase PAI-1 elaboration from adipocytes, 3T3-L1 mouse preadipocytes were differentiated into adipocytes and co-incubated with selected concentrations of glucose with or without insulin for 5 days. The conditioned media were assayed for PAI-1 by Western blotting and for plasminogen activator (PA) activity by zymography.

Results: Glucose stimulated PAI-1 production in a dose-dependent manner (100 ± 22 at 5 mM, 321 ± 12 at 20 mM, 399 ± 21 at 30 mM glucose; mean ± SEM; n = 6), and PA activity was decreased in proportion to the increased PAI-1. Concomitant stimulation of insulin (2 nM) with glucose boosted PAI-1 production in adipocytes (100 ± 22 at glucose 5 mM, 165 ± 13 at glucose 10 mM, 225 ± 29 at glucose 10 mM with insulin 2 nM).

Conclusions: Production of PAI-1 by adipocytes is augmented in response to glucose and insulin in concentrations seen in obese patients with NIDDM. These results indicate that increased PAI-1 is likely to be attributable to direct effects of glucose on the synthesis of PAI-1 by adipose tissue. Because insulin can augment the effect of glucose on PAI-1 production in adipocytes, it might be suggested that cytoplasmic glucose level is more important at least in adipocytes than that of outside of the cells. The increased PAI-1 may account for the diminished fibrinolytic capacity that can exacerbate atherogenesis in patients with NIDDM.

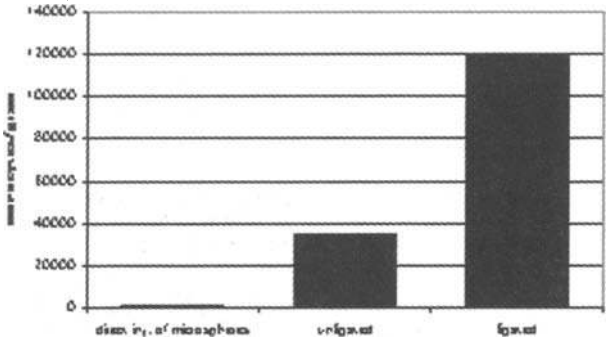
P538 Microsphere loaded monocytes: new insights into monocyte kinetics in collateral artery formation

I. Hoefer, I. Buschmann, N. van Royen[1], M. Heil, E. Katzer, W. Schaper.
Experimental Cardiology Dept, Max-Planck-Institute, Bad Nauheim, Germany; [1]Department of Cardiology, Academic Medical Centre, Amsterdam, Netherlands

Introduction: Ligation of the art. femoralis in the rabbit leads to rapid proliferation of collateral arteries (arteriogenesis). This effect is mediated by circulating monocytes that attach to and penetrate activated endothelium in the collateral arteries under conditions of elevated shear stress. In the present study we evaluated the kinetics of monocytes in collateral artery via monocyte loading with fluorescent microspheres.

Methods: The right art. femoralis was ligated. Isolated rabbit monocytes were loaded with fluorescent microspheres (*2 mm) and reinfused intravenously. 48 hours after reinfusion animals were killed and biopsies were taken of the adductor and quadriceps muscle in both hindlimbs whereby the biopsies of the left hindlimb served as control. In a second control group microspheres were directly infused. With FACS analysis the total number of monocytes per gram muscle tissue was quantified.

Results: Number of monocytes/gram muscle tissue: direct infusion of microspheres = 1000 ± 725, unligated hindlimb = 35000 ± 7200; ligated hindlimb = 120000 ± 10500 (see figure). All differences were significant.



Conclusion: This is the first report evaluating the kinetics of monocytes in collateral artery formation by loading these cells with fluorescent microspheres. It is shown that accumulation of small microspheres in the hindlimb muscle tissue only occurs when they are loaded into monocytes. Furthermore the quantified number of monocytes is significantly higher in the ligated hindlimb as compared to the unligated hindlimb, indicating that monocyte invasion is an obligatory and highly selective step in collateral artery formation.

P539 Sustained transmyocardial loading with bFGF following single intrapericardial delivery: local kinetics and tissue penetration

H.P. Stoll, A. Szabo[1], K.L. March[2]. *Indiana University, Indianapolis IN; [1]National Institute of Health, Bethesda MD [2]Roudebush VA Medical Center, Indianapolis IN, USA*

Recent data have demonstrated angiogenesis in the context of continuous or repetitive local delivery of bFGF protein. We wished to determine pharmacokinetics and myocardial penetration of bFGF following a single intrapericardial delivery; and we developed and tested a novel mathematical model for myocardial penetration from the pericardial space. Two doses of bFGF (30 ug, 200 ug) admixed with either 131-I- or 125-I-bFGF were delivered, with or without adjunctive heparin, into the porcine pericardial space by a transmyocardial route using a helix-needle catheter. Washout was assessed over 24 hours by serial scintigraphy and by direct activity measurement to define agent loss from the region of interest. Epi-to-endocardial concentration gradients (n = 5) established 1 hour and and 24 hours after delivery were assessed by gamma-counting of myocardial tissue series obtained by cryosectioning tangential to the epicardial surface. A mathematical model was developed based on a reaction-diffusion equation describing agent transfer into myocardium as a function of interstitial diffusion and transcapillary washout. The data revealed substantial transmyocardial concentration gradients, with penetration half-depths ranging from 0.5–1.5 mm; these profiles were closely fit by our mathematical model using reasonable parameters (typical r = 0.95). After intrapericardial delivery, epicardial bFGF levels were 164 ± 59 (mean ± SEM) fold and endocardial levels were 15 ± 9 fold increased over serum concentations; and these gradients were maintained for 24 hours. Adjunctive heparin did not markedly alter these results. Pericardial delivery of bFGF results in well-modeled, prolonged transmyocardial loading. These data provide a clearer understanding of the pericardial space as an advantageous administration route for angiogenic peptides.

P540 Non-invasive prediction of angiographic progression of coronary artery disease by dipyridamole stress echocardiography

O. Rodriguez, S. Fedele, I. Ungi, R. Sicari, M. Morelos, P. Landi, M. Marzilli, E. Picano. *CNR, Institute of Clinical Physiology, Pisa, Italy*

Background: coronary angiography is the currently accepted gold standard to assess progression of coronary artery disease. Dipyridamole stress echo (DSE) might provide an alternative non-invasive method for this purpose, since the extent and severity of anatomic coronary artery disease (CAD) are mirrored by the extent and severity of stress-induced wall motion abnormalities.

Aim: to assess whether variations in serial DSE match variations in angiographically assessed CAD.

Methods: from the IFC-CNR 15 years stress echo data bank (1983–1998), we selected 60 pts meeting the selection criteria of 2 repeat coronary angiography and DSE, each test performed and interpreted independently and within one week of each other. The second angiographic-stress echocardiographic assessment was repeated 45.1 ± 30.2 months after the initial one. Angiographic progressors were defined a priori, according to Kaski, as patients with any stenosis progressing to occlusion and/or any significant stenosis with >20% stenosis progression. Stress echocardiographic progressors were defined as patients with a previously negative test becoming positive or with a positive test with increase in peak Wall Motion Score Index > 0.12 (1 = normal to 4 = dyskinetic in a 16 segment model) at repeat testing.

Results: of the 60 patients, 44 were angiographic "progressors" and 16 "non-progressors". Stress echo response was concordant with angiographic identification in 39/44 progressors and 15/16 non progressors, with an overall concordance of 90%. The greatest rate of concordance was achieved with a positive DSE response becoming negative (4/4, 100% concordance with angiographic "non progressors") and with a negative DSE becoming positive (18/19, 95% concordance with angiographic "progressors").

Conclusions: dipyridamole stress echo response allows to efficiently separate angiographic "progressors" and "non progressors", simply taking into account the presence, extent and severity of stress-induced wall motion abnormalities.

P541 Quantification of aortic atherosclerosis by dynamic three-dimensional echocardiography

J. Drozdz, M. Zwierzak, J.D. Kasprzak, K. Wierzbowska, M. Plewka, M. Ciesielczyk, M. Krzeminska-Pakula. *Cardiology Dept, Bieganski Institute, Lodz, Poland*

Atherosclerotic plaques in the thoracic aorta are visualized by transesophageal echocardiography (TEE). The ability to render the volume of desired structure by three-dimensional echocardiography (3-D) provides the opportunity for quantitation.

To determine whether 3-D could be used for the evaluation of aortic atherosclerosis we performed serial volumetric calculations of the thoracic aorta in three levels using rotational TEE acquisition.

Group of consecutive 38 patients (26 men, 54 ± 14 y.) referred for TEE was studied. TEE probe was placed at the depth of 30 cm, 35 cm, and 40 cm from incisors and volumetric datasets were sampled using 3° intervals. The reformatted datasets were reviewed and the border between the aortic wall, plaque and lumen was determined. Two-cm segments of the thoracic aorta were analyzed to calculate the volume of protruding aortic plaques, and maximal and minimal volume of the aortic lumen – the difference being aortic pulsation.

The results of volumetric measurements in cm^3 are presented in three levels of aorta are:

	Range	30 cm	35 cm	40 cm
Aortic lumen – max	7.2–19.7	12.0 ± 3.2	11.5 ± 3.1	10.9 ± 2.5
Aortic lumen – min	4.2–19.5	10.9 ± 3.4	10.3 ± 2.9	10.0 ± 2.6
Aortic pulsation	0.0–3.4	1.1 ± 0.9	1.2 ± 0.7	1.0 ± 0.6
Aortic plaque	0.0–2.8	1.3 ± 0.5	1.2 ± 0.7	1.1 ± 0.6

There was a correlation between plaque volume and aortic volume in all three levels ($r = 0.81$, $r = 0.72$, $r = 0.73$, all $r = 0.75$, $y = 0.17x - 0.74$, $p < 0.001$). There was no correlation between the aortic pulsation and plaque volume ($r = -0.04$, p = NS). The correlation coefficients of inter-and intraobserver variability ranged from 0.89 to 0.98, $p < 0.05$, being the highest for intraobserver off-line volume calculation.

Conclusions: Aortic atherosclerosis of the thoracic aorta can be reproducibly quantitated using three-dimensional transesophageal echocardiography by aortic plaque volume and aortic pulsation calculation. Both aortic plaque volume and aortic pulsation represent different indicators of aortic physiology. There is an evidence for aortic remodeling with aortic enlargement corresponding to increase of plaque volume.

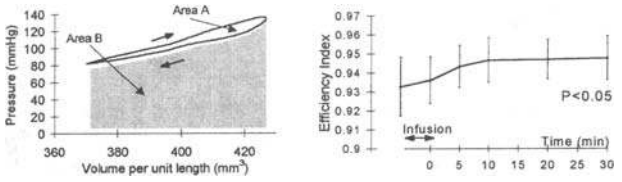
CONSEQUENCES OF HYPERTENSION: ARTERIES AND VASCULAR FUNCTION

P542 Enalapril improves aortic energetics in hypertensive patients

C. Vlachopoulos, C. Stefanadis, C. Pitsavos, P. Toutouzas. *Hippokration Hospital, Athens Medical School, Athens, Greece*

The aorta (Ao), by virtue of its elastic nature, stores a considerable amount of the LV power generated during cardiac systole, which is returned by Ao recoiling during diastole. To study the effect of ACE inhibitors on regional Ao energetics, serial pressure (P)-volume (V) loops were obtained from simultaneous recordings of the thoracic Ao V per unit length and P, before and for 30 min after the i.v. administration of enalaprilat (EN, 1.25 mg over 5 min.) in 10 hypertensives. Ao V was measured by an intravascular dimension catheter, developed in our institution (Circulation 1995; 92: 2210–9) and Ao P by a Millar micromanometer. The area under the systolic (ascending) portion of the clockwise loop (left fig., areas A + B), represents the energy stored by the Ao, the area under the diastolic (descending) portion of the loop represents the energy returned by the Ao (area B), whereas the area within the loop (area A) the energy dissipated by the Ao due to its viscosity.

Results: Efficiency index of the Ao (= energy returned/stored) was increased with EN (right fig.), indicating decreased Ao energy loss.



Conclusions. Ao energetics are improved and energy loss is reduced after EN administration. This effect may contribute to the beneficial effects of enalapril on hypertensive patients.

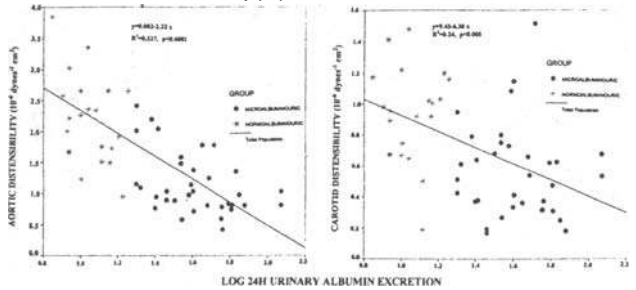
P543 Microalbuminuria is associated with greater large elastic-type artery stiffening in untreated essential hypertensive patients

C. Tsioufis, S. Lambrou, C. Stefanadis, D. Antoniadis, I. Kallikazaros, P. Toutouzas. *Department of Cardiology, University of Athens, Greece*

Microalbuminuria (MA) is a marker of increased cardiovascular risk in essential hypertension, but the mechanisms underlying its prognostic significance have not been elucidated. Large artery elastic properties represent an important determinant of left ventricular pulsatile load and coronary blood flow and are impaired in hypertensive patients (pts).

Methods: To investigate any possible relations between MA and large artery mechanic performance in this setting, we measured the distensibility of the ascending thoracic aorta (AoDist) and common carotid arteries (CCADist) in 83 non-diabetic pts (50 men, 33 women, aged 53 ± 10 years) with untreated JNC-VI stage 2 or 3 essential hypertension. Thirty-five pts had MA (mean urinary albumin excretion [UAE] of 20–200 mg in 3 consecutive 24-hour urine collections) and 48 pts were normoalbuminuric. AoDist and CCADist were calculated by use of the formula: 2 × (pulsatile change in diameter)/([diastolic diameter] × [pulse pressure]). Arterial diameters were measured by ultrasonography, while arterial pressure was measured simultaneously by sphygmomanometry at the brachial artery.

Results: The 2 patient subgroups did not differ significantly with respect to age, sex, smoking habits and plasma lipid values. Both AoDist and CCADist were significantly lower in pts with MA compared with normoalbuminuric pts (1.2 ± 0.4 vs. 2.3 ± 0.7 and 0.6 ± 0.3 vs. 0.9 ± 0.3 dyne^{-1} cm^2 × 10^{-6}, respectively, $p < 0.005$). Forward multiple linear regression analysis identified a significant association between the logarithm of 24-hour UAE and both AoDist and CCADist in the entire study population (scatterplots).



Conclusions: Our findings support the view that MA is a renal manifestation of widespread arterial damage rather than of damage confined to the renal vascular bed alone. The additional increase of left ventricular pulsatile load and offsetting of left ventricular-vascular functional coupling induced by greater large artery stiffening proposes one explanation for the increased cardiovascular risk of pts with essential hypertension and MA.

P544 Angiotensin-(1–7) and lisinopril act in synergism to inhibit angiotensin II-induced vasoconstriction in rat aorta

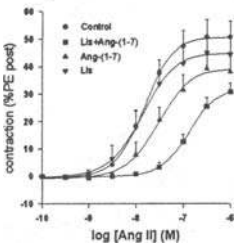
Anton J.M. Roks, Vincent F.M. Segers, Dieter M.M. De Cleen, Hendrik J. Buikema, Wiek H. Van Gilst. *Department of Clinical Pharmacology, University of Groningen, A. Deusinglaan 1, 9713 AV Groningen, Netherlands*

From experimental studies it is evident that angiotensin-(1–7) (Ang-(1–7)) is involved in vascular functions, e.g. by decreasing Ang II-induced vasoconstriction and angiotensin-converting enzyme (ACE) activity. Thus, Ang-(1–7) acts as a modulator of the renin-angiotensin system (RAS). The RAS is an important target for treatment of cardiovascular diseases, e.g. by ACE inhibitors. Strikingly, ACE inhibitors increase plasma and tissue Ang-(1–7) concentrations, which might further inhibit the RAS. Therefore, we investigated whether the ACE inhibitor lisinopril potentiates antagonism of Ang II-induced vasoconstriction by Ang-(1–7) in vitro.

Methods: The effect of pretreatment with either 10 μM Ang-(1–7), 1 μM lisinopril, or both on Ang II-induced constrictions of isolated rat aortic rings was measured in parallel rings from each of 7 rats. After Ang II, a single dose of 1 μM phenylephrine was given (PE post). All experiments were performed in the presence of 0.1 mM L-nitromonomethyl-arginine to inhibit Ang-(1–7)-induced vaso-dilatation by nitric oxide release. Responses to Ang II were expressed as a percentage of PE post, and statistical significance tested with ANOVA for repeated measure. The potency of Ang II (EC_{50}) was calculated via logistic curve fitting, and statistical significance tested by one-way ANOVA with Bonferroni correction.

Results: Only combined treatment with Ang-(1–7) and lisinopril inhibited dose-dependent vasoconstrictions to Ang II significantly (Fig. 1) and also decreased the potency of Ang II tenfold from −7.84 ± 0.10 (control) to −6.82 ± 0.12 (Ang-(1–7) + lisinopril) log M.

Fig. 1



Discussion: Lisinopril potentiates antagonism of Ang II-induced vasoconstriction by Ang-(1–7). Considering the RAS inhibiting and vasodilator properties of Ang-(1–7), it may be an important contributor during treatment of cardiovascular disease with ACE inhibitors.

P545 Evaluation of endothelial function in essential hypertension

G.V. Simonia, N.I. Tatishvili, M.R. Kutateladze, I.M. Jashi[1], I.T. Andronikashvili. *Department of Internal Medicine, State Medical University, Tbilisi; [1]Institute of Clinical and Experimental Cardiology, Tbilisi, Georgia*

Endothelial dysfunction is detected at early stages of essential hypertension. Abnormal endothelium-dependent vascular relaxation is largely related to reduced activity of nitric oxide (NO). In the target cells NO increases concentration of cGMP by activation of soluble guanilatcyclase and causes vascular relaxation. Membrane mechanisms of vascular response can be detected by measurement of Ca,ATPase activity that is also cGMP-dependent. The purpose of our study was detection of endothelial dysfunction by vascular response to NO inhibition and evaluation of Ca,ATPase activity.

Methods: We performed randomized trial on 25 hypertensive patients (stage I, mean age 42 ± 5 yrs) and age-matched 10 healthy subjects. NO activity was estimated by vascular response to oral administration of methylene blue (5 mg/kg) – NO activity blocker. Ca,ATPase activity was measured in red blood cell membranes (Vincenzi and Raess method).

Results: Our study revealed that oral administration of methylene blue caused elevation of arterial blood pressure, especially diastolic blood pressure. Vasoconstrictive response was less significant in hypertensive patients. Basal Ca,ATPase activity did not differ significantly in both groups while after administration of methylene blue Ca,ATPase activity decreased in normotensive patients (0.62 ± 0.04 mcmol Pi/mg*h vs 1.15 ± 0.07 mcmol Pi/mg*h, $p < 0.01$) and did not change significantly in hypertensive patients (0.94 ± 0.05 mcmol Pi/mg*h vs 1.10 ± 0.06 mcmol Pi/mg*h, $p > 0.05$).

Conclusion: Patients with essential hypertension have impaired endothelium-dependent vasoconstrictive response to NO inhibition that may be partially due to inadequate changes in Ca,ATPase activity.

P546 Concentric remodelling is accompanied by an impairment of aortic distensibility and an increased urinary albumin excretion rate in untreated patients with essential hypertension and normal left ventricular mass

C. Tsioufis, C. Stefanadis, M. Toutouza, C. Pitsavos, E. Sevdalis, C. Stratos, P. Toutouzas. *Department of Cardiology, University of Athens, Hippokration Hospital, Athens, Greece*

The prognostic contribution of left ventricular (LV) geometry in the presence of normal LV mass in hypertensive patients (pts) has not been well defined.

Methods: Towards this end, in 210 untreated, non-diabetic, newly diagnosed patients (pts) with stage I–II (JNC VI) essential hypertension (mean age 53 ± 8 years), LV mass index (LVMI), relative wall thickness (RWT), aortic distensibility (Ao-Dist) and urinary albumin excretion (UAE) were evaluated. Ao-Dist was calculated as a function of changes in aortic diameter (d) (determined by echocardiography) and pulse pressure (determined sphygmomanometrically in the brachial artery) by the use of the formula: Ao-Dist = 2 × (pulsatile changes in d)/[(diastolic d) × (pulse pressure)]. UAE was evaluated in three non-consecutive 24 h-urine samples.

Results: In the entire study population, office systolic and diastolic BP was 155 ± 17/99 ± 9 mmHg, LVMI was 100.9 ± 22 g/m^2, Ao-Dist was 1.83 ± 1.1 dyne^{-1}cm^{2}10^{-6} and UAE was 26.6 ± 24 mg/24 h. LVMI was positively correlated with UAE ($r = 0.49$, $p < 0.001$) and negatively correlated with Ao-Dist ($r = -0.21$, $p < 0.005$). LVMI was within normal values (<125 g/m^2) in 176 pts. From these pts, 105 had LV normal geometry (NG) (LVMI 90.7 ± 16 g/m^2 and RWT 0.39 ± 0.03) while 71 had LV concentric remodeling (CR) (LVMI 98.7 ± 14 g/m^2 and RWT 0.49 ± 0.03). The group with CR compared to the group with NG, had significantly increased age (56 vs 48 years), BSA (1.93 vs 1.87 m^2), office systolic BP (157 vs 149 mmHg) and UAE (34.5 vs 15.5 mg/24 h) and significantly decreased Ao-Dist (1.49 vs 2.17 dyne^{-1}cm^{2}10^{-6}).

In conclusion, hypertensive patients with LV CR exhibit a reduction in Ao-Dist and an increase in UAE. These findings may contribute in the unfavorable prognosis of hypertenive pts with CR and normal LV mass.

P547 Effects of doxazosin and atenolol on endothelin-1 and von Willebrand factor in hypertensive middle-aged men

Ingebjørg Seljeflot, Harald Arnesen, Per Andersen, Trude Aspelin, Peter Kierulf. *Ullevaal University Hospital, Oslo, Norway*

The endothelium plays an important regulatory role in hypertension. Elevated levels of endothelin-1 (ET-1) and von Willebrand factor (vWF), both markers of endothelial function, are associated with hypertension.

In a randomized study we have investigated the effect of antihypertensive treatment with the α-blocker doxazosin (n = 23) or the β-blocker atenolol (n = 22) for 22 weeks on circulating levels of ET-1 and vWF in middle-aged men with essential hypertension.

Blood pressure reduction was satisfactorily achieved with both drugs. A reduction in the levels of vWF occurred in both groups being more pronounced in the α-blocker group than the decrease on β-blockers: median values 148% to 124% ($p = 0.004$) versus 170% to 143% ($p = 0.056$), respectively. In the α-blocker group, there was a significant correlation between the reduction in blood pressure and the decline in vWF; $r = 0.57$ ($p = 0.074$) for SBP and $r = 0.50$ ($p = 0.022$) for DBP. A highly significant decrease in plasma ET-1 was obtained during β-blockade (0.67 pg/mL to 0.60 pg/mL, $p = 0.007$), whereas no significant change occurred within the α-blocker group. There was no significant correlation between the fall in blood pressure and the reduction in ET-1 in the β-blocker group.

The different effects of α- and β-blockers on endothelial function expressed as vWF and ET-1, could indicate that the effects are probably not only related to the blood pressure *per se*, but also to the different pharmacological mechanisms of the drugs.

P548 Antihypertensive and vascular effects of omapatrilat, a vasopeptidase inhibitor, in salt-induced hypertension

L.V. d'Uscio, T. Quaschning, T.F. Lüscher. *Cardiology, University Hospital Zurich; Cardiovascular Research, Institute of Physiology, University of Zurich, Switzerland*

The involvement of natriuretic peptides in salt-sensitive hypertension is still unclear. Our objective was to determine the effects of a new, orally available dual inhibitor of neutral endopeptidase (NEP) and angiotensin-converting enzyme (ACE), omapatrilat, on systolic blood pressure (SBP) and structure of small resistance arteries in a model of salt-induced hypertension. Dahl salt-sensitive (DS) rats were treated for 8 weeks with 4% NaCl alone or in combination with either omapatrilat (35 mg/kg/day) or captopril (100 mg/kg/day). Placebo-treated rats served as controls (n = 5–6/group). Small mesenteric arteries (SMA; 270 μm) were isolated and their geometry was studied in vitro under perfused and pressurized conditions.

Chronic salt administration increased SBP by 56 ± 2 mmHg in DS rats, as compared to 7 ± 2 mmHg in control DS rats ($P < 0.05$; tail cuff method). This increase was in part prevented by concomitant omapatrilat or captopril administration (23 ± 5 mmHg and 20 ± 7 mmHg, respectively; $P < 0.05$ vs salt-treated DS rats). The media/lumen ratio of the SMA increased in the DS rats on 4% NaCl diet by hypertrophic remodeling (growth index: 19 ± 2%, $P < 0.05$). Omapatrilat prevented the structural changes (−4 ± 6%; $P < 0.05$ vs salt-treated DS rats). In contrast, captopril did not significantly affect vascular structure (11 ± 3%) despite lowering in SBP. The media/lumen ratio of SMA was significantly correlated with SBP ($r = 0.80$, $P < 0.0001$, linear regression).

These findings suggest that inhibition of the degradation of natriuretic peptides together with ACE-inhibition by omapatrilat may be therapeutically useful to lower arterial pressure and to prevent vascular remodeling of resistance arteries in salt sensitive individuals.

P549 Activation of extracellular signal-regulated kinases is essential for pure transmural pressure-induced vascular smooth muscle cell proliferation

Y. Tsuda, M. Okazaki, Y. Uezono[1], H. Kato, A. Osajima, H. Okuda, Y. Nakashima. *The Second Dept. of Internal Medicine, Univ. of Occupa. and Environ. Health, Kitakyushu; [1]Department of Pharmacology, Univ. of Occupa. and Environ.Health, Kitakyushu, Japan*

Background: Vascular wall is constantly exposed to mechanical forces such as transmural pressure, stretch and shear stress. In hypertension, increased transmural pressure directly affects vascular smooth muscle cells (VSMCs), which results in cell proliferation, and finally causes atherosclerosis. Little is known, however, about mechanisms by which transmural pressure promotes proliferation of VSMCs. We have developed a system with which to investigate the effect of pure transmural pressure on cell functions without effect of shear stress or stretch. In the present study with this system, we investigated the possible involvement of several protein kinases in the mechanisms underlying transmural pressure-induced proliferation of VSMCs.

Methods: DNA synthesis and cell number were measured by [^{3}H]-thymidine incorporation and a cell proliferation kit, respectively. Pressure was applied to quiescent rat VSMCs in culture for 1–30 min by compressed helium gas in the loading apparatus in which the partial pressure of oxygen was kept constant. The cells were then incubated in a CO_2 incubator for determination of DNA synthesis and cell number. Phosphorylation of ERKs was measured by Western blotting, and ERK activity was measured by an enzyme assay kit.

Results: Transmural pressure up to 120 mmHg increased [^{3}H]-thymidine incorporation (220 ± 42.5%, $p < 0.05$) in a pressure-dependent manner. Transmural pressure (120 mmHg) also significantly increased cell number. Protein kinase C inhibitors H7 (3 μM) and Bisindolylmaleimide I (1 μM) both inhibited pressure (120 mmHg)-induced [^{3}H]-thymidine incorporation. A tyrosine kinase inhibitor genistein (5 μM) also inhibited pressure (120 mmHg)-induced [^{3}H]-thymidine incorporation, whereas a stretch-activated mechanosensitive channel blocker $GdCl_3$ (10 μM) did not cause any effect. Transmural pressure (120 mmHg) increased phosphorylation (1.6 fold) and activation (3.1 fold) of ERK. Further, an ERK kinase inhibitor PD98059 (25 μM) completely blocked pressure (120 mmHg)-induced [^{3}H]-thymidine incorporation.

Conclusions: These results suggest that activation of ERK is essential for pure transmural pressure-induced proliferation of VSMCs, in addition to PKC and tyrosine kinase activation, and these multiple activation of protein kinases could be involved in the pathogenesis of atherosclerosis induced by transmural pressure in hypertension.

P550 Parallel unfavourable effects of essential hypertension on arterial pressure waveform, large arteries elasticity and urinary albumin excretion rate

C. Tsioufis, C. Stefanadis, I. Kallikazaros, D. Antoniadis, M. Toutouza, C. Pitsavos, P. Toutouzas. *Department of Cardiology, University of Athens, Hippokration Hospital, Athens, Greece*

Although hypertension induces structural and functional changes in both arterioles and large arteries, the interaction between arterial pressure wave (APW) contour, carotid distensibility (CD), aortic distensibility (AoD) and urinary albumin excretion (UAE) rate has not been adequately described.

Methods: For this purpose, in 81 untreated, newly diagnosed patients (pts) with stage I–II (JNC VI) essential hypertension (aged 54 ± 10 years, office BP 154 ± 18/97 ± 12 mmHg), the LV mass index (LVMI), relative wall thickness (RWT), APW, AoD, CD and UAE were evaluated. APW was recorded by carotid applanation tonometry and waveform shape was expressed by the augmentation index (AI). Subjects were classified to group 1 (with a dominant early systolic peak, AI ≤ 0) and group 2 (with a dominant late systolic peak, AI > 0). AoD and CD were calculated as a function of changes in Ao and C diameter (determined by echocardiography) and pulse pressure (determined sphygmomanometrically in the brachial artery) by the use of the formula: Distensibility = 2 × (pulsatile changes in diameter)/[(diastolic diameter) × (pulse pressure)]. UAE was evaluated in three non-consecutive 24-h urine samples.

Results: In the entire study population LVMI was 92 ± 19 gr/m^2, RWT was 0.48 ± 0.06, AI was 0.11 ± 0.25, AoD and CD was 1.6 ± 1.1 and 1.2 ± 0.9 dyne^{-1}cm^{2}10^{-6} respectively and UAE was 25 ± 24 mg/24 h. Group 2 (54 pts, AI = 0.16 ± 0.1) compared to group 1 (27 pts, AI = −0.001 ± 0.3) were older (49 vs 56 years) and had significantly increased office BP (158 ± 18/100 ± 12 vs 145 ± 15/91 ± 9 mmHg), LVMI (98 vs 82 gr/m^2), RWT (0.49 vs 0.45) and UAE (29 vs 14 mg/24 h) and significantly impaired AoD and CD (1.2 ± 0.1 vs 2.6 ± 0.1 and 0.9 ± 0.1 vs 1.4 ± 0.1 dyne^{-1}cm^{2}10^{-6}, respectively). In the entire study population, AI was positively correlated with age ($r = 0.38$, $p < 0.05$), LVMI ($r = 0.44$, $p < 0.001$) and UAE ($r = 0.29$, $p < 0.005$) and inversely correlated with AoD and CD ($r = -0.23$, $p < 0.05$ and $r = -0.22$, $p < 0.05$ respectively).

Conclusion: Hypertension induced changes in APW shape are closely related with changes in both the physical properties of large arteries and the UAE rate.

P551 Uteroplacental perfusion and vascular endothelial growth factor in normotensive and pre-eclamptic pregnancy

L.A. Simmons, A. Hennessy, A.G. Gillin, R.W. Jeremy. *Departments of Cardiology and Renal Medicine, Royal Prince Alfred Hospital, Sydney NSW, Australia*

Aim: Preeclampsia is characterised by impaired uteroplacental perfusion. Vascular endothelial growth factor (VEGF), important in vasculogenesis, is upregulated by hypoxia. This study examined placental VEGF distribution in relation to uterine artery blood flow.

Methods: Third trimester Doppler recordings of uterine artery flow velocities were performed in 11 normotensive women (*NT*) and 9 women with preeclampsia *HT* matched for age and gestation. Resistance index ($RI = (V_s - V_d)/V_s$) and pulsatility index ($PI = (V_s - V_d)/V_m$) were calculated, where V_m is mean flow, V_s peak systolic flow and V_d end-diastolic flow velocity. Biopsies of placental tissue following delivery were examined for the presence and distribution of VEGF with avidin-biotin-peroxidase immunohistochemistry.

Results: Uterine artery V_s was increased and V_d decreased in *HT* (V_s: *NT* mean ± S.D. 101 ± 26 cms^{-1}, *HT* 126 ± 42; V_d: *NT* 57 ± 16 cms^{-1}, *HT* 53 ± 21). *RI* and *PI* were thus significantly increased in *HT* (*RI*: *NT* 0.44 ± 0.05, *HT* 0.58 ± 0.11, $p = 0.002$; *PI*: *NT* 0.62 ± 0.10, *HT* 1.05 ± 0.37, $p = 0.023$). Placental VEGF was increased in intensity and distribution in *HT* in both the extravillous trophoblast of the decidua (65 ± 25% cells stained for VEGF in *HT* vs 36 ± 23% in *NT*, $p = 0.014$) and in the villous syncytiotrophoblast (circumferential staining score 1.9 ± 0.4 in *HT* vs 1.4 ± 0.3 in *NT*, $p = 0.023$).

Conclusions: Impaired uteroplacental blood flow in preeclampsia is associated with abnormal uterine artery Doppler waveforms. The relative hypoxia characterising preeclampsia may be responsible for the increase in placental VEGF. Increased VEGF may act as a compensatory mechanism by promoting vasculogenesis to restore blood flow towards normal.

P552 Endothelium-dependent relaxation in rabbit mesenteric arteries: role of calcium

F. Fabi, T. Stati, P. Del Basso. *Pharmacology Dept, Istituto Superiore di Sanita, Rome, Italy*

Agonist-induced Ca^{2+} entry is a major determinant for the vascular endothelial release of relaxing factors. In particular, the release of nitric oxide (NO) and EDHF is associated with an increase of free intracellular calcium in the Ca^{2+} rise occurs through influx from extracellular space or through the release from intracellular stores. The aim of the present study was to characterize the Ca^{2+} mobilization process involved on vasodilating responses to carbachol in rabbit mesenteric artery (RbMa).

Methods: Ring segments of superior mesenteric artery from male New Zeland rabbits were suspended in a 20 ml bath with oxygenated krebs solution containing 0.01 mM indomethacin. Isometric responses of the vessels contracted with noradrenaline (NA, 1 μmol) were recorded. Drugs were added to the bath in a cumulative manner. In some vessels endothelium was mechanically removed.

Results: In the presence of intact endothelium carbachol (0.01–10 μmol) elicited dose related relaxing responses. In the presence of the NO-synthase L-NNA, 10 mM or with hyperpolarizing solution (K^+ 30 mM) caused a rightward shift of the dose-respone curves. In the combined presence of high K^+ and L-NNA carbachol failed to elicit any relaxing response. Removing calcium from the bathing solution shifted to the right the concentration respose curves and the addition of L-NNA to the Ca^{2+} free solution completely prevented the vasodilator effects of carbachol. The combined presence of the specific inhibitor of endoplasmic reticulum Ca^{2+} ATPase thapsigargin (1–10 μmol) and L-NNA into the bathing solution abolished the carbachol induced relaxation.

In conclusion the present data demonstrate that carbachol relax RbMa by inducing the release of both NO and EDHF from the endothelium. Moreover it is suggested that: 1) NO production does not depend on extracellular calcium and 2) EDHF-induced effects require Ca^{2+} influx from extracellular space and depend on refilling of intracellular Ca^{2+} stores.

P553 Differing benefit of haemodialysis on aortic mechanics in normotensive versus hypertensive patients with chronic renal failure

L. Soubassi[1], C. Aggeli[2], S. Lambrou[2], C. Pitsavos[2], C. Stephanadis[2], P. Soubassis[2], P. Toutouzas[2]. [1]*Renal Unit, "Alexandra" Hospital;* [2]*Dept. of Cardiology Hippokration University Hospital, Athens, Greece*

Aortic elastic properties represent an important determinant of left ventricular pulsatile load and coronary blood flow. Aortic mechanics are markedly impaired in patients (pts) with chronic renal failure (CRF), while evidence has appeared of an acute beneficial effect of hemodialysis (HD) on this physiological parameter. Little is still known, however, regarding the magnitude of this effect in different subgroups of CRF pts.

Methods: In an attempt to further clarify this issue, we measured the distensibility of the proximal ascending thoracic aorta (AoDist) in 48 CRF pts (31 men, 17 women, aged 45 ± 14 years) undergoing regular HD, before and immediately after a mid-week dialysis session. Twenty-eight pts were hypertensive (17 men, 11 women, aged 51 ± 14 years) while the remaining 20 pts were normotensive (14 men, 6 women, aged 38 ± 11 years). AoDist was calculated as a function of changes in aortic diameter and pulse pressure, using the formula: 2 × (pulsatile change in diameter)/([diastolic diameter] × [pulse pressure]). Aortic diameters were measured by transthoracic echocardiography, while arterial pressure was measured simultaneously by sphygmomanometry at the brachial artery.

Results: The 2 groups did not differ with respect to the prevalence of coronary risk factors other than hypertension, neither regarding body mass index, body weight before and after HD, ultrafiltration volume, EPO therapy, plasma fibrinogen, plasminogen, fibronectin, creatinine and calcium/phosphorus ratio values. AoDist was significantly lower in hypertensive compared with normotensive CRF pts both before (1.7 ± 0.7 vs. 2.2 ± 0.6 $cm^2.dyn^{-1}.10^{-6}$, $p < 0.01$) and immediately after completion of the HD session (2.1 ± 1.1 vs. 3.2 ± 0.9 $cm^2.dyn^{-1}.10^{-6}$, $p < 0.001$). A significant improvement of AoDist was noted in both groups of pts after HD; The magnitude of the improvement, however, was significantly greater in normotensive compared with hypertensive pts (0.9 ± 0.6 vs. 0.4 ± 0.5 $cm^2.dyn^{-1}.10^{-6}$, $p < 0.001$).

In conclusion, our findings are in accordance with previous data indicating an acute beneficial effect exerted by HD on the aortic mechanical performance of pts with CRF. In addition, it is shown that hypertensive CRF pts gain less than normotensive CRF pts in this respect, possibly due to more severe structural changes of the aortic wall in the former. Improvement of aortic mechanics after HD, although likely passive in nature and possibly of limited duration, may however add considerably to the overall hemodynamic benefit offered by regular HD in CRF pts.

HYPERTENSION: PERSPECTIVES ON THERAPY

P554 Sildenafil citrate is a well-tolerated treatment for patients with erectile dysfunction taking concomitant antihypertensive therapy

I. Osterloh[1], M. Boolell[1], M. Prisant[2]. [1]*Pfizer Central Research, Sandwich, Kent, UK;* [2]*Medical College of Georgia, Augusta GA, USA*

Erectile dysfunction (ED) is a common problem in patients with hypertension and in those receiving antihypertensive agents (anti-HTNs). Oral sildenafil is effective in restoring erectile function in response to sexual stimulation in patients with ED. This retrospective subanalysis assessed the safety of sildenafil in men with ED receiving various classes of anti-HTNs [ie, diuretics, β blockers, α blockers, ACE inhibitors (ACE-I), and calcium channel blockers (CCB)].

A total of 4274 men (1393 of whom were receiving anti-HTNs) received sildenafil (5–200 mg) or placebo for 6 weeks to 6 months in 18 double-blind, placebo-controlled studies, with a dose taken approximately 1 hour before sexual activity. The combined incidences of all adverse events (AEs) and AEs potentially related to decreased blood pressure between the beginning and the end of treatment for men taking each of the anti-HTNs are shown below.

	Incidence of Treatment-Related AEs for Sildenafil-Treated Patients					
	Diuretic n = 123	β blocker n = 137	α blocker n = 124	ACE-I n = 303	CCB n = 278	None n = 1837
Exposure (patient-yr)	80	34	38	87	80	430
All AEs	35%	34%	31%	36%	33%	38%
Hypotension	0%	0%	<1%	<1%	0%	<1%
Flushing	11%	11%	11%	16%	10%	14%
Dizziness	2%	3%	2%	2%	2%	2%
Syncope	0%	0%	0%	0%	0%	0%

The overall incidence of treatment-related AEs in patients taking sildenafil and anti-HTNs (34%) was comparable to that observed in patients taking sildenafil only (38%). The incidences of headache, dyspepsia, and abnormal vision also were comparable for all sildenafil treatment groups.

The results indicate that sildenafil is a well-tolerated treatment for ED in patients taking various classes of antihypertensive medication.

P555 Control of hypertension in patients with coronary artery disease – Polish Hypertension Survey

R. Szczech, L. Bieniaszewski, J. Furmanski, K. Narkiewicz, B. Krupa-Wojciechowska. *Dept. of Hypertension and Diabetology, Medical University of Gdansk, Gdansk, Poland*

Hypertensive patients with coronary artery disease are at very high risk for cardiovascular mortality. Appropriate blood pressure control may be of particular importance in such patients. The aim of the present study was to determine awareness and control of hypertension in patients with coronary artery disease (CAD).

Methods: We studied 355 154 subjects enrolled in the Polish Hypertension Survey in 1997. Hypertension was defined as SBP > 140 mm Hg and/or DBP > 90 mm Hg, or taking antihypertensive treatment. Drug compliance was assessed by questionnaire. In treated hypertensives, control of hypertension was defined as SBP < 140 mm Hg and DBP < 90 mm Hg.

Results: Prevalence of CAD in the studied cohort was 17.1% (n = 60 882). Among patients with CAD, 67.7% had hypertension. In comparison to general population, patients with CAD had higher rates of hypertension awareness (76.4% vs 58.0%; P < 0.001) and higher rates of anti-hypertensive drug compliance (85.1% vs 76.8%; P < 0.001). However, control of hypertension in drug compliant patients with CAD (27.4%) was similar to that observed in general population (26.9%).

Conclusion: Despite relatively high rates of hypertension awareness and drug compliance, blood pressure control in hypertensive patients with CAD is poor. Nearly three fourths of treated hypertensives with CAD have their blood pressure uncontrolled. These findings may have important implications for prevention of future cardiovascular events in hypertensive patients with CAD.

P556 Study on cognition and prognosis in the elderly (SCOPE): design, objectives and baseline characteristics

L. Hansson. *For the SCOPE Group; University of Uppsala, Department of Geriatrics, Clinical Hypertension Research, Uppsala, Sweden*

Intervention studies have demonstrated the prognostic benefit of antihypertensive treatment in the elderly. However, there is currently little data in patients above 70 years of age with mild hypertension. In addition to being a risk factor for cardiovascular events, hypertension also appears to play a role in the evolution of cognitive impairment in the elderly.

SCOPE is a multinational, double-blind, prospective study which will evaluate the ability of antihypertensive treatment to improve cardiovascular prognosis and prevent cognitive impairment in elderly patients with mild hypertension. The primary objective is to assess the reduction of major cardiovascular events, which is defined as a combined end-point of cardiovascular deaths, non-fatal myocardial infarction and non-fatal stroke. Secondary end-points include cognitive function measured by the Mini Mental State Examination (MMSE), total mortality, renal function, hospitalisation, quality of life and health economics.

A total of 4964 patients from 15 countries have been randomly assigned to treatment with the long-acting angiotensin II antagonist, candesartan cilexetil, or to placebo and will be followed for an additional 2 years. Any previous antihypertensive treatment was standardised, at enrolment, to hydrochlorothiazide 12.5 mg once daily with the study drug given in addition. The starting dose of candesartan cilexetil is 8 mg once daily, which is increased to 16 mg once daily if needed to control blood pressure. In patients with a blood pressure repeatedly above 160/90 mm Hg, in either treatment group, additional antihypertensive treatment is recommended.

Baseline characteristics for the randomised population is given below.

Age (years)	76	Treated at enrolment (%)	52
Male/Female (%)	36/64	MMSE at randomisation (score)	28
Previous MI (%)	4	SBP/DBP at randomisation (mmHg)	166/90
Previous stroke (%)	4		

P557 An Italian intervention study on the quality of the antihypertensive treatment based on jointly produced, field-tested guidelines

F. Avanzini, A. Corsetti, C. Alli[1], F. Colombo, V. Torri, G. Tognoni. *On behalf of the "Italian Collaborative Group on Rational Ambulatory Antihypertensive Therapy", Department of Cardiovascular Research, Mario Negri Institute, Milan; [1]Niguarda Hospital, Milan, Italy*

Aim of the study was to assess the feasibility of improving blood pressure (BP) control and the choice of antihypertensive therapy with evidence-based guidelines produced and tested with the participation of doctors concerned.

Methods: Forty-eight doctors – 38 general practitioners (GPs) and 10 hospital specialists – agreed to monitor the implementation of the collectively produced guidelines for one year on a random sample of their treated hypertensive patients (intervention group). A control group of 42 GPs recruited and followed-up for one year a random sample of their treated hypertensive patients in the framework of an observational epidemiological survey on the current status of treatment and control of hypertension.

Results: At the 12-month follow-up, the 722 hypertensives of the control group presented no changes in any of the variables evaluated. In the 1049 hypertensives enrolled in the intervention group both systolic and diastolic BP control improved (<140 mmHg from 23 to 40%; <90 mmHg from 65 to 87%; both $p < 0.001$); the prescription of poorly tolerated drugs decreased (from 12 to 7%; $p < 0.001$); the use of drugs with documented preventive efficacy – diuretics and β-blockers – increased (from 48 to 58%; from 22 to 30%, both $p < 0.001$); hypertensive patients receiving indicated drugs (with no contraindications) increased from 66 to 73% ($p = 0.006$); savings amounted to approximatively 1.5 Euro per patient/month of treatment ($p < 0.001$).

Conclusion: An intervention strategy based on collaboratively produced guidelines tested for applicability in a representative sample of patients appear to be effective in improving the quality of antihypertensive therapy.

P558 Quality of life after PTCA or CABG in hypertensive patients with coronary heart disease

M. Klocek, P. Jankowski, A. Kubinyi, W. Szot, K. Kawecka-Jaszcz. *I Cardiac Department, Medical College of Jagiellonian University, Kraków, Poland*

Aim: The aim of the study was to assess quality of life in hypertensive males and females with coronary heart disease (CHD) 1 year after PTCA or CABG.

Material: Study population consisted of 189 subjects with essential hypertension (H) (129 males and 60 females, aged 54.1 ± 7.2 and 56.2 ± 8.7 years respectively), who underwent PTCA (75 males and 30 females) or CABG (54 males and 30 females). Mean time interval after PTCA was 14.6 ± 2.5 months, and after CABG was 16.1 ± 3.8 months. Mean duration of H and CHD were similar in both groups – 12.5 years and 7 years, respectively. Control group consisted of 100 patients with H and CHD (50 males and 50 females, aged 52.6 ± 8.1 and 55.3 ± 9.1 respectively), without revascularization. Mean duration of H in controls was 11.6 ± 3.1 years, and mean duration of CHD was 5.5 years.

Methods: All the patients were randomly selected from the population of ambulatory treated hypertensives with CHD and completed the Psychological General Well-Being Questionnaire (PGWB) and the Health Complaints Scale in CHD (HCS) – disease specific – during their visit in the clinic. Data about BMI, education, concomitant diseases, complication of H and CHD during last year, consumed drugs, cholesterol level and systolic and diastolic BP were collected. Statistical analyses were performed (parametric and non-parametric).

Results: In all groups women had lower total quality of life indexes (in PGWB and HCS) than men ($p < 0.01$). Women were also more depressive, felt less healthy and vital in PGWB. There was no difference between PTCA, CABG and control groups in general quality of life perception. In PTCA group 38.1% of the patients underwent re-PTCA during the last year. Males and females after PTCA or CABG had lower frequency of health complaints in HCS (cardiovascular, fatigue, sleep) than controls ($p < 0.05$). As compare to controls, worrying about disease was higher in PTCA pts (especially in restenosis subgroup) and negative impact of CHD on everyday activity was most frequently reported by CABG pts.

Conclusions: Male gender is associated with better general quality of life. Both PTCA and CABG improve health perception in hypertensives. However, PTCA may diminish well-being due to risk of restenosis and CABG due to worsening ability to everyday activity in both sexes.

P559 Prognostically important coronary artery disease in patients with hypertensive reaction and myocardial ischaemic episodes during cardiac catheterization

D. Psirropoulos, N. Lefkos, G. Boudonas, A. Efthimiadis, G. Mamadas[1], G. Tsapas. *Cardiology Unit of 2nd Dept. of Internal Medicine, Hippokration Hospital, Aristotelian University of Thessaloniki; [1]Cardiology Dept. of General Clinic of Thessaloniki, Greece*

Aim of our study is the evaluation of prognostically important coronary artery disease (piCAD) and its correlation with strongly hypertensive reaction and simultaneous myocardial ischaemic episodes (MI) appearance during cardiac catheterization (CC) in hypertensive and normotensive patients.

Methods: Files of 1085 patients (M = 930, F = 498, mean age 51.2 ± 8.8 years), 589 hypertensive and 496 normotensive, have been studied. All of them underwent LCA catheterization, RCA catheterization and left ventriculography (hypertensive patients under treatment). As hypertensive reaction was defined the elevation of systolic blood pressure-SBP > 200 mmHg (width of elevation more than 60 mmHg) and the elevation of diastolic blood pressure-DBP > 110 mmHg. The time point just before the onset of procedure was defined as BP baseline-point and the time point just after the RCA catheterization was defined as BP end-point. As piCAD was defined the disease for which early by-pass surgery might be considered purely on prognostic grounds irrespective of symptom status. Patients with symptomatic heart failure (EF ≤ 40%), chronic renal failure and heavy valve diseases were excluded.

Results: 1) 242 (22.3%) patients, out of 1085 patients had piCAD and 153 (63.2%) of them were hypertensive whilst 89 (36.8%) were normotensive. 2) 95 (16.13%) patients, out of 589 hypertensive patients, and, 39 (7.86%) patients, out of 496 normotensive patients, expressed myocardial ischaemic episodes 3) 62 (42.3%) patients, out of 144 hypertensive patients, and, 26 (34.65%) patients, out of 74 normotensive patients, with strongly hypertensive reaction, demonstrated signs of MI. 4) 41 (42.8%) patients, out of 95 hypertensive patients with signs of MI, and, 112 (25.3%) patients out, of 494 hypertensive patients (total 153), without signs of MI, demonstrated piCAD. 5) 17 (42.3%) patients, out of 39 normotensive patients with expressed MI episodes, and, 72 (15.7%) patients, out of 457 normotensive patients (total 89), without signs of MI, demonstrated piCAD. 6) 41 (26.8%) patients, out of 153 hypertensive patients with piCAD, experienced MI episodes during CC and 30 (73.2%) of them did elevate the BP significantly at the BP end-point. 7) 17 (19.1%) patients, out of 89 normotensive patients with piCAD, expressed MI episodes during CC and 12 (70.5%) of them showed significant BP elevation at the BP end-point.

Conclusion: a) The existence of prognosticaly important coronary artery disease in hypertensive patients is almost twice as in normotensive patients. b) The incidence of piCAD in patients who expressed MI episodes on the ground of BP elevation is almost three times over the incidence of piCAD in patients with MI episodes but without BP elevation.

HYPERTENSION: LIPID AND METABOLIC ASPECTS

P560 Sex-specific associations of hypertension with lipid levels in a representative sample

J. Ferrières[1], S. Raetz[1], P. Amouyel[2], D. Arveiler[3], J.B. Ruidavets[1], D. Cottel[2], N. Lamamy[3], A. Bingham[4], P. Ducimetière[4]. *[1]Department of Epidemiology, INSERM 518 Toulouse; [2]INSERM 508 Lille; [3]Department of Epidemiology Strasbourg; [4]INSERM 258 Paris, France*

Through associations between hypertension (HT) and other risk factors, hypertensive subjects are burdened with a greater risk of premature cardiovascular disease (CVD) than that imposed by their blood pressure alone. The aim of this study was to investigate the relationship of HT with lipid levels in a random sample of the French population aged 35–64 years. Risk factors, medication use, blood pressure (two measurements), fasting serum total cholesterol (TC), HDL-cholesterol (HDL-C), triglycerides (TG) and glucose were measured according to standard protocols in 1654 men and 1625 women from Northern, Eastern and South-western France in 1995–97. The prevalence of HT (blood pressure ≥ 160/95 mmHg and/or drug treatment) was 29.9% in men (14.2% untreated and 15.7% treated HT) and 24.9% in women (7.1% untreated and 17.8% treated HT). After adjustment for age, centre, body mass index, tobacco and alcohol consumption, glycemia and TC lowering drugs, untreated hypertensive women had higher levels of TC (6.14 vs 5.85 mmol/L, $p < 0.05$), LDL cholesterol (3.95 vs 3.71 mmol/L, $p < 0.05$), and TG (1.07 vs 0.93 mmol/L, $p < 0.01$) than normotensive women; treated hypertensive women had lower levels of HDL-C (1.59 vs 1.67 mmol/L, $p < 0.05$) than normotensive women. Normotensive and hypertensive (untreated and treated) men had similar levels of TG, LDL and HDL cholesterol. In conclusion, the greater than normal CVD risk of hypertensive subjects could be partly due to abnormal lipid levels in a sex-specific manner. Further studies are needed to explain the HDL-C lowering effect of antihypertensive treatment.

P561 Peroxide lipid oxidation status in erythrocytes of hypertensive patients

E.G. Moutalova, L.N. Mingazetdinova, G.A. Muchetdinova, R.M. Fazlyeva, L.F. Strekalova. *Bashkir Medical University Ufa, Russian Federation*

Activation of peroxide lipid oxidation (PLO) reactions is considered as one of the main mechanisms of cell membranes destruction. Since, arterial hypertension (AH) is connected with structural and functional defects of cell membranes it was interesting to look for any changes in PLO status of erythrocytes in patients with AH. Erythrocytes were selected because of more intensive PLO processes in them in comparison with plasma.

Methods: there were examined 252 patients both sexes with different forms of AH aged between 32 and 60. 86 patients had mild AH. 84 – moderate AH and 82 were with severe AH, complicated with stroke and 26 healthy persons of the same age and sex as control group. PLO status of erythrocytes was evaluated by defining of malone dialdehyde (MDA) level, superoxidedismutase (SOD) and katalase (Ka) activities with using standard methods.

Results: it was revealed that even mild AH was characterized by activation of PLO reactions, especially of MDA concentration, but efficacy of antioxidant defense was rather strong in these patients, because SOD and Ka activities didn't differ so significantly from control group levels. Moderate AH was accompanied with more marked changes in all studied parameters than mild AH. Two opposite processes, influencing on erythrocyte state, received subsequent development: damaging coercion of PLO products on cell membrane, on the one hand, and the opposing to it antioxidant system, on the other hand. It was established MDA level rise on 86.2% in comparison with control group and significant suppression of SOD activity. In the third group of patients this strengthening of radicalproducing reactions achieved its maximum level. The accumulation of MDA concentration composed 260.7% and the state of antioxidant system was defined as the most depressed (SOD activity was 62.3%). It was determined that the activity of PLO processes in membranes was especially increased in patients in the nearest period after crisis therefore hypertensive crisis may be regarded as peroxide-lipid crisis on a level of cell membranes.

In conclusion, we can state that AH is characterized with disturbance of balance of oxidant-antioxidant systems, antioxidant defense failure and accumulation of PLO products.

P562 Polymorphism of angiotensin-converting enzyme gene, thrombomodulin and tissue factor pathway inhibitor levels in untreated hypertensive patients

P. Krespi, Th. Makris, A. Hatzizacharias, G. Stavroulakis, R. Gialeraki, N. Hatzizacharias, V. Votteas, M. Kyriakidis. *Cardiology Dept., 2nd Reg. BTC, Haemost. Lab, LAIKO Hospital and Medical School, University of Athens, Greece*

The association of the angiotensin converting enzyme (ACE) gene polymorphism with essential hypertension (EH) is still controversial. Increased tissue factor pathway inhibitor (TFPI) levels have been reported in acute ischaemic episodes. Moreover, thrombomodulin (TM) is known to have inhibitory effects on thrombin. This study examined the possible association between ACE gene polymorphism TM and TFPI levels in untreated hypertensive patients (pts).

Methods: The I/D polymorphism of ACE gene was determined in 104 hypertensives aged 56 ± 12 yrs. Forty-two pts had DD genotype (Group A), 30 pts had ID genotype (Group B) and 32 pts had II genotype (Group C). The TM and TFPI levels were determined (ELISA method) in the whole population. The three groups are matched for age, sex and body mass index.

Results: The results are shown in the table:

	Group A	Group B	Group C
TM ng/ml	33.16 ± 10	38.4 ± 8.3	38.6 ± 7.1
TFPI ng/ml	113.4 ± 28	99 ± 25	98 ± 22

TM: A–B, $p < 0.01$; A–C, $p < 0.01$; B–C, p = NS
TFPI: A–B, $p < 0.05$; A–C, $p < 0.05$; B–C, p = NS

Conclusions: Our findings suggest that DD genotype of ACE gene polymorphism is associated with significantly decreased levels of TM and increased levels of TFPI, supporting the hypothesis that ACE gene polymorphism through this mechanism plays an important role in the development of cardiovascular events.

P563 Platelet activity and immune factors interaction in hypertension

O. Kovaljova, T. Ambrosova, V. Smirnova. *State Medical University, Kharkov, Ukraine*

Previous studies showed that there are abnormalities in the humoral immunity system in the hypertensive patients, which are characterized by increased serum levels of various types of Ig. The data suggest that IgE and IgG benefit not only in the development of vessels spastic reaction, but also influence on the platelet functional properties. The aim was to study the relationship between platelet functional activity and IgE, IgG levels in the patients with mild hypertension.

Methods: 28 male with mild hypetension and 10 healthy male, aged 20.3 ± 2.3 years have been examined. IgE and IgG serum levels was determined using IFA method. Platelet activity was assessed by means of platelet adhesion and aggregation degree with parallel measuring the time maximum index aggregation. Exercise test with computer devices have been performed in all persons.

Results: This study indicated statistically increase serum IgE levels (17.5 ± 0.9 g/l) and IgG (218 ± 12 ME/l) in the patients with mild hypertension as compared to control group (12.7 ± 0.9 g/l, 115 ± 10 ME/l). Platelet adhesion percentage (13.8 ± 2.6%) and aggregation degree (8.9 ± 2.7%) increase in the patients with mild hypertension as compared to control group (13 ± 1.0% and 7.7 ± 1.2 accordingly). Platelet aggregation was activated by exercise test, and resulting in increase of aggregation degree in the patients with mild hypertension – 14.5 ± 1.1% ($p < 0.05$), the time maximum index decreased simultaneously (26.9 ± 2.2 sec and 24.4 ± 1.0 sec accordingly). Adhesion percentage increase after exercise test was insignificant. Increased Ig levels rate after exercise in the patients with mild hypertension was higher IgG 45.2% – initial, 56.2% after testing, IgE 7.25% – initial, 84.7% – after testing.

Conclusion: Obtained data demonstrate that exercise testing causes more significant platelet aggregation and immune response in hypertensive patients as compared to control group. We consider relationship these factors associated with hemodynamic vascular damage contribute to the thrombogenic complications.

P564 Prognostic implications of plasma renin activity in essential hypertension: role of oxidative stress

K. Allikmets, T. Parik, M. Zilmer[1], K. Zilmer[1], R. Teesalu. *Department of Cardiology, University of Tartu, Tartu; [1]Department of Biochemistry, University of Tartu, Tartu, Estonia*

High plasma renin activity (PRA) as well as oxidative stress (OS) have both been linked to increased risk of atherosclerotic complications in essential hypertension (EH). The aim of this study was to investigate the parameters of OS, a potential source of endothelial injury, as well as some markers indicative of endothelial dysfunction, in association with PRA in patients with EH.

Methods: Diene conjugates (DC), basal and Fe-stimulated levels of thiobarbituric acid reactive substances (TBARS, Fe-TBARS) and serum antioxidative capacity (AOC) as markers of OS were measured in 32 patients with uncomplicated EH (DBP 95–114 mmHg, mean age 32.4 ± 7.2 yr). Assessment of PRA related to concurrent 24-h urinary sodium excretion was used to define subgroups of patients with high (n = 12) and low/medium renin activity (n = 20). Urinary excretion of albumin (UAE) as a marker of endothelial dysfunction and urinary excretion of cyclic GMP (cGMP) as an indicator of endothelial nitric oxide (NO) formation were measured.

Results: Lipid peroxidation (LP) parameters were significantly ($p < 0.05$) elevated in patients with high PRA (DC 37.9 ± 8.1 vs. 34.3 ± 6.5 mmol/ml; TBARS 0.90 ± 0.16 vs. 0.61 ± 0.11 nmol/ml; Fe-TBARS 1.34 ± 0.17 vs. 1.11 ± 0.11 nmol/ml), while serum AOC was decreased in high PRA group (30.1 ± 1.8 vs. 35.2 ± 2.1%, $p < 0.05$), in comparison to the low/medium renin group. Urinary cGMP excretion was positively related to both basal TBARS (r = 0.468, p = 0.044) and Fe-stimulated TBARS (r = 0.568, p = 0.036), suggesting more pronounced NO formation at higher serum LP levels, which is consistent with previous evidence about reduced efficacy rather than decreased formation of NO in face of enhanced LP. Serum AOC was inversely related to UAE (r = −0.402, p = 0.01), indicating that impaired antioxidant status might contribute to higher UAE. Also, UAE was positively related to PRA (r = 0.473, p = 0.03) and high-renin patients had significantly higher UAE when compared to the low/medium PRA group (16.1 ± 2.1 vs. 9.8 ± 3.6 mg/min, $p < 0.05$).

Conclusions: High-renin EH patients display more pronounced abnormalities suggestive of oxidative stress. The associations between oxidative stress markers and indices of endothelial dysfunction (UAE and urinary excretion of cGMP) may point to the role of oxidative stress in the development of early vascular injury, thus potentially contributing to the higher risk of atherosclerotic complications previously reported in the high-renin subgroup of patients with EH.

P565 Decreased myocardial mRNA expression of insulin-dependent transmembrane glucose transporter in human hypertension. A key for the interdependence of disturbed glucose metabolism and hypertension?

W. Klein[1], I. Friehs[4], B. Rigler[2], S. Barth[3], H. Brussee[1], R. Gasser[1]. *Depts. of [1]Cardiology; [2]Cardiac Surgery; [3]Medical Biochemistry, University of Graz, Austria; [4]Dept. of Cardiac Surgery, Harvard University, Boston MA, USA*

Transmembrane glucose transport, cellular metabolism and thus the contractile state of the cardiovascular system as well as H_2O distribution in the compartments depend largely on the insulin resposnsive GLUT 4 isoform of the transmembrane glucose transport molecule.

Here we investigate probes (60–150 mg) of right atrial auricle from non diabetic patients subjected to cardiac surgery which were snap frozen in liquid NO and stored at −70°C until homogenisation. Total RNA was isolated using guanidium thiocyanate, phenolchloroform extraction and alcohol precipitation (for details see our earlier paper Mol Cell Biol 8: 2394–2400, 1988). Total RNA was hybridised with 32P labelled human GLUT 4 cDNA and re-hybridised with a human G3PDH cDNA probe to correct for equal amounts of RNA. Quantification was performed by a laser scanner.

Our results represent the first measurements of GLUT 4 mRNA in human myocardial tissue. Sixteen patients had systemic hypertension (RR ≥ 140/90 or ≥ 160/90 if aged over 65), 24 served as controls. GLUT 4 mRNA expression was 56.2 ± 2.5 (± SEM) in the control group and 42.5 ± 3.7 (± SEM) in the hypertensive group (P = 0.0028).

Our results are in agreement with similar findings in hypertensive rats and clearly show that myocardial mRNA expression of GLUT 4 isoform is decreased in myocardium of patients with systemic hypertension. The data indicates that altered cellular GLUT 4 expression of the cardiovascular system occurs with the development of systemic arterial hypertension and may constitute a missing link between disturbed cellular glucose metabolism and systemic hypertension.

P566 11β-hydroxysteroid dehydrogenase deficiency blunts nitric oxide-mediated endothelial function: a novel mechanism in hypertension?

F. Ruschitzka, S. Shaw[1], G. Noll, T. Quaschning, T.F. Lüscher. *Cardiology Dept., University Hospital, Zurich; [1]University Hospital, Department of Clinical Research, Bern, Switzerland*

Background: Mineralocorticoid receptors derive specifity for aldosterone over cortisol from co-expression of the enzyme 11β-hydroxysteroid dehydrogenase (11β HSD) that inactivates cortisol to inactive metabolites. In patients with liquorice-induced and low-renin essential hypertension 11β HSD activity is decreased and cortisol activates the mineralocorticoid receptor resulting in sodium retention and hypertension.

Methods: To evaluate the potential importance of endothelial factors in 11β HSD deficiency normotensive Wistar-Kyoto rats received licorice-derived glycyrrhetinic acid that inhibits 11β HSD activity in a dose-dependent manner (50 mg/kg bodyweight i.p. for one week; saline in the controls; n = 7). Endothelium-dependent and -independent function were assessed as response to acetylcholine (ACh, 0.01–300 μmol/L) and sodium nitroprusside (SNP, 0.01–300 μmol/L) in isolated aortic rings. Aortic tissue levels of nitric oxide were assessed by nitrate/nitrite conversion. In addition, endothelial nitric oxide synthase (eNOS) protein levels were determined by western blot analysis.

Results: Glycyrrhetinic acid induced a significant blood pressure increase (157 vs 127 mmHg in the controls; $p < 0.01$), while heart rate remained unchanged. ACh-induced endothelial nitric oxide release was blunted ($p < 0.05$ vs controls) and completely blocked by NO-synthase inhibitor L-NAME, while responses to SNP remained unchanged. Similarly, eNOS protein and nitric oxide tissue levels (1120 vs. 490 mg/g protein; $p < 0.05$ vs controls) were decreased indicating blunted nitric oxide bioavailability in 11β HSD deficiency.

Conclusions: These data show for the first time that decreased 11β HSD activity results in an attenuated bioavailability of nitric oxide and may thus contribute to the development of hypertension in patients with 11β HSD deficiency.

MECHANISMS OF HYPERTENSION: NEUROHUMORAL AND AUTONOMIC ABNORMALITIES

P567 Chronic imidazoline-1 receptor agonism with moxonidine: effect on sympathetic reflex responses in patients with essential hypertension

J.P. Greenwood, E.M. Scott, J.B. Stoker, D.A.S.G. Mary. *Cardio-Respiratory Unit, St. James's University Hospital, Leeds, UK*

Microneurographic studies have demonstrated increased resting muscle sympathetic nerve activity (MSNA) in essential hypertension. Although some antihypertensive agents increase sympathetic drive, which may have prognostic implications, we have recently shown that chronic moxonidine therapy reduces resting MSNA in essential hypertension. This preliminary study was designed to investigate the effects of oral moxonidine on sympathetic reflex responses.

Methods: Nine newly diagnosed essential hypertensives (DBP > 95 mmHg) were examined before and after 4 weeks of oral moxonidine (200/400 mcg od). Following the acquisition of resting haemodynamic and neural data, the cold pressor test (CPT) was used to stimulate sympathetic reflex responses. Heart rate (HR) and blood pressure (BP) were recorded from an ECG and Finapres device, and venous occlusion plethysmography was used to derive calf vascular resistance (CVR) in arbitrary units (U). Peroneal microneurography was used to quantify MSNA as bursts per 100 cardiac beats (b/h).

Results: There were no significant differences in the response of HR or mean BP induced by the CPT before and after moxonidine therapy (paired t tests). Moxonidine reduced the absolute and percentage change in MSNA and CVR induced by the CPT (table). Data as mean ± SEM.

	MSNA (b/h)	CVR (U)
No therapy	135 ± 31 (235% ± 48)	34.7 ± 9.7 (85% ± 19)
Moxonidine	27.8 ± 7.4* (69% ± 16)‡	21.0 ± 5.2† (60% ± 15)†

Compared to no therapy, * = $p < 0.02$; ‡ = $p < 0.03$; † = $p < 0.04$.

Conclusions: These results indicate that in essential hypertension, chronic moxonidine therapy attenuates sympathetic reflex responses and its effect on calf vascular resistance induced by noxious cold stimulation.

P568 Effects of nitric oxide synthase inhibition on baroreceptor regulation of muscle sympathetic nerve activity and haemodynamics in man

L. Spieker, R. Corti, C. Binggeli, G. Sütsch, T.F. Lüscher, G. Noll. *Cardiology Dept., University Hospital, Zurich, Switzerland*

Endothelial dysfunction, leading to an imbalance of endothelial-derived relaxing and constrictive factors, plays an essential role in cardiovascular disease. We investigated whether inhibition of nitric oxide (NO) synthesis alters baroreceptor regulation of sympathetic nervous activity.

In healthy volunteers, we recorded muscle sympathetic nerve activity (MSA) using microneurography and central hemodynamics at different levels of central venous pressure induced by lower body negative pressure (LBNP). After administration of the NO synthase inhibitor NG-monomethyl-L-arginine (L-NMMA, 1 mg/kg/min), systolic blood pressure increased by 24 mmHg (P = 0.01) while stroke volume index (measured by thermodilution) fell from 53 to 38 mL/min/m^2 ($p < 0.002$). Heart rate, but not MSA, failed to increase in response to LBNP which under control conditions led to compensatory rises in MSA and heart rate in response to falling blood pressure. The altered response of heart rate was not due to a higher blood pressure level, since heart rate responses to orthostatic stress were not altered during infusion of the alpha-1-adrenoceptor agonist phenylephrine (titrated to an equal increase of systolic blood pressure). In the presence of equal systolic blood pressure and right atrial pressure, MSA was significantly higher during phenylephrine than during L-NMMA infusion but was not different from control conditions despite higher systolic blood pressure.

This study demonstrates alterated baroreceptor regulation of heart rate but not peripheral sympathetic activity after inhibition of NO synthesis in healthy volunteers.

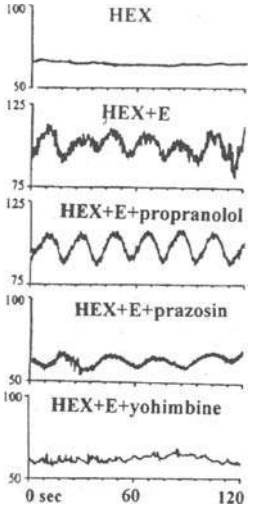
P569 Adrenergically-mediated low-frequency blood pressure oscillations in conscious rats

A. Radaelli, I. Mori, L. Mircoli, M. DiRienzo, P. Castiglioni, G. Mancia, A.U. Ferrari. *Catt. Cardioangiol Med, Ctr Fisiol Clin Ipertens, Univ Milan; Med Interna, Osp S. Gerardo, Monza (MI); Div Cardioriab Seregno, Az Vimercate (MI); CNR; IRCSS Osp Magg; LaRC, Ctr Bioing, Milan, Italy*

Sympathoadrenergic contribution to LF-BP oscillations is debated: we previously showed in rats that ganglionic blockade by hexamethonium (Hex) drastically lowers BP and almost entirely abolishes LF-BP spectral power (0.025–0.1 Hz, sequential FFT technique). In this study we tested in Hex-treated rats whether i) restoration of BP by an adrenergic agent also restores LF-BP power and ii) which is the adrenergic receptor involved.

Methods: in 41 conscious, instrumented rats BP was recorded for 60 min under administration of i) Hex, 1.5 $mg.kg^{-1}.min^{-1}$; ii) Hex + epinephrine (E), 4 $\mu g.kg^{-1}.min^{-1}$; iii) Hex + E + propranolol, 1 $mg.g^{-1}$; iv) Hex + E + prazosin, 0.2 $mg.kg^{-1}.min^{-1}$; v) Hex + E + yohimbine, 2 $mg.kg^{-1}.min^{-1}$.

Results: when Hex-treated rats had their BP restored by E (but not by a non-adrenergic agent such as vasopressin, data not shown), distinct LF- (period 30 to 40 sec) BP oscillations appeared; they persisted under β- or α_1-receptor blockade but disappeared after α_2-receptor blockade. Examples of the recordings obtained under each condition are shown in Figure (mean BP, mmHg). Such oscillations were shown in separate groups of rats to be similarly elicited by infusing norepinephrine rather than E and not to be abolished by administration of l-NAME or losartan (data not shown).



Thus adrenergic agonists, acting via the α_2-adrenergic receptor, have the potential to elicit vasomotor oscillations in the LF range, possibly by amplifying the intrinsic oscillatory properties of vascular smooth muscle.

P570 Vasodilator potency of proadrenomedullin N-terminal 20 peptide is apparently less than that of adrenomedullin in humans

M. Nakamura, H. Yoshida, S. Saito, T. Akatsu, H. Kon, K. Endoh, N. Arakawa, K. Hiramori. *Second Department of Internal Medicine, Iwate Medical University, Morioka, Japan*

Adrenomedullin (ADM) and proadrenomedullin N-terminal peptide (PAMP), both of which are derived from preproadrenomedullin, are reported to have a potent hypotensive effect in animals. Plasma level of PAMP has been reported to be elevated in patients with essential hypertension ($\simeq$1 fmol/ml). However, no data are available concerning the vasodilatory potency of PAMP or comparing this potency to that of ADM in human vasculature.

Methods: We examined the effects of intra-arterial infusion of graded doses of ADM (1.25, 2.5, 5.0 and 7.5 pmol/min/100 ml of tissue) and PAMP (12.5, 25, 50 and 75 pmol/min/100 ml of tissue) on total forearm blood flow and forearm skin blood flow in 8 healthy subjects.

Results: ADM increased total forearm blood flow from 3.1 $\pm$ 0.4 to 9.3 $\pm$ 0.9 ml/min/100 ml ($p < 0.01$), and skin blood flow from 0.08 $\pm$ 0.02 to 0.15 $\pm$ 0.03 volts ($p < 0.01$). In contrast to this potent vasodilatory effect, a significant rise in forearm skeletal blood flow was seen only in response to the maximum dose of PAMP (from 3.4 $\pm$ 0.4 to 4.5 $\pm$ 0.7 ml/min/100 ml; $p < 0.05$). However, PAMP had no significant vasoactive effect on skin blood flow (from 0.07 $\pm$ 0.01 to 0.08 $\pm$ 0.01 volts; NS).

Conclusion: This study has demonstrated for the first time that the peripheral resistance vasodilator potency of PAMP is less than one tenth of that of ADM in humans. Given its calculated circulating level during PAMP infusion in the experimental arm ($\simeq 10^4$ fmol/ml), it seems unlikely that PAMP alone could significantly regulate resistance vessel tone as a circulating hormone in humans.

P571 Circadian rhythm of blood pressure and brain involvement in essential hypertension

G. Semke, M. Shahmatov, S. Pekarski, V. Mordovin. *Hypertension Dept., Institute of Cardiology, Tomsk, Russian Federation*

Objective: In order to investigate whether non-dipping is associated with more severe brain involvement in essential hypertension

Methods: Fifty five essential hypertensives, stage I and II, 26 men and 29 women, aged 30–55 underwent ambulatory blood pressure monitoring, brain MR tomography and electroencephalography with mapping of power distribution of EEG rhythms(alfa, beta, gamma and teta) in rest and during counting. ABP was recorded during 24 hours at 15 minutes interval, night time was defined as 22.00–6.00. Four types of distribution of spectral power of EEG rhythms were defined: I type – normal; II, III, IV type – mild, moderate and severe disfunction correspondently, taking into account proportion of power of slow rhythms and alfa-rhythm, abnormality of spatial distribution of power of rhythms. All patients were divided into two groups according to difference between blood pressure daytime and nighttime means: dippers (more then 10%, n = 35) and non-dippers (less then 10%, n = 20). The number of lacunae per person, subarachnoidal and brain ventricular space dimensions were significantly greater in non-dippers. Average spectral power of slow teta-rhythm was significantly higher in non-dippers ($p < 0.005$) and average power of alfa-rhythm during counting was significantly less ($p < 0.01$) in non-dippers. Significantly greater propotion of non-dippers had periventricular hyperintensity and III and IV types of power distribution of EEG rhythms. Thus, non-dipping associated with more severe brain damage according to EEG and MRI in essential hypertension.

EFFECTS OF HYPERTENSION ON THE HEART

P572 Microalbuminuria is associated with unfavourable left ventricular geometry patterns in untreated, non-diabetic, patients with essential hypertension

C. Tsioufis, C. Stefanadis, D. Antoniadis, M. Toutouza, C. Pitsavos, P. Toutouzas. *Department of Cardiology, University of Athens, Hippokration Hospital, Athens, Greece*

Both a slightly elevated urinary albumin excretion rate and concentric left ventricular (LV) hypertrophy has been associated with increased risk for future cardiovascular events but the interaction between microalbuminuria (MA) and the spectrum of LV geometry has not been well established.

Methods: For this purpose, 249 untreated, nondiabetic, non-proteinuric patients (pts) with stage I–II (JNC VI) essential hypertension underwent echocardiography and 24 hour urine collection. Our pts were classified according to 1) the level of MA into group A (MA > 20 mg/24 h) and group B (MA < 20 mg/24 h) and 2) the relative wall thickness (RWT) and LV mass index (LVMI) into four groups [normal geometry (NM), concentric remodeling (CR), eccentric hypertrophy (EH) and concentric hypertrophy (CH)].

Results: The two groups A and B were matched for age, sex, BSA, smoking status and plasma cholesterol level. In comparison to group B (140 pts), group A (109 pts) had a significant increase in MA (42.16 $\pm$ 31 vs 9.92 $\pm$ 4 mg/24 h, $p < 0.001$), in LVMI (110 $\pm$ 22 vs 90 $\pm$ 17 g/m^2, $p < 0.0001$), in RWT (0.46 $\pm$ 0.06 vs 0.41 $\pm$ 0.04, $p < 0.001$) and in office systolic and diastolic BP (161 $\pm$ 17 vs 148 $\pm$ 15 and 101 $\pm$ 9 vs 97 $\pm$ 9 mmHg, respectively, $p < 0.005$). In the entire study population, NG, CR, EH and CH was found in 135 pts (54.2%), 76 pts (30.5%), 20 pts (8%) and 18 pts (7.3%) respectively. For the pooled population, MA was positively correlated to LVMI ($r = 0.46$, $p < 0.001$), RWT ($r = 0.47$, $p < 0.001$), and office pulse pressure ($r = 0.29$, $p < 0.001$). The incidence of NG was significantly higher in group B compared to group A (77.8% vs 23.8%, $p < 0.001$) while the incidence of CR, EH and CH was significantly higher in group A compared to group B (49.5% vs 7%, 12.8% vs 2% and 13.7% vs 3.1% respectively, $p < 0.005$ for all cases).

In conclusion, the higher prevalence of unfavorable LV geometric patterns in the microalbuminuric pts along with the increased pulse pressure may account for a worse cardiovascular outcome associated with the presence of MA in hypertensive pts.

P573 Role of insulin-like growth factor-1 in left ventricular hypertrophy in hypertensive patients

Edyta Karasek, Bogumił Halawa, Maria Witkowska. *Dept. of Cardiology Medical School of Wrocław, Wrocław, Pasteura 4, Poland*

Several lines of evidence suggest that left ventricular hypearophy (LVH) observed in hypertension (HT) occurs in response to haemodynamic and nonhaemodynamic stimulus as hormones and growth factors. A number of experimental data indicates that IGF-1 affects myocardial growth and structure. Thus in order to gain insight into the possible involvement of IGF-1 in LVH of HT the levels of this factor were measured in plasma of the patients with HT and the relation between IGF-1 and left ventricuar mass index (LVMI) as well as MBP and other neurohumoral factors were examined. **Patients and method.** The studies were carried out in 121 HT patients aged 17 to 79 (mean 48 ± 15.3) years and in 39 normotensive controls aged 18 to 73 (mean 50.21 ± 17.17) years. According to V JNC, HT patients were devided into three groups: I- 53 patients with mild HT, II- 44 pts. with moderate and III- 24 pts with severe HT. Groups I and II were derided into subgroups with and willaout LVH. All patients of group III (severe HT) had LVH. 73 out of 121 HT patients had echocardiographically documented LVH and 48 pts had no LVH. Plasma level of IGF-1, plasma renin activity (PRA), aldosterone, proendothelin-1 (proET-1) and ANP were quantitated by radioimunoassay. **Results.** MBP and the levels of IGF-1, PRA, proendothelin-1 and ANP were significantly higher in patients with severe HT compared to mild and moderate HTs. In HT patients with LVH the values of MBP and levels of IGF-1, PRA, aldosterone, proET-1 and ANP were significantly higher compared to the patients without LVH ($p < 0.001$, $p < 0.001$, $p < 0.0001$, $p < 0.001$, $p < 0.001$, $p = 0.001$ respectively). There was significant correlation between IGF-1 level and LVMI in patients with moderate HT ($r = 0.54$, $p < 0.001$) and severe HT ($r = 0.58$, $p < 0.001$) and in patients with LVH ($r = 0.7$, $p < 0.001$). Additionally only in HT patients with LVH, IGF-1 plasma levels correlated with other neurohumorals (PRA, aldosterone, proET-1 and ANP) and with MBP ($r = 0.7$, $p < 0.001$). **Conclusions.** Our results demonstrate that in HT patients LVH is associated with increased levels of IGF-1. There was significant correlation between IGF-1 level and LVMI, MBP and PRA, aldosterone, proET-1. These data suggest that circulating IGF-1 is one of the nonhaemodynamic factors involved in the development of LVH in essential HT. Additionaly our results also confirm that IGF-1 plasma levels are related to pressure load leading to cardiac remodeling in hypertension.

P574 Association between left atrial size and left ventricular geometry pattern in untreated patients with essential hypertension

C. Tsioufis, C. Stefanadis, C. Pitsavos, E. Tsiamis, D. Antoniadis, S. Viana, P. Toutouzas. *Department of Cardiology, University of Athens, Hippokration Hospital, Athens, Greece*

Although left atrial (LA) enlargement is thought to be an early sign of hypertensive heart disease in patients (pts) with essential hypertension, the relation between LA size and the spectrum of left ventricular (LV) geometry has not been well established.

Methods: For this purpose, 210 untreated, newly diagnosed pts with stage I–II (JNC VI) essential hypertension (mean age 53 ± 10 years) underwent echocardiography for estimation of LV, LA and aortic (Ao) dimensions. Our pts were classified according to the relative wall thickness (RWT) and the LV mass index (LVMI) into four groups [normal geometry (NM), concentric remodeling (CR), eccentric hypertrophy (EH) and concentric hypertrophy (CH)]. LA size was evaluated by calculating LA dimension (determined at its largest diameter), LA index (LA dimension/BSA) and LA/Ao ratio (LA/Ao diastolic diameter)

Results: In the entire study population LVMI was 101 ± 22 g/m^2, RWT was 0.43 ± 0.06, office BP was 155 ± 17/99 ± 9 mmHg, Ao diastolic diameter was 2.93 ± 0.3 cm, LA dimension was 3.38 ± 0.4 cm, LA index was 1.78 ± 0.2 cm/m^2 and LA/Ao ratio was 1.15 ± 0.5. Multiple regression analysis performed on demographic characteristics, BP data and LVMI, identified age and LVMI as significant predictors of LA index and LA/Ao ratio ($p < 0.005$). Furthermore, NG, CR, EH and CH was found in 105 pts (50%), 71 pts (34%), 18 pts (9%) and 16 pts (7%) respectively. LA dimension was significantly greater in pts with LV EH compared to LV NG (3.6 ± 5 vs 3.3 ± 4 cm, $p < 0.005$) and LA/Ao ratio was significantly increased in pts with LV EH compared to LV CH and LV CR (1.27 vs 1.07 vs 1.15, $p < 0.005$, respectively).

Conclusion: LA enlargement is closely related with LVMI in essential hypertension and it accompanies LV eccentric hypertrophy.

P575 Relation of ambulatory versus office pulse pressure with patterns of left ventricular geometry in essential hypertension

C. Tsioufis, S. Lambrou, C. Stefanadis, C. Pitsavos, P. Toutouzas. *Department of Cardiology, University of Athens, Greece*

Pulse pressure (PP) has been recently gaining acceptance as a predictor of cardiac risk in patients with essential hypertension. The relative value of office versus ambulatory PP measurements in this respect is an unresolved issue of considerable interest.

Methods: In 210 consecutive previously untreated patients (130 men, 80 women, aged 52 ± 10 years) in whom a first diagnosis of stage I or II essential hypertension was confirmed in our Department between January and December 1998, office PP (mean of difference between systolic and diastolic blood pressure values on 3 consecutive measurements) as well as ambulatory PP (mean of difference between systolic and diastolic blood pressure values on all measurements performed over 24 hours by standard equipment) was determined prior to initiation of treatment. These values were correlated with 4 well-defined types of left ventricular (LV) geometry categorized in order of increasing adverse prognostic significance as normal geometry, cardiac remodeling, eccentric hypertrophy, and concentric hypertrophy on the basis of LV mass index and LV relative wall thickness assessed by transthoracic echocardiography.

Results: A good correlation was demonstrated between office PP (mean ± SD: 55 ± 15 mmHg) and ambulatory PP (53 ± 9 mmHg) measurements ($r = 0.46$, $p < 0.001$). Normal LV geometry was revealed in 105 pts, the remodeling pattern in 71, eccentric hypertrophy in 18 and concentric hypertrophy in 16 pts. Office PP and ambulatory PP values correlated equally well with LV mass index ($r = 0.31$ and $r = 0.23$, respectively, $p < 0.001$ for both correlations). Both office and ambulatory PP values were lowest in pts with normal LV geometry (51 ± 15 and 51 ± 9 mmHg, respectively) and highest in pts with concentric LV hypertrophy (70 ± 14 and 57 ± 9 mmHg, respectively), with intermediate values in pts with the remodeling pattern (56 ± 14 and 53 ± 8 mmHg, respectively) and eccentric hypertrophy (57 ± 16 and 57 ± 10 mmHg, respectively). Office PP was significantly higher in pts with concentric hypertophy compared with all the other LV geometry subgroups ($p < 0.05$ for all comparisons), as well as in pts with the remodeling pattern versus pts with normal LV geometry ($p < 0.05$). Ambulatory PP was significantly higher in pts with concentric as well as eccentric hypertrophy versus pts with normal LV geometry ($p < 0.01$ and $p < 0.05$, respectively).

Conclusions: In a group of untreated hypertensive pts, increasing PP values paralleled the increasing prevalence of patterns of LV geometry associated with progressively higher cardiac morbidity. Acquisition of 24-hour ambulatory PP values revealed this relation equally well as (but not better than) plain office PP measurements.

P576 Aldosterone synthase promoter −344 C/T polymorphism determines left ventricular structure by differences in sodium handling in arterial hypertension

C. Delles, J. Erdmann[1], J. Jacobi, K.F. Hilgers, M.P. Schlaich, E. Fleck[1], V. Regitz-Zagrosek[1], R.E. Schmieder. *Dept. of Medicine/Nephrology, University of Nuremberg; [1]Dept. of Internal Medicine/Cardiology, Charité, Campus Virchow Klinikum, Humboldt University Berlin, Deutsches Herzzentrum Berlin, Germany*

Objective: High oral salt intake is associated with arterial hypertension and left ventricular (LV) structural adaptive processes. The −344 C/T polymorphism of human aldosterone synthase (CYP11B2) promoter has been found to be related to LV size, arterial hypertension, and adrenocortical function. Therefore, we questioned whether differences in sodium handling are responsible for LV structural changes in human arterial hypertension.

Methods: We enrolled 122 male, white, young (age: 26 ± 3 years) subjects with normal or mildly elevated blood pressure (but never treated for that). LV structural parameters were assessed by 2-D guided M-mode echocardiography. Urinary sodium excretion over 24 hours was measured under a standard Bavarian diet and after an additional oral sodium load (salt tablets, 6 g/day over 1 week). Serum aldosterone levels were measured by radioimmunoassay. The −344 C/T polymorphism of the aldosterone synthase promoter was determined by restriction endonuclease *Hae* III digestion after DNA amplification with polymerase chain reaction.

Results: In the entire study population, the T/T, C/T, and C/C genotype of the −344 C/T aldosterone synthase polymorphism were found in 35, 57, and 29 subjects, respectively. Baseline urinary sodium excretion and blood pressure were similar across the genotypes. After oral sodium load, hypertensive subjects with the T/T genotype had significantly higher urinary sodium excretion (291 ± 85 vs 158 ± 81 mmol/d at baseline) than hypertensive subjects with the C/C genotype (212 ± 68 *vs* 207 ± 100 mmol/d at baseline) ($p < 0.05$), with similar serum aldosterone levels at baseline and after oral sodium load. Hypertensive subjects with the C/C genotype had greater LV diastolic and systolic diameter (54 ± 2 and 34 ± 3 mm, respectively) than those with the T/T genotype (50 ± 4 and 30 ± 4 mm, respectively; all $p < 0.05$). LV mass was similar (C/C, 260 ± 53; T/T, 272 ± 57 g; n.s.), but posterior (C/C, 9.9 ± 1.6; T/T 11.0 ± 1.2 mm) and, consequently, relative LV wall thickness (C/C, 0.37 ± 0.07; T/T, 0.44 ± 0.06) were reduced in hypertensive subjects with the C/C genotype (all $p < 0.05$).

Conclusion: Our data suggest a pattern of early excentric LV hypertrophy in hypertensive subjects with the C/C genotype of the −344 C/T aldosterone synthase polymorphism. This could be caused by a reduced ability to excrete sodium and, therefore, by a higher intravascular volume load.

P577 Association between aldosterone synthase *(CYP11B2)* gene polymorphism and left ventricular hypertrophy of mechanical overload

F. Navarro-López, M. Enjuto[1], A. Francino, E. Gómez-Angelats, A.M. Ballesta[2], C. Paré. *Dept. of Cardiology; [1]Molecular Cardiology; [2]Biochemistry Labs. IMCV/Hospital Clínic-University of Barcelona, Spain*

Aim: Aldosterone (Aldo) has been shown to be a contributing factor to myocardial growth. Since synthesis of Aldo might be influenced by *CYP11B2* promoter polymorphism, we tested the hypothesis that left ventricular hypertrophy (LVH) of pressure overload is associated with *-344CYP11B2* promoter genotype.

Methods: 78 consecutive untreated patients (pts) with essential hypertension (HBP) as well as 85 pts with aortic stenosis (AoS) were studied. Exhaustive clinical and biochemical examination was performed, including echocardographic studies (ECO) and peripheral blood determination of *CYP11B2* polymorphism by PCR amplification and restriction endonuclease digestion.

Results: The three genotype groups *-344TT, -344TC* or *-344CC* did not differ with regard to blood pressure, plasma renin activity, plasma Aldo levels (HBP group) or in severity of AoS, as assessed by Eco-Doppler. M-mode ECO measurements of septal (SWTh) and posterior wall thickness (PWTh) in mm (mean ± SD) revealed that *T* alelle was associated with a significantly greater wall thickness. Regression analysis showed that *T* alelle was an independent predictor of hypertrophy in HBP ($p = 0.003$) and in AoS ($p = 0.002$).

	Hypertension (n = 78)		Aortic stenosis (n = 85)	
	SWTh	PWTh	SWTh	PWTh
TT	12.0 ± 1.5	11.2 ± 1.2	14.6 ± 2.2	12.8 ± 1.8
CT	12.2 ± 1.5	11.1 ± 1.4	15.0 ± 2.6	13.1 ± 1.7
CC	10.7 ± 1.2	10.6 ± 1.4	12.9 ± 2.0	11.9 ± 1.8
p value	0.004	ns	0.001	0.02

Conclusions: Those findings suggests that the *T* alelle of the *-344CYP11B2* polymorphism is an independent factor associated with hypertrophy of pressure overload. Increase in Aldo synthesis might be exerted at the local myocardial level, since no association with plasma Aldo concentration was observed.

P578 Left ventricular geometry and vascular structural changes in hypertensive patients

M. Muiesan, D. Rizzoni, M. Salvetti, C. Monteduro, E. Porteri, G. Bettoni, S.M. Giulini, E. Agabiti-Rosei. *Cattedra Medicina Interna, University of Brescia, Brescia, Italy*

Arterial hypertension is associated with the presence of structural changes in the heart and both large and small arteries. It has been observed that the spectrum of geometric patterns observed in the heart of hypertensive patients (Hpts) may parallel the structural alterations detected in the carotid arteries. The relation between structural changes in subcutaneous small arteries and left ventricular (LV) geometry has never been evaluated.

Twelve normotensives (NT) and 66 Hpts with essential (n = 18) or secondary (n = 48) hypertension were included in the study. All subjects underwent an echocardiographic study for the measurement of LV mass index (LVMI) and relative wall thickness (RWT). Twelve normotensives had a normal LVMI (96.4 23 g/m^2) and geometry, 46 patients had normal RWT (RWT < 0.45) (LVMI 115.3 29 g/m^2) and 20 had concentric remodeling or hypertrophy (RWT > 0.45) (LVMI 130 31 g/m^2). All subjects were submitted to a biopsy of subcutaneous fat and morphologic characteristics of subcutaneous small resistance arteries were evaluated by a micromyographic technique (Mulvany's technique). The media/lumen ratio (M/L) was calculated.Hpts with concentric geometry had a greater M/L as compared with normotensives or Hpts with normal RWT (1.12 0.048 vs 0.06 0.01 vs 0.10 0.0031 in Hpts RWT > 0.45, NT and Hpts RWT < 0.45, respectively, $p < 0.01$).

The correlation coefficient between the M/L in subcutaneous small arteries and LVMI was 0.44, $p < 0.05$; the correlation coefficient between the M/L in subcutaneous small arteries and RWT was 0.45, $p < 0.05$.

In conclusion, the presence of a concentric geometry of the left ventricle is associated with more pronounced structural changes in small subcutaneous resistance arteries in patients with essential or secondary hypertension.

P579 Peripheral arterial disease is associated with decreased systolic left ventricular function and increased arterial stiffness: the LIFE study

V. Papademetriou, B. Dalhof, P. Narayan, K. Wachtell, E. Gerdts, M. Nieminne, J. Nielsen, R.B. Devereux. *Georgetown University & VA Medical Centers, Washington DC; New York Hospital-Cornell Medical Center, New York NY, USA; Skelleftea Lasarett, Skelleftea, Sweden; Dept. of Medicine, Glostrup University Hospital, Glostrup, Denmark; Haukeland University Hospital, Bergen, Norway; Dept. of Cardiology, Helsinki University Central Hospital, Helsinki, Finland*

Background: Changes in LV structure and function in pts with peripheral arterial disease (PAD) & LVH have not been adequtely explored.

Methods: We studied 840 pts with hypertension and ECG LVH (Cornell Voltage-Duration product > 2,440 or $SV_1 + RV_{5-6} > 38$ mm) participating in the Losartan Intervention for Endpoint Reduction in Hypertension (LIFE) Trial. Of those, 37 pts had PAD and 793 did not (NO PAD). Echocardiograms were obtained by trained sonographers and read by a single central reading center.

Results: The groups were similar in age (66 vs 67 yrs), BMI (27.4 vs 26.7), systolic and diastolic BP (173/98 vs 172/97 mm Hg), septal and posterior wall thickness, LVMI (121 vs 125 gr/m^2 and relative wall thickness (0.41 vs 0.47). FS and diastolic function measures were also similar. Differences in Echocardiographic Measures between groups were as follows:

	NO PAD (n = 793)	PAD (n = 37)	p = Value
MWS (%)	0.15	0.14	0.05
SA-MWs	96.00	90.00	0.03
CO (L/min)	5.20	4.60	0.01
TPR	2028	2368	0.07
PP/STVOL	1.02	1.14	0.04

MWS = Midwall fractional shortening, SA = Stress adjusted, pp/STVOL = pulse pressure/stroke volume ration.

Conclusion: We conclude that pts with PAD and ECG LVH have early evidence of systolic LV dysfunction and increased arterial stiffness.

P580 Influence of hypertension, left ventricular hypertrophy and left ventricular systolic dysfunction on plasma cardiotrophin-1 levels

S. Talwar, A. Siebenhofer[1], B. Williams[1], L.L. Ng. *Dept of Medicine & Therapeutics, Leicester University, Leicester; [1]Cardiovascular Research Institute, Leicester Royal Infirmary, Leicester, UK*

Objective: Cardiotrophin-1 (CT-1), a member of the interleukin-6 related cytokines that acts via the gp130 signalling pathway, has been shown to stimulate the assembly of sarcomeric units in series in cardiomyocytes. Furthermore increased expression of CT-1 mRNA is evident in the hypertrophied ventricles of hypertensive rats. We set out to determine whether CT-1 was elevated in plasma of hypertensive patients (with and without left ventricular hypertrophy {LVH}) and in patients with left ventricular systolic dysfunction (LVSD) & a history of hypertension as compared to controls.

Design and Methods: A competitive immunoluminometric assay using a methyl acridinium ester to label the peptide and an in-house polyclonal antibody to amino acids 105–120 of the CT-1 sequence was developed. We compared plasma CT-1 levels between 15 echocardiographic normal controls (8 male, median age 41 yrs [range 30–76] = Group 1), 30 patients with HT, normal left ventricular systolic function and no LVH (15 male, 43.5 yrs [22–72] = Group 2), 14 patients with HT, normal left ventricular systolic function & LVH (5 male, 47 yrs [29–74] = Group 3), 18 patients with history of HT (no history of Ischaemic heart disease) and left ventricular wall motion index (WMI) between 1.9–1.3 (12 male, 74.5 yrs [56–91], median WMI 1.6 [1.–1.9] = Group 4) and 17 patients with a history of HT (no history if ischaemic heart disease) and WMI of <1.2 (10 male, 66 yrs [43–83], median WMI 0.6 [0.2–1.2] = Group 5). Medians fmol/ml [ranges] are reported.

Results: CT-1 levels were 27.8 [7.6–42.1], 51.6 [13.4–95.7], 48.6 [35.7–93.9], 54.4 [20.5–95.8] & 76.1 [28.2–130.6] for groups 1–5 respectively. Mean LogCT-1 differed among all 5 groups ($p < 0.0001$, ANOVA) and between group 1 vs group 2–5 ($p < 0.001$). Mean Log CT-1 levels were higher in group 5 compared to group 4 and group 2 ($p < 0.05$ for both). There was no difference in log CT-1 levels between group 2 & 3 ($p = 0.49$) and group 3 & 5 ($p = 0.12$). The patients in group 4 & 5 were older than those in group 1–3 ($p < 0.001$). There was no difference in ages between groups 1–3.

Conclusion: Our results suggest there is a significant rise in CT-1 levels both in HT and LVSD compared to controls. Also those patients with severe LVSD had the highest CT-1 levels. There was no difference in CT-1 levels of hypertensives with or without LVH. This is the first demonstration of significant elevation of plasma CT-1 in patients with HT and LVSD. The exact role of CT-1 in these patients remains to be defined.

P581 QT dispersion in hypertensive patients who had normal coronary angiogram with or without left ventricular hypertrophy

F. Özerkan, M. Zoghi, C. Gürgün, O. Yavuzgil, M. Kayıkçıoğlu, R. Önder. *Ege University Medical School, Department of Cardiology, İzmir, Turkey*

The aim of this study was to investigate whether QT dispersion (QTd) was different in hypertensive patients who had normal coronary angiogram with or without left ventricular hypertrophy. The study population consisted of 61 hypertensive and 23 control subjects. All hypertensive patients had normal coronary angiogram. The electrocardiograms (ECG) of thirty-two hypertensive patients with left ventricular hypertrophy (mean age 53 ± 9), twenty-nine hypertensive patients without left ventricular hypertrophy (mean age 55 ± 2) and twenty-three normal healthy subjects were evaluated. Dispersion of QT interval was measured from 12-lead ECG at rest. Systolic (SBP) and diastolic (DBP) blood pressure, body mass index (BMI), left ventricular mass index (LVMI), QTd and QTcd were compared between groups.

(n = 23)	Hypertensive Patients		Control	p
	LVH(+) (n = 32)	LVH(−) (n = 29)		
SBP (mmHg)	147.5 ± 26.3	143.0 ± 16.3	120.6 ± 12.6	1–3*, 2–3*
DBP (mmHg)	90.8 ± 10.8	91.0 ± 7.3	76.7 ± 7.9	1–3*, 2–3*
BMI (kg/m2)	26.9 ± 4.2	26.7 ± 3.5	24.9 ± 5.3	ns
LVMI (gr/m2)	148.2 ± 31.9	96.1 ± 14.3	90.0 ± 12.3	1–3*, 1–2*
QTd (msn)	61 ± 24	64 ± 23	35 ± 10	1–3*, 2–3*
QTcd (msn)	68 ± 29	70 ± 27	38 ± 10	1–3*, 2–3*

*: $p < 0.05$, ns: non-significant

In conclusion: (1) QT dispersion was significantly increased in hypertensive patients with or without left ventricular hypertrophy.

(2) Ventricular arrythmias may be seen similarly in both left ventricular hypertrophic and non-hypertrophic hypertensive patients.

P582 Comparison of changes of heart and its function in renoparenchymal and essential hypertensive patients after more than a decade

J. Barta, T. Kovács, J. Nagy. *2nd Department of Medicine, University Medical School, Pécs, Hungary*

Although renoparenchymal disease is the most common cause of secondary hypertension there are no data in literature about its effects on heart.

Methods: We compared 35 IgA nephropathy hypertensive patients with normal renal function (IHTP) with 35 patients with essential hypertension (EHTP) all treated by combined therapy. Blood pressure was checked regularly and lab tests were taken. Heart function was measured by echocardiography.

Results: (Data are mean ± SEM) Duration of hypertension was 12.0 ± 1.02 ys and 13.1 ± 1.37 ys p: not significant. The onset of hypertension was earlier in IHTP than in EHTP (35.4 ± 1.7 ys vs. 43.0 ± 2.2 ys; $p < 0.01$). No significancy was found between left ventricle enddiastolic diameters (50.88 ± 1.07 vs. 53.8 ± 1.38) and endsystolic diameters (32.2 ± 1.1 vs. 33.7 ± 1.48) but left atrium was significantly bigger in EHTP than in IHTP (53.8 ± 1.7 ys vs. 43.0 ± 2.2 ys $p = 0.026$). The septum and posterior wall was also significantly thicker in EHTP than in IHTP (12.3 ± 0.37 vs. 11.3 ± 1.38 p $p < 0.05$ and 11.9 ± 0.33 vs. 10.9 ± 0.38 $p < 0.05$). Left ventricle mass index (LVMI) in women was also higher in EHTP than in IHTP (154.2 ± 13.1 vs. 129.3 ± 9.5) and in men (170.7 ± 7.8 vs. 149 ± 9.0). Ejection fraction was significantly higher in IHTP than in EHTP (66.7 ± 1.41 vs. 60.5 ± 1.94 $p < 0.02$). E/A also showed significant differency: in IHTP 1.03 ± 0.058 and in EHTP 0.863 ± 0.054 $p = 0.025$. Body mass index (BMI) was significantly higher in EHTP than IHTP (30.1 ± 0.66 vs. 28.1 ± 0.58 $p = 0.024$). There was a significant correlation between BMI and left atrium in IHTP ($p < 0.01$) whereas in EHTP was not.

Conclusion: Our data show that systolic and diastolic heart function is less damaged and left atrium enlargement and left ventricle hypertrophy are milder in renoparenchymal hypertensive patients eventhough hypertension existed for longer period then in essential hypertensives. The main cause is still to be found but more frequent and regular checking and follow-up because of renal disease and less degree of obesity may play role in it.

P583 Myocardial perfusion abnormalities in hypertensive patients without known coronary artery disease

Abdou Elhendy, Ron T. van Domburg, Jos R.T.C. Roelandt, Peter R. Nierop, Don Poldermans, Jeroen J. Bax, Galal M. El-Said, M. Mohsen Ibrahim, Roelf Valkema. *Thoraxcenter, Rotterdam, Netherlands*

Rationale. Myocardial perfusion abnormalities may occur in hypertensive patients in absence of significant coronary artery disease (CAD). However, it is not well established whether hypertensive patients without known CAD have a higher prevalence of myocardial perfusion abnormalities compared with non hypertensive patients with similar clinical features. This study compares the prevalence and extent of rest and stress-induced myocardial perfusion abnormalities in patients with and without hypertension.

Methods. Dobutamine (up to 40 μg/kg/min) stress 99 m technetium myocardial perfusion SPECT imaging was performed for evaluation of myocardial ischemia in 350 patients (mean age = 60 ± 13 years, 146 men) without history of previous infarction or known CAD. One hundred forty eight patients were hypertensive. Rest SPECT images were acquired 24 hours after the test. Abnormal perfusion was defined as the presence of reversible or fixed perfusion defects.

Results. No significant difference was detected between patients with and without hypertension regarding gender, prevalence of symptoms, risk factors, pretest probability of CAD (52 ± 28% vs 53 ± 29%), peak rate pressure product (21040 ± 4755 vs 20774 ± 4865) or number of patients achieving the target heart rate during stress (85% vs 86%). The prevalence of myocardial perfusion abnormalities was not different between patients with and without hypertension (28% vs 31% in patients with low, 38% vs 33% in patients with intermediate and 60% vs 58% in patients with high pretest probability of CAD respectively). No significant difference was detected between both groups regarding stress perfusion defect score (1.45 ± 2.5 vs 1.50 ± 2.6) or rest score (0.72 ± 1.8 vs 0.68 ± 1.6).

Conclusion. Hypertensive patients without known CAD have similar prevalence and severity of myocardial perfusion abnormalities at rest and at dobutamine stress compared to non hypertensive patients with similar pretest probability of CAD.

P584 Ischaemic heart disease in patients with arterial hypertension

O.V. Korkushko, I.V. Dolot, S.V. Kozlov. *Institute of gerontology, AMS of Ukraine, Kyiv, Ukraine*

A high incidence of hypertension and a rapid development of heart failure in elderly people account for a growing interest among research workers in this problem.

Methods: For the purpose of diagnosing IHD and studying its effect on the contractile force of left ventricular (LV) myocardium 77 elderly patients with 2nd stage hypertension (age range, 60–79 years) were investigated by means of stress testing using dipyridamole test with ECG recordings in 48 leads and transesophageal atrial electrical pacing (TAEP) of the heart. The systolic and diastolic functions of the left ventricle were studied at baseline and at each frequency of pacemaker-induced heart rate using M-mode echocardiography. On the basis of stress testing IHD was diagnosed in 87% of the patients investigated (1st group). The rest of the subjects investigated (13%) were the patients with 2nd stage hypertension without IHD (2nd group).

Results: In patients of the 1st group a decrease in contractile force of LV myocardium was observed already at rest, the ejection fraction (EF) being retained, whereas in the patients of 2 nd group the LV systolic and pumping functions remained preserved. In the patients of 1st group a pronounced disturbance of systolic and diastolic functions, and a drop of EF by 15% and over occurred during TAEP at the heart rate of 118 impulses/min. In the patients of 2nd group the contractile force of LV myocardium was retained during stress testing but a further deterioration of diastolic function proceeded. In all patients of both groups a hypertrophy of left ventricle was noted. The analysis of results obtained showed that the development of hypertrophy in 92% of the 1st group patients could be classified as such that took an eccentric way, whereas in 80% of 2nd group patients it was of concentric type.

Conclusion: The TAEP is a highly informative method of IHD diagnosing and studying the functional state of LV myocardium. In elderly patients with hypertension the IHD was detected already at early stages of the disease which determines the development of LV dysfunction and the decrease in contractile force of the myocardium.

P585 Clinical characteristics of the hypertensive patients with myocardial perfusion defects and normal coronary arteries

D. Ural, A. Vural, T. Şahin, O. Caymaz[1], B. Komsuoglu. *Department of Cardiology, Kocaeli University Medical Faculty, Kocaeli; [1]Department of Cardiology, Marmara University Medical Faculty, Istanbul, Turkey*

Perfusion defects in myocardial scintigraphy (MPD) is a common finding in hypertensive patients with angiographically normal coronary arteries. The aim of our study was to investigate clinical, echocardiographic and electrocardiographic characteristics of the patients with essential hypertension and MPD (MPD+) and to compare them with hypertensive patients with normal scintigraphic findings (MPD-).

Methods: Fifty-seven patients (34 F, 23 M, age 59 ± 9) with MPD and angiographically normal coronary arteries and 91 hypertensive patients with normal MP (MPD-) were included to the study. Each patient underwent physical, laboratory, echocardiographic and ambulatory Holter monitoring examination. Presence of the other risk factors for coronary artery disease, left ventricular diameters, geometry, systolic and diastolic function, arrhythmic events and autonomic function were compared between the two groups.

Results: Significant clinical differences in MPD+ patients were the higher frequency of male gender, complaint of angina pectoris, smoking and longer duration of hypertension ($p = 0.006$, $p = 0.03$, $p = 0.02$ and $p = 0.01$ respectively). HDL levels were significantly lower ($p = 0.01$) and LDL was higher ($p = 0.04$) than MPD-s. In echocardiographic examination left ventricular diameters and geometry were similar in the two groups, but left ventricular internal diameter and mass index were slightly higher in MPD+s. Ejection fraction was significantly lower in MPD+ patients ($p = 0.03$), but none of the diastolic filling indexes showed significant difference in the two groups. Frequency of supraventricular and ventricular arrhythmias, dispersion of repolarization (QT-D, QTc-D, JT-D, JTc-D) were not different in both groups. Parameters of heart rate variability were slightly but significantly reduced in MPD+s.

It is concluded that MPD develops in hypertensive patients with more risk factors for coronary artery disease than MPD-s. Its frequency is similar in patients with and without left ventricular hypertrophy and its arrhythmogenic effect is not as strong as left ventricular hypertrophy.

PROGNOSIS IN MYOCARDIAL FUNCTION AND HEART FAILURE

P586 Long-term follow-up after percutaneous transluminal septal myocardial ablation for hypertrophic obstructive cardiomyopathy: sustained clinical and haemodynamic benefit

L. Krater, A. Meissner, L. Faber, P. Ziemssen, H. Seggewiss. *Department of Cardiology, Heart Center NRW, Ruhr-University Bochum, Bad Oeynhausen, Germany*

PTSMA by alcohol injection into septal branches of the left coronary artery is a new treatment option for symptomatic patients (pts.) with HOCM, leading to reduction of the left ventricular outflow gradient (LVOTG) and marked clinical improvement. We analyzed the long-term follow-up in the pts. treated with PTSMA in 1996.

In 39 pts. with successful PTSMA between 1/96 and 12/96, 2 died during in-hospital stay (VF and pulmonary embolism 1 pt. each). Mean CK rise was 722 ± 401 U/l. A permanent DDD-pacemaker (DDD-PM) had to be implanted in 7 pts. Mean follow-up duration was 29 ± 4 months. Four pts. had to undergo second effective PTSMA during follow-up because of inadequate primary result. Ventricular tachyarrhythmia or late death were not observed. Further clinical and echocardiographic data are displayed in the table:

	Baseline	Follow-up	p-value
NYHA class	2.7 ± 0.5	1.1 ± 1.0	<0.001
LV enddiastolic diameter (mm)	48 ± 5	48 ± 6	n.s.
LVOTG at rest (mm Hg)	51 ± 33	4 ± 8	<0.0001
LVOTG at Valsalva (mm Hg)	141 ± 56	12 ± 19	<0.0001
Maximum workload (Watts)	76 ± 66	108 ± 39	<0.02

Conclusions: PTSMA leads to sustained and significant LVOTG reduction and symptomatic improvement without global left ventricular dilatation during long term follow-up. Possible acute complications are AV-conduction disturbances (trifascicular-block) requiring permanent DDD-PM implantation and tachycardiac arrhythmias..

P587 Prognostic value of cytokines in patients with congestive heart failure

R. Kell, T.J. Dengler, C. Zugck, C. Krüger, M. Haass. *Department of Cardiology, University of Heidelberg, Germany*

Elevated levels of the proinflammatory cytokines TNF-a, IL-1 and IL-6 have been reported in patients with congestive heart failure (CHF). The purpose of this study was to further assess the prognostic impact of cytokines in patients with reduced left ventricular ejection fraction (LVEF, <35%).

Plasma concentrations of IL-1, IL-6, IL-10, IL-12, sCD14 and GM-CSF were measured by ELISA in 158 patients (age: 55 ± 11 years, 87% male, 22% coronary artey disease, 78% dilated cardiomyopathy) with CHF. These patients were characterized by a LVEF of 20.3 ± 12.5% and a peak oxygen uptake (pVO_2) of 13.1 ± 7.2 ml/min/kg.

During a follow-up period of 510 ± 155 days 64 patients (41%) reached an endpoint, i.e. died and/or were hospitalized due to worsening heart failure. In comparision to clinically stable patients (n = 94), these patients were characterized by a significantly higher plasma concentration of IL-6 (9.93 ± 12.69 pg/ml vs. 4.35 ± 4.89 pg/ml, $p < 0.0001$). However, the plasma concentrations of IL-1 (1.08 ± 1.96 vs. 1.77 ± 2.85 ng/ml), IL-10 (78.4 ± 145.47 vs. 52.55 ± 89.15 pg/ml), IL-12 (3.97 ± 3.65 vs. 4.60 ± 5.73 pg/ml), sCD14 (5.75 ± 3.26 vs. 5.37 ± 3.64 mg/ml) and GM-CSF (16.67 ± 30.78 vs. 13.86 ± 34.15 pg/ml) showed no significant difference between both groups. When the patients were subdivided into quartiles according to their IL-6 concentrations, only 20% (8 out of 40 patients) of the quartile with the lowest, but 65% (26 out of 40 patients) of the quartile with the highest IL-6 concentrations reached an endpoint. There was neither a significant relationship between IL-6 and pVO_2, nor between IL-6 and LVEF, suggesting an independency of IL-6 as a prognostic marker in CHF patients.

Among all the cytokines measured in the present study only IL-6 appears to possess a prognostic value.

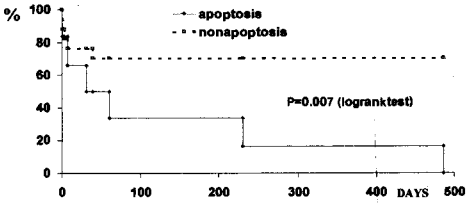
P588 Positive correlation between apoptosis of myocardial fibres and bad outcome after partial left ventriculectomy

M.L. Higuchi, E. Bocchi, M.F. Chaves, J.B. Castelli, F. Bacal, L.F. Moreira, N. Stolf, G. Bellotti, J.A. Ramires. *Heart Institute (InCor), University of São Paulo, Brazil Medical School*

The high postoperative mortality after partial left ventriculectomy or Batista operation (BO) is the major problem in this procedure. Here we analysed if apoptosis could be involved in this problem.

Methods: We performed immunohistochemical detection of apoptotic cells using TUNEL reaction labeled with fluorescein (Boehringer-Mannheim Kit), and confocal laser microscope, in 5 μm myocardial sections from 23 patients submitted to BO. Cases were grouped in: **positive** when presenting high number of apoptotic cells – several foci of myocytes and interstitial cells; and **negative** when apoptosis was absent or only in few interstitial cells or rare (<2) myocytes, per myocardial section.

Results: The mean number of 20× microscopic fields analysed/case was 86 (±33). Apoptotic cells were seen in foci near to microvessels. There was a significant correlation between presence of cardiomyocyte apoptosis and bad outcome after BO, as showed in the above survival curve after surgery, using logrank test.



In conclusion, apoptosis seems to be an important mechanism for development of heart failure and its presence may be one important factor for bad outcome after Batista operation. As the number of myocardial fields negative for apoptosis is high, endomyocardial biopsy would not be indicated as a method to detect it.

P589 Is the prognosis of heart failure improving?

A. Khand, J.G.F. Cleland[1], I. Gemmell[2], A. Boddy[2]. *Cardiology Dept, Glasgow Royal Infirmary, Glasgow; [1]Cardiology Dept, Castlehill hospital, Hull[2]Public Health Research Unit, University Of Glasgow, Glasgow, UK*

Background and Methods: Clinical trials have suggested that a number of recent treatments for heart failure may improve mortality and prevent hospitalisation but as yet no evidence exists for this either in a community or hospital setting. We sought to determine if mortality, re-admission with heart failure and re-admission for any cause, had changed between cohorts of first-time admissions for heart failure identified in 1984, 1988 and 1992 using linked hospital discharge and mortality data from Scotland (population approximately 5 million)

Results: The number of first time admissions for heart failure increased by 30% between 1984 and 1992, from 9716 to 12640. Their mean age was 74 years and 54% were women. Over the same period 3-year mortality declined in patients < 65 years from 53% to 41% (reduction in risk 12%, 95% confidence interval 9–15%. Log rank 70.0; $p < 0.001$])and for patients ≥ 65 from 71% to 66% (reduction in risk 5%, 95% confidence interval 3–6%. Log-rank 74.5; $p < 0.0001$]). Time to death or first re-admission with heart failure also improved but not time to death or first re-admission for any cause. The total number of re-admissions increased between 1984 and 1992 but bed-days occupancy for heart failure and for any cause, adjusted for days alive, declined due to a reduction in length of stay.

Conclusions: These data suggest that the prognosis of patients with a first admission for heart failure is improving. The timing of improvements coincides with the gradual increase in the use of angiotensin converting-enzyme inhibitors for heart failure although a causal link cannot be proved from these data.

P590 Prediction of death in chronic heart failure

A. Morley-Davies, J.J. Morton[1], H.J. Dargie[1], S.M. Cobbe. *Cardiology Dept., GRI, Glasgow; [1]CRI, Glasgow University, Glasgow, UK*

Chronic heart failure (CHF) is a common condition with an adverse prognosis. Accurate identification of those most likely to die remains elusive. We hypothesised that abnormalities of ventricular repolarisation and autonomic dysfunction would predict death in CHF.

We studied 199 patients age less than 75 years with stable CHF. We determined established clinical variables: age (59 ± 9 years), aetiology of CHF (ischaemic n = 163, nonischaemic n = 36), NYHA status (2.7 ± 0.8), maximal oxygen consumption (VO_2 max 16.9 ± 4.9 ml/kg/min). Investigational variables were: plasma brain natriuretic peptide (BNP, median 48 pg/ml), 24 hour heart rate variability (HRV, median SDNN 118 msec), baroreflex sensitivity by phenylephrine bolus injection (BRS median 5.4 msec/mmHg), signal averaged ECG (SAECG 25 positive) QT dispersion by manual digitisation (QTd median 94 msec). Events were categorised by established standards using information from death certificates, autopsy findings and hospital and GP case records. Mean duration of follow-up was 971 ± 378 days. There were 54 all cause deaths, 47 cardiac deaths and 24 sudden deaths.

A Cox-proportional hazards analysis was performed with age, NYHA class, aetiology of CHF, presence/absence of bundle branch block and LVEF as forced baseline variables. QTd and SAECG did not add prognostic power. The univariate addition of plasma BNP (hazards ratio HR 3.67, p = 0.006), plasma noradrenaline (HR 3.77, p = 0.0019), HRV (SDNN-I) (HR 1.93, p = 0.0532) or baroreflex sensitivity (HR 2.94, p = 0.003), predicted cardiac death significantly. With multivariate analysis of these new variables, plasma BNP was the most significant additional co-variate and strongly predicted cardiac death (HR 3.94, $p < 0.02$). BNP retained prognostic power in patients with severe LV dysfunction (EF < 20%).

Simple venous blood sampling aids risk stratification in this common and highly lethal condition.

P591 Prognostic significance of atrial fibrillation during long-term follow-up in 409 patients with advanced chronic heart failure

H.J.G.M. Crijns, G. Tjeerdsma, P.J. de Kam, F. Boomsma, M.P. van den Berg, D.J. van Veldhuisen. *Dept. of Cardiology, Thoraxcenter, University Hospital Groningen, Netherlands*

Atrial fibrillation (AF) is common in patients with chronic heart failure (CHF). It has been suggested that the presence of AF in CHF predicts an adverse prognosis, but data are scarse and inconclusive.

Methods: We studied 409 patients with moderate to severe CHF (NYHA class III–IV), who had either sinus rhythm (SR, n = 325), or atrial fibrillation (n = 84), and who were all part of a recent survival trial. At baseline the 2 groups differed with respect to age (67 vs. 70 yr, for SR and AF, resp.), etiology, duration of CHF (33 vs. 48 months, resp), blood pressure (slightly higher in SR), and plasma neurohormones (renin, atrial natriuretic peptide [ANP], N-terminal ANP, and endothelin, all higher in AF), and concomitant medication (particularly digoxin, antiarrhythmics, and anticoagulants, all higher in AF patients), but left ventricular ejection fraction (LVEF), NYHA class and gender were not significantly different. During 3.4 yr (range 2.0–5.4 yr) follow-up, 211 patients (52%) died; 52/84 patients with AF (62%), compared to 159/325 patients with SR (48%, p = 0.038, univariate analysis). On multivariate analysis, LVEF, NYHA class, renal function, age, diastolic blood pressure, and use of digoxin, were all significantly related to mortality, but AF was not (p = NS).

Conclusion: Although AF was associated with an increased mortality in the present study, AF does not appear to be an independent predictor of mortality in this patient group. The observed difference in prognosis may be due to other clinical factors, such as severity of CHF, and comparison of AF and SR will remain difficult.

P592 Prognosis of heart failure in the general population: the Rotterdam study

A. Mosterd[1,2], B. Cost[2], A.W. Hoes[3], A. Hofman[2], J.W. Deckers[1,2], D.E. Grobbee[2,3]. *[1]The Thoraxcentre; [2]Department of Epidemiology, Erasmus University, Rotterdam; [3]Julius Centre for Patient Oriented Research, Utrecht University, Utrecht, Netherlands*

There is no information on the prognosis of heart failure in the general population in the nineties. We determined the prognosis of heart failure in the large, prospective, population-based Rotterdam Study.

Methods: In 5.255 participants (age 68.9 ± 8.6 yr, 2.142 men) the presence of heart failure was assessed at the baseline visit (1990–1993) using validated criteria. Vital status and cause of death were verified during follow-up ending May 1 1996.

Results: 181 participants (age 77.3 ± 8.0 yr, 72 men) had heart failure. With an average follow-up of 4 years there were 55 deaths; 30 due to cardiovascular disease, 15 of which were sudden. Survival was 90% at one and 60% at four years.

The age adjusted hazard ratio for death in participants with heart failure was 2.1 (95% C.I. 1.6–2.8), the age adjusted hazard ratio for sudden death was 4.8 (95% C.I 2.6–8.9)

Conclusion: The prognosis of heart failure in the general population is poor. Patients with heart failure have a fivefold increase in the risk for sudden death.

P593 Prognostic value of the atrial natriuretic peptide in asymptomatic patients with Thalassemia major: ten-year follow-up

G. Derchi, G.L. Forni[1], A. Fonti. *Cardiology Dept, Ente Ospedaliero Ospedali Galliera, Genoa; [1]Pediatric Dept, Ente Ospedaliero Ospedali Galliera, Genova, Italy*

In the present study, we evaluated the relation between Atrial Natriuretic Peptide (ANP) and long-term clinical course and survival in patients with Thalassemia Major (TM).

Purpose of our investigation was to determine the prognostic role of neurohumoral activation in this disease.

Background: when cardiac involvment, due to iron overload, becomes clinically manifest in patients with TM, clinical course evolves rapidly towards refractory heart failure.

Methods: we compared ANP levels in 31 asymptomatic patients with TM who had normal left ventricular dimensions and normal right and left ventricular systolic function, and in 30 aged and sex matched normal control subjects.

Results: ANP levels were significantly higher in patients with TM compared to control patients (65 ± 14 vs 18 ± 7 pg/ml;$p < 0.001$). Neuropeptide Y, plasmatic renin activity, aldosterone, urinary sodium and catecholamines levels did not differ significantly in the two groups ($p > 0.05$). During follow-up ranging from 72 to 120 months, 13 of the 31 study patients (42%) developed heart failure and/or left ventricular dilatation, and three of these 13 patients died of congestive heart failure.

ANP concentrations, measured at initial evaluation, were significantly higher in these 13 patients with an unfavourable clinical course than in the remaining 18 patients who were clinically stable and had normal left ventricular dimensions during follow-up (96 ± 26 vs 39 ± 34 pg/ml, respectively; $p < 0.001$).

No patients with normal ANP level at baseline experienced heart failure and/or left ventricular cavity dimensions enlargement.

Conclusions: our results show that the plasma level of ANP is a predictor of clinical course and prognosis in asymptomatic patients with Thalassemia Major who have still normal systolic function and normal left ventricular cavity dimensions.

P594 Prognostic implications of QT interval and dispersion in patients with congestive heart failure

B. Brendorp, H. Elming, L. Kober, M. Malik[1], L. Jun, C. Torp-Pedersen. *Dept. of Cardiology, Gentofte University Hospital, Copenhagen, Denmark; [1]Dept. of Cardiological Sciences, St. George's Hospital, London, UK*

Background: In studies of less than 100 patients with congestive heart failure (CHF), increased QT dispersion has been associated with increased mortality. Large investigations are warranted and we have therefore studied patients enrolled in the Danish Investigation of Arrhythmia and Mortality on Dofetilide (DIAMOND-CHF) Study.

Methods: 1518 patients hospitalised with CHF and left ventricular dysfunction were enrolled in the DIAMOND-CHF Study. Technically acceptable ECGs without atrial fibrillation or bundle branch block were available in 490 patients. QT intervals were measured before randomisation using a digitizer tablet. QT dispersion was calculated as maximum minus minimum QT interval.

Results: During a minimum follow-up of one year, 188 of the 490 patients died. Table 1 below shows two Cox multivariate models of survival including either QTc interval or QT dispersion.

Table 1

	Risk ratio	95% CI		Risk ratio	95% CI
Mean QTc	1.002	0.998–1.007	QT dispersion	1.000	0.996–1.004
Age	1.054**	1.035–1.073	Age	1.053**	1.035–1.072
Heart rate	1.010*	1.000–1.020	Heart rate	1.010	0.999–1.020

**p < 0.0001 *p < 0.05. Both Cox analysis also included gender, dofetilide/placebo, beta-antagonist, diabetes mellitus, and ischaemic heart disease. None of these variables were statistically significant.

Conclusion: Prolongation of the QTc interval and QT dispersion is not associated with increased mortality in a large population of patients with congestive heart failure and reduced left ventricular function.

P595 Prognostic value of neurohumoral activation in left ventricular dysfunction: coronary heart disease versus dilated cardiomyopathy in 428 non-selected patients

T. Kottmann, C. Bergmeier, M. Bangert, A. Kilkowski, T. Kleemann, G. Taubert, D. Nagel[1], D. Seiler[1], J. Senges. *Herzzentrum Ludwigshafen; [1]Institut for Clinical Chemistry, Ludwigshafen, Germany*

Background: Left ventricular dysfunction (LVD) is associated with neurohumoral activation. The impact of etiology on the neurohumoral activation is unknown.

Question: Are there differences in prognostic meaning of various neurohumoral parameters in patients with coronary heart disease (CHD) versus dilated cardiomyopathy (DCM)?

Methods: 428 consecutive nonselected patients with ejection fraction (EF) ≤ 45% were registrated. Follow-up time was 498 ± 287 (median 454) days. Neurohumoral parameters at discharge were measured. We compared mortality of patients with high and low levels of neurohumoral parameters. Medians of neurohumoral parameters were taken as cut-off points. Patients: 78% male, age 64 ± 11 years, EF 29 ± 9%. Etiology: 60% CHD, 29% DCM, 11% other.

Results: Mortality was 24% in CHD and 16% in DCM (p = 0.02).

n = 428		Mortality in CHD		Mortality in DCM	
	Median	>Median	≤Median	>Median	≤Median
Norepinephrine	298 pg/ml	37%	11%*	25%	9%*
ANP	314 pg/ml	32%	17%*	32%	5%*
Vasopressin	2.8 pg/ml	28%	21%*	28%	5%*
Endothelin	7.6 pg/ml	29%	20%	27%	5%*
Renin	37 μU/ml	26%	21%	20%	12%
Aldosteron	58 pg/ml	27%	21%	21%	10%

*: p < 0.05

Conclusion: 1. Increased norepinephrine- and ANP-values are associated with higher mortality in LVD caused by CHD and DCM. 2. Vasopressin and endothelin are of prognostic importance in LVD caused by DCM but not in CHD. 3. There is no prognostic value of renin and aldosteron in patients with LVD independent of etiology.

P596 A parameter of recovery after a maximal exercise is an independent predictor of survival in patients with left ventricular systolic dysfunction

P. de Groote, V. Aumégeat, T. Meurice, A. Millaire, G. Ducloux, J.-M. Lablanche. *University of Lille, France*

Peak VO_2 is an independent predictor of survival in patients (pts) with congestive heart failure (CHF). However, several studies have demonstrated that peak VO_2 predicts survival in pts with severe exercise intolerance. Thus, other parameters are required in order to improve the prognostic information derived from the cardiopulmonary exercise test. We prospectively analyzed the kinetics of VO_2 during exercise and recovery (Rec), in 411 consecutive pts with CHF (53 women, mean age: 53 ± 11.3 years, NYHA I–II/III–IV: 276/135, ischemic cardiomyopathy: 43%). Left ventricular ejection fraction (LVEF) was 30.5 ± 10%, peak VO_2 was 16.5 ± 5.3 ml/min/kg, % of maximal predicted VO_2 (%VO_2) was 60.8 ± 18.6%. We determined the ratio between total VO_2 during exercise and during Rec, the half Rec time of peak VO_2, the % of decrease in VO_2 at 1 min, 3 min (%Rec3), 5 min and 7 min of Rec and the slope of VE/VCO_2 during exercise and recovery. During a median follow-up period of 845 days, there were 80 cardiovascular related deaths (CD), 32 transplantations (8 were UNOS1), 11 non cardiovascular related deaths and no pt was lost to follow-up. Independent predictors of CD + UNOS1 (Cox analysis) were: %VO_2 (p = 0.0001), NYHA (p = 0.0001), %Rec3 (p = 0.0005), peak blood pressure (p = 0.003) and LVEF (p = 0.01). Cardiac event rates (CD + UNOS1) in the 4 subgroups divided according to %VO_2 (< or >50%) and %Rec3 (< or >60%) were: group 1: %VO_2 < 50% and %Rec3 < 60% = 46%; group 2: %VO_2 < 50% and %Rec3 > 60% = 19%; group 3: %VO_2 > 50% and %Rec3 < 60% = 21%; group 4: %VO_2 > 50% and %Rec3 > 60% = 10%.

In conclusion: %Rec3 is an independent predictor of survival in patients with stable congestive heart failure. %Rec3, an easy new parameter to determine, could be useful in the selection of patients at risk of cardiac events.

P597 Comparative value of plasma atrial natriuretic peptide and cardiopulmonary exercise testing to assess prognosis of patients with congestive heart failure

R. Isnard, F. Pousset, J.N. Trochu[1], F. Masson, O. Chafirovskaia, J.L. Golmard, P. Lechat, D. Thomas, J.B. Bouhour[1], M. Komajda. *Cardiology Dept, Pitie-Salpetriere Hospital, Paris; [1]Cardiology Dept, Laennec Hospital, Nantes, France*

Although atrial natriuretic peptide (ANP), norepinephrine (NE), and endothelin-1 (ET1)plasma levels have been recognized as valuable predictors of prognosis in patients with congestive heart failure (CHF), their measurements are rarely performed in routine. On the opposite, peak oxygen consumption (VO_2), which is considered as one of the best marker of prognosis, is widely used. Surprisingly, the comparative value of these 2 approaches has been poorly investigated.

We studied 244 patients with CHF(mean age 51 ± 11 years, left ventricular ejection fraction (LVEF) < 40%). All patients had a measurement of plasma ANP, NE, and ET-1 at rest, and underwent a symptom-limited maximal exercise with VO_2 determination.

After a mean follow-up of 868 ± 598 days, 47 deaths and 24 heart transplantations occurred. In univariate analysis, NYHA functional class (p = 0.0003), systolic blood pressure (p = 0.016), LV end diastolic diameter (p = 0.0014), LVEF (p = 0.0002), peak VO_2 (p = 0.0011), percent of maximal predicted VO_2 (p = 0.0006), plasma ANP (p = 0.0001), plasma ET-1 (p = 0.0042) and plasma NE (p = 0.0002) were associated with survival. In multivariate stepwise regression analysis, only plasma ANP (p = 0.0001), NYHA functional class (p = 0.007) and plasma NE (p = 0.035) were independent predictors of survival. Similar results were obtained for the combined end-point of death or heart transplantation, and when the analysis is restricted to patients with a determinable ventilatory threshold.

In this study, plasma ANP appears to be a stronger marker of prognosis than peak VO_2 or percent of maximal predicted VO_2. Measurements of plasma neurohormones should therefore be considered routinely for prognosis assessment in CHF.

P598 Left atrial size predicts mortality in patients with left ventricular systolic dysfunction

A. Rossi, L. Zanolla, R. Sandrini, G. Golia, M. Anselmi, P. Marino, P. Zardini.
Divisione Clinicizzata di Cardiologia, Ospedale Civile Maggiore, Verona, Italy

Background: Atrial enlargement has long been known to be associated with increased mortality rate in general population, but little is known about its prognostic power in specific cardiac disease. Left ventricular (LV) systolic dysfunction is frequent and has a dismal prognosis, incompletely predicted by ejection fraction. The concomitant diastolic dysfunction accounts better for symptomatic status and survival. We aimed to verify the prognostic power of atrial enlargement, determined by diastolic impairment, since in pts with LV systolic dysfunction a wide range of atrial size occurs.

Method: An echo-Doppler exam was performed in 205 pts (age 59 ± 10; 85% male) between April 1993 and October 1996, subsequently followed-up through June 1998. Inclusion criteria was an EF < 50%. LA and LV dimensions and EF were taken directly from the echoreport. LA end-systolic volume (LAmax) (area-length method), LV volumes (Simpson' s method) E velocity, E/A and Dte were measured off-line. The end point was survival free from cardiac transplantation (HT).

Results: LA-d was univariately and multivariately the strongest predictor of CHF symptoms. During follow-up 43 pts did not reach the end-point Univariate analysis using a Cox model demonstrated that LA diameter (HR = 1.1; p < 0.000), LAmax (HR = 1.01; p < 0.000), LV systolic diameter (HR = 1.07; p < 0.000), EF (HR = 0.9; p < 0.000), DTe (HR = 0.99; p = 0.06) and E velocity (HR = 4.4;p < 0.005), mitral regurgitation degree (HR = 1.3; p = 0.005) and NYHA (HR = 2.2; p = 0.05) were significant predictors of outcome. However with multiple multivariate models the strongest variable significantly related to mortality remained LA diameter.

Conclusion: LA diameter, easily measured with M-mode echocardiographty, correlates with CHF symptoms and is the strongest prognostic factor in pts with LV systolic dysfunction.

P599 Insertion/deletion polymorphism of the angiotensin I-converting enzyme gene and the evolution of patients with heart failure

M.A.R. Cuoco, J.E. Krieger, G.F. Mota, H.F.G. Freitas, E.A. Bocchi, A.J. Mansur. *Heart Institute, (InCor), University of São Paulo, São Paulo, Brazil Medical School*

We performed this study to evaluate the association between insertion/deletion polymorphism of the angiotensin I-converting enzyme gene and the time elapsed from birth until the onset of symptoms and the time of survival of patients with heart failure.

Methods: 332 patients with heart failure, aged from 13–68 (43.3 ± 10.6) years, 259 (78%) male and 73 (22%) female, were studied. The etiologies were: idiopathic dilated cardiomyopathy in 125 (37.7%) patients, ischemic cardiomyopathy in 63 (19%), Chagas' disease in 57 (17.2%), hypertensive in 41 (12.3%), alcoholic in 24 (7.2%) and other in 22 (6.6%). The DD, DI and II genotypes were determined by polymerase chain reaction. Recessive, codominant and dominant effects were analised. Kaplan-Meier method and log rank test were used in statistical analysis.

Results: DD genotype was associated with an earlier onset of symptoms in patients with alcoholic cardiomyopathy compared to those in the DI and II group (p = 0.033) as well as an earlier onset of symptoms in patients with hypertensive cardiomyopathy compared to those in the DI and II group (p = 0.024) or with the DI or II (p = 0.048) genotypes. In patients older than 50 years, the DD genotype was associated with a higher mortality compared to those in the DI and II group (p = 0.002) or with the DI or II (p = 0.007) genotypes.

In conclusion, the DD genotype may be associated with an earlier onset of symptoms in patients with alcoholic or hypertensive cardiomyopathy. The DD genotype may be associated with a higher mortality in patients with heart failure older than 50 years.

P600 Viability on combined low–high dose dobutamine echocardiography predicts improvement in LVEF, symptoms and event-free survival

J.J. Bax, D. Poldermans, A. Elhendy, J.H. Cornel, E. Boersma, R. Rambaldi, J.R.T.C. Roelandt, P.M. Fioretti. *Leiden; Rotterdam, Netherlands; Udine, Italy*

DSE can predict improvement of wall motion after revascularization. The relation between viability, improvement of function, improvement of heart failure symptoms and long-term prognosis has not been studied. This study was designed to address, in patients with severe ischemic left ventricular dysfunction, whether dobutamine stress echocardiography (DSE) can predict improvement of left ventricular ejection fraction (LVEF), functional status and long-term prognosis after revascularization.

Methods: We studied 68 patients with DSE before revascularization; 62 patients underwent resting echocardiography/radionuclide ventriculography before and 3 months after revascularization. Long-term follow-up data (NYHA functional class, CCS classification and events) were acquired up to 2 years.

Results: Patients with ≥ 4 viable segments on DSE (group A, n = 22) improved in LVEF at 3 months (from 27 ± 6% to 33 ± 7%, P < 0.01), in NYHA functional class (from 3.2 ± 0.7 to 1.6 ± 0.5, P < 0.01) and in CCS classification (from 2.9 ± 0.3 to 1.2 ± 0.4, P < 0.01); in patients with < 4 viable segments (group B, n = 40) LVEF and NYHA functional class did not improve, while CCS classification improved significantly (from 3.0 ± 0.8 to 1.3 ± 0.5, P < 0.01). A higher event-rate was observed at long-term follow-up in group B vs group A (47% vs 17%, P < 0.05).

Conclusions: Patients with substantial viability on DSE demonstrated improvement in LVEF and NYHA functional class after revascularization; viability was associated with a favorable prognosis following revascularization.

P601 Can variations of mitral regurgitation during exercise be used to predict adverse events in patients with chronic heart failure?

Soccorso Capomolla, Oreste Febo, Giorgio Riccardi, Angelo Caporotondi, Maria Teresa La Rovere, Franco Cobelli. *"Salvatore Maugeri" Foundation Institute of Medical Care and Research Montescano (Pavia), Italy*

Background: in patients with chronic heart failure (CHF) mitral regurgitation at rest is an important predictive marker of adverse outcome. The prognostic significance of variations of mitral regurgitation (MR) during exercise has not, however, been investigated.

Objective: this study was performed in order to evaluate MR variations during exercise and to determine the prognostic power of these changes.

Methods: 55 consecutive patients with CHF (EF 24 ± 7%) who were in sinus rhythm and in optimized medical therapy, performed transthoracic echo-Doppler at baseline and during bicycle ergometry. MR was quantified by echo-Doppler. All measurements were made at rest and during exercise. According to MR at baseline and during exercise we identified the following groups: MR− (absence MR), MR+ (presence of MR), MR↑ (MR increase). Over a follow-up of 22 ± 13 months cardiac events, defined as cardiac death, heart transplant in status 1 and heart failure requiring hospitalization, were evaluated.

Results: hemodynamic profile and functional class at baseline were similar in all subgroups. Maximal workload capacity was 50 ± 20 watts. 17/46 (37%) patients developed mitral regurgitation during exercise. 8/9 (89%) patients had increased MR and in one patient mitral regurgitation was unchanged during exercise.

	Baseline			Exercise		
	ALL	MR+	MR−	MR−	MR+	MR↑
Patients	55	9	46	29	17	8
Events	29	8	21	7	14	8
% pts	53%	89%	45%	24%	82%	100%

Logistic regression analysis showed the mitral regurgitation at baseline and its changes during exercise provided the best estimate of risk: risk ratio (95% CL): 26.6 (5.1–137).

Conclusions: in patients with CHF and without mitral regurgitation at rest, exercise induced MR in 37%. Variations of MR during exercise identified a subgroup with an increased risk of adverse cardiac events. These data need to be verified in a multicenter, prospective, clinical trial.

P602 Heart rate variability enhances the prognostic value of established parameters in patients with chronic heart failure

C. Krüger, T. Lahm, C. Zugck, R. Kell, A. Haunstetter, D. Schellberg, M. Haass. *Department of Cardiology, University of Heidelberg, Heidelberg, Germany*

Purpose: The heart rate variability assessed from the 24-hr-ECG (HRV) during sinus rhythm has been proposed as a prognostic parameter in patients with chronic heart failure (CHF). The aim of this prospective unicenter study was to evaluate if HRV has a prognostic value additional to that of the widely used parameters left ventricular ejection fraction (LVEF) and peak oxygen consumption during cardiopulmonary exercise testing ($peakVO_2$).

Methods: 222 patients (with sinus rhythm) (age 54 ± 1 yr, male:female 86:14%) with dilative ($n = 151$) or ischemic ($n = 71$) cardiomyopathy with marked LV dysfunction (LVEF < 40% measured by radionuclide ventriculography) were included. Data were analyzed by uni- und multivariate Cox regression.

Results: During a mean follow-up of 15 ± 1 months (± SE), 38 patients (17%) died (all due to cardiac events) ("†"), and 45 (20%) were hospitalized due to deterioration of CHF ("HOSP"). The HRV parameter SDNN (standard deviation of mean interval between normal beats) was lower in patients with "† or HOSP" in comparison to patients without adverse events ("free") (118 ± 6 vs. 142 ± 5 ms), as well as LVEF (18 ± 1 vs. 23 ± 1%) and $peakVO_2$ (12.8 ± 0.5 vs. 15.6 ± 0.5 ml/min/kg) ($p < 0.01$ each). *Univ*ariate analysis revealed that each of these 3 parameters was unconfounded by the two others and was a predictor for "† or HOSP" vs. "free" and for "†" vs. "alive" (SDNN: $p = 0.0001$ and $p = 0.03$, LVEF: $p = 0.0001$ and $p = 0.0002$, $peakVO_2$: $p = 0.0007$ and $p = 0.002$). In the *multi*variate analysis SDNN enhanced the prediction of "† or HOSP" vs. "free" given by LVEF and $peakVO_2$ ($p < 0.05$), but not of "†" vs. "alive". None of other traditional parameters included in the analysis, such as cardio-thoracic ratio, heart rate, plasma concentrations of sodium, atrial natriuretic peptide and norepinephrine, improved the prognostic power of LVEF and $peakVO_2$.

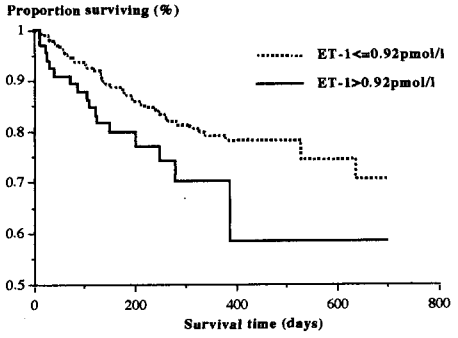
Conclusions: In CHF patients with sinus rhythm, HRV can be considered as an independent prognostic parameter. It enhances the power of the widely used parameters LVEF and $peakVO_2$ in the prediction of the adverse events "cardiac death or hospitalization due to worsening of CHF". Thus, the easily measurable HRV improves risk stratification in patients with CHF.

P603 Endothelin-1 is a better important prognostic predictor than atrial and brain natriuretic peptide in elderly inpatients for rehabilitation

H. Sayama, Y. Nakamura, N. Saitou[1], F. Hatta[1], H. Sakurai[1], M. Kinoshita, S. Nakayama[1]. *First Department of Internal Medicine, Shiga University of Medical Science, Shiga; [1]Dept. of Internal Medicine, Miyazaki AIWA Hospital, Miyazaki, Japan*

Purpose: The purpose of this prospective study was to evaluate the prognostic value of plasma endothelin-1 (ET-1) in comparison with atrial and brain natriuretic peptide (ANP, BNP) in elderly inpatients for rehabilitation.

Methods: Our 252 patients consisted of 81 men and 171 women, aged 65 to 101 years (83.9 ± 7.7 y; mean ± SD). Their diseases were cerebrovascular diseases (74%), cardiovascular diseases (23%), hypertension (34%), diabetes mellitus (14%), chronic renal failure (6%) and hyperlipidemia (11%). The endpoint was mortality due to all causes.



Kaplan-Meier survival plot for inpatients subdivided into 2 groups according to the upper normal ET-1 limit (0.92 pmol/l). (P = 0.043, Log-Rank test.)

Results: We followed up for 311 ± 119 days, during which time 56 deaths occurred (22 pneumonia, 12 heart failure, 5 cancer, 9 cerebral infarction and 8 other causes). The levels of plasma ANP, BNP and ET-1 in the cardiac deaths (n = 12) were greater than those in the non-cardiac deaths (n = 44), but these differences were not significant. A multivariate Cox proportional hazards regression analysis revealed that the following were significant independent contributors to the endpoint: ET-1, male gender, history of hypertension, serum creatinine, triglyceride and albumin. However, ANP and BNP were not prognostic indicators in this study population. Patients with an ET-1 level greater than 0.92 pmol/l had a significantly higher mortality rate than did those with a lower level (n = 65 vs 187, 26.2% vs 20.9%, P = 0.043, Log-Rank test).

Conclusion: In conclusion, plasma ET-1 may be superior to ANP and BNP as a predictor of mortality in elderly inpatients for rehabilitation.

P604 Hospitalisations and deaths in a population-based cohort of incident (new) cases of heart failure

M.R. Cowie, K.F. Fox[1], D.A. Wood[1], S. Bond[1], R.M. Turner[2], A.J.S. Coats[1], P.A. Poole-Wilson[1], G.C. Sutton[1]. *Department of Medicine & Therapeutics, University of Aberdeen, Aberdeen; [1]Cardiac Medicine, Imperial College School of Medicine, London[2]Medical Statistics & Evaluation, Imperial College School of Medicine, London, UK*

Background: The number of hospital admissions due to heart failure has been rising steadily in all developed countries. The factors predictive of hospitalisation on a population basis are not known.

Methods: All incident (new) cases of heart failure arising in a population of 292 000 in Bromley, South London, UK were identified by in-patient monitoring and from a rapid-access heart failure clinic over a period of 15 months. Cases were followed up for death and hospitalisation.

Results: 332 incident cases of heart failure were identified (178 M: 15 4F; median age 77 years). 211 (64%) were identified from acute admission to the hospitals serving the population and 121 (36%) from the rapid access clinic. During the follow-up period (median 14 months) there were 78 deaths (86% due to cardiovascular disease). Survival was 87% at 1 month, 81% at 6 months and 80% at 12 months. During the follow-up period there were 209 hospitalisations in 127 (38%) of the 332 patients. 78 patients had 1 subsequent hospitalisation and 49 had 2 or more hospitalisations (maximum of 5). 44% (93/209) of the admissions were related to the worsening of heart failure. The average duration of a hospital admission was 5 days (range 1–84 days). In those that survived the first 4 weeks after diagnosis, the factors independently predictive of subsequent hospitalisation for worsening of heart failure or cardiovascular death were: previous history of vascular disease (p = 0.001); serum sodium (p = 0.02); first presentation as inpatient rather than outpatient (p = 0.04); and age (p = 0.07).

Conclusions: patients with a new diagnosis of heart failure have a high rate of subsequent hospitalisation with almost half of the admissions being related to worsening of heart failure. A subgroup of patients can be identified at especially high risk of death or hospitalisation. Interventions designed to reduce hospitalisation should be targeted at this group.

P605 How right ventricular function relates to pulmonary artery pressure in advanced congestive heart failure: prognostic implications

S. Ghio, A. Gavazzi, C. Inserra, C. Campana, A. Giusti, R. Sebastiani, C. Opasich, C. Klersy[1], F. Recusani, L. Tavazzi. *Cardiology Division, IRCCS Policlinico S. Matteo, Pavia; [1]Biometry Unit, IRCCS policlinico S. Matteo, Pavia, Italy*

Aim of the study was to ascertain as to whether the evaluation of the coupling between right ventricular function and pulmonary artery pressure may improve the prognostic assessment in pts with congestive heart failure (CHF).

Methods: Between 1992 and 1998, 380 consecutive pts (mean age 51 years) with chronic CHF due to severe left ventricular systolic dysfunction (LVEF < 35%) underwent right heart catheterization; all pts received an optimized pharmacological treatment. Etiology was primary dilated cardiomyopathy (DCM) in 66% and ischemic heart disease (IHD) in 34% of pts; pts with valvular heart disease or miscellaneous etiology were excluded.

Results: In the whole population an inverse relationship was observed between thermodilution-derived right ventricular ejection fraction (RVEF) and mean pulmonary artery pressure (PAPm), with an "r" coefficient of −0.66 (p < 0.001); this relationship was similar in DCM and in IHD pts. During a follow-up period of 17 ± 9 months 104 pts died. The population was subdivided into 4 groups according to the presence or absence of pulmonary hypertension (cut-off = PAPm > 20 mmHg) and to the presence or absence of RV dysfunction (cut-off = RVEF < 30%). At the Cox survival analysis the pts in the "high PAPm-low RVEF" group (N = 209) had the worst prognosis: the hazard ratio indicated a risk 5 times larger than that of the pts in the "low PAPm-good RVEF" group (N = 97) (95% CI: 2.9–9.8, p = 0.000) and 2.4 times larger than that of the pts in the "high PAPm-good RVEF" group (N = 28) (95% CI: 1.1–5.5, p = 0.03). The prognosis of the pts in the "low PAPm-low RVEF" group (N = 44) was indistinguishable from that of the pts in the "low PAPm-good RVEF" group or in the "high PAPm-good RVEF" group.

Conclusions: In pts with heart failure due to DCM or IHD, RVEF is inversely related to PAPm. When pulmonary artery pressure is normal, RV dysfunction is uncommon and shows no clear impact on prognosis. In the presence of pulmonary hypertension however, the coexistance of RV dysfunction is clearly associated with a worse prognosis.

P606 Prognostic value of 6-minute walk corridor test in patients with congestive heart failure

C. Rostagno, S. Vena, V. Turchi, V. Boddi, M. Banchelli, G. Galanti, G.F. Gensini. *Clinica Medica Generale e Cardiologia, University of Florence, Florence, Italy*

Aim of present study was to evaluate the prognostic value of 6-minute walk test in unselected patients with mild to moderate congestive heart failure (CHF) and to compare it to other indexes of cardiovascular function.

Methods: 214 patients (119 men and 95 women, mean age 64 years) with CHF who were consecutively admitted to our institution from 01.01.94 to 06.30.95 were followed-up for a median of 34 months to assess mortality

Results: At the end of follow-up 66 patients (34%) died, 63 for cardiovascular causes, 2 for cancer and 1 for stroke. 5 patients underwent heart transplantation. In patients who walked less than 300 m at 6 minute-walk test survival was 62% in comparison to 82% in patients who walked between 300 and 450 m and patients who walked >450 m.

Mortality was was significantly higher in patients with lower LV ejection fraction (<30%) and higher NYHA functional class (III-IV). At univariate analysis no significant relation was found between survival and respectively peak VO_2 and AT:

	Hazard ratio	(CI 95%)	Z	p
Age	1.007	(0.98–1.03)	0.600	0.58
Etiology	1.37	(0.82–2.28)	1.231	0.21
LVEF (%)	0.96	(0.94–0.97)	–4.37	0.000
LVFS(%)	0.92	(0.88–0.95)	–4.61	0.000
LVEDD	1.04	(1.02–1.06)	3.61	0.000
NYHA class	2.58	(1.87–3.57)	5.78	0.000
AT	0.99	(0.85–1.15)	–0.12	0.85
pVO_2	1.01	(0.91–1.11)	0.202	0.84
6 min WCT	0.995	(0.993–0.997)	–4.04	0.000
MPAP	1.03	(1.00–1.06)	2.19	0.028
E/A ratio	1.23	(0.90–1.69)	1.33	0.181

At multivariate analysis using Cox-stepwise regression model LV fractional shortening ($p < 0.009$) and the distance covered at 6 minute walk test ($p < 0.000$) were the strongest prognostic markers (table)..

Conclusion: Distance covered at 6 minute walk test is a simple and useful independent prognostic marker of subsequent cardiac death in patients with mild to moderate CHF.

P607 N-terminal proANP: a marker of clinically significant diastolic dysfunction

B. Andersson, C. Hall[1]. *Cardiology Dept, Sahlgrenska University Hospital, Gothenburg, Sweden; [1]Institute of Surgical Research, University of Oslo, Oslo, Norway*

Diastolic dysfunction as a cause of congestive heart failure has been considered as common as systolic heart failure. The long-term prognosis in diastolic heart failure is less severe, but no prognostic marker has been identified in this condition. In a population of patients with idiopathic congestive heart failure, we studied long-term survival and symptoms and the relation to N-terminal proANP in patients with diastolic dysfunction. Because concentration of N-terminal proANP is increased by elevated filling pressures, this peptide might reflect the degree of congestive heart failure.

Method: In a group of patients with idiopathic heart failure from western Sweden (n = 293), 60 patients with normal systolic function (EF < 40%), and concomitant signs of disturbed left ventricular function were identified. N-terminal proANP was analysed in relation to long-term survival (7 years).

Results: Patients with increased concentration of N-terminal proANP >1200 pmol/L had significantly poorer survival as compared with patients with lower values. In a multivariate analysis, N-terminal proANP was the only independent variable that correlated to mortality: RR 2.71 (95%CI 1.32–5.59), P = 0.007. A larger proportion of patients with high concentration experienced death or hospitalisation during follow-up (67% vs. 33%, P = 0.028). They also tended to develop more symptoms and to receive more diuretics (93 ± 66 vs. 55 ± 42 mg, P = 0.015).

Conclusion: Patients with diastolic heart failure and high concentration of N-terminal proANP experienced clinically significant events, with increased mortality and morbidity. We postulate that an elevation of plasma N-terminal proANP might be one of few markers of clinically important diastolic dysfunction.

P608 Prognostic value of circulating cardiac natriuretic peptides in patients with coronary artery disease

T. Omland, H. Vik-Mo[1], L. Woie[2], A. Aakvaag[3]. *Department of Medicine, Ullevaal Hospital, Oslo; [1]Department of Medicine, University Hospital of Trondheim, Trondheim[2]Department of Medicine, Central Hospital in Rogaland, Stavanger[3]Department of Clinical Biochemistry, University of Bergen, Bergen, Norway*

Natriuretic peptides have been shown to be poweful prognostic indicators after acute myocardial infarction and in chronic heart failure. Whether natriuretic peptide levels are predictive of survival in patients with coronary artery disease (CAD) without symptomatic heart failure is unknown.

Methods: Plasma concentrations of atrial natriuretic peptide (ANP), N-terminal pro-atrial natriuretic peptide (N-ANP), and brain natriuretic peptide (BNP) were measured in 215 consecutive patients (mean age 60 (± 10) years, 80% male) with angiographic evidence of significant CAD. Patients with symptomatic heart failure (NYHA functional class III or IV) were ineligible for participation in the study.

Results: During a median follow-up of 52 months 10 patients died. By univariate Cox proportional hazards regression a history of diabetes mellitus, ($p = 0.002$), left ventricular dysfunction, defined as ejection fraction less than 45% ($p = 0.024$), the presence of pathological Q-waves on the electrocardiogram ($p = 0.044$) and plasma levels of N-ANP ($p = 0.025$) and BNP ($p = 0.030$) were identified as significant predictors of all-cause mortality. In multivariate models N-ANP ($p = 0.037$) and BNP ($p = 0.042$), but not ANP ($p = 0.244$) added significant prognostic information to a history of diabetes mellitus ($p = 0.0008$) and left ventricular dysfunction ($p = 0.0048$).

Conclusion: Plasma N-ANP and BNP provide prognostic information beyond that obtained from standard risk markers in patients with CAD without symptomatic congestive heart failure. Natriuretic peptide determination may have a role in risk stratification of this low-risk patient group.

P609 Chronic heart failure in the very elderly: survival and prognostic factors in 186 patients over 70 years of age

M. Cicoira, S. Varney[1], V. Florea[1], W. Shamim[1], S.D. Anker[1], A.J.S. Coats[1]. *Divisione Clinicizzata di Cardiologia, Ospedale Civile Maggiore, Verona, Italy; [1]Cardiac Medicine Dept, Royal Brompton Hospital & NHLI, London, UK*

Chronic heart failure (CHF) is a disease with high morbidity and mortality and increasing incidence and prevalence, particularly in the elderly, but little is known about prognosis in this population. Our aim is to describe survival and to assess whether there are any predictors of mortality in this subset.

Methods: we retrospectively evaluated 186 consecutive patients with CHF over 70 years of age (mean age 74 ± 4, range 70–87; 54 female). Clinical, biochemical, and echocardiographic data were recorded and cardiopulmonary exercise test was performed (peak VO_2, mean 15.1 ± 4.7 ml/min/kg). Left ventricular ejection fraction (LVEF%) was determined by radionuclide angiography (39 ± 17). The primary endpoint of the study was all-cause mortality.

Results: at the end of follow-up (42 ± 32 months, range 6–172), 55 patients (29%) had died. No patient received heart transplantation. 63% of patients had preserved systolic function, defined as LVEF>45%. Using Cox proportional hazard model, at the univariate analysis the following parameters were identified as the strongest predictors of mortality: age (HR = 1.1; $p < 0.0001$), NYHA class (HR = 3.1; $p < 0.0001$), peak VO_2 (HR = 0.88; $p = 0.014$), left ventricular end-systolic diameter on echocardiography (HR = 1.5; $p < 0.0001$), LVEF% (HR = 0.9; $p = 0.0003$) systolic blood pressure (HR = 0.9; $p = 0.0003$) and plasma sodium (HR = 0.9; $p = 0.002$). The multivariate analysis, with the most powerful model obtained combining NYHA class, age, LVEF% and peak VO_2, showed that only NYHA class ($p = 0.0028$) and age ($p = 0.03$) were independent predictors of mortality. At the log-rank test, patients with systolic dysfunction had a worse prognosis compared to those with preserved systolic function (survival at 100 months, 27% vs. 67%, $p = 0.0092$).

Conclusions: prognosis in elderly patients with CHF is poor. NYHA functional class and age are the strongest prognostic factors in this population. Patients with LV systolic dysfunction seem to be at particularly high risk of death.

MEDICAL TREATMENTS: INOTROPES, ACE INHIBITORS, AT2 BLOCKERS, VASODILATORS AND OTHERS

P610 Effects of levosimendan, a novel Ca^{2+} sensitizer, on ionic currents of human cardiac cells

Y. Katsube, N. Hagiwara[1], H. Kasanuki[2], K. Momma[3], N. Sperelakis[4]. *Pediatrics Dept, Nippon Medical School 2nd Hospital, Kawasaski; [1]Cardiology Dept, The Heart Institute of Japan, TWMC, Tokyo[2]Cardiology Dept, The Heart Institute of Japan, TWMC, Tokyo[3]Pediatric Cardiology Dept, The Heart Institute of Japan, TWMC, Tokyo, Japan[4]Mol. & Cell. Physiology Dept, University of Cincinnati, Cincinnati, USA*

The chemical structure of levosimendan (LS) is related to pimobendan, a Ca^{2+} sensitizing and PDE III inhibitory positive inotropic agent. In experimental animals, LS was reported to exert its action by increasing Ca^{2+} sensitivity of myofilament. However, in human hearts, the mechanism of LS actions has not been clarified. The present study was undertaken to elucidate the elctrophysiological actions of LS in human cardiac cells using whole-cell voltage clamp technique. LS stimulted the nifedipine sensitive Ca^{2+} current ($I_{Ca(L)}$) which was evoked by applying step pulses from a holding potential of −40 mV. Stimulation of $I_{Ca(L)}$ by LS was dose-dependent with EC_{50} value of 0.056 μM (n_H = 1.2), which is close to the effective concentration in human subjects (i.e., 0.02 μM). Even at 0.01 μM, LS stimulated $I_{Ca(L)}$ by 14 ± 3% (n = 4). As maximal effect, $I_{Ca(L)}$ was increased by 131 ± 12% at 1 μM LS (n = 5). In the presence of 1 μM LS, application of rolipram (10 μM, a selective PDE-IV inhibitor) or IBMX (100 μM, a non-selective PDE inhibitor) produced further stimulation of $I_{Ca(L)}$ by 250 ± 45% (n = 5) and 270 ± 72% (n = 5), respectively. This suggests that LS is a selective inhibitor for PDE III. On the other hand, a higher dose (10 μM) of LS stimulated the outward currents evoked by ramp pulses, and they intersected at the expected value for E_K. Increase in the outward current (at −40 mV) was 21 ± 7 pA/pF (n = 5), and it was completely abolished by 2 μM glibenclamide, suggesting that it was ATP-sensitve K^+ (K_{ATP}) current. In conclusion, the positive inotropic effect of LS on human heart may be partly due to the increase in $I_{Ca(L)}$, because clinically relevant concentrations of LS stimulated it. Furthermore, LS might act as a cardioprotective agent by opening K_{ATP} channels in the pathophysiological conditions such as regional ischemia.

P611 Functional effects of mild hypothermia in isolated human myocardium

B. Pieske, R. Bornemann, W. Horn, L.S. Maier, J. Weisser, G. Hasenfuss. *Abt. Kardiologie und Pneumologie, Zentrum Innere Medizin, Göttingen, Germany*

Mild hypothermia increases contractility in some animals species but its direct effects in human myocardium are not characterized. We investigated the functional effects and the mechanism of action of mild hypothermia in isolated human ventricular myocardium from 5 nonfailing and from 20 end-stage failing hearts.

Methods: Isolated muscle strip preparations, isometric contractions, electrical stimulation (1 Hz). Influence of stepwise reduction in organ bath temperature from 37°C to 29°C on isometric twitch force, intracellular Ca transients (aequorin method) and sarcoplasmic reticulum (SR) Ca content (rapid cooling contractures). Furthermore, the influence of mild hypothermia (31°C) on force-frequency behavior was tested.

Results: Stepwise cooling resulted in a significant increase in isometric force to maximally 189 ± 16% in nonfailing (n = 7) and to 201 ± 23% in failing (n = 20) myocardium (37°C vs. 29°C; $p < 0.05$). The inotropic effect was associated with a significant prolongation of time-to-peak tension and relaxation times. In aequorin-loaded muscle strips (n = 10), reduction of temperature to 30°C increased force to 165 ± 22% without any increase in aequorin light emission. Likewise, the inotropic response to hypothermia was not associated with an increase in RCCs. At 37°C, the isometric force did not change with increasing stimulation rates up to 2.0 Hz and then slightly declined at 2.5 and 3.0 Hz (blunted force-frequency response in failing myocardium). However, after cooling these muscle strips to 30°C at 0.5 Hz, despite an initial inotropic effect isometric force steeply declined already at stimulation rates > 1.5 Hz (from 15.5 ± 3.9 to 6.2 ± 0.9 mN/mm², $p < 0.05$). The deterioration of force-frequency behavior at 30°C was due to a pronounced increase in diastolic tension at higher stimulation rates (by maximally 3.1 ± 0.7 mN/mm² at 37°C, and by 10.8 ± 2.2 mN/mm² at 30°C, $p < 0.05$).

Conclusion: Mild hypothermia exerts significant positive inotropic effects in human ventricular myocardium. These effects are not related to increased intracellular Ca transients or increased SR Ca content and may result from enhanced myofilament Ca responsiveness. However, at higher stimulation rates, diastolic dysfunction occurs under hypothermic conditions. Mild hypothermia may be a new therapeutical approach in patients with severe cardiogenic schock.

P612 L-NAME is effective in the treatment of cardiogenic shock

G. Cotter, E. Kaluski, A. Blatt, R. Zaidenstein, A. Salah, O. Milovanov, M. Metzger, Z. Vered, A. Golik. *Department of Medicine "A" and the Cardiology Institute, Assaf Harofeh Medical Center, Zerifin, Israel*

Objective: To assess the safety and efficacy of L-NAME (a nitric oxide synthase inhibitor) in the treatment of cardiogenic shock.

Methods: Four consecutive patients with persistent cardiogenic shock despite treatment by mechanical ventilation, intra-aortic balloon pump (IABP) and high-doses of cateholamines, in whom all revasculrization options have been exhausted and were deemed beyond treatment by two expert cardiologists were enrolled in this study. All patients were continuously monitored by Swan-Ganz catheter, arterial line, pulse oxymetry and arrhythmia monitor. L-NAME (Clin-Alpha, Cal-Biochem) was administered as an IV bolus of 0.5 mg/kg and continuous drip of 1 mg/kg/hour for 6 hours. During treatment inotrope doses, fluid administration, mechanical ventilation and IABP were kept constant. Results: Within 10 minutes of L-NAME administration, mean arterial blood pressure increased from 78 ± 7 to 100 ± 8 mmHg (+28%), Urine output increased from 118 ± 100 cc/hour to 183 ± 117 cc/hour (+55%). The pulse rate has not changed 101 ± 13 versus 102 ± 31 beats/min. The cardiac output decreased at first (during the steep increase in blood pressure and afterload) from 3.1 ± 1.4 l/min. to 2.7 ± 1.2 l/min. (−13%) however it gradually increased to 2.9 ± 1.0 l/min after 5 hours of treatment (−6%). The Wedge pressure increased initially from 25 ± 15 to 27 ± 15 mmHg (+8%), however by 5 hours of treatment it decreased below baseline to 22 ± 11 mmHg (−12%). No adverse events, new ischemia nor arrhythmias were detected during L-NAME administration. Two out of four patients were able to be weaned from mechanical ventilation and IABP during L-NAME administration.

Conclusion: In this preliminary communication of an ongoing study, L-NAME administration has favorable clinical and hemodynamic effects on patients in cardiogenic shock. It increases mean arterial blood pressure and urine output with marginal effect on heart rate, cardiac output and pulmonary wedge pressure. No adverse effects could be detected.

P613 Blood pressure independent effects of AT_1 receptor blockade on left ventricular dysfunction in hypertensive transgenic (mRen2) 27 rats

L. Rothermund, N. Herfort, Y.M. Pinto, R. Kreutz, M. Paul. *Department of Clinical Pharmacology and Toxicology, Freie Universität Berlin, Germany*

We investigated the effects of long term treatment with low dose eprosartan (E), an AT_1 receptor antagonist, and low-dose quinaprilat (Q), an ACE inhibitor, on cardiac hypertrophy and -function in transgenic rats (TGR) with renin overexpression (TGR (mRen2) 27).

Five groups of TGR and one control group of Sprague-Dawley (SD) rats (n = 12, each) were treated for 20 weeks via osmotic mini pumps implanted intraperitonealy. SD: 0.9% NaCl; TGR: 0.9% NaCl; TGR-E6: E 6 mg kg^{-1} d^{-1}; TGR-E60: E 60 mg kg^{-1} d^{-1}; TGR-Q: Q 0.1 mg kg^{-1} d^{-1}; TGR-QE6: E 6 mg kg^{-1} d^{-1} combined with Q 0.1 mg kg^{-1} d^{-1}. Body weight (BW), systolic arterial blood pressure (SBP), left ventricular weight (LVW), left ventricular enddiastolic pressure (LVEDP), systolic dP/dt (SHI), and diastolic dP/dt (DHI) were measured after treatment:

	SD	TGR	TGR-E6	TGR-E60	TGR-Q	TGR-QE6
BW (g)	581 ± 14	558 ± 10	570 ± 15	544 ± 9	527 ± 8$^{\$}$	569 ± 10
SBP (mmHg)	128 ± 3$^{*\#}$	186 ± 5	185 ± 5	129 ± 5$^{*\#}$	153 ± 5*	159 ± 3*
LVW (mg g^{-1})	2.2 ± 0.06*	2.9 ± 0.1	2.3 ± 0.06*	1.8 ± 0.05$^{\&}$	2.1 ± 0.06*	1.9 ± 0.02$^{*\#}$
LVEDP (mmHg)	4.5 ± 0.4*	8.4 ± 0.5	5.3 ± 0.4*	4.8 ± 0.4*	6.7 ± 0.8*	4.2 ± 0.2$^{*\#}$
SHI($s^{\pm1}$)	27.1 ± 0.32*	23.7 ± 1.0	26.4 ± 0.32*	26.8 ± 0.53*	27.2 ± 0.8*	27.4 ± 0.33*
DHI(s^{-1})	24.8 ± 0.64*	20.5 ± 0.5	23.3 ± 0.54*	24.4 ± 0.49*	22.4 ± 0.99*	26.1 ± 0.56$^{*\#}$

Mean ± SEM, n = 6–12, $p < 0.05^{*}$ vs R, $^{\#}$ vs Q, $^{\$}$ vs SD, $^{\&}$ vs E6

Conclusion: Low dose E did not decrease blood pressure, but still prevented left ventricular hypertrophy and -dysfunction in hypertensive TGR (mRen2) 27. Furthermore, combined E with Q had an additional effect. Therefore, this study is the first to demonstrate that left ventricular dysfunction in hypertensive Ren-2 rats can be prevented by AT_1 blockade, even without lowering blood pressure. This suggests an important role for enhanced AT_1 receptor stimulation in the pathophysiology of comparable hypertension related left ventricular dysfunction.

P614 Effect of age on outcome in the ATLAS study

J.G.F. Cleland, P. Armstrong[1], J.D. Horowitz[1], B. Massie[1], M. Packer[1], P.A. Poole-Wilson[1], L. Rydén[1]. *Foundation Chair in Cardiology, Castle Hill Hospital, Nottingham; [1]on behalf of the ATLAS investigators, , UK*

The mean age of patients (pts) with chronic heart failure (CHF) in the community is about 75 years (yrs), but few pts > 75 yrs have been randomised in the landmark studies of CHF. Age may be a major determinant not only of the likelihood of treatment with an ACE inhibitor (ACEi) but also of the dose employed.

In the ATLAS study 3,164 pts with CHF and left ventricular ejection fraction ≤ 30% were randomised to either low dose (LD) 2.5–5 mg or high dose (HD) 32.5–35 mg lisinopril (Lis) and followed for a median of 46 months. 988 (31%) pts were ≥70 yrs and 437 (14%) ≥75 yrs. Baseline characteristics of older pts revealed they were more often women, more likely to have ischaemic heart disease, atrial fibrillation, renal dysfunction and a lower body weight. Mortality and morbidity rates by age are shown in the table.

	<60 yrs (n = 990)	60–69 yrs (n = 1186)	70–74 yrs (n = 551)	≥75 yrs (n = 437)
All Cause Mortality (%)	34%	43%	52%	57%
Death or Hosp (%)	76%	82%	86%	88%
Death or CHF Hosp (%)	49%	58%	64%	69%
No.Hosp/100 pt yrs	74	89	98	108
No.CHF Hosp/100 pt yrs	24	32	31	38

Compared to LD, HD Lis showed greater reductions in the composite (principal secondary) end-point of all-cause (AC) mortality or hospitalisation (hosp), death or hosp for CHF, the total number of AC hosp (p = 0.021) and CHF hosp (p = 0.002). Trends to a reduction in AC mortality (primary end-point) with HD Lis were not significant. Analyses showed no interaction between age above or below 70 yrs (pre-specified) or above or below 75 yrs (post-hoc) and effect of Lis dose, suggesting that the benefit of HD on outcome was unaffected by age. However, HD Lis reduced the risk of AC mortality by 12% (p = 0.036) in pts < 75 yrs. Although ATLAS did not show statistical evidence for less benefit of HD Lis in older pts, few elderly patients with CHF and concomitant problems such as renal dysfunction were randomised in the ATLAS study. The results of ATLAS should be extrapolated to frail, elderly patients with CHF with caution.

P615 Ramipril reduces ischaemia only when blood pressure is lowered: results of the LORAMI trial

S. Juul-Möller, R. Willenheimer[1], J. Holm[1], L. Forslund[1], L. Erhardt[1]. *Department of Cardiology, University Hospital, Malmö[1]Department of Cardiology, University Hospital, Malmö, Sweden*

ACE-inhibitors are proposed to have an antiischemic effect in patients with coronary artery disease (CAD).

Methods: To test this hypothesis we randomised (1:1:1) 346 patients with proven stable CAD and preserved left ventricular systolic function to double blind treatment for 6 months with placebo, low dose (1.25 mg/d) or high dose (5 mg/d) of ramipril. Inclusion criteria included prior myocardial infarction, PTCA, CABG or angina pectoris with ST-segment depression (STD) at a maximal exercise test. All patients had at least 10 minutes of STD at a baseline 48 h Holter. Antiischemic drug effect was measured as reduction of STD (duration and total area of ST-segment depression)between baseline and 6 months treatment.

Results: While no change in STD was found in any of the three treatment groups, a significant antiischemic effect was seen in ramipril patients with ≥20 mm Hg reduction in BP. These patients had a more pronounced antiischemic effect than patients with 10–20 mm Hg BP reduction, while patients with a reduction of <10 mm Hg had no antiischemic effect. The BP-reducing effect was partly dose-related. The ramipril effect on STD during Holter was mainly found in patients in whom heart rate (HR) increased prior to the maximal ST-segment depression. With a more increased HR (+7%, +10% or +15%) a more pronounced effect was seen on STD.

Conclusions: Six months ramipril treatment demonstrated an antiischemic effect as measured by ST-segment depressions during 48 hours Holter in patients with stable CAD and preserved left ventricular systolic function. This was seen only if ramipril induced a clear fall in systolic blood pressure and mainly in patients with increased heart rate prior to ST-segment depression. Patients with increased heart rate prior to myocardial ischemia are considered to have exercise induced ischemia.

Our results indicate, that a group of patients with expected antiischemic effect of an ACE-inhibitor may be identified in a clinically simple manner.

P616 Inhibitory effects of valsartan on angiotensin II-induced release of norepinephrine from rat atria

S. Shetty, D. DelGrande. *Novartis Inst. for Biomedical Research, Novartis Pharmaceuticals Corporation, Summit NJ, USA*

The effects of valsartan and other nonpeptide angiotensin II receptor (AT_1) antagonists on the prejunctional actions of angiotensin II were investigated in the isolated left atria of rat. Norepinephrine (NE) stores in the rat atria were loaded with [^{3}H]-NE, and neuronal NE release was deduced from the radioactivity efflux. Angiotensin II (1 micromolar) enhanced (46.5%) the electrical stimulation-induced (SI) efflux of [^{3}H]-NE from the preparation. Valsartan (10 micromolar) did not affect the control SI efflux of [^{3}H]-NE, but inhibited (83.0%) the angiotensin II-mediated augmentation of the response when administered concurrently with the agonist. Comparable inhibitions of the angiotensin II-mediated responses were also effected by a similar concentration of losartan, eprosartan and irbesartan, the other AT_1 antagonists tested. Thus, there appear to be no discernable differences among the four AT_1 antagonists when tested at this concentration, as regards their effects on the prejunctional actions of angiotensin II. Pretreatment of the tissues with a lower, albeit therapeutically pertinent concentration (1 micromolar) of valsartan, also resulted in a significant inhibition (40.4%) of the angiotensin-evoked response. This indicates that valsartan indeed inhibits the prejunctional facilitatory effect of angiotensin II on the release of NE from peripheral sympathetic nerves. Thus valsartan affords the potential therapeutic benefits emanating from such an inhibition in addition to the benefits ensuing from its inhibition of the other pathophysiological actions of angiotensin II.

P617 Excessive in vivo formation of superoxide during metabolism of glyceryl trinitrate but not pentaerithrityl tetranitrate: prevention by antioxidant vitamin c

B. Fink, S. Dikalov, D. Stalleicken, E. Bassenge. *Institute of Applied Physiology, Albert-Ludwigs University, Freiburg, Germany*

Background: Glyceryl trinitrate (GTN) and pentaerithrityl tetranitrate (PETN) are frequently used nitrates in cardiovascular therapy. However, anti-ischemic therapy with nitrates is complicated by the induction of tolerance potentially resulting from a coproduction of reactive oxygen species (ROS) e.g. superoxide ($O_2^{\bullet}$). Until now nitrate-induced increases of formation of ROS *in vivo* have not been reported. Our aim was to analyze the *in vivo* formation of ROS induced by treatment with PETN or GTN and the modulating effect of the antioxidant vitamin C (Vit-C) using electron spin resonance spectroscopy.

Methods: 22.5 mg/kg of spin trap 1-hydroxy-3-carboxy-pyrrolidine (CP-H), which after reaction with ROS forms nitroxyl radical 3-carboxy-proxyl (CP), and 130 μg/kg of GTN or PETN were infused IV. into anesthetized rabbits. Formation of ROS was determined from contents of nitroxyl radical CP in the blood drown from the carotid artery.

Results: Both PETN and GTN show similar vasodilator effects. Formation of CP in blood after infusions of GTN or PETN were 2.0 ± 0.4 μM and 0.98 ± 0.23 μM. Pretreatment with 20 mg/kg Vit-C led to significant decreases in CP formation: 0.27 ± 0.14 μM (Vit-C plus GTN) and 0.34 ± 0.15 μM (Vit-C plus PETN).

Conclusion: *In vivo* infusions of GTN or PETN in rabbits enhance formation of superoxide radicals in the vasculature and can be detected in blood. Thus, formation of peroxynitrite (a strong oxidant) eliciting vascular dysfunction is a relevant consequence. However PETN provokes only a minimal stimulation of ROS formation. The significant effects of Vit-C on nitrate induced ROS production documented by CP formation establish Vit-C as an effective antioxidant *in vivo*.

P618 Formation of reactive oxygen species in blood during in vitro application of pentaerithrityl tetra/tri/di and mononitrate

B. Fink, H. Weise, O. Sommer, E. Bassenge. *Institute of Applied Physiology, Albert-Ludwigs University, Freiburg, Germany*

Recent studies on the development and prevention of nitrate tolerance report about the decisive role of reactive oxygen species (ROS) in the development of tolerance. The analyses of ROS formation during in vivo nitroglycerin (GTN) and pentaerithrityl tetranitrate (PETN) infusions showed a more favorable ROS during PETN than during GTN. Here ROS develop either through the interaction of PETN-induced NO release with the $O_2^{\bullet}$ radicals in the vessel lumen or during the oxidative metabolism of PETN. In order to test this hypothesis we studied ROS formation in blood following application of pentaerithirityl tetra/tri/di/ and mononitrate.

ROS formation was analyzed in blood of mongrel dogs using an electron spin resonance spectrometer and the ascorbate and thiol resistant spin trap l-hydroxy-3-carboxy-pyrrolidin (CP-H; 0.8 mM). The heparizined blood sample (1250 I.E. heparin/ml) was mixed with CP-H, deferoxamin (50 μM) and with PETN or with a PETN derivative (0.5 mM). Quantification of the formation of $O_2^{\bullet}$ $ONOO^-$ was performed through the inhibition of $ONOO^-$ formation following addition of DMSO (0.1%) to the probe.

The ROS release in blood increased significantly compared to control values from 7.5 ± 0.4 to 11.8 ± 0.3 a.U/min during PETriN and to 32.8 ± 0.6 a.U./min during PETN which was still 3fold less than during administration of GTN. An addition of PEMN and PEDN led to no significant increase in ROS formation. Furthermore an addition of 0.1% DMSO during PETN and its derivatives significantly inhibited ROS formation.

These results justify the statement that the efficacy and rate of release of NO during the metabolism of pentarithrityl tetra/tru/di and mononitrate in blood determines the rate of subsequent peroxynitrite formation. In contrast to GTN (e.g. significant formation of $O_2^{\bullet}$) this may explain the absence of tolerance during administration of PETN in vivo.

P619 Transforming growth factor-β-induced differentiation of cardiac fibroblasts to myofibroblasts is accompanied by an increase in angiotensin-converting enzyme activity

V. Petrov, R. Fagard, P. Lijnen. *Hypertension Unit, Department of Molecular and Cardiovasular Research, University of Leuven (KULeuven), Belgium*

Cardiac fibrosis is accompanied by an increase in the level of transforming growth factor β (TGF-β) and by the appearance of angiotensin converting enzyme (ACE) and myofibroblasts in the fibrotic tissue. Whether TGF-β induces ACE activity during TGF-β-induced differentiation of fibroblasts to myofibroblasts is investigated in the present study.

The effect of TGF-β on the ACE activity, the proliferation and the differentiation of cardiac fibroblasts (passage 2), obtained from male adult Wistar rats, is studied. Cells are characterised as fibroblasts or myofibroblasts by morphology, by Western blotting and immunostaining with antibodies to von Willebrand factor (endothelial cells), to desmin (vascular smooth muscle cells), to vimentin (fibroblasts) and to α-smooth muscle actin (α-SMA) (myofibroblasts). DNA synthesis is estimated by [^{3}H]thymidine incorporation and cells are counted with a hemacytometer. The assay for ACE is based on the conversion of Hippuryl-Histidyl-Leucine to Histidyl-Leucine which is quantified fluorometrically.

TGF-β (in a concentration range from 0.2 to 10.0 ng/ml) inhibits dose-dependently the proliferation of fibroblasts cultured for 7 days in its presence. At 10 ng/ml, TGF-β decreases the cell number by 65.0 ± 2.3% (n = 5, SEM) and the [^{3}H]thymidine incorporation by 95.4 ± 1.5%. The basal ACE activity in fibroblasts (13.4 ± 2.4 pmol/min per 106 cells) is inhibited by 94.4 ± 2.0% in the presence of 1 μM lisinopril. TGF-β does not induce ACE activity at concentrations less than 5 ng/ml. After 7 days, but not after 1–3 days, TGF-β at 5 and 10 ng/ml induces an increase in the ACE activity by 51.3 ± 7.4% and 82.4 ± 8.0%, respectively, as well as the appearance of α-SMA, a marker of myofibroblasts.

Our data show that TGF-β induces a change in the cell morphology and an increase in the ACE activity as well as in the level of α-SMA. We suggest that TGF-β induces the differentiation of fibroblasts to myofibroblasts which contain ACE activity.

P620 Long-term effects of pentoxifylline in patients with idiopathic dilated cardiomyopathy: One-year results

D. Skudicky, K. Sliwa, A. Bergemann, G. Candy, P. Sareli. *Cardiology Department, Baragwanath Hospital, Johannesburg, South Africa*

We recently reported a significant improvement of left ventricular (LV) function in patients with idiopathic dilated cardiomyopathy (DCMO) treated with pentoxifylline. However, if this effect is maintained at 1 year is unknown.

Methods: in a prospective, double blind, randomized, placebo controlled trial we enrolled 49 patients (mean age 52 ± 11 years, 57% males) with idiopathic DCMO. Patients were randomized to pentoxifylline 400 mg TDS or placebo. All patients received treatment with diuretics, digoxin and ACE inhibitors. Clinical, echocardiographic and radionuclide evaluation were performed at baseline (B), at 6 months (6 m) and at 1 year (1 y) after randomization.

Results: 12 patients died (9 in the placebo group ($p = 0.05$ between groups). All deaths were due to progression of heart failure. LV ejection fraction improved from 21 ± 8% at B to 35 ± 17% at 6 m and 30 ± 16% after 1 y of treatment with pentoxifylline ($p = 0.002$ B vs 6 m and $p = 0.004$ B vs 1 y. P = NS 6 m vs 1 y). No significant changes were observed in the placebo group. TNF-α and IL 6 plasma levels significantly declined with pentoxifylline (6.4 ± 5 to 2.0 ± 1 pg/ml, $p = 0.003$; and 5.4 ± 4 to 1.8 ± 1 pg/ml, 0.001 respectively). No significant reduction in the cytokine levels were noted in the placebo group.

Conclusion: treatment with pentoxifylline is associated with a sustained improvement on LV function in patients with idiopathic DCMO.

P621 Optimal chronic intravenous therapy in managing unloading therapy and improving clinical outcome in severe congestive heart failure

Soccorso Capomolla, Oreste Febo, Cristina Opasich[1], Giorgio Riccardi, Angelo Caporotondi, Andrea Mortara, Franco Cobelli. *Dept. of Cardiology "Salvatore Maugeri" Foundation Institute of Medical Care and Research, Montescano-(Pavia); [1]Dept. of Cardiology Policlinico "S Matteo" Institute of Medical Care and Research, Pavia, Italy*

Background: In patients with severe heart failure awaiting transplantation, intravenous inotropic or vasodilator drugs are frequently employed in the attempt to obtain hemodynamic control. The choice between these treatments is often based on clinical criteria. The efficacy of chronic dobutamine (DOB) or nitroprusside (NTP) infusion have not been prospectively compared.

Aims: the aim of this study was to compare the efficacy of both drugs in managing unloading therapy and improving clinical status.

Methods: 105 consecutive patients with severe heart failure (EF 19 ± 6%) who received 7 ± 3 γ/kg/min 12 h/day of DOB (35 pts) for 9.2 ± 5 days, or 0.76 ± 0.99 γ/kg/min 12 h/day NTP (70 pts) for 10.8 ± 6 days as a first-line therapy were evaluated. Hemodynamic profile, NYHA functional class, unloading management defined as Ace-inhibitor (ACE) optimization and clinical outcome defined as weaning from intravenous therapy, heart failure requiring hospitalization, cardiac death, and heart transplantation in status 1 (HTX1) were considered in two groups.

Results: hemodynamic profile and functional class at baseline were similar in both groups. Unloading therapy was significantly greater in patients receiving NTP than in those receiving DOB (ACE: 127 ± 30 vs 80 ± 46 mg $p < 0.002$). Weaning from intravenous support was significantly more frequent among patients receiving NTP (73% vs 45% $p < 0.006$). In the NTP subgroup, cardiac death due to CHF and HTX 1 occurred less than in the DOB subgroup (36% vs 88% $p < 0.0001$). Time to adverse clinical outcome from initiation of therapy was longer among patients receiving NTP (245 ± 70 vs 117 ± 93 days $p < 0.007$). The cost of daily therapy was significantly higher in patients receiving NTP ($14.4 vs $11.5 $p < 0.03$).

Conclusions: in patients with severe congestive heart failure requiring intravenous support, NTP has a greater unloading effect and clinical benefit than DOB, used as first choice therapy. These data need to be verified in a multicenter, prospective, randomized clinical trial.

P622 Early, long-term therapy with the mixed endothelin-1 receptor antagonist, bosentan, preserves left ventricular function in dogs with progressive heart failure

H.N. Sabbah, T. Mishima, M. Tanimura, G. Suzuki, V.G. Sharov, A. Todor, S. Goldstein. *Department of Medicine, Division of Cardiovascular Medicine, Henry Ford Heart and Vascular Institute, Detroit MI, USA*

We examined the effects of early, long-term monotherapy with bosentan (BOS), a mixed endothelin-1 ET_A and ET_B receptor antagonist, on the progression of LV dysfunction and remodeling in dogs with moderate heart failure (HF).

Methods: LV dysfunction (ejection fraction, EF = 30% to 40%) was produced in 14 dogs by multiple intracoronary microembolizations. Dogs were randomized to 3 months therapy with BOS (30 mg/kg Bid, n = 7) or to no therapy at all (control, CON, n = 7). The change (Δ) in cardiac index (CI), LV EF, end-systolic (ESV) and end-diastolic (EDV) volumes between pre- and post-treatment are shown in the table. Cardiomyocyte cross-sectional area (CCSA), a measure of cell hypertrophy, and LV volume fraction of interstitial fibrosis (VFIF) were determined histomorphometrically.

Results: In CON dogs, LV EF and CI decreased and LV volumes increased after 3 months while in BOS dogs, CI increased and EF, EDV, and ESV were preserved. Compared to CON, BOS treated dogs had a smaller CCSA (699 ± 107 vs 850 ± 36 μm^2, P = 0.002) and lower VFIF (10.6 ± 0.5 vs 14.3 ± 0.7%, P = 0.017).

	Control	BOS	P-value
Δ CI (l/min/m^2)	−0.4 ± 0.1	0.7 ± 0.3	0.005
Δ LV EF (%)	−6 ± 1	5 ± 2	0.001
Δ LV EDV (ml)	13 ± 6	−4 ± 2	0.020
Δ LV ESV (ml)	14 ± 5	−5 ± 1	0.003

Conclusion: In dogs with moderate HF, early, long-term therapy with BOS prevents progressive LV dysfunction and attenuates LV remodeling. The results support the use of mixed endothelin-1 receptor antagonists in the treatment of chronic HF.

P623 Multicentre, double-blind, placebo-controlled study of long-term endothelin blockade with bosentan in chronic heart failure: results of the Reach trial

M. Packer, K. Swedberg, J.J.V. McMurray, W. Kiowski, H. Krum, B. Massie, A. Caspi, A. Cohen-Solal, W. Kostuk, B. Levine, P. Rizzon, J. Soler, V. Charlon. *For the Reach-1 Investigators; Columbia U. New York NY, USA; Glasgow, UK*

Endothelin (ET) may play a role in the pathophysiology of chronic heart failure (CHF), but the long-term effects of ET blockade have not been studied. To do so, 370 patients with NYHA class IIIB–IV CHF (EF < 35%) receiving diuretics and an ACE inhibitor, were randomized (double-blind in a 2:1 ratio) to receive the ET_A + ET_B antagonist bosentan (target dose 500 mg BID) or placebo for 6 months. The primary endpoint was a clinical composite which assessed symptoms and major events. The trial was stopped due to concerns about elevations in hepatic transaminases when 47% of the pts (N = 173) had been followed for 6 mos. In the entire study population, there was no difference in efficacy between bosentan and placebo. However, in patients followed for the intended duration of the study (6 months), Bosentan significantly increased the likelihood of clinical improvement (bosentan 27%, placebo 19%) and decreased the likelihood of CHF deterioration (bosentan 27%, placebo 43%), P = 0.045. In these patients bosentan decreased the total number of hospitalizations for any reason by 41%. The benefits of bosentan increased with the duration of follow-up. Bosentan was generally well tolerated but produced asymptomatic, reversible elevations in hepatic transaminases and decreases in hematocrit. These results indicate that long-term blockade of ET_A and ET_B receptors with bosentan has the potential to decrease symptoms and favourably alter the progression of CHF.

P624 Clinical variables predicting the use of β-blockers in heart failure: the BRING-UP study

E. Balli, D. Lucci, M. Gorini, G. Fabbri, M. Scherillo, L. Tavazzi, A.P. Maggioni. *On behalf of BRING-UP Investigators, ANMCO Research Center, Florence, Italy*

BRING-UP (BetablockeRs IN patients with congestive heart failure: Guided Use in clinical Practice) is an observational study designed to guide the introduction of betablockers (BB) in the therapy of heart failure (HF) in the clinical practice of Italian cardiologists. The treatment (bisoprolol, carvedilol, metoprolol) was started according to the clinical decision of the responsible cardiologist.

Out of 2975 pts enrolled in the study, 734 (24.7%) were already on BB: these pts were not included in the analysis. 836 (28.1%) started BB therapy, while 1405 (47.2%) did not. We analyzed the baseline characteristics of the pts receiving or not BB.

NYHA IV class needing iv inotropes, hypotension, heart rate < 50 bpm and/or hypokinetic arrhythmia, respiratory insufficiency and severe peripheral vasculopathy were considered absolute contraindications to BB therapy.

At univariate analysis: (a) younger age, higher SBP and heart rate (HR), recent diagnosis of HF and a hystory of hypertension were significantly associated with a higher use of BB; (b) advanced (III-IV) NYHA class and atrial fibrillation were significantly associated with a lower use of BB; (c) gender, etiology, ejection fraction and history of diabetes did not influence BB prescription.

At adjusted analysis the only variables that resulted independently associated with BB therapy are reported in the table:

	Odds Ratio	95% CI	p
Age*	0.968	0.960–0.977	0.0001
SBP*	1.017	1.012–1.022	0.0001
HR*	1.013	1.007–1.019	0.0001
NYHA class III–IV vs I–II	0.601	0.493–0.732	0.0001

*As continuous variables.

Conclusions: In routine clinical practice cardiologists prescribe less frequently BB to patients with advanced age, low SBP, low HR and advanced NYHA class.

P625 Effects of acute administration of irbesartan on myocardial metabolism and coronary haemodynamics

G. Fedeli, C. Iacoboni, A. Di Roma, R. Badagliacca, E. Pensalfine, F. Fedele. *Cardiovasc and Respiratory Dept.; "La Sapienza" University of Rome, Italy*

The aim of this study was to consider the effect of Ibesartan, a new Angiotensin II Receptor Antagonist, on coronary haemodynamics and myocardial metabolism, in order to clarify the mechamism underlying the beneficial effects on cardiovascular performance. We have studied eleven patients with hypertensive cardiomyopathy, without lesions of the coronary vessels. All patients underwent cardiac catheterization and measurements were made at rest and two hours after oral administration of 150 mg Ibesartan. We have calculated the following parameters: mean sistemic arterial pressure (MSAP), mean pulmonary arterial pressure (MPAP), systemic vascular resistance (SVR), pulmonary vascular resistance (PVR), anterior coronary resistances (ACR), coronary flow (CF) (determined by Doppler flow wire), and myocardial oxygen consumption (by Double Product) (DP).

Results:

Pre-Irbesartan

	MSAP (mmHg)	MPAP (mmHg)	SVR (dynes cm^{-5})	PVR (dynes cm^{-5})	ACR (mmHg) min ml^{-1})	CF (ml/min)	DP
Mean value	93.18	13.45	1321.64	197.64	40.84	210.15	9847.73

Our data indicate the effectiveness of Ibesartan in improving coronary haemodynamics, probabily due to the activation of receptors AT2 and to the inhibition of simpatic nervous system, independently from prostaglandin action.

P626 Effects of losartan on e-NOS and i-NOS mRNA expression and myocytes apoptosis in isolated working rat hearts

P. Di Napoli, R. Spina[1], L. Stuppia[2], A.A. Taccardi[1], A. Maggi[1], G. Contegiacomo[1], G. Palka[2], A. Barsotti[1]. *Cardiology Dept, Casa Di Cura Villa Pini, Chieti; [1]Cardiology Dept, University of Chieti, Chieti [2]Med. Genetic, Inst. of Cytomorphology, University of Chieti, Chieti, Italy*

Angiotensin II produced by endothelium through the activity of ACE plays an important role in ischemia-reperfusion (I/R) injury. Recent studies suggest that Angiotensin II-receptor antagonist may induce a cardioprotective effect against I/R damage. Apoptotic cell death might be ab integral part of the pathogenesis of cardiac dysfunction related to I/R.

The aim of our study was to evaluate in isolated working rat hearst the effects of Losartam (L) on post-ischemic endothelial dysfunction, Nitric Oxide Synthase (NOS) mRNA expression (inducible, i-NOS; endothelial, e-NOS) and myocytes apoptosis.Hearts were subdivided in 3 groups: A) control; B) ischemia and reperfusion; C)L 1 μM. hearts submitted to 15 min. ischemia and 190 min. reperfusion. The L was added to the perfusion buffer at the beginning of experiment. Hemodynamic parameters,CPK release, morphological alterations and endothelial permeability (FITC-albumin extravation) were valuad; e-NOS and i-NOS mRNA were valued by multiplex RT-PCR, and results were expressed as Glyceraldheyde-3-Phosphate Dehydrogenase (G-3PDH)/e-NOS and G-3PDH/i-NOS ratio. Detection of apoptosis was based on electron microscopy and in situ end-labeling assay (TUNEL).

In C group we detected a significant reduction of functional deterioration and coronary endothelium post-ischemic hyperpermeability and ultrastructural damage; a significant decrease of G-3PDH /e-NOS ratio also occurred respect to B group. Furthemore, in C group the electrophoretic pattern of apoptotic DNA bands was observed and confirmed by TUNEL; i-NOS expression was detected only in B group.

In conclusion our data evidenced that L may acutely induce a coronary endothelium protection against reperfusion injury by means of an e-NOS mRNA over-expression; it has no effect on myocytic apoptosis.

P627 Impact of neurohormonal antagonists on left ventricular remodelling: comparison of carvedilol versus captopril in chronic heart failure

R.S. Khattar[1], R. Senior[1], R. van der Does[2], A. Lahiri[1]. *[1]Northwick Park Hospital, Harrow, UK; [2]IST GmbH, Mannheim, Germany*

The independent effects of carvedilol (CAR) versus ACE-inhibitors on ventricular (LV) remodelling in chronic heart failure (CHF) are not known. We investigated 57 patients with CHF (ischaemic or non-ischaemic, NYHA II–III, EF < 40%) randomized double-blind to treatment with CAR or captopril (CAP) at maximum doses of 25 mg b.d. for 12 weeks, followed by 12 weeks of combined treatment. Serial echocardiography was performed to assess LV mass, end-systolic volume (ESV), sphericity index (SI) and systolic wall thickening index (SWTI). Medians for baseline values and changes with monotherapy versus baseline and combination therapy versus monotherapy are given below:

	Baseline		Monotherapy		Combination Therapy	
	CAR	CAP	CAR	CAP	CAR+ CAP	CAP+ CAR
LV ESV (ml)	117	100	$-10^{\dagger***}$	0	-7^{***}	-8^{***}
LV mass (g)	291	219	−20	-7.5^{*}	-16^{***}	-11^{***}
SI	1.4	1.4	$+0.04^{*}$	$+0.04^{***}$	$+0.06^{***}$	$+0.08^{***}$
SWTI	2.7	2.8	-0.25^{***}	-0.16^{***}	-0.08^{**}	$-0.25^{\dagger***}$

comparision between groups $^{\dagger}p \leq 0.05$; within groups: $^{*}p \leq 0.05$, $^{**}p \leq 0.01$, $^{***}p \leq 0.001$

Each drug produced favourable changes in LV mass, SI and SWTI with further improvements on combined treatment. These findings suggest synergistic effect of CAR and ACE-inhibitors on LV remodelling in CHF.

ATRIAL FLUTTER

P628 A constant interval between the stimulus artifact and the local atrial electrogram: a new electrophysiological technique for radiofrequency ablation of the cavotricuspid isthmus

J. Villacastin, J. Almendral, A. Arenal, N.P. Castellanos, M. Ortiz, S. Gonzalez, J. García, E.P. David, J.L. Delcan. *Hospital G Marañon, Madrid, Spain*

Background: Previous studies performed in patients with atrial flutter (AF1) have shown a clock-wise homogeneous activation front (with conduction velocities lower than 1 m/s) through the cavotricuspid isthmus (CTI), during pacing from the coronary sinus (CS) in sinus rhythm. Thus, a constant interval stimulus artifact-local atrial electrogram (S-A) recorded with the ablation catheter (Abl C) could be useful to create a line of bi-directional block along the CTI.

Patients and Methods: In 17 consecutive patients (P) who underwent RF ablation of typical AF1 in sinus rhythm, radiofrequency (RF) linear lesions were made sequentially (with point-by-point ablation) during pacing at 500 ms from the CS. The Abl C (8-mm-tip) was positioned at the tricuspid annulus (TA) recording a bipolar electrogram with an A/V ratio $\leq$ 0.1 and a S-A between 30 and 80 ms at a paper speed of 200 mm/s. After each 30 s RF application, the Abl C was withdrawn 5 mm (in right anterior oblique view) toward the right atrium, trying to maintain a constant S-A (variation $\leq$ 10 ms). The presence of bi-directional block across the CTI was confirmed by comparing the timing and sequence of 10 standard bipolar electrograms of a catheter positioned along the TA.

Results: In all patients a constant S-A interval (mean 46 $\pm$ 15 ms) could be maintained during the RF applications. In 11 P bidirectional CTI block was created with the first RF line (mean of RF pulses 8 $\pm$ 6). Three P required 2 RF lines and 2 P 4 RF lines. In one P it was not possible to block the CTI. A good correlation was observed between the lengthening or shortening of the S-A interval and the lateral or septal displacement of the Abl C in the left anterior oblique view.

Conclusion: A constant S-A interval seems to be an useful electrophysiological tool to guide linear RF ablation of the CTI.

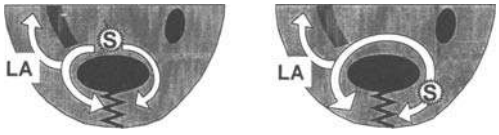
P629 Terminal crest permeability can prevent evaluation of isthmus block after flutter ablation

A. Pastor, A. Núñez, R. Tavernier, M. Montero, C. Kallmeyer, A. Karoni, M. Ramos, F.G. Cosío. *Servicio Cardiología, Hospital Universitario de Getafe, Madrid, Spain*

Background: Descending anterior right atrial (RA) activation pacing the low septum suggests cavo-tricuspid isthmus CTI block after typical flutter (FL) ablation.

Objective: To report 7 cases with anterior RA activation suggestive of CTI conduction, probably due to conduction across terminal crest (TC).

Methods: Anterior RA activation was compared pacing low septal and low posterior RA. Conduction through TC should produce a stimulus (S) to low anterior (LA) RA interval shorter pacing posterior RA (fig left) than low septal RA (fig right). The opposite should occur with CTI conduction.



Results: In 6 cases with anterior RA activation compatible with collision pacing the posterior RA produced the same pattern with shorter S-LARA than pacing the septal isthmus. In 2 there was apparent rate-dependent CTI block, that according to these intervals was rate-dependent TC block. In a 7th case with lateral wall scar, ablation between scar and inferior caval vein changed anterior RA activation from apparent collision to descending.

Conclusions: Conduction through TC can prevent detection of CTI block. Shorter S-LA RA intervals pacing posterior RA than pacing septal RA should suggest conduction through posterior RA-TC.

P630 Effect of restored sinus rhythm on right atrial status following radiofrequency catheter ablation of chronic atrial flutter

J.A. Cabrera, A. Medina, F. Wanguemert, E. Gross, J. Grillo, D. Sánchez-Quintana, S.Y. Ho, R.H. Anderson. *Pino Hospital, Las Palmas, Spain; National Heart and Lung Institute, London, UK*

Restoration of normal sinus rhythm after RF-ablation (RFA) in patients with chronic atrial flutter (AF) and cardiomyopathy has been shown to result in substantially improved left ventricular function. However, the effect of restored sinus rhythm on right atrial (RA) size and function has not been examined.

Methods: Twenty patients (59 ± 15 years old; 12 men) undergoing successful RFA of common AF underwent right atrial angiography to evaluate the size and function of the right atrium in sinus rhythm 30 minutes after the ablation procedure and at reevaluation 10 ± 2 months (range: 6–12 months) post-ablation follow-up. For comparison, 30 normal control subjects were also studied.

The linear diameter of the right atrium was measured in right anterior oblique projection and the RA function was assessed by estimating the contraction fraction measuring the end-diastolic and end-systolic areas of the right atrium by digital planimetry.

Results: The mean length of the RA diameter was larger in patients with common AF than in the control group ($p < 0.001$) (table). There were no significant differences in the dimensions of the right atrium in patients with AF measured in sinus rhythm post-ablation and at reevaluation 6–12 months later. Atrial contractility, however, improved significantly, as shown by differences in the contraction fraction obtained in both periods ($p < 0.001$). Additionally, the mean contraction fraction of the right atrium at reevaluation in patients with previous AF was similar to that previously obtained in the control group.

	Control group	AF post-RFA	AF at follow-up
RA dimensions	48.5 ± 6 mm	57.6 ± 9 mm	57.1 ± 8 mm
RA contractility	0.51 ± 0.1	0.23 ± 0.06	0.53 ± 0.1

Conclusions: 1. After ablation of patients with chronic AF there is a recovery time to achieve normal contractility of the right atrium. 2. The persistence of an enlarged right atrium after the ablation, but with normal contractility, suggests a previously dilated right atrium which may predispose to the development of atrial flutter.

P631 Incidence and characteristics of new developed atrial flutter and monomorphyc atrial tachycardia after lung transplantation

M.T. Lazaro, J.L. Merino[1], I.F. Lozano, M.J. Ferreiro, M.C. Carreño, A. Varela, J. Estada. *Clinica Puerta de Hierro, Madrid; [1]Lab. Electrofisiologia Cardiaca, Hospital Universitario "La Paz", Madrid, Spain*

A high incidence of "incisional" atrial reentrant tachycardia or flutter has been reported after the creation or implantation of atrial suture lines and patches during corrective surgery of congenital heart disease. Similarly, atrial anastomosis between the receptor left atrium and one or two donor pairs of ipsilateral pulmonary veins could provide a potential substrate for intra-atrial reentry after lung transplantation (LTx).

Methods: The study included 77 consecutive adult patients with LTx (30 bilateral LTx, 47 unilateral LTx). Patients were monitored during the first postoperative with continuous single lead ECG. A conventional 12 lead ECG was performed whenever a cardiac rhythm disorder was suspected. None of the patients had history of atrial arrhythmias prior to LTx and none were on antiarrhythmic drugs.

Results: 9 patients (38 ± 18 y, 7 male, 6 bilateral LTx, 3 unilateral LTx) developed atrial monomorphic arrhythmias: 7 developed non-common atrial flutter and 2 atrial tachycardia (mean cycle lenght 232 ± 66 ms). None had atrial arrhythmias in relation to graft rejection but one. Time between LTx and arrhythmia onset was 9.8 ± 6.3 days (range 1–18). All patients had the tachycardia controlled with amiodarone, which was discontinued at hospital discharge. At follow-up (8 ± 8.7 months), there were no arrhythmia recurrences.

Conclusions: 1) A high incidence of regular monomorphic atrial arrhythmias is seen in the early stage after LTx. 2) The mechanism of these arrhythmias is uncertain. However, similarly to that described after congenital heart disease surgery, left atrial suture lines could act as conduction barriers around which a circular reentry circuit can occur.

P632 Presence of preferable activation patterns during atrial fibrillation as assessed by three-dimensional mapping of the conduction velocity vectors

L. Gepstein, G. Hayam, T. Wolf, U. Dror, A. Zaretzky, R. Shofty, S.A. Ben-Haim. *Faculty of Medicine, Technion, Haifa, Israel*

Atrial fibrillation (AF) is believed to result from multiple reentrant wavefronts that wander randomly in the atria. We tested the hypothesis that atrial activations during AF are not completely random, by examining the possible presence of preferred activation patterns during AF in a chronically paced goat model.

Methods and Results: A new method, which utilizes a custom-built tripole locatable catheter, was developed to measure the atrial conduction velocity (CV) vector. The location and local activation time of each electrode (derived from the 3 recorded unipolar electrograms) is used to calculate the CV vector of each atrial activation. By recording 30 seconds of AF activity at each endocardial site, the changes in the activation direction can be analyzed by the construction of detailed CV vector direction histograms (describing the number of atrial activations for each vector angle). Four different types of histograms were noted: endocardial sites with no preferable activation direction (type 1), sites with one preferable activation direction (type 2), and sites with two preferable activation patterns positioned 180° apart with equal number of activation (type 3) or one direction being more dominant (type 4). Significant variations in the regional distribution of the different types of the CV angle histograms were found (table).

Distribution of CV Angle Histograms

	IVC	SVC	Anterolateral	Isthmus	Posterior	Septum
Type 1	0	0	6	9	58	73
Type 2	88	60	58	38	13	9
Type 3	6	13	14	15	21	9
Type 4	6	27	22	38	8	9

Conclusions: (1) Significant regional differences are present in the RA CV directional histograms. (2) The septum and posterior walls are associated with no preferable activation dirrection, indicating the presence of multiple wavefronts propagating in all directions. The tube like areas (SVC, IVC and Isthmus) and the anterolateral free wall are characterized by one or two preferable activation directions, indicating the dominance of anatomical reentry.(3) Assessment of regional differences in the activation patterns of AF may become a useful tool in evaluating the underlying mechanisms of AF and may aid in designing therapeutic strategies.

P633 Intravenous sotalol in the treatment of atrial flutter: a randomised, double-blind, placebo-controlled study

F. Doni, E. Staffiere, M. Manfredi. *Cardiology Dept, Policlinico San Pietro, Ponte San Pietro, Italy*

Introduction: A prospective, randomised, double-blind, placebo controlled study was conducted to investigate the efficacy and tolerability of intravenous sotalol for the conversion of atrial flutter (AF) to sinus rhythm.

Methods: Of 70 consecutive patients (44 men, mean age 59 ± 10 years) with AF lasting from 2 hours to 28 days, 35 were randomised to receive a single intravenous dose of sotalol (1.5 mg/kg over 10 minutes) and 35 to receive an identical amount of saline solution. Baseline clinical characteristics were similar in the two groups.

Results: The number of patients that converted to sinus rhythm was significantly higher in the sotalol group than in the placebo group (17/35 vs 2/35, 49% vs 6%; $p = 0.00005$). Mean time to AF termination after initiation of sotalol was 34 minutes. As a consequence of sotalol prolonging effect on the refractory period, a rapid (within the time of infusion) reduction of arrhythmia cycle length has been observed. The resulting lower ventricular rate (from 153 ± 5 to 116 ± 11 beats per minute – $p < 0.01$) rendered the arrhythmia better tolerated during the time preceding the restoration of sinus rhythm. 18 episodes of mild, transient hypotension occurred in 11 patients treated with sotalol versus 7 treated with placebo. No severe side effects necessitating termination of drug administration were observed.

Conclusion: The intravenous administration of sotalol appears to be safe and effective for acute termination of atrial flutter. The reduction of ventricular rate induced by the drug may offer clinical benefits even in those patients in whom sinus rhythm is not obtained.

P634 IC drug induced atrial flutter during treatment of atrial fibrillation: usefulness of a combined pharmacological and ablative therapy

A. Bonso, S. Themistoclakis, G. Gasparini, A. Perkan, F. Giada, A. Raviele.
Cardiology Division, Umberto I Hospital, Mestre-Venice, Italy

It is well known that patients (pts) chronically treated with IC antiarrhythmic drugs for recurrent atrial fibrillation (AF) can experience conversion of AF to typical atrial flutter (AFl) during the follow-up. In these cases the radiofrequency catheter ablation (RF) of the inferior vena cava-tricuspid valve (IVC-TV) isthmus could theorically avoid further arrhythmic recurrences of both AF and AFl. Aim of this study was to verify the clinical efficacy of this therapeutical strategy.

Methods and Results: We studied 9 pts (mean age 58 ± 11 yrs) with frequently recurrent episodes of AF alone, without documented episodes of AFl, who were treated with IC antiarrhythmic drugs (flecainide in 6 pts and propafenone in 3 pts) to prevent AF recurrences and who experienced only episodes of typical AFl after the onset of treatment (mean 5 ± 1.5 episodes per pt during a mean period of 12 ± 0.3 months). All 9 pts underwent successful RF of AFl with the achievement of bidirectional isthmus conduction block. After the ablation procedure no pt was treated with any antiarrhythmic drug until the first arrhythmic recurrence. At least one episode of AF occurred in all pts within 1 month. After the AF recurrence IC antiarrhythmic treatment was restored at the same dosage as before RF. During a mean follow-up period of 14 ± 9 months only one pt (11%) had one recurrence of AF 7 days after the onset of therapy and no pt experienced further recurrences of AFl.

Conclusion: These results suggest that combined therapy with RF catheter ablation of IVC-TV isthmus and IC antiarrhythmic drugs may be useful in preventing further arrhythmic recurrences in AF pts who experience episodes of typical AFl during chronic treatment with flecainide or propafenone. Randomized controlled studies are needed to confirm these preliminary data.

P635 Persistent atrial flutter in patients treated for atrial fibrillation with amiodarone and propafenone: risk prediction and radiofrequency ablation

C.T. Tai, C.E. Chiang, S.H. Lee, Y.J. Chen, W.C. Yu, A.N. Feng, Y.A. Ding, M.S. Chang, S.A. Chen. *Division of Cardiology, National Yang-Ming University, School of Medicine, Veterans General Hospital-Taipei, Taiwan, China*

Antiarrhythmic drugs (AAD) have been reported to promote the conversion of atrial fibrillation (AF) to atrial flutter (AFL) in patients (pts) with paroxysmal AF. The purpose of this study was to investigate the electrophysiologic characteristics, radiofrequency catheter ablation (RFCA) and determinants of persistent (>24 hours) AFL in 136 pts treated for AF with amiodarone and propafenone.

Methods: A 20-pole halo catheter was placed around the tricuspid annulus to map the activation sequence of AFL. Entrainment of the tachycardia was attempted by pacing from the low right atrial isthmus. The clinical variables including sex, age, presence of structural heart disease, presence of atrial enlargement, left ventricular ejection fraction, and maximal sinus P wave duration were analyzed in relation to the occurrence of persistent AFL.

Results: Fifteen pts (11%, mean age 65.5 ± 12.3 years) were identified to have subsequent development of persistent AFL during AAD treatment. The mean interval between the beginning of drug treatment and the onset of AFL was 5.0 ± 5.5 months. Eleven pts had counterclockwise typical AFL, and 4 had clockwise typical AFL. All 15 pts underwent successful RFCA with creation of complete bidirectional isthmus conduction block. After a mean follow-up of 12.3 ± 4.2 months, 14 (93%) of 15 pts who underwent successful RFCA and continued on AAD have remained in sinus rhythm. Univariate analysis of clinical variables demonstrated that only the atrial enlargement was significantly related to occurrence of persistent AFL.

Conclusion: In pts with AF, persistent typical AFL might occur during AAD treatment, and atrial enlargement was a risk factor for the development of such arrhythmia. RFCA and continuation of pharmacological therapy offered a safe and effective means of achieving and maintaining sinus rhythm.

P636 Initial experience with a new non-contact mapping system for catheter ablation of atrial flutter

Karlheinz Seidl, Axel Drögemüller, Harald Schwacke, Jochen Senges.
Herzzentrum Ludwigshafen, Germany Cardiology

Catheter ablation of typical atrial flutter (AF) was performed in 13 patients (pts) using a non-contact endocardial mapping system. This new non-contact multielectrode array (MEA) enables reconstruction of 3360 electrograms using inverse solution mathematics. The MEA is a 64 wire braid woven around a 8 ml ballon, mounted on a 9F catheter. The reconstructed electrograms are superimposed onto a computer simulated 3 dimensional model of the endocardium. Using the MEA a replica of the right atrium was created enabling us to design the ablation lines and to check their completeness. In addition, conventional mapping with a "halo" catheter was performed. Aim of this study was to report the inital experience with the MEA for mapping and catheter ablation of atrial flutter.

Results: 8 pts presented with a pattern of typical, counter-clockwise AF during mapping with the Halo. However, the MEA showed a focal origin in 1 of these 8 patients in the posteroseptal region. In 2 pts with clockwise AF determined by a Halo-catheter, the MEA identified a focal activation originating from the crista terminalis. 3 pts had atypical AF. In 1 pt a focus was found at the crista terminalis, in 2 pts conventional mapping showed left atrial origin. MEA identifies the entrant point into the right atrium at the Bachmann bundle and ostium of the coronary sinus. Successful ablation was performed in all 11 AF originating in the right atrium. During ablation of typical AF, MEA was helpful to identify activation gaps in the isthmus region. The ablation catheter was navigated to the site of the activation gap and ablation was performed until MEA showed complete line of block.

Conclusions: 1. The MEA is helpful to identify different mechanism of AF, especially focal AF mimicking typical AF. 2 The MEA identifies activation gaps at the isthmus site more precisely than conventional mapping techniques.

P637 Is it worth to use radiofrequency catheter ablation as the first treatment of atrial flutter for patients with dilated cardiomyopathy?

A. Lagrange, P. Lagrange, S. Boveda[1], E. Espaliat, J.P. Penot, J. Bensaid, P. Blanc. [1]*University hospitals, Limoges-Toulouse, France*

Clinical cases of reversible dilated cardiomyopathy (DCM) with atrial flutter (AF) have been reported after conversion to sinus rhythm. Previous reports showed that recurrent AF is more frequent after overdrive pacing, cardioversion or antiarrhythmic drugs than after radiofrequency catheter ablation (RFCA): >50% versus 10 to 20%. The aim of this study was to evaluate the left ventricular end diastolic diameters (LVDD) and function (Shortening fraction: SF) by echocardiography after successful RFCA.

Methods: We studied 30 patients (pts) with DCM and chronic AF. The DCM was idiopathic (n = 15) or secondary (n = 15, 10 ischemic, 4 valvular diseases and 1 hypertrophic). There was no significant difference between the 2 groups. Pts were 63 ± 11 years old, 97% male, with 16 months duration of AF; and a ventricular rate of 112/min. A first echocardiography was performed 48 hours after ablation and a second later during follow up (FU): mean FU = 11.4 ± 6.6 months.

Results:

	LVDD (mm)	SF (%)	LVDD FU (mm)	SF FU (%)
Idiopathic DCM	62.6 ± 6*	23 ± 8*	56.1 ± 3*	30 ± 4*
Secondary DCM	62.1 ± 5	30 ± 8	58.9 ± 5	31 ± 7

Student test: *: $p < 0.05$

In the group of idiopathic DCM, we observed a significative improvement of LVDD and SF during the FU but not in the group of secondary DCM. In the idiopathic DCM group, a total recovery of left ventricular parameters was observed in 53% of cases and for 80% of pts LVDD was normalized.

In the 2 groups, NYHA cardiac heart failure class improved from 2.5 to 1.1.

Conclusions: 1) The only predictive factor of normalization of the left ventricular function is the diagnosis of idiopathic DCM 2) AF seems to be a real and frequent cause of DCM: "tachycardiomyopathy" 3) When idiopathic DCM with AF is presumed an aggressive therapy with RFCA should be considered early.

P638 Isoproterenol to evaluate resumption of conduction following right atrial isthmus ablation in type I atrial flutter

A. Nabar, L.M. Rodriguez[1], C. Timmermans[1], J.L.R.M. Smeets[1], H.J.J. Wellens[1]. *Cardiology Dept., Academic Hospital Maastricht, Maastricht; [1]Cardiology Dept., Academic Hospital Maastricht, Maastricht, Netherlands*

Following radiofrequency (RF) ablation of atrial flutter (AFL) the demonstration of bidirectional isthmus conduction (BIC) block is considered the hallmark of a successful procedure. Purpose of our study was to test the persistence of BIC block following isoproterenol administration and to evaluate the importance of this finding on AFL recurrences.

Methods: RF ablation of AFL was performed in 44 consecutive pts with type I AFL by a linear ablation of the posterior (n = 29 pts), septal (n = 4 pts) or both right atrial (RA) isthmi (n = 11 pts). Procedural endpoint was complete BIC block and noninducibility of AFL. In case of noninducibility and apparent BIC block the pacing protocol was repeated under isoproterenol infusion (1–3 mcg/min).

Results: Reversal of apparent BIC block occurred in 7/44 (15.9%) pts. Six pts had bidirectional and 1 pt unidirectional resumption of isthmus conduction. Counterclockwise AFL could be reinduced in 4 of these pts. 2–24 (median 4) additional RF applications were required to acheive a permanent BIC block. At a mean follow-up of 7.3 ± 7.6 (2–31) months 2/44 (4.5%) pts had AFL recurrences.

Conclusions: Partial linear RF ablation could possibly aggravate the pre-existing nonuniform anisotropic conduction in the RA isthmus resulting in profound conduction slowing and apparent BIC block. Isoproterenol can unmask apparent BIC block thus providing an opportunity to assess the possibility of reversal of BIC block and completeness of isthmus ablation during the same procedure. The low incidence (4.5%) of AFL recurrences at follow-up suggests that noninducibility and BIC block under isoproterenol infusion may be a better endpoint for successful AFL ablation.

P639 Electrophysiology of "class IC atrial flutter"

A. Nabar, L.M. Rodriguez[1], C. Timmermans[1], H.J.J. Wellens[1]. *Cardiology Dept., Academic Hospital Maastricht, Maastricht; [1]Cardiology Dept., Academic Hospital Maastricht, Maastricht, Netherlands*

A combination of class IC antiarrhythmic drug [AAD] therapy and right atrial isthmus [RAI] ablation has been effective in a subset of pts with recurrent atrial fibrillation [AF] who develop atrial flutter [AFL] on class IC AADs, the "class IC AFL".

Methods: Twenty-three pts (54 ± 12 years, 18 males) with recurrent AF who developed a "class IC AFL" underwent an electrophysiology study and linear RAI ablation. AFL induction was not attempted in 8 pts and 22 patterns of AFL (262 ± 36 ms) were documneted in the remaining 15 pts. Ablation was performed during AFL (n = 7), coronary sinus [CS] pacing (n = 12) or both (n = 4).

Results: The RAI conduction was slower in antegrade (104 ± 32 ms) than in retrograde direction (75 ± 34 ms) direction. Ten AFLs (46%) were incessant. In the remaining 12 cases AFL was initiated following spontaneous transition from ongoing AF (n = 3), programmed atrial stimulation (n = 5), catheter induced atrial premature beats (n = 1), isoproterenol infusion (n = 2) and immediately after external cardioversion (n = 1). 20/22 AFLs were sustained and predominantly counterclockwise (CCW) (n = 18, 82%). The available CS recordings (17/22 pts) suggested a AFL (n = 16) most commonly, while a AF in only 1 instance. Inadvertantly induced sustained AF (n = 12) was "organized" along the crista terminalis, cranio-caudally, during 6/12 patterns. Sinus rhythm was restored by external/internal cardioversion (n = 8), flecainide (n = 1) or overpacing (n = 1). Isthmus dependence was suggested by termination of AFL in the RAI or near CS (10/24, 42%) and noninducibility of AFL following RAI ablation (21 pts, 91%). AFL persisted despite ablating both the RAI in 2 pts.

Conclusions: "Class IC AFL" is predominantly CCW, possibly based on slow RAI conduction antegradely. Most "class IC AFL" circuits seem to be RAI dependent. Sustained AF may be frequently complicate the ablation procedure.

P640 Surface ECG characteristics and endocardial activation sequence in patients with counterclockwise and clockwise atrial flutter

G. Ndrepepa, B. Zrenner, M. Schneider, M. Karch, I. Deisenhofer, C. Schmitt. *Department of Cardiology, Deutsches Herzzentrum München, Munich, Germany*

Due to the lack of high resolution mapping systems, the relations between activation patterns within the human atria and surface ECG morphology in patients with atrial flutter (AFl) have never been satisfactorily defined.

In 41 patients with AFl, (mean age 62 ± 12 years), a 64-elecrode basket catheter was deployed in the right atrium (RA). Out of 64 electrodes, 56 bipolar electrograms are derived. A decapolar catheter was inserted within coronary sinus (CS) to record from the left atrium (LA). Temporal relations between endocardial and surface ECG activity, were determined with the use of electronic calipers.

Results: In counterclockwise (Ccw) AFl, (32 patients) the impulse conduction through the lateral wall produced the upstroke component in inferior leads and positive deflection in V1. The impulse conduction through isthmus coincided with the plateau in inferior leads, which lasted until the beginning of activation in low septum area. Plateau duration (121 ± 27 ms) correlated strongly with isthmus conduction time(117 ± 23 ms), (r = 0.93). Septal and LA conduction accounted for the negative component in lead I, inferior leads and V6. In Ccw AFl, the spread of impulse in CS electrograms was invariably from proximal to distal.

In clockwise (Cw) AFl, (11 episodes) the impulse propagation through septum and posterior wall produced the first positive component in inferior ECG leads. The impulse propagation through the LA produced the second positive deflection. The distance between two deflections (60 ± 18 ms) correlated strongly with interatrial conduction time (57 ± 19 ms), (r = 0.83). Interatrial conduction interval was prolonged during AFl as compared to sinus rhythm (60 ± 18 ms vs 43 ± 13 ms, p = 0.04). The impulse spreading through lateral wall of RA produced the negative component in inferior leads. Contribution of impulse conduction through the isthmus was hidden by ongoing impulse propagation in the LA. The CS activation patterns were proximal-to-distal, simultaneous or undetermined.

Conclusions: 1) Impulse conduction through lateral and septal walls of RA and isthmus conduction time are major determinants of RA contribution to ECG morphology, 2) Sequential use of lower or upper interatrial connections, determines contribution of LA in Ccw or Cw episodes of AFl, 3)Polarity of the F wave in an ECG derivation is determined by a resultant of opposing activities generated in the lateral wall of RA and the LA.

P641 Intercaval block in atrial flutter: is there a physiologic basis?

Wolfgang Schoels, Ruediger Becker, Reinhard Klinkott, Kirsten Freigang, Alexander Bauer, Julia Senges, Frederik Voss. *Department of Cardiology, University of Heidelberg, Germany*

Typical atrial flutter in dogs is due to reentry around the caval veins and a line of functional conduction block (CB) in between. The interindividual reproducibility of this activation pattern suggests a physiologic basis for the intercaval (IC) CB. In 6 dogs, a high density patch electrode (7 × 13 bipolar electrodes, spacing 1.5 mm) was placed in the IC region, perpendicular to the IC axis. Using a computerized mapping system, epicardial activation maps were constructed during pacing (cycle-length 200 ms) from 2 different sites, eliciting a wavefront parallel and perpendicular to the IC axis, respectively. Local refractory periods (ERP) were determined at 13 adjacent electrode sites along the center row of the patch (extrastimulus technique).

Results: Local ERPs did not show any systematic pattern, but seemingly random de- and increases instead. Mean ERP was 102 ± 26 ms. The maximum local ERP gradient reached 30 ms, the mean local gradient was 10.3 ± 4.6 ms. Activation maps revealed marked anisotropic conduction patterns, with fast conduction parallel and slow conduction perpendicular to the IC axis in the crista terminalis (CT) region, as opposed to slow conduction parallel (0.5 ± 0.1 m/s) and fast conduction perpendicular (1.5 ± 0.6 m/s) to the IC axis in the pectinate muscle (PM) region ($p < 0.05$).

Conclusions: Dispersion of ERP is not likely to facilitate IC block. The location of the CT and of IC blocks suggests a causal relation, but conduction properties of the CT do not. The PMs, however, exhibit fast conduction and a reduced safety factor for propagation perpendicular to the IC axis. Thus, insertion sites of the PMs into the CT might be the crucial link providing a physiological basis for IC block.

P642 Electrocardiographic patterns of flutter wave in "Class IC atrial flutter"

A. Nabar, L.M. Rodriguez[1], C. Timmermans[1], H.J.J. Wellens[1]. *Cardiology Dept., Academic Hospital Maastricht, Maastricht; [1]Cardiology Dept., Academic Hospital Maastricht, Maastricht, Netherlands*

Recent reports suggest a clinical benefit following right atrial [RA] isthmus ablation in pts who experience conversion of atrial fibrillation [AF] to atrial flutter [AFL] during antiarrhythmic drug [AAD] therapy. Our aim was to study the electrocardiographic morphology of a new AFL developing after class IC AAD therapy in pts with recurrent AF, so called "Class IC AFL".

Methods: Thirty recordings of "Class IC AFL" observed in 23 consecutive pts (mean age 54 ± 12 years, 18 males) during a clinical episode (n = 8) or electrophysiological study (n = 22) were analyzed. All pts developed their AFL (paroxysmal, 12 pts; incessant 12 pts) while on class IC AADs (propafenone, 12 pts; flecainide, 11 pts) for recurrent episodes of AF. Most of the pts (96%) did not have significant structural heart disease. The mean left atrial size was 4.6 ± 0.4 cm.

Results: The mean AFL cycle length was 262 ± 32 (190–320) ms. The flutter wave (FW) polarity in the inferior leads (II,III,aVF) was: negative and angled (n = 4), negative and rounded (n = 8), positive and rounded (n = 9), flat (n = 1) or undetermined (n = 1). In lead V1 the polarity of FW was: positive (n = 19), negative (n = 8), flat (n = 1) or undetermined (n = 2). The majority of AFL patterns (n = 27, 90%) had an isoelectric interval between two consecutive FWs. Atrioventricular response was 2:1 (n = 21) or >2:1 (n = 9). Importantly, none of the AFL patterns had the combination; "saw-tooth" pattern in inferior leads, a positive or negative FW in lead V1 and no isoelectric interval between FWs, as found in "common AFL".

Conclusions: Electrocardiographically, "Class IC AFL" is pleomorphic and not entirely identical to the "common AFL". The pleomorphism of FW could be based on slow intra-atrial conduction with detours of the macro-reentrant circuit when propagating at non-isthmic atrial sites. Electrocardiographic FW patterns may have implications for proper selection and results of ablation therapy.

P643 P on T ectopics predict the occurrence of atrial fibrillation after ablation of typical flutter

M. Hocini, D.C. Shah, P. Jaïs, S. Garrigue, M. Haïssaguerre, J. Clémenty. *Hôpital Cardiologique du Haut-Lévêque, 33604 Bordeaux-Pessac, France*

Background: Most patients with pulmonary vein ectopy initiating atrial fibrillation (AF) exhibit a P on T pattern during ectopy. We investigated the pronostic value of such ectopics in patients (pts) during the first 24 hours. after undergoing ablation of typical atrial flutter (Afl).

Methods: 53 pts (9 female, 44 male), mean age: 61 ± 2 were studied after ablation of typical Afl in the cavo-tricuspid isthmus. 22 pts had structural heart disease but only 1 had an ejection fraction < 50%. 27 had previously documented AF. After ablation, each patient underwent 24 hr holter monitoring and remained under telemetric surveillance for the 5 day duration of their hospital stay. The occcurence and frequency of P on T ectopy (a coupling interval of ≤500 ms) as well as AF was documented.

Results: Of the 17 pts who developed AF after flutter ablation; 5 did so on the first day after the procedure and the remaining later. The only significant predictive factors of post ablation AF were the presence of P on T ectopy and a previous history of AF (Table). A previous history of AF did not significantly correlate with the occurrence of post procedure P on T ectopy.

	AF post = 17	No AF = 36
P on T present*	15	13
no ectopy	2	23
History of AF†	13	14
No prev AF	4	22

*p = 0.0004, †p = 0.017

Conclusions: Most patients who exhibit a P on T pattern of ectopy after ablation of typical Afl or have a previous history of AF have a high risk of developing subsequent AF. This may indicate that the elimination of stable arrhythmia such as flutter permits a common trigger (P on T ectopy) to induce atrial fibrillation.

P644 Cavo-tricuspid isthmus width in relation to the radiofrequency ablation of the common atrial flutter

Thierry Chalvidan, Philippe Heno, Gilles Cellarier, Nicolas Barra, Nicolas Savon, Olivier Roux, Jean-Claude Deharo, Pierre Djiane. *Cardiology Department, Ste Marguerite University Hospital, Marseille, France*

The aim of this prospective study was to correlate the width of the cavo-tricuspid isthmus (CTI) with the immediate outcome of radiofrequency (RF) ablation for common atrial flutter (AFl).

Methods: In 15 consecutive patients (pts) undergoing their first AFl ablation, right atrial angiography was performed immediately before the RF procedure. Cineangiography of the right atrium and inferior vena cava was performed in the 30° right oblique projection with the RF catheter in place (4 mm tip electrode). The CTI width was measured manually and the true value was calculated by reference to the distal electrode of the RF catheter. After RF ablation, conduction block in the CTI was evaluated by pacing from the proximal coronary sinus and the right postero-lateral atrium.

Results: Bidirectional block in the CTI could be achieved in 13 pts. Number of RF applications was 21.2 ± 13.1. Width of the CTI was 30.8 ± 10.5 mm. Significant correlation was found between the CTI length and the number of RF applications (r = 0.62, p < 0.05). A CTI length of < 30 mm was associated with a higher success rate and a lower number of RF applications.

	CTI width <30 mm (n = 10)	CTI width >30 mm (n = 5)	*p*
RF applications	14.5 ± 8.5	31.8 ± 12.5	*<0.01*
Block achieved	10/10 pts	3/5 pts	*<0.05*

Conclusion: 1) CTI length is correlated with the number of RF applications; 2) A CTI length > 30 mm is associated with more difficult ablation procedures with 4 mm tips. Longer distal electrodes might be more appropriate for these pts.

P645 Initial experience with a novel multielectrode catheter ablation system for atrial flutter

Erik Kongsgaard, Peter O'Callaghan, Wyn D. Davies[1], David Ward, Edward Rowland. *St. George's Hosp Med Sch, London; [1]St. Mary's Hosp and Imperial Coll Sch of Medicine, London, UK*

Catheter ablation of atrial flutter (AFl) is performed by creating bidirectional conduction block in the isthmus area. Traditionally, a catheter pullback approach is used to create linear lesions. We investigated the feasibility and efficacy of a novel temperature controlled multielectrode catheter ablation system in the treatment of AFl.

Methods: Fourteen consecutive patients were studied (mean age 57 yrs, 11 males, 3 females). Six patients had structural heart disease and six patients were in Afl at the time of ablation. The 7 F ablation catheter has four 4 mm band electrodes each with its own thermocouple (Quadrapolar Steerable Ablation Electrophysiology Catheter, IBI, CA). Power was delivered either to a single electrode or to multiple electrodes simutaneously. Radiofrequency (RF) energy was delivered via a 150 W RF generator (IBI, 1500 T) in the temperature controlled mode (set at 65°C). The ablation catheter electrodes spanned the tricuspid annulus/IVC isthmus (5.30 to 6.30 o'clock position in the LAO60° view) and a linear lesion was created without dragging the catheter.

Results: Bidirectional conduction isthmus block was achieved in all patients. In one patient a standard 7 F 4 mm ablation catheter had to be used to complete the line of block. Median procedure time was 90 minutes (range 55–180) and median fluoroscopic time was 18.1 minutes (range 6.8–65.2). A median of 15 RF applications (range 6–40) were delivered. Carbonisation on the catheter tip occurred during two energy applications. All patients were in sinus rhythm after the ablation procedure. After a mean follow up of 4 months only one patient has had a clinical recurrence of Afl.

In conclusion, these preliminary results show that bidirectional isthmus block can be induced safely with a multielectrode ablation catheter system.

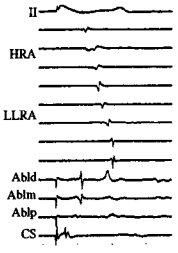
P646 Critical appraisal of local double spikes analysis as criteria for achievement of complete bi-directional isthmus block during typical atrial flutter ablation

F. Anselme, A. Kasaï, A. Cribier, N. Saoudi. *Hôpital Charles Nicolle, Service de Cardiologie, Rouen, France*

Activation mapping (AM) at the tricuspid ring-inferior vena cava isthmus (I) is the method of reference to assess achievement of complete bi-directional isthmus block (CBIB) during typical atrial flutter (AFl) ablation. It has been recently suggested that recording of widely separated double spikes (WSDS) at the ablation line could be a marker of CBIB after radiofrequency (RF) ablation. We therefore prospectively looked for WSDS during RF ablation of AFl, while simultaneously monitoring isthmus conduction using AM.

Methods: Patient population consisted of 20 consecutive patients (pts, 18 males) with a mean age of 63 ± 12 years (35–78). Seven pts had structural heart disease. In all pts, a decapolar catheter was inserted into the coronary sinus (CS), and a depolar Halo shaped catheter was positioned at the low lateral right atrium (LLRA) with the distal bipole located as close as possible to the line of ablation. AM and analysis of local WSDP were performed during LLRA and proximal CS pacing before, during and after each RF pulse delivery.

Results: CBIB was obtained in 18 patients, incomplete IB in 1 pt and procedure failed in 1 pt. In 2 pts, WSDS were recorded whereas there was either no IB (1 pt) or incomplete IB (1 pt, Fig). In 3 pts, CBIB was obtained using AM whereas WSDS could not be recorded at the site of ablation because of the presence of a wide electrically silent area. In 3 additional pts, triple spikes were recorded during LLRA pacing only, whereas AM showed CBIB.



Conclusions: WSDP recording is an adequate end point in the majority of the pts. However, WSPS does not necessarily correlate with activation mapping in assessing CBIB especially in difficult cases where high number of RF pulses are required.

VALUE OF SIGNAL-AVERAGED ECG OF P WAVE AND ATRIAL FIBRILLATION

P647 Value of the P-wave signal-averaged electrocardiogram for predicting atrial fibrillation early and long term after coronary bypass surgery

P. Ptaszyński, J. Ruta, H. Bolińska, A. Iwaszkiewicz-Zasłonka, R. Jaszewski, J. Zasłonka. *Institute of Cardiology, Medical University, Łódź, Poland*

Atrial fibrillation (AF) occurs commonly after coronary artery bypass surgery. Prolonged P-wave duration (PWD) on atrial signal averaged ECG (A-SAECG) recorded before cardiac surgery is predictor of AF following operation.

The purpose of this study was 1) to evaluate the influence of coronary artery bypass grafting (CABG) on PWD 2) to assess the relationship between PWD and prevalence of AF in one year follow up.

Methods: Study population consisted of 170 patients, 108 men and 62 women, aged 33–70 years (58 ± 8) with 2–3 vessel coronary disease who had no prior history of AF and were refered to CABG. All patients 2 days before and 14 days/1 year after cardiac surgery underwent A-SAECG recordings from orthogonal XYZ leads using digital 3-channel Holter monitoring. Filtered P wave triggered R wave signals averaging at noise level of ≤ 0.3 μV was analysed.

Results: Twenty two (13%) of the patients developed AF only 2–7 days after surgery. No one had AF during one year follow up. The P wave duration ≥ 130 msec predicted perioperative AF with sensitivity of 73%, specificity of 80%, positive predictive value of 57% and negative predictive value of 96%.

Values of P wave duration:

	PWD 1	PWD 2	PWD 3	
AF(+) 22 pts (13%)	135 + 19 ms	124 + 20 ms	125 + 24 ms	NS
AF(−) 170 pts (87%)	117 + 11 ms	119 + 17 ms	120 + 16 ms	NS
	p < 0.01	NS	NS	

PWD1-before operation; PWD2-14 days after; PWD3-1 year after

Conclusions: Prolonged P wave duration is good predictor of atrial fibrillation only in early period after coronary artery bypass grafting.

P648 Signal-averaged P-wave ECG in prediction of paroxysmal atrial fibrillation in patients with enlarged atrium

P. Scisło, J. Kochanowski, K. Filipiak, A. Oręziak, G. Opolski. *Department of Cardiology, Warsaw Medical School Banacha Ia St., 02-097 Warsaw, Poland*

The aim of our study was to evaluate sensitivity, specificity and positive predictive value of signal averaged P wave ECG duration (hfP) and root mean square of the signal in the first 30 ms of P wave (sRMS30) in identification the risk of paroxysmal atrial fibrillation (PAF) in group of patients with enlarged left atrium. We studied 87 patients (pts) with left atial dimension (LAD) greater then 40 mm, divided in two groups: 1. PAF – 50 (29 men/21 women) pts with PAF (62 ± 8.6 yrs old), 2. nPAF – 37 (26 men/11 women) healthy objects (62 ± 8.9 yrs old). Using an IBM PC based, special developed signal averaging system we aquire 256 PQRS complexes using P wave as a dynamical template from orthogonal, bipolar XYZ. Finally, SAP was filtered using Kaiser window 45–150 Hz. Echocardiographical measurments of LAD were carried by Hewlett-Packard Sonos 2500 in M-mode parastemal long axis examination.

Results: We determinate normal values for hfP as ≤123 ms and sRMS30 > 5.40 μV. We found in PAF group 46 pts with hfP > 123 ms, 8 pts with hfP ≤ 123 ms, 40 pts with sRMS30 < 5.4 μV and 10 pts with sRMS30 > 5.4 μV. In nPAF group we found 3 pts with hfP > 123 ms, 34 pts with hfP ≤ 123 ms, 11 pts with sRMS30 < 5.4 μV and 26 pts with sRMS30 > 5.4 μV.

	Sensitivity	Specificity	Positive predictive value
hfP	85%	91%	93%
sRMS30	80%	70%	78%

Conclusion: Both hfP and sRMS30 have value in identification pts at risk of PAF in group with enlarged atrium. However hfP has better sensitivity, specificity, positive predictive value than sRMS30.

P649 P-wave dispersion: the simple electrocardiographic marker for the detection of patients with paroxysmal atrial fibrillation

K. Aytemir, E. Sade, N. Özer, S. Aksöyek, G. Kabakci, A. Oto, S. Kes. *Department of Cardiology, Hacettepe University, Fac. of Medicine, Ankara, Turkey*

The prolongation of intraatrial and interatrial conduction time and the inhomogeneous propagation of sinus impulses have been shown in patients with atrial fibrillation. Recently P wave dispersion (PWD), which is believed to reflect inhomogeneous atrial conduction, has been suggested to be useful in predicting patients with paroxysmal atrial fibrillation (PAF).

Methods: Eighty-one consecutive patients, 51 men and 30 women aged 43 ± 18 years with a history of idiopathic PAF and 40 healthy subject (25 men and 15 women, mean age 41 ± 19 years) were studied. Twelve leads ECG was obtained from all patients and control subjects in the supine position during sinus rhythm. The P wave duration was calculated in all 12 leads of the surface ECG. The difference between the maximum P wave duration and minimum P wave duration was calculated and this difference was defined as P wave dispersion (PWD = Pmax − Pmin). All patients and controls were also evaluated by echocardiography to measure the left atrial diameter.

Results: There was no difference between patients and controls in age (43 ± 18 vs 41 ± 19 years, p = 0.6) and left atrial diameter (3.7 ± 1.1 cm vs. 3.6 ± 1.0 cm, p = 0.8). P maximum was found to be significantly higher in patients with a history of PAF (119 ± 13 ms) than controls (101 ± 11 ms, p = 0.001). P wave dispersion was also significantly higher in patients than controls (42 ± 13 ms vs 23 ± 9 ms, p < 0.001). There was no correlation between age, left atrial diameter and P wave dispersion (p > 0.05). A P maximum value of 108 ms separated patients with PAF from control subjects, with sensitivity 66%, a specificity of 65%, positive predictive accuracy of 79% and negative predictive accuracy of 49%. A P wave dispersion value of 35 ms separated patients from control subjects, with sensitivity 71%, a specificity of 72%, positive predictive accuracy of 84% and negative predictive accuracy of 55%.

Conclusion: P maximum and P wave dispersion calculated on standard surface electrocardiogram are simple electrocardiographic markers that could be used to identify the patients with idiopathic paroxysmal atrial fibrillation.

P650 Is there any relationship between signal-averaged ECG P-wave duration and P-wave dispersion?

K. Aytemir, N. Özer, E. Sade, S. Aksöyek, A. Oto. *Department of Cardiology, Hacettepe University, Fac. of Medicine, Ankara, Turkey*

P wave signal-averaged electrocardiography (SAECG) and P wave dispersion (PWD = Pmax-Pmin) have been shown to be useful to detect the patients at risk of atrial fibrillation. However the relationship between the SAECG P wave duration and PWD has not been evaluated yet.

Methods: Thirty-four consecutive patients, 19 women and 15 men, aged 49 ± 12 years with a history of idiopathic paroxysmal atrial fibrillation and 30 healthy subject (5 women and 25 men, mean age 48 ± 11) were enrolled in this study. SAECG P wave recordings and 12-lead surface ECGs were obtained from all patients and control subjects in the supine position. The P wave duration was calculated in all 12 leads of the surface electrocardiogram. The difference between the maximum P wave duration and the minimum P wave duration was calculated and this difference was defined as P wave dispersion. Filtered P wave duration was calculated on SAECG recordings.

Results: P maximum was found to be significantly higher in patients with a history of PAF (117 ± 14 ms) than controls (98 ± 9 ms, p = 0.000). P wave dispersion was also significantly higher in patients (40 ± 12 ms) than in control subjects (22 ± 8 ms, p = 0.000). Filtered P wave duration was longer in PAF patients than controls (131 ± 12 ms vs 107 ± 9.7 ms, p = 0.00). There was a positive correlation between PWD and SAECG P wave duration (r = 0.79, p = 0.000).

A P maximum value of 105 ms separated patients with PAF from control subjects, with a sensitivity 70%, a specificity of 76%, and a positive predictive accuracy of 77% and negative predictive accuracy of 69%. A P dispersion value of 30 ms separated patients from control subjects, with a sensitivity 83%, a specificity of 80%, and a positive predictive accuracy of 77% and negative predictive accuracy of 69%. These values for SAECG P wave duration > 120 ms were 79%, 86%, 87% and 78% respectively.

Conclusion: 1) There is a relationship between P wave dispersion and SAECG P wave duration. 2) P maximum, P wave dispersion and SAECG P wave duration could be useful to identify the patients with history of PAF during sinus rhythm. 3) P wave dispersion, as a simple ECG parameter, can be used instead of SAECG P wave duration.

CARDIOVERSION OF ATRIAL FIBRILLATION

P651 Left atrial appendage stunning in atrial fibrillation: comparison between pharmacological and DC cardioversion

C. Pandullo, S. Scardi[1], C. Mazzone[2], M. Miccio[3], R. Salvi[3], G. Cattarini[4], T. Morgera[4]. *Trieste; [1]Centro Cardiovascolare, Trieste [2]Centro Cardiovascolare, Trieste [3]Servizio di Medicina d'Ugrenza, Trieste [4]Servizio di Cardiologia, Monfalcone-Gorizia, Italy*

Background: The stunning of the left atrial appendage (LAA) and the left atrium (LA)after cardioversion (CV) is a phenomenon that could increase the embolic risk. It seems more evident after DC (DCV)than pharmacological (PCV) CV, for this reason a four-weeks of oral anticoagulation after successfull procedure is usually recommended.

Aim of the study: To evaluate the LA function, the emptying (EV)and filling velocity (FV) profiles of LAA we evaluated a group of randomized patietns (P) with recent (<6 months) onset non rheumatic AF (NRAF) with TTE and TEE immediately before and after 48 hours from DCV or PCV and with TTE alone 24 hours after CV.

Study population: Thirty P (17 females) with NRAF lasting 85 ± 34 dd, age 66 ± 9 were randomized to PCV with quinidine or DCV.

Results: Twenty P reverted to sinus rhythm (11 DCV, 9 PCV)

Comparison between DCV and PCV

	DCV	PCV	p
FV basal (cm/sec)	37 ± 18	38 ± 12	ns
EV basal (cm/sec)	26 ± 9	31 ± 14	ns
FV aft 48 h (cm/sec)	44 ± 16	39 ± 9	ns
EV aft 48 h (cm/sec)	40 ± 20	41 ± 14	ns
A 24 h aft CV (m/sec)	0.6	0.53	ns

Conclusion: 1. In P with recent onset NRAF DCV does not induce more evident

LA and LAA stunning in coparison with PCV

2. Our data demonstrate a good LAA function just 48 h after successfull CV, for this reason a four-weeks antocoagulation therapy may be unnecessary in this group of patients.

P652 Evidence of atrial stunning after acute infusion of class 1C anti-arrhythmic agents

A. Pizzuti, E. Antonielli[1], N. Gandolfo, F. Delnevo, R. Palmiero, A. Bassignana[1], M. Di Leo[1], G. Baduini. *Departments of Cardiology, Ospedale Mauriziano Umberto I, Torino; [1]Cardiology Dept., Ospedale SS.Annunziata, Savigliano, Italy*

Restoration to normal sinus rhythm is responsible for the transient left atrial dysfunction ("stunning") observed after cardioversion of atrial fibrillation (AF). In recent onset AF class 1C anti-arrhythmic agents are often used as a first line intervention to restore the normal sinus rhythm. Aim of the study was to evaluate the left atrial and left atrial appendage (LAA) function during acute administration of these drugs in patients not converted to sinus rhythm.

Method: Using data from our registry on transesophageal echocardiography (TEE) in AF management, 41 patients were identified who underwent chemical cardioversion; 21 patients successfully reverted to sinus rhythm were excluded. 14 patients (group 1) received propafenone (P) and 6 patients (group 2) received flecainide (F). Both drugs were administered i.v. at a dosage of 2 mg/kg body weight in 10 minutes during continuous TEE monitoring. Presence and intensity of spontaneous echo contrast (SEC) (from 0 = absent to 3 = intense) and LAA function (average of peak Doppler derived outflow velocities over 5 consecutive cardiac cycles) were evaluated.

Results: Baseline characteristics (Age, AF duration, left atrial dimension, SEC and LAA function) were similar in both groups. At the end of bolus infusion, in both groups SEC was increased and LAA outflow velocities were decreased.

	Group 1 (n = 14)	Group 2 (n = 6)
Age (years)	64 ± 11	71 ± 3*
AF duration (days)	18 ± 9	28 ± 24*
Left Atrial diameter (mm)	43 ± 5	47 ± 6*
Mean SEC degree:		
Baseline	0.64 ± 0.6	0.83 ± 0.4*
End of bolus	1.29 ± 0.8+	1.17 ± 0.4**
LAA flow (cm/sec):		
Baseline	32.1 ± 18.1	25.1 ± 10.1*
End of bolus	16.9 ± 12.3#	14.8 ± 3.0†

Abbreviations: see text. *p = NS vs group 1; **p = NS vs baseline. +p = 0.007 vs baseline; #p = 0.000 vs baseline; †p = 0.028 vs baseline.

Conclusion: Left atrial stunning, a known risk of thromboembolic events, develops during acute administration of propafenone and flecainide. This phenomenon is not due to restoration to normal sinus rhythm.

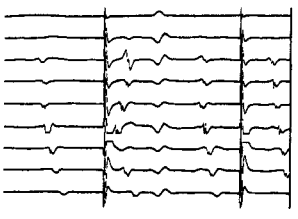
P653 Measurement of atrial effective refractory period during ongoing atrial fibrillation in man allows study of anti-fibrillatory drug effects

A. Kasaï, F. Anselme, A. Cribier, N. Saoudi. *Rouen University Hospital, Rouen, France*

Variations in local atrial fibrillation intervals (AFI) can be due to variations in refractory period and (ERP)/or excitable gap (EG). Class I drugs are known to increase AFI. We studied the effects of a Class I drug on ERP, EG and AFI during AF in man.

Methods. In 5 patients (pts) with sustained AF, a 20 poles Halo catheter was positioned anterior to the Crista Terminalis for unipolar atrial recordings (A), and another bipolar catheter within 1 mm of the Halo catheter for pacing. After local AF entrainment was performed, pacing at a cycle length of 500 ms was delivered in an asynchronous mode. Coupling intervals (CI) of captured beats were measured at the closest electrode from the pacing site. Capture was said to occur if local A potential morphology was changed after the pacing spike, and when impulse radiated from the paced site to neighboring electrodes (Figure shows lead 1 and 8 atrial unipolar recordings). Mean CI of a minimum of 15 captured beats was taken as local AERP. Before pacing, 100 consecutive AFI were evaluated at same site. The same procedure was repeated after IV Cibenzolin (cib) injection in 3 pts.

Results. In all 5 pts, a strict correlation was found between AERP and AFI (r = 0.95, p < 0.0001). Cib prolonged AERP in the 3 pts (from 159 ms to 211 ms). After Cib, EG/AFI was shortened in 2 pts (−4 and −13%), One converted to SR and one to Aflutter. In 1 pt EG/AFI increased and AF persisted.



Conclusion. This method may be of value for the measurement of the effects of anti-fibrillatory drugs on AERP and EG during AF in man.

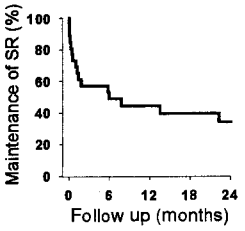
P654 Restoration and maintenance of sinus rhythm with amiodarone after initial unsuccessful electrocardioversion in patients with persistent atrial fibrillation

B.A. Schoonderwoerd, I.C. Van Gelder, A.E. Tuinenburg, R.G. Tieleman, H.J.G.M. Crijns. *Thoraxcenter, University Hospital Groningen, Netherlands*

Background When external electrical cardioversion (ECV) fails to restore sinus rhythm (SR) in patients with persistent atrial fibrillation (AF), a second ECV attempt after pre-treatment with amiodarone is an option. However, the efficacy of amiodarone in restoring and maintaining SR using this strategy is yet to be established.

Methods After unsuccessful ECV 39 patients (25 male, mean age 62 ± 11 years) with AF (median duration of current episode 304 days) were treated with amiodarone 200 mg t.i.d. during four weeks before a second ECV was attempted. If SR was restored, amiodarone treatment was continued at 200–300 mg daily as a prophylactic drug, depending on amiodarone and desethylamiodarone plasma levels.

Results Five (13%) patients converted on amiodarone to SR within the four weeks prior to the second ECV. Two others (5%) did not undergo a second ECV because of unstable heart failure. The remaining 32 patients underwent the re-ECV which was successful in 21 patients. Mean follow up was 14.5 ± 17.3 months. Of the 26 patients who converted to SR, 44% were in SR after 12 months (figure) which equals an overall success rate of 30%.



Conclusions After an unsuccessful ECV 30% of patients maintained long-term SR after pre-treatment with amiodarone. Therefore, this strategy may be considered before attempting internal defibrillation or accepting AF.

P655 Pharmcokinetics and pharmacodynamics of atrial versus peripheral infusion of flecainide acetate in patients with atrial fibrillation

A. Capucci, G.Q. Villani, A. Rosi, F.F. Tarantino, D. Aschieri, M.F. Piepoli. *Cardiology Dept., Polichirurgico, Piacenza, Italy*

Background: the automatic chemical cardioverter defibrillator may be a near future chance in the treatment of atrial fibrillation (AF). There is little knowledge about possible different antiarhythmic properties of the antiarrhythmic drugs according to rate and site of infusion.

Methods: We compared pharmacokinetics and conversion efficacy of different administration routes of flecainide (Fl) in 16 patients with paroxysmal AF in which sustained AF (>20 min duration) was induced during EP study. Pts were divided into 3 groups: A (6 pts, 2 mg/kg 5′ i.v. infusion), B (5 pts, 2 mg/kg 10′ intraatrial infusion) and C (5 pts, 2 mg/kg 5′ intraatrial infusion). We evaluated: Fl plasma concentrations at 1′–2′–5′–10′–15′–20′ after the beginning of the infusion; the samples were simultaneously drawn from pulmonary artery (PA), coronary sinus (CS), femoral artery (FA). Mean AF cycle length, efficacy to restore sinus rhythm (SR, C) and proarrhythmic events were evaluated.

Results: Significant lower peak Fl concentration in the PA blood was observed in group A vs B and C (1.7 vs 3.6 vs 2.6 mg/L, $p < 0.05$ A vs B or C respectively) while no differences were detected in the Fl concentration in CS or FA among the three study groups (p = NS). No difference in sinus rhythm conversion was observed among the three groups, but a faster sinus conversion time in the group C vs A and B (3 vs 8 and 8 min respectively, $p < 0.05$) In all 3 groups AF mean cycle lengths significantly prolonged prior to sinus rhythm conversion (A: from 156 msec to 191 msec, B: from 151 to 196 msec, C: from 155 to 197 msec; $p < 0.01$). No proarrhythmic events or hypotension were reported.

Conclusion: Fl intraatrial infusion: i) allowed a faster sinus rhythm restoration compared to peripheral infusion; ii) was not accomplished by high peripheral plasma concentration because of a strong lung first-pass absorption. This behaviour could contribute to reducing the rate of adverse events or allow a lower acute i.v. Fl dose maintaining a good efficacy rate.

P656 Once-a-day formulation of diltiazem or metoprolol to control ventricular rate in patients with permanent atrial fibrillation: a randomized, crossover, placebo-controlled study

G.L. Botto, G. De Nittis, T. Broffoni, W. Bonini, G. Ferrari. *From Department of Cardiology, S. Anna Hospital, Como, Italy*

Calcium-blockers and beta-blockers have been successfully used to control ventricular rate (VR) in permanent atrial fibrillation (PAF). No data are avalaible about the administration of once-a-day formulation drugs in this field.

Methods. The study concerns 25 patients (pts) (mean age 63 ± 7, range 52–76 years) with stable (>6 months) PAF, without organic heart disease or with arterial hypertension only (22/25 pts; 88%), NYHA functional class I, and VR > 100 beats/min on resting ECG. The effect on VR of once-a-day formulations of Diltiazem 300 mg (DLT) or Metoprolol 200 mg (MTP) were compared to placebo (PLA) and to oral digoxin (DGX) (mean dose 0.304 ± 0.063 mg/day, serum concentration 0.8–1.4 ng/ml). Treatments were administred randomly (each for a week) in a cross-over fashion, and were assessed by 24-hour Holter during daily life and by three-minute walking-test (WT). We evaluated: mean VR (AVR) over 24 hours, minimal VR (mVR), maximal VR during WT (MVR), VR impairment (VRi) {MVR/maximal VR for age × 100}, pauses >2 sec (PAU), phases of brady < 50/min (BRD) over 4 consecutive RR cycles.

Results:

	AVR	mVR	MVR	VRI	PAU	BRD
PLA	111 ± 14	79 ± 10	164 ± 19	105 ± 14	1 ± 1	1 ± 3
DGX	93 ± 13*	65 ± 11*	147 ± 20*	94 ± 12*	13 ± 21**	23 ± 32**
DLT	88 ± 10*°	60 ± 11**	138 ± 17**	88 ± 13**	15 ± 25**	60 ± 95**
MTP	92 ± 13*^	69 ± 12*°^^	138 ± 22*°	88 ± 14*°	4 ± 10^^	19 ± 50^

p value vs. PLA: * < 0.001; ** < 0.01. p value *vs* DGX: * < 0.05; ° < 0.01. p value *vs* DLT: ^ < 0.05; ^^ < 0.001

None of the study-pts experienced either RR cycles > 3 sec or phases of bradycardia < 30/min. No seriuos adverse effects causing discontinuation of the drug-trial were noted in either group.

Conclusion. Once-a-day formulations of diltiazem or metoprolol are equally superior to DGX or PLA to control the VR during mild exercise and to minimize VRi in patients with permanent atrial fibrillation without organic heart disease. The reduction of peak VR is obtainable without critical slowing of resting VR.

P657 Intravenous amiodarone versus glucose-insulin-potassium-magnesium infusion in cardioversion of new-onset atrial fibrillation: preliminary results

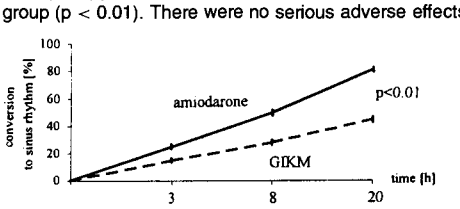
J. Cybulski, P. Kułakowski, A. Budaj, H. Danielewicz[1], J. Maciejewicz[2], T. Kawka-Urbanek[3], L. Ceremużyński. *Department of Cardiology, Postgraduate Medical School, Grochowski Hospital, Warsaw; [1]Biegańskiego, Hospital, Grudziądz; [2]Dietla Hospital, Kraków; [3]Provincial Hospital, Skierniewice, Poland*

Paroxysmal atrial fibrillation (PAF) is one of the most common causes of hospitalisation. However, until now, no standard antiarrhythmic therapy has been accepted for pharmacological cardioversion of PAF. Amiodarone seems to be a promising candidate, but only a few randomized trials are available and the results are inconsistent.

Aim of the study: To compare efficacy of intravenous amiodarone with standard electrolyte supplementation in cardioversion of PAF.

Methods: 65 patients with PAF lasting less than 24 hours were randomly assigned to amiodarone group (n = 32) (5 mg/kg as a 30 min. iv infusion, followed by iv infusion of 10 mg/kg during 20 hours), or iv infusion of 10% glucose, 10 IU of rapid action insulin, 40 mEq of kalium chloride and 4 g of magnesium sulphate (GIKM) (n = 33). Patients requiring emergency DC cardioversion were excluded.

Results. Twenty hours after initiation of therapy sinus rhythm was restored in 26 (81%) patients in the amiodarone group and in 15 (45%) patients in GIKM group ($p < 0.01$). There were no serious adverse effects in either group.



Conclusion. Amiodarone is a very effective drug for termination of PAF lasting less than 24 hours, with the conversion rate much higher, than reported for spontaneous conversion of PAF. The study is ongoing and the final results will be reported after inclusion of 150 patients.

P658 Combined administration of quinidine and propafenone for atrial fibrillation: the CAQ-PAF pilot study

G.E. O'Hara, F. Philippon, M. Gilbert, L. Charbonneau, J. Champagne, G. Pruneau, B. Hamelin, P. Geelen, Jacques Turgeon. *Quebec Heart Institute, Laval Hospital, Ste-Foy PQ, Canada*

The need for innovative approaches in the prevention of recurrence of atrial fibrillation (AF) is well recognized. The objective of the CAQ-PAF study was to evaluate the potential of low dose quinidine (QUI) to improve propafenone (PPF) efficacy by causing chronic inhibition of its metabolism mediated by CYP2D6. This would favor PPF instead of its 5-hydroxy metabolite as the active compound in the plasma; PPF being a product with a potentially more favorable profile including β-blocking effects. This prospective, double-blind study consisted of 102 pts (48 males and 54 females; 60 ± 11 y), with AF lasting >1 hour. All pts received PPF 150 mg TID but were randomized to combined therapy with either placebo or QUI (100 mg BID). Clinical profile, history of AF and antiarrhythmic use, CYP2D6 genotype and left atrial size were documented: 77% had ≥2 episodes of AF in the previous year, 38% had AF recurrence while on antiarrhythmics and 21% had *de novo* AF. First recurrence of AF (≥7 days), side-effects, ECG and plasma concentrations of PPF and its metabolites were monitored for 1 year. Throughout the study, PPF concentrations (ng/mL) were increased by QUI compared to patients receiving placebo ($P < 0.05$).

	1 month	3 months	9 months	End of study
PPF + QUI	115 ± 567	1013 ± 511	1073 ± 698	1033 ± 611
PPF + placebo	349 ± 282	376 ± 399	330 ± 240	328 ± 229

Thirty-five patients completed the study without recurrence of AF: 20 were receiving PPF + QUI while 15 were receiving PPF + placebo. 78% of pts with PPF levels > 1500 ng/mL were in sinus rhythm at 1 year compared to 58% when levels were >1000 ng/mL. In contrast, recurrence of AF occurred in 22/23 pts with PPF levels < 1000 ng/mL. In addition, 10/11 pts with a genetically-determined nonfunctional CYP2D6 activity and increased PPF concentrations remained in sinus rhythm and completed the study. Finally, 14% of the pts were excluded due to side-effects. In conclusion, our results indicate the potential benefits of increased plasma concentrations of PPF to prevent recurrence of AF. Strategies aimed at improving bioavailability of PPF during oral treatment could represent new avenues in the treatment of AF.

P659 Pre-treatment with verapamil in patients with persistent or chronic atrial fibrillation who underwent electrical cardioversion

A. De Simone, G. Stabile, D.F. Vitale[1], P. Turco, M. Di Stasio, V. Larocca, G. Senatore[2], M. Gasparini[3], C. De Matteis[4], R. Rotunno[5], T. Di Napoli[5]. *Electrophysiology Laboratory, "San Michele" Hospital Maddaloni (CE); Department of [1]Geriatrics; [2]Cardiology, Federico II University, Naples; [3]"Humanitas" Hospital, Rozzano (MI); [4]Civil Hospital, Arienzo (CE); [5]Civil Hospital, Polla (SA), Italy*

The increased vulnerability for atrial fibrillation (AF) recurrence is probably due to AF induced changes in the electrophysiologic properties of the atria. This electrical remodeling seems to be due to intracellular calcium overload. The aim of our study was to evaluate, in a prospective and randomized fashion, the efficacy of a pretreatment with Verapamil (V) in reducing recurrences of AF after electrical cardioversion (C).

Methods. One hundred-seven patients with persistent or chronic AF underwent external and or internal C. Three days before C patients were randomized in three groups. All patients received oral Propafenone (P) (900 mg per day) 3 days before and during the entire period of follow-up (3 months). In the first group patients received only the P. In the second group, in adjunct to P oral V (240 mg per day) was initiated 3 days before C and continued during the follow-up; finally, in the third group oral V was administered 3 days before and continued only for 3 days after electrical C.

Results. In 7 (6.5%) patients sinus rhythm was documented at the time of C. Eight (8%) patients were dropped from the follow-up because of pharmacological side effects. During the three months follow-up 23 patients (23.7%) had AF recurrence. Mantel-Haenszel cumulative χ^2 reached a significant level only when comparing AF free survival curves of group I versus group II and group III ($\chi^2 = 5.2$ and $\chi^2 = 4$, respectively, $p < 0.05$). Significantly, fifteen (65.2%) AF relapses occurred during the first week after C with an higher incidence in group I (10/33 patients, 30.3%) than group II (2/34 patients, 5.9%, $p = 0.01$) and group III (3/30 patients, 10%, $p = 0.04$).

Conclusions. Six days oral V administration centered on the C day, combined with P, significantly reduce the incidence of early recurrences of AF compared to P alone. The time course of AF relapses, and the lack of benefits of long-term therapy with V, strongly support the hypothesis that calcium antagonists just facilitate the recovering from electrical remodeling.

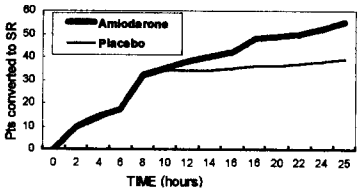
P660 High-dose i.v. amiodarone in the conversion to sinus rhythm of paroxysmal atrial fibrillation. When is it necessary?

F. Bellandi, R.P. Dabizzi[1], R. Palchetti. *2o Medicina; [1]Cardiologia, Prato, Italy*

The rate of spontaneous conversion of paroxysmal atrial fibrillation (PAF) to sinus rhythm (SR) is high and not affected by low dose amiodarone (Am) treatment. We evaluated high-dose Am in the treatment of PAF.

Methods: 120 patients (pts) with PAF (<48 h) were randomized to receive for 24 hours: (1) Group A (n. 60), Placebo; (2) Group B (n. 60), continuous IV Am 120 mg/hour (total 3 gr). Group A pts not converting to SR within 24 hr were crossed over to Am therapy. All pts received digoxin.

Results: Baseline ventricular rate (MVR) was 123 ± 21 and ± 23 beats/min in groups A and B. In group A, 39 pts (65%) converted to SR vs 55 (92%) in group B ($p = 0.001$). Thirty-four of 39 pts (87%) converting spontaneously (in group A) have converted within 10 hours. Seventeen pts (81%) in group A not converting on placebo have converted after being crossed over to high dose Am treatment.



Finally 9 pts (in both groups) did not convert on high dose Am, 6 converted after electrical cardioversion, but 8 pts (89%) were in chronic AF after 1 month. In pts still in AF after 8 hours of treatment, the MVR decreased to 117 ± 24 beats/min in group A vs 81 ± 19 beats/min in group B ($p = 0.001$). No adverse events requiring treatment occurred in group B pts.

Conclusion: IV high-dose Am treatment (120 mg/hr) is safe and facilitates conversion of PAF to SR. Spontaneous conversion commonly occurs within 10 hours, therefore, high-dose Am may be reserved for pts requiring rate control or not converting within 10 hours. Pts resistant to high-dose Am are at high risk of developing chronic AF.

P661 Sinus node chronotropy following isoproterenol challenge in patients with chronic atrial fibrillation after cardioversion

T. Mesiskli, G.N. Theodorakis, E.G. Livanis, P. Flevari, E. Zarvalis, D.Th. Kremastinos. *2nd Dept of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

Animal studies have shown that sinus node chronotropy is attenuated after atrial fibrillation induced with rapid atrial pacing. Limited studies are available in humans. The purpose of our study was to examine the sinus node chronotropy following isoproterenol challenge in patients with chronic atrial fibrillation after cardioversion (CV) and correlate it to the recurrence of atrial fibrillation.

Methods: Twenty-eight patients (pts) with chronic atrial fibrillation (mean duration 2 ± 1 months, range 1–3 months) were successfully cardioverted to sinus rhythm with external defibrillation. All were free of any medical treatment except anticoagulants and ACE inhibitors. They had been evaluated by echocardiography before CV. Ten minutes after CV, isorpoterenol was infused in all pts (10 γ for one minute). Heart rate was recorded at baseline, at the end of isoproterenol infusion and 10 minutes later. Pts were discharged with oral therapy (sotalol) and followed-up at six months for atrial fibrillation recurrence. ANOVA was used for analysis.

Results: Twelve pts remained in sinus rhythm (group I) and the rest 16 recurred (group II). No statistical difference was noted between the two groups regarding the age of the patients (52 ± 5 vs 49 ± 7 years) the atrial fibrillation duration (1.9 ± 1 vs 2 ± 2 months) as well as the left atrial dimensions (45 ± 3 vs 46 ± 2 mm).

Time	Group I	Group II	p value
Baseline	69 ± 8 bpm	61 ± 20 bpm	0.01
End of infusion	105 ± 7 bpm	83 ± 35 bpm	0.001
10 min	76 ± 11 bpm	65 ± 21 bpm	0.017

Conclusions: Heart rate is higher in pts who remain in sinus rhythm six months following electrical cardioversion not only ten minutes after the procedure but also after isoproterenol challenge. Atrial fibrillation recurrence might be related to sinus node dysfunction as well.

LOW-ENERGY INTERNAL CARDIOVERSION OF ATRIAL FIBRILLATION

P662 Low-energy internal cardioversion of persistent atrial fibrillation

T. Toselli, G. Guardigli, M.S. Argnani, G.F. Percoco, G.E. Antonioli. *Div. of Cardiology, Arcispedale S. Anna, Ferrara, Italy*

Background: Low energy internal cardioversion has recently been developed and proposed in patients (pts) with persistent atrial fibrillation.

Methods: Thirty-three pts (mean age 68 yrs, range 50–75, 24 M, 9 F) affected by chronic atrial fibrillation dating from 40 to 250 days, were included in the study.

The selection criteria for the enrollment were the following: a) persistent atrial fibrillation for at least 1 month; b) effective anticoagulation for at least 3 weeks, c) previous unsuccessfull attempts of cardioversion (drugs or DC shock).

Initially, three intracavitary temporary leads were used: two 6 F catheters with a large surface coil (>500 sqmm, InControl Inc.) for shock delivery and one 5 F bipolar or quadripolar lead for ventricular synchronization. More recently, a single lead double coil catheter was used for defibrillation.

The configuration catheter was Right Atrium (RA) and Left Pulmonary Artery (22 pts) (LPA) or coronary sinus (9 pts) (CS). In 2 pts a tripolar configuration was necessary (RA, CS, LPA). All the pts received a mild sedation with Diazepam. Shocks were delivered from a defibrillator system analyzer (DSA 2101 InControl Inc.), at 250 V (4J), 300 V (6J), 350 V (7.5J) and 400 V (10J). All the shocks were properly synchronized and no ventricular arrhythmia was induced.

Results: Sinus rhythm was restored with a mean energy of 6.5 J (mean impedance 58 ohm) using RA + LPA configuration catheters, and 3.1 J (mean impedance 50 ohm) using RA + CS configuration. Internal cardioversion was successful in 31/33 pts, restoring sinus rhythm in 93.94%. No pts referred severe discomfort or pain from the procedure: the sensation produced by the internal shock was defined as a moderate precordial punch.

Conclusions: Low energy internal cardioversion is a safe, simple and highly effective procedure in restoring sinus rhythm.

P663 Clinical results with a new device for internal cardioversion of atrial fibrillation and dual-chamber pacing

A. Plewan, E. Alt. *German Heart Center; 1. Med. Clinic, Klinikum rechts der Isar, Technical University Munich, Germany*

Background: Based on the experience that internal cardioversion (IntCV) of atrial fibrillation (AF) is effective with electrodes in the right atrium and pulmonary artery, a new balloon guided catheter and external defibrillation device with optional dual chamber pacing was evaluated.

Methods: IntCV of AF was performed in 81 patients (pts) (age: 58 ± 12 years, duration: 11 ± 14 months, postcardiothoracic surgery: 16 pts). A single lead balloon guided 7.5 french catheter for intCV (EP MedSystem) was introduced via the brachial (76 pts) or femoral vein (5 pts). The distal shock array was placed in the left pulmonary artery, the proximal shock array had firm contact to basal atrial tissue. Each array consits of five 5 mm ring electrodes with a total surface of 2.5 cm^2. Via a distal lumen haemodynamic measurements can be performed. R-wave triggered biphasic shocks of 50% tilt were delivered by a new external defibrillator (Alert, EP MedSystem) device that incorporates combined 12 lead surface ECG, intraatrial and ventricular EGM online recording and monitoring. Optional atrial stimulation (AAI, AOO) for overdrive suppression of atrial premature beats after intCV for prevention of early recurrence of AF could be performed. For safety backup pacing in case of post shock bradycardia ventricular stimulation (VVI, VOO) was available.

Results: In 76 of 81 pts (94%) sinus rhythm (NSR) was restored with a mean energy of 6.7 ± 4.8 Joules. In 14 pts with early recurrence of AF (within 30 s) after initially successful intCV atrial pacing (2–5 minutes) for overdrive suppression of atrial premature beats was performed after the following successful shock application. All of those pts remained in NSR. The fluoroscopy time was 1.8 ± 1.6 minutes.

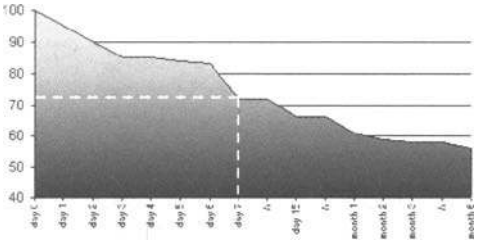
Conclusion: IntCV of AF by the means of this new device proofed to be save, effective and easily performable. Our data indicate that post shock atrial pacing for overdrive supppression of atrial premature beats might be helpful for prevention of early recurrence of AF. With the additional option of ventricular stimulation and heamodynamic monitoring also post cardiac surgery pts might benefit of the from this system.

P664 Low-energy endocavitary electrical cardioversion: characteristics of patients undergoing sure relapse

A. Michelucci, G. Barletta[1], L. Padeletti, A. Colella, R. Del Bene, M.C. Porciani, P. Pieragnoli, A. Morettini, C. Nozzoli, A. Costoli, S. Vena, A. Sabini, R. Zipoli, G.F. Gensini. *Istituto Clinica Medicae Cardiologia, Careggi Hospital, Florence; [1]Biomedical Engineering Laboratory, Istituto Superiore di Sanità, Rome, Italy*

Identification of pts with atrial fibrillation (AF) relapse (AFR) after low energy electrical cardioversion (LEEC) is important to choose therapy.

Methods: 100 pts (mean age 64 ± 12 yrs) who underwent LEEC for chronic AF were studied: 38 (65 ± 10 yrs) had AFR within 7 days, 13 (63 ± 13 yrs) had AFR between 7 days and 6 months and 49 (65 ± 14 yrs) did not have AFR. The 3 groups were age-matched. Evaluated parameters: age, associated cardiopathy, left atrial dimension (LAd, 44 ± 5 mm), arrhythmia duration (AD, 4 ± 11 months), months since the first AF episode (1^{th}AFT: 29 ± 44 months), left ventricular EF (0.53 ± 0.12), and antiarrhythmic theraphy (AT: amiodaron, propafenone, Ca-antagonists, digitalis, flecainide). The time behaviour of AFRs is shown in the figure.



Results: Kaplan-Meyer analysis: 1. all pts with Lad > 52 mm or age > 76 yrs or AD > 8 months or 1^{st}AFT > 100 months had AFR; 2. AFR was always within 7 days when LAd > 49 mm or AD > 8 months or 1^{th}AFT > 40 months.Valvular heart disease showed a greater incidence of AFR (p = 0.015). AT did not significantly change the incidence of AFR.

Conclusions: Results of this study help both to identify pts with AFR and to predict the time to AFR after LEEC. This is important to decide whether to perform LEEC and what therapy to choose after LEEC.

P665 Ineffective shocks results on local atrial fibrillation intervals and different types of sinus rhythm restoration during low-energy internal cardioversion

C. Pandozi, M. Villani, G. Gentilucci, M.C. Scianaro, F. Lamberti, A. Castro, M. Santini. *Department of Cardiology, San Filippo Neri Hospital, Rome, Italy*

Background. The effect on unsuccessful shocks (US) on local atrial fibrillation (AF) as well as the modality of termination of AF has not been carefully evaluated in humans.

Methods. In 29 patients undergoing low energy internal cardioversion of persistent AF an octopolar lead was positioned in the right lateral atrial wall. The mean local fibrillation intervals (FF) were recorded in basal condition (3 sec), before (3 sec), during and after each shock (first 3 sec). The interval between the last atrial electrogram and the shock (AS) was evaluated in the unsuccessful and successful shocks (SS). Beginning from 100 V a 50 V step-up protocol was used until sinus rhythm (SR) restoration. The modalities of AF termination after shock delivering were classified in the following types. Type A: no atrial electrogram (AE) before the sinus beat (SB); Type B1: only 1 recorded AE before the sinus beat; type B2: 2–5 recorded AE before the SB; type B3: more than 5 AE before the sinus beat.

Results. A total of 104 endocavitary shocks were analysed. A significant difference between pre-shock and 0–3 post-shock FF intervals was found at the 50% and 75% of the defibrillation threshold energy (162.7 ± 33.7 ms vs 176.8 ± 7.1 ms and 183.8 ± 20.1 ms vs 194.9 ± 32.5 ms respectively, $p < 0.05$ in both). The mean AS was 63.3 ± 40.9 ms in the SS and 96.9 ± 47.7 ms in the US shocks ($p < 0.001$). Type A termination was observed in 12 (43%) pts, type B1 in 7 (22%), type B2 in 7 (22%) and type B3 in 3 (13%). Pts with type A and B1 termination compared to pts with type B2 and B3 termination showed a less complex local AF (Type 1 AF in 80% and in 12%, respectively, $p < 0.005$) and a significantly shorter AS interval (64.6 ± 48 ms vs 103.7 ± 38 ms, respectively, $p < 0.05$).

Conclusions. 1) FF interval prolongation lasts up to 3 seconds and predicts the efficacy of the following shocks. 2) This suggests the possibility to restore SR delivering a second low energy shock within 3 seconds after the first. 3) The chance of AF termination is greater when the AS interval is short, implying the importance of synchronisation of the shock with at least a portion of the atrial tissue. 4) The modality of AF termination seems related to the complexity of the AF preceding the shock and 5) to the duration of the AS interval.

P666 Efficacy and pain perception using a low peak voltage biphasic waveform for internal atrial cardioversion

A. Heisel[1], J. Jung[1], S. Siaplaouras[1], B. Schubert[2], K. Wittke[2], U. Michel[2]. [1]*Innere Medizin III, Universitätskliniken des Saarlandes, Homburg/Saar, Germany;* [2]*Guidant CPI Research, Brussels, Belgium*

Background: To evaluate the influence of peak voltage of different waveforms (WF) used for internal cardioversion (IC) of atrial fibrillation (AF) on defibrillating efficacy and pain perception (PP) we compared a low peak voltage 500 μF, 40% tilt biphasic WF (LV-WF) to a 60 μF, 80% tilt standard peak voltage biphasic WF (SV-WF).

Methods: In 19 patients (pts) with paroxysmal AF the atrial defibrillation threshold (ADFT) for both WF was determined under sedation in a paired randomized order using a step-up protocol. A single lead with one coil in the coronary sinus and the other in the right atrium position was used. After ADFT testing, sedation of the pts was reversed. One shock (S) at ADFT with each WF was given in random order to the conscious pts. When the ADFT was >3 J, PP was determined at 3 J. Pts compared their PP in response to the 2 different WF.

Results: In 1/19 pts AF could not be terminated. In 15/18 pts IC could be achieved at delivered energies < 4 J. The mean values of the delivered energies revealed a reduction from 3.5 ± 3.9 J for the SV-WF to 2.1 ± 2.4 J for the LV-WF ($p < 0.01$). Peak voltage level at ADFT was lower for LV-WF than for SV-WF (100 ± 53 V vs. 290 ± 149 V, $p < 0.01$). Mean duration of the LV-WF at ADFT was longer than the value for SV-WF (16.6 ± 1.2 ms vs. 6.4 ± 0.4 ms, $p < 0.01$). ADFTs were above the pain threshold in 17/18 pts. One pt perceived no pain at all. In another pt the PP testing was terminated because of intolerable pain at 0.5 1 with the LV-WF. Ten out of the remaining 16 pts perceived the LV-WF as more painful. In 8 of these 10 pts the LV-WF was tested after the SV-WF has been applied. Six pts out of 16 perceived the SV-WF as more painful. In all these 6 pts the SV-WF was tested in the 2nd place. The 2nd S was perceived as more painful in 88% of pts independent of the WF used.

Conclusion: ADFT can be significantly reduced at lower peak voltages and longer shock duration by using a 500 μF, 40% tilt biphasic WF instead of a 60 μF, 80% tilt biphasic WF. However, this did not affect PP. PP increases with the number of applied shocks.

P667 Low-energy intracardiac cardioversion of chronic atrial fibrillation by single femoral approach

F. Zardo, F. Antonini-Canterin, M. Brieda, E. Hrovatin, D. Pavan, E. Cervesato, G.L. Nicolosi. *Cardiology Dept. ARC, Pordenone, Italy*

The low energy intracardiac cardioversion of atrial fibrillation is usually performed positioning an electrode in right ventricle, a second one in right appendage (RA), and a third one in the coronary sinus (CS) or in the left branch of pulmonary artery (LPA). The RA-CS configuration is normally preferred, but it is frequently time-consuming requiring a second venous access (subclavian or internal jugular) with additional risk of complications. The aim of this study was to assess the effectiveness of a systematic single femoral venous access, with unselected RA-CS or RA-LPA configuration.

Methods. We studied 40 patients (24 males, 16 females, mean age 64 years) with chronic atrial fibrillation. All patients were treated with a mild sedation (diazepam). These information were collected: 1) acute efficacy; 2) mean energy and impedence required; 3) mean number of shocks needed; 4) mean time required to perform the procedure; 5) level of discomfort related to the intrathoracic shock, 6) incidence of complications.

Results. Twenty patients had RA-CS and 20 RA-LPA electrode configuration for defibrillation. In all patients sinus rhythm was acutely restored. No significant differences were found concerning mean energy and impedance required to obtain cardioversion in RA-CS and RA-LPA groups (10.1 ± 3.0J vs 10.6 ± 3.9 J J and 50.9 ± 10.1 Ohms vs 57.2 ± 10.2 Ohms, respectively, p = ns). Mean number of shocks required was 2.35 ± 1.35 in RA-CS group and 2.30 ± 1.30 in RA-LPA group (p = ns). Mean time required to complete the whole procedure was 42 ± 11 minutes for RA-CS group and 38 ± 8 minutes for RA-LPA group (p = ns). The chest discomfort was minimal or mild in 80% and moderate in 20% without differences in the two groups. No major complications was observed (only one case had a femoral arterovenous fistula, surgically treated).

Conclusion. Low energy intracardiac cardioversion of atrial fibrillation by single femoral approach is safe and effective. The RA-LPA electrode configuration allows restoration of sinus rhythm with the same efficacy as the RA-CS configuration. The systematic single femoral approach with unselected RA-CS or RA-LPA configuration is well-tolerated and it allows to obtain a very short procedure time.

P668 Immediate recurrence of atrial fibrillation following internal DC cardioversion predicts subsequent late recurrence

D.M. Todd, S.P. Fynn, W.J. Hobbs, K. Armstrong, C.J. Garratt. *Manchester Heart Centre, Manchester, UK*

Background: Internal DC cardioversion (ICV) for atrial fibrillation (AF) is highly effective at restoring sinus rhythm (SR), however the recurrence rate is high. Previous reports have suggested that immediate recurrence of atrial fibrillation (IRAF -recurrence of AF within 1 minute of restoring SR) does not predict subsequent late recurrence of AF.

Methods: Fifty-one consecutive patients (40 male, mean age 59 years), undergoing ICV for chronic persistent AF (mean duration 33 months [3–384]) were studied. Patients had all cardioactive medication stopped 3 days before the procedure (except for 2 patients on amiodarone), and cardioactive medication was not recommenced for the duration of the study. Patients were closely monitored for recurrence of AF by Holter monitor and daily trans-telephonic monitoring.

Results: Forty-seven patients had successful ICV and 15 of these patients experienced IRAF (mean of 2 episodes per patient). Patients with IRAF were no different in clinical characteristics to those without IRAF (mean age 58 v 61 years, mean duration AF 29 v 25 months, mean LA size 4.11 v 4.06 cm, all $p > 0.25$). IRAF occurred a mean of 21.6 seconds (range 1–72) following cardioversion. IRAF episodes were treated by further shocks alone (n = 11), flecainide (n = 3) and pacing (n = 1). Of the 15 patients with IRAF 7 left the lab in SR. Subsequent late recurrence of AF occurred in all 7 (100%) of patients with IRAF and in 23 of 37 (62%) of patients without IRAF (p = 0.029).

Conclusions: IRAF is an important predictor of late recurrence of AF. Patients with IRAF are at increased risk of late recurrence of AF and prophylactic antiarrhythmic strategies should be considered in these patients.

P669 A new steerable electrode for internal cardioversion of atrial fibrillation with a solely transfemoral approach

T. Korte, G. Borchert, M. Niehaus, O. Meyer, J. Tebbenjohanns. *Cardiology Dept, Hannover Medical School, Hannover, Germany*

The use of regular electrodes for internal cardioversion of atrial fibrillation is performed by placement of one cardioversion electrode (CE) in the coronary sinus (CS) via the subclavian or internal jugular vein. A solely transfemoral approach to IC is desirable for both chronic AF (cAF) or intermittent AF (iAF) occurring during ablation procedures. The feasibility of a solely transfemoral IC was systematically studied in 30 consecutive patients (Pt) (cAF:15 Pt, iAF:15 Pt, atrial size: 43 ± 6 mm) with the use of a newly designed steerable CE for placement in the CS in combination with a regular CE for placement in the lateral right atrium (RA). A special sheath for CE introduction in the CS was used in case of unsuccessful placement.

Results: In 27 of 30 Pt (90%) the placement of the steerable CE in the CS was feasible, in 3 Pt (10%) CS placement was successfully performed making use of the introduction sheath. A distal CS position was achieved in 21 Pt (70%), a proximal CS position in 9 Pt (30%). The IC to sinus rhythm was possible in all Pt with 12 ± 10 Joules (397 ± 127 Volt, 60 ± 9 Ohm) after 2 ± 1 shock deliveries. The energy needed was not significantly different comparing Pt with cAF and iAF and Pt with proximal and distal position of the steerable CS electrode ($p > 0.05$). Fluoroscopy time was 10 ± 5 min, procedure duration 30 ± 15 min. In 9 Pt (30%) 3 ± 2 AF recurrence were documented in minute 1–3 after IC. In all Pt with iAF ablation was successfully performed after IC. No IC-related complications were seen.

Conclusion: (1) Internal cardioversion of atrial fibrillation with a solely transfemoral approach is feasible and safe making use of a newly designed steerable cardioversion electrode. (2) The transfemoral internal cardioversion is proven to be particularly useful in patients with the onset of atrial fibrillation during ablation procedures.

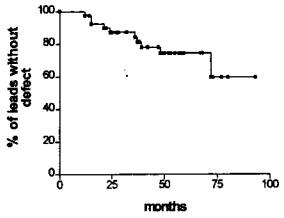
ATRIAL AND VENTRICULAR DEFIBRILLATION

P670 High failure rate among the first Endotak C-leads in patients with implantable defibrillators

C. Mewis, V. Kühlkamp, V. Dörnberger, K. Kettering, L. Seipel. *Department of Cardiology, University Tübingen, Germany*

The Endotak-C lead series was the first lead introduced for transvenous implantation of ICD-systems. The Endotak-C lead is a tripolar lead with a silicone insulation (IN) which used thicker lead body diameters and thinner isolators at the terminals of the anode and cathode proximal to yokes compared with the newer Endotak lead generations. Therefore the goal of this study was to assess the long term performance of this lead system. We included in this analysis 41 patients (pat.) (age: 62 ± 10 years) with ICD and Endotak C leads of the 0060 anf 0070 series. All pat. received an abdominal implant and the leads were inserted in 42% via the left V. cephalica.

Results: The mean follow up (FU) time of all leads was 49 ± 19 months (m) (range: 12–93 m). 10 lead IN failures were detected after a mean FU of 30 ± 19 m. In 8 pat. the sensing electrode near to the generator was affected, 1 IN was broken in between the shock coils and in 1 pat. an IN break of the proximal shock electrode was detected during ICD replacement. 8 pat. received multiple inadequate shock deliveries, in 6 pat. the stored ECG of the device and in 2 pat. impedance-measurements led to the diagnosis of lead failures. The incidence of lead failure was age-dependent but not related to implantation techniques or pat. characteristics.



Conclusion:. Potentially life threatening lead failures occurred due to IN breaks in 24% of the pat. After 5–6 years an incidence of 24% of lead failures which lead to surgical revisions has to be expected. Whether the decreased lead body diameters and increased diameters of IN at the lead terminals in the newer Endotak lead-generation is associated with a better long term performance has yet to be determined. Detailed follow-up visits and regular applications of test shocks are mandatory to detect insulation failures in this type of old lead systems.

P671 Reduction of the defibrillation threshold by half using a novel transvenous technique of epicardial electrode placement

P.R. Roberts, S. Allen, J.F. Urban[1], D.J. Zytkovicz[1], D.E. Euler[1], R.W. Dahl[1], S.J. Crick[2], R.H. Anderson[2], M.J. Kallok[1], J.M. Morgan. *[1]Angeion Corporation, Minneapolis MN, USA; [2]National Heart and Lung Institute, Imperial College School of Medicine, London; Wessex Cardiothoracic Centre, Southampton, UK*

This study aimed to emulate epicardial patch placement using a transvenous approach to placing multiple electrodes on the epicardial surface of the heart in the middle cardiac vein (MCV). Detailed anatomical evaluation of the MCV was performed to elicit its similarities with human anatomy.

Method & Results: In 8 anaesthetised pigs (35–71 kg) an Angeflex™ electrode was advanced via the jugular vein to the right ventricular apex (RV), with the proximal electrode positioned in the superior vena cava (SVC). Three electrodes (length: 2 × 25 mm + 1 × 50 mm) were then placed in branches of the MCV using a novel delivery system incorporating a modified 8F angioplasty guide catheter. Each electrode was deployed via a sheath/stylet that was withdrawn after electrode placement. An active-can electrode (43 cc) was implanted in the left pectoral region. Ventricular fibrillation was induced with 60 Hz AC and rectangular biphasic defibrillation shocks were delivered by an external defibrillator. The DFT was measured using a 4-reversal binary search with 4 different electrode combinations being randomised. The data were analysed using repeated measures ANOVA. Detailed post-mortem anatomical analysis of the MCV was performed using angiography, latex casting and dissection. This demonstrated that the MCV drained into the coronary sinus at a location close to its orifice (2.7 ± 2.2 mm), bifurcating into two main branches that drained the right and left ventricles, the left branch being the dominant vessel in the majority of cases.

Electrode Configuration	RV→Can	MCV + RV →Can	MCV→ Can	RV→ SVC + Can
DFT ± SD (J)	27.3 ± 9.6	11.9 ± 2.9	15.2 ± 4.3	21.8 ± 9.3
P Value (vs RV→Can)		<0.001	<0.001	<0.05
P Value (vs RV→SVC + Can)	<0.05	<0.01	<0.05	

Conclusion: Placement of specialised electrodes within the coronary venous system provides more efficacious defibrillation than conventional electrodes, used either alone or in combination with traditional lead systems.

P672 European long-term experience with a dual-chamber defibrillator

N. Sadoul[1], L.J. Jordaens[2], W. Jung[3], T. Lavergne[4], A. Leenhardt[5], R. Mletzko[6], M. Santini[7], M. Volkmer[8], E. Mouton[9], C. Henry[9]. *On behalf of IDEF01, IDEF02, IDEF03 and IDEF05 Study Group; [1]University Hospital of Nancy; [4]University Hospital Broussais, Paris; [5]University Hospital Lariboisières, Paris; [9]Ela Medical, Le Plessis-Robinson, France; [2]Universitair Ziekenhuis, Ghent, Belgium; [3]University of Bonn; [6]Herz-Kreislauf Klinik, Bevensen; [8]St. Georg Hospital Hamburg, Germany; [7]S. Filippo Neri Hospital, Rome, Italy*

For ICDs, sensitivity is the most important criterion, with the risk of lowering the specificity. Dual chamber (DC) ICDs have a better discrimination between VT and supraventricular tachycardia (SVT) and allow the programming of a lower cut-off rate (COR) without increasing the risk of inadequate therapies.

Methods: We report the first pooled data of 4 clinical studies concerning Defender I & II (Ela Medical, France) ICDs. In total 187 patients (pts) (170 M, LVEF = 38 ± 14%, 62 ± 12 years) were analysed. These pts were implanted for malignant ventricular arrhythmias (42 VF, 112 VT, 25 VT/VF, 5 na). The indication for 67 was sudden cardiac death, for 54 syncopal VT and 66 other. All but 7 pts had cardiopathy. 57 pts had AV block, 30 sinus dysfunction (SND), 24 AV block + SND and 55 pts a previous history of atrial arrhythmias.

Results: The mean follow-up was 13 ± 8 months. 827 spontaneous events were recorded in Tachy zone (with PARAD Algorithm). Slow VT are characterised by a rate ≤ 153 bpm. These slow VTs are not detected with single chamber (SC) ICDs since they are generally programmed with COR ≥ 160 bpm. The overall sensitivity and specificity were 99% and 93% respectively. 4 false negative (FN) occurred in 4 pts, 2 were due to VA crosstalk and spontaneous terminated in less than 50 seconds, the 2 others did not meet the acceleration criteria (1 initiated on a rapid sinus tachycardia (ST) and 1 was below the COR). 31 false positive (FP) were also documented in 11 pts due to ST post shock therapy (1), loss of atrial sensing during exercise ST (2), ventricular bigeminy with stable RR intervals (1), atrial tachycardia after a PVC (1), atrial fibrillation (25) and atrial flutter (1). Only 11 FP were treated by shock in 6 pts. The sensitivity and specificity were 98.4% and 96.5% for spontaneous events detected at rates < 153 bpm and 99.5% and 80.0% for those detected at rates ≥ 153 bpm. The latter parameter would have been 96.8% if PARAD+ (the new detection algorithm) had been used and therefore only 2 fast AF would have been inappropriately detected. Success rate on documented ventricular arrhythmias was 85.6% for ATP. All the ventricular arrhythmias treated by shocks were successfully reverted.

Conclusions: Due to the limitation of SC ICDs, we are used to consider the sensitivity only for fast VTs. Our experience demonstrates that DC ICDs have a high sensitivity, regardless of the VT rate and preserves an overall specificity greater than 92%.

P673 Evaluation of coronary vein availability for placement of pacing and/or defibrillating lead system on the left ventricle

Ch. Butter[1], E. Meisel[2], M. Glikson[3], L. Engelmann[4], B. KenKnight[5], B. Schubert[5], U. Michel[5], D. Pfeiffer[4]. *[1]Virchow Clinic & Berlin Heart Center, Berlin; [2]Heart & Circulation Center, Dresden; [4]University Hospital, Leipzig, Germany; [3]Sheba Medical Center, Tel Hashomer, Israel; [5]Guidant, St. Paul MN, USA; Brussels, Belgium*

Background: The use of a lead inserted tranvenously into a coronary vein residing on the left ventricle has been proposed for CHF pacing therapies. We evaluated the coronary venous system in twenty-eight patients (Pts) receiving an ICD system.

Methods: A balloon occlusion catheter was inserted into the patient's coronary sinus (CS). After balloon inflation contrast media was hand-injected. X-ray images were analyzed to assess the presence, position and course of coronary veins.

Results: The location, size, visibility and course of four major coronary veins identified varied considerably from patient to patient. A prominent anterior interventricular vein (V. interventricularis anterior) was visible in 25/26 (96%) Pts and typically traversed at least half way down the interventricular groove before dividing into numerous smaller branches. A prominent posterior vein (V. posterior ventriculi sinistra) was visible in 18/26 (69%) Pts. Its ostium was seen anywhere from next to the CS ostium to well out onto the left free wall. It typically branched 3–4 cm down the ventricular wall and did not always extend toward the apex. An additional small left marginal (lateral) vein was clearly visible in 30% of x-ray images. A larger diameter middle cardiac vein (V. cordis media) was identified in 90% of venograms due to filling with contrast media via collateral flow. This vein proceeded in a straight path to the apex down the posterior interventricular grove.

Conclusion: This is the first extensive, systematic study of the coronary vein system structure in a patient population that potentially could benefit from using a pacing and/or defibrillating lead residing on the left ventricle. Despite the considerable variability in the presence and location of the coronary veins, an acceptable vessel for lead introduction was always seen. Use of the coronary vein system for CHF pacing and/or defibrillation systems should be feasible.

P674 Method for increased energy field distribution during defibrillation evaluated by catheter mapping

T. O'Buckley, J. Rosborough[1], E. Alt, M. Coenen[1]. *I. Med. Clinic, Klinikum rechts der Isar, Technical University Munich, Germany; [1]Biological Test Facility, Sulzer Intermedics, Angleton, USA*

Purpose: A further reduction in the size of implantable cardic defibrillators can be achieved by decreasing the total energy requirements needed for termination of ventricular fibrillation (VF). Assuming that a minimum energy density is necessary for successful defibrillation, efforts should be made to equalize field distribution across the heart.

Methods: A 3.5 cm standard right ventricular (RV) defibrillation coil was placed in the RV of eight mongrel dogs. Shocks were applied between the coil and a subcutaneous can that was either fully conductive or conductive only along the outer edge (edgeband). An additional subcutaneous ring electrode was placed over the apex of the left ventricle; the ring electrode was connected to the can in parallel for active mode and disconnected for passive. Six treatments were tested: standard can to RV coil; standard can to RV with active and passive ring electrode; edgeband can to RV coil; and edgeband can to RV with active and passive coil. Shocks of increasing voltage from 100 to 600 V were applied during NSR and induced VF for each treatment. Measurements were made at the apex of the left ventricle (LV), the mid-coronary sinus (CS) and the right ventricular outflow tract (RVOT) and recorded via a custom-designed three-dimensional electrical field sensor (EFS) system (Sulzer Intermedics, USA).

Results: Using the EFS system, an electric field of 9.0 ± 11.6 V/cm/100 V was found at the LV apex when using a standard titanium Res-Q can and RV defibrillation coil. The addition of an active subcutaneous ring electrode increased the LV electric field to 13.1 ± 12.8 V/cm/100 V ($p < 0.0001$). Furthermore, by combining the edgeband defibrillator can with the active subcutaneous ring electrode, the electric field of the LV apex was elevated to 14.1 ± 14.2 V/cm/100 V ($p < 0.0001$). The use of the edgeband can alone and in conjuction with the passive ring electrode showed no significant increase in field strength. No significant increases or decreases were noted in the mid-CS or the RVOT during the experiment.

Conclusion: During RV-can defibrillation, there is an inhomogenous electrical field distribution, which can result in a low electric field in the LV apex. By combining the edgeband can and an active subcutaneous ring electrode, a significant increase in the field density of the LV can be brought about without an increase in shock voltage or loss of field strength elsewhere.

P675 Atrial pacing during atrial fibrillation may influence the defibrillation thresholds

A. Capucci, M. Fazzari[1], G.Q. Villani, D. Aschieri, F.F. Tarantino, G.F. Pistis[1], E. Caruzzo[1], S. Grossi[1], L. Sallusti[2], M.F. Piepoli. *Cardiology Dept., Polichirurgico, Piacenza; [1]Cardiology Dept., Mauriziano Hospital, Turin; [2]Guidant-, CPI, Italy*

Synchronization of atrial activation during atrial fibrillation may be related to a lower defibrillation threshold (DFT). We evaluated the effect of a single site right atrial pacing on atrial DFT in patients (pts) with idiopathic paroxysmal atrial fibrillation (PAF)

Methods: Two series of randomized step up internal cardioversion tests, with increasing energy levels from 0.2 to 10 joules, were performed in 10 pts with recurrent episodes of PAF (7 male, 57 ± 12 yrs, LVEF 61 ± 5%). We used a single 6F lead defibrillation system with two defibrillation coils and a proximal sensing ring (ATAK) positioned in high right atrium and coronary sinus; the capture was validated by MAP signal. After induction of sustained AF (>10 min), internal shocks were delivered, preceded or not by at least 20 sec overdrive local atrial pacing, according to a randomized protocol using external cardioverter defibrillator (ECD, 2815 model – CPI).

Results: A total amount of 133 shocks was delivered. There was no significant difference overall in DFT whether or not the overdrive atrial stimulations preceded the cardioversion (3.2 ± 1.8 J vs. 4.9 ± 2.6 J respectively, p = NS). No correlation was found between FF intervals preceding the successful shock and DFT. However analyzing the DFT according to the stability of capture during atrial pacing, a significant reduction was observed in pts with stable capture (SC) in comparison with those with unstable capture (UC) (SC 4 pts 5.2 ± 3.2J vs. 3.0 ± 2.3J, UC 5 pts 3.1 ± 1.7J vs. 3.4 ± 1.6J). In 70%(14/20 successful shocks) the shock discharge was observed to be synchronized to spontaneous or stimulated atrial activation.

Conclusions: In our study a stable atrial capture of pacing during atrial fibrillation is followed by a lower DFT. Whether this approach could lead to a DFT decrease of clinical relevance has to be confirmed.

P676 Comparison of a new 2-lead system with a 3-lead system for atrial defibrillation

C. Timmermans, S. Masset, L.M. Rodriguez, G. Ayers, H. Lambert, A. Nabar[1], H.J.J. Wellens. *Cardiology Dept., Academic Hospital Maastricht, Maastricht; [1]Cardiology Dept., Academic Hospital Maastricht, Maastricht, Netherlands*

For safe and effective low energy defibrillation, an implantable atrial defibrillator (IAD) currently requires a 3-lead system: a right atrial (RA) and a coronary sinus (CS) defibrillation lead and a right ventricle (RV) bipolar lead for R-wave synchronization and post-shock pacing.

Methods: We studied a new 2-lead system consisting of a catheter with bipolar RV electrodes distal and a proximal RA shock electrode array and a CS decapolar defibrillation catheter in 16 pts (14 men, mean age 54 ± 9 year) who underwent cardioversion of atrial fibrillation (AF). For the 3-lead system, a third catheter was added in the RA. AF signal amplitude detection (RA-CS) and AF defibrillation thresholds (ADFT) were compared in each patient using the 2-lead and 3-lead system in a randomized order. ADFT were determined twice for each lead system using a 2 success, 40V step-up protocol.

Results: Successful defibrillation was obtained in all pts with a mean ADFT of 370 ± 112 V(9.3 ± 5.2J) in the 2-lead system and 316 ± 100 V (6.8 ± 4.2J) in the 3-lead system. ADFT in the 2-lead system was significantly higher caompared to the 3-lead system (voltage: $p < 0.05$, energy: <0.05). In contrast, there was an increase in impedance for the 3-lead system (77 ± 16 vs 68 ± 13 ms, $p < 0.05$). The mean RA-CS signal amplitudes were 1.70 ± 0.80 mv during sinus and 0.86 ± 0.17 mV during AF using the 2-lead system and 2.54 ± 1.07 mV during sinus rhythm and 1.59 ± 0.53 mV during AF using the 3-lead system ($p < 0.05$).

Conclusions: The use of a 2-lead system in this configuration is not superior to a 3-lead system regarding AF signal amplitude detection and AF defibrillation threshold. Further study is needed using actual leads in place of the catheters used in this study.

P677 Atrial lead stability and sensing during detection of spontaneous tachyarrhythmias in a dual-chamber ICD

Burkhard Hügl[1], Bruce D. Gunderson, Jeffrey M. Gillberg, Ann M. Pearson, Robert W. Stadler, Walter H. Olson, James H. Baker II[2]. *[1]The Gem DR™ Clinical Worldwide Investigators, Medtronic, Inc., Minneapolis MN; [2]Nashville TN, USA; Leipzig, Germany*

Introduction: Atrial sensing in the Gem DR dual chamber ICD uses auto-adjusting sensitivity with no atrial blanking after ventricular sensed events and 30 ms atrial blanking after ventricular paced events. While this allows maximal sensing of atrial events during atrial tachyarrhythmias, oversensing (OS) of far-field R-waves (FFRW) may occur. The effects of FFRW OS on ICD function are minimized by using pacemaker refractory periods and a FFRW rejection algorithm. The purpose of this study was to evaluate clinically significant atrial undersensing (US) and FFRW OS and to determine the effect of atrial lead placement.

Methods: Patients (pts) implanted with the Gem DR and a bipolar atrial lead (tip-ring spacing = 10 mm) were studied. Spontaneous SVT and VT/VF episodes (n = 1105, 91 pts) stored in the Gem DR were reviewed. The atrial leads were positioned in the right atrial appendage (RAA, n = 51), high right atrium (HRA, n = 21), lateral wall (LW, n = 16) or atrial septum (SEP, n = 3). Episodes were classified into 3 categories: FFRW OS (≥1 beat), atrial US during AF (≥3 beats), and atrial US during non-AF (≥1 beat).

Results: The % of pts with atrial OS and/or US is listed by atrial lead position. Atrial OS was observed in 23% of pts, and resulted in inappropriate VT/VF detection in 5% of pts. Atrial lead position had a significant effect on FFRW OS ($p < 0.05$), with the LW having the lowest incidence (0/16). Atrial US was observed in 13% of pts during AF and in 7% of pts during non-AF rhythm, and resulted in inappropriate detection in 3% of pts. All reported inappropriate VT/VF detections occurred during SVTs that were rapidly conducted into the VT detection zone and were a direct result of atrial US or atrial OS. Atrial lead dislodgements were observed in 5 patients (2 HRA, 1 LW and 2 RAA).

Atrial Sensing	RAA (51)	HRA (21)	LW (16)	SEP (3)	Total (91)
OS, FFRW	14 (27%)	5 (24%)	**0 (0%)**	2 (67%)	21 (23%)
US, AF	5 (10%)	2 (10%)	4 (25%)	1 (33%)	12 (13%)
US, non-AF	2 (4%)	2 (10%)	1 (6%)	1 (33%)	6 (7%)

Conclusion: Bipolar atrial leads placed on the right atrial LW significantly reduce the amount of FFRW OS without causing significant atrial US.

P678 Detection and treatment of slow ventricular tachycardias: a new concept for dual chamber defibrillators

E. Aliot[1], N. Sadoul[1], M. Borggrefe[2], K. Kuck[3], T. Lavergne[4], A. Leenhardt[5], R. Mletzko[6], K. Seidl[7], E. Mouton[8], C. Deniaud[8]. *On behalf of IDEF05, Study Group; [1]University Hospital of Nancy; [4]University Hospital Broussais, Paris; [5]University Hospital Lariboisière, Paris; [8]Ela Medical, Le Plessis-Robinson, France; [2]University Hospital of Münster; [3]St. Georg Hospital Hamburg; [6]Herz-Kreislauf Klinik, Bevensen; [7]Herzzentrum Ludwigshafen, Germany*

Defender dual chamber implantable defibrillator (ICD), with algorithms based on atrial and ventricular detection (PARAD, Ela Medical, France), allows the programming of a lower cut-off rate (COR) to better diagnose slow ventricular tachycardias (VT), therefore increasing the specificity without modifying the sensitivity.

Methods: The IDEF05 study is an ongoing prospective randomised clinical trial performed to evaluate the result of programming COR at 128 or 153 bpm in patients implanted with Defender II (Ela Medical, France). 63 patients (pts) (59 M, LVEF = 40 ± 17%, 63 ± 12 years) were included in IDEF05 and implanted for clinical malignant ventricular arrhythmias (17 VF, 39 VT, 7 VT/VF). 24 pts had AV block or bundle block branch, 7 sinus node dysfunction (SND), 8 AV block + SND and 12 pts a previous history of atrial arrhythmias. In this study we defined slow VT as VT with a rate ≤ 153 bpm.

Results: During a mean follow-up period of 30 weeks ± 14, 244 spontaneous events were recorded, 224 of them in VT zone.

Spontaneous events	Sensitivity %	Specificity %	No. of spont. events
≤153 bpm	97.7 (42/43)	98.5 (133/135)	178
>153 bpm	100 (49/49)	94.1 (16/17)	66

In this series, 1 non sustained slow VT (rate: 128 bpm) was not diagnosed due to VA crosstalk (because of an atrial lead with space between tip and ring > 23 mm). One post shock sinus tachycardia was treated by the device (false positive), as well as one atrial tachycardia treated in VF zone and one episode of ventricular bigeminy. Success rate on documented ventricular arrhythmias was 92.5% for ATP and 100% for shocks.

Conclusions: The first results of this study show that the Defender II can diagnose slow VTs with a high sensitivity and a high specificity. Depending on the slow VTs' tolerance and patient's clinical profile, this new algorithm offers the possibility to detect and treat this type of tachycardia.

P679 Patient alert: clinical experience with a new patient monitoring system in a dual-chamber defibrillator

G.E. O'Hara, M.Y. Rashtian[1], B. Lemke[2], F. Philippon, M. Gilbert, A.M. Brown[3], A.C. Cuijpers[3], J. Koehler[3], B. Soucy[3], A.N.D.T.H.E. Gem DR Worldwide Investigators[3]. *Service de Cardiologie, Institut de Cardiologie/Hôpital Laval, Ste-Foy, Canada; [1]Huntington Memorial Hospital, Passadena, USA; [2]BG Krankenanstaten Bergmannsheil, Bochum, Germany; [3]Medtronic Inc, Minneapolis, USA*

The Patient Alert (PA) feature of the Medtronic Models 7271Gem DR and 7227 Gem ICD notifies the pt that a condition exists in the ICD that may require investigation by the physician. It does so, when turned ON, by emitting an audible sound at the programmed time once a condition(s) is met. Two different alert signals can sound depending upon the condition and programming.

A total of 497 pts were implanted with the Gem DR ICD as part of the worldwide Gem DR study. Of these, 485 (98%) pts had the PA turned on at pre-hospital discharge. PA was later programmed off in 14 (3%) pts due to notification of an alert condition that was not clinically meaningful. At 2 months post-implant, clinicians conducted a telephone interview to ascertain if the PA tone could be heard by the pt as well as the clinician over the telephone, and whether the type of tone could be identified by the pt and clinician. Of the 296 telephone contacts that were completed, there were 291 [98.3%, 95% C.I. (96.1–99.5)] cases where the tone was audible to both the pt and clinician and 286 [96.6%, 95% C.I.(93.8–98.4)] cases where the different tones were identifiable by the pt and clinician. During a mean follow-up of 2.8 months, there were 3 instances where the PA tone was primiraly responsible for identification of a lead dislodgement. In one each, the following was seen: a ventricular lead dislodgement identified by PA for ventricular pacing lead impedance > 2000 ohms, a SVC lead dislodgement identified by PA for the delivery of multiple shocks for the same episode (episode of VF that was successfully terminated but only after delivery of 3 maximum energy shocks), an atrial lead dislodgement identified by PA for atrial pacing lead impedance out of range.

Conclusions: The PA is a useful tool for identification of device functionality between in-office visits. Long term follow-up will further demonstrate the utility of the PA feature.

P680 Evaluation in the electrophysiology laboratory of the performance of a pattern-based dual-chamber (DDD) ICD algorithm

M. Zardini, M. Tritto, C. Tomasi, R. De Ponti, J.A. Salerno. *Mater Domini Clinic, Div. Cardiology, University of Insubria, Castellanza (VA), Italy*

The DDD-ICDs are expected to provide improved detection of supraventricular tachycardias (SVT), but assessment of this benefit may require a long clinical follow-up. We tested the algorithm of one of the newest DDD-ICD on SVTs induced during electrophysiology studies (EPS) and report its efficacy.

Methods: in 46 patients (pts) [24 men, mean age ± SD 46 ± 18 years] undergoing an EPS for SVT [31 pts], ventricular tachycardia (VT) [6 pts] and sincope/palpitations [9 pts], the atrial (A) and ventricular (V) sensing channels of a Medtronic 7271 GEM DR ICD were connected via custom made adaptors to standard EP catheters in the right A and V. All ICD therapies were disabled. SVT detection criteria were all on; VT stability off. Detection (lower rate 500–600 ms) was tested during spontaneous SVTs or induced with premature stimuli and/or isoprenaline. V pacing (VP) at 300–400 ms was performed in 24 cases during atrial fibrillation (AF) or atrial flutter (AFl), to simulate the onset of VT during an ongoing SVT.

Results: 70 SVTs were observed: all the 24 sinus tachycardias, 11 AFl and 13 AF were correctly detected. Overdetection occurred in 5/11 atrial tachycardias, due to a long AV interval, causing detection of VT with long 1:1 VA conduction. VT was detected in 4/9 AVNRT and 2/2 AVRT. Both VT and SVT were correctly detected in all 24 cases of V pacing during SVT. Excluding AVNRT and AVRT, clinically not relevant in ICD pts, the overall accuracy was 91%, with 54/59 SVTs correctly detected.

Conclusions: All SVTs usually responsible for inappropriate ICD therapies were correctly detected by the algorithm tested. Overdetection of SVT with a long AV interval may be possible and requires simple algorithm software adjustments.

P681 Potential pitfalls of a new dual-chamber detection algorithm: implications for patient selection and device programming

C. Wolpert, W. Jung, S. Spehl, R. Schimpf, B. Schumacher, B. Esmailzadeh[1], C. Schneider[1], A. Welz[1], B. Lüderitz. *Depts. of Cardiology; [1]Cardiovascular Surgery, University of Bonn, Bonn, Germany*

Dual-chamber implantable cardioverter-defibrillators include the atrial sensing information into the detection algorithm to discriminate supraventricular from ventricular tachyarrhythmias. However, to dateit has not yet been studied, if ventriculo-atrial sensing can cause arrhythmia misinterpretation in dual-chamber ICDs. A new PR-recognition based algorithm, dividing the RR-intervals into zones of antegrade and retrograde conduction, may harbour the risk of misclassification in the clinical setting of atrial tachycardias with long PR or ventricular tachycardias with long RP intervals. This prospective study was conducted to assess the incidence of inappropriate device detections in order to guide patient selection and device programming.

Patients and Methods: 34 patients (pts) with a Medtronic Jewel AF 7250 were included in the study. A total of 399 supraventricular (SVT) (225) and ventricular (174) tachyarrhythmias. (VT) were used for analysis. Arrhythmia classification was based on atrioventricular stored electrograms and stored RR and PP-intervals.

Results: A total of 12/399 (3%) episodes (E) were falsely classified by the device due to failure of the PR-pattern recognition detection algorithm. 11 sinus tachycardias (ST) with a long PR-interval were misclassified in 2 pts as VT due to the allocation of the atrial signal to the zone of retrograde conduction. One of the two pts had an AV-block I°. The other pt had normal AV-conduction at rest and experienced several shocks during a ST with a PR/RR cycle length ratio < 50% i.e. the limit for antegrade conduction zone in the device algorithm.

Conclusions: 1. The incidence of algorithm failure of the new PR-pattern recognition algorithm in the clinical setting for 1:1 tachycardia is low with 3%. **2.** However, pts with AV-block I° or long PR during sinus tachycardia and overlap of sinus rate and VT rate may receive inappropriate therapies. Thus, AV-nodal conduction should be assessed by exercise test also in pts without AV-block I°.

P682 Influence of anaesthetic agents on the endocardial ventricular defibrillation threshold

T. Chalvidan, J.C. Deharo, F. Bregeon, D. Lambert, M. Balle, J.P. Auffray, P. Djiane. *Cardiology and Anesthesiology Departments, Sainte-Marguerite University Hospital, Marseille, France*

Anesthetic agents are known to interfere with cardiac cellular electrophysiology. We studied the influence on the ventricular defibrillation threshold (DFT) of drugs used for anesthesia or sedation in clinical practice.

Methods: The DFT was assessed in 20 pigs (26.0 ± 1.6 kg) using a right ventricular endocardial defibrillation lead (Endotak-CPI) and a subcutaneous patch-electrode. Ventricular fibrillation (VF) was induced by 50 Hz AC, and the DFT was evaluated using the "3 reversal up and down" method. Acido-basic equilibrium and hemodynamic parameters were maintained constant throughout the procedure. Each animal received Halothane (H) and Propofol (P) in a random order. DFT was evaluated with the first drug and reevaluated with the second drug after complete wash-out. After elimination of the second drug, the DFT was measured under simple sedation by Flunitrazepam (F) as a control situation. This situation was always tested last because of the long elimination half-life of F.

Results: The animals received a mean of 43.9 ± 7.2 shocks per animal. DFT was higher with H than with P or F (12.94 ± 3.04 J versus 12.08 ± 3.09 J and 11.88 ± 3.17 J respectively, $p < 0.05$ both); it was not statistically different with F than with P.

Conclusion: Endocardial ventricular DFT is higher with Halothane than with Propofol or Flunitrazepam. Halothane might be less appropriate for anesthesia when the DFT is evaluated.

P683 VDD for dual chamber ICDs: a new single lead electrode

M. Niehaus, T. Korte, A. Schuchert[1], S. Thamasett[2], D. Pfeiffer[3], R. Belke[4], J. Tebbenjohanns. *Dept. of Cardiology and Angiology, Hannover Medical School, Hannover; [1]Cardiology, University Hospital Eppendorf, Hamburg[2]Cardiology Dept., University, Ulm[3]Cardiology Dept., University Leipzig, Leipzig[4]Biotronik GmbH, Berlin, Germany*

Background: Dual chamber ICD systems use two separate leads for sensing and pacing in the atrium and the ventricle. Complications due to the atrial (A) lead have been reported several times. So we designed and evaluated a new single lead dual chamber VDD-lead for dual chamber ICDs.

Methods: In a German multicenter study we tested a prototype VDD-lead, a single-coil defibrillation electrode with two additional fractally coated rings for bipolar sensing in the atrium. In 28 pts. A. arrhythmias were induced using a bipolar stimulation catheter or an A. screw tip electrode. A. and ventricular (V.) signals were recorded during sinus rhythm (SR), A. flutter (AFLU), A fibrillation (AF) and V tachycardia (VT) or ventricular fibrillation (VF). Terminations of V. arrhythmias were performed by internal DC-shock. The position of the A. sensing rings was in close contact to the lateral A. wall.

Results: In 26 of of 28 pts. (92.8%) the implantation of the electrode in the apex of the right ventricle and the atrial sensing rings at the lateral right-atrial wall was successful. Mean A. pacing threshold was 2.4V/0.5 ms, mean A. impedance was 216 ± 27.7 Ohms. For A. sensing see Tab.1. The mean V. sensing was 13.3 ± 7.1 mV, mean V. impedance was 559 ± 86.3 Ohms. DFT was <20 J. Under the induced arrhythmias the A sensing by the VDD-sensing rings was reliable (Tab. 1).

Table 1. Atrial Sensing of the VDD electrode and reliability of detection by Phylax 06

	SR/SD (mV)	AFlu/SD (mV)	AF/SD (mV)	VF/SD (mV)
Atr. VDD signals	2.6/1.6	1.47/0.59	0.94/0.38	1.42/0.95
Reliability of atrial detection by Phylax	99.7%	86.2%	57.5%	90%

Conclusions: The new designed single lead dual chamber electrode with fractally coated atrial sensing rings provides stable detection of atrial and ventricular signals independent of the induced arrhythmias in the acute clinical experiment. To evaluate the long-term stability of the new electrode further investigations with a chronical implanted VDD-electrode are necessary.

P684 A single centre experience of implantable atrial defibrillators

T.R. Betts, T.J. Edwards, S. Allen, J.M. Morgan. *Wessex Cardiothoracic Centre, Southampton, UK*

Between October 1997 and February 1999 we have implanted atrial defibrillators (Metrix 3020, InControl) in 8 pts (7 male, mean age 57 years). Indications for implant were frequent, symptomatic paroxysms of atrial fibrillation (AF) resistant to drug therapy or persistent AF requiring regular DC cardioversion. Pts chose defibrillator implant rather than AVN ablation and pacemaker implant. Mean follow-up is 8.4 (1–16) months. 2 pts had lead repositioning for high defibrillation thresholds.

7 pts have had documented AF since implant (median 2 episodes/month, range 0–6/month). Not all episodes have been symptomatic (required for pt activation mode). Sinus tachycardia was misinterpreted as AF in one pt (25/27 episodes) but the device algorithms would not allow shock synchronisation. 6/8 pts have undergone shock therapy (median 3 shocks per month, range 1–8) which successfully cardioverted AF in 70% of episodes (47% of shocks delivered). A single shock was required in 36% of cases, multiple shocks (± additional drug therapy) in 64%. 2 pts have suffered early recurrence of AF after every shock (i.e. within 60 seconds). In 2 pts the device was unable to administer shock therapy as the ventricular rate was too rapid. Additional drug therapy was required to slow the heart rate. No pt has shown a reduction in frequency of AF episodes since implant. No pt has inappropriately self-administered shock therapy. No complications have occurred from shock therapy. 2 pts who have had successful cardioversion of AF have had symptomatic paroxysmal atrial flutter (not previously documented).

Although these devices accurately identified AF, frequent shock therapy resulted in sustained sinus rhythm in only a minority of pts. Further follow-up will evaluate the long-term efficacy of these devices in the treatment and prevention of AF.

P685 Multicenter experience with a new dual-chamber defibrillator

W. Jung, C. Wolpert, C. Henry, S. Spehl, B. Esmailzadeh[1], B. Schumacher, T. Lewalter, R. Schimpf, A. Welz[1], B. Lüderitz. *For the Defender Investigator Group; Depts. of Cardiology; [1]Cardiovascular Surgery, University of Bonn, Bonn, Germany*

The high incidence of inappropriate therapy due to supraventricular tachycardias (SVTs) is a major challenge and has been reported to affect up to 25% of patients with implantable cardioverter-defibrillators (ICDs). In a multicenter clinical study, the sensitivity and specificity of the dual-chamber ICD (Defender, ELA Medical, France) was evaluated in 128 patients (pts). The new algorithm (PARAD) is based on the following criteria: rate, RR interval stability, atrioventricular (AV) relation analysis and atrial or ventricular acceleration in case of 1:1 AV relation.

Results: During a follow-up of 16 ± 9 months (range 1–41 months), a total of 1048 spontaneous episodes were recorded in 87 pts and classified by the device as ventricular fibrillation (VF, n = 63), ventricular tachycardia (VT, n = 512), SVT (n = 465), or undetermined (n = 8). Stored data was reviewed by independent investigators. In 15 pts, 45 episodes of atrial fibrillation with a stable ventricular rate and 2 episodes of sinus tachycardia due to loss of atrial sensing during exercise were inappropriately detected as VT. In 6 pts, 4 VTs were detected just below the programmed VT cut-off rate and 3 episodes of irregular VT were classified as SVTs. All of the irregular VTs were <12 s in duration. In 4 pts, 6 VT episodes did not meet the ventricular acceleration criterion. This resulted in a specificity of 87% and in an overall sensitivity for all detected VTs/VFs of 98%. Success rates were 81% for antitachycardia pacing and 92% or 95% for the first shock therapy for the VT or VF episodes, respectively. 13 deaths were reported: 3 arrhythmic, 8 non-arrhythmic, and 2 non cardiac deaths.

Conclusions: Dual-chamber ICDs provide equivalent efficacy and safety rates compared to single-chamber ICDs. With the new PARAD algorithm based on analysis of atrial and ventricular signals, dis-crimination of ventricular from supraventricular tachycardia is achieved with a specificity of 87% and with a sensitivity of 98% for all ventricular tachyarrhythmias.

P686 Long-term efficacy of ablation procedures in ICD patients with multiple inappropriate shocks

T. Korte, M. Niehaus, O. Meyer, J. Tebbenjohanns. *Cardiology Dept, Hannover Medical School, Hannover, Germany*

Multiple consecutive shocks due to drug-refractory rapid atrial fibrillation (rAF) and atrial flutter type I (AFL) remain an unsolved problem in defibrillator therapy. This is the first systematic, prospective study of the efficacy of radiofrequency (RF) modification/ablation of the AV node in 12 consecutive patients (pts) with rAF and RF isthmus block in 6 pts with AFL (CAD: 65%, EF: 35 ± 10%, NYHA III-IV: 100%) causing 34 ± 17 (14–104) shocks (15 ± 10 shocks/6 months) during a follow-up of 45 ± 25 months.

Results: Modification of the AV node was successfully performed in 10 of 12 pts (83%) with rAF after 4.5 ± 3.3 RF applications and a significant mean/maximum ventricular rate reduction of 30/32% in holter recording, respectively. In the remaining 2 pts (17%) AV node ablation was performed in a second procedure. A complete isthmus block was achieved in 5 of 6 pts (83%) and a unidirectional block in 1 pt (17%) with AFL after 8.7 ± 5.5 RF applications. During a follow-up of 15 ± 6 months none of the 18 pts had recurrences of inappropriate shocks for the index supraventricular arrhythmia ($p < 0.01$ versus before ablation procedure). NYHA classification and ejection fraction were unchanged in the pts with AV node modification/ablation after 3 months ($p > 0.05$, respectively).

Conclusion: 1. RF catheter modification/ablation of the AV node for rAF and RF isthmus block for AFL type I are demonstrated to be highly effective in ICD pts with drug refractory multiple inappropriate shocks. 2. In pts with rAF RF ablation of the AV node should only be performed after RF modification without sufficient drop in heart rate. 3. Left ventricular function and NYHA classification are not effected after AV node modification/ablation in ICD pts with severe chronic heart failure.

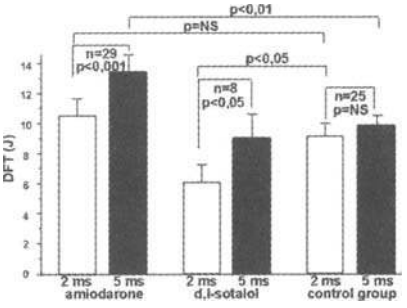
P687 Effects of antiarrhythmic drugs on defibrillation threshold applying biphasic shock in humans

B. Merkely, A. Lubinski[1], O. Kiss, L. Geller, T. Gyongy, E. Lewicka-Nowak[1], F. Horkay, G. Swiatecka[1], J. Pilz[2], M. Schaldach[2]. *Dept. of Cardiovascular Surgery, Semmelweis Medical University, Budapest, Hungary; [1]University, Gdansk, Poland[2]University, Erlangen-Nürnberg, Germany*

Background: The biphasic waveform and antiarrhythmic drugs are known to influence defibrillation efficacy. However, the optimal biphasic waveform for 2nd phase duration has not been clarified yet in man.

Methods: In a multicenter, randomised and prospective study, the defibrillation efficacy of 2 msec vs. 5 msec 2nd phase duration of biphasic pulses using two 100 μF capacitors was compared in 62 patients (age: 54 ± 13 years, male: 74%, CAD: 60%, DCM: 19%, EF: 43 ± 17%, amiodarone: 47%, d,l sotalol 13%) with a unipolar pectoral transvenous defibrillation system (RV-E vs. can; fractally coated SPS-lead vs. Phylax 06 or XM active housing, BIOTRONIK). The 1st phase parameters for both biphasic waveforms were as follows: charging voltage 100%, switching voltage 40%. Defibrillation threshold (DFT) was determined in a random order with either 2 msec or 5 msec second phase tested first during ICD implantation.

Results: significant difference was found in stored energy at DFT between 2 msec and 5 msec 2nd phase duration pulse form (9.5 ± 0.6 vs. 11.3 ± 0.7 p < 0.01). In subgroup analysis in patients treated with class III drugs, such as amiodarone or d,l sotalol, there was a markedly significant difference between DFTs with shocks of longer or shorter 2nd phases, but in the control group there was no difference (figure).

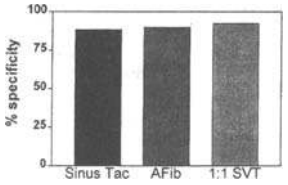


Conclusions: chronic amiodarone treatment increases DFT using biphasic shock only with the longer second phase duration. In patients treated with class III drugs DFT is significantly lower with shorter second phase duration.

P688 Single center experience with a dual-chamber detection algorithm

Volker Kühlkamp, Volker Dörnberger, Ralf Suchalla, Ralph Bosch, Christian Mewis, Ludger Seipel. *Medical Department III, University of Tübingen, Germany*

Non specificity of detection is one of the major shortcomings of therapy with an implantable defibrillator (ICD). Theoretically the disadvantages of single chamber detection can be overcome if additional atrial information is added to a detection algorithm. 53 consecutive patients (60 ± 14 years, 57% coronary artery disease, left ventricular ejection fraction 37 ± 14%) received the Medtronic 7271 GEM DR, an ICD with dual chamber detection. ICD's were programmed to a tachycardia detection interval of 500 ms and an supraventricular tachyarrhythmias (SVT) limit of 240 ms: During a median follow up of 207 days a total of 600 episodes with a stored electrogram occurred. 113 episodes of ventricular tachycardia or ventricular fibrillation, all classified by the device as ventricular tachyarrhythmia. In the SVT zone 484 SVT's were recorded, 429 classified as SVT by the device (specificity 88.6%). 89.8% (n = 49) of atrial fibrillation (AFib) episodes in 6 patients were identified by the device as AFib. Mean atrial rate during AFib was 356 ± 93/min, mean ventricular rate was 185 ± 38/min. In 361 out of 409 episodes (88.3%) of sinus tachycardia therapy was withhold (14 patients). In 5 patients 26 episodes of atrial tachycardia occurred, all but 2 classified as SVT (92.3%).



Conclusion: Sensitivity for VT detection was 100%. With the use of the detection algorithm in the GEM DR 88.6% of SVT's were classified as SVT. Sinus tachycardia with long PR-interval was frequently miss classified as VT with retrograde conduction.

P689 Detection of myocardial ischaemia is possible using implantable defibrillators

M. Brunner, T.W. Baron, A. Grom, M. Zehender. *Innere Medizin III, Kardiologie, Universitätsklinik Freiburg, Germany*

Implantable defibrillators (ICDs) provide a unique opportunity to register continuous intra-thoracic ECGs (IT-ECG). For IT-ECG the defibrillation-coil in the right ventricle and the superior vena cava, and the can of the ICD are used for bipolar leads. With these triangular electrodes an IT-ECG similar to the standard ECG (SECG) leads I, II, III, aVR, aVL, aVF can be recorded.

Patients and Methods: In a prospective PTCA-study we first investigated the presence of ischemic ST-segment changes in comparison to 12-lead SECG. In 22pts we recorded IT-ECGs and SECG in 27 PTCAs, an IT-ECG was shown to be more senstive to ischemic ST-changes than SECG during PTCA. In a subsequent study in 5 pts with residual ischemia SECG and IT-ECG were analyzed during and after 10 episodes of ischemia induced by 16.0 sec (± 4.6) of ventricular fibrillation (VF) while testing the defibrillation threshold during ICD-implantation. ECGs were recorded using a high resolution digitizer.

Results: After VF and ICD-shock, ST-deviations (STD) were present in all IT-ECG leads and were more pronounced than in SECG: post-Shock STD for all leads of IT-ECG was (max/mean/std.dev): 1.2/0.3/0.33 mV and in SECG 0.4/0.04/0.08 mV. After 2 min STD > 0.1 mV was observed in one or more leads in 1 of 10 episodes in SECG but in 10 of 10 IT-ECGs.

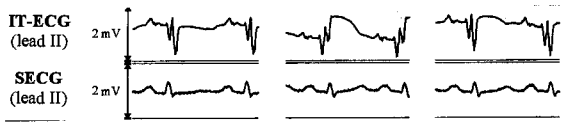


Figure 1 demonstrates lead II on the SECG and IT-ECG before, immediately after and 4 min after ICD shock for VF.

Conclusion: IT-ECG can be recorded with standard electrodes and only minor changes in defibrillator design. IT-ECG is superior to SECG in assessing ST-segment changes independent from the underlying cause and may provide a reliable method to monitor myocardial ischemia.

P690 Reduction in defibrillation threshold using an auxiliary shock delivered in the middle cardiac vein: a comparison of configurations incorporating the superior vena cava and an active pectoral can

P.R. Roberts, J.F. Urban[1], A.C. Dietz[1], D.E. Euler[1], T.A. Whitman[1], M.J. Kallok[1], J.M. Morgan. *[1]Angeion Corporation, Minneapolis MN, USA; Wessex Cardiothoracic Centre, Southampton, UK*

A low amplitude auxiliary shock (AS) from an electrode sutured to the left ventricle at thoracotomy has previously been shown to reduce defibrillation threshold (DFT) if delivered immediately prior to a conventional biphasic shock delivered between electrodes in the right ventricle (RV) and superior vena cava (SVC). This study investigates the effect of delivering an AS from a lead system deployed transvenously in the middle cardiac vein (MCV).

Method and Results: An Angeflex® electrode was positioned in the RV in 8 anaesthetised pigs (35–43 kg) with its proximal electrode in the SVC. A 50 × 1.8 mm electrode was inserted in the MCV through a modified 8Fr angioplasty guide catheter. A monophasic AS of 150 V leading edge was delivered from a 95 μF capacitor. A Sentinel® (95 μF capacitor, phase 1: 44% tilt, 1.6 ms extension and phase 2: 2.5 ms fixed duration) primary biphasic shock (PS) was delivered from RV → Can/SVC ± AS delivered from MCV → Can/SVC with three differing pulse widths (3, 5, 7 ms). The six configurations were randomised and DFTs (PS + AS) assessed using a modified 4-reversal binary search. Ventricular fibrillation was induced with 60 Hz AC followed 10s later by the test shock. The DFTs were compared using repeated measures analysis of variance (ANOVA).

PS	RV→Can				RV→SVC	
AS	MCV→Can				MCV→SVC	
	No AS	3 ms	5 ms	7 ms	No AS	5 ms
Mean DFT (J)	13.8	11.0*	11.5*	10.6*	14.3	11.9**
S.D. (J)	7.4	5.4	6.0	5.3	4.5	4.4

* = $p < 0.05$ (compared to No AS, RV→Can) ** = $p > 0.05$ (compared to No AS, RV→SVC)

Conclusion: Delivering an AS from a transvenous lead system deployed in the MCV reduces the DFT by 23% compared to a conventional RV→Can shock alone. Delivering an AS produced a non-significant reduction in DFT.

P691 The reliability of the electrogram width criterion in implanted cardioverter defibrillators depends on changes of the body position

R. Leuenberger, H. Tanner, A. Kruse, J. Fuhrer. *Cardiology, University Hospital, Berne, Switzerland*

Background: In some implanted cardioverter defibrillators (ICD) the electrogram (EGM) width criterion is a feature discriminating supraventricular from ventricular tachyarrhythmias. We report a case whose change of body position led to a widening of the EGM analysed by the ICD. The patient's sinus-tachycardia was detected as ventricular tachycardia, leading to antitachycardia pacing and finally inducing ventricular fibrillation. As a consequence, we studied prospectively the reliability of the EGM width criterion depending from changes of the body position.

Methods: In 15 patients with ICDs (PCD 7223, Medtronic) and narrow QRS in the surface ECG, the EGM width criterion was programmed following the recommendations of the manufacturer analysing 50 consecutive complexes in the EGM sources HVA/HVB, HVA/P+, and P−/HVB, respectively, in supine position. The correct classification of the measured EGM in narrow and wide complexes was assessed using the surface ECG. The results were controlled in sitting position.

Results: In 10 of 15 patients (67%) in the supine position correctly as narrow classified EGMs were misclassified as wide in the sitting position. In none of the three EGM sources the dependence on body position was significantly different (misclassification rates in 30%, 50%, and 50% of patients in HVA/HVB, HVA/P+, and P−/HVB, respectively). No correct classification was achieved neither by programming the EGM width criterion first in the sitting position with control in the supine position, nor by repeating the complete protocol with the next higher slew treshold.

Conclusions: The EGM width criterion strongly depends on body position. To avoid potentially lethal complications, programming of the EGM feature requires an accurate examination with the patient's body in different positions.

P692 Far-field R-wave oversensing in a new dual-chamber-defibrillator: incidence and influence on device detection performance

C. Wolpert, W. Jung, S. Spehl, R. Schimpf, B. Schumacher, C. Schneider[1], B. Esmailzadeh[1], A. Welz[1], B. Lüderitz. *Depts. of Cardiology; [1]Cardiovascular Surgery, University of Bonn, Bonn, Germany*

R-wave far-field oversensing could be observed in dual-chamber pacemaker systems. Little is known on the incidence of far-field R-wave sensing in modern dual-chamber implantable defibrillators (ICD). Multiple counting of R-waves in ICD-patients can in contrary to pacemaker patients induce atrial therapies and in the worst case inhibit ventricular therapies by mimicking a supraventricular rhythm with fast rapid conduction. Aim of this prospective study was, to assess the incidence of R-wave far-field oversensing and its influence on device detection.

Patients and Methods: 27 patients were implanted a Jewel 7250 AMD (Medtronic Inc.). All patients received a common right ventricular lead in the right ventricular apex and an *atrial* pace/sense or pace/sense/shock lead.

Results: The atrial lead was located in the right atrial appendage (RAA) in 19 patients, right lateral free wall (RFW) in 4 patients and the high right atrium (HRA) in 4 patients. R-wave oversensing occurred in 3/19 patients with the lead in the RAA, one patient in RFW and one patient in the HRA. In all but one patient, who experienced an inappropriate atrial shock therapy for R-wave oversensing due to multiple counting in the atrial channel, oversensing could be eliminated by decreasing atrial sensitivity from 0.3 to 0.45 or 0.6 mV. In the patient with the inappropriate shock oversensing was not further seen at 0.9 mV sensitivity.

Conclusions: 1. R-wave far-field oversensing occurs frequently in 5/27 patients. 2. It appears independently from the location of the atrial lead. 3. It is recommended to test all patients accurately for R-wave far-field oversensing, because it has potential proarrhythmic effect and may inhibit ventricular tachycardia detection in the worst case scenario. 4. Of note, if detected, R wave oversensing can be abolished in all patients by decreasing atrial sensitivity.

P693 Morphology discriminator algorithm for improved tachycardia discrimination in implantable cardioverter-defibrillators

F. Duru, D. Radicke, M. Schönbeck, T.F. Lüscher, R. Candinas. *Cardiology Dept, University Hospital Zurich, Zurich, Switzerland*

Background: The Morphology Discriminator (MD) feature is a recently introduced, dynamic electrogram template matching algorithm in implantable cardioverter-defibrillators (ICD) that aims to improve the discrimination of supraventricular tachycardia (SVT) from ventricular tachycardia (VT). We aimed to evaluate the performance of this algorithm during spontaneous tachyarrhythmias and exercise-induced sinus tachycardia.

Method: 16 pts (14 M; 55 ± 6 yrs) with Ventritex Contour MD/Angstrom MD devices were studied. Prior to discharge, morphology templates were acquired during sinus rhythm and activated if similarity scores were consistently greater than 90%, indicating a good match to the baseline. Matching threshold was set to 60%. Stability of the acquired template and performance of the algorithm during spontaneous tachyarrhythmias were evaluated during follow-up. A chronotropic assessment treadmill test was also performed along with telemetric monitoring of matching scores.

Results: Variations in electrogram morphology necessitated new template acquisition in 5 pts (31%) at first follow-up visit (6–8 weeks post-implant). 14 spontaneous SVT episodes in 8 pts and 4 spontaneous VT episodes in 3 patients were appropriately discriminated by the MD feature during follow-up. A common observation was post-shock changes in electrogram morphology that resulted in transient mismatch with the template. Exercise testing showed appropriate discrimination of sinus tachycardia in 12/13 pts (92%). Minimum observed matching scores were 90% in 2 pts, 85% in 2 pts, 75% in 4 pts, 70% in 2 pts, 65% in 2 pts and <60% in 1 pt.

Conclusion: The recently introduced MD feature in ICDs improves discrimination of SVT from VT. Programming the matching threshold to 60% may avoid inappropriate VT confirmation during sinus tachycardia in most pts. Variations of electrogram morphology over time may be a concern, especially during the maturation of the electrode.

P694 Implantable cardioverter/defibrillators: lead-related complications in 340 patients over a period of 7 years

Harald Schwacke, Axel Drögemüller, Gregor Siemon, Monika Rameken, Jochen Senges, Karlheinz Seidl. *Herzzentrum Ludwigshafen, Ludwigshafen, Germany*

Aim of this study was to evaluate the rate of lead-related complications (LRC) in 340 consecutive patients (pts) with an implantable cardioverter/defibrillator (ICD).

Methods: From 2/91 to 5/98 340 pts had an ICD implanted. Mean age was 64 ± 9 years, ejection fraction 38 ± 14%, 82% of pts were male, 60% had coronary artery disease, 31% dilative cardiomyopathy, 9% others. Indication for an ICD was in 57% of pts ventricular tachycardia and in 43% ventricular fibrillation. 93% of pts received a single-chamber ICD and 7% a dual-chamber ICD. In 8% of pts an additional patch or array electrode was implanted. In 27% implantation site was abdominal, in 73% pectoral.

Results: During 7 years overall 38 LRC occurred (9.7%), after a median of 2 months after implantation. Diagnosis was made by routine chest x-ray in about 55% of LRC, by clinical presentation (inadequate therapy, pain) in 24% and by electrical parameters in 21%. In pts with abdominal implantation site LRC occurred in 20% in contrast to 6% in pts with pectoral implantation site ($p < 0.0001$). Regarding pts with pectoral implantation site LRC were observed in 12% of pts with a dual-chamber ICD vs 4% with a single-chamber ICD ($p = 0.05$) due to dislocation of atrial electrodes with dual-chamber ICD. There were no differences in clinical parameters between pts with pectoral vs abdominal and between single vs dual-chamber ICD.

Conclusions: 1. In ICD pts with abdominal implantation site LRC were three times as frequent as in pts with pectoral implantation site. 2. Regarding pts with pectoral implantation site LRC occurred three times as frequent as in pts with dual-chamber than in pts with single-chamber ICD.

P695 Optimized programming in patients with implantable cardioverter-defibrillator and atrial fibrillation

C. Unterberg, A. Wieckhorst[1], A.B. Buchwald. *[1]Dep. of Cardiology, University of Göttingen; Dept. of Cardiology, University Clinic of Kiel, Germany*

Differentiation of supra- (SVT) versus ventricular (VT) tachycardias is a problem to avoid inadequate therapies in patients (Pts) with cardioverter-defibrillator (ICD). Therefore, detection criteria such as onset (0), stability (ST) and QRS-width may be used to differentiate. The sustained rate duration (SRD) initiates the programmed therapy at a present tachycardia in spite of ST or 0, that are not fulfilled after a programmed time and represents a safety criterion. The aim of the study was to evaluate if the SRD is useful in Pts with atrial fibrillation (AF) and to assess an optimal progamming.

Results: In 292 Pts with ICD of the third generation, 44 Pts (15%) had AF (36 Pts CAD, 8 Pts DCM, LVEF 36 ± 18%); 18 Pts had known tachyarrhythmic episodes (TAE) in range of the programmed VT-zone (>160 bpm); in 15 Pts a new TAE was observed; and 11 Pts had normofrequent AF. After a mean follow up of 12 ± 11 months, 172 tachycardias were observed in 34 of these 44 Pts (77%). The tachycardias could be classified as SVTs by stored electrograms of the device (in all cases stored electrograms of the known VT were available). ST (22–26 msec) was fulfilled in 16 pts (36%) and they were treated inadequate with antitachycardia pacing (ATP) in 7 Pts (16%) and with ATP and consecutive shocks (CS) in 9 (20%) Pts. In 18 Pts of the 44 Pts (41%) ST was not fulfilled at a present ongoing TAE (39 episodes) and the SRD-criterion initiated the therapy: these Pts were treated inadequately with ATP in 7 (16%) Pts and with ATP and CS in 11 pts (25%). The mean programmed SRD was 25 sec in all Pts. After the first inadequate therapy (IAT) SRD was prolonged to a mean value of 85 sec and after recurrence of a IAT at TAE up to a mean of 195 sec (150–300 msec).

Conclusion: In our ICD-collective of 292 Pts AF occurs in 15% (44 pts). In these 44 Pts, TAE were observed and treated inadequately in 77%, and released by SRD in 41%. The primary programming of SRD should be long (>90 sec) in Pts with known TAE as wells as in Pts with normofrequent AF who can hemodynamically tolerate the cycle length of the programmed zone with SRD as additional feature.

P696 Heart rate variability in patients with thalassemia major: association with clinical and echocardiographic features

L. Antoniades, K. Simamonian, M. Ioannides, V. Panagopoulos, D. Faitatziades, D. Petrondas, C. Zambartas. *Department of Cardiology, Nicosia, Cyprus General Hospital*

Cardiac arrhythmias and heart failure are the main cause of death in patients with Thalassemia Major (TM). Impaired sympathovagal balance might contribute to the genesis of arrhythmic events in these patients. Heart rate variability (HRV) is an accepted tool for the assessment of cardiovascular autonomic tone. The aim of this study was to evaluate cardiac autonomic control in patients with TM and to assess indexes of HRV in relation to clinical and echocardiographic data of TM patients.

Methods: We studied 40 patients with TM, 20 men and 20 women, age ranging between 17–40 years (mean age 27 ± 6 years). All patients were in synus rhythm. Patients with clinical evidence of heart failure, suffering from diabetes melitus and on chronic therapy with beta blockers were excluded from this study. Ambulatory 24 hour ECG recordings were analyzed. After standard holter analysis the following time domain measures of HRV were obtained: Percentage of cycles differing from preceding one by >50 ms for entire 24-hour recording (pNN50), Standard deviation of normal RR intervals (SDNN), Root mean square of successive differences of R-R intervals (RMSSD). In this study pNN50 and PMSSD time domain measures considered to represent the parasympathetic modulation of HRV. Forty healthy volunteers, 20 men and 20 women, (mean age 26 ± 5 years) not taking any medication, were used as control group.

Results: Values of pNN50, SDNN and RMSSD were lower in patients with TM than in control group. pNN50 was 8.0 ± 7.0% in patients with TM and 18.2 ± 9.7% in normal subjects ($p < 0.001$) SDNN was 116.0 ± 28.7 ms in patients with TM and 154.9 ± 40.9 ms in the control group ($p < 0.001$). RMSSD was found 28.4 ± 10.8 ms in TM compare to 42.8 ± 13.3 ms in normal subjects ($p < 0.001$). The same significantly statistical diferences were found between the two groups according to sex. The relationship between the above dependent variables of time domain measures of HRV and the independent variables of clinical and echo measurements (Compliance to chelation therapy, endiastolic diameter of left ventricle, L.V. Mass on M-Mode Echo) using multiple regression and correlation analysis, showed that pNN50 and RMSSD, which represent the vagal control, were found directly related to the compliance to chelation therapy ($p < 0.005$) and inversely related to LVMass ($p < 0.05$).

Conclusions: Measures of vagal modulation of HRV were lower in TM patients than in control subjects indicating cardiac autonomic dysfunction and decreased parasympathetic activity in patients with TM. We hypothesize that this deminished parasympathetic activity may be responsible (with other factors) for the electrical instability and the pathogenesis of arrhythmias in patients with TM and may be an important index for risk stratification of these patients.

P697 Prevalence of baroreflex heart rate reaction for the detection of autonomic nervous system impairement at insuline resistance syndrome

D. Voita, V. Mackevics[1], A. Vitols. *Latvia Institute of Cardiology; [1]Latvia Academy of Medicine, Riga, Latvia*

We aimed to compare the sensitivity of baroreceptor (BR) cardiac reflex and heart rate (HR) variability analysis for an early detection of autonomic nervous system impairement in non-insulin dependent diabetus mellitus (NIDM).

Methods: on 15 pts with NIDM (men, 63 ± 1.8 yr aged, HbA_{1C} 10.1 ± 0.9%, ranged from 8.7 to 11.2%, with time of manifestation syndrome 9 ± 1.5 yrs) and 19 controls (C, gender and age matched), beat-to-beat HR, finger mean arterial pressure (MAP) were monitored before and during BR reflex activation by neck suction (−60 mmHg, for 5 s) and 512 R-R (ECG) interval files in supine and upright postures were stored, analysing mean R-R interval, its standard deviation (SD), total power spectrum, power of the low (LF, 0.04–0.15 Hz) and high-frequency (HF, 0.15–0.4 Hz) bands and LF:HF ratio. All medications with the exception of hypoglycemic agents were discontinuated 2 weeks before the study. Values are expressed as means ± standard error.

Results: for sitting NIDM pts, the HR (80 ± 2 vs 70 ± 3 bpm; $P < 0.05$) and finger MAP (113 ± 2.7 vs 90 ± 1.4 mmHg; $P < 0.05$) were increased, but BR reflex bradycardic reaction (1.8 ± 0.3 vs. 10 ± 0.6 bpm, $P < 0.02$) was reduced comparing to C. In supine position, mean R-R interval (772 ± 25 vs. 1017 ± 28 ms; $P < 0.001$) and its standard deviation (27 ± 2.5 vs. 54 ± 5.3 ms; $p < 0.001$) as well as R-R interval decrease in upright position (108 ± 12 vs 254 ± 21 ms; $P < 0.001$) were less in NIDM pts. than in C, but LF, HF and LF:HF ratio (1.07 ± 0.2 vs. 1.33 ± 0.21) values and LF:HF ratio increase failure in upright position ($\chi^2 = 3.2$), didn't reveal to be significant.

Conclusions: For NIDM patients, BR reflex bradycardic reaction is superior to HR variability analysis to ascertain an early impairment of cardiovascular neuropathy.

P698 Haemodynamical specfics in essiential hypertensive patients with various degree of left ventricular hypertrophy

Abdul Qawir Khan. *Ukrainian Scientific Research institute of cardiology , Ukraine*

Aim: To assess the haemodynamic indicies in essential hyper ten sive (EHTN) pts in dependence of left ventriculer mass (LVM)

Methods: Echo cardiography (Echo) Radionuclide ventriculography (RVG)

Eighty four (84) EHTN Pts with II stage (WHO) and 20 healthy persons as control group, all with average age of 44.3 ± 0.8 years, were examined

Results: LVH was diagnosed when left ventricular mass index (LVMI) was greater them 131 gm/m^2 in males and greater them 108 gm/m^2 in females. Pts were divided into three groups according of the LVM Indicies of structural and functional status of myocardium in EHTN pts with various degree of LVH

Groups	LVMI	ΔP	BPs	BPd	SVR 5 dyn.cm.m^2
Healthy persons (n = 20)	85 ± 3	0.38	56.4 ± 4.0	78 ± 2	1145 ± 56
Pts with normal LVM. (n = 36)	106 ± 2	0.40	71.6 ± 3.9	102 ± 2	1980 ± 105
Pts with Mild LVH (n = 37)	149 ± 3	0.43	85.6 ± 8.9	105 ± 3	2165 ± 126
pts with Severe LVH (n = 11)	189 ± 19	0.45	88.1 ± 8.4	113 ± 9	2394 ± 133

LVMI correlated with systolic and diastolic blood pressure (BPs BPd) relative well thickness (ΔP) was directly proportional to BP. End systolic tension (EST) was directly proportional to LVH. ΔP was directly proportional to systemic vascular resistance (SVR)

Conclusion: the haemodynamic determinants of left ventricular hyper trophy are blood pressure and systemic vascular resistance and systolic tension.

DUAL-CHAMBER IMPLANTABLE DEFIBRILLATORS

699 Worldwide clinical experience with a dual-chamber implantable cardioverter defibrillator in patients with atrial fibrillation and flutter

Neil Sulke, Steven J. Bailin, Charles D. Swerdlow. *For the Worldwide 7250 Jewel AF-Only Investigators; Cardiology Eastbourne District General Hospital, Eastbourne, UK*

Atrial tachycardia (AT) and fibrillation (AF) as well as ventricular tachycardia (VT) and fibrillation (VF) can be discriminated by the Medtronic 7250 Jewel® AF dual chamber ICD based on the rate and regularity of the atrial rhythm. Programmable atrial therapies include antitachycardia pacing (ATP), 50 Hz burst pacing, and shocks.

Methods: In a multi-center study, we analyzed detection and therapy of spontaneous arrhythmias in patients with symptomatic AT/AF and no prior VT/VF.

Results: There were 51 patients (37 US and 14 Europe), left-ventricular ejection fraction: 55% ± 16%, left atrial dimension: 43 mm ± 9 mm. 35% of the patients were in NYHA Class II or III. During follow-up (averae 3.2 ± 2.5 months) a total of 156 spontaneous AT and 206 AF episodes were detected in 13 and 28 patients, respectively. The table shows the efficacy of the last programmed therapy for treated episodes:

Therapy	AT	AF
ATP	33/37 (89%)	Not applicable
50 Hz Burst	22/95 (23%)	22/55 (40%)
Atrial Shock	24/24 (100%)	139/151 (92%)

Of 151 spontaneous AF episodes treated with shocks, 43/44 were successfully treated by 9 patients themselves using the patient activator (Model 9464). One patient with structural heart disease had 2 double-tachycardia episodes (VF + AF) that were treated successfully by two 27 J shocks. One of 2 patients, who were not known to have a prior history of VT and/or VF, did receive successful therapy for a spontaneous VF episode. There were 28 clinical adverse events of which 5 required surgery.

Conclusion: 1) Painless therapies successfully terminated 41% of AT episodes. 2) AF shock efficacy is 92%. 3) Observed adverse clinical events are comparable to those observed with dual chamber ICD patients. 4) The availability of ventricular therapy in patients with AF who have structural heart disease may be a significant advantage of the Jewel® AF.

700 Dual-chamber pacing and sensing with a single lead: first results with a new single pass defibrillation lead

R. Gradaus, M. Block, A. Dorszewski, Ch. Schriever, D. Hammel[1], M. Borggrefe, G. Breithardt, D. Böcker. *Department of Cardiology & Angiology; [1]Cardiovascular Surgery, Westfälische Wilhelms-Universität Münster, Germany*

Background: Dual chamber defibrillators are increasingly used to avoid inappropriate shocks. However, placing of an atrial pacing and sensing lead is associated with a higher morbidity and complication rate. The purpose of this study was to investigate a new single pass right ventricular defibrillation lead designed for bipolar atrial and ventricular sensing and pacing.

Methods: In 8 pts (all CAD, 66 ± 8 years; NYHA 2.1 ± 0.4; EF 44 ± 17%), the new single pass, right ventricular defibrillation lead with integrated bipolar ventricular and true bipolar right atrial pacing and sensing was tested (Medtronic, model 14108). Pacing and sensing in the right atrium occurred between an atrial ring and an electrode on a tine 15.5 cm proximal to the right ventricular tip. In order to enhance the contact between these electrodes and the atrial wall, the lead had a 90° curve just distal to the atrial electrodes.

Results: Implantation of the new lead was successful in all pts, the operation time was 76 ± 30 minutes, the fluoroscopy time 4.2 ± 2.3 minutes. The defibrillation threshold was 9.0 ± 3.2 Joule. The intraoperative atrial sensing measured 1.6 ± 0.6 mV, the atrial threshold product was 0.20 ± 0.15 (median 0.15) V*ms. At pre-hospital-discharge (PHD), 1-month follow-up (1-FU), and 3-month follow-up (3-FU) the atrial sensing was as high as 1.5 ± 0.6 mV, 2.0 ± 0.6 mV, and 2.5 ± 0.9 mV (p = ns, p = ns, p = 0.05 to implant), the median of the atrial threshold product was 0.66 V*ms, 0.60 V*ms, and 0.45 V*ms. At PHD, 1-FU, and 3-FU, no significant differences of atrial sensing or atrial threshold product were measured during resting supine, lying on the left side, right side, sitting, standing, or at deep inspiration, respectively. All spontaneous, (13× SVT, 11× MVT) and inducted (2× MVT, 9× pVT, 4× VF) episodes of tachycardia were detected and terminated correctly.

Conclusions: Atrial and ventricular sensing and pacing with a single lead is feasible and likely to shorten operation time and possibly to decrease morbidity and complication rate associated with an atrial lead.

701 Analysis of dual-chamber cardioverter-defibrillators electrograms for discrimination of ventricular from supraventricular tachycardia: implication for ICD-specificity and programming

C. Kouakam, D. Klug, M. Jarwé, D. Lacroix, P. Delfaut, N. Elbaz, S. Kacet. *Cardiology Dept, Lille University Hospital, Lille, France*

Background: Inappropriate therapy (shock and antitachycardia pacing) remains a major problem in patients with implantable cardioverter defibrillators (ICDs), and the ability to differentiate ventricular (VT) from supraventricular (SVT) tachycardia is a major objective of discrimination algorithms.

Methods: On the basis of AV relationship, this study aimed to evaluate the clinical performance of the CPI dual-chamber ICDs algorithms for discrimination of VT from SVT or sinus tachycardia (ST). The analysis of 175 spontaneous episodes of tachycardia from electrograms (EGMs) source was performed in 10 patients with Ventak AV ICDs (Model 1810, 1820 and 1821). ICDs were interrogated every 3 months or when patients received shocks. A double-blind review of EGMs for arrhythmia diagnosis and appropriateness of therapy was performed by two senior physicians and by a third one in case of conflict. Algorithms for discrimination of VT from SVT or ST were onset, stability and V rate > A rate. Sustained rate duration (SRD) criterion was also programmed.

Results: After review of the 175 stored EGMs, the final diagnosis were VT = 98, SVT = 29, ST = 42 and artifacts connector related = 6. Among the 98 VT episodes, V rate was > to A rate in 91 cases and therapy was always appropriate. V rate was equal to A rate in 7 cases: retrograde 1/1 conduction was found in 6 cases, and bitachycardia in 1 case. Therapy was delivered to 3 of these 7 cases, and inhibited in the 4 others (instability = 3, instability and progressive onset = 1) until spontaneous termination of VT before SRD. SVT episodes were atrial flutter (n = 8) and atrial tachycardia (n = 21). Inappropriate therapy occurred in 11 (38%) of SVT episodes, and therapy was adequately withheld in the 18 others. Inappropriate VT detection of true SVT was primarily due to SVT with 1/1 AV conduction. No inappropriate therapy was delivered among the ST episodes owing to progressive onset. Finally, detection algorithms appropriately classified 94/98 (96%) true VT episodes as VT and 60/71 (84.5%) true SVT episodes as SVT. Sensitivity of the Ventak AV algorithms was 100% (owing to the SRD criterion) and specificity was 89%.

Conclusions: The programming of detection criteria based on onset, stability, V rate > A rate and SRD allows a 100% sensitivity in Ventak AV ICDs. However, discrimination between VT and 1/1 SVT remains difficult, and additional algorithms may be useful for significant reduction of inappropriate therapy.

702 Does a dual-chamber detection algorithm really improve discrimination between supraventricular and ventricular tachycardias in implantable cardioverter-defibrillators recipients?

Renato Ricci, Giuliano Altamura, Salvatore Toscano, Alessio Gargaro[1], Francesco Miraglia[1], Francesco de Seta[1], Massimo Santini. *Department of Cardiology, San Filippo Neri Hospital, Rome; [1]Medtronic, Italy*

Background. Single-chamber Implantable Cardioverter-Defibrillators (ICDs) face up to 30% of inappropriate shock delivery. New single chamber criteria based on the onset and stability of tachycardia and on the width of ventricular electrogram can improve specificity of tachycardia detection, but on the other side can reduce sensitivity and need careful follow-up and tailored programming. Dual chamber pacing combined with ICD therapy has recently become available in clinical practice.

Aim of our study was to evaluate the overall performance of a new dual chamber detection algorithm (PR Logic) which has been introduced in the DDDR-ICD Gem DR 7271 and in the Dual-ICD Jewel AF 7250 (Medtronic, Inc., Minneapolis, MN). The device first utilizes the single chamber rate-only VT/VF detection algorithm, and then applies the PR Logic rules which withhold detection if one of three specific SVT rules are met: atrial fibrillation or flutter (AF), sinus tachycardia (ST) or other 1:1 SVT.

Patient population. 38 patients, 31 male and 7 female, mean age 67 + 9 years, have been implanted with a dual chamber ICD, 27 with the model 7250 and 11 with the model 7271. Ischaemic cardiomyopathy was present in 77% of patients, dilated cardiomyopathy in 23%. VF was the primary indication for ICD implantation in 31% of patients, sustained recurrent and poorly tolerated VT in 67% and recurrent AF in 2%. 13 patients experienced AF before implantation. Follow-up lasted 1–20 months.

Results: 56 episodes of VF were appropriately detected and successfully treated. 495 episodes of VT were detected. 490/495 (99%) were correctly detected and treated with a success rate of 96%. 5/495 (1%) were inappropriately detected as VT while they were SVT episodes. Inappropriate detection episodes included: ST with long PR interval and P wave falling in the retrograde conduction zone, 1:1 SVT with P wave in the retrograde zone and AF with ventricular rate higher than the SVT limit (rejection rules excluded). 404 Atrial Tachycardia episodes and 107 AF episodes were appropriately detected. The detection Positive Predictive Value was 93%.

Conclusions. The dual chamber detection algorithm PR Logic performed very well in our experience. Strong points of the system seem to be: improved specificity without decreased sensitivity; easy programming independent from the individual arrhythmic profile of the patient.

703 Efficacy of anti-tachy-pacing and low energy cardioversion in terminating spontaneous atrial tachyarrhythmias in patients with dual implantable defibrillator

R. Ricci, G. Altamura, C. Pandozi, S. Toscano, M.C. Scianaro, A. Gargaro[1], F. Miraglia[1], F. deSeta[1], M. Santini. *Department of Cardiology, San Filippo Neri Hospital, Rome; [1]Medtronic, Italy*

About 30% of patients with low left ventricular ejection fraction (LVEF) implanted with ICD suffer from recurrent atrial tachyarrhythmias. Recently, a dual implantable defibrillator (Medtronic model 7250) has been introduced for clinical implantation. The device combines DDD pacing with atrial and ventricular arrhythmia automatic detection and treatment. Available atrial therapies for Atrial Tachycardia (AT) include Ramp, Burst+, 50-Hz Burst and Low-Energy Cardioversion. Atrial therapies for Atrial Fibrillation (AF) include 50-Hz Burst and Low-Energy Cardioversion. Aim of our study was to evaluate the efficacy of the dual defibrillator in detecting and treating atrial tachyarrhythmias. Patient population included 22 patients, 18 M, 4 F, mean age 67 ± 9 years. 15 pts had ischaemic dilated cardiomyopathy (DCM), 6 idiopathic DCM and 1 no structural heart disease. Mean LVEF was 38 ± 17%. Indication to ICD implantation was ventricular tachycardia in 16 pts and ventricular fibrillation in 6. 11 had AT/AF before implantation. A two lead configuration (right atrium and double coil right ventricle) has been utilized. The follow-up ranged between 1 and 19 months.

Results: 589 atrial episodes were detected, 450 classified as AT (76%) and 139 as AF (24%). AT/AF detection sensitivity was near 100% with no known missed spontaneous symptomatic episodes The detection Positive Predictive Value was 93%. 62 atrial episodes (10%) were automatically treated. The success rates in the AT zone were: ATP therapy (Burst+ and/or Ramp) 77% (10/13 episodes), 50-Hz Atrial Burst 79% (15/19). In the AF zone 14/15 episodes (93%) were successfully terminated by 50-Hz Burst and 10/15 (67%) by atrial shock. The mean energy delivered was 13.8 ± 8.3 J, with a mean impedance of 42 ± 9 Ω.

Conclusions: Atrial ATP Therapies and Low-Energy Cardioversion available in the dual defibrillator represent an effective option to treat atrial arrhythmias in patients candidated to ICD implantation. Optimization of ATP therapy programming and lead configuration are needed to increase success rate, to reduce atrial defibrillation threshold and to improve patient tolerance.

704 Reconstructed "farfield" ECG leads in the ICD versus standard surface ECG: a new option to monitor myocardial ischaemia

A. Grom, T.S. Faber, M. Brunner, T. Baron, M. Zehender. *Innere Medizin III, Universitätsklinik Freiburg, Freiburg, Germany*

ICDs with the capability of analysing multiple intrathoracic "farfield" ECGs with respect to acute ischemic episodes (IE) will soon be available. These systems will use the ST-segment for analysis of IE. Aim of our study was to investigate the diagnostic accuracy of detecting IE in 6 ECG leads available in the ICD in comparison to the surface ECG by brief periods of PTCA-induced myocardial ischemia.

Methods: We prospectively assessed ST-segment deviations at 27 sites (22 pts.) during PTCA using ECG leads available in an implantable ICD (electrodes: RV apex, VCS, cutaneous patch at typical location of ICD generator over left pectoral muscle (LPM): 3 bipolar leads = BI–III; 3 tripolar leads = TI–III) and compared these findings with surface ECG. ST-segment deviations due to occlusion and reperfusion of a coronary artery were measured during PTCA.

Results: Mean ST-segment deviations in mV after certain times of balloon insufflation are given in the following table:

Lead	PTCA:	30 s	60 s	max..	5 min post
Surface I	0.01 ± 0.03	0.01 ± 0.02	0.03 ± 0.06	0.00 ± 0.01	
II		0.02 ± 0.03	0.05 ± 0.06	0.05 ± 0.07	0.01 ± 0.03
III		0.03 ± 0.04	0.04 ± 0.06	0.05 ± 0.06	0.01 ± 0.03
V4		0.18 ± 0.27	0.22 ± 0.38	0.26 ± 0.38	0.07 ± 0.10
V5		0.13 ± 0.18	0.17 ± 0.24	0.21 ± 0.24	0.09 ± 0.07
V6		0.11 ± 0.11	0.16 ± 0.18	0.19 ± 0.18	0.06 ± 0.06
BI (VCS vs. LPM)	0.12 ± 0.21	0.42 ± 0.27	0.50 ± 0.31	0.08 ± 0.04	
BII (LPM vs. RVA)	0.31 ± 0.31	0.46 ± 0.53	0.51 ± 0.54	0.16 ± 0.20	
BIII (VCS vs. RVA)	0.28 ± 0.33	0.40 ± 0.43	0.43 ± 0.44	0.13 ± 0.15	
TI (RVA + LMP vs. VCS)	0.20 ± 0.19	0.25 ± 0.30	0.30 ± 0.29	0.08 ± 0.09	
TII (RVA + VCS vs. LPM)	0.14 ± 0.11	0.18 ± 0.15	0.20 ± 0.15	0.09 ± 0.12	
TIII (VCS + LMP vs. RVA)	0.28 ± 0.30	0.35 ± 0.34	0.39 ± 0.36	0.11 ± 0.12	

At 30 sec of PTCA the bipolar leads (BI 40%, BII 78%, BIII 67%) and the tripolar leads (TI 67%, TII 67%, TIII 78%) were superior to surface ECG (V4 37%, V5 37%, V6 41%) to detect ischemic ST-changes.

Conclusion: Detection of IE by ECG leads available in the ICD is feasible. Early assessment and diagnostic accuracy are superior to the surface ECG.

MECHANISMS AND MAPPING OF VENTRICULAR TACHYCARDIA

705 Use of the electroanatomical Carto™ mapping to design an individual strategy for catheter ablation of ischaemic monomorphic ventricular tachycardias

M. Volkmer, M. Antz, J. Hebe, F. Ouyang, D. Bänsch, S. Ernst, P. Hansen, R. Cappato, K.-H. Kuck. *St. Georg Hospital, Hamburg, Germany*

Catheter ablation of monomorphic ischemic ventricular tachycardia (VT) is limited in regard to mapping and ablation success. The aim of the present study was to investigate the safety and efficacy of VT catheter ablation using an electroanatomical (EA) mapping approach (CARTO™). Between 6/97 and 10/98, 13 post-MI pts (67 ± 6 yrs) were referred for RF ablation of VT (12 already under AA drugs and 8 ICD therapy). The clinical VT (cycle length, 420 ms; range, 300–540 ms) was inducible in all pts. In all pts, EA map of the left ventricle (LV) was attempted during sinus rhythm (map 1) and during VT (map 2); map 1 was completed in 11 pts (2 pts were in incessant VT) and map 2 in 6 pts (4 pts had VT mechanical block and 3 were hemodynamically unstable during VT). RF pulses delivered at scar sites of slow conduction within the reentrant circuit abolished VT in 7 pts (acute success) during 1 (1–2) procedure; an irrigation catheter was used in 2 such cases to consolidate the transient effect obtained with conventional techniques. In the remaining 6 pts, superimposition of map 1 and 2 was used to sever the scar area with a linear lesion; a second linear lesion was made to connect the scar boundary to the closest anatomical barrier. Procedure duration was 531 ± 119 min. At discharge, AA drugs were discontinued in 6 of 7 pts with acute success and were continued in remaining pts. One pt died 28 days after the procedure due to progressive heart failure. During a FU of 8.5 (1–15) mos, 1 pt had VT recurrence.

Conclusion: In pts with post-MI VT, use of EA mapping allowed: 1) identification of scar sites with slow conduction within the reentrant circuit with high accuracy; 2) to produce linear ablation models severing the scar surface as well as ventricular isthmuses between the scar area boundary and closest anatomical barriers. Combination of these techniques was used to design an individualized strategy for RF ablation of post-MI VT which allowed to extend the indications to new pts categories and was associated with a 92% success rate over an intermediate FU.

706 Mapping and ablation of re-entrant ventricular tachycardia using a three-dimensional non-fluoroscopic system

F.M. Leonelli, S. Beheiry, M. Richey, B. Wides, G. Tomassoni, A. Natale. *Cardiology Dept, University of Kentucky, Lexington KY, USA*

We report our experience and results with mapping and ablation of reentrant ventricular tachycardia (VT) using a three dimensional non-fluoroscopic mapping system. A total of 19 patients with either ischemic ventricular tachycardia (16 pts) or right ventricular dysplasia (RVD)(3 pts) underwent ablation for the occurrence of multiple defibrillator shocks. In the 3 patients with RVD, a total of 12 different VTs were mapped and ablated. In the remaining 16 patients with ischemic heart disease, a total of 30 VTs were induced and mapped. In all VTs the site of earliest activation was identified with the three dimensional activation map. Pacing at the earliest site showed concealed entrainment in 25 of the 42 tachycardias (59%). In the remaining VTs, concealed entrainment was demonstrated in an area close to the earliest site on the three dimensional activation map. After termination of VT was obtained during radiofrequency energy delivery ablation was extended radially in the same region. This approach was facilitated by the real time visualization of the catheter location and tagging of each ablation site on the 3-D map. In 5 patients ablation had to be completed using a 8 mm tip catheter. At the end of the procedure no monomorphic VT was inducible. In 4 patients ventricular flutter was induced with an aggressive pacing protocol during isoproterenol infustion. At follow-up, 1 patient with RVD experienced 1 episode of VT successfully terminated by pacing through the ICD. Two patients with ischemic heart disease experienced recurrence of VT. Both patients underwent successful re-ablation and had no recurrence. In conclusion, this 3 dimensional non-fluoroscopic mapping system has the potential to facilitate identification of successful ablation sites for reentrant ventricular tachycardia and to allow a more accurate and adequate ablation of the tissues surrounding the earliest site of activation which could result in a lower long term recurrence rate.

707 Non-contact mapping-guided radiofrequency ablation of ventricular tachycardia in patients with frequent defibrillator therapy

A.W.C. Chow, R.J. Schilling, N.S. Peters, D.W. Davies. *Imperial College School of Medicine, St. Mary's Hospital, London, UK*

Patients (pts) with implantable defibrillators (ICD) and frequent episodes of ventricular tachycardia (VT) or slow VT, receive unacceptably frequent and/or inappropriate device therapies. 10 patients with recurrent VT and ICD had RF ablation guided by a non-contact mapping system, because of slow VT in 1 and frequent device therapy in 9. Mean age was 58 ± 12 years, all were male. 6 had coronary artery disease and the remaining 4 had dilated cardiomyopathy. Mean LV diastolic dimension was 6.4 ± 0.45 cm and follow-up was 12.4 ± 13.7 months.

Results: 40 VT morphologies were mapped. The non-contact mapping system identified 40 exit sites, 9 complete and 17 partial diastolic pathways (mean 43 ± 37.8% of diastolic interval). 19 VT were ablated with a mean of 11.7 ± 12.1 RF applications given per patient. Over a mean follow-up of 12.4 ± 13.7 months, ICD shocks were reduced after ablation from 9.4 ± 7 to 0.22 ± 0.52 discharges per month ($p < 0.01$) and anti-tachycardia pacing was reduced from 42.5 ± 96 to 2.5 ± 6.2 episodes per month ($p < 0.03$). Total device therapy was reduced from 62 ± 126 to 2.76 ± 6.7 episodes ($p < 0.02$). During follow-up there has been 4 deaths, 3 from non-arrhythmic events with no therapies recorded by their device post mortem, the remaining patient died of incessant VF. Complications: 2 patients developed false femoral aneurysms requiring surgical repair and 1 patient sustained a minor stroke during the study from which he made a full recovery.

Conclusion: In patients with drug refractory VT, ablation guided by non-contact mapping system is able to effectively reduce frequent ICD therapy.

708 Bystander activation of the His-Purkinje system during ventricular tachycardia after myocardial infarction

D. Lacroix, D. Klug, C. Kouakam, M. Jarwe, P. Delfaut, A. Gay, R. Logier, S. Kacet, H. Warembourg, S. Kacet. *Cardiology Dept. Cardiology Hospital, University of Lille, Lille, France*

Apart from bundle branch reentry we tested the incidence and consequences of a bystander activation of the His-Purkinje system during VT following myocardial infarction (MI). We considered this activation to occur when the following criteria were met: (1) variation in the activation pattern of a monomorphic VT due to secondary optional breakthroughs (BKT) (2) spatial coincidence of these secondary BKTs with BKTs in sinus rhythm (3) remoteness of these BKTs from the scar. The study was conducted prospectively during isochronal mapping of 99 VTs obtained at surgery in 32 MI pts, with a 128-electrode system, using an epicardial sock and a left ventricular endocardial balloon.

Results: At least one VT following these criteria was mapped in 5 pts (16%), 2 with an inferior and 3 with an anterior MI, 2 of them having a bundle branch block in sinus rhythm. These tachycardias represented 5% of the total VT number, 4 of them were clinical. These VTs originated from the septum or from the left free wall in 2 and 3 cases respectively. Changes in the activation sequence involved the right bundle branch in 2 VTs, the left posterior fascicle in 2 VTs, both in the remaining VT. The VT cycle length was unaffected in 2 cases and either slower or faster in the 3 other cases. Changes in ECG morphology were analyzed at surgery in the frontal plane only, the QRS axis rotation ranged from 15 to 150° (mean 55°). Therapy (resection or cryoablation) was not targeted to the elements of the His-Purkinje system.

In conclusion, A bystander activation of the His-Purkinje system may occasionally be observed during postMI VT inducing dramatic changes in the surface ECG. This phenomenon has important implications in the interpretation of intraoperative or catheter-based activation maps.

709 Short-long-short sequences are important arrhythmia mechanisms in over 1000 analysed spontaneous ventricular arrhythmias

A. Schaumann, C. Neufert[1], O. Fabian[1], B.-D. Gonska[1]. *Cardiology Dept., St. George Hospital, Hamburg; [1]Cardiology Dept., Univ. of Göttingen, Germany*

In this study the importance of short-long-short sequences as a trigger mechanism of spontaneous ventricular tachycardias (VTs) was analysed. The short-long-short sequence was defined for RR intervals with changes of ≫30% directly preceding the arrhythmia. In 250 patients with survived sudden cardiac death and implantable cardioverter-defibrillators (ICD) spontaneous arrhythmias were analysed for the preceding rhythm stored in the recorded ECG strip of the implanted device. Patients with atrial fibrillation and pacemaker dependent rhythm were excluded.

Results: During a follow-up of 31 ± 12 months 1004 spontaneous VTs in 102 patients were analysed. A short-long-short interval with ≫30% changes of RR intervals was obtained in 337 (33.6%) of 1004 spontaneous VTs and in 66 (65%) of 102 patients with spontaneous arrhythmia recurrences. The prolonged (long) RR interval was terminated in 60% by a sinus beat in 41 patients with coronary artery disease compared to 33% in 18 patients with cardiomyopathy. A pacer-induced ventricular complex was seen at the end of the prolonged RR interval in 57% of patients with cardiomyopathy but only in 30% of patients with coronary artery disease.

Conclusion: Short-long-short sequences are an important trigger mechanism in 33% of spontaneous VT and were seen in 65% of the patients with recurrent arrhythmias.

710 Wavefront velocity and turning characteristics of the diastolic pathway during human ventricular tachycardia

A.W.C. Chow, R.J. Schilling, D.W. Davies, N.S. Peters. *Imperial College School of Medicine, St. Mary's Hospital, London, UK*

Conduction properties of the diastolic pathway (DP) in human ventricular tachycardia (VT) are poorly characterised. We used a non-contact mapping system, which simultaneously reconstruct over 3,300 unipolar electrograms on a virtual endocardium to determine wavefront velocities within the DP and at entry and exit sites. Endocardial distances were calculated from Cartesian co-ordinates and angles of turn by 3 dimensional vector geometry. 7 patients (61.7 ± 5.3 years) with poor left ventricular function (EF 36 ± 5.3%) undergoing VT ablation were studied. 6 had ischaemic heart disease and 1 had dilated cardiomyopathy. 10 VTs with a cycle length of 354 ± 76 ms were mapped. All patients had ≥ 40% of the DP identified (mean 83%, range 40–100%). The 6 DP fully defined were 102 ± 40 mm long and occupied 71 ± 7.1% of VT cycle length. Overall, DP wavefront velocity was 0.81 ± 0.49 m/s. Angulations of the DP were defined as regions where trajectory of propagation changed by >7 degrees/mm. A total of 8 angulations were identified within the course of the DPs, which slowed the activation wavefront to 0.41 ± 0.1 m/s compared with a mean of 0.99 ± 0.26 m/s ($p < 0.0004$) in the immediate segments preceding and following angulation. 166 ± 41 degrees of angulation were seen during turning within the DP.

18 entry and 19 exit turns were mapped. Wavefront velocity changed from 1.25 ± 0.42 ms to 0.62 ± 0.26 ms ($P < 0.0001$) at entry site turning points (TP) and from 0.72 ± 0.28 m/s to 0.83 ± 0.25 m/s ($p = 0.11$) at exit TP. Entry TP is slower than exit TP velocity ($p < 0.008$). Wavefront turning at entry and exit were 115 ± 28 and 137 ± 69 degrees respectively.

Conclusion: Wavefront slowing occurs at entry and exit points of DP and also during turning within the DP.

HEART FAILURE: NON-INVASIVE MARKERS OF OUTCOME

711 Depressed frequency domain measures of heart rate variability as an independent predictor of sudden death in chronic heart failure

M. Galinier, J. Fourcade, Ch. Androdias, A. Pathak, D. Curnier, S. Varnous, S. Boveda, Ph. Cabrol, P. Massabuau, J.M. Fauvel, J.P. Bounhoure. *Department of Cardiology, Rangueil University Hospital, Toulouse, France*

Identification of patients with chronic heart failure (CHF) at risk for sudden death remains difficult. Time domain measures of heart rate variability were an independent predictor of all-cause mortality but failed to predict sudden death in CHF. We sought to assess the prognostic value for sudden death of frequency domain measures of heart rate variability in CHF.

Methods: we prospectively enrolled 190 patients with CHF in sinus rhythm, mean age 61 ± 12 years, 109 (57.4%) in NYHA class II and 81 (42.6%) in class III or IV, mean cardiothoracic ratio 57.6 ± 6.4% and mean left ventricular ejection fraction 28.2 ± 8.8%, 85 (44.7%) with ischemic and 105 (63.3%) with idiopathic dilated cardiomyopathy. Time and frequency domain measures of heart rate variability were obtained from 24-h Holter ECG recordings, spectral measures were averaged for calculation of daytime (10 am to 7 pm) and nighttime (11 pm to 6 am) values.

Results: during follow-up (22 ± 18 months), 55 patients died, 21 of them died suddenly and 2 presented a syncopal spontaneous sustained ventricular tachycardia. In univariate analysis, predictors for sudden death were: ischemic heart disease, cardiothoracic ratio ≥ 60%, left ventricular ejection fraction < 30%, standard deviation of the averages of RR intervals in all 5 min segments (SDANN) < 55 ms, root-mean square of difference of successive RR intervals (RMSSD) < 14 ms, daytime total frequency power < 2.4 ln (ms^2/Hz) and daytime low frequency power < 3.3. ln (ms^2/Hz). In multivariate analysis, independent predictors for sudden death were: ischemic heart disease (RR = 4.1, 95% CI 1.6–10.5) and daytime low frequency power < 3.3 ln (ms^2/Hz) (RR = 2.8, 95% CI 1.2–8.6).

In conclusion: spectral analysis of heart rate variability identifies an increased risk for sudden death in patients with CHF.

712 QT-dispersion in patients with end stage heart failure prior to cardiac transplantation correlates with dispersion in refractoriness in the explanted perfused heart

R. Coronel, J.R. de Groot, F.J.G. Wilms-Schopman, R. Derksen, R.N.W. Hauer, M.J. Janse, J.M.T. de Bakker. *Department of Experimental Cardiology, Academic Medical Center, Amsterdam; Heart Lung Institute University of Utrecht and the Interuniversity Cardiology Institute, Amsterdam, Netherlands*

Introduction: Patients with increased QT-dispersion are at increased risk for sudden death. QT-dispersion is thought to correlate with heterogeneity in repolarization, but direct evidence for this is lacking.

Methods: ECGs were obtained from 6 patients (4 ischemic heart disease, 1 hypertrophic cardiomyopathy, 1 dilated cardiomyopathy) with end stage heart failure on the day of cardiac transplantation. Explanted hearts were stored in cold Tyrode's solution, connected to a Langendorff apparatus and perfused with a blood-Tyrode mixture at 37°C. Refractory periods were determined with the extrastimulus technique at a cycle length of 600 msec with 2 msec accuracy at 8 to 16 epicardial sites across the heart (6 hearts). At the same sites monophasic action potentials (MAP) were recorded. MAPduration was measured at 80% repolarization. When measuring QT-dispersion (largest QT interval difference) the investigators were blinded to the identity of the patients. Bazett's correction was applied.

Results: QT_c-dispersion was measured based on an average of 10 leads per patient and ranged from 37 to 194. Dispersion of MAP duration ranged from 40 to 80 msec, in refractory period from 26 to 176. QT-dispersion correlated with refractoriness (r^2 0.87, $p < 0.01$) but not with MAP duration.

Conclusion: This study validates the use of QT-dispersion for the detection of heterogeneity in refractoriness.

713 Dispersion of QRS and QT in patients with advanced congestive heart failure: relation to cardiac and sudden death mortality

M.I. Anastasiou-Nana, J.N. Nanas, L.A. Karagounis[1], G. Alexopoulos, J. Stathopoulos, I. Skotiniotis, S.F. Stamatelopoulos, S.D. Moulopoulos. *Dept. of Clinical Therapeutics, University of Athens, Athens, Greece; [1]University of Utah, Salt Lake City UT, USA*

This study examined the significance of QT and QRS dispersion (QTd, QRSd) in the prognosis of patients (pts) with advanced congestive heart failure and correlated these measurements with other known indices of left ventricular dysfunction that are predictors of increased mortality.

Methods: The study population consisted of 104 pts (mean age = 53 ± 13 yrs, mean left ventricular ejection fraction = 22 ± 10%), who were followed prospectively for 19.6 mo. QRSd and QTd were defined as the maximum difference in QRS and QT interval durations, respectively, measured among all leads of standard 12-lead electrocardiograms. The endpoints of the study were non sudden and sudden cardiac mortality.

Results: There were 13 non sudden and 10 sudden deaths. QTd and QRSd were significantly greater in non survivors (95 ± 48 ms and 54 ± 17 ms, respectively), than in survivors (78 ± 31 ms and 46 ± 16 ms, respectively, $p < 0.03$ and $p < 0.02$, respectively). Death rate in patients with QTd > 90 ms was 2.8-fold higher than those with QTd ≤ 90 ms (95% CI 1.2 to 6.4). Similarly, the death rate in patients with QRSd > 46 ms was 3.9-fold higher than in those with QRSd ≤ 46 ms (95% CI 1.6 to 9.5). The actuarial survival between 14 pts who had QRSd > 46 ms and QTd > 90 ms and 90 pts who had QRSd ≤ 46 ms and QTd ≤ 90 ms was 50% and 82% ($p = 0.0008$), respectively, at 36 mo. In a multivariate analysis, functional class ($p = 0.0007$), QRS dispersion ($p = 0.001$) and QT dispersion ($p = 0.01$) were the only predictors of cardiac mortality. Bundle branch block or intraventricular conduction defects ($p = 0.02$) and QRS dispersion ($p = 0.04$) were the only predictors of sudden death mortality.

In conclusion, these findings suggest that variability in QT and QRS durations on 12-lead electrocardiograms are useful predictors of mortality in patients with advanced congestive heart failure.

714 Comparison of the effect of coronary angioplasty on signal-averaged electrocardiogram in patients with normal and depressed left ventricular function

G. Gajos, I. Pietrzak, A. Gackowski, J. Matysek, D. Mroczek-Czernecka, W. Piwowarska. *Department of Coronary Disease, Jagiellonian University, Krakow, Poland*

Whether successful myocardial revascularisation can alter arrhythmia substrate is still a subject of controversy. **The aim** of the study was to evaluate the effect of coronary angioplasty (PTCA) on parameters of signal averaged electrocardiogram (SAEG) in patients with normal and depressed LV function.

Methods: 55 consecutive pts undergoing successful coronary angioplasty (43 men, 12 women, mean age 54 ± 9.9 yrs) were included. Before the procedure there were 25 pts with normal LV ejection fraction (LVEF > 59%) and 30 pts with depressed LVEF (mean 46.2 ± 10.3%). Before PTCA and 19.6 ± 4.3 days after the procedure parameters of signal averaged ecg (filtered QRS duration-fQRS, low amplitude signal duration of the terminal part of QRS-LAS and terminal root mean square voltage-RMS40) were assessed.

Results: Late ventricular potentials (LP) according to Simpson's criteria were present in 10 pts (50%) with normal and in 14 (47%) pts with depressed LVEF. After PTCA there was a significant improvement in SAEG parameters (f-QRS and LAS) in pts with normal LVEF. Despite highly significant increase after angioplasty of LVEF (to 51.4 ± 10.9%; p < 0.00001) in pts with depressed LV function there was no change in SAEG parameters.

	Normal LVEF			Depressed LVEF		
	f-QRS	LAS	RMS-40	f-QRS	LAS	RMS-40
Before PTCA	107.6±24.7	46.9±26.2	25.7±21.6	106.9±21.9	40.0±17.3	25.3±20.8
After PTCA	93.6±9.4	33.6±7.1	30.6±17.1	102.0±17.4	37.9±13.5	25.2±19.9
p	<0.05	<0.05	NS	NS	NS	NS

After PTCA LP were present in 14 (47%) pts with depressed LV function (there was a disappearance of LP in 7 pts but also appearance of new LP in another 7 pts). In pts with normal LV function LP disappeared after PTCA in 50% of pts.

Conclusion: Successful relief of ischaemia with coronary angioplasty may improve delayed ventricular activation and modify arrhythmogenic substrate only in pts with normal LV function.

715 Magnetocardiographic late fields and electrocardiographic late potentials in post-myocardial infarction patients with ventricular tachycardia and cardiac dysfunction

P. Korhonen[1,2], J. Montonen[3], M. Mäkijärvi[1], L. Toivonen[1]. *Division of [1]Cardiology; [2]BioMag Laboratory, Helsinki University Central Hospital, Helsinki; [3]Laboratory of Biomedical Engineering, Helsinki University of Technology, Espoo, Finland*

High-resolution magnetocardiographic (MCG) late fields following QRS complex indicate high risk to ventricular arrhythmias after myocardial infarction (MI). We compared MCG to signal-averaged ECG (SAECG) in identifying which patients with significant post-infarction myocardial damage are prone to sustained ventricular tachycardia (VT).

Methods: Sixty-three patients with remote MI were studied, 30 without and 33 with documented VT. Left ventricular ejection fraction was 28 ± 6% in the VT and 29 ± 10% in the non-VT group. MCG with 7 axial channels and SAECG with three orthogonal bipolar leads were signal-averaged and 40 Hz high-pass filtered. The QRS duration (QRSd), low amplitude signal duration (LAS) and the root mean square amplitude of the QRS end (RMS) were analyzed.

Results: Optimal combinations of dichotomized parameter values (maximum sum of sensitivity and specificity) were calculated for MCG and the Simson criteria for SAECG (2/3 of the following: QRSd > 114 ms, LAS > 38 ms, RMS < 20 μV) to separate the VT and non-VT groups. The results are shown in table:

	Sensit.	Specif.
MCG: QRSd > 138 ms *or* RMS < 520 fT	73%	67%
SAECG: Simson criteria	58%	43%

This is the first study showing the discriminative power of high-resolution techniques in comparable post-MI patients with a large MI. Better performance of the MCG method may be due to its higher sensitivity to tangential myocardial currents present in damaged myocardium, whereas SAECG may lose discrimination if post-infarction lesion is extensive.

Conclusion: The new technique of high-resolution MCG is superior to SAECG in detecting propensity to malignant ventricular arrhythmias in patients with severe left ventricular dysfunction after MI.

716 Improvement of heart rate variability by exercise training in chronic heart failure is associated with a reduction of future cardiac events

M.C. Iliou, K. Zerhouni, L. Prunier, J.C. Verdier, T. Lavergne, X. Copie, J.Y. Le Heuzey, P. Sellier. *Department of Cardiac Rehabilitation, Broussais Hospital, Paris, France*

In patients (pts) with chronic heart failure (CHF), a low heart rate variability (HRV) is associated with a poor prognosis. Exercise training has been shown to increase HRV. This improvement may be related to an increased parasympathetic tone.

The aim of this study was to assess the relation between cardiac events and changes in HRV following exercise training in CHF pts. We included 51 CHF pts referred for a cardiac rehabilitation program (mean age: 53.3 ± 12.6 years, 47 men). All pts underwent a 24-hour Holter monitoring with temporal and spectral analysis of HRV before and after the cardiac rehabilitation program. Pts were submitted to a training program including calisthenics and bicycle training (21 ± 10 sessions).

Results: At a mean follow-up of 9.7 ± 5.3 months, 20 pts had cardiac events: rehospitalization (12 pts), heart transplant (4 pts) or death (4 pts). Exercise training improved exercise tolerance parameters: peak VO_2 + 2.2 ± 2.6 ml/kg/mn (+15%). Comparison of HRV parameters between pts with and without cardiac events are presented in the table:

	No cardiac event	Cardiac events	p
Age (yrs)	53.4 ± 11.9	53.3 ± 14.0	NS
Ejection fraction (%)	27.1 ± 7.5	23.5 ± 8.1	NS
Δ VO_2 (%)	+14.1 ± 14.7	+15.6 ± 16.9	NS
Δ Heart Rate (%)	−4.2 ± 6.6	−2.9 ± 2.3	NS
Δ SDNN (%)	+33.1 ± 37.9	+4.5 ± 34.9	<0.01
Δ LF/HF (%)	−26.7 ± 50.2	+23.3 ± 72.9	<0.01

In **conclusion,** pts with or without cardiac events had similar ejection fraction, and improvement in peak VO_2 and heart rate. However improvement in HRV was significantly higher in pts without cardiac events. These results suggest that changes in HRV may be of prognostic significance after cardiac rehabilitation.

RISK FACTORS: NEW AND OLD

727 Reduced risk of acute myocardial infarction at high serum levels of a mammalian lignan, enterolactone: a prospective population-based case-control study

M. Vanharanta, S. Voutilainen[1], T.A. Lakka[1], M. van der Lee[2], H. Adlercreutz[2], J.T. Salonen[1]. *University of Kuopio, Research Institute of Public Health, Kuopio; [1]University of Kuopio, Research Institute of Public Health, Kuopio[2]The Institute for Preventive Medicine, Folkhälsan Research Center, Helsinki, Finland*

Background: The mammalian lignan, enterolactone, is produced from diet derived precursors by the intestinal microflora. Enterolactone has been postulated to have a role in the prevention of chronic diseases such as cancer. We investigated the association of serum enterolactone concentration with the risk of acute myocardial infarction (AMI) in a prospective nested case-control study in middle-aged men from eastern Finland.

Methods: Serum enterolactone measurements were carried out for 169 men who had an AMI during an average 7.7 years follow-up and for 167 control men. Both the cases and controls were from a cohort of 2005 men who had no clinical coronary heart disease (CHD) at baseline. The controls were matched for age, examination year and residence. AMIs were registered prospectively. Serum enterolactone measurements were done with time-resolved fluoroimmunoassay.

Results: The mean baseline serum enterolactone concentration was 21.5 percent lower among the cases than the controls (95 percent confidence interval, 4.0 to 44.3 percent; P = 0.02 for difference). The men in the highest enterolactone quarter (>30.1 nmol/l) had 62.5 percent (95 percent con-fidence interval, 29.8 to 80.0 percent; P = 0.002) reduced risk of AMI. After an adjustment for the eleven most predictive risk factors, men in the highest enterolactone quarter had 64.5 percent (95 percent con-fidence interval, 23.9 to 83.4 percent; P = 0.008) reduced risk of AMI compared to men in the lowest quarter.

Conclusion: Healthy men with high serum levels of enterolactone had a greatly reduced risk of AMI, supporting the hypothesis that plant-dominated fiber rich food lowers the risk of CHD.

728 Long-term prognosis of exercise-induced premature ventricular contraction: the Paris prospective study I

X. Jouven[1,2], M. Zureik[1], M. Desnos[2], D. Courbon[1], C. N'Guyen Tan Cuong[2], P. Benoit[2], C. Guerot[2], P. Ducimetiere[1]. *[1]INSERM U-258, Hopital Paul Brousse, Villejuif; [2]Service de Cardiologie, Hopital Boucicaut, Paris, France*

The long term prognosis of the occurrence of premature ventricular contraction (PVC) during exercise test remains unknown in the population. Therefore we used the long follow up period of this cohort study to assess cardiovascular mortality in asymptomatic subjects with negative exercise test.

Methods: 7746 working men employed by the city of Paris aged 43–52 in 1967–72 underwent physical examination plus ECG, provided blood for laboratory tests and answered questionnaires. Men with cardiac failure, coronary or valvular heart disease, high blood pressure or abnormal resting ECG were excluded. 6032 men completed exercise test using standardized procedure (0–2 mn: 82 W, 2–8 mn: 164 W and 8–10 mn: 191 W).

Subjects with a positive exercise test (defined as a $\geq$1 mm horizontal or descending ST depression) or labile ST changes were excluded from analysis. Men were divided in 3 groups according to the percentage of PVC during 30 s: GR1 PVC = 0, GR2 PVC $\leq$ 10% and GR3 PVC > 10%. Men were followed for survival until January 94 and vital status was obtained for 96% of men.

Results: Of 5830 men who had a negative exercise test, 389 died from cardiovascular cause. There were 5203 men in GR1, 497 in GR2 and 130 in GR3. The rate of cardiovascular death was 6.5% (n = 336) in GR1, 6.4% (n = 32) in GR2 and 16.2% (n = 21) in GR3 (p = 0.001). The relative risk of cardiovascular death associated with the occurrence of PVC was 0.96 for GR1 (ns) and 2.70 for GR2 (p = 0.001). The occurrence of PVC ($\leq$10 or >10) before exercise (n = 75) or during recovery (n = 116) was not associated with an increased cardiovascular mortality.

Conclusion: There is an increased cardiovascular mortality associated with the occurrence of >10% PVC/30 s during exercise but not before exercise or during recovery in middle aged asymptomatic Frenchmen with negative exercise test.

729 QT interval and its prognostic value for death in Warsaw Pol-MONICA population

A. Pytlak, W. Piotrowski, S. Rywik. *Department of CVD Epidemiology and Prevention, National Institute of Cardiology, Warsaw, Poland*

QT interval in the resting electrocardiogram (ecg) is the sum of ventricular repolarization and depolarization time. It's prolongation is associated with bad prognosis for survival due to severe ventricular arrhythmia.

Aim: to evaluate the association between QT duration and total, cardiovascular (CVD) and ischaemic heart disease (IHD) mortality.

Methods: Warsaw Pol-MONICA population of 2646 men and women, aged 35–64, screened in 1984 was followed-up to 1996. All deaths were registered based on death certificate diagnosis. QT interval was measured manually in 3 consecutive QRST complexes in each ecg and corrected using Bazett's formula (QT corrected-QTc). For statistical analyses mean values of three QTc measurements were used. To assess the relationship between QTc and mortality Cox proportional hazard model was performed.

Results: Out of screened persons 459 died (309 men, 150 women), 226 of them due to CVD (162 men, 64 women) and 81 due to IHD (59 men and 22 women). Both men and women who died were significantly older at baseline and had significantly longer mean QTc compared to survivors (men: 457 ms vs 446 ms, p = 0.0001; women: 469 ms vs 459 ms, p = 0.0011). In men, after adjustment for age, mean QTc was significantly associated with total, CVD and IHD mortality. In women QTc was related to CVD and IHD mortality. The risk of death rose with increase in QTc duration. In men, with every increase in QTc by 20 ms the risk of all cause and CVD death rose by 14% (p – respectively 0.0001 and 0.02) and the risk of IHD death – by 17% (p = 0.02). In women, the risk of all cause death increased by 9% (NS), CVD death – by 28% (p = 0.004) and IHD death – by 43% (p = 0.009).

Conclusion: QTc interval was significantly related to all cause, cardiovascular and ischaemic heart disease mortality. The risk of death increased with longer QTc duration.

730 Unrecognized hypertension in diabetic patients with coronary disease: prevalence and prognostic significance

A. Tenenbaum, E.Z. Fisman, V. Boyko[1], U. Goldbourt[1], I. Auerbach, J. Shemesh, A. Shotan[1], H. Reicher-Reiss[1], S. Behar[1], M. Motro. *Cardiac Rehabilitation Institute; [1]Neufeld Cardiac Research Institute, the Chaim Sheba Medical Center, Tel-Hashomer, Israel*

Recent studies have shown a wide spreading of undiagnosed and accordingly untreated hypertension. However, scarce data are available regarding the prevalence and prognostic significance of the triple coexistence of undiagnosed hypertension, diabetes and ischemic heart disease. This study was aimed to evaluate the prevalence and prognostic significance of undiagnosed hypertension in cardiac diabetic patients defined previously as "normotensives" over a 5-year follow-up period.

Methods. The study sample comprised 11515 patients aged 45–74 with a previous myocardial infarction and/or anginal syndrome who were screened but not included in the Bezafibrate Infarction Prevention (BIP) study. Among them, 9033 were nondiabetics and 2482, diabetics. The diabetics were divided into 3 groups: 1) 1272 normotensives; 2) 152 patients without history of hypertension but with elevated blood pressure ("unrecognized hypertensives"); 3) 1058 hypertensives with established diagnosis.

Results. The prevalence of both diagnosed and unrecognized hypertension in diabetics pooled together rose from 49% to 69% when WHO and new JNC-VI criteria were compared. Crude all-cause mortality was lower in the nondiabetics than in diabetics (11.2% vs. 22.0%; p < 0.001). Among diabetics the lowest all-cause mortality was documented for the normotensives (19.3%), whereas the highest mortality was observed in unrecognized hypertensives (26.3%, p = 0.003). Both unrecognized and established hypertensives demonstrated a significant stroke-related mortality excess: about four-fold and three-fold increased of CVA death was observed, respectively (p = 0.002). On multivariate analysis both unrecognized and diagnosed hypertension were consistent predictors of increased all-cause mortality with a hazard ratio of 1.28 (95% CI 0.90–1.82) and 1.24 (95% CI 1.03–1.49), respectively.

Conclusions. We demonstrated a wide spreading of unrecognized hypertension in diabetic coronary patients; their 5-year mortality was significantly increased as compared with normotensives and tended to be even higher than in the diabetics previously identified as hypertensives.

731 Apoprotein E serum level and polymorphism in six European countries: the ApoEurope project

F. Schiele, D. De Bacquer[1], M. Vincent-Viry[2], G. De Backer[1]. *On behalf of the ApoEurope study Group, Université H. Poincaré, Vandoeuvre-Les-Nancy, France[1] Department of Public Health, University of Ghent, Ghent, Belgium[2] Lab. du Centre de Médecine Préventive, Université H. Poincaré, Vandoeuvre-les-Nancy, France*

As part of the ApoEurope project, the apolipoprotein E serum levels and polymorphism were determined in 6934 presumably healthy subjects aged 25 to 64 years recruited in six European countries: Finland, France, Greece, United Kingdom, Portugal and Spain. Age and sex influence apo E level with values significantly higher in men than in women aged 25 to 44 years. The effect of age was different by sex after the age of 50 years with a linear increase in women and a plateau in men. As expected the serum apo E concentration was the highest in epsilon2 carriers and the lowest in epsilon4 carriers in each country with a significantly higher frequency of epsilon4 allele in the Northern regions. The main finding of this study was a clear North-South increasing gradient in serum apo E concentration independently of age, sex and apo E genotype. Apo E levels increased from North to South by up to 20% for men and 32% for women in subjects aged less than 45 years having the epsilon3/epsilon3 genotype. In addition to genetic polymorphism, the geographical areas will be an important factor to take into account for studying serum apo E concentration in multicentric studies.

THROMBOTIC RISK AND CORONARY EVENTS

738 Social support as a risk factor for coronary heart disease and mortality in Warsaw Pol-MONICA population

J. Piwoński, D. Szcześniewska, S. Rywik, A. Pytlak. *Department of CVD Epidemiology and Prevention, National Institute of Cardiology, Warsaw, Poland*

The aim of the study is to evaluate the association between social support level (SSL) and coronary heart disease (CHD) prevalence and subsequent total and cardiovascular mortality in Warsaw Pol-Monica population cohort.

Methods: In a random sample of 1474 men and 1498 women, aged 35–64, screened in 1988 and 1993 in the frame of Warsaw Pol-Monica Project the mortality was followed-up to 1995. All deaths were registered on the basis of death certificate diagnosis. SSL was evaluated by means of Berkman and Syme questionnaire and was categorized into 3 groups: low, moderate and high with the lowest level of SSL as a reference category. CHD was defined on the basis of Rose CVD questionnaire and/or ischaemic changes in ECG (by Minnesota code). For analysis of the association between SSL and CHD prevalence and between SSL and CHD mortality the Cox proportional hazard model was used.

Results: Out of 2972 persons, 500 had CHD symptoms (195 men and 305 women). Low SSL was observed in 23% of all men and in 35% women. Among men with CHD symptoms low SSL was observed in 30% in comparison to 21% in men without CHD (in women respectively – 40% vs 34%). We found the significant association between moderate SSL and CHD in men (OR = 0.66, p = 0.02) and almost significant association between moderate SSL and CHD in women (OR = 0.79, p = 0.09)). So there is a 34% lower chance to find a man with CHD symptoms among men with moderate SSL in comparison to men with low SSL (for women this chance is lower of about 21%). During follow-up – 129 persons died (85 men and 44 women) and 48 due to cardiovascular diseases (CVD) (35 men and 13 women). Among men who died low SSL was observed in 28% of them in comparison to 22% in men who survived (in women respectively 38% vs 35%). Among men who died from CVD cause low SSL was observed in 24% of them in comparison to 22% in those who survived (in women respectively 57% vs 35%). No significant association of SSL and mortality was proved although both in total as well as in CVD mortality the risk of death decreased with higher SSL. The relative risk of all cause death of man with moderate SSL was about 38% lower comparing to man with low SSL (RR = 0.62, p = 0.08).

Conclusion: Moderate SSL was significantly related to CHD symptoms in men. No significant association of SSL and mortality was found although the risk of all cause and CVD death decreased with higher SSL.

739 Acute psychological stress decreases plasma tissue plasminogen activator and tissue plasminogen activator/plasminogen activator inhibitor-1 complexes in cardiac patients

D. Hevey, H.M. McGee, J.H. Horgan. *Department of Psychology, Royal College of Surgeons in Ireland, Dublin; Department of Cardiology, Beaumont Hospital, Dublin, Ireland*

BACKGROUND: Tissue plasminogen activator (tpa) promotes fibrinolysis and impaired fibrinolysis is associated with atherosclerosis and thrombosis. Plasminogen activator inhibitor-1 (PAI-1) inhibits t-PA expression. The present study examines the effects of acute laboratory stressors on tPA and tPA/PAI-1 complexes in a sample of clinically stable coronary artery bypass patients.

Methods: Eleven male patients were randomly assigned to either a stress or relaxation condition at time 1 and the alternative condition at time 2. The stress condition consisted of a series of standardised psychological stressors (the Stroop test PASAT, discussion of life events). In the relaxation condition participants listened to music or read. Blood samples were taken pre and post each session and tPA and tPA/PAI-1 levels were assessed by enzyme immunossay. Participants completed a battery of psychological questionnaires.

Results: Two-way repeated analysis of variance revealed a statistically significant decrease in tPA (P = 0.01) and t-PA-PAI-1 complexes (P = 0.04) during the mental stress condition. Furthermore, anger-in had a strong relationship to decreases in tPA/PAI-1 levels in the stress condition (R = 0.68, P = 0.04). In contrast, relaxation had no significant effect on tPA and tPA/PAI-1 levels.

Conclusion: Mental stress was associated with a statistically significant decrease in tPA and tPA/PAI-1 complexes. The strong correlation between anger-in and changes in tPA/PAI-1 level is consistent with research on repression and cardiovascular disease. These data suggest that decreased fibrinolysis may mediate the relationship between mental stress and atherosclerosis.

740 Baseline platelet aggregation and major receptor expression predict subsequent activity following thrombolysis for acute myocardial infarction

V.L. Serebruany, D.J. Kereiakes[1], D. Atar[2], P.A. Gurbel. *Sinai Center for Thrombosis Research, Baltimore MD; [1]Cardiovascular Research, Lindner Center, Cincinnati OH, USA; [2]Div. of Cardiology, Zurich University Hospital, Zurich, Switzerland*

The early identification of patients with heightened platelet activity for targeted antiplatelet regimens represents a critical clinical issue. It has been reported that platelets are not uniformly activated in patients presenting with acute myocardial infarction (AMI), but are most active at 24 hours after coronary thrombolysis. We correlated individual data on platelet aggregability and surface receptor expression at baseline and at 24 hours after coronary thrombolysis.

Methods: Platelets were investigated by aggregometry, (5 μM ADP, 10 μM ADP, thrombin, collagen, ristocetin), and flow cytometry (GP IIb/IIIa, P-selectin, PECAM-1, and vitronectin receptor) in 19 AMI patients treated with reteplase (n = 11), or alteplase (n = 8) enrolled in the GUSTO-III trial.

Results: Regression analysis reveals a significant positive correlation between baseline and at 24 hours after thrombolysis for 5 μM ADP (r^2 = 0.529), 10 μM ADP (r^2 = 0.445), thrombin (r^2 = 0.226), collagen (r^2 = 0.568), and ristocetin-induced aggregation (r^2 = 0.964). Platelet receptor expression was also highly linearly correlated for GPIIb/IIIa (r^2 = 0.337), P-selectin (r^2 = 0.817), PECAM-1 (r^2 = 0.586), and vitronectin expression (r^2 = 0.634).

In conclusion, the data strongly suggest that pre-reperfusion baseline platelet characteristics predict post-reperfusion activity, and may prospectively identify those patients who will exhibit heightened platelets after coronary thrombolysis. These patients can be detected early, and will probably benefit most from selective aggressive antiplatelet therapy.

741 Thrombotic factors and left ventricular ejection fraction in postinfarction patients

W. Zareba, A.J. Moss, V.J. Marder[1], S. Natarajan, H.J. Weiss[2], L.F. Miller-Watelet[3]. *Cardiology, University of Rochester, Rochester; [1]Vascular Medicine, University of Rochester, Rochester, NY [2]Hematology, Columbia University, New York [3]Biostatistics, University of Rochester, Rochester, NY, USA*

Postinfarction patients with depressed left ventricular function have an increased risk of recurrent coronary events. The aim of this study was to determine the association between thrombogenic profile, potentially predisposing to recurrent coronary events, and left ventricular function, measured by ejection fraction in stable postinfarction patients.

Methods: Study population consisted of 769 patients who had blood drawn 2 months after myocardial infarction to evaluate levels of the following thrombotic factors:

fibrinogen, D-dimer, factor VII and VIIa, plasminogen activator inhibitor (PAI-1), soluble fibrin, and von Willebrand factor (vWF). Only patients who did not take warfarin at the time of blood drawing were included in the analysis. A long-term follow-up was acquired to determine the occurrence of coronary events (defined as nonfatal myocardial infarction or cardiac death).

Results: Table below shows median levels of thrombotic factors and number (%) of cardiac events that occurred during a mean 26-month follow-up in the studied postinfarction patients stratified by ejection fraction.

Thrombotic Factors by Ejection Fraction

	EF>50% n = 329	EF = 41–50% n = 254	EF = 31–40% n = 126	EF≤30% n = 60	p value
Fibrinogen	330	337	326	355	0.069
D-dimer	359	363	473	544	<0.001
F VII	112	108	105	111	0.777
F VIIa	2.5	2.7	2.3	3.0	0.189
PAI-1	19	19	22	26	0.200
Soluble Fibrin	3.3	3.6	5.1	7.5	<0.001
vWF	124	126	135	153	<0.001
Cardiac Events	17 (5%)	20 (8%)	14 (11%)	13 (22%)	<0.001

Median values for tested factors are shown. P values were calculated with the Kruskal Wallis test.

Conclusions: The levels of thrombotic factors, especially D-dimer, soluble fibrin, and VWF, demonstrate a significant and stepwise association with the extent of left ventricular dysfunction in postinfarction patients. This observation indicates that postinfarction patients with decreased ejection fraction may benefit from an antithrombotic therapy.

742 Prospective evaluation of gender differences in thrombotic risk reduction during lipid lowering therapy with pravastatin

G. Dangas, J.A. Ambrose, D.A. Smith, M.A. Peterson, J.M. Ahmed, A.M. Cohen, J.T. Fallon, J.J. Badimon. *Cardiovascular Institute, Mount Sinai School of Medicine, New York NY, USA*

Background: Clinical trials of cholesterol (c) have included mostly men (M). The benefit rendered during statin therapy may be in part due to improved thrombotic profile. The association of coronary heart disease risk to HDL-C, LDL-C, lipid therapy and thrombosis in women (W) is unclear.

Methods: We prospectively studied markers of systemic thrombogenicity at 0, 3 and 6 months (mo) of therapy with pravastatin and AHA step I diet in 28 M and 29 W (93% postmenopausal) with untreated, fasting LDL-C > 145 mg/dl and triglycerides < 275 mg/dl. Thrombosis under dynamic flow conditions was also evaluated in a validated experimental perfusion chamber system.

Results: At baseline, M vs W differed in age (62 ± 2 vs 69 ± 2 y, $p < 0.05$) and HDL-C (39 ± 2 vs 55 ± 2 mg/dl, $p < 0.05$); p = NS for body mass index, CHD, risk factors, aspirin use, Lp(a), and homocysteine. Baseline thrombus area (TA) and hemostatic markers were similar in M vs W, except prothrombin fragment $F_{1.2}$ (1.4 ± 0.3 vs 2.4 ± 0.3 nmol/L, $p < 0.05$); $F_{1.2}$ at 6 mo was 1.5 ± 0.2 vs 1.6 ± 0.2 nmol/L, p = NS. Within 1 mo, LDL-C was reduced equally in M and W by 30% (188 ± 123 mg/dl). Trends at 3 mo and significant changes at 6 mo occurred in both M and W in tPA, PAI-1, and TA (table). Nonsignificant changes occurred in factor VIIa, fibrinopeptide A, and d-dimer in both M and W.

	tPA ng/ml	PAI-1 ng/ml	$F_{1.2}$ nmol/L	TA $\mu m^2 \times 10^3$
Men	−1.4 ± 0.4*	−11.5 ± 2.3*	0.0 ± 0.3	−2.9 ± 0.9*
Women	−1.5 ± 0.4*	−7.0 ± 2.2*	−0.8 ± 0.3*	−4.0 ± 1.3*

*change from baseline to 6-months $p < 0.05$

Conclusions: Despite higher HDL-C, W had higher baseline thrombin generation than M. Pravastatin abolished that difference and improved fibrinolytic markers related to endothelial function to similar levels in both M and W thereby decreasing blood thrombogenicity in both genders.

743 The influence of folate supplementation on coagulation factors in mild hyperhomocysteinaemia

O. Mayer jr., J. Šimon, H. Rosolová. *Centre of Preventive Medicine, 2nd Dept. of Internal. Med.., University Hospital, Pilsen, Czech Republic*

Introduction: Homocystein (tHcy) is a new risk factor of both atherosclerotic a trombotic vascular diseases. The core of Hcy metabolism is influenced by folates that enable to modify the tHcy levels. The aim was to evaluate in a pilot study the efficacy of folate supplementation on tHcy levels and several coagulation factors in the subject with mild hyperhomocysteinemia (MHHcy)

Methods: This pilot study included 18 subject without systematic pharmacotherapy (11 males, 7 females, mean age 58.8 y) with fasting tHcy ≥ 20 μmol/l. tHcy levels were estimated fasting and 6 hour after methinone load (100 mg/kg) using HPLC methods. The study included 1 month placebo intake, followed by 2 month treatment with 10 mg of folic acid daily. Biochemical and coagulation test were done in a routine laboratory using commercial kits. Statistical evaluation was done by Wilcoxon paired test.

Results: The table compares estimated variables at the end of placebo period and after 1 month therapy with folic acid supplement.

Variable	After 1 month placebo	After 2 month of folic acid treatment	p
Fasting tHcy [μmol/l]	30.2 (3.5)	13.3 (0.7)	<0.0001
Postload tHcy [μmol/l]	66.0 (8.93)	40.9 (5.05)	<0.001
Serum folates [μg/l]	5.63 (0.68)	18.4 (0.6)	<0.001
Serum B12 [ng/l]	322.1 (54.8)	380.5 (81.0)	ns
Fibrinogen [g/l]	3.29 (0.57)	2.30 (0.13)	<0.0001
Plasminogen [%]	92.9 (4.28)	109.1 (4.9)	<0.01
PAI-1 [A.U./ml]	16.7 (2.2)	16.9 (2.2)	ns

Conclusion: Two-month supplementation with folates in subject with mild hyperhomocysteinemia resulted in a significant tHcy and fibrinogen decrease and plasminogen increase.

Folates supplementation influenced favourably not only tHcy levels, but also the coagulation factors predisposing to thrombotic events.

Supported by grants Ministry of Health CR 3734-3 and 3719-3

METHODOLOGY AND DIAGNOSIS IN CORONARY DISEASE

744 Reproducibility of exercise-induced ECG changes in patients with documented coronary artery disease

R. Jagathesan, P. Kaufmann, R.A. Foale, P.G. Camici. *MRC Cyclotron Unit, Imperial College of Science and Technology, Hammersmith and St Mary's Hospitals, London, UK*

Although exercise induced ECG changes are widely used as screening test for the assessment of coronary artery disease (CAD), little is known about its reproducibility.

Methods: 44 patients (42 males, 2 females, age 63 ± 8 years) with documented CAD underwent two symptom limited exercise tolerance test to a standard Bruce protocol performed within 9 ± 5 days. The following ECG parameters were assessed: time (sec) to 0.1 (n = 44) and 0.2 mV (n = 26) ST segment depression, maximal ST segment depression (ST depr; mV) and recovery (time to ST normalization, sec). Reproducibility was assessed both by regression analysis and using the Bland-Altman repeatability coefficient (rep. coeff.)

Results: Heart rate and mean arterial blood pressure were similar at rest and at peak exercise during both tests.

	First	Second	Rep. coeff.	r	p
ST depr (mV)	2.4 ± 0.9	2.3 ± 0.8	1.1	0.82	0.0001
0.1 mV (sec)	266 ± 115	294 ± 106	181	0.68	0.0001
0.2 mV (sec)	331 ± 109	353 ± 115	99	0.89	0.0001
recovery (sec)	337 ± 126	345 ± 142	165	0.81	0.0001

Conclusion: For patients with CAD maximal ST depression and recovery time were equally reproducible during symptom limited exercise tolerance testing. Correlation exists for both the time to 0.1 mV and 0.2 mV ST depression is but the latter is clearly more reproducible and, thus, more reliable. However, this criteria was only achieved in 60% of the patients.

745 Diagnostic value of exercise-induced ST-segment elevation in Q-wave leads in patients after myocardial infarction

M. Zielinska, W. Koniarek[1], M. Maciejewski[1]. *Clinic of Cardilogy, Institute of Cardiology, Lodz; [1]Clinic of Cardiology, Institute of Cardiology, Lodz, Poland*

Exercise-induced ST segment elevation (STel.) in an infarct territory with abnormal Q waves is a known marker for more severe left ventricular wall motion abnormalities and an adverse prognosis. However, it is reported, that STel. during exercise in infarct leads may indicate residual viability in the infarct region.

The aim of the study was to test, if exercise induced STel. is related to LV dysfunction or to persistent viability in patients (pts) with previous myocardial infarction (MI). We investigated the relation between STel. on infarct-related leads during exercise with: (a) the severity of the regional LV dysfunction, (b) myocardial viability (evaluated by low dose dobutamine stress echo- LDSE).

145 consecutive pts (119 men, 26 women, age 58 ± 11 yrs) 2–3 weeks after Q wave MI (anterior: 67, inferior: 78) but without STel. at rest EKG, were enrolled in the study. All pts underwent a target heart rate or symptom limited exercise testing (ET) with Bruce protocol. ST segment was quantified using an automated software (Marquette Inc). Exercise induced STel. > 1 mm above the baseline ST segment level (80 ms after J point) in more than 1 ECG lead with Q wave was considered significant. Pts were divided in 2 groups according to ET results: G1 – 25 pts (after anterior MI: 17, inferior: 8) with significant stress induced STel. and G2- 120 pts without STel. during ET.

All pts underwent rest ECHO and LDSE within 7 days after ET. LV function was estimated using ejection fraction (EF). More severe LV dysfunction was observed in pts from G1(EF 31 ± 8.16% vs. EF 45 ± 10.3% in G2).

Myocardial viability (defined as an improvement of regional systolic wall thickening in the regions with resting regional wall motion abnormalities during LDSE −5 to 15 (g/kg/min.) was recognised in 8 pts (32%) in G1 and 31 pts (25.8%) in G2. There was no relation between exercise induced STel. and myocardial viability (Chi-squared test: 0.809; NS).

Conclusion: 1. Exercise-induced STel. in most cases is associated with left ventricular dysfunction. Pts with exercise-induced STel. have a lower EF than those without and greater severity of resting wall motion abnormalities.

2. Our results suggest that exercise induced STel. is not related to residual myocardial viability.

746 The relative prognostic importance of clinical, exercise electrocardiography and stress echocardiography data in patients with known or suspected coronary artery disease

L. Cortigiani, P.R. Mariani, E.A. Paolini, A. Boni, A. Azzarelli, M. Masini, E. Nannini. *Cardiology Dept, Hospital of Lucca, Lucca, Italy*

In this study we sought to investigate the relative value of clinical, exercise electrocardiography (ExECG) and stress echo (SE) findings in risk stratification of patients (pts) referred for proven or suspected coronary artery disease (CAD). The study group was 696 pts (400 men; 59 ± 10 yy) who underwent both bycicle ExECG (incremental workloads of 25 W every 2') and SE with either dipyridamole (n = 454) (up to 0.84 mg/kg over 10' + atropine up to 1 mg) or dobutamine (n = 242) (up to 40 mgr/kg/min+atropine up to 1 mg). ExECG was positive (ST-segment shift ≥0.1 mV at 80 msec after the J point) in 260 pts; SE was positive (new or worsening of preexisting wall motion abnormality) in 173 pts. During the follow-up (43 ± 26 months), 36 hard cardiac events (12 deaths, 24 infarctions) and 93 revascularizations occurred. With an interactive stepwise procedure, ipercholesterolemia (OR = 3.0; 95% CI = 1.5–5.9; p = 0.0012), prior infarction (OR = 2.8; 95% CI = 1.4–5.4; p = 0.0022), age > 70 years (OR = 2.3; 95% CI = 1.0–4.9; p = 0.0388) and family history of CAD (OR = 1.7; 95% CI = 0.9–3.4; p = 0.0978) were clinical predictors of hard events; the global chi-square was 31.6. After the addition of ExECG data, ipercholesterolemia (OR = 3.0; 95% CI = 1.5–5.8; p = 0.0015), prior infarction (OR = 2.8; 95% CI = 1.4–5.4; p = 0.0020) and ExECG positive result (OR = 2.3; 95% CI = 1.2–4.6; p = 0.0139) showed prognostic power; at this second step the global chi-square increased to 38.4. At the third step, with the addition of SE findings, ipercholesterolemia (OR = 2.7; 95% CI = 1.4–5.2; p = 0.0036), prior infarction (OR = 2.4; 95% CI = 1.2–4.7; p = 0.0145) and SE positive result (OR = 2.5; 95% CI = 1.1–5.4; p = 0.0205) had independent prognostic value; the global chi-square was 43.5. The 4-year infarction-free survival rate was 97% for pts with negative and 83% for pts with positive SE (p = 0.0000); it was 97% for pts with negative and 89% for pts with positive ExECG (p = 0.0023).

In conclusion, in pts with known or suspected CAD, SE data provide incremental prognostic power when compared with clinical and ExECG ones. However, a simple negative ExECG is able to identify a vey low-risk population in whom additional imaging testing seem not to be warranted.

747 QRS width changes during exercise as an index of ischaemia: high-resolution computer analysis in patients with false positive ST response

N. Tahara, H. Takaki, T. Kawada, M. Sugimachi, K. Sunagawa. *Division of Cardiology, National Cardiovascular Center, Osaka, Japan*

False-positive ST response limits the diagnostic value of exercise ECG test. We have demonstrated with use of high-resolution computer analysis of multiple ECG leads that QRS width prolongs during exercise in patients with inducible ischemia and ST depression. Since QRS width changes seem independent of repolarization abnormality (i.e., ST change), patients with false-positive ST responses might be correctly diagnosed with QRS width changes.

Methods: Continuous 12-leads exercise ECG data sampled at 500 Hz during conventional treadmill test were analyzed in 22 false-positive (FP, 8 women, 9 with hypertension) and 25 true-positive (TP) ST depression responses. The diagnosis of coronary artery disease (CAD) was determined by angiography and/or exercise scintigraphy. The onset of the QRS was defined by the earliest deflection and the end was defined as the latest deflection among 12 leads with use of algebraic sum of the absolute voltage from 12 leads and that of the absolute value of the first derivative (dV/dt) from 12 leads. We compared QRS complexes from the averaged data of 5 complexes before and 1-min after exercise. We also examined 24 age-matched healthy subjects.

Results: QRS width did not significantly alter after exercise in either healthy controls (+0.5 ± 1.4 ms) or FP subjects (+1.2 ± 1.7 ms), while patients with TP showed a significant QRS prolongation (+4.0 ± 2.9 ms, p < 0.0001). When we tried to identify the ischemia by QRS prolongation ≥ 2 ms (Mean ± SD of controls), 14 of 22 patients (63%) with FP were correctly diagnosed as normal (negative), and 22 of 25 patients with TP (88%) were identified correctly (positive).

Conclusions: QRS width after exercise did not significantly change in subjects with false positive ST response as well as in healthy contrlos. QRS width analysis is a useful tool to discriminate false-positive from true-poistive ST responses.

748 Non-invasive metabolic evidence of myocardial ischaemia in patients with early non-obstructive atherosclerosis and coronary risk factors

D. Baller, G. Notohamiprodjo, U. Gleichmann, D. Horstkotte. *Clinic of Cardiology, Heart Center NRW, University of Bochum, Bad Oeynhausen, Germany*

It is still unclear whether a reduced endothelial-modulated vasodilator function may really induce myocardial ischemia on the cellular metabolic level due to nonobstructive coronary atherosclerosis (CA) on the basis of risk factors. Since free fatty acid transport into myocardial tissue was demonstrated to be an endothelium carrier-mediated process and decreased fatty acid influx is a marker of myocardial ischemia, we investigated consecutive patients with angina, risk factors but without obstructive CA assessing noninvasively myocardial fatty acid influx rates (vi).

Methods: All fasting patients underwent dual isotope studies after symptom-limited exercise and at rest. Dual isotope technique with 37 MBq Tl-201 as perfusion tracer and 74 MBq 15-(p-123-I-Iodophenyl)-pentadecanoic acid (IPPA) as metabolic tracer for fatty acid turnover were applied simultaneously at peak exercise and 4 hours after exercise at rest. The ratio between metabolic and perfusion uptake was defined as a measure of regional fatty acid extraction rates. From this, vi was calculated. The results were compared to that obtained in 10 healthy age- and sex-mathed controls without risk factors. Baseline data: 13 patients (8 men, 5 women), mean age: 55 ± 11 years, EF: 73 ± 8%, LV-mass: 91 ± 19 g/m^2, PLVED: 14 ± 7 mmHg, risk factors: mild-to-moderate hypertension and/or hypercholesterolemia (LDL > 150 mg/dl), near normal or mildly affected coronary arteries (minimal stenosis < 30%).

Results: (mean ± SD) Regional fatty acid influx rates at exercise was significantly reduced in patients with early CA: vi: 0.136 ± 0.03 vs 0.225 ± 0.04 μmol/g·min in controls (p < 0.01). Involved myocardial regions were predominantly septal (63%), posterolateral (40%) and anteroapical (38%), inferoposterior to a minor degree (32%). In addition, all patients had both inhomogeneous perfusion and IPPA distribution with regional defects.

Conclusions: As far as to our best knowledge, this study demonstrates for the first time noninvasively stress-induced myocardial ischemia with consequent alteration of fatty acid metabolism in patients with nonobstructive CA and associated coronary risk factors. This dual isotope technique might be a promising approach to assess vasodilator function and myocardial metabolism under risk factor interventions to prevent progression or induce functional improvement in early stages of CA.

749 Magnitude of ST-segment elevation during exercise correlates to the severity of myocardial sympathetic nerve denervation after Q-wave myocardial infarction

T. Miyazaki, T. Yamamoto[1], K. Nakagawa[1], T. Shibutani[1], R. Katori[2], K. Ishikawa[1]. *First Department of Medicine, Kinki University School of Medicine, Osakasayama; [1]First Department of Medicine, Kinki University School of Medicine, Osakasayama[2]Showa Hospital, Amagasaki, Japan*

Exercise-induced ST segment elevation after Q-wave myocardial infarction (MI) is recognized as a marker of larger wall motion abnormalities of the left ventricle, but the exact mechanism for ST elevation is uncertain. To test the hypothesis that the magnitude of such ST elevation would be dependent on the severity of myocardial sympathetic nerve denervation, we examined the relation between exercise-induced ST elevation and single photon emission computerized tomographic images with I-123 metaiodobenzylguanidine (MIBG) and thallium-201 (Tl) in 25 patients with first documented anterior MI one month after onset. Each tomographic image at four hours after administration was divided into 26 segments and visually analyzed using a 0 to 3 scale to provide a defect score. The degree of mismatch between MIBG and Tl images was evaluated by expressing the differences between the defect scores (delta defect score). ST segment changes during supine bicycle exercise was gauged. All 25 patients showed more extensive defects of MIBG than those of Tl (defect score; 45.0 ± 9.8 vs 29.7 ± 7.3, P < 0.01). The sum of exercise-induced ST changes in leads V2, V3, and V4 (delta ST) positively correlated to MIBG (R = 0.58, P < 0.01) but not to Tl defect scores (R = 0.24, NS). In addition, delta ST correlated to delta defect scores (R = 0.62, P < 0.01), indicating that the magnitude of ST elevation was more pronounced as the degree of mismatch between MIBG and Tl imaging became larger.

Conclusion: The magnitude of exercise-induced ST elevation gives an estimate for the severity of sympathetic nerve denervation as assessed by MIBG imaging after Q-wave MI. The positive correlation between the ST elevation and the degree of mismatch between MIBG and Tl imaging suggests that ST elevation could be arisen from regional disparities of the sensitivity to beta-adrenergic stimulation between the infarcted and denervated noninfarcted myocardium.

NITRIC OXIDE IN MYOCARDIAL ISCHAEMIA AND REPERFUSION

753 Sarcoplasmic calcium release contributes substantially to the positive chronotropic effect of nitric oxide donors

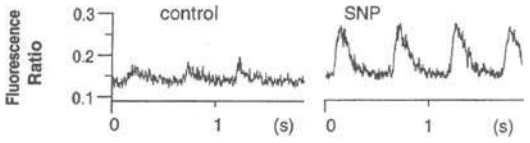
P. Musialek[1], L. Rigg[2], D.A. Terrar[2], D.J. Paterson[3], B. Casadei[1]. *[1]Dept. of Cardiovascular Medicine, John Radcliffe Hospital; [2]Dept. of Pharmacology; [3]University Laboratory of Physiology, Oxford, UK*

Nitric oxide (NO) exerts a positive chronotropic effect in vitro by stimulating the pacemaker current I_f without affecting I_{CaL}. If activity is modulated by $[Ca^{2+}]_i$ and recent evidence indicates that NO can activate ryanodine receptors in cardiac sarcoplasmic (SR) vesicles.

The aim of this study was to test whether exogenous NO stimulates pacemaker activity by promoting SR Ca^{2+} release.

Methods: In isolated guinea-pig atria, we examined the chronotropic response to increasing concentrations (from 0.1 μmol/L to 1 mmol/L) of the NO donors SIN-1 (+superoxide dismutase 100 U/mL, n = 6) or DEA/NO (n = 8), *(i)* alone, or *(ii)* after pre-treatment (40 min) with 2 μmol/L ryanodine (n = 7) to block the SR Ca^{2+} release or 60 μmol/L cyclopiazonic acid (2 h) to deplete SR Ca^{2+} stores (n = 9). In addition, we evaluated the intracellular Ca^{2+} transient (fluorescence with 5 μmol Indo-1 AM) in guinea pig isolated sinoatrial node cells (n = 6) before and after application of sodium nitroprusside (SNP, 5 μmol/L.

Results: SIN-1 or DEA/NO alone progressively increased heart rate (HR) with a peak effect of +51 ± 5 bpm and +41 ± 5 bpm at 0.1 mmol/L ($p < 0.05$). Ryanodine reduced HR from 169 ± 7 to 125 ± 7 bpm (mean ± SEM, $p < 0.05$), whereas CPA caused a transient increase in HR (from 163 ± 6 to 196 ± 9 bpm) followed by a reduction to 133 ± 6 bpm ($p < 0.05$). After pre-treatment with ryanodine or CPA, the peak increase in HR was only +19 ± 4 bpm with SIN-1 and +16 ± 3 bpm with DEA/NO ($p < 0.05$). In isolated sinoatrial node cells, SNP significantly augmented diastolic Ca^{2+} (+13 ± 9%), peak Ca^{2+} (+33 ± 21%), and the amplitude of the Ca^{2+} transient (+102 ± 49%) (figure), and increased the spontaneous beating rate by 34 ± 12% ($p < 0.05$).



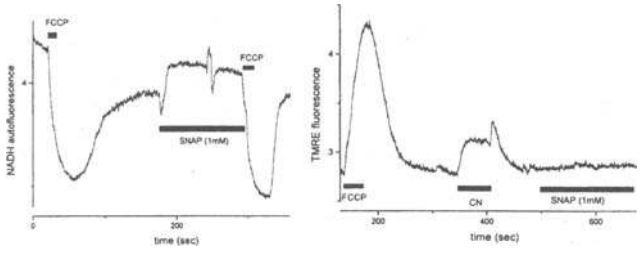
In conclusion, exogenous NO stimulates SR Ca^{2+} release in sinoatrial node cells. This novel pathway contributes substantially to the positive chronotropic effect of NO donors.

754 Nitric oxide modulates mitochondrial function in neonatal cardiocytes by reversible inhibition of respiration

R.D. Rakhit, R.J. Edwards, A. Aldous, M. Duchen[1], M.S. Marber. *Departments of Cardiology, KGT School of Medicine, The Rayne Institute, St. Thomas' Hospital; [1]Physiology, University College London, UK*

Mitochondrial dysfunction is a critical component of ischaemia-reperfusion injury which is associated with ATP depletion, dissipation of the mitochondrial membrane potential and induction of the mitochondrial permeability transition. Nitric oxide (NO) can cause both irreversible and reversible inhibition of respiratory chain complexes but the latter may represent an important physiological mechanism for the regulation of mitochondrial function and the protective adaptation to hypoxia.

Methods: Fluorescence microscopy was performed on cultured rat neonatal cardiocytes. We studied the effect of the NO donor s-nitroso-N-acetyl-L-penicillamine (SNAP) on redox state, using NADH autofluorescence, and mitochondrial membrane potential, using teramethyl ethyl ester (TMRE 10 μg/ml). Maximum and minimum signals were achieved using the uncoupler FCCP and Cyanide.



Results: SNAP 100 μM–1 mM produced a sustained increase in NADH autofluorescence suggesting inhibition of mitochondrial respiration which was not associated with dissipation of the membrane potential. These responses were reversed by FCCP.

Conclusion: We have demonstrated reversible inhibition of mitochondrial respiration by NO in neonatal cardiocytes in culture. This may represent an important physiological mechanism by which NO modulates mitochondrial function in the myocardium.

755 The control of cardiac function and nitric oxide production by the extract of Ginkgo biloba in ischaemic/reperfused rat hearts

T. Pataki, P. Kovacs, P. Ferdinandy[1], I.E. Blasig[2]. *Department of Pharmacology and Ist Department of Medicine, School of Medicine, Debrecen; [1]Department of Biochemistry, School of Medicine, Szeged, Hungary; [2]Institute of Molecular Pharmacology, Berlin, Germany*

The aim of the present study was to evaluate the effect of Ginkgo biloba extract (EGb 761) on the production of nitric oxide (NO) in relation to the recovery of postischemic cardiac function in isolated working rat hearts.

Methods: Rats were orally treated with various doses (25, 50, 75 and 100 mg/kg/day) of EGb 761 for 10 days. Hearts were isolated and subjected to 30 min ischemia followed by 120 min of reperfusion. NO was directly measured by electron spin resonance spectroscopy (ESR). The expression of inducible nitric oxide synthase (iNOS) mRNA was detected by reverse transcription-polymerase chain reaction (RT-PCR) in the ischemic-reperfused myocardium.

Results: EGb 761 inhibited NO production and improved the recovery of postischemic cardiac function in ischemic/reperfused hearts. Thus, rats (n = 6 in each group) treated with 25, 50, 75, and 100 mg/kg/day of EGb 761 and hearts subjected to ischemia/reperfusion, aortic flow was increased from its postischemic drug-free control value of 8.0 ± 4 ml/min to 8.6 ± 0.4 ml/min (NS), 17.3 ± 0.9 ml/min ($p < 0.05$), 21.5 ± 1.1 ml/min ($p < 0.05$), and 23.6 ± 1.2 ml/min ($p < 0.05$), respectively. The same improvement of postischemic recovery in coronary flow, left ventricular developed pressure and its first derivative was also observed. In the initial phase of reperfusion, NO production was reduced by 90% in the 75 mg/kg/day of EGb 761 treated group in comparison with the drug-free ischemic/reperfused group. iNOS mRNA measured by RT-PCR was also reduced by 41% and 58% in the groups treated with 75 mg/kg/day and 100 mg/kg/day of EGb 761, respectively.

Conclusion: The results show that EGb 761 directly acts as an NO scavenger and concomitantly inhibits the expression of iNOS mRNA improving the recovery of postischemic cardiac function in isolated ischemic/reperfused rat hearts.

756 The endothelin A receptor antagonist LU 135252 protects against myocardial ischaemia and reperfusion injury via a nitric oxide-dependent mechanism

A. Gourine, A. Gonon, J. Pernow. *Department of Cardiology, Karolinska Hospital, Stockholm, Sweden*

The hypothesis of the present study was that the previously demonstrated protective effect of ET receptor antagonists against ischaemia and reperfusion injury is due to enhanced nitric oxide (NO) production. We therefore evaluated the cardioprotective effect of the ETa receptor antagonist LU 135252 (LU) in the absence and presence of the NO synthase inhibitor L-NA.

Methods: Anaesthetised pigs were subjected to 45 (protocol I) or 30 (protocol II) min ligation of the left anterior descending coronary artery followed by 4 hours of reperfusion. In protocol I, four groups were given vehicle (n = 6), LU (5 mg/kg i.v.) 10 min before ischaemia (n = 6), the NO synthase inhibitor L-NA (10 mg/kg i.v.) 30 min before ischaemia (n = 5) or L-NA in combination with LU (L-NA+LU) 30 and 10 min before ischaemia (n = 6). In protocol II, two groups were given vehicle or L-NA as above.

Results: In protocol I, mean arterial pressure and rate pressure product were higher in both groups treated with L-NA compared to the LU and vehicle groups. The infarct size was 74 ± 7% of the area at risk in the vehicle group and 95 ± 2% in the L-NA group. LU reduced the infarct size to 43 ± 7% ($p < 0.05$ vs. vehicle). When L-NA was administered prior to LU, the the infarct limiting effect of LU was completely abolished (infarct size 76 ± 6%; $p < 0.05$ vs. LU). In protocol II, infarct size produced by 30 min ischaemia in the vehicle group (62 ± 14) was not increased by L-NA.

Conclusion: Inhibition of NO synthase abolishes the cardioprotective effect of the selective ETa receptor antagonist LU, suggesting that the effect is mediated by release of NO.

757 Essential role of endogenous nitric oxide for perfusion-contraction matching in short-term hibernating myocardium

H. Post, R. Schulz, A. Jalowy, H. Dörge, M. Behrends, S. Belosjorow, G. Heusch. *Department of Pathophysiology, University of Essen, Germany Medical School*

In isolated rabbit hearts the activity of NO-synthase III increases during low-flow ischemia. Whether the subsequent increase in the interstitial NO concentration impacts on myocardial function in situ, however, is still a matter of debate. We therefore investigated the role of endogenous NO in short-term hibernating myocardium, i.e. a situation where contractile function is reduced in adaptation to reduced flow. In 16 enflurane-anesthetized pigs the LAD coronary artery was cannulated and perfused from an extracorporeal circuit. Anterior wall thickness was measured and a work index (WI, mm·mmHg, sonomicrometry and micromanometry) calculated. Transmural blood flow (TMF) was measured with radioactive microspheres. Six pigs (G1) were subjected to 90 min moderate ischemia and 120 min reperfusion. In 5 pigs, NO synthesis was blocked by 30 mg/kg L-NA i.v. before coronary inflow was reduced (G2). Since NO blockade significantly increased LV pressure from 97 ± 11 (SD) to 124 ± 28 mmHg, LV pressure was increased by aortic banding in 5 additional pigs (G3) to match the LV pressure observed in group 2. Following 90 min ischemia and 120 min reperfusion, the myocardium remained completely viable (TTC) in all pigs, indicating successful hibernation. With a comparable decrease in TMF, WI was lower in pigs with NO blockade than in pigs with or without LV pressure match.

	5 min ischemia		85 min ischemia	
	TMF	WI	TMF	WI
G1	50 ± 12	52 ± 12	49 ± 18	46 ± 21
G2	44 ± 13	11 ± 17*	45 ± 11	14 ± 16*
G3	57 ± 16	54 ± 10	57 ± 19	55 ± 16

Values are expressed as % control ± SD. All values are significantly different from control
*: $p < 0.05$ vs. groups 1 and 3; 2-way ANOVA

We conclude that NO is essential for perfusion-contraction matching in short-term hibernation.

NON-LIPID RELATED EFFECTS OF STATINS

759 Improvement of nitric oxide-dependent vasodilatation by HMG-CoA reductase inhibitors through suppression of endothelial superoxide anion formation

A.H. Wagner, T. Koehler, U. Rueckschloss[1], I. Just[2], M. Hecker. *Dept. of Cardiovascular Physiology, University of Goettingen, Göttingen[1] Inst. of Pathophysiology, University of Halle, Halle[2] Inst. of Pharmacology and Toxicology, University of Freiburg, Freiburg, Germany*

Recent reports suggest that the increased production of reactive oxygen species in the vessel wall may lead to enhanced expression of atherosclerosis-associated gene products. The aim of this study was to show that besides the well documented reduction in serum LDL cholesterol, the anti-atherosclerotic effects of the HMG-CoA reductase inhibitors may be explained by a shift in the nitric oxide (NO)/superoxide anion (O_2^-) balance in the vessel wall towards an increased bioavailability of NO.

Methods: The effects of HCRI on phorbol ester-stimulated O_2^- formation by endothelium-intact segments of the rat thoracic aorta were measured by lucigenin-enhanced chemiluminescence and ferricytochrome c reduction. RT-PCR analysis and enzyme measurements were performed to elucidate the effect of HCRI on superoxide dismutase (SOD), NADPH oxidase and endothelial NO synthase (ecNOS). Vascular reactivity studies were performed in a superfusion bioassay system.

Results: Exposure of the segments to the HCRI (0.1–10 μmol/L) resulted in a time- and concentration-dependent decrease of both basal and stimulated O_2^- formation (maximum inhibition of 70% after 18 hours), the latter of which was predominantly endothelium-dependent. Mevalonic acid (400 μmol/L) reversed the inhibitory effect of the HCRI which was mimicked by Clostridium sordellii lethal toxin that inactivates p21 Rac, but not by Clostridium botulinum exoenzyme (C3) that inactivates p21 Rho. HCRI did not reveal any effect on SOD or NADPH oxidase (p91-phox subunit) expression, while that of ecNOS was enhanced twofold. Acute or long-term inhibition of ecNOS activity, however, did not affect O_2^- formation. Exposure of the segments to atorvastatin resulted in a significant improvement of endothelium-dependent NO-mediated relaxation, and this effect was abolished in the presence of SOD.

In conclusion, these findings suggest that apart from augmenting endothelial NO formation, HCRI prevent the isoprenylation of p21 Rac which is critical for NADPH oxidase activity and hence endothelial O_2^- formation. The resulting shift in the balance between NO and O_2^- in the endothelium, namely the decrease in O_2^- formation, improves endothelial function even in healthy blood vessels and therefore may provide a reasonable explanation for the beneficial effects of HCRI in patients with coronary heart disease besides or alternative to the reduction in serum LDL cholesterol.

760 Effects of HMG-CoA reductase inhibition on human saphenous vein endothelial and smooth muscle cells: molecular basis for local drug delivery system to prevent venous bypass graft disease

Z. Yang, P. Birkenhauer[1], F.C. Tanner, L. Rathgeb, H. Joch, B. Gander[1], H.P. Merkle[1], T.F. Lüscher[2]. *Institut of Physiology, Cardiovascular Research, Zürich[1] Institute of Pharmacy, Federal Institute of Technology (ETH), Zürich[2] Cardiology, University Hospital Zürich, Zürich, Switzerland*

Venous bypass graft failure is an important cause of morbidity and mortality in patients with coronary artery disease. Endothelial cell (EC) dysfunction and smooth muscle cell (SMC) proliferation is involved in venous bypass graft disease. Substances that improve EC function and inhibit SMC proliferation would therefore be of clinical relevance, if they could be delivered locally to the blood vessel wall and remain there for a prolonged periods of time. We studied the effect of a HMG-CoA reductase inhibitor cerivastatin on human saphenous vein EC and SMC and developed a local drug delivery system.

Methods and Results: EC and SMC were isolated from human saphenous veins. Endothelial nitric oxide synthase (eNOS) expression and NO production were analysed by immunoblotting and porphyrinic microsensor. SMC proliferation was analysed by ^{3}H-thymidine incorporation. Cerivastatin (1 nmol/L to 1 μmol/L) concentration-dependently upregulated eNOS protein level and increased NO release in EC in response to calcium ionophore (10 μM) and inhibited ^{3}H-thymidine incorporation ($n = 9$; $p < 0.001$) to platelet-derived growth factor (PDGF; 5 ng/ml) in SMC; the latter was associated with complete inhibition of Cdk2 activation, pRb hyperphosphorylation and partial prevention of p27Kip1 downregulation, while MAPK and p70S6K remained unaffected. Encapsulation of cerivastatin into biodegradable and biocompatible PLA/PLGA polymers produced a sustained long-term release of the active drug over 60 days.

Conclusion: In human saphenous veins cerivastatin improves human EC eNOS expression, NO release and inhibits SMC growth and cell cycle progression via a mechanism(s) other than inhibition of MAPK and p70S6K pathways. These effects on vascular EC and SMC could contribute to vascular protective effects of HMG-CoA reductase inhibitors. Microencapsulation of cerivastatin into biodegradable PLA/PLGA microspheres for local delivery could be used in patients for prevention of venous bypass graft disease

761 Statin therapy increases coronary vasodilator capacity in 30 patients with early stages of coronary atherosclerosis assessed non-invasively with positron emission tomography.

D. Baller, J. Holzinger, G. Notohamiprodjo, J. Lehmann, R. Weise, U. Gleichmann, D. Horstkotte. *Clinic of Cardiology, Heart Center NRW, University of Bochum, Bad Oeynhausen, Germany*

Background: Aim of our study was to assess noninvasively coronary flow reserve (CFR) after short-term therapy (≈6 months) with simvastatin (20–40 mg) in 30 patients with angina and very early stages of coronary atherosclerosis and mild-to-moderate hypercholesterolemia on an average.

Methods: Regional and averaged myocardial blood flow was measured at rest (MBFR) and after dipyridamol-induced maximal vasodilation (MBFD) with 0.56 mg dipyridamole/kg using positron emission tomography (PET) and N-13-ammonia as flow tracer. Each patient, previously not receiving lipid-lowering drugs, served as his or her own control. Exclusion was smoking, diabetes, cardiomyopathy, leftventricular hypertrophy, uncontrolled hypertension and hormonal replacement. Coronary angiogram was normal overall in 13 and mildly affected in 17 patients (focal luminal irregularities and/or minimal stenosis ≤ 30%). Baseline data: 21 males; 9 females; mean age: 56.9 ± 7.7 years. Total cholesterol: 243 ± 43 mg/dl, LDL-cholesterol: 168 ± 34 mg/dl, HDL: 45 ± 16 mg/dl, averaged dipyridamole flow: 187 ± 40 ml/min·100 g; minimal coronary resistance (MCR = mean arterial pressure/MBF_D): 0.51 ± 0.1 mmHg/ml/min·100 g; CFR was reduced at baseline: 2.2 ± 0.6. MBFR: 89 ± 19 ml/min·100 g.

Results: After 6-month follow-up (mean ± SD): LDL: 96 ± 25 mg/dl ($p < 0.001$); HDL: 49 ± 11 mg/dl ($p < 0.02$); MBF_D: 235 ± 55 ml/min·100 g ($p < 0.01$); MCR: 0.4 ± 0.1 mmHg/ml/min·100 g ($p < 0.01$); CFR: 2.7 ± 0.6 ($p < 0.01$); MBF_R: 91 ± 18 ml/min·100 g (n.s). Concomitantly, a significant regression of effort angina or atypical angina ($p < 0.01$) was observed in the majority of patients.

Conclusions: Short-term statin therapy increases overall coronary vasodilator capacity in patients with early stages of coronary atherosclerosis in conjuction with a regression of anginal symptoms suggesting improved endothelial function.

762 Cholesterol lowering drugs reduce recurrences of ventricular arrhythmias after defibrillator implantation in patients with coronary artery disease

J. De Sutter, R. Tavernier, J. Kazmierckzak, W. Fonteyne, L. Jordaens, D. Clement. *Department of Cardiology, University Hospital, Ghent, Belgium*

Cholesterol-lowering drugs (CLD) reduce total and cardiac mortality in patients with coronary artery disease (CAD). We evaluated a possible effect of CLD on ventricular arrhythmias (VA) in a population of patients with CAD and life-threatening VA that required internal defibrillator (ICD) implantation.

Methods: We studied the recurrence of VA (VT or VF) requiring ICD therapy and the combined endpoint of cardiac death and hospitalization (hospitalization for angina, heart failure and electrical storm) in 78 consecutive patients (age 66 ± 9 years, 73 males, ejection fraction 33 ± 13%) with CAD and VA requiring ICD implantation. At discharge 27 (35%) patients were on CLD (16 statines, 11 fibrates) (group I) and 51 (65%) patients were not on CLD (group II)

Results: Baseline characteristics (including age, gender, ejection fraction, extent of coronary artery disease, presenting arrhythmia and medication at discharge) were comparable for both groups. After a mean follow-up of 476 ± 330 days, events in both groups were the following:

	Group I	Group II	p-value
ICD therapy for recurrences of VA	6 (22%)	29 (57%)	0.004
Total death	3 (11%)	9 (18%)	0.528
Cardiac death	2 (8%)	8 (16%)	0.479
Cardiac hospitalization	2 (8%)	15 (29%)	0.041
Cardiac death and hospitalization	4 (15%)	23 (45%)	0.015

Conclusions: CLD reduce recurrences of VA after ICD implantation in patients with CAD and life-threatening VA. Furthermore, the combined endpoint of cardiac death and hospitalization is significantly reduced in patients on CLD after ICD implantation.

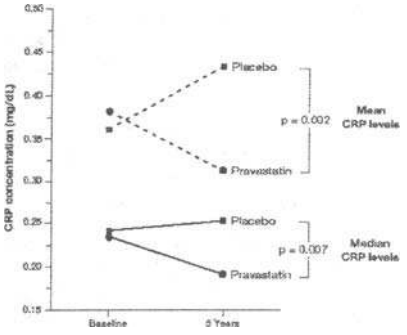
763 Long-term effects of pravastatin on plasma concentration of C-reactive protein

P.M. Ridker, N. Rifail, M.A. Pfeffer, F. Sacks, E. Braunwald. *For the CARE investigators; Boston MA, USA*

Elevated plasma concentrations of C-reactive protein (CRP) are associated with increased risk of myocardial infarction (MI) and stroke. In this study, we evaluated whether long-term therapy with pravastatin alters levels of this inflammatory parameter.

Methods: We employed a high-sensitivity assay to determine CRP levels among a randomly selected group of 472 participants in the CARE trial (pravastatin 40 mg orally qd, n = 258; placebo, n = 214) in whom both baseline and 5-year blood samples were available and who had remained free of recurrent vascular events during follow-up.

Results: Statistically significant differences were observed at 5 years between the pravastatin and placebo groups in terms of median CRP levels and absolute mean change in CRP.



These effects persisted in analyses stratified by age, body mass index, smoking status, blood pressure, and baseline lipid levels. There was no obvious relationship between the magnitude of change in CRP and lipid levels in both groups.

Conclusion: Pravastatin therapy significantly reduces CRP in post-MI patients. These data further support the potential for non-lipid lowering effects of this agent.

764 Statin therapy reduces adhesion molecule (VCAM-1) levels: evidence for an anti-atherosclerotic effect independent of LDL reduction

D. Baller, T. Brinkmann[1], G. Notohamiprodjo, R. Weise, U. Gleichmann, D. Horstkotte, K. Kleesiek[1]. *Clinic of Cardiology; [1]Institute of Laboratory and Transfusion Medicine, Heart Center NRW, University of Bochum, Bad Oeynhausen, Germany*

Background: Cellular adhesion molecules such as vascular cell adhesion molecule-1 (VCAM-1) mediate adhesion of leucocytes to the endothelium and play a key role in human atherosclerosis under the impact of risk factors. Previous data of our laboratory revealed a significant reduction after 6-month lipid lowering therapy with simvastatin. To assess the question of a possible independancy from concomitant LDL reduction VCAM-1 levels were measured ≈4 weeks after initiation of simvastatin therapy (20–40 mg) and after ≈5 months follow-up in 21 patients with mild-to-moderate hypercholesterolemia and reduced coronary flow reserve on positron emission tomography.

Methods: Soluble adhesion molecule VCAM-1 levels were measured by commercially available solid phase sandwich enzyme linked immuno sorbent assay (ELISA) in venous blood. 15 apparently healthy blood donors (10 males, 5 females) at equivalent age (51–60 years) served as a reference group: VCAM-1: 810 ± 243 ng/ml. Baseline data: 14 males, 7 females; mean age: 58 ± 8 years. LDL before lipid-lowering: 164 ± 32 mg/dl, after ≈4 weeks simvastatin therapy: 108 ± 41 mg/dl (−34%).

Results: (Mean ± SD) VCAM-1 levels decreased from 1108 ± 327 to 787 ± 313 ng/ml (p = 0.002) during ≈5 months (5.6 ± 2.1) simvastatin therapy. During the same period LDL only slightly decreased from 108 ± 41 mg/dl to 91 ± 30 mg/dl (p = n.s).

Conclusion: Statin therapy with simvastatin exerts, at least partly independent of LDL reduction, a favorable effect on atherosclerotic inflammation assessed in terms of decrease in VCAM-1. This non-lipid property may help to explain early cardiovascular event reduction in clinical trials of statin therapy.

NEUROHORMONAL CONTROL IN HUMANS

765 Physiological correlates of complexity of R-R interval dynamics

M. Tulppo, T.H. Mäkikallio[1], K.E.J. Airaksinen[1], H.V. Huikuri[1]. *Merikoski Rehab Center, Oulu; [1]Department of Medicine, University of Oulu, Oulu, Finland*

Reduced complexity of R-R interval dynamics is related to aging and to various cardiovascular disorders, but the physiological background for complexity or predictability in heart rate (HR) behavior is not well know.

Methods: Approximate entropy (ApEn), a measure of complexity, along with traditional measures of HR variability were analyzed during physiological and pharmacological adrenergic stimulation: 1) noradrenaline (nor) 100 ng $kg^{-1}min^{-1}$, 2) combined noradrenaline and adrenaline (adr) (nor 100 + adr 16 ng $kg^{-1}min^{-1}$), were infused in 12 healthy volunteers (mean age 26 ± 5) who also underwent 3) passive head-up tilt test (60 degrees) and 4) dynamic treadmill exercise test with a steady-state work load of 4 km/h (Table 1).

Results: Noradrenaline resulted in an increase of mean blood pressure (from 94 ± 8 to 117 ± 13 mmHg, p < 0.001) and reduction in HR (from 61 ± 10 to 51 beats/min, p < 0.001) along with reduced ApEn and increased nuHF.

Table 1

	Base	Nor	Nor + Adr	Tilt	Exercise
ApEn	1.16 ± 0.15	0.98 ± 0.22**	1.04 ± 0.27	1.01 ± 0.18	1.28 ± 0.15*
HF (nu)	53 ± 20	71 ± 19**	58 ± 19	17 ± 12**	20 ± 13**
LF (nu)	47 ± 21	29 ± 18**	41 ± 19	85 ± 20**	80 ± 13**

*p < 0.05, **p < 0.001

Conclusion: Physiological and pharmacological adrenergic stimulation result in divergent effects on complexity of R-R intervals. Reduced complexity is most closely related to increased levels of noradrenaline, reflecting concomitant, accentuated sympathetic and vagal outflow to the sinus node.

766 Different effect of age on the autonomic modulation of sinus and AV nodes

P. Kowallik, P. Voigtlaender, C. Braun, M. Meesmann. *Department of Medicine, Würzburg, Germany University*

Parasympathetic modulation of the sinus node decreases with age. We investigated, whether autonomic modulation of the AV node also changed with age. Concomitant changes are not necessarily, because we have shown, that in healthy young man the autonomic nervous system can independently modulate sinus node and AV node.

Methods: A high-resolution (500 Hz) ECG was continuously recorded from about 10 pm to 6 am in 9 young (Group A, 25 ± 1 years) and 9 middle-aged (Group B, 52 ± 5 years) healthy subjects. The onset of P-waves and QRS-complexes was identified for all heart cycles by a computer algorithm with an accuracy of ±1 ms. Power spectra from the PP and PR intervals were integrated in the low frequency (LF) and the high frequency (HF) bands. The normalized HF power (nHF) of PP and PR intervals was used as an index of efferent vagal modulation and the LF/HF-ratio as an index of the sympathovagal balance of the sinus node (PP) and the AV node (PR).

Results:

	Sinus node (PP)		AV node (PR)	
	Group A	Group B	Group A	Group B
nHF	0.39 ± 0.14	0.20 ± 0.12*	0.38 ± 0.08	0.35 ± 0.15
LF/HF	1.84 ± 0.86	5.24 ± 2.86*	1.74 ± 0.64	2.30 ± 1.23
Sqr (TP) [ms]	145.2 ± 50.3	75.6 ± 22.9*	5.52 ± 1.16	5.24 ± 3.30

(mean ± SD; TP: total power; *p < 0.05 Group A vs. Group B)

In contrast to the known age-dependent decrease in the parasympathetic modulation of the sinus node, parasympathetic modulation and sympathovagal balance of the AV node was not significantly influenced by age.

Conclusion: Unlike autonomic modulation of the sinus node, autonomic modulation of the AV node was independent of age. Thus, changes in the autonomic modulation of the heart, that might be caused by different diseases, can be investigated irrespective of age on the AV node level but not on the sinus node level.

767 Baro receptor sensitivity and heart rate variability during acclimatization to high altitude

K. Sevre, A.R. Nakstad, J.D. Lefrandt[1], M. Rostrup. *Division of Medicine, Ullevål Hospital, Oslo, Norway[1] University Hospital, Groningen, Netherlands*

Introduction: Hypobaric hypoxia may modify autonomic function. In the present study we assessed heart rate variability (HRV) and baroreflex sensitivity (BRS) during acclimatization to a simulated altitude of 4500 m (The Trysil Study).

Material and Methods: 8 healthy volunteers were examined during a one week stay in a hypobaric chamber built as a modern apartment. During the first 3 days there was a stepwise increase in simulated altitude up to 4500 m. The subjects then stayed at this altitude for 4 days before returning to sea level. HRV was assessed by 24 hour Holter recordings (Oxford). BRS was determined by the "transfer function" method, analyzing the relation between spontaneous fluctuations of 300 seconds of systolic blood pressure and heart rate (Finapres). A paired t-test was performed after log transformation of non normally distributed parameters.

Results: At a simulated altitude of 4500 m there was a significant decline in total power from 9200 ± 1779 ms.ms (Mean ± SEM) to 3135 ± 557 ms.ms ($p = 0.003$) compared to sea level. LF power decreased significantly (2423 ± 504 vs. 981 ± 204 ms.ms, $p = 0.007$) as did HF power (723 ± 193 vs. 252 ± 66 ms.ms, $p = 0.01$). BRS decreased significantly from 15.5 ± 2.0 ms/mmHg to 9.5 ± 2.6 ms/mmHg ($p = 0.004$).

Conclusion: We found evidence of blunted autonomic activity and reflexes during acclimatization to hypobaric hypoxia.

768 Plasma levels of volume regulating hormones in patients with obstructive sleep apnea syndrome treated with nasal continous positive airway pressure therapy

M.R. Schulze, F. Schmidt[1], K. Ploetze, T. Zerm, R. Henssge. *University Dresden, Cardiovascular Institute, Dresden; [1]Medical Clinic I, University Dresden, Dresden, Germany*

In obstructive sleep apnea syndrome (OSAS) patients (pts.) develop short-term and long-term alterations (systemic and pulmonary hypertension, left and right heart failure) of the cardiovascular system. Increased venous return induced by pathologically high negative intrathoracic pressure during obstructive apnea leads to acute cardiac volume load. Secretion of natriuretic peptides from atria (Atrial natriuretic peptide; ANP) and ventricles (Brain natriuretic peptide; BNP) are stimulated by increased cardiac volume load. Aim of our study was to evaluate the course of volume regulating hormones in pts. with OSAS treated with nCPAP.

Methods: In 10 consecutive pts. (10 m; mean age 52 ± 11) we measured the circulating levels of atrial natriuretic peptide(NT-proANP) and brain natriuretic peptide (NT-proBNP) taken from an antecubital vein at 4 occasions: 8 pm (Rest), 5 am after diagnostic-night (Diag.), 5 am after therapy 1-night (Ther.1) and 5 am after therapy 2-night (Ther.2), respectively. During Ther.1 and Ther.2 pts. were treated with nasal continous positive airway pressure (nCPAP) therapy. Respiratory disturbance index (RDI) was determined during Diag., Ther.1 and Ther.2 by polysomnography.

Results: NT-proANP and NT-proBNP were significantly elevated after Diag. and dropped significantly after Ther.1 and Ther.2 parallel to a significant drop of RDI (Table 1).

Table 1

	Rest	Diag.	Ther. 1	Ther. 2
RDI [n/h]		61.09 ± 21.77	25.93 ± 19.14*	8.33 ± 8.44*
NT-proANP [nM]	0.24 ± 0.08	0.33 ± 0.07*	0.26 ± 0.07*	0.22 ± 0.05*
NT-proBNP [nM]	0.26 ± 0.09	0.41 ± 0.08*	0.24 ± 0.08*	0.20 ± 0.05*

Values are means ± SD; *p < 0.05; Rest vs Diag.; Diag. vs Ther.1; Diag. vs Ther.2

Conclusion: 1. Secretion of ANP and BNP increase during phases of apnea in pts. with OSAS. 2. Adequate treatment with nCPAP results in a normalization of ANP and BNP levels, respectively. 3. ANP- and BNP-concentrations could be a helpful marker to register successful treatment with nCPAP in pts. with OSAS.

769 Abnormal autonomic response to high-altitude exposure in acute mountain sickness

P.A. Lanfranchi, P. Baderna, L. Spagnolatti, G. Cremona, R. Colombo, G. Mazzuero, P. Wagner, P. Giannuzzi. *Salvatore Maugeri Foundation IRCCS, Veruno (NO), Italy; Dept. of Physiology, UCSD San Diego CA, USA*

Acute Mountain Sickness (AMS) is characterised by a variety of symptoms which frequently occur in lowlanders ascending to high altitude. AMS, usually self-limited, may progress to life-threatening cerebral edema. Although the exact mechanism is still unclear, it seems to be related to cerebral vasodilatation in response to hypobaric hypoxia, possibly mediated by the sympathetic nervous system.

Methods and results: To evaluate the role of the autonomic nervous system in the genesis of AMS, we studied baroreflex sensitivity (BRS) by means of a non-invasive technique (alpha-index) in 47 normal subjects (12 F, 16–57 yrs), a few hours after reaching high altitude (4559 m; HA). Medical history, physical examination, spirometry, arterial oxygen saturation, EKG, heart rate variability, and Lake Louise questionnaire were also performed. Nineteen subjects repeated the protocol at low altitude (200 m; LA). At HA, 17 subjects (36%) had AMS (Lake Louise score ≥ 3). No differences were found between subjects with and without AMS in terms of anthropometric and respiratory function data. In contrast, the subjects with AMS were older (40 ± 10 vs 34 ± 9 yrs, $p < 0.05$) and had a lower BRS (5.6 ± 3.1 vs 10.1 ± 7.3 ms/mmHg, $p < 0.05$). At LA the 8 subjects with AMS showed a tendency toward a lower BRS compared with the subjects who were asymptomatic at HA (9.7 ± 3.2 vs 12.4 ms/mmHg, ns).

Conclusions: These results show that AMS is associated with an abnormal autonomic reactivity to acute exposure to high altitude and suggest a possible role of the individual autonomic function in the genesis of symptoms at high altitude.

770 Assessment of autonomic control of the heart in patients with cardiac syndrome x

A. Cevese, R. Cemin[1], G. Gulli, P. Pancera[2], C. Vassanelli[1]. *Departments of Human Physiology; [1]Cardiology; [2]Internal Medicine, University of Verona, Italy*

Recent studies suggested a possible role of increased sympathetic activity in patients (pts) with cardiac syndrome X (SX) (angina, inducible myocardial ischemia and angiographically normal coronary arteries). In 18 pts (59 ± 3 years) with diagnosed SX we recorded standard ECG and finger arterial pressure (Finapres). 10 min records were taken in supine position (S) and after passive 60° tilting (T). Spectral analysis on time series of R-R period (RR) and systolic blood pressure (SAP) was performed by an autoregressive method, to quantify low (LF) and high (HF) frequency oscillations. Values are reported as means ± standard error. On 13 out of 18 pts a set of standardized vagal stimulation tests (VST), such as lay-to-standing, squatting, deep breathing, 40 mmHg Valsalva maneuver and cold face (pooled score). In 13 pts HF power of RR (67 ± 24 ms^2) in S was low and T induced a slight increase in the heart rate (814 ± 37.2 to 767 ± 27.8 ms), with an increase of LF power of SAP (from 4.8 ± 1.1 to 10.8 ± 1.9 $mmHg^2$), while the frequency domain values of RR did not change 9 of these pts performed the VST, and 8 showed vagal impairment. In the remaining 5 pts, heart rate (RR = 909 ± 65 ms) was lower and HF power of RR (231 ± 121 ms^2) was higher in S, and T induced the expected changes of RR. VST in 4 pts showed unaltered vagal responses. The results of spectral analysis suggest a vagal impairment in 13 pts, which is partially confirmed by VST. Thus, most of the pts with cardiac SX show a reduced vagal function not a sympathetic hypertone, as previously suggested. This finding may be important for the assessment of pathogenetic mechanisms of SX as well as for a novel treatment protocols.

MECHANISMS OF ATHEROSCLEROSIS

771 The GPI-anchor of T-cadherin is important for interaction with lipoproteins

Thomas Niermann, Frances Kern, Elena Kouzmenko, Thérèse Resink. *Dept. Research, Cardiovascular Labs., University Hospital, Basel, Switzerland*

Differential lipoprotein-binding studies on intact smooth muscle cells (SMC) have indicated binding sites with novel characteristics which might represent candidate cellular lipoprotein-binding sites associated with intracellular signalling by lipoproteins. Two proteins, 105 kDa and 130 kDa, in lysates from SMC retain the property to bind lipoproteins after PAGE and blotting. Amino acid sequences of tryptic peptides of the purified proteins matched with human (pro) T-cadherin (T-cad), and with peptide-based anti T-cad antisera we could show that anti T-cad immunoreactivity colocalizes with LDL-binding. We expressed recombinant T-cad in stably transfected 293 cells to confirm identity of p105/p130 as T-cad. The transfectants express two anti-T-cad immunoreactive proteins of 105 and 130 kDa. The correct location of T-cad to the outer cell membrane of intact cells was demonstrated by FACS analysis and by its release upon incubation with PI-PLC. To date, binding studies on intact cells show only a moderate, albeit significant, increase in lipoprotein binding in T-cad expressing cells which is not accordance with their high expression of T-cad protein. The ligand binding characteristics of recombinant T-cad on blot are indistinguishable from SMC T-cad, since both bind native LDL, oxLDL, acLDL and also HDL_3 and delipidated HDL_3 with similar affinities. Unexpectedly, T-cad released by PI-PLC from transfectants and SMC is unable to bind lipoproteins on ligand blots. A T-cad variant which is expressed without the signal peptide for GPI anchor attachment and which is secreted into the culture medium as a soluble protein also lacks lipoprotein binding on blot. Taken together we conclude that the lipid anchor of T-cad is the important structural component for the binding of lipoproteins. Control experiments do not give any indication that lipoprotein binding is a property common to GPI-anchored proteins in general.

772 Overexpression of tissue inhibitor of metalloproteinase-3 inhibits neointima formation in porcine saphenous vein-to-carotid interposition grafts in vivo

A.H. Baker, C.T. Lloyd, S.J. George, G.D. Angelini, A.C. Newby. *Bristol Heart Institute, University of Bristol, Bristol, UK*

Drug or gene-based treatments to prevent neointima formation in coronary vein grafts remain elusive. Recent studies implicating metalloproteinases (MMPs) in vein graft neointima formation suggest inhibition of MMPs by tissue inhibitor of metalloproteinases (TIMPs) as possible therapy. Recently, we have demonstrated that TIMP-1, -2 and -3 equipotently inhibit smooth muscle cell migration while TIMP-3 uniquely promotes SMC apoptosis.

Methods: Adenoviruses expressing lacZ (RAdlacZ) or human TIMP-3 (RAdTIMP-3) were exposed to the lumenal surface of pig saphenous veins at 2.5 × 10^{10} plaque forming units (pfu)/ml for 30 minutes ex vivo prior to grafting into the carotid artery. Infection efficiency was evaluated by staining for β-galactosidase *en face* and in cross sections. MMP activity was evaluated by *in situ* zymography, proliferation by proliferating cell nuclear antigen (PCNA) staining and endothelial coverage by immunocytochemistry with DBA-lectin. Apoptosis was quantified by *in situ* end labelling (ISEL), terminal dUTP nick end labelling (TUNEL) and immunocytochemistry for the pro-apoptotic bcl-2 antagonist, bak. Neointimal and medial areas at 1 month were measured by planimetry.

Results: 40% of lumenally exposed cells expressed recombinant β-galactosidase 7 days post-implantation. RAdTIMP-3 induced high levels of TIMP-3 in the near lumenal extracellular matrix and powerfully inhibited MMP activity throughout the veins. SMC apoptosis was increased both in the neointima and media at day 7 but not at day 28. TIMP-3 overexpression reduced neointima formation at 28 days post-infection from 3.9 ± 0.5 mm2 for vehicle-treated and 4.8 ± 1.1 mm2 for RAdlacZ-treated to 2.0 ± 0.1 mm2 ($p < 0.05$ vs both controls, n = 6/group) without significantly affecting medial area, medial cell proliferation or endothelial coverage.

In conclusion: Our results clearly identify TIMP-3 gene therapy as a candidate for prevention of vein graft neointima formation.

773 Helicobacter pylori infection does not influence atherogenesis in vivo in mice

F. Mach, M. Michetti[1], P. Michetti[1], P. Libby[2]. *Vascular Medicine Dept, Brigham and Women's Hospital, Boston MA; [1]Gastroenterology Division, Beth Israel Deaconess Medical Center, Boston MA[2]Vascular Medicine Dept, Brigham and Women's Hospital, Boston MA, USA*

Helicobacter pylori is now widely recognized as an important cause of gastric disease, and some reports have suggested a link to ischemic heart disease (IHD). Since the first report of a high incidence of H. pylori seropositivity in patients with coronary heart disease, numerous epidemiological studies have explored an association between H. pylori infection and IHD. The contradictory results of these studies have highlighted the debate between inflammation, infection and the development of IHD. Although H. pylori has not been detected within atherosclerotic lesions in situ, this infection might still promote vessel-wall cells activation and atherosclerotic lesions indirectly. To seek direct evidence for a role of H. pylori infection in atherogenesis, we examined the effect of this infection in atherosclerosis-prone mice.

Male wild-type C57/Bl6 mice and LDL-receptor deficient syngeneic mice (LDLR−/−) were randomly assigned to be infected with H. pylori strain SS1, a mouse-adapted cag+ strain or sham-infected (n = 8 per group). All animals were fed a high cholesterol diet (1.25%) lacking added cholate. After 6 or 12 weeks, mice were sacrificed and atherosclerotic lesion formation as well as lipid deposition measured using a quantitative computer-assisted image analysis, as described previously. H. pylori infection was confirmed by rapid urease test and by histology on gastric biopsies. Infected or uninfected mice had similar total cholesterol, triglycerides, circulating leukocytes, hematocrit or fibrinogen.

H. pylori infection did not influence aortic atherosclerotic lesions or aortic lipid deposition in this model of atherosclerosis. Aortic arch lesions were minimal in wild-type mice infected or not with H. pylori after 6 or 12 weeks of high cholesterol diet. In contrast, LDLR−/− mice showed extensive atherosclerotic lesions, as defined by aortic wall area and thickness ($p < 0.001$ for both parameters vs. wild-type values; Wilcoxon rank sum test), but H. pylori infection did not affect the severity of these lesions. Lipid deposition was minimal in infected (2.5 ± 1.0% of abdominal aortic surface area) and non-infected (2.3 ± 0.9) wild-type mice. In LDLR−/− mice, however, lipid deposition was 21 ± 3% ($p < 0.001$ vs. wild-type) in non-infected animals but was not modified by H. pylori infection (22 ± 4%).

To the best of our knowledge, this is the first experimental study investigating in vivo the influence of H. pylori infection on atherogenesis. Under the conditions of this experiment, H. pylori infection does not contribute to the development of atherosclerotic lesion formation.

774 Association between the lipoproteinlipase gene polymorphism, cholesterol levels and myocardial infarction

S.R. Holmer, C. Hengstenberg, B. Mayer, G.A.J. Riegger, H. Löwel, S. Engel, H. Schunkert. *Internal Medicine II, University of Regensburg, Regensburg, Germany*

Small studies have reported inconsistent data on the associations between the H2H2 lipoproteinlipase (LPL) genotype with dyslipidemia or premature coronary artery disease. This study involved 2585 individuals with complete pheno- and genotyping.

Methods: The association of LPL genotypes with cholesterol levels was assessed in survey participants from the general popultion of Augsburg, Germany (n = 1357. Genotype frequency in this healty population was compared to that in patients who had experienced a myocardial infarction (MI) under 60 years of age (population-based MI-register Augsburg), n = 613. In addition, to condensate genetic factors, 138 siblings of MI patients affected with MI and 477 siblings with no known coronary artery disease were genotyped.

Results: In the general population a significant association between the H2H2 genotype and unfavorable lipid levels was observed:

	H1H1	H1H2	H2H2	p-value H1H2 vs. H2H2
LDL-C (mg/dl)	143 ± 1	141 ± 2	147 ± 2	0.001
HDL-C (mg/dl)	55 ± 2	55 ± 1	53 ± 1	0.01
Total/HDL-C	4.6 ± 0.1	4.6 ± 0.1	4.9 ± 0.1	0.04

It persisted after adjustment for age, gender, body mass index, alcohol intake, smoking, hormone replacement, and lipid lowering therapy. However, neither men nor women displayed an association between the H2 allele frequency and MI: general population (men/women) 71.5/72.1%, MI register 71.6/70.6%, non-affected siblings 73.4/72.4%, affected siblings 73.3/72.4%. Similarly, genotype frequencies were not different between groups with and without MI.

This large study shows that the H2H2 genotype of the LPL gene polymorphism is associated with unfavorable lipid levels in the general population. However, these effects were not strong enough to reveal a significant association with MI in 751 patients with premature MI.

775 Role of oxidized low-density lipoprotein in the progression of coronary atherosclerosis in humans

Y. Tsukamoto, M. Ueda[1], A.C. van der Wal, R. Komatsu[1], T. Matsuo[1], Y. Ikura[1], M. Oogami[1], H. Itabe[2], T. Takano[2], A.E. Becker. *Academic Medical Center, Amsterdam, Netherlands; [1]Osaka City University Medical School, Osaka; [2]Teikyo University, Kanagawa, Japan*

Previous pathological studies have shown that inflammatory processes are associated with progression of coronary atherosclerosis. In vitro studies have suggested that oxidized low density lipoprotein (OxLDL) plays a key role in the genesis of the inflammatory processes in atherosclerotic lesions. Recently, a new anti-OxLDL monoclonal antibody, DLH3, which recognizes oxidized phosphatidylcholine (OxPC), has been developed by one of us. This antibody is specific for OxLDL, and does not bind to either native, acetylated, or malondialdehyde-treated LDL. To verify the role of OxLDL in the progression of atherosclerosis in human coronary arteries, we have immunohistochemically studied the presence of OxPC, using this new antibody.

Methods: Eighty-six segments of coronary arteries were harvested at autopsy from patients over 50-year-old. Antibodies were used against smooth muscle cells (SMCs), macrophages (Mϕs), endothelial cells, T lymphocytes, apolipoprotein B and OxPC. For the identification of cell types which show staining positivity for OxPC, immunodouble (OxPC/SMC, OxPC/Mϕ) and immunotriple (SMC/Mϕ/OxPC) stainings were also performed.

Results: Fibrous plaques containing abundant SMCs without Mϕs showed no staining for OxPC. In contrast, fibrous plaques with foci of clustered foam cells (FCs) revealed distinct positivity for OxPC in these FCs. In atheromatous plaques, fibrous caps with inflammatory cells also showed OxPC positivity in FCs, however, a lipid core generally showed no staining for OxPC.

Conclusion: These results suggest that during human coronary atherogenesis, OxLDL plays a crucial role in the development of inflammatory processes and foam cell formation, which may be one of the mechanisms of plaque destabilization in human coronary atherosclerosis.

776 Total cholesterol/HDL ratio, but not LDL cholesterol, predicts the risk for future cardiovascular events: the Chin-Shan Community Cardiovascular Cohort Study – 8-year follow-up

Tzung-Dau Wang, Tsung-Ming Lee, Kuo-Liong Chien, Wen-Jone Chen, Ming-Fong Chen, Chiau-Suong Liau, Yuan-Teh Lee. *Dept. of Internal Medicine (Cardiology), National Taiwan University Hospital, Taipei, Taiwan, China*

Despite clinical guidelines designed to decrease the risk for coronary heart disease (CHD) have focused on identifying persons with increased levels of low-density lipoprotein (LDL) cholesterol, controversy still exists about the relative ability of different measures of cholesterol to discriminate CHD risk. In this study, we evaluated this ability of 4 measures of cholesterol (total cholesterol, LDL cholesterol, total cholesterol/high-density lipoprotein (HDL) ratio, and LDL/HDL ratio) and the appropriateness of current LDL cholesterol-based assessment in comparison with approaches by other measures of cholesterol.

Methods: The incidence of CHD was assessed in 2,572 participants (aged ≥35 years old at baseline) from the Chin-Shan Community Cardiovascular Cohort Study, a prospective, population-based study begun in 1990, over an 8-year follow-up period. Serum lipid determinations at baseline were used in this study.

Results: During this time, 152 subjects developed CHD (5.9%). After adjustment for age and sex, only total cholesterol/HDL ratio (p = 0.005) and LDL/HDL ratio (p = 0.01), rather than total cholesterol (p = 0.36) and LDL cholesterol (p = 0.09), were associated with occurrence of new CHD events in proportional hazard models. The relation to total cholesterol/HDL ratio, but not LDL/HDL ratio, remained significant after adjustment for other risk factors (risk ratio, 1.15 for 1.0 increment in ratio; p = 0.01). Furthermore, the incidence of CHD in subjects with LDL cholesterol ≤ 160 mg/dl and total cholesterol/HDL ratio > 5 was significantly higher than the incidence in those with LDL cholesterol > 160 mg/dl and total cholesterol/HDL ratio ≤ 5 (44/456 (9.7%) vs 7/156 (4.5%); risk ratio, 2.4; p = 0.03).

Conclusion: Contrary to the clinical guidelines, the total cholesterol/HDL ratio, but not LDL cholesterol, is the only predictor of future CHD events. Current LDL cholesterol-based strategy for risk assessment may misclassify persons and reduce the cost-effectiveness of lipid-lowering therapy.

NEW METHODS OF CORONARY SURGICAL TREATMENT: PROBLEMS AND REMEDIES

781 Is minimally invasive coronary bypass surgery (MIDCAB) the favorite treatement for single high-grade LAD lesion? Experience with 520 MIDCAB patients

A. Diegeler, M. Matin, V. Falk, C. Binner, R. Krakor, T. Walther, R. Autschbach, F.W. Mohr. *Cardiac Surgery Dept, University Leipzig, Leipzig, Germany*

Objectlve: Minimally invasive direct coronary artery bypass surgery (MIDCAB) is performed since November 1996 in an increasing number for patients with single high grade LAD lesion.

Methods:520 patients underwent MIDCAB surgery without cardiopulmonary bypass. Early post-Op angiography was performed before discharge in 353 patients. Mid-term follow-up angiography after 6 to 12 months is available in 214 patients so far.

Results: Preoperatively 5.6% of the patients had Type B-lesion of the proximal LAD, 50.8% Type C-lesion, 28.1% an occluded LAD and 17.0% an "in-stent" restenosis. In 501 patients a single ITA to LAD bypass was performed, and in 19 patients a double Y-graft, including the radial artery for revascularization of a major diagonal branch. Duration of the procedure was 93.2 ± 17.4 minutes. Operative mortality was 1/520 (0.2%). Early reintervention was necessary in 1.9% of the patients due to graft failure. On early angiography, patency was 98.1%, 3.4% of the patients showed severe stenosis of the anastomosis. On follow-up angiography 3.7% of the patients had moderate to severe anastomosis stenosis, 4 grafts were occluded. Follow-up patency was 95.6%. The total rate of reinterventions was 5.4% during follow-up, 6 patients underwent redo-CABG, and 6 patients successful PTCA of the stenosis. Three patients died during follow-up, thus follow-up survival was 99.1%.

Conclusion: MIDCAB-surgery is a safe and effective treatment for high grade single LAD lesion. In competition with PTCA the minimally invasive surgical treatment provides significant less restenosis and less need for reinterventions. Therefor, MIDCAB is the favorite therapy in patients having high grade Type C-lesion of the LAD with an expected restenosis rate of >20% for PTCA. Furthermore, MIDCAB should be the treatment of choise in patients with "in-stent" restenosis.

782 Does persistence of internal thoracic artery side branches after off-pump CABG affect myocardial perfusion? A preliminary SPECT study

R. Lorusso, E. Milan[1], R. Giubbini[1], S. Pentiricci, V. Borghetti, P. Totaro, G. Coletti, M. Zogno. *Cardiac Surgery Division, Civic Hospital, Brescia; [1]Nuclear Medicine Dept, Civic Hospital, Brescia, Italy*

We sought to assess the effects on myocardial perfusion of the persistence of proximal side branches arising from the internal thoracic artery (ITA), usually unresected during minithoracotomy (MINI) exposure for off-pump myocardial revascularization.

Methods: Twenty-five patients underwent CABG without extracorporeal circulation. Ten patients (group 1) received ITA on the LAD after conventional midsternotomy and total isolation of the arterial conduit, whereas 15 patients (group 2) underwent MINI CABG on the LAD with partially harvested ITA. No differences existed between groups in terms of age, severity of CAD, or function of left ventricle (LV). After surgery, all patients were evaluated by Tc-99m SESTAMIBI SPECT at rest, during exercise, or after dypiridamole infusion. Extent (% of LV surface) and severity (arbitrary units) of reversible defects at SPECT scan in LAD territory (revascularized vessel) were quantified in comparison to gender matched polar map, subtracting the rest value to the stress one.

Results: No significant differences either in the severity or in the extent of myocardial perfusion were found between groups at rest. Although not statistically significant, a reversible perfusion defect >20% of LV surface occurred more frequently in group 2 patients (23% of G2 vs 12% of G1 after dypiridamole, and 33% of G2 vs 11% of G1 after exercise testing, respectively). Taking into account patients with a reversible perfusion defect < 20% of LV surface, a significant difference between groups was observed after dypiridamole (179 in G1 vs 499 in G2, respectively, $p < 0.05$), but not after exercise testing. A significant difference was also found between G1 and G2 patients in relation to the severity of perfusion defects (258 in G1 vs 602 in G2, respectively, $p < 0.05$).

Conclusions: Persistence of unresected ITA side branches during MINI CABG may account for mild myocardial perfusion defects due to steal phenomena in presence of maximal coronary vasodilation. Stress SPECT appears to represents a valuable tool to assess persistence of postoperative inducible ischemia in off-pump CABG patients

783 The beneficial effect of off-pump bypass surgery in patients with left ventricular dysfunction

K. Kirali, M. Balkanay, S. Omeroglu, M.B. Rabus, M. Guler, B. Daglar, E. Akinci, G. Ipek, A. Gurbuz, T. Berki, O. Isik, C. Yakut. *Cardiovascular Surgery, Kosuyolu Heart and Research Hospital, Istanbul, Turkey*

The adverse effects of extracorporeal circulation increase the morbidity and mortality risk of coronary bypass surgery, espacially in patients with poor left ventricular function. The purpose of this study was to provide a comparison of long-term survival and intervention-free outcome between patient groups with poor ventricular function (LVEF < 40% or LVPS≥15) subjected to one-vessel coronary bypass accomplished with or without the use of cardiopulmonary bypass.

From October 1992 to March 1994, 51 patiens, who were operated on at Kosuyolu Heart and Research Hospital, with poor left ventricular function were investigated retrospectively. They were divided in two groups: beating heart group included 26 patients and cardiopulmonary bypass group 25 patients. Mean age (54 ± 9.5 versus 50.5 ± 8; $p > 0.05$) and risk factors were identical. All of the patients operated on only for one vessel (LIMA-LAD).

At 6 year follow up, all patients in both groups were alive. In the early postoperative period the need of cardiac support therapy (inotropic support or IABP) was significantly higher in the cardiopulmonary bypass group than the beating heart group: 8 (32%) patients versus 2 (7.7%) patients, $p < 0.05$. Perioperative myocardial infarction was not seen in any patient. No patient in both groups had anginal or congestive symptoms in the postoperative period (mean 68.5 ± 3.5 months) and required reoperation or reintervention (PTCA or stent). The need of blood products (for FFP 3.63 ± 2.15 u versus 2.5 ± 1.34 u and $p < 0.01$; for packed red blood cells 1.8 ± 0.75 u versus 1.25 ± 0.46 u and $p < 0.01$), the ICU-stay (2.8 ± 1.9 days versus 2.04 ± 0.9 days; $p < 0.05$) and hospital stay (10.64 ± 3.2 days versus 7.92 ± 2.25; $p < 0.001$) were higher in the cardiopulmonary group than in the beating group.

Despite one less graft per patient, survival and cardiac death rates were similiar for both groups. However, more than four times as many patients in the CPB group required inotropic support after surgery. Off-pump bypass surgery conserves the blood constituents. The benefits of both techniques to improve the left ventricular performance skore and EF were similiar, but postoperative extubation time, lenght of ICU and hospital stay were reduced significantly in the beating heart group. With these good results of the beating heart group and the performing coronary revascularization more cheeper, coronary bypass on beating heart can be an alternative to cardiopulmonary bypass technique in selective patient groups.

784 Cardiogenic shock following postinfarction ventricular septal defect: need for immediate surgical repair despite initial stabilization with intraaortic balloon counterpulsation

K.H. Scholz, S. Ragab, I. Aleksic[1], B. Schorn[1], W. Ruschewski[1], T. Schröder[2], G.S. Werner, H. Kreuzer. *Department of Cardiology, Center for Internal Medicine; [1]Department of Thoracic and Cardiovascular Surgery; [2]Department of Medical Informatics, Georg-August-University of Göttingen, Göttingen, Germany*

Aims The aim of this study was to analyse the potential of intraaortic balloon counterpul-sation to reverse cardiogenic shock and to delay surgical repair in patients with ischemic ventricular septal defect.

Methods and Results Between 1981 and 1997, a total of 25 consecutive patients presenting with cardiogenic shock following postinfarction ventricular septal defect were treated with intraaortic balloon counterpulsation. In all patients hemodynamics improved immediately after initiation of intraaortic balloon counterpulsation with a significant increase in mean aortic pressure from 61 to 84 mmHg (n = 25; $P < 0.01$) and in cardiac index from 1.70 ± 0.32 to 2.08 ± 0.23 $L^{*}min^{-1}{}^{*}m^{-2}$ (n = 16; $P < 0.01$). Simultaneously, left-to-right shunting significantly decreased from 279.9 ± 73% to 175.7 ± 92% (n = 16; $P < 0.01$).

Fourteen patients underwent early surgical repair within 24 (6.5 ± 5.3) hours after insertion of intraaortic balloon counterpulsation because of the extent of shunting and the hemodynamic compromise. In this group, in hospital mortality was 42.9% (6/14 pts). In the remaining 11 patients, initial counterpulsation-related stabilization encouraged to delay operation as an attempt to reduce operative risk. However, in all of these patients, hemodynamics deteriorated within the following days: 5 patients had to be operated within 48 h, 3 patients within 4 days, and the remaining 3 pts who had not been operated died on days 2, 7 and 9 after balloon pump-insertion. Thus, no patient could be stabilized to perform a strategy of delayed repair of septal defect. In patients operated within the first 48 h, in hospital mortality was 47.4% (9 of 19 pts). In contrast, in patients not operated within 48 h, mortality was 100% (6 of 6 pts).

Conclusion Intraaortic balloon counterpulsation enables marked preoperative hemodynamic improvement in patients presenting with cardiogenic shock following ischemic ventricular septal defect. Despite initial stabilization, such patients need immediate surgical repair of septal defect to avoid hemodynamic deterioration.

785 The role of bi-atrial pacing in the prevention of atrial fibrillation after coronary artery by-pass surgery: a randomised control study

T. Levy, G. Fotopoulos, S. Walker, M. Octave, M. Amrani[1], V. Paul. *Cardiology Dept, Harefield Hospital, Harefield; [1]Cardiac Surgery, Harefield Hospital, Middlesex, UK*

After coronary artery by-pass surgery (CABG) atrial fibrillation (AF) is common and its management problematic. In this setting prophylactic drug therapy has limited success in suppressing AF. Alternative non-pharmacological approaches are therefore required. We have performed a randomised study comparing bi-atrial pacing to a control group of no pacing on the incidence of AF post CABG.

Methods: Patients undergoing first time CABG are included in the study. At the time of surgery temporary pacing wires are placed in the lateral wall of the right atrium and the roof of the left atrium (Bachmanns bundle) to allow bipolar pacing at both sites. After surgery all patients are connected to an external pacemaker (Chorum ELA) that also acts as a Holter monitor. Patients are consecutively randomised to either resynchronised biatrial pacing at a base rate of 80bpm or no pacing (base rate 30bpm) for 4 days. The primary endpoint is an episode of AF lasting longer than 1 hr.

Result: 100 patients have been randomised so far. The incidence of AF in the control group is 36% (18/50) and in the biatrial group 16% (8/50), p = 0.03.

In conclusion: Our initial experience suggests bi-atrial pacing significantly decrease the incidence of AF after CABG. The completed study results will be available at the meeting.

786 The UK trial of transmyocardial laser revascularisation: clinical and cost effectiveness

S. Burns, P.M. Schofield, L.D. Sharples, N. Caine, S. Tait, H. Campbell, M. Buxton, J. Wallwork. *Papworth Hospital NHS Trust, Cambridge; MRC Biostatistics Unit, Cambridge; Health Economics Research Group, Brunel University, Uxbridge, UK*

TMLR is used to treat patients with refractory angina due to severe coronary artery disease, which is not suitable for conventional revascularisation.

Purpose: The aim of the MRC UK trial was to evaluate the effectiveness of TMLR versus medical management (MM).

Methods: 188 patients were randomised to TMLR plus usual medication (n = 94) or continued medication alone (n = 94), between October 1993 and September 1997. The primary outcome measure was exercise capacity secondary measures were clinical status, radionuclide myocardial perfusion and health related quality of life, which were all assessed at baseline and at 3, 6 and 12 months following surgery (TMLR) or baseline (MM). Detailed health service resource use was recorded for the assessment, follow up care and drug therapy in both groups plus the surgical procedure and hospital stay for the TMLR group.

Results: The trial was powered to detect a clinically significant increase in exercise tolerance: at 12 months, exercise time was 40 seconds (−15 to 94) greater in the TMLR group than in the controls (p = 0.152) and in 25% of TMLR patients there was a significant improvement in physician rated angina. Peri-operative mortality was 5%. Survival rates at 12 months were 89% (83% to 96%) in the TMLR group and 96% (92% to 100%) in the MM group (p = 0.14). Based on detailed itemised costing of 50 of the 94 procedures and using trial centre costs for 1997, the mean cost of a TMLR procedure was £5746 (95% CI £5103 to £6389). Follow-up hospital admissions in the TMLR group were 1.3 (95% CI 1.1 to 1.5) per patient year compared to 1.1 (95% CI 0.9 0 1.3) per patient year for MM patients (p = 0.110). Outpatient visits were 1.5 (95% CI 1.2 to 1.8) per patient year in the TMLR group compared to 1.7 (95% CI 1.4 to 2.0) for MM patients (p = 0.64).

Conclusion: It is clear that the significant cost of the procedure compared to continued medical therapy, together with the perioperative mortality risk and the slim chance of improvement in angina, all lead to the conclusion that on both clinical and cost effectiveness evidence the adoption of TMLR cannot be recommended.

EMERGING TREATMENT MODALITIES IN DILATED CARDIOMYOPATHY

787 Is the clinical course of dilated cardiomyopathy changed over the last 20 years? The experience of the Heart Muscle Disease Registry of Trieste

A. Di Lenarda, G. Sabbadini[1], D. Gregori[2], L. Mestroni[3], G. Scherl, M. Davanzo, G. Sinagra. *Cardiology Dept, Ospedale Maggiore, Trieste; [1]Dept of Internal Medicine/Geriatrics, University of Trieste, Trieste[2]Dept of Statistics, University of Trieste, Trieste, Italy[3]Dept of Cardiology, University of Colorado, Denverm CO, USA*

Since 1978, 343 pts with idiopathic dilated cardiomyopathy (IDC) were enrolled and sistematically followed up in our Heart Muscle Disease Registry. Ninety-four pts (group 1) were enlisted between 1978 and 1987, while 249 (group 2) between 1988 and 1997.

Changes in the baseline clinical parameters in group 2 included a younger age (43 ± 9 vs 47 ± 10 years, p = 0.01) and a shorter duration of heart failure symptoms before diagnosis (16 ± 15 vs 25 ± 22 months, p = 0.04). Moreover, an increasing use of ACE inhibitors (92% vs 25%, p < 0.0001) and beta-blockers (77% vs 3%, p < 0.0001), while a less frequent treatment with amiodarone (34% vs 61%, p < 0.0001) were evident in the group 2. Two, 5 and 8 year transplant-free survival was respectively 87%, 74% and 67% in group 2 vs 85%, 58% and 50% in group 1 (p = 0.04 after stratification for heart failure severity). Two, 5 and 8 year risk of death due to refractory heart failure or heart transplant decreased in more recent cohort (respectively 8%, 20% and 22% in group 2 vs 11%, 33% and 36% in group 1; p = 0.04), while the incidence of sudden death did not change (2%, 9% and 18% in group 2 vs 4%, 11% and 19% in group 1; p = NS). The risk of primary events related to heart failure progressively decreased, while sudden death tended to increase during long-term follow-up.

The analysis on 343 IDC patients enrolled in our Registry shows that an earlier diagnosis and a clear change in heart failure treatment determined an improvement of transplant-free survival over the last 20 years. These results were partially lost during long-term follow-up because of an increasing incidence of sudden death.

788 Effect of short-term immunosuppressive therapy on chronic inflammatory cardiomyopathy: six-month follow-up results

R. Wojnicz, E. Nowalany-Kozielska[1], G. Glanowska[1], C. Wojciechowska[1], P. Wilczewski[1], J. Wodniecki[1], M. Zembala, L. Połoński, M.M. Rozek[2]. *Silesian Centre of Heart Disease, Zabrze; [1]Second Department of Cardiology, Silesian Medical School, Zabrze, Poland; [2]University of Texas, HSC at San AntonioSan Antonio TX, USA*

The treatment of idiopathic dilated cardiomyopathy (IDCM) remains problematic and therapeutic modalities involving non-selective anti-inflammatory agents continue to be controversial. We hypothesised that criteria for such therapy should be based on immunohistological hallmarks of chronic myocarditis in biopsy specimens, rather than on the Dallas criteria. Accordingly, we prospectively studied 40 patients (pts) with chronic congestive heart failure due to IDCM confirmed by echocardiography, radionuclide ventriculography, coronary angiography and positive immunohistology (expression of HLA-class I and/or II). Mean duration of symptoms was 3.6 years (range: 8 months to 6 years. Mean LVEF was 25.6% (range: 17–35%). NYHA functional class was as follows: II in 12 pts, III in 26 pts, IV in 2 pts. The baseline clinical assessment included physical examination, ECG, 24-hours ECG monitoring, echocardiography, radionuclide ventriculography and coronary angiography. All pts were treated with conventional therapy (digitalis, metocard, captopril and diuretics). Twenty one pts (16 M, 5 F, age 42 ± 4 years) who were randomised to the immunosuppressive therapy group (IT), were also treated with encorton (1 mg/kg/day, for 12 days, then tapered off every 5 days by 5 mg/day until reaching a maintenance dose of 0.2 mg/kg/day) and azathioprine (1 mg/kg/day) for a total 100 days. Nineteen pts (18 M, 1 F, age 40 ± 6) were randomised to the placebo group (CT). Pts were assessed at baseline, 3 and 6 months. Pts in which the LVEF increased >5% (by radionuclide ventriculography), LV fractional shortening increased >5% (by ECHO), LV diastolic diameter decreased >5 mm (by ECHO), and decreased NYHA class were considered as pts who demonstrated clinical improvement. The differences between groups were analysed using the two-tailed Fisher exact test.

The baseline characteristics were similar in both groups. At the time of 3 month follow-up, 16 pts (76%) in the IT group showed clinical improvement compared to 4 pts (21%) in the CT group (p < 0.01). At the time of 6 month follow-up clinical improvement was observed in 17 pts (81%) in the IT group versus 6 pts (31%) in the CT group (p < 0.01). One patient from the IT group withdrew from the study. There was one death in the CT group.

Conclusions. It appears that short duration immunosuppressive therapy may be beneficial in the treatment of chronic myocarditis. However, the qualification of patients for such treatment should be based on immunohistological assessment using endomyocardial biopsy rather than on the Dallas criteria.

789 Immunoadsorption improves cardiac performance in patients with severe dilated cardiomyopathy

J. Müller, G. Wallukat[1], K. Dandel, H. Bieda, K. Hummel, R. Hetzer. *Deutsches Herzzentrum Berlin; [1]Max Delbrück Centrum, Berlin, Germany*

A causative therapy of idiopathic dilated cardiomyopathy (IDC) is not known. In 70% of patients with IDC a pathological level of auto-antibodies directed against cardiac β_1-adrenoceptors (AAB) can be found.

Methods: We wanted to evaluate whether immmunoadsorption has a positive effect on cardiac function and dimension, i.e. left ventricular ejection fraction (EF) and left ventricular internal diameter in diastole (LVIDd). Thirty-four patients with IDC were devided into two groups (I, C) of 17 patients each. Both groups were not statistically different regarding the following parameters: age, sex, NYHA class, EF, LVIDd, level of AAB and drug therapy regarding cardiac insufficiency. After study recruitment all patients who were not on β-blocker medication received these additionally. After synchronisation of both groups, group received immunoadsorption whereas group C was not treated.

Results: Two patients out of group C were transplanted two and five months, respectively, after recruitment. The table shows the results one year after immunoadsorption as compared to the data at the beginning of the study.

	At the time of recruitment			After one year		
	EF [%]	LVIDd [mm]	AAB [LU]	EF [%]	LVIDd [mm]	AAB [LU]
Group I (n = 17)	22 ± 3	75 ± 7	6.0 ± 1.4	38 ± 8	64 ± 6	not detectable
Group C (n = 17)	24 ± 3	76 ± 6	4.7 ± 1.0	25 ± 6 (n = 15)	73 ± 7 (n = 15)	5 ± 1.0 (n = 15)
P-values	n.s.	n.s.	0.0104	0.0001	0.0004	0.0001

In conclusion: Immunoadsorption led to a significant improvement of cardiac function and dimension. AAB directed against cardiac β 1-receptors seem to be a suitable parameter to assess the success of immunoadsorption. The reason why the cardiac function of the control group also improved may be due to the positive effect of the β-blocker therapy.

790 The beneficial effect of beta blockade on cytokine levels in patients with dilated cardiomyopathy

T. Ohtsuka, M. Hamada, G. Hiasa, O. Sasaki, S. Ikeda, H. Hashida, M. Suzuki, Y. Hara, Y. Shigematsu, K. Hiwada. *Ehime University, Ehime, Japan*

Numerous studies have suggested a beneficial effect of beta-blocker therapy in patients with dilated cardiomyopathy (DCM). Although circulating levels of tumor necrosis factor-alpha (TNF-α) have been reported to increase in patients with DCM, the effect of beta-blockers on cytokine levels in DCM is unknown. This study was designed to evaluate whether the cytokine TNF-α was reduced with beta-blocker therapy in patients with DCM.

Methods We studied 25 patients with DCM in New York Heart Association functional class III or IV, who had been treated with digitalis, diuretics and angiotensin-converting enzyme inhibitors. In all patients, beta-blockers (metoprolol or bisoprolol) were added. Plasma levels of TNF-α were measured by enzyme-linked immunosorbent assey at baseline and at 12 weeks after the initiation of beta-blockers. Plasma norepinephrine (NE; pg/ml) and brain natriuretic peptide (BNP; pg/ml) were also measured. Left ventricular dimension at end-diastole and end-systole (LVDd and LVDs; mm) and fractional shortening (FS; %) were measured. Ten age-mached subjects with no cardiac disease served as the normal control (NC).

Results The baseline plasma levels of TNF-α were significantly higher in patients with DCM than in normal subjects (DCM; 30.7 $\pm$ 17 pg/ml, NC; 17.8 $\pm$ 4.9 pg/ml, $p < 0.05$). Plasma TNF-α levels significantly decreased after the treatment with beta-blockers. Plasma NE and BNP were also reduced, and left ventricular dimension and function were improved.

	TNF-α	NE	BNP	LVDd	LVDs	FS
Baseline	30 $\pm$ 17	341 $\pm$ 144	253 $\pm$ 462	69 $\pm$ 11	59 $\pm$ 12	15 $\pm$ 6
12 weeks	15 $\pm$ 4§	218 $\pm$ 140§	184 $\pm$ 470§	64 $\pm$ 7*	50 $\pm$ 9*	22 $\pm$ 7*

$^{*}P < 0.001$, $^{\S}P < 0.005$ vs. baseline

Conclusion Our data indicate that beta-blocker therapy lowered circulating TNF-α levels in patients with DCM. The beneficial effect of beta-blockade in DCM may be partly due to a reduction of cytokines such as TNF-α.

791 Treatment of patients with dilated cardiomyopathy with human recombinant growth hormone for 3 and 6 months: effects on left ventricular size and function

K.J. Osterziel, O. Strohm, A.E. Ellmer, M.B. Ranke[1], R. Dietz. *Charité Franz-Volhard-Klinik, Humboldt University Berlin; [1]Sektion Pädiatrische Endokrinologie, Kinderklinik der Universität Tübingen, Germany*

Short term studies suggest that therapy with human recombinant growth hormone (GH) may improve cardiac function in patients with heart failure. We conducted a randomised, double-blind, placebo-controlled study in 50 patients with dilated cardiomyopathy (DCM). The average NYHA class was 2.2 $\pm$ 0.1 and the mean LV-EF was 27 $\pm$ 2%. After 3 months of blind therapy with 2 U/d GH or placebo (P) every patient received 1 U GH daily for 3 months (GH-GH and P-GH group) in an follow-up trial. Cardiac size and function was determined by cine-magnetic resonance imaging. LV mass was calculated from 10 mm slices of the left ventricle in the short axis.

Results: At baseline both groups did not differ in the severity of heart failure measured by NYHA class, 6 minutes walking distance and central hemodynamics. Blood pressure, heart rate and left ventricular ejection fraction were unaltered after 3 and 6 months. The significant increase in LV mass after therapy for 3 months with 2 U GH s.c. daily was sustained with 1 U/d GH. LV mass increased with 1 U/d GH for 3 months to a similar degree compard to the group treated for 6 months with GH. Progressive ventricular dilatation did not occur in both groups.

Summary: Therapy with GH for 3 and 6 months induces left ventricular hypertrophy and no significant decrease of cardiac function. As the cardiac effects of 1 U/d GH are comparable to 2 U/d GH a low dose of GH substitution therapy is sufficient to decrease systolic wall stress.

792 Beneficial effect of angiotensin-converting enzyme inhibitor on dilated cardiomiopathy induced by autoimmune mechanism against β1-adrenoceptor

S. Matsui, M.L.X. Fu[1], S. Katsuda, M. Hayase, K. Teraoka, T. Kurihara, N. Takekoshi, H. Wakabayashi[2]. *Kanazawa Medical University, Ishikawa; [2]Niigata College of Pharmacy, Niigata, Japan; [1]Gothenberg University, Gothenberg, Sweden*

We have previously shown that a peptide corresponding to the sequence of 2nd extracellular loop of the human β1-adrenoceptor (β1-peptide) as an autoantigen was able to induce an autoimmune cardiomyopathy in rabbits (JMCC 29: 641, 1997), and β-blockade protected the myocardial injury induced by this autoimmune mechanism (ISHR 1998, Greece). In this study, we investigated the effect of angiotensin converting enzyme inhibitor (ACEI) on β1-peptide induced cardiomyopathy in rabbits.

[Methods] NZW rabbits were divided into 4 groups. 1) control group (n = 6): saline injection, 2) β1-immunized group (n = 8): β1-peptide injection, 3) ACEI group (n = 6): lisinopril (3 mg/day) orally and saline injection, 4) ACEI + β1-immunized group (n = 7): lisinopril (3 mg/day) orally and β1-peptide injection. Study duration was one year. Saline or peptide was injected once a month.

[Results] All rabbits in both β1-immunized groups had the high titre of anti-β1-adrenoceptor autoantibodies in their sera, whereas none of the sera from all rabbits in control and ACEI groups was positive. Rabbits in the β1-immunized group showed an increase in heart weight, wall thinning and dilatation of bi-ventricles. On the other hand, rabbits in ACEI group and ACEI + β1-immunized group had normal heart weight and shape. All rabbits in β1-immunized group showed multifocal degeneration and necrosis of myocardial cells with moderate infiltration of inflammatory cells. In ACEI group, two rabbits showed no histological changes in the heart, but four showed an occasional focus of scant mononuclear cell infiltration with normal myocardial cells. In ACEI + β1-immunized group, five rabbits showed slight mononuclear cell infiltration with mild degeneration of myocardial cells.

[Conclusion] ACEI (lisinopril) protects the myocardium from injury induced by autoimmune mechanism against β1-adrenoceptor.

NITRIC OXIDE IN HUMAN VASOMOTION AND VENTRICULAR FUNCTION

803 Cardiac sympathoexcitatory effects of nitric oxide synthase inhibition in humans

M. Lepori, H. Duplain, C. Sartori, P. Nicod, U. Scherrer. *Department of Internal Medicine, and Botnar Center for Clinical Research, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland*

It is now clear that nitric oxide (NO) plays an important part in the regulation of sympathetic vasoconstrictor outflow to the peripheral vasculature, but little is known regarding its role in the regulation of sympathetic outflow to the heart. To provide such evidence, we examined, in 8 healthy subjects, effects on heart rate and arterial pressure of NO-synthase inhibition by systemic L-NMMA infusion (0.5 mg/kg/min for 10 min), in the presence and absence of parasympathetic blockade (atropine 0.4 mg/m^2 bolus, followed by 0.3 mg/kg/h for 30 min). The major new finding was that L-NMMA infusion which increased mean arterial pressure by roughly 15 percent, had markedly differential effects on heart rate in the presence and absence of parasympathetic blockade; when infused alone, heart rate decreased by 16 $\pm$ 3% ($\bar{X} \pm$ SE, $P < 0.01$ vs. baseline), whereas when infused during atropine infusion, the L-NMMA-induced increase in arterial pressure was accompanied by a 15 $\pm$ 4% increase in heart rate ($P < 0.01$ vs. L-NMMA alone). This chronotropic effect is sympathetically mediated, because it was abolished by coinfusion of propranolol. These findings provide the first evidence for a cardiac sympathoexcitatory effect of NO-synthase inhibition in humans. We speculate that in clinical conditions associated with a defect in NO-synthesis, exaggerated cardiac sympathoexcitation may contribute to augmented cardiovascular morbidity and mortality.

804 Critical role of endogenous nitric oxide on systolic and diastolic function in hypertensive cardiomyopathy

A. Piech, P.E. Massart, C. Dessy, N. Morel, J. Donckier, J.L. Balligand.
Medicine, Pharmacology, FATH 5349, University of Louvain Medical School, Brussels, Belgium

The role of nitric oxide synthase in the myocardial dysfunction of hypertensive cardiomyopathy is unclear. We used an in vivo model of perinephritic hypertensive (PHT) dogs to linearly correlate changes in cardiac and vascular contractile parameters with NOS activity and sensitivity to NOS inhibitors.

Methods: Echocardiographic and invasive parameters of systolic and diastolic function were acquired in 9 mongrel dogs before and 8 weeks after kidney wrapping. At both time points all measurements were repeated after 48 h intravenous infusion of the NOS inhibitor, L-NAME (10 μg/kg/min) with a mini-pump. NOS activity (^{3}H-citrulline formation) in heart extracts and contraction of coronary and mesenteric macro- and micro-vessels measured by video-microscopy were analysed in additional dogs at 0, 3 and 8 weeks.

Results: In normotensive dogs, 48 h L-NAME induced an increase in BP (mmHg; 116 ± 4 to 128 ± 2°) and SVR (mmHg/ml/min.10E4; 286 ± 43 to 436 ± 25*) while systolic and diastolic functions were unaltered. PHT dogs had severe high BP (141 ± 6°) but normal SVR (289 ± 44). They had increased LV mass (g; 152 ± 5° vs 124 ± 4) with enhanced systolic parameters but impaired diastolic relaxation (T1, msec; 26.6 ± 0.9° vs 22 ± 1).Their coronary and mesenteric vessels displayed maximal contraction to KCl similar to controls, but an impaired endothelium-dependent relaxation to Acetylcholine at 8 w (% max. contraction; 9.1 ± 4.8 vs 32.4 ± 6.5°). Ca-dependent NOS activity was transiently increased at 3 W, but sharply decreased in all 4 heart chambers at 8 w (LV, fmol/min/mg; 16.9 ± 1 down to 0.1 ± 0.1*). In PHT dogs, L-NAME infusion markedly reduced both diastolic (T1; 31.9 ± 1.3*) and systolic (DP40, sec^{-1}; 47.9 ± 2.2° vs 60.6 ± 3.6) functions (°: P < 0.05; *: P < 0.01).

Conclusion: PHT dogs develop a time-dependent impairment of endothelial function and Ca-dependent NOS activity in the myocardium. Their super-sensitivity to NOS inhibitors suggests a critical compensatory role of myocardial NO to maintain systolic and diastolic function in the face of myocardial hypertrophy.

805 Cardiac vagal modulation by endogenous nitric oxide in humans

S. Chowdhary, J.C. Vaile, M.R. Farmer[1], J.H. Coote[1], J.N. Townend.
Departments of Cardiology; [1]Physiology, University of Birmingham, Queen Elizabeth Hospital, Birmingham, UK

The control mechanisms of the cardiac autonomic nervous system remain poorly defined. Animal data suggest that endogenous nitric oxide (NO) modulates this system, acting both as a vagotonic and a sympatholytic agent. We have used heart rate variability (HRV) to assess the role of endogenous NO in the baroreflex modulation of human cardiac autonomic activity.

Fourteen healthy male volunteers, aged 20–36 years (mean = 26), were studied in a single blind, crossover protocol. In random order, we administered equipressor infusions of the nitric oxide synthase inhibitor N^G-methyl-L-arginine (L-NMMA, 3 mg/kg/hr) or a control vasoconstrictor, phenylephrine (Phe, 0.2–1.4 μg/kg/min). Analysis of HRV was performed on 256 beat segments of ECG data digitally recorded under fixed metronomic breathing at baseline (saline infusion) and then at a stable mean arterial pressure (MAP) measured by Portapres during the pressor infusion. This was repeated on each of the two study visits, 2–14 days apart. Time domain indices of high frequency (vagally mediated) HRV included RMSSD and pNN50. Autoregressive modelling was used to assess spectral power at low frequency (LF, combined sympathetic and vagal activity) and at the respiratory frequency (HF, vagal activity) in normalised units (nu). Results are expressed below as the absolute increase from baseline values (mean ± SD):

	MAP (mmHg)	Mean RR (ms)	RMSSD (ms)	pNN50 (%)	HF (nu)	LF (nu)
Phe	11 ± 3	156 ± 110	51 ± 48	14 ± 12	9 ± 8	−9 ± 7
L-NMMA	11 ± 5	100 ± 55	23 ± 32	6 ± 14	−1 ± 7	−2 ± 8
p value*	0.8	0.08	<0.01	<0.05	<0.01	<0.05

*Wilcoxon signed ranked test

In conclusion, L-NMMA infusion significantly attenuated baroreflex mediated increases in HRV indices of cardiac vagal activity compared to a control infusion of phenylephrine. These results suggest that endogenous NO augments cardiac vagal control of heart rate in humans.

806 Diagnostic value of plasma nitrate in patients with septic shock

M. Kelm, T. Schumacher, C. Buhn, M. Heydthausen, B.E. Strauer. *Department of Medicine, Divison of Cardiology, Pneumology and Angiology, Heinrich-Heine-University Düsseldorf, Germany*

In experimental models of sepsis it has been demonstrated that following induction of nitric oxide synthase (iNOS) circulating levels of serum nitrate increase and that inhibition of iNOS by either glucocorticoids or NOS inhibitors decrease nitrate, paralelled by improvement of septic circulatory situation. However, these data could not be reproduced in humans. We therefore aimed to test whether or not nitrate represents a new diagnostic marker for patients with septic circulatory situation. 424 consecutive patients admitted to an intensive care unit (ICU) were studied on a total of 2274 days. Every morning each patients was clinically assessed via a score invented by Bone et al. to confirm or reject the diagnosis of septic shock. In addition, in septic patients the extent of septic circulatory situation was graded using the Düsseldorfer Sepsis Severity Score (DSSS, <7 points: non-septic, and >7 points: septic). Plasma nitrate was determined every day using the Griess reaction after reduction of nitrate to nitrite. Only those patients (n = 159 studied on 1143 observation days) on intravenous standardized nutrition and with serum creatinine levels < 2 mg/dl were included into the final study population. Serum nitrate was higher in patients with septic shock as compared to non septic patients: 51 ± 6 vs 36 ± 2 μmol/L. Plasma nitrate increased with progressive shock. An increase or a decrease in sepsis score was associated with concomitant changes in nitrate: r = 0.46, p < 0.0001. Mortality rate increased with increasing nitrate levels. The probability of dying was highest in those patients with nitrate levels exceeding 50 μmol/L.

Conclusions: Levels of plasma nitrate are increased in patients with septic circulatory situation suggesting sepsis associated induction of nitric oxide synthase in humans. Changes in nitrate are tightly coupled to changes in septic circulatory situation and therefore nitrate may represent a diagnostic parameter to monitor septic shock in individual patients.

807 Calcitonin gene-related peptide induced vasodilation depends on the release of nitric oxide

L.M.A.B. Van Bortel[1], J.N.J.M. de Hoon[1], P. Pickkers[2], P. Smits[2], H.A.J. Struijker-Boudier[1]. *[1]Dept. of Pharmacology, Maastricht University, Maastricht; [2]Depts. of General Internal Medicine and Pharmacology, University Hospital Nijmegen, Nijmegen, Netherlands*

Aims: To investigate *in vivo* in man whether nitric oxide (NO) and/or vasodilating prostaglandins (PG) contribute to the vasodilation induced by calcitonin gene-related peptide (CGRP).

Methods: Venous occlusion plethysmography was used to assess the forearm blood flow (FBF) response to increasing infusion rates of CGRP (3-10-30 ng/min/dl forearm) into the brachial artery of 24 healthy subjects. Dose-response curves were constructed before and during the co-infusion of placebo (NaCl 0.9%), the NO-synthase inhibitor N^G-monomethyl-L-arginine (L-NMMA, 0.2 mg/min/dl forearm) and the PG-synthase inhibitor indomethacin (5 μg/min/dl forearm). Forearm vascular resistance (FVR) was calculated (FVR = mean arterial pressure/FBF) and presented as percentage change from baseline in FVR (ΔFVR). Dose-response curves were compared using ANOVA with repeated measures and Wilcoxon's matched-pairs signed-rank tests. Data are presented as mean ± SEM.

Results: CGRP (n = 24) increased FBF from 2.6 ± 0.3 at baseline to 5.4 ± 0.5, 9.8 ± 0.7 and 14.1 ± 1.1 ml/min/dl forearm, respectively (p < 0.001). Repeated infusions of CGRP with placebo (n = 8) or indomethacin (n = 8) showed comparable responses. L-NMMA (n = 8) decreased CGRP-induced ΔFVR (p < 0.001) (Table, NS = not significant).

CGRP (ng/dl forearm/min)	ΔFVR (%) Placebo	Δ FVR (%) L-NMMA	P-value
3	−61 ± 3	−26 ± 5	<0.05
10	−78 ± 2	−57 ± 4	<0.05
30	−84 ± 3	−81 ± 2	NS

Conclusions: The intra-brachial infusion of CGRP results in a dose-dependent and repeatable decrease in FVR. CGRP-induced vasodilation in man does not involve PG but depends, at least in part, on the release of NO.

808 Chronic ace-inhibition modulates vascular extracellular superoxide dismutase activity in patients with coronary artery disease: a new mechanism for increased bioavailability of nitric oxide after ACE-inhibition?

Ulf Landmesser, Stephan Spiekermann, Ralph Heithorn, Helmut Drexler, Burkhard Hornig. *Department of Cardiologyand Angiology, Medical School of Hannover, Germany*

Endothelial function, including flow-dependent, endothelium-mediated vasodilation (FDD), is impaired in patients with coronary artery disease (CAD). Increased inactivation of nitric oxide (NO) by oxygen free radicals has been suggested as an underlying mechanism. We hypothesized that chronic ACE-inhibition enhances the vascular activity of extracellular superoxide dismutase (EC-SOD), the most important antioxidant enzyme system of the human vessel wall, leading to increased bioavailability of NO.

Methods: Endothelial-bound EC-SOD activity and FDD of the radial artery were determined at baseline and after 4 weeks of ACE-inhibition with ramipril (5 mg bid) in 15 patients with angiographically documented CAD. EC-SOD has a strong affinity to heparin and was released from endothelium to plasma by heparin bolus injection (SOD I: 1000 IE; SOD V: 5000 IE) and was determined in the plasma by a combination of chromatography and a spectrophotometric SOD-assay. High resolution ultrasound (10 Mhz; precision 2 μm) and Doppler (8 Mhz) were used to measure radial artery diameter and blood flow (ml/min) at rest and during reactive hyperemia (diameter change in % representing FDD). To determine the portion of FDD mediated by NO the effect of the NO-synthase inhibitor N-monomethyl-L-arginine (NMMA; 7 μmol/min i.a.) on FDD was determined and the Delta-value was calculated (Delta-FDD = FDD at baseline minus FDD after NMMA).

Results: Endothelial-bound EC-SOD activity and the portion of FDD mediated by NO were significantly increased after chronic ACE-inhibition.

	FDD (%)	FDD-NMMA (%)	Delta-FDD (%)	SOD I (U/ml)	SOD V (U/ml)
Control	6.7 ± 0.5	4.2 ± 0.4	2.6 ± 0.5	0.6 ± 0.2	3.9 ± 1.1
4 weeks	10.7 ± 0.6*	4.3 ± 0.5	6.4 ± 0.5*	2.0 ± 0.3*	14.1 ± 1.3*

(all data ± SEM; *p < 0.01 vs control)

Conclusion: In patients with CAD chronic ACE-inhibition increased vascular activity of EC-SOD, the most important antioxidant enzyme system of the human vessel wall, by up to 350%. This represents a potential underlying mechanism for the increase of the bioavailability of NO.

PERIPHERAL VASCULAR INTERVENTIONS

809 Transluminal recanalization of deep vein thrombosis: long-term results

C. Unterberg, L. Mindel, K.-H. Scholz, A.B. Buchwald. *Dep. of Cardiology, University Clinic of Göttingen, Germany*

Systemic thrombolysis of deep vein thrombosis is contraindicated in patients with recent surgery or major trauma due to the high risk of major bleeding.

Methods: In 28 patients (pts) (15 men, 13women, age 29 ± 12 years) with deep vein thrombosis (clinical duration 8.9 ± 6.3 days) and contraindication against systemic thrombolysis we performed a local low dose thrombolytic therapy. A temporal vena cava filter was placed via a brachial vein to prevent pulmonary emboli, and a perfusion catheter was placed either in the iliac (n = 13) or superficial femoral vein (n = 15). Urokinase was infused in a dose of 30000 IU/h up to 5 days. Doppler measurements were performed daily to control flow in the veins. In addition local fragmentation of the thrombi was done in 16 (57%) pts 24 to 96 hrs after start of the lytic therapy. Hemoglobin and hematocrit were controlled every 6 hrs: no transfusions were necessary. Recanalization was successful after 5 days in all iliac and 11/15 femoral veins. All pts were anticoagulated with a oral phenprocoumon for at least 6 months and were advised to wear compression stockings. A control of the functional results and a vein doppler was performed 12 to 36 months after the thrombosis (21 ± 7.8 months). All venous segments that had been successfully recanalized were still open. A persistent swelling of the leg was observed in 4 pts (14%). None of the pts developed extensive varicosis or hyperpigmentation as a sign of postthrombotic syndrome.

Conclusion: Local intraluminal thrombolysis is a highly effective therapy for patients with deep vein thrombosis and contraindication against a systemic thrombolytic therapy. Long-term results are excellent in these pts.

810 Percutaneous intervention in haemodialysis fistula disease: is it the answer?

R. Siegel, A. Bhaskaran, B. Barker, W. Breisblatt, P. Underwood, R. Neyra, J. Ferraro, D. Walton, P. Santos, D. Swanson. *Advanced Cardiac Specialists & Phoenix Memorial Hospital, Phoenix AZ, USA*

Failing dialysis vascular access sites pose a serious challenge in the management of patients on chronic hemodialysis (HD). Vascular access failure occurs in >30% of cases within 6 months after placement and represents the leading cause of morbidity in the HD population. Prolonged patient survival has added emphasis to the importance of maintaining patent vascular access. Surgical repair consumes the limited vascular sites available. Percutaneous intervention by angioplasty (PTA) is being performed in HD shunts, but has not been adequately evaluated. We present our experience of 5 years in PTA of failing HD vascular access sites. From 1/94 to 12/98, PTA was performed in 288 patients (51% female; mean age 67; range 25–90). Significant co-morbidities included atherosclerotic heart disease in 43%, hypertension in 81% and diabetes in 48%. Vascular access sites treated were 315, of which 40% were Brescio-Cimino arteriovenous fistulas and 60% were PTFE grafts. There was history of prior intervention at the same site, in 32%. The average age of the graft was 16 months (range 1–28 months). Nearly 35% were referred for elevated venous resistance or extremity swelling. The remainder presented with access site thrombosis, which included arterial thrombotic occlusions and multiple stenoses along the arterial and/or venous tracts of the HD fistulas. All patients received IV heparin bolus of 2,000–7,000 U. Adjunctive urokinase was administered in 20.4%. Balloon angioplasty was performed with 3-minute dilatations utilizing 6–8 mm balloons. Stent was deployed in 195 (62%). Once effective flow was restored, all catheters were removed and pressure was applied to the site.

Results: Procedural success was achieved in 99.3%. Clinical success (graft successfully used for HD 3 times or remaining patent for 1 week) was 95.1%. One patient (0.3%) required emergency surgery for vessel rupture. Two dissections resulted in hematomas, which were treated with prolonged balloon inflation; 2 minor dissections healed spontaneously. There was no incidence of pulmonary embolism. Mean hospital stay was 1.59 days. Functional patency of the graft was assessed by flow during dialysis and calculated as a measure of the ratio of urea clearance to dialysis time (k/tv ratio; normal range 1.2–1.4). The mean pre-PTA KTV ratio was 0.42 ± 0.001, which increased to 1.24 ± 0.60 post-PTA. The mean primary patency rate was 86% at 6 months and 72% at 2 years. Only 10.4% of the patients required a repeat intervention during the follow up period (mean 2.4 years). No shunt infection was reported.

Conclusions: (1) The application of endovascular therapies for PTA of the arterial limb and venous outflow stenoses in HD access fistulas can significantly prolong its patency and function. (2) This is helpful in increasing the life span and improving the salvage rate of the access sites. (3) Our series did not demonstrate an increase in infection rate with percutaneous intervention by either PTA or ST.

811 Endoluminal treatment of sub-clavian occlusive diseases: percutaneous angioplasty and stenting

M. Henry, M. Amor, I. Henry, K. Tzvetanov, Z. Chati. *U.C.C.I., Polyclinique, Essey-les-Nancy, France*

Purpose: To review feasibility, risks, long term results of PTA of subclavian artery with and without Palmaz stent placement.

Methods: Over 10 years, 135 patients (pts) underwent percutaneous treatment of sub-clavian occlusive diseases. M: 75, F: 60, mean age: 63 ± 11 years (27–87). Indications: superior limb ischemia (n = 70), vertebro-basilar insufficiency (n = 72), vertebro-basilar and superior limb ischemia (n = 30), coronary steal (n = 9). Asymptomatic patients with severe coronary diseases (before internal mammary bypass) (n = 14), 110 stenosed arteries, 25 occluded. Right sub-clavian artery: 19 (11%), left: 112 (83%), innominate: 4 (3%). Mean % stenosis: 80.9 ± 7.4 (70–100). Mean lesion length: 23.5 ± 8.7 mm (10–50). Access way: retrograde femoral (n = 95), brachial artery (n = 26) access or both (n = 14), with balloon dilatation of the lesion. Since 1989 Palmaz stents were implanted for 66 lesions in case of sub-optimal PTA (n = 39), important dissection (n = 9), restenoses (n = 3). Primary stenting performed for 15 lesions.

Results: 122/135 lesions successfully treated (94%), 12 occlusions were recanalized (48%). 3 procedural complications (1.5%): 1 T.I.A., 1 major stroke, 2 arterial thromboses: 1 24 hours after the procedure, treated medically, 1 at 30 days, treated by new PTA. 19 restenoses (14%) were treated by new PTA (n = 5), by PTA + stent (n = 7), by surgery (n = 7). Primary (PI) and secondary patency (PII) for all treated lesions (n = 135) at 8 years follow-up: 76.6 and 83.7%. Without stent, respectively 67.5 and 75.5%, with stent 88.2 and 96.1% (p < 0.01). PI and PII for recanalized lesions (n = 125), 83.1%, 90.8%, without stent: 79.1%, 88.5%, with stent: 88.2% and 96.1% respectively (p = ns).

Conclusion: PTA with/without stenting is safe, effective to treat sub-clavian artery occlusive diseases with good long term patency. Occluded vessels do not respond well to PTA. Stents (implanted only for suboptimal PTA results) do not seem to improve long term results.

812 Efficacy of ultrasound thrombus disruption in vivo

A.G. Mrochek, I.E. Adzerikho, Y.P. Tarakanov, V.V. Dmitriev, O.A. Kozmidiani. *Belorussian Institute of Advanced Medical Training, Department of Cardiology, Minsk, Belarus*

Recently, we have shown that the *in vitro* treatment of thrombi with continuous low frequency ultrasound (US), in combination with streptokinase (SK) or alone, is a potent method of clot destruction. The present study was aimed at testing efficacy and safety of intravascular (IV) destruction of thrombi *in vivo* by using a novel catheter-based system for US treatment.

Materials and methods. Acute IV thrombosis was modeled on *a. femoralis* in the 15 mongrel dogs. In 2 h after thrombus formation, thrombolysis was performed by: (1) IV catheter-delivered US treatment (22 kHz, 10 W/cm^2); (2) a combined administration of SK (35,000 U/kg) and US of the same intensity. Condition of the thrombus and distal circulation were examined before the thrombus destruction and 1, 5, 40, 90 and 120 min after its destruction, using the methods of angiography, impedance reography and direct measurement of blood AP in the distal to the thrombus formation zone. Blood coagulation parameters were also assayed. Moreover, histological examination of vessel wall was performed after thrombus destruction.

Results. Intra-arterial application of US resulted in fast destruction of the thrombi. Additional administration of SK did not decrease significantly the time of US thrombus disruption (1.5 ± 0.8 min for US, 1.2 ± 0.6 min for US + SK, $p > 0.05$). However, proteolytic cleavage of fibrin was enhanced (9.1 ± 0.8 μg/ml of D-dimers for US, 13.3 ± 3.3 μg/ml for US + SK, $p < 0.05$). After the US treatment, circulation was always restored. However, complete destruction of thrombi, with no signs of thromboembolia of distal microcirculation, was achieved only for combined application of US and SK. Blood coagulation tests revealed an US-induced activation of thrombin system, the effect was less significant in the presence of SK. Histological examination did not show the thermal, cavitational damage of vessel wall, as well as its perforation after US treatment.

Conclusion. Combined administration of US and SK is an efficient and safe method for the treatment of peripheral vessel thromboses.

813 Infiltration-thrombolysis with recombinant tissue-type plasminogen activator and prostaglandin E1 in alternating order for recanalisation of peripheral arterial occlusions

K. Kröger, C. Buss, G. Rudofsky. *Department of Angiology, University of Essen, Essen, Germany*

Background: The efficacy, duration and dosages for intra-arterial thrombolytic treatment is still under discussion, especially for the recanalisation of chronic peripheral artery occlusions. The combination of low dose recombinant tissue-type plasminogen activator (rt-pa) and prostaglandin E1 (PGE1) for long-term intra-arterial thrombolysis has not been described before. We did a retrospective analysis to look for the use of the continuation of the local intra-arterial thrombolysis if a short-term thrombolysis up to 3 h during an intervention was not successful.

Methods: From 323 patients with peripheral arterial occlusions 142 could be effectively thrombolysed with intra-arterial rt-pa in the first 3 h. In 119 patients the thrombolysis was continued as a long-term therapy (3 mg rt-pa in 3 h followed by PGE1 (2.1 ml/h for 3 h, concentration: 20 microgram/50 ml NaCl) in alternating order). Treatment times ranged from 1 to 13 days (2.8 ± 2.2). If necessary, angioplasty was performed after a wire was passed through the lumen.

Results: Long-term thrombolysis succeed in complete recanalisation in 72 (61%) patients and partial recanalisation in 28 (23%) out of the 119 patients. Recanalisation at all occurred up to the 7th day whereas 91.7% showed racanalisation within the first 4 days. 10 patients suffered from severe bleedings. All bleedings occurred in the first 24 h after extraction of the catheter. No bleeding occurred during thrombolytic treatment.

Conclusion: The combination of low dose rt-pa and PGE1 for infiltration-thrombolysis is useful for long-term thrombolysis in patients with peripheral arterial occlusion. Treatment can reach up to the 4th day without increasing the risk of complications.

814 A new cerebral protection device for carotid angioplasty and stenting: first clinical experience with the percusurge GuardWire™

M. Henry, M. Amor, I. Henry, I. Masson, K. Tzvetanov, A. Polydorou, M. Hugel. *U.C.C.I., Polyclinique, Essey-les-Nancy, France*

Purpose: To study feasibility and safety of carotid angioplasty and stenting with cerebral protection with the new PercuSurge GuardWire™ device.

Methods: The device consists of a 0.014″ GuardWire™ with protection balloon incorporated into its distal segment. The proximal end of the hypotube wire incorporates a Microseal™ allowing inflation/deflation of occlusion balloon. Angioplasty + stenting are performed under cerebral protection. The dilated area is then cleaned before deflation of the protection balloon, either by aspiration, or by a flushing, derivating flow towards external carotid artery. Blood samples are analyzed. 35 carotid angioplasty + stenting procedures performed using this technique in 31 high-risk pts (M: 25, F: 6, mean age: 70.8 ± 6.7 years (56–86)) with implantation of 30 Palmaz stents, 8 Expander stents. Mean % stenosis: 82.2 ± 8.3 (70–96), mean lesion length: 16 ± 8.4 (6–50). 19 calcified lesions, 22 ulcerated, 18 echolucent on Dupplex scan. Contralateral internal carotid artery was stenosed (n = 8) or thrombosed (n = 2).

Results: Immediate technical success in all patients. Very good tolerance of occlusion (34/35). 1 case of intolerance (patient with contralateral carotid occlusion). No neurological complication. Occlusion balloon was deflated between pre-dilatation and stenting in 11 patients. Mean pre-dilatation occlusion time: 324.7 ± 141.1 sec (162–540). Mean stent implantation occlusion time: 602.5 ± 212.5 sec (372–905). In 29 cases occlusion balloon remained inflated during the whole procedure. Mean occlusion time: 550.4 ± 212.7 sec (245–991). Debris aspirated in all patients.

Conclusion: Cerebral protection with the PercuSurge GuardWire™ device seems safe/efficient to reduce risk of cerebral embolization during carotid angioplasty with stent implantation. It is easy to use, and should be developed in the near future to enlarge carotid angioplasty indications and make the procedure safer and an alternative to surgery. Larger studies are expected.

RISK FACTOR MANAGEMENT

826 Does the provision of support by a cardiac rehabilitation liaison nurse within the immediate discharge period improve patient's recovery at 6 months following first myocardial infarction?

K.M. Smith, A. Mackintosh[1]. *School of Nursing and Midwifery*, Department of Cardiology, Dundee; [1]Department of Cardiology, Ninewells Hospital & Medical School, Dundee, UK*

Introduction: There is increasing evidence that comprehensive cardiac rehabilitation (CR) programmes following acute myocardial infarction (MI) can reduce mortality and morbidity, reduce psychological distress, enhance secondary prevention and improve quality of life. In contrast when such a service is not provided there is evidence of poor progress and recovery from disease, which may result in a preoccupation with physical symptoms, a general loss of confidence, and often inappropriate use of health services. The immediate post discharge period has been identified as a problematic time for the patient (and partner), when they require but do not necessarily receive support from health care staff. This may be exacerbated by a lack of information transferred by the health care staff to the primary care sector. This study therefore aims to evaluate whether the provision of education and support by a specialist CR Liaison nurse in the immediate discharge period improves recovery.

Subjects and Methods: 100 patients admitted to Ninewells Hospital with a definite diagnosis of MI have currently entered the study and been randomly assigned to either normal care or the intervention group. Those assigned to normal care will receive CR via the existing programme i.e. individual education and counselling by the CR nurses during the in-patient phase and an invitation to attend the out patient educational programme. All these patients will receive telephone follow up in the normal manner within 1 week of discharge and they will have access to the rehabilitation advice line. In the intervention group the patients will be seen by CR liaison nurse at home within 1 week of discharge, again on week 3 of discharge and contacted by telephone on week 5. These patients will also have access to the rehabilitation advice line. A comparison of risk factor modification, mood, knowledge, health status and quality of life will be made between the two groups at 6 and 12 months. Health service utilisation will also be evaluated.

Results: The results of the 6 month outcomes of these two groups of patients will be presented to determine any differences in outcomes in terms of mood, knowledge, health status, quality of life, risk profiles and health service utilisation.

Conclusion: These results will be used to inform clinicians and managers within primary and secondary care of the impact of the CR liaison nurse service on recovery following MI. This will contribute to the development and provision of a high quality CR service to meet the varied needs of patients following first MI.

827 Age and preoperative comorbidities as factors influencing, on the lenght of icu stay for cardiac surgery patients

M. Carrera, I. Novo, C. Muñoz. *Postoperative Cardiac Surgery Intnesive Care Unit, Hospital "Marques de Valdecilla", Santander, Spain*

The improvement in quality of life and a more public-health education have contributed to increase the elderly population who undergo cardiac surgery. In order to know the relationship of the age and the preoperative comorbidites with the length of ICU stay, we perfomed a descriptive, transversal, and retrospective study for patiens after cardiac sugery.

Methods: 376 patients, which a postoperative lenght of stay > 3 days were selected from the population treated during the last three years, 1996–98. They were divided into four groups base on the age: <60, 60–69, 70–79 and >80 years. The datas colletion were categorized into the following sections. Demographic characteristics, preoperative factors, operative variables and postoperative complications.

Results: there has been an increase in the lenght of ICU stay, being of 3.08 in 1998, however the proportion of patients >80 years has risen as well. The observed preoperative risk factors influencing the length of stay were: creatinine > 2 mgrs/dl, ejection fraction < 50%, diabetes mellitus, and hypertension, along with atrial fibrillation and need for supplemental oxigen

Years	High outcomes patients	Stay average	Readmiting	Cases per year > 3 days			
				<60	60–69	70–79	>80
1996	699	2.71	32 OF 28	27	37	43	2
1997	731	2.66	37 OF 33	29	46	39	8
1998	749	3.08	28 OF 25	25	48	56	11

In conclusion, the elderly and comorbidities increase the risk of postoperative complications and the length of ICU stay, therefore a more intense nurse care is required.

828 Experience of and need for cardiac rehabilitation care after cardiovascular disease in 490 women

G. Sjöberg, B. Fridlund[1]. *Centre for Caring Sciences, University of Uppsala, Taby; [1]Centre for Health Promotion Research, Halmstad University, Halmstad, Sweden*

Background: Despite the high incidence of cardiovascular disease in women, there is a paucity of nursing research that addresses women's needs for cardiac rehabilitation care. Women are less prone to attend cardiac rehabilitation programs than men are, they also have a higher drop out rate before completion of the rehabilitation programs. Few studies have investigated the reasons why.

Objective: The purpose of this study was to survey women's reported experience of and need for rehabilitation after AMI, PTCA or CABG.

Method: An exploratory study was carried out. A sample of 490 eligible women who had suffered from AMI, or undergone PTCA or CABG took part in the study. A 282-item questionnaire at an ordinal scale level was used.

Results: The 490 women attended one or more parts of a cardiac rehabilitation program; in a physical training group n = 182 (37%), in a dietary modification group n = 48 (10%), in a conversation group n = 73 (15%), in a smoking cessation group n = 5 (1%) and in a stress modification group n = 35 (7%). Smokers were n = 54 (11%) and ex-smokers n = 153 (31%). Smoking cessation group was considered as the most important part of cardiac rehabilitation program and in decreasing order of importance physical training group, stress modification group, dietary modification group and last the conversation group.

Conclusion: Smoking cessation group was considered to be the most important part in cardiac rehabilitation program, however only 1% of the smokers and ex-smokers had attended a smoking cessation group.

829 Risk factors, clinical and angiograpic characteristics in young patients (≤45 years) recovering from acute myocardial infarction

A. Francis, B. Mazouz, A. Keren, S. Stem, S. Gottlieb. *The Heiden Department of Cardiology, Bikur Cholim Hospital, Jerusalem, Israel*

AMI in young adults is rare. There are few data regarding the angiographic findings in young AMI pts compared with older ones.

Methods: We compared the baseline characteristics, risk factors and angiographic findings of 761 consecutive pts with AMI; 120 young (age ≤ 45 yrs) and 641 older (age > 45 yrs) pts hospitalized between 1986–1996. Coronary angio was performed within the first 100 days after AMI. CAD was defined as ≥50% stenosis.

Results (see table; numbers are percentages):

	Age ≤ 45 yr	Age > 45 yr	p value
Age, yrs (mean ± SD)	41 ± 4	61 ± 9	<0.0001
Males	92	77	0.003
No. Risk factors (mean ± SD)	2.1 ± 1.1	1.9 ± 1.2	ns
Current smokers	68	31	<0.0001
Positive family history	43	29	0.003
Hypertension	18	37	<0.0001
Diabetes mellitus	13	21	0.02
Hyperlipidemia	50	50	ns
Obesity (BMI > 28 kg/m^2)	19	26	0.1
Inferior location	57	42	0.003
Q-wave MI	83	67	0.008
Thrombolysis	57	42	0.003
Angiographic findings:			
Normal/Nonobstructive	8	2	
Single vessel disease	46	20	<0.0001*
Multiple vessel disease	46	78	
Lesions per patient† (mean ± SD)	2.4 ± 1.8	3.4 ± 2.0	<0.0001
Proximal lesions‡	67	83	<0.0001
Proximal LAD	39	63	<0.0001

*Comparing between the 3 categories of diseased vessels. †No. of segments with stenosis ≥ 50%, using a 17 coronary segments/pts model. ‡Significant stenosis in ≥1 of the proximal segments of LAD, LCx, RCA.

Conclusions: Compared with older pts, young pts with AMI are more often current smokers, with a family history of CAD. They presented more often with first AMI, Q-wave MI, inferior location and had a better residual LV function. They had less diffuse CAD and had less often proximal coronary lesions.

830 Presence of risk factors and risk factor modification in women undergoing coronary revascularization

S. Alexiou, S. Giannou, A. Papathanasiou, A. Tziovas, K. Achenbach, K. Ekonomidis, J.A. Goudevenos. *Division of Cardiology, University Hospital of Ioannina, 45110 Ioannina, Greece*

Findings suggest that effective secondary prevention programs to control cholesterol in women after revascularization should include smoking cessation and weight loss components. The aim of our study was to determine to which extent those women of our area modify their risk factors.

Methods: Risk factors for CAD were examined in 182 women (mean age 62.4 ± 9.6 years) at the time of coronary angiography and at least one year after revascularization (113: CABG, 69: PTCA). Presence of risk factors at the time of coronary angiography were as follow: total cholesterol > 200, 65.6%; and 45% were taking statins; smoking (current), 8.24%; diabetes, 20.3%; hypertension, 36.3% obesity (BMI > 30%, 21.4%; BMI > 25% and <30%, 37.5%; family history, 14%. All except one were postmenaupausal

Results: Risk factor modification at least one year after intervention was assessed in all 182 women and lipids were measured in 119 women. Antihypertensive and antidiabetics drugs were used by all women stating they had hypertension or diabetes respectively. 25% of women did not quit smoking after intervention. During follow-up 87% of women had TC < 200 mg/dL and under statin treatment were 71% and in none the target level of LDL cholesterol < 115 mg/dL was reached. Decrease of at least 20% in BMI was achieved by 5 women. None was taking hormone replacement therapy Almost all women (85%) were taking low-dose aspirin and b-blockers (55.5%).

Conclusions: The inadequate cholesterol management is due to insufficient LDL lowering and not from failure to initiate statins. Smoking and obesity in women of our area do not constitute common risk factors compared to other countries.

831 Adults in Poland underestimate cardiovascular risks of sedentary life style and profits of regular physical activity

T. Zdrojewski, M. Kakol, R. Pienkowski[1], B. Krupa-Wojciechowska. *Dept of Hypertension & Diabetology, Medical University of Gdansk, Gdansk; [1]Centre for Social Research, Sopot, Poland*

The aim of our study was to assess knowledge about life style habits predisposing to cardiovascular (CV) diseases and arterial hypertension (HT) among adults in Poland. Thus, we conducted a cross-sectional survey based on a questionnaire interview on a representative sample of 1664 men and women aged 18 years and over. The subjects were selected from Polish population by stratified and cluster random sampling with quotas. In all of them blood pressure and anthropometric parameters were measured. The respondents answered the following questions: What causes of HT and CV diseases do you know? What methods of prevention of HT and CV diseases do you know? The results were analysed according to age, sex, education, income, place of living, presence of hypertension and/or obesity.

Respondents mentioned the causes of HT and CV diseases in the following order: stress (39%), overeating (37%), alcohol abuse (25%), smoking (22%), coffee (9%), salt excess in diet (8%), sedentary life style (7%), oral contraceptives (5%), heredity (4%). A list of preventive methods started with "taking drugs" (50% !!!). The subjects also mentioned regular style of life (22%), limitation of fat in diet (23%), weight reduction (14%), alcohol restrictions (14%), giving up smoking (13%), regular physical activity (13%), and reduction of salt intake (10%). They have learnt about these preventive methods from physicians (43%), radio and TV (34%), newspapers and magazines (34%), and from relatives (21%). School was hardly ever mentioned (<1%). The results show that adults in Poland underestimate cardiovascular profits of regular physical activity and risks resulting from lack of exercise. Our study univocally points out the tasks relevant to education and prevention of HT and CV diseases in Poland.

LONG-TERM OUTCOME OF PERCUTANEOUS INTERVENTIONS

841 A randomized comparision of elective stenting versus balloon angioplasty with two years follow-up

A. Witkowski, W. Ruzyłło, R. Gil, Z. Purzycki, M. Kośmider, L. Poloński, K. Żmudka, P. Buszman, D. Ciećwierz, B. Górecka. *On behalf of AS Investigators; Institute of Cardiology, Warsaw, Poland*

Angioplasty or Stent (AS) Trial is a Polish multicentre, randomized comparision of elective, high pressure PS 153 stenting (S) without IVUS guidance with balloon angiolpasty (BA) of single de novo lesions in native coronary arteries.

Patients: between Feb and Dec 1996 a total of 388 pts were enrolled, 192 in S group and 196 in BA group. Both groups were well matched with regard to all clinical and angio parameters. Ticlopidine 250 mg bid and ASA 300 mg/day were used in both arms.

Results: the procedural success did not differ significantly (96.35% vs 95.41%, p. = NS). There were no stent thrombosis. At six months on angio restudy MLD was 1.82 ± 0.63 mm (S) vs 1.57 ± 0.58 mm (BA), p. = 0.004; restenosis rate (>50% diam) was 18.82% (S) vs 24.74% (BA), p. = 0.05.

At two years adverse event (AE) rates were as followed:

AE	S	BA	p =
Death	0.052%	0	NS
Cerebrovacs. accident	0	0	NS
QMI	1.04%	1.02%	NS
Target lesion rev. (TLR)	16.15%	24.5%	0.05

The event-free survival (no death, cerebrovascular accident, QMI or TLR) at 6, 12 and 24 months was: 86.77% vs 78.84%, 84.13% vs 76.70% and 83.07% vs 73.54%, p. = 0.0172 (Log-Rank), for S group and BA group respectively.

Conclusion: High pressure elective coronary stenting with antiplatelets regimen eliminates stent thrombosis. In comparision to balloon angioplasty angiographic restenosis rate is significantly lower at six month. During two years of follow-up event-free survival of the stented patients was better because of 34% reduction in repeat revascularization rate.

842 Minimal invasive bypass surgery versus stentimplantation in proximal high-grade lesions of the left anterior descending coronary artery

N. Spyrantis, A. Diegeler[1], B. Lauer, R. Hambrecht, F.-W. Mohr[1], G. Schuler. *Dept of Cardiology; [1]Dept of Cardiac Surgery, Heart Center Leipzig, Univ. of Leipzig, Germany*

Background: Minimal invasive bypass surgery (MIC) has been shown to yield comparable results to conventional bypass grafting with less operative trauma. Therefore it may be considered an alternative treatment to stentimplantation (S) in patients with proximal high grade lesions of the Left Anterior Descending Coronary Artery (LAD).

Methods: 136 patients (P) with high grade lesion of the proximal LAD were randomized between MIC (65) and S (71). Clinical symptoms were assessed by CCS-class. After 6 months P underwent repeat coronary angiography, coronary lesions were measured by quantitative coronary angiography.

Results: At baseline all P had stress induced angina pectoris (CCS: MIC: 2.6 ± 0.8; S: 2.7 ± 0.9). After revascularization 98% of P were free of angina pectoris. During MIC 3 P (4.6%) were converted to conventional bypass surgery with sternotomy and 2 P (4%) required repeat operation due to stenosis of the distal anastomosis within one week. Acute stent thrombosis occurred in 2 P (3%) after S. After 6 month 18/50 P (36%) in the S-group showed in stent restenosis > 50%, 14 P (28%) underwent re-PTCA. In the MIC-group 5/33 P (15%) showed stenosis > 50% of the distal anastomosis, 3 P (9%) required PTCA (p = 0.05). Relieve of angina at 6 months was more complete in MIC as compared to S (CCS: 0.21 ± 0.54 vs 0.73 ± 1.13; p < 0.05), although physical work capacity did not differ between the groups (S: 120 ± 35 Watt; MIC: 130 ± 33 Watt; p: n.s.)

Conclusion: In P with high grade stenosis of the proximal LAD both MIC and S yield excellent results with few clinical events. Relieve of angina pectoris is more complete in MIC. In the face of reduced operative trauma, MIC may be considered an alternative treatment to S in these P.

843 Continued benefit of coronary stenting versus balloon angioplasty: five-year clinical follow-up of BENESTENT-I trial

Patrick W. Serruys. *The BENESTENT-I study group; Erasmus University, Thoraxcenter, 3015GD, Rotterdam, Netherlands*

Objectives: This study sought to determine the 5-year clinical follow-up of patients included in the BENESTENT-I trial.

Background: The BENESTENT-I trial is a randomized study comparing elective Palmaz-Schatz stent implantation with balloon angioplasty in patients with stable angina with a single de novo lesion. Seven-month follow-up data have shown a decreased rate of restenosis and fewer clinical events in the stent group. It is not established whether this favourable clinical outcome is maintained for longer periods or whether coronary stenting defers restenosis and its subsequent clinical manifestations.

Method: To clarify this uncertainty, we updated clinical information on 491 of 516 patients (25 patients are still pending) enrolled in the BENESTENT-I trial at least 5 years after the intervention.

Results: Major Adverse Clinical Events (MACE) in descending order of severity:

	Events per patient		*p-value*	Ranking	
	BA (243)	S (248)		BA (243)	S (248)
Death (D)	3.3%	6.0%	0.20	3.3%	6.0%
Cardiac D	1.6%	2.8%	0.54	1.6%	2.8%
Non-cardiac D	1.6%	3.2%	0.38	1.6%	3.2%
CVA	1.2%	0.4%	0.37	1.2%	0%
Q-wave MI	3.3%	7.7%	0.046	2.9%	7.3%
Non-Q MI	2.5%	1.2%	0.34	2.5%	1.2%
CABG	9.5%	12.1%	0.38	8.2%	10.1%
TLR	27.2%	17.3%	0.009	21.4%	10.1%
No MACE	60.5%	65.3%	0.30	60.5%	65.3%

Conclusion: The original difference of 10% in TLR observed at 7 months (23.3% for BA vs 13.5% for S) has remained unchanged at 5 years (27.2% vs 17.3%) emphasizing the extraordinary long-term stability of the dilated or stented target site. In the stent group, the relatively high proportion of non-cardiac death and the Q-wave MI potentially unrelated to the deterioration of the target lesion may have dampened the global long-term benefit of stenting (no MACE, log rank test: p = 0.18).

844 Stent implantation after successful balloon angioplasty of a chronic coronary occlusion (SARECCO): 2 years follow-up

H. Sievert[1], S. Rohde[1], A. Utech[3], R. Schulze[2], H. Spies[1], R. Ensslen[1], D. Scherer[1], R. Schräder[1], A. Fach[1], H. Merle[1]. [1]*Cardiovascular Center Bethanien CCB, Frankfurt;* [2]*Klinik Dr. Haerer, Ulm;* [3]*Rot-Kreuz Krankenhaus, Kassel, Germany*

The restenosis rate after angioplasty for chronic total coronary occlusion is much higher compared to coronary stenoses. The long-term benefit of stent implantation after successful recanalization is unknown.

110 Patients were randomized after successful balloon angioplasty of a chronic coronary occlusion (vessel diameter ≥ 2.5 mm) to "stent" implantation or to "no stent". The baseline characteristics of both groups showed no difference. Follow up (FU) angiogram was performed after 4–6 months and clinical follow-up obtained for 2 years.

	No stent	Stent	P
MLD post (mm)	1.85 ± 0.44	2.54 ± 0.53	<0.01
MLD FU (mm)	1.15 ± 0.73	1.81 ± 0.9	<0.01
Reocclusion FU	14%	2%	<0.05
Restenosis (>50% FU)	62%	26%	<0.01
Event free survival (2 yrs.)	48%	74%	<0.05

Conclusion: The beneficial effect of stent implantation after successful recanalization and balloon dilatation of a chronic coronary occlusion is maintained after 2 years.

845 Argentine randomized study optimal coronary balloon angioplasty and stenting versus coronary bypass surgery in multiple vessel disease (ERACI II): acute and mid term outcome

A.E. Rodriguez, O. Santaera, L. Grinfeld, V. Bernardi, J. Baldi, J. Navia, D. Guastavino, M. Martinez Peralta, I. Palacios, W. O'Neill. *On behalf of ERACI II Investigators; Otamendi Hospital, Buenos Aires, Argentina; Massachussets General Hospital, Boston MA; William Beaumont Hospital, Royal Oak MI, USA*

Purpose: The use of stents during coronary interventions reduce acute complications and late restenosis. The aim of this study was to compare coronary angioplasty with stents (PTCA) vs coronary by pass surgery (CABG) in patients with multiple vessel coronary artery disease (CAD).

Methods: From November 1996 to September 1998, 450 pts with multiple vessel CAD were included and randomized to PTCA (225 pts) or CABG (225 pts). The end point of this study was to compare major adverse cardiac events (MACE) defined as death, myocardial infarction (AMI) and requirement of repeat, PTCA/CABG (TLR) at 30 days, one, three, and five years after the randomization. At 30 days stroke was also included as MACE.

Results: Basal demographic and angiographic characteristics were similar, Unstable Angina class II, III, and C 83% vs 90.2% in PTCA and CABG groups respectively.

	PTCA	CABG	P
Death (30 days)	0.9%	5.7%	= 0.012
AMI (30 days)	0.9%	5.7%	= 0.012
Death + AMI (30 days)	1.8%	11.4%	= 0.0002
Stroke (30 days)	0%	1.8%	NS
MACE (30 days)	3.6%	12.5%	= 0.003
Death + AMI (6 Months)	4.5%	13.3%	= 0.007
TLR (6 Months)	13.7%	4.8%	= 0.005

Conclusions: Patients randomized to PTCA Group had significantly lower, 30 days MACE than patients randomized to CABG group. At 6 months freedom from death and AMI was also better in PTCA arm.

846 GABI-II: 1 year follow up of a prospective, multicenter study for the treatment of patients with symptomatic multivessel disease

Stephan Baldus[1], Jacobus Reimers[1], Robert Küchler[2], Alexander Sasse[3], Jürgen V. Dahl[3], Ulrich Dietz[4], Bettina Sieburg[5], Wolfram Voelker[5], Christian W. Hamm[1]. [1]*Kerckhoff Clinic, Bad Nauheim;* [2]*Hospital St. Georg, Hamburg;* [3]*RWTH Aachen;* [4]*University Hospital Mainz;* [5]*Hospital Mannheim, Germany*

Patients (pts.) with symptomatic multivessel coronary disease benefit from both percutaneous angioplasty (PTCA) and aortocoronary bypass grafting (CABG). In the GABI trial (GABI-I) which randomized pts. to either PTCA or CABG in the years 1986–1991 the symptomatic improvement in both treatment groups was not significantly different, however, after one year of follow up pts. in the PTCA arm required more reinterventions than pts. randomized to CABG.

In order to evaluate the impact of current technology including coronary stents the GABI-II trial included pts. according to the initial GABI criteria. Between 2 '1996 and 10 '1997 136 pts. (79% male, mean age 63 years) with symptomatic multivessel coronary disease were enrolled, 98.5% underwent PTCA for 2.1 ± 0.6 vessels. Stents were deployed in 74% of the pts., 7% of the pts. underwent rotational atherectomy and 7% of the pts. received abciximab. During initial hospitalization no patient required emergency bypass operation (vs. 8.5% in GABI-I, $p < 0.01$). After 12 months, 19% of the pts. remained symptomatic with a CCS-class > II vs. 29% in the PTCA-arm of GABI-I ($p = 0.05$). The incidence of q-wave myocardial infarction was 1.5% after 12 months vs. 5% in the PTCA arm of GABI-I (n.s.). Within the first year 7% of the pts. had undergone CABG (vs. 21% in GABI-I, $p < 0.001$) and 23% underwent Re-PTCA (vs. 23% in GABI-I). The total reintervention rate was reduced by 32% ($p < 0.05$) but remained higher compared to the CABG-arm in GABI-I ($p < 0.001$).

Conclusions: PTCA in pts. with coronary multivessel disease is still associated with a higher reintervention rate compared to CABG. However, compared to the PTCA arm of GABI-I, the reintervention rate is significantly lower, which is mainly driven by the reduced necessity for CABG. This is most probably a result of intracoronary stents.

INTRACORONARY IRRADIATION: BASIC MECHANISMS

852 The effects of external beam irradiation in stented pig coronary arteries

S. Verheye, M.Y. Salame, N.A.F. Chronos, S.P. Mulkey, T.R. Fox[1], S.B. King III, I.R. Crocker[1], K.A. Robinson. *The Andreas Gruentzig Cardiovascular Center, Dept. of Medicine (Cardiology);* [1]*Dept. of Radiation Oncology, Emory University School of Medicine, Atlanta GA, USA*

Background: External beam irradiation (EBI) has some potential advantages for vascular radiotherapy and has been shown to reduce neointima formation and lumen loss in balloon injured pig coronary arteries at a dose of 21 Gy. However in stented coronary arteries, EBI failed to show any benefit at 8 Gy. We therefore investigated the effects of EBI at the higher dose of 21 Gy in pig coronary arteries after stent implantation.

Methods: Intracoronary stent implantation was performed in all 3 epicardial vessels of 15 pigs. Pigs were randomized to receive EBI at 21 Gy delivered to the entire heart or placebo. Quantitative coronary angiography (QCA) was performed at implantation and at 28 days just prior to harvest. Sections were prepared by saw-and-grinding after plastic embedding and lumen area, neointimal area, injury score and maximal neointimal thickness were measured by computer-assisted histomorphometry.

Results: On QCA, there were no differences in reference vessel diameter, balloon to artery ratio or post stent lumen diameter between treated and control groups at baseline. EBI resulted in a significant decrease in late lumen loss compared to controls; (0.08 mm vs 1.21 mm, $p < 0.05$) respectively. The histomorphometry results are shown below.

	Lumen area	Intimal area	Intima/injury score	Intimal thickness
Control	4.69 ± 1.87	3.67 ± 1.94	2.90 ± 1.44	0.76 ± 0.36
21 Gy EBI	7.40 ± 1.40	0.39 ± 0.60	0.36 ± 0.57	0.12 ± 0.13
p-Value	0.003	<0.001	<0.001	<0.001

Conclusions: In stented pig coronary arteries, external beam irradiation at 21 Gy significantly reduced neointima formation and lumen loss. EBI by linear accelerator for clinical in-stent restenosis prevention warrants further investigation.

853 Impairment of isolated coronary reactivity one month post-angioplasty and irradiation in the pig

D. Meerkin, E. Thorin, P. Paiement, R. Bonan. *Montreal Heart Institute, Montreal PQ, Canada*

The effects of post-angioplasty (PTCA) radiation therapy for restenosis prevention on coronary vasomotion and endothelium-dependent regulation is unknown. To address this issue, vascular reactivity was assessed following PTCA and intracoronary radiation therapy (ICRT) in pigs.

Methods: PTCA and ICRT (using a β-emitter, Sr/Y90) were performed using a non-centered 5F closed end catheter alternatively to the LAD or Cx arteries. A dose of 16 Gy to a depth of 2 mm from the source center was delivered over 3 cm segment. At 6 weeks, the pigs were sacrificed and treated coronary arteries were isolated. Rings were mounted on a myograph to record isometric changes in tension. Data are expressed as mean ± SEM. Using a Student's t test, p was considered significant <0.05.

Results: Rings were stretched to 5 g and allowed to reach their baseline tension. Tension stabilized at 1.28 ± 0.09 g in the control group (CG) (n = 7) but was lower in treated animals (0.42 ± 0.12 g, P < 0.05), indicating a weakening in the stiffness of the vascular walls. The initial contractions induced by a depolarizing solution (40 mM KCl) and PGF2α (40 μM) were similar in the 2 groups. After 4 hours, PGF2α-induced contraction was blunted (1.5 ± 1.5% 40 mM KCl response, P < 0.05) compared to the response of time-control arterial rings (16 ± 5% 40 mM KCl response). In preconstricted depolarized vessels, substance P (0.1 μM)-induced relaxation was negligible (1.7 ± 1.7%, P < 0.05) compared to CG (33 ± 5%), indicating a lack of NO release, effect or production. Sodium nitroprusside (SNP, 1 nM-10 μM)-induced relaxation was facilitated by endothelial denudation in the CG (P < 0.05) due to the increase in guanylate cyclase sensitivity associated with the loss of endothelium-derived NO. In the treated group, SNP-induced relaxation was similar to the denuded CG further suggesting decreased NO bioavailability 6 weeks post-PTCA and ICRT.

Conclusion: PTCA and ICRT in pigs resulted in a decrease in arterial wall stiffness, a weakening of smooth muscle cell contractility and a loss of endothelium-derived NO effect.

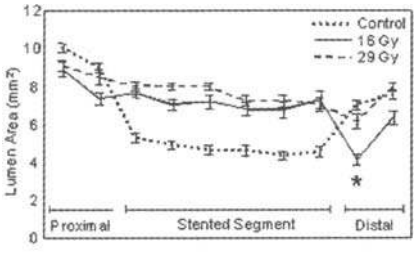
854 Edge stenosis after "low dose" radiation therapy using a Re-188 liquid-filled balloon system

J. Hausleiter, H. Honda, A. Li, M. Sebastian, F. Litvack, J. Whiting, N. Eigler. *Dept. Medical Physics & Imaging, Cedars – Sinai Medical Center, Los Angeles CA, USA*

Background: Early clinical results with the 3–6 mCi ^{32}P-stents showed instances of restenosis at the ends of the radiation zones creating a "candy wrapper" appearance. In addition, pig studies with balloon injury have demonstrated that low dose radiation therapy may promote proliferation. Edge stenoses after radiation therapy with a liquid-filled balloon have not been reported yet.

Methods: 24 pig coronary arteries (RCA and LAD) were radiated at 0, 16 and 29 Gy at 0.5 mm tissue depth using a Re188 liquid-filled, 20 mm long balloon. Subsequently, 17 mm long stents were placed with oversizing. At follow up, the stents and the edges were systematically evaluated by angiography and intravascular ultrasound (IVUS).

Results: Within the stented segment, radiation therapy produced a significant dose-dependent reduction of intimal thickening. By angiography, the minimal luminal diameter tended to be at the distal portion of the radiated stent segments compared with diffuse in-stent restenosis seen in controls. At 16 Gy, IVUS demonstrated a significant, focal decrease of the lumen area at the distal edge of the stent. At this site intima proliferation was increased by >200% as compared to controls (p < 0.01).



IVUS analysis.

Conclusions: Increased injury at the distal stent edge due to vessel tapering, in combination with insufficient radiation dose due to rapid dose fall-off at the balloon ends, may enhance intima proliferation. This paradoxical event may be prevented by the use of longer radiation balloons to fully cover the injured segment.

855 Effects of endovascular irradiation on platelet recruitment in ballon-injured coronary arteries

M.Y. Salame, S. Verheye, J. Lampkin, S.P. Mulkey, J. Cui, R.A. Hillstead[1], I.R. Crocker[2], N.A.F. Chronos, S.B. King III, K.A. Robinson. *The Andreas Gruentzig Cardiovascular Center, Dept. of Medicine (Cardiology); [2]Dept. of Radiation Oncology, Emory University School of Medicine, Atlanta GA; [1]Novoste Corporation, Norcross GA, USA*

Background: Endovascular irradiation (EI) is effective in animals in preventing neointima formation after balloon angioplasty and early clinical data on restenosis prevention appears promising. However, little is known about the vascular biological consequences of EI. In this study we examined the effect of EI at therapeutic and supra-therapeutic doses on platelet deposition in coronary arteries at serial time points after angioplasty.

Methods: Adult Yucatan miniature pigs received balloon angioplasty in all 3 epicardial arteries. They were immediately treated with doses of 0 (controls), 15, or 30 Gy at 2 mm from the source center. Autologous platelets were isolated from whole blood and labeled with ^{111}In-oxine (labeling efficiency was consistently >90%) then reinjected the same day or 1, 3, 7 or 28 d after angioplasty. Two hr after injection hearts were harvested and perfusion fixed; coronary arteries were excised and radioactivity determined in a -counter. Platelets/vessel was determined from activity and platelet counts of whole blood sampled at the time of tissue harvest.

Results: EI had no effect on platelet recruitment compared to control except 30 Gy at 28 d (table). Means and SD are shown.

Time	Number of platelets/vessel segment/10^{-6}		
	Control	15 Gy	30 Gy
2 hr	32.6 (21.0)	6.8 (4.6)	14.5 (7.3)
1–3 d	8.7 (11.0)	12.6 (7.7)	22.5 (36.7)
7 d	4.4 (0.9)	15.7 (24.9	5.8 (2.3)
28 d	2.1 (0.6)	5.1 (2.8)	15.3 (8.6)*

*P = 0.03 compared to 28 d control

Conclusions: EI at a dose (15 Gy) within the range currently employed in clinical trials had no effect on platelet recruitment in pig coronary arteries through 1 month after angioplasty. However with twice this dose (30 Gy) in this initial series, more platelets were recruited at the angioplasty site at one month after the procedures. Caution needs to be exercised in using higher dose EI for restenosis prevention. Studies are ongoing to extend these data.

856 Gallium-68 positron radiation effectively reduces neointima proliferation in the porcine coronary overstretch model

H.P. Stoll, W.L. Winkle, G.D. Hutchins, J. Howard, R.C. Appledorn, K.L. March[1]. *Indiana University, Indianapolis IN; [1]Roudebush VA Medical Center, Indianapolis IN, USA*

Background: We have recently proposed the use of Ga-68 for liquid-filled balloon brachytherapy since it combines anti-proliferative efficacy in cell culture assays with markedly superior safety in case of balloon failure, based on its short half-life (68 min). This study investigates the impact on neointima proliferation in the porcine coronary overstretch model.

Methods: 25–50 mCi 68-GaCl3 eluted from a Ge-68/Ga-68 generator was delivered into the fluid port of conventional autoperfusion balloon catheters and used to irradiate sites of coronary overstretch (B:A ratio = 1:3, n = 25) in juvenile farm pigs (n = 15). Therapeutic doses were directed to a prescription point 1 mm beyond the intimal surface and included groups of arteries treated with 8 Gy, 12 Gy, 16 Gy, and 24 Gy. Overstretched but unirradiated arteries served as control. Animals were sacrificed 28 d later and hearts were perfusion fixed. Serial sections were evaluated by histomorphometric analysis. Intimal area (IA), intimal area to fracture length ration (IA/FL), and maximal intimal thickness (MIT) were measured.

Results:

	n	IA (mm^2)	IA/FL (mm)	MIT (mm)
Control	9	0.51 ± 0.04	0.47 ± 0.06	0.40 ± 0.05
8 Gy	5	0.75 ± 0.15	0.68 ± 0.10	0.62 ± 0.08*
12 Gy	3	0.46 ± 0.16	0.34 ± 0.12	0.32 ± 0.11
16 Gy	3	0.07 ± 0.04*	0.05 ± 0.03*	0.09 ± 0.01*
24 Gy	3	0.07 ± 0.02*	0.05 ± 0.02*	0.08 ± 0.04*

Data are mean ± SEM, *p < 0.05 vs. control.

Conclusion: Ga-68 positron radiation significantly reduces neointima formation in the porcine model in both high dose groups. Since Ga-68 is effective, safe, and available from a generator, it should be considered as an isotope optimally suited for liquid-filled balloon brachytherapy.

PAEDIATRIC ARRHYTHMIAS/ELECTROPHYSIOLOGY

873 Molecular and ionic mechanisms of complete congenital heart block

M. Boutjdir. *Dept. of Medicine/Cardiology (IIIA), V.A. Medical Center, Brooklyn, NY, USA*

An important advance in the description and understanding of congenital heart block (CHB) came in the 1970s with the observation that mothers of affected infants frequently had autoimmune diseases and, in particular, that many maternal sera contained antibodies to SSA/Ro and SSB/La ribonucleoproteins. While the molecular biology of the candidate antigens has been extensively defined, the arrhythmogenic and electrophysiologic effects of their cognate antibodies on the human fetal and rat heart are unknown.

Methods and Results: Here we provide evidence that IgG-enriched fractions and anti-52 kD SSA/Ro antibodies affinity purified from sera of mothers whose children have CHB induce complete atrio-ventricular (AV) block in the human fetal and rat heart perfused by the Langendorff technique and in multicellular AV nodal preparation, inhibit L-type Ca currents at the whole cell and single channel level. Confocal immunofluorescent studies showed sarcolemmal staining of the isolated myocyte to IgG containing anti-Ro/La antibodies but not to normal IgG. Double staining using both Ca channel anti-alpha1 subunit antibody and IgG showed areas stained by both antibodies. Immunization of female BALB/c mice with recombinant SSA/Ro protein generated high titer antibodies which crossed the placenta during pregnancy and were associated with varying degrees of AV conduction abnormalities, including complete AV block, in the pups.

In conclusion, these findings strongly suggest that maternal autoantibodies from mothers of children with CHB are causally related to the development of CHB. The data suggest that sarcolemmal Ca channel subunits and/or associated regulatory proteins could be the possible binding sites for the maternal antibodies. Taken all together, the present data provide new insights into the pathogenesis and etiology of CHB.

873 QT interval prolongation in infants with maternal anti-SSA/Ro antibodies

M. Stramba-Badiale[1,2], P. Meroni[2], A. Brucato[3], K. Goulene[1], F. Ciambellotti[1], R. Cimaz[4]. [1]*IRCCS Istituto Auxologico Italiano;* [2]*IRCCS Ospedale Maggiore;* [3]*Ospedale Niguarda Cà Granda;* [4]*Dept Pediatrics, ICP; Milan, Italy*

The neonatal lupus syndromes are characterized by anti-SSA/Ro positivity and AV conduction defects. To our knowledge, a prolonged QT interval has not been described in these patients. We have reported a positive infant with QT interval prolongation (QTc = 473 msec) that persisted during the first year of follow-up. To confirm this finding, we retrospectively analyzed the electrocardiograms of 21 SSA/Ro positive infants and of 10 infants who did not receive antibodies from their positive mothers. None of the infants had extreme bradicardia in the fetal period or AV conduction defects after birth and all possible causes of prolonged repolarization had been excluded. QTc was greater in the positive infants (442 ± 35 vs 403 + 16 msec, p = 0.001), while QT interval dispersion expressed as QTcmax-min and coefficient of variation of QTc did not differ. When we analyzed the individual values of QTc, we observed that 9/21 (43%) of the positive infants (range 441–529 msec) and none of the negative infants had a QTc greater than 440 msec. In 5 infants with prolonged QTc on the standard ECG a 24-hour Holter ECG was recorded and automatic QT analysis from 2880 30-sec segments (ELA Medical) confirmed the QT interval prolongation that remained constant throughout the 24 hours. Since a higher mortality has been reported with QT prolongation during infancy, a prophylactic treatment with beta-blockers was started in these newborns who remained free of arrhythmias or symptoms during follow-up. Thus, a significant portion of infants who received anti-SSA/Ro antibodies from their mother and did not develop AV conduction defects, showed a prolongation of the QT interval that persisted in the following months. Since most of these infants were treated prophilactically with beta-blockers we do not know if life-threatening arrhythmias might have occurred. However, QT interval should be measured in the first months of life in this population. The observation that none of the negative infants born from positive mothers had a prolonged QT interval may suggest that anti-SSA/Ro antibodies may interfere with ventricular repolarization during development.

874 Electrophysiologic characterisation and radiofrequency ablation of atrial tachycardia in patients after fontan surgery using a non-contact mapping system

T.R. Betts, S. Allen, A.P. Salmon, T.J. Edwards, J.M. Morgan. *Wessex Cardiothoracic Centre, Southampton, UK*

Atrial tachycardia (AT) is a common late complication of surgical procedures involving the atria used to palliate certain forms of congenital heart disease. Suture lines, surgical incisions, prosthetic material and distorted anatomy all create the substrate for these complex arrhythmias, which are believed to be macroreentry in nature. Mapping by conventional techniques is difficult and time consuming.

We have used a non-contact multielectrode array (EnSite 3000, Endocardial Solutions Inc.) to construct isopotential and isochronal maps of the systemic venous return ("right atrial") chamber in 3 patients with AT after Fontan surgery. The multi-electrode array allows reconstruction of over 3300 unipolar electrograms which are superimposed on a 3-D model of the endocardial surface. The low amplitude electrical activity in the dilated, diseased atrium challenges the accuracy of this new technology. Nevertheless, AT reentry circuits could be identified in 2 pts and an ectopic atrial focus in 1. Known features of the Fontan anatomy could be correlated with the chamber geometry and isopotential maps. The path of activation was determined by atriotomy scars, cardiac structures or patch tissue. The radiofrequency ablation catheter was guided by a locator signal superimposed on the map and used to create focal or linear lesions. This abolished AT in 2 patients. In the third patient the chronic AT was initially terminated but remained inducible, although with a longer cycle length (420 msec vs 340 msec) and has not clinically recurred.

Conclusion: Non-contact mapping of the systemic venous atrium after Fontan surgery can characterise AT. It may be superior to conventional mapping techniques and allow successful catheter ablation of these complex arrhythmias.

875 Medical treatment of children with atrial ectopic tachycardia and tachycardia-induced cardiomyopathy

E. Villain, D. Bonnet, G. Butera, L. Iserin, J. Kachaner. *Hopital Necker Enfants-Malades, Paris, France*

Due to its good results, radiofrequency ablation has been advocated as a first line therapy for children with atrial ectopic tachycardia (AET) and cardiomyopathy (CMP). The purpose of this study was to assess the efficacy and tolerance of antiarrhythmic drugs in these patients.

From 1990 to 1997, 8 children aged 3 mths to 12 yrs (m: 4.5 ± 4.7 yrs) were admitted for AET with severe CMP (SF < 10%). All pts had cardiac failure, 3 being referred for heart transplantation. All had permanent AET with heart rate 160 to 400 bpm. Oral antiarrhythmic drugs were given in all cases and success was defined as achievement of a stable sinus rhythm with normal ventricular function. Main trials included amiodarone (*Amio:* 250 mg/m^2), propranolol (*Pr:* 2–3 mg/kg), digoxine (*Dig:* 10–15 μg/kg) and flecaïnide (*Fleca:* 3–8 mg/kg), alone and in combination.

	Dig	Amio	Dig + Pr	Amio + Pr	Amio + Pr + Dig	Fleca	Fleca + Pr
Failure	3	2		2	2	1	
Success	0	3	1	2	2	1	2
Trials	3	5	1	4	4	2	2

100% of pts achieved successful treatment without side effect. Follow-up is 2–years (m: 5.1 ± 3 yrs) and all pts have permanent sinus rhythm with normal echocardiography. AET has totally resolved in 5 cases within 2 to 5 years and the treatment has been reduced in 3 others.

Conclusions. In children with AET resulting in CPM, restoration of sinus rhythm and normal echocardiography can be achieved with medical treatment. Spontaneous resolution of AET is expected. Due to the possible late complications of ablation, we recommend a conservative approach in all children with AET, including those with severe CPM.

876 Radiofrequency catheter ablation in children

D. Bakšienė, R. Šileikienė, A. Puodžiukynas, V. Šileikis, T. Kazakevičius. *Kaunas Medical University Clinic, Kaunas Institute of Cardiology, Kaunas, Lithuania*

Radiofrequency ablation therapy is the current therapy of choice in adults with some types of supraventricular and ventricular tachycardias. The aim of this study was to evaluate the efficacy and safety of radiofrequency ablation therapy in children.

Methods: radiofrequency ablation therapy was used in 40 consecutive children with a mean age of 11.8 ± 3.4 years (range = 3–15). Twenty-seven patients had Wolf-Parkinson-White syndrome, 7 had atrioventricular node re-entry tachycardia, two had atrial tachycardia and four had idiopathic ventricular tachycardia. Follow-up clinical data, electrocardiograms and 24-h Holter monitors were obtained and analysed.

Results: all patients were alive, and none were lost to follow-up after a mean follow-up of 46 months (range 3 to 85). Success at last follow-up included accessory pathways in 25 (92.5%) of 27 patients, atrioventricular node re-entry in 6 (85.7%) of 7, atrial tachycardia in 1 (50%) of 2, ventricular tachycardia in 3 (75%) of 4. Seven recurrences were observed within one month of ablation (three with accessory pathway-mediated tachycardia, three with AV node re-entry and one with idiopathic ventricular tachycardia). Five patients were successfully ablated by second trial. First degree AV block followed the procedure in 2 patients.

In conclusion, radiofrequency ablation therapy is effective and safe in paediatric patients with supraventricular and ventricular tachycardia and should be considered as the therapy of choice in this group of patients.

877 Long-term results using epicardial stimulation with "autocapture" in children

B. Nowak, U. Bauersfeld[1], H. Schüller[2], O. Przibille, C. Kampmann, F. Wippermann, E. Himmrich, J. Meyer. *II. Medical Clinic and Pediatric Cardiology, University Mainz, Germany; [1]Pediatric Cardiology, Children's University Hospital, Zurich, Switzerland; [2]Cardiothoracic Surgery, University Lund, Sweden*

An automatic adaptation of the pulse amplitude to the measured threshold is provided by the "Autocapture" algorithm, thereby providing low-energy stimulation. A reliable performance of this function has been schown with endocardial leads. We studied for the first time the long-term effectivity and reliability of Autocapture in children, using epicardial leads.

Methods: In 14 children, age 38 ± 10 month (1 day to 10 years) weight 12.2 ± 2.5 kg (1980 g–29.3 kg) a VVIR-Pacemaker (PM) with Autocapture-function (9 Regency SR+, 5 Microny SR+, Pacesetter) was implanted together with a steroid-eluting bipolar epicardial electrode (10366, Medtronic). Threshold values and measured data were obtained pre-discharge and after 3, 6 and 12 months.

Results: The mean follow-up time is 9 ± 1.8 months. Holters have been performed in 11/14 pts., showing a correct PM function without loss of capture. Autocapture functioned as specified due to reliably epicardially measured evoked potentials with a low polarisation in 12/14 pts. (86%). Low evoked potentials precluded the activation of the algorithm in 2 pts.. For both devices life spans of 7.8 ± 1.4 (Microny) and 21.1 ± 1.6 y (Regency) have been calculated. Measured values:

	Discharge	3 months	6 months	
Evoked potential (mV)	11.0 ± 2.1	12.8 ± 2.4	9.6 ± 2.7	n.s.
Pulse amplitude (V)	1.1 ± 0.3	1.2 ± 0.2	0.9 ± 0.3	n.s.
Pulse width (ms)	0.31 ± 0.06	0.36 ± 0.03	0.36 ± 0.03	n.s.

Conclusion: In the majority of children epicardial stimulation with Autocapture is feasible. Autocapture saves energy, extending battery service life, and providing high stimulation safety.

BASIC AND CLINICAL ASPECTS OF INOTROPIC MODULATION

888 Mechanism underlying the stronger positive inotropic effects of LND-623 a new cardotonic drug: exclusion of cellular sites of contractile control and specific inhibition of Na,K-ATPase isoforms or digitalis receptors

J.M. Maixent. *Laboratoire de Recherche Cardiologique; Marseille; Procter & Gamble Pharmaceuticals, Neuilly sur Seine, France*

LND-623 is a new aminosteroid analog of ouabain with a greater separation between efficacy and toxicity than ouabain and digoxin. To precise its mechanism of action, we studied its biochemical and physiological effects on human red blood cell sodium transports, on different cellular structures regarded as sites of contractile control and we compared its relative efficacy to ouabain in rat heart preparations and in membrane bound fractions with purified Na,K-ATPase isoenzymes. The responsiveness to ouabain was evaluated in Langendorff-perfused hearts and on purified membrane-bound Na,K-ATPase.

Results: LND-623 was 6.8-fold more efficient than ouabain in inhibiting the human Na + pump (IC_{50} = 0.098 ± 0.001 μM vs IC_{50} = 0.67 ± 0.02 μM ($p < 0.0001$). LND-623 did not have effects on the following cellular functions: Na-Ca exchange, Na-K cotransport, Ca-ATPase, slow calcium channels, adenylate cyclase system, phosphodiesterase and calcium sensitivity of the contractile protein system. The dose response curve for the positive inotropic effect and the inhibitory efects on rat cardiac isoenzymes produced by LND-623 were clearly biphasic. The amplitude of the maximun inotropic effect, without any toxic effect, was up to 3-fold higher with LND-623 than with the same dose of ouabain ($p < 0.05$).

Conclusion: The strong positive inotropic effect of LND-623 in rat could be related to a specific inhibition of the two rat cardiac isoforms of the Na,K-ATPase and not to myocyte sites of contractile control.

889 Pyruvate acts positive inotropic and does not change economy of myocardial contraction in rabbit and human myocardium

B. Keweloh, M. Hünlich, U. Siegel, O. Zeitz, P.M.L. Janssen, G. Hasenfuss. *Kardiologie und Pulmonologie, Universitätsklinik Göttingen, Göttingen, Germany*

The glycolysis metabolite pyruvate has been shown to act as a positive inotropic agent in several animal models. Recent investigations from our group showed a marked increase in cardiac output when 3–6 mM pyruvate was given intracoronary to patients with severe cardiogenic shock. The long term use of many other positive inotropic agents, especially catecholamines, is limited because of an overproportional increase in myocardial energy demand. Therefore we investigated the effect of pyruvate on contractile force and on economy of isometrical contraction in isolated multicellular myocardial preparations from rabbit hearts and from explanted human failing hearts. The measurements were performed with a recently developed microelectrode technique for quantification of myocardial oxygen consumption in muscle preparations.

Developed force increased after addition of 20 mM sodium-pyruvate by 65% (from 7.10 ± 1.15 to 11.73 ± 3.17 mN/mm^2 in rabbit preparations, $n = 7$, $p < 0.05$) and by 116% (from 8.71 ± 0.35 to 18.9 ± 0.51 mN/mm^2, $n = 8$, $p < 0.01$) in preparations from human failing myocardium.

At the basic stimulation rate of 1 Hz, 37° and 2.5 mM calcium the oxygen consumption was 1.77 ± 0.52 ml O_2/min · 100 g. After addition of 20 mM pyruvate the oxygen consumption increased to 3.18 ± 0.76 ml O_2/min · 100 g ($p < 0.01$) in rabbit myocardium and increased from 2.87 ± 0.17 to 4.47 ± 0.19 ml O_2/min · 100 g ($p < 0.01$) in human failing myocardium. Economy of myocardial contraction was calculated as the ratio of active developed force-time-integral to oxygen consumption. We observed a slight but non significant ($p = 0.13$) improvement in economy of contraction in presence of 20 mM pyruvate compared to control values (124.3 ± 52.6 N s m/ml O_2 at control, 145.8 ± 46.9 N s m/ml O_2 at 20 mM pyruvate, rabbit myocardium, similar results in human myocardium). In contrast to the unchanged economy values basal metabolism (the absolute amount of oxygen consumption in absence of mechanical energy demand) increased to 347% of control in presence of 20 mM pyruvate (from 0.70 ± 0.27 to 2.41 ± 1.18 ml O_2/min · 100 g, $p < 0.01$) in rabbit myocardium, similar results were obtained in human myocardium.

We conclude that pyruvate causes an increase in the energy costs for basal metabolism but does not change economy of myocardial contraction while acting directly postive inotropic. As mechanism of action we hypothesize an increase in cytosolic phosphorylation potential by improved mitochondrial ATP produktion.

890 Gingerol, ouabain and isoproterenol normalize impaired post-rest-behaviour but not force-frequency relation in failing human myocardium

L.S. Maier, C. Schwan, W. Schillinger, B. Pieske. *Abt. Kardiologie und Pneumologie, Zentrum Innere Medizin, Göttingen, Germany*

Potentiation of twitch force after a rest interval is considered to be an index for Ca^{2+}-uptake capacity of the sarcoplasmic reticulum (SR). Post-rest potentiation of force is blunted and frequency-dependent increase in force is absent in failing human myocardium. These alterations were related to changes in intracellular Ca^{2+}-handling. We investigated whether inotropic agents with different subcellular mechanisms can normalize these pathological alterations.

Methods: Isolated muscle strips, isometric contractions (1 Hz; 37°C; post-rest behavior: rest intervals: 1–240 s; force-frequency relation: stimulation frequencies: 0.5–3 Hz). We tested the influence of the β-adrenoceptor agonist isoproterenol (10^{-8}–10^{-6} M; n = 35), the Na^+/K^+-ATPase inhibitor ouabain (3×10^{-8} M; n = 11) and [10] gingerol, which specifically stimulates SR Ca^{2+}-ATPase (10^{-5} M; n = 13;). In addition, the specific inhibitor of SR Ca^{2+}-ATPase thapsigargin was used (10^{-5} M; n = 14). Furthermore, Ca^{2+}-uptake in crude myocardial homogenates was measured for gingerol (n = 6).

Results: Isoproterenol, ouabain and gingerol significantly increase twitch force which can be prevented by blocking SR Ca^{2+}-ATPase with thapsigargin. In addition, all inotropic agents greatly improve post-rest behavior. In contrast, force-frequency relation was only slightly improved by low concentrations of isoproterenol or gingerol. In contrast, blocking SR Ca^{2+}-ATPase deteriorates both post-rest behavior and force-frequency relation. The specific stimulation of SR Ca^{2+}-ATPase with gingerol could also be shown by Ca^{2+}-uptake measurements in crude myocardial homogenates.

Conclusions: The blunted post-rest potentiation of twitch force and force-frequency relation in failing human myocardium result from altered intracellular Ca^{2+}-handling. Stimulation of SR Ca^{2+}-uptake normalizes post-rest behavior but not force-frequency relation in failing human myocardium.

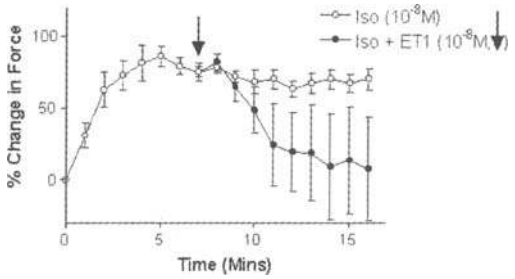
891 Endothelin-1 antagonises β-adrenergic stimulation in human right atrial myocardium

S.J. Leslie, C. Campanella[1], S. Prasad[1], D.J. Webb, M. Denvir[2]. *Medicine Dept, University of Edinburgh, Edinburgh; [1]Cardiac Surgery Dept, Royal Infirmary, Edinburgh[2]Cardiology Dept, University of Edinburgh, Edinburgh, UK*

Endothelin (ET1) and isoprenaline (ISO) are known to have positive inotropic effects on human myocardium. However, beta-adrenergic stimulation in human right atrium increases adenyl cyclase (AC) activity while ET1 has been shown to reduce AC activity in isolated tissue homogenates. This study examined the functional significance of this opposing effect.

Methods: Human right atrial tissue was obtained from right atrial appendage during routine coronary by-pass surgery in patients with no evidence of left ventricular dysfunction (n = 6). Small trabeculae were dissected (0.5–0.9 mm diameter, 3–4 mm length), mounted for isometric tension measurement and stimulated at 1 Hz at Lmax. Preparations were allowed to equilibrate for 1–2 hours and repeatedly stimulated with ISO until stable responses were obtained.

Results:



ISO (10^{-8} M) alone produced a maximum increase in isometric force of 63.4 ± 6.2% from baseline after 4–5 minutes while ET1 (10^{-8} M) alone produced an initial fall in force (2.6 ± 2.4%) after 1–2 minutes followed by a 14.2 ± 12.1% increase after 7–9 minutes. However, in the presence of ISO (10^{-8} M), addition of ET1 (10^{-8} M) to the bathing solution (arrow, see figure) resulted in a reduction in developed force of 16 ± 9.6% (n = 5, P = 0.07).

Conclusions: ET1 attenuates the positive inotropic effects of ISO in isolated human right atrial myocardium. The functional significance of this is unclear, however it may be of importance in conditions where both the ET and adrenergic systems are activated such as heart failure. Furthermore, the effects of ET antagonists, which are currently in clinical trials, on this mechanism are unknown and require further examination.

892 Influence of amlodipine and diltiazem on contractility and force-frequency behaviour in isolated human myocardium from ischaemic and dilated cardiomyopathy

B. Pieske, D. Frohnmüller, E. Bisping, L.S. Maier, G. Hasenfuss. *Abt. Kardiologie und Pneumologie, Zentrum Innere Medizin, Göttingen, Germany*

The long-acting Ca channel antagonist amlodipine (Amlo) does not adversely affect outcome of heart failure patients and may even be beneficial in dilated (DCM) but not ischemic (ICM) cardiomyopathy. We tested the direct effects of Amlo on contractile behavior of isolated muscle strips from 26 end-stage failing human hearts (14 DCM, 12 ICM). Diltiazem (Dil) was investigated for comparison.

Methods: Left ventricular muscle strips, isometric contractions, electrical stimulation (1 Hz, 37°C). Cumulative concentration-response curves for Amlo and Dil (0.01–100 μM). In a subset of muscles, the influence of the compounds on intracellular Ca transients (aequorin method) or sarcoplasmic reticulum (SR) Ca content (rapid cooling contractures) was characterized. Furthermore, systolic and diastolic force-frequency behavior (0.5–3.0 Hz) before and in the presence of the compounds was established.

Results: Amlo and Dil concentration-dependently depressed isometric twitch force in a similar fashion. With both compounds, the negative inotropic effect started at 0.1 μM and was maximal at 100 μM (decline by 89 ± 2 and 93 ± 3%, respectively, $p < 0.05$). The IC50 values were 4.63 μM (CI 1.96–7.30 μM) for Amlo, and 5.58 μM (CI 3.09–8.10 μM) for Dil (differences not significant). These negative inotropic effects were related to parallel declines in aequorin light emission and rapid cooling contractures. There was no difference between myocardium from ICM or DCM hearts. Preincubation with Amlo (0.44 and 8.8 μM, n = 14) or Dil (0.1 and 3 μM, n = 14) slightly improved the pathological inverse force-frequency relation. This was attributable to a clear improvement in diastolic function in the subset of muscle strips with increasing diastolic tension at higher stimulation rates (e.g., diastolic tension increased by 58 ± 9% before, and by 18 ± 12% after Amlo, $p < 0.05$, upon increasing stimulation rate from 0.5 to 3.0 Hz; n = 8).

Conclusion: Amlo and Dil exert similar direct negative inotropic effects in human ventricular myocardium with no differences between ischemic or dilated cardiomyopathy. The negative inotropic effects are associated with parallel declines in intracellular Ca transients and SR Ca content, and both compounds may improve diastolic dysfunction. Therefore, potential differences in the tolerability of Amlo and Dil in heart failure patients are not related to their direct effects on the myocardium, and Ca channel antagonists may prove especially beneficial in patients with predominant diastolic dysfunction.

893 β-Endorphin improves left ventricular systolic function in patients with mild chronic heart failure

D. Cozzolino, R. Iengo, S. Masi, F. Ciaramella, L. Damiano, G. Sodo, D. Torella, F.C. Sasso, T. Salvatore, R. Torella. *Department of Geriatrics, II University of Naples, Naples, Italy*

The evidence of opioid receptors on ventricular myocytes in experimental models and of high plasma levels of β-endorphin (BE), an endogenous opioid peptide, in patients with congestive heart failure (CHF) led to suppose that BE might play some role in regulation of the cardiovascular system in humans. This study was designed to investigate on the effects of BE on left ventricular systolic function in patients (P) affected by mild CHF.

Eight P (5 M/3 F; age: 47.4 ± 8.3 yrs, M ± SD; BMI: 25.9 ± 0.4 kg/m^2; HR: 84 b/min; SBP: 111 ± 9 mmHg; DBP: 79 ± 6 mmHg) affected by idiopathic dilated cardiomyopathy (IDC) and in II–III NYHA functional class, were enrolled in the study; all were treated with diuretics, digitalis and/or ACE-inhibitors until 72 h before the starting of the study. Seven sex-, age-, and BMI-matched healthy subjects served as controls (C). All subjects received an infusion of synthetic human BE at a constant rate of 500 μg/h for 1 h. In all subjects two dimensional and pulsed Doppler echocardiographic scans were performed at baseline and during BE infusion, and blood pressure (BP) and heart rate (HR) were measured even 5 min during BE infusion. ANOVA analysis for repeated measures was performed for statistics.

At baseline, plasma levels of BE in P were significantly higher than in C (5.6 ± 2.1 vs 2.9 ± 1.0 pmol/L, p = 0.008). When infused, BE plasma levels reached pharmacological concentrations (~400 pmol/L) in both groups. BE infusion induced a significant increase in stroke volume, cardiac output and left ventricular ejection fraction (basal vs steady-state: 64.7 ± 12.3 vs 74.4 ± 11.7 mL, p = 0.008; 5.4 ± 1.0 vs 6.0 ± 1.0 L/min, p = 0.030; 29.7 ± 2.7 vs 34.2 ± 3.1%, p = 0.008, respectively) and a significant decrease in systemic vascular resistance (1384 ± 371 vs 1227 ± 264 dyn•sec•cm^{-5}, p = 0.031) in P, no significant changes in C, and no significant variations of BP and HR in both groups.

In conclusion, these data suggest that high doses of BE for short periods might improve ventricular systolic function in P affected by IDC with mild CHF.

NEW INSIGHT IN HEART TRANSPLANTATION AND GRAFT DISEASE

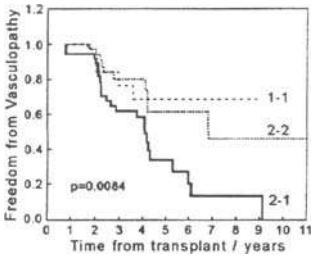
894 Clinical significance of haptoglobin polymorphism on the development of cardiac transplant vasculopathy

C.G. Densem, J. Wassel, A. Cooper, N. Yonan, N.H. Brooks, B. Keevil.
Cardiac Transplant Unit, Wythenshawe Hospital, Manchester, UK

Haptoglobin polymorphism (HP) confers phenotype-dependent modulation of free haemoglobin binding, oxidative stress, immune responses, prostaglandin synthesis and angiogenesis. Clinically HP has been associated with the prevalance and clinical evolution of atherosclerosis and autoimmune diseases. We investigated the effect of HP on the development of cardiac transplant vasculopathy (CTV).

Methods: Haemoglobin (10%) was added to plasma of 131 cardiac graft recipients. Agar electrophoresis with peroxidase dye identified HP. Haptoglobin was measured by immunonephelometry. Angiographic data were available for 93 patients (78.5% male, mean age at transplant 45.6 ± 1.3). Analysis was by a Kaplan-Meier actuarial curve and log rank.

Results: Phenotype 1-1 was found in 18.3%, 2-1 in 44.3%, and 2-2 in 37.4% with haptoglobin levels of 2.1 (± 0.58), 1.78 (0.88), 1.3 (± 0.81) g/l respectively. Patients with the 1-1 phenotype had the lowest incidence of CTV; individuals with a 2-1 phenotype had the highest rate of CTV (p = 0.0084). The results were independent of other clinical variables.



Conclusions: Haptoglobin polymorphism may be important in the pathogenesis of CTV. Differing functional properties of the 3 phenotypes may explain the increased prevalence of CTV in the 2-1 cohort. Manipulation of haptoglobin expression may be an important new area for therapeutic intervention of CTV.

895 Peripheral endothelial dysfunction after heart transplantation: possible role of proinflammatory cytokines

T. Holm, P. Aukrust[1], A.K. Andreassen, T. Ueland, S. Simonsen, L. Gullestad.
Cardiology Department, Rikshospitalet, Oslo; [1]Medical Department, Rikshospitalet, Oslo, Norway

Conflicting results have been obtained regarding nomalization of peripheral endothelial dysfunction after heart transplantation. We therefore examined microvascular endothelium-dependent vasodilatation together with acknowledged markers of endothelial dysfunction (von Willebrand factor (vWf), plasma NO_2^- + NO_3^- (NO) and big-endothelin), and further explored the possible role of proinflammatory cytokines in this process.

Methods: The vasodilatory responses to acetylcholine (Ach) (endothelium-dependent) and sodium nitroprusside (SNP) (endothelium independent), were evaluated by forearm skin laser Doppler perfusion measurements in 63 clinically stable HTx pts (56 ± 1 years, mean ± SEM), 6 (range 1–13 years) years after HTx, and compared with 20 age- and sex-matched healthy controls. The HTx pts received standard immunosuppression. Plasma vWf, NO, big-endothelin and cytokines were measured by enzyme immunoassay.

Results: Vascular responses to both Ach and SNP were significantly attenuated in the HTx patients compared to healthy controls ($p < 0.001$ and $p = 0.02$, respectively). Plasma VWf, NO and big-endothelin, were also significantly raised in HTx pts, further supporting endothelial dysfunction in these patients. HTx pts also had significantly raised plasma levels of the proinflammatory cytokines TNF-a, IL-6 and IL-1b, and as for TNF-a, the level was significantly correlated with raised b-ET levels ($r = 0.34$, $p = 0.007$) and impaired Ach response ($r = -0.36$, $p < 0.001$). In contrast, there were no correlation's between markers of endothelial dysfunction and neither, lipid-levels, hemodynamics, time since HTx, age, aetiology of heart failure, or serum levels of ciclosporine.

Conclusion: Endothelial dysfunction in long term follow-up of HTx pts was in periods with no rejection or intercurrent illness, demonstrated by both impaired endothelial-dependent vasodilatation as well as by raised levels of markers of endothelial activation. This endothelial dysfunction may be related to enhanced activation of proinflammatory cytokines in these patients.

896 Absence of L-arginine effect on the coronary hypersensitivity to serotonin in cardiac transplant recipients

G. Berkenboom, V. Crasset, P. Unger, M. Rahnama, J.L. Vachiery, J.L. LeClerc. *Cardiology Department, Erasme Hospital, Free University of Brussels, Brussels, Belgium*

Background. Coronary hypersensitivity to serotonin (5HT) promotes platelet aggregation and therefore, the progression of the atherosclerotic process. This abnormality occurs in the early stages of coronary atherosclerosis (CA) when the responses to bradykinin (Bk) are still preserved.

Methods. To determine whether such changes also occur early after cardiac transplantation (Tx), intracoronary injections of Bk and 5HT were performed in 7 control patients (CTRL), in 19 patients with dyslipidemia (CA) and 15 cardiac Tx recipients. Coronary angiography was normal in the 3 groups. In the segments where 5HT effects were the most pronounced, the diameter changes (expressed as % of baseline) were measured by quantitative angiography.

Results.

	Bk 60 ng	Bk 200 ng	Bk 600 ng	5HT 3 μg	ISDN 200 μg
CTRL (n = 7)	108 ± 2	117 ± 2	122 ± 2	107 ± 3	125 ± 5
CA (n = 19)	106 ± 2	113 ± 4	116 ± 2	81 ± 2*	127 ± 2
Tx (n = 15)	103 ± 1	113 ± 2	115 ± 2	85 ± 3*	121 ± 3

*P < 0.05 vs CTRL; ISDN = isosorbide dinitrate

After selective infusion of L-arginine (40 mg/min for 12 min) the 5HT-induced constriction was significantly attenuated in CA group (from 82 ± 3 to 95 ± 4%, n = 8) but not in Tx group (from 83 ± 3 to 77 ± 6, n = 9).

Conclusions: In the early stages of the graft vasculopathy, the response to Bk is preserved. However, in contrast to patients with CA, the absence of L-arginine effect on the responses to 5HT suggests that other mechanisms than reduced EDNO availability are involved in the abnormal response to this amine. Immune process promoting the release of EDCFs such as endothelin and/or, superoxide anion might play a role.

897 Evidence of myocardial blood supply: demand uncoupling in non-rejecting orthotopic heart transplant recipients

J. Schwitter, T. DeMarco[1], H. Arheden, G. Reddy, K. Chatterjee[1], W.W. Parmley[1], C.B. Higgins. *Department of Radiology, MRI-Section; [1]Department of Cardiology, University of California San Francisco, San Francisco CA, USA*

Experimental models demonstrated impaired metabolic efficiency of chronically denervated myocardium. Concentric left ventricular hypertrophy (LVH) develops early after orthotopic heart transplantation (OHT). Further, LVH reduces wall stress and is associated with impaired contractile function. Aim: To measure in OHT recipients myocardial blood supply together with indices of oxygen consumption, i.e. peak LV wall stress and indices of contractility in order to answer the question, whether the myocardial blood supply – demand relationship is altered in OHT recipients.

Methods: In 10 OHT recipients (11 ± 4 months after surgery) and 15 healthy volunteers (matched to donor's age and sex) coronary sinus flow (CSF) was measured by a cine phase contrast (PC) MR technique (TR/TE 20/7 ms, temporal and spatial resolution 40 ms and 1.25 × 0.8 mm^2, respectively) at rest and during hyperemia (dipyridamole 0.56 mg/kg). In order to obtain estimates of myocardial blood flow (MBF) in ml/min/g, CSF was divided by LV mass. Additionally indices of LV loading (end-systolic and peak-systolic wall stresses) and contractile function (afterload-corrected midwall circumferential fiber shortening: cFS_{norm}) were determined. Results: In OHT recipients the left ventricle was concentrically hypertrophied (LV mass: 203 ± 30 vs 149 ± 25 g in controls; $P < 0.0001$). Meridional peak-systolic LV wall stress (mS_{peak}) was reduced in OHT recipients (178 ± 32 vs 236 ± 31 kdyn/cm^2 of controls, $P < 0.0003$) as was cFSnorm (17.8 ± 4.0 vs 23.6 ± 3.0% in controls, $P = 0.0005$). CSF was increased in OHT recipients (174 ± 25 vs 71 ± 18 ml/min in controls; $P < 0.0001$) as was MBF (0.86 ± 0.11 vs 0.49 ± 0.13 ml/min/g, $P < 0.0001$); MBF corrected for rate-pressure product in OHT recipients was not different from controls ($P = 0.33$). However, correlations of cFS_{norm} and mS_{peak} versus MBF/beat in OHT recipients were shifted towards higher flows ($P < 0.0001$ vs controls). When MBF was corrected for these two parameters, again the regression line of the patients was shifted upwards ($P < 0.0001$). This shift reflected the degree of blood supply – demand imbalance and showed a direct correlation ($r = 0.74$, $P = 0.023$) with blood cyclosporine levels measured on the day of the MR study. Coronary flow reserve was reduced in OHT recipients (2.0 ± 0.5 vs 3.9 ± 1.3 in controls, $P < 0.001$).

Conclusions: In relation to major determinants of oxygen demand MBF is elevated in OHT recipients suggesting an uncoupling of blood supply and oxygen demand in transplanted human hearts. Cyclosporine seems to modify this supply – demand relationship.

898 Expression of molecular markers of apoptosis during acute rejection after heart transplantation

E.J. Birks, K.J.M. Morrison, N.R. Banner, M.H. Yacoub. *National Heart and Lung Institute at Imperial College of Science, Technology and Medicine, Royal Brompton and Harefield Hospital, Harefield, Middlesex, UK*

The role of apoptosis in acute rejection after heart transplantation has not been adequately defined. In an attempt to clarify this we have investigated the changes in several molecular markers of apoptosis and proteins involved in the regulation of the apoptotic pathway.

Methods: Ten patients were prospectively followed for 3 months after heart transplantation. Biopsies were performed at 1, 2, 3, 4, 5, 6, 8, 10 and 12 weeks and on clinical indication of rejection and a total of 108 biopsies were obtained. The International Society of Heart & Lung Transplantation (ISHLT) grades of rejection were no rejection in 60, Grade 1A in 26, Grade 1B in 6, Grade 3A in 12, Grade 3B in 2 and Grade 4 in 2. Fas, bax, bak, bclxs and CPP32 act as pro-apoptotic regulators whereas bcl-2 acts as an anti-apoptotic regulator. All biopsies were examined for expression of bax, bcl-2, bclxs, bak, Fas and CPP32 using immunocytochemistry. The C-terminal deoxynucleotydyl transferase-mediated dUTP-fluoroscein nick end labelling (TUNEL) technique was applied to biopsies from patients before and during episodes of moderate/severe acute rejection to detect evidence of apoptosis.

Results: The TUNEL technique detected occasional foci of apoptotic cells in biopsies before rejection and an increase in the number of apoptotic cells during rejection. Fas, bax, bclxs and bak were strongly expressed in cardiac myocytes both prior to and during episodes of rejection, but expression did not appear to change with rejection. CPP32 (pro-apoptotic) and bcl-2 (anti-apoptotic) were not expressed during no rejection, but were weakly expressed in cardiac myocytes during rejection episodes. Strong CPP32 and bcl-2 staining was seen in inflammatory cells during moderate/severe rejection.

Conclusions: Apoptosis appears to play a role in acute cardiac allograft rejection, but rejection is accompanied by variable expression of different apoptotic markers.

899 Clinical usefulness of pulsed-wave tissue Doppler imaging in the non-invasive follow-up of patients with transplant coronary artery disease

M. Dandel, J. Müller, M. Hummel, E. Wellnhofer, R. Ewert, R. Hetzer. *Deutsches Herzzentrum Berlin, Germany*

Graft coronary artery disease (TxCAD) is the major factor that limits the long-term results of cardiac transplantation. Routine annual coronary angiography, in combination with intracoronary ultrasound (ICUS), is generally accepted as the only means for the detection of early disease. Nevertheless, noninvasive detection of signs for TxCAD development or aggravation continues to be a challenge. We designed the present study to investigate the usefulness of the pulsed-wave tissue Doppler imaging (PWTD) velocity and time parameters in the detection of functional abnormalities due to TxCAD.

Methods: Twohundred heart transplant recipients underwent PWTD before and/or after a combined examination of coronary angiography and ICUS. In all patients endomyocardial biopsies were also performed. The registration of a phonocardiogram simultaneously with the PWTD from the posterior wall allowed us to measure not only the peak early systolic and diastolic velocities, but also the systolic and diastolic time intervals.

Results: As expected, the incidence of diastolic dysfunction was significantly higher ($p < 0.01$) in patients with TxCAD, but more striking were the differences with regard to the PWTD parameters during systole. The mean peak early systolic velocity in the 51 patients without TxCAD (12.7 ± 1.9 cm/s) was significantly higher ($p < 0.001$ and $p < 0.01$, respectively) than in the 67 patients with severe disease (9.6 ± 2.2 cm/s), as well as in the 82 patients with only moderate TxCAD (10.7 ± 1.9 cm/s). Significant differences ($p < 0.001$ and $p < 0.01$, respectively) were also found for the time from the onset of the first heart sound to the peak of the systolic wave. With a cut off value of less than 9.6 cm/s, the specificity and the positive predictive value of peak myocardial contraction velocities for TxCAD were 97.8% and 98.3%, respectively. The same specificity and positive predictive value for TxCAD was found also with a cut off value of less than 70 cm/s^2 for the systolic wall acceleration.

In conclusion, the PWTD provides important information, which improves the diagnostic value of the noninvasive follow-up, for the detection and monitoring of functional changes produced by TxCAD.

LESSONS FROM GENE MUTATIONS IN ATHEROSCLEROSIS: FOCUS ON ANGIOTENSIN-CONVERTING ENZYME AND NITRIC OXIDE SYNTHASE GENE

904 Large-scale test of hypothesized associations between the ACE I/D polymorphism and MI in over 10,000 cases and controls

B. Keavney, C. McKenzie[1], S. Parish[2], A. Palmer[2], S. Clark[2], L. Youngman[2], M. Lathrop[1], R. Peto[2], R. Collins[2]. *Cardiovascular Medicine Dept, Oxford University, Oxford; [1]Wellcome Trust Genetics Centre, Oxford University, Oxford; [2]Clinical Trial Service Unit, Oxford University, Oxford, UK*

Background: The original report of a possible association between MI and the I/D polymorphism of the ACE gene indicated an odds ratio with the DD genotype of 1.34 (95% CI 1.05–1.70), and the association appeared to be particularly strong in a retrospectively defined "low risk" subgroup. Subsequent investigations reached varying conclusions, but all were small, and a much larger study is needed to test these hypothesised associations.

Methods: Comparison of ACE I/D genotypes in 4629 cases who had presented to hospital with confirmed MI, and were enrolled in the ISIS-3 study of thrombolytic therapy in MI, with 5934 controls, first-degree relatives of MI survivors or spouses of such relatives, who had no history of cardiovascular disease.

Fiindings: The DD genotype was found in 1359 (29.4%) of the MI cases and in 1637 (27.6%) of the controls (odds ratio 1.09; 95% CI 1.00–1.19). No clear association between MI and the DD genotype was observed in the subgroup defined as low risk by previous criteria (232 [28%] of 832 cases and 914 [28%] of 3256 controls: odds ratio 0.99; 95% CI 0.84–1.17), or in any other subgroup. Nor was ACE I/D genotype associated with subsequent survival.

Interpretation: The present study involved about ten times as many MI cases as the previous largest study of this polymorphism, but did not confirm the existence of any substantial risk of MI with the DD genotype. So, although an increase in risk of up to about 20% cannot be ruled out, more extreme risks can be – and in particular, there is not an especially strong association in subgroups previously selected for emphasis. These findings demonstrate the need for such studies of candidate genes to be conducted in much larger populations than is currently customary.

905 No association of the I/D polymorphism of the angiotensin-converting enzyme with myocardial infarction in 4941 probands

S.R. Holmer, C. Hengstenberg, B. Mayer, G.A.J. Riegger, H. Löwel[1], S. Engel[1], H. Schunkert. *Internal Medicine II, University of Regensburg, Regensburg; [1]GSF – Institute of Epidemiology, Munich, Germany*

The DD genotype of the angiotensin converting enzyme (ACE) gene polymorphism has been found to be associated with cardiovascular diseases including myocardial infarction (MI). However, sample sizes of many studies showing positive association were small and data were inconsistent.

Methods: Genotype distribution was analysed in 1328 patients who had had an MI below 60 years of age and in 2398 individuals from a survey of the general population in Augsburg. In addition, to condensate genetic factors, 707 siblings of MI patients affected with MI and 883 siblings with no known coronary artery disease were genotyped.

Results: Compared with the general population MI patients did not show a higher frequency of the D allele of the DD genotype:

	II (%)	ID (%)	DD (%)	Freqency of D-allele
MI	21.9	51.0	27.1	52.6
General population 20.3	48.6	31.1	55.4	

Genotype distributions were similar in affected and unaffected siblings. This result was unchanged when men and women were analysed separately. In addition, a low risk group (male, body mass index < 26, total cholesterol/HDL-ratio < 5) selected from MI patients displayed a similar frequency of the D allele (52.4%;n = 85) as a control group selected from the general population (55.4%;n = 167).

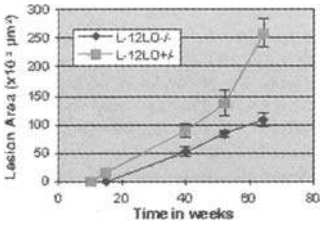
This study included thus far the largest number of MI patients and a population based sample for comparison, but no association of the D allele of the ACE I/D polymorphism with myocardial infarction could be observed.

906 12/15-Lipoxygenase deficiency results in delayed atherosclerotic lesion initiation and progression in vivo

T. Cyrus, J.L. Witztum[1], D.J. Rader[2], C.D. Funk. *Pharmacology Dept, University of Pennsylvania, Philadelphia; [1]Medicine Dept, University of California, San Diego CA[2]Cardiology Dept, University of Pennsylvania, Philadelphia, USA*

Background: 12/15-Lipoxygenase (12/15-LO)has been implicated in oxidative modification of LDL and in atherogenesis. The relative contribution of macrophage-expressed 12/15-LO to atherogenesis in vivo remains controversial.

Methods and Results: 12/15-LO deficient (L-12LO−/−) mice, generated by targeted gene disruption, were cross-bred with atherosclerosis-prone apoE knockout (apoE−/−) mice. Mice were fed a normal mouse chow diet and atherosclerotic lesion development was studied at 10, 15, 40 weeks, and 12 and 15 months of age. Lesion areas in the whole aortas (en face preparations)developed earlier in apoE−/−/L-12LO± mice than apoE−/−/L-12LO−/− double-knockout mice (at 10 weeks: 677 ± 365 vs. 52 ± 52 square-micrometer, mean ± SEM, n = 10, P = 0.03 (Mann-Whitney test)) respectively, and lesion progression was enhanced in the heterozygous mice as compared to the double-knockout mice (258696 ± 24374 vs. 108075 ± 11964 square-micrometer, n = 9, P = 0.002) at 15 months of age. The total plasma cholesterol levels and lipoprotein profiles were not significantly different between genotypes at any given time point.



12-LO-pict.

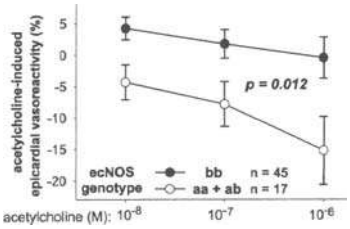
Conclusions: Lipoprotein oxidation via enzymatic action of 12/15-LO is a major component of atherogenesis in apoE−/− mice, and this animal model provides in vivo evidence for the importance of 12/15-LO in the initiation and propagation of atherosclerotic lesions.

907 ecNOS-polymorphism is associated with coronary endothelial dysfunction

M.B. Britten, V. Schächinger, S. Dimmeler, A.M. Zeiher. *Clinic of Internal Medicine IV, Dept. of Cardiology, J.W. Goethe University of Frankfurt/Main, Germany*

Nitric oxide (NO) plays a central role in endothelium-dependent dilation of coronary arteries. The a allele of the 4a/b polymorphism of the endothelial NO-synthase (ecNOS) was shown to be associated with an increased risk for atherosclerosis. Therefore in 63 patients with an angiographically normal or only minimally diseased (<30% focal stenosis) left coronary artery or left circumflex, we examined the impact of the ecNOS-polymorphism on coronary endothelial vasodilator function. Endothelium dependent vasoreactivity was assessed by i.c. infusion of acetylcholine (Ach 10^{-8}–10^{-6} M), endothelium independent vasoreactivity was analyzed by i.c. infusion of nitroglycerine (NTG 200–300 µg).

Results: Coronary arteries of patients with the aa/ab genotype of the ecNOS poly-morphism had an enhanced epicardial vasoconstriction to Ach compared to patients with the bb genotype. NTG-induced vasodilation was also reduced in patients with the aa/ab genotype (26 ± 3.8% [mean ± SEM], n = 17 versus bb genotype 37 ± 3.5%; n = 45; p = 0.05).



Conclusion: These results point towards a functional relevance of the ecNOS-polymorphism, a gene encoding for an enzyme producing nitric oxide, on coronary vasotonus regulation.

908 High CA repeat numbers in intron 13 of the endothelial nitric oxide synthase gene and increased risk of coronary artery disease

K. Stangl, I. Cascorbi[1], M. Laule, V. Stangl, I. Roots[1], G. Baumann. *Med. Klinik, Kardiologie, Campus Mitte, Charité, Humboldt Universität, Berlin, Berlin[1]Klinische Pharmakologie, Charite, Humboldt Universität, Berlin, Germany*

Background: Endothelial nitric oxide synthase (eNOS) plays a key role in vascular homeostasis. As its product, nitric oxide, possesses vasodilatory and antiatherogenic properties, an altered eNOS function could promote atherosclerosis. We investigated the association between variations in CA repeat copy number ((CA)n polymorphism) in intron 13 of the eNOS gene and the risk of coronary artery disease.

Methods: (CA)n polymorphism was investigated in 1000 consecutive patients with angiographically confirmed coronary artery disease and 1000 age- and gender-matched controls by a PCR based fragment length calculation.

Findings: 28 different alleles were identified containing 17 to 44 CA repeats. Presence of one allele containing more than 38 repeats was associated with an excess risk of coronary artery disease (odds ratio: 1.94; 95% confidence interval: 1.31–2.86; p = 0.001). Carriers of alleles containing more than 38 CA repeats were, in particular, overrepresented in the subgroup without common cardiovascular risk factors, odds ratio 3.39 (95% confidence interval: 1.30–8.86, p = 0.009). Logistic regression analysis disclosed, that the (CA)n polymorphism proved to be an independent risk factor (relative risk: 2.17; 95% confidence interval: 1.44–3.27, p = 0.0002).

Interpretation: Our findings indicate that high numbers of CA repeats in intron 13 of the eNOS gene are associated with an excess risk of coronary artery disease.

ENDOTHELIUM DYSFUNCTION IN DIABETES

910 Non-insulin-dependent diabetes mellitus subjects exhibit an increase in lipid peroxidation and augmented endothelial dysfunction in response to post-prandial lipaemia

R.A. Anderson, L.M. Evans, G.R. Ellis, S.K. Jackson, M.J. Lewis, A. Rees, M.P. Frenneaux. *Wales Heart Research Institute, University of Wales College of Medicine, Cardiff, UK*

Secondary markers of lipid peroxidation are elevated in diseases with increased oxidative stress. Elevated levels of malondialdehyde (MDA)-LDL complexes are thought to suggest plaque instability in coronary artery disease patients and 4-hydroxynonenal (4-HNE) has been implicated in vascular smooth muscle mitogenesis and atherosclerosis. We therefore studied the effect of post-prandial lipaemia (PPL) on lipid peroxidation and endothelial function (EF) in NIDDM.

Methods. 15 NIDDM patients (8 M, 7 F, mean age 47.7 yrs) with moderate glycaemic control (Av. HbA1c 8.2%) were studied following a 12 hour overnight fast and 4 hours after a standard fatty meal and were compared with 15 healthy controls (7 M, 8 F, mean age 42.3 yrs) with normal EF. EF was assessed by measuring flow-mediated vasodilatation (FMD) in the brachial artery and expressed as % change in brachial artery diameter. A commercially available (R&D Systems) colorimetric assay for products of lipid peroxidation was used, to measure MDA and 4-HNE from plasma frozen at −70°C.

Results. [Mean + S.D.] There were significantly greater amounts of MDA and 4-HNE in NIDDM subjects compared to healthy controls (8.75 ± 4.7 vs. 5.55 ± 2.7 p < 0.05) in association with endothelial dysfunction (ED) (3.4 ± 1.7% vs 6.25 ± 1.3%, p < 0.05) at baseline. PPL results in augmented ED (3.4 ± 1.7% to 1.6 ± 1.1%) and significantly higher TG levels (3.1 ± 2.1 to 7.9 ± 7.9 mmol/L) and MDA/4-HNE (8.75 ± 4.7 to 10.38 ± 4.7 µmol/l) at 4 hours (both p < 0.05).

Conclusions. NIDDM subjects have enhanced lipid peroxidation in association with ED compared to healthy controls. Furthermore PPL augments ED associated with an increase in MDA and 4-HNE. This data offers a possible mechanistic explanation for the markedly raised macrovascular disease risk in NIDDM and the deleterious effects of PPL.

911 Increased soluble E-selectin expression in diabetics with acute coronary syndromes

N. Mulvihill, G. Pate, J.B. Foley, R. Murphy, P. Crean, M. Walsh. *Department of Cardiology, St. James Hospital, Dublin, Ireland*

Diabetes Mellitus (DM) is associated with chronic endothelial dysfunction. Diabetic patients presenting with acute coronary syndromes have a worse prognosis than non-diabetics. An acute inflammatory reaction at the site of coronary plaque rupture with increased expression of surface and soluble cellular adhesion molecules (CAMs) is a pathological feature of acute coronary syndromes. We set out to characterise the expression of soluble CAMs in diabetics and non-diabetics presenting with unstable angina (UA) and subendocardial infarction (SEMI).

Methods: Patients presenting with UA and SEMI had serum samples taken at presentation, 72 hours and 3 months after discharge. Levels of soluble ICAM-1, VCAM-1 and E-selectin were measured using an ELISA technique.

Results: 87 patients entered the study, 15 diabetic (M/F = 13/2, mean age 65 ± 14 yrs) and 72 non-diabetics (M/F = 57/15, mean age 61 ± 11 yrs). Levels of soluble E-selectin were elevated in diabetics in comparison to non diabetics at all measured time points (74 ± 10 ng/ml vs 53 ± 2 ng/ml, $p < 0.035$ at T = 0 hrs, 53 ± 5 ng/ml vs 45 ± 2 ng/ml, $p < 0.1$ at T = 72 hrs and 68 ± 12 ng/ml vs 55 ± 2 ng/ml, $p < 0.14$ at T = 3/12 respectively). There was no significant difference in levels of soluble ICAM-1 and VCAM-1 between diabetics and non-diabetics at any measured time point.

Conclusion: Levels of soluble E-selectin are significantly elevated in diabetic patients presenting with UA and SEMI in comparison to non-diabetics. This enhanced endothelial activation may contribute to the adverse prognosis of diabetics with acute coronary syndromes.

912 Ciprofibrate blunts post-prandial lipaemia and attenuates the associated endothelial dysfunction and oxidative stress in non-insulin-dependent diabetes mellitus

R.A. Anderson, L.M. Evans, G.R. Ellis, S.K. Jackson, M.J. Lewis, A. Rees, M.P. Frenneaux. *Wales Heart Research Institute, University of Wales College of Medicine, Cardiff, UK*

Elevated fasting and post-prandial (PP) triglyceride (TG)-rich lipoproteins predict the severity and progression of coronary artery disease. Post-prandial lipaemia (PPL) causes endothelial dysfunction (ED) in healthy individuals and attenuated by vitamin C. We recently reported exaggerated PP oxidative stress and ED in NIDDM in association with increased PP hypertriglycerideamia. Fibrate therapy lowers fasting TG, VLDL and increases HDL-C. We therefore studied the effects of 3 months of ciprofibrate on the above parameters.

Methods 20 NIDDM subjects with moderate control (Av.HbA1c 8.4), were studied, assessing endothelial function (EF) and oxidative stress in response to a fatty meal, and were randomised in a double-blind placebo controlled manner to Ciprofibrate therapy 100 mg od. for 3 months. Subject responses to a fatty meal were then reassessed with measurements of EF and FR's. EF was assessed non-invasively by flow-mediated vasodilatation (FMD) of the brachial artery; Venous FR's were measured by electron spin resonance spectroscopy. 3 patients withdrew, 9 were enrolled into the ciprofibrate arm and 8 into the placebo arm.

Results (mean ± SD) Ciprofibrate reduced both fasting and post-prandial TG (3.0 ± 2.1 to 1.5 ± 0.8 mmol/l) and (7.1 ± 6.5 to 2.9 ± 1.13 mmol/l) respectively both $p < 0.05$. It improved both fasting and post-prandial FMD (4 ± 2.1 to 4.9 ± 1.2%) and (1.77 ± 1.4 to 3.4 ± 1.2%) respectively both $p < 0.05$. These effects of ciprofibrate were associated with an attenuation of the PP rise in free radicals (1.5 ± 1.1 pre to 0.3 ± 0.6 arbitrary units after therapy) $p < 0.05$.

Conclusions Ciprofibrate therapy lowers pre and post-prandial TG levels in NIDDM and blunts the rise in FR and worsening ED associated with a fatty meal. This confirms work implicating TG-rich lipoproteins in this process.

913 Atorvastatin attenuates glucose-induced increases in superoxide anion formation in coronary endothelium

M. Christ, J. Bauersachs[1], C. Liebetrau[1], M. Heck, A. Günther, M. Wehling. *Inst. of Clin. Pharmacol., [1]II. Med. Clinic, Klinikum Mannheim; University of Heidelberg, Germany*

Increased vascular superoxide anion ($O_{2\cdot-}$) formation contributes to the pathogenesis of atherosclerosis. Chronic hyperglycemia induces endothelial dysfunction, probably due to increased formation of reactive oxygen intermediates. The aim of the present study was to characterize the localization, modulators and molecular mechanisms of vascular O_2^--formation during hyperglycemia in native coronary arteries.

Methods and Results: In porcine coronary segments, high-glucose (25 mM, 48 h) significantly increased O_2^--formation (measured by lucigenin -enhanced-chemiluminescence) vs. controls and isoosmotic sucrose. This effect was completely blocked after removal of the endothelium. Endothelial-dependence of glucose-induced increase in O_2^--formation was also demonstrated by staining with nitro-blue-tetrazolium. Coincubation with atorvastatin (1, 10 μmol/L), a lipophilic inhibitor of 3-hydroxy-3-methylglutaryl-coenzyme A reductase, attenuated both basal and glucose-induced O_2^--formation. This effect was reversed by mevalonic acid. Furthermore, high-glucose significantly increased expression of the oxidase subunits $p22^{phox}$ and $gp91^{phox}$ measured by RT-PCR. Atorvastatin prevented the glucose-induced increase in $gp91^{phox}$ expression and reduced $p22^{phox}$ expression even below control levels.

In conclusion, these data demonstrate for the first time that glucose-induced increase of vascular O_2^--formation is endothelium-dependent and may be mediated by increased oxidase subunit expression. Beneficial effects of statins in diabetic patients may be explained in part by attenuation of vascular O_2^--formation independent of lipid lowering.

914 Does type of diabetes and metabolic control have influence on antioxidative status in diabetics?

M. Zamaklar, D. Trifunovic-Zamaklar[1], T. Milicic, S. Markovic, N. Rajkovic, P. Djordjevic. *Department of Diabetology, Institute for Endocrinology, Belgrade; [1]Cardiology II, Institute for cardiovascular diseases, Belgrade, Yugoslavia*

High endogenous lipid peroxidation and altered antioxidative status are considered to be important for accelerated atherosclerosisis in diabetes mellitus (DM). It is not quite clear whether antioxidative status in diabetics is influenced by the type of DM and quality of metabolic control. This study was aimed to compare antioxidative profile in patients with DM type 1 (DM1) and DM type 2 (DM2), regarding metabolic control.

Methods: in 21 patiens with DM1 and 29 with DM2 antioxidative profile was estimated by: Erythrocyte Superoxid Desmuthase (E-SOD) and Erythrocyte Glutation Peroxidase (E-GPx) activity and Plasma Total Antioxidative Status (P-TAS). All parameters were determined by spectrophothometric methods. Marker of metabolic control, HbA1, was determined colorimetricaly. Groups were similar in duration of DM (about 10 years), patients ages (35–50 years) and sex ratio (female: male -= 1:1). All patients were non-smokers.

Results: are shown in table.

		DM type 1			DM type 2		
		HbA1 < 8% (n = 9)	vs.	HbA1 > 8% (n = 12)	HbA1 < 8% (n = 18)	vs.	HbA1 > 8% (n = 21)
E-SOD	(U/gHb)	999.0 ± 78.9	vs.	767.2 ± 164.4**	902.3 ± 132.0	vs.	812.3 ± 131.7*
E-Gpx	(U/gHb)	27.67 ± 5.18	vs.	29.7 ± 10.58	24.66 ± 4.03	vs.	25.95 ± 6.63
p-TAS	(nmol/l)	1.39 ± 0.03	vs.	1.25 ± 0.19*	1.51 ± 0.28	vs.	1.21 ± 0.10**

* $p < 0.05$; ** $p < 0.01$.

Comparing antioxidative profile between well controled DM1 and well controled DM2, significant difference was founded only in E-SOD activity ($p < 0.05$). In poor controlled diabetics there were no significant differences in antioxidative profile between DM1 and DM2. Correlation (linear regression model) between HbA1 and markers of antioxidative activity was significant among: HbA1 and E-SOD in DM1 ($r = 0.56$; $p < 0.01$), HbA1 and P-TAS in DM2 ($r = -0.54$; $p < 0.01$) and HbA1 and E-SOD in poor controlled DM2 ($r = 0.54$; $p < 0.05$).

Conclusion: Our results suggest that metabolic control influence atioxidative profile in both types of DM, specially E-SOD and P-TAS activity. However, it seems that type of DM has little influence on antioxidative activity, except on E-SOD, but only when DM is well controlled.

915 Does a glass of red wine improve the endothelial function?

S. Agewall, S. Wright[1], R. Doughty[1], G. Whalley[1], N. Sharpe[1]. *Dept of Medicine, Sahlgrenska, Gothenburg, Sweden; [1]Dept of Medicine, Auckland, New Zealand*

The objective of this study was to examine the acute effect of red wine and de-alcoholised red wine on endothelial function. High frequency ultrasound was used to measure blood flow and percentage brachial artery dilatation after reactive hyperemia induced by forearm cuff occlusion in twelve healthy subjects, less than 40 years, without known cardiovascular risk factors. The subjects drank either 250 ml de-alcoholised red wine or 250 ml of red wine during 10 minutes according to a randomization procedure. Another two examinations of the brachial artery dilatation were done 30 and 60 minutes after the subjects finished the drinking. The second study of the subjects were performed within a week in a cross-over design.

After red wine the resting brachial artery diameter, resting blood flow, heart rate and plasma-ethanol increased significantly. After de-alcoholised red wine these parameters were unchanged. Flow-mediated dilatation of the brachial artery was significantly higher ($p < 0.05$) after drinking de-alcoholised red wine (5.6 ± 3.2%) than after drinking red wine (3.6 ± 2.2%) and before drinking (3.9 ± 2.5%).

Thus, after ingestion of red wine the brachial artery dilated and the blood flow increased. These changes were not observed following the de-alcoholised red wine and were thus attributable to ethanol. These hemodynamic changes may have concealed an effect on flow-mediated brachial artery dilatation which did not increase after drinking red wine. Flow-mediated dilatation of the brachial artery increased significantly after de-alcoholised red wine and this finding may support the hypothesis that antioxidant qualities of red wine, rather than ethanol in itself, may protect against cardiovascular disease.

IMPROVED NON-INVASIVE QUANTITATION OF VALVULAR LESIONS

920 Aortic valve stenosis assessment by Doppler echocardiography: simplified or more complex calculations?

F. Calvo, V. del Campo, R. Mantilla, V. Platero, J.L. Escribano, R. Ruiz, E. Ponce, R. Castellanos, J. Pasalodos. *Hospital do Meixoeiro, Vigo, Spain*

New simplified and less time-consuming Doppler-echocardiography (DE) methods have been proposed during recent years to evaluate the severity of aortic valve stenosis. The aim of the study was to investigate the value of new simplified and classic DE methods.

Methods: We studied 70 consecutive patients with aortic valve stenosis in sinus rythm (69 ± 10 years, 32 females). DE studies were performed 1 hour prior to cardiac catheterization. The selected gold standard was the Gorlin formula and severe aortic valve stenosis was defined if aortic valve area (AVA) was <0.75 cm^2. The selected DE methods included more complex calculations as AVA either by planimetry in short-axis parasternal view (2D) or continuity equation (CE) and aortic valve resistance (AVR). More simplified calculations were: Percent stroke work loss (PSWL), fractional shortening-velocity-ratio (FSVR), the velocities ratio between outflow tract and vena contracta (V1/V2) and the acceleration time and ejection time ratio in the vena contracta flow (AT-ET).

Results: Mean AVA (Gorlin) was 0.8 ± 0.4 cm^2. The cut-off values, the number of valuable studies (N), agreement (kappa) with Gorlin formula and sensitivity and specificity for each method were as follows:

	N	Kappa	Gorlin < 0.75 cm^2	
			Sensitivity	Specificity
AT-ET, >0.34	70	0.23	81%	66%
V1/V2, <0.2	70	0.50	78%	80%
FSvR, <0.4	64	0.45	77%	79%
2D, <0.75 cm^2	53	0.41	87%	70%
CE, <0.75 cm^2	70	0.53	95%	75%
AvR, >300	70	0.65	85%	85%
PSWL, >25%	70	0.51	88%	77%

In conclusion, continuity equation and aortic valve resistance were the best methods in our study. Among simplified calculations, PSWL and V1/V2 exhibited best sensitivity and specificity.

921 Reproducibility of Doppler echocardiographic measures of aortic stenosis

F. Antonini-Canterin, D. Pavan, F. Macor, E. Cervesato, R. Mimo, V. Dall'Aglio, F. Zardo, E. Hrovatin, G.L. Nicolosi. *Cardiology Dept. ARC, Pordenone, Italy*

Background. Several "new" Doppler echocardiographic measures of aortic stenosis severity have been recently introduced and validated in addition to the traditional *"flow-corrected"* indexes, that are continuity equation (CE) and aortic valve resistance (AVR). These "new" indexes are 1) *"pressure-corrected"*: stroke work loss (SWL = mean gradient/mean gradient + cuff systolic blood pressure); 2) *"function-corrected"*: fractional shortening-velocity ratio (FSVR = left ventricular fractional shortening/4 $Vmax^2$) and ejection-fraction velocity ratio (EFVR = ejection fraction/4 $Vmax^2$). The additional usefulness of these indexes is still under discussion; there is however little information about the reproducibility of each of these measures.

Methods. One hundred consecutive patients with aortic stenosis (53 males, 47 females, aged 72 ± 11 years, mean valve area 0.8 ± 0.4 cm^2) were studied by Doppler echocardiography within 1 hour by two experienced investigators in a blinded, independent fashion. The observer variability for each index was calculated using coefficients of variation. Furthermore the two investigators classified all patients into two groups (respectively with severe and nonsevere aortic stenosis, using the same previously validated cut-off values for each index) and the respective levels of agreement were assessed.

Results. The coefficients of variation were significantly higher for "flow-corrected" indexes (CE = 28%, AVR = 33%) rather than for "pressure-" and "function"-corrected ones (SWL = 11%, FSVR = 20%, EFVR = 14%); this could be explained by the coefficients of variation observed for the respective correcting factors (cardiac output = 29%, cuff systolic blood pressure = 5%, ejection fraction = 7%). The best agreement between the investigators in the classification of severity was obtained using EFVR (93%); lower agreement levels were oberved considering FSVR (89%), SWL (86%), AVR (80%), CE (72%). The dimentionless CE (obtained considering a costant value of left ventricular outflow tract diameter = 2.0 cm) allowed to improve the inter-observer agreement in the classification of severity from 72% to 86%.

Conclusion. "Pressure-corrected" and "function-corrected" indexes not requiring left ventricular outflow tract measurements (such as SWL, EFVR, FSVR) are more reproducible than flow-corrected indexes (CE and AVR). The knowledge of these findings could be relevant in order to assess which index could be best applied in clinical practice.

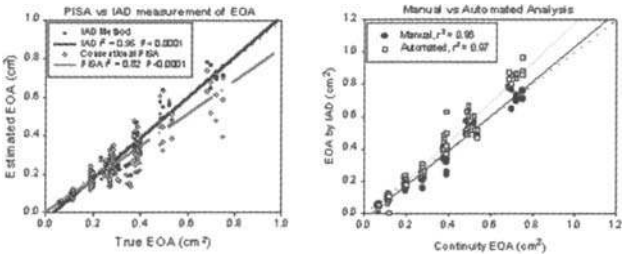
922 A novel echocardiographic method for quantification of orifice area using colour Doppler of the proximal convergence zone: in vitro validation and automated analysis

D.L. Prior, M.S. Firstenberg, N.L. Greenberg, J.D. Thomas, M.J. Garcia. *Cardiology Desk F15, Cleveland Clinic Foundation, Cleveland OH, USA*

Non-invasive measurement of regurgitant orifice area can be performed using proximal convergence analysis (PISA), but requires localization of the true orifice to measure the radius of the first aliasing contour. Errors in estimating the orifice location lead to errors in orifice area measurement. To avoid this, we examined a method using the interaliasing distance (IAD), the distance between the first and second aliasing contours, to calculate orifice area.

Methods: Using a model of continuous flow through circular orifices (0.05–0.8 cm^2), color M-mode recordings of the proximal convergence zone were made for measurement of the first aliasing contour radius and the IAD. Flow was calculated from these measurements. Using flow velocity by CW Doppler, effective orifice area (EOA) was determined by PISA and IAD methods. EOA measurements made by both methods were compared with those by continuity. An automated method of IAD analysis was compared with the manual method. The effects of varying aliasing velocity and orifice size were examined.

Results: EOA estimated by the IAD method correlated more closely with that obtained by continuity (r^2 0.95, $p < 0.0001$) than did PISA (r^2 0.82, $p < 0.0001$). Aliasing velocity affected EOA measurement by PISA ($p < 0.0001$), but not by IAD ($p = 0.39$). EOA derived by automated analysis of color M-modes to yield IAD values correlated well with true EOA (r^2 0.97), but tended to overestimate EOA with larger orifices.



EOA by IAD, PISA and automated IAD.

Conclusions: In vitro, the IAD method measures orifice area accurately and with less variability than PISA due to independence from the aliasing velocity and to elimination of errors associated with orifice localization. Automated analysis using the IAD method is feasible and this promising method deserves further investigation.

923 A new method for calculation of mitral valve area based on colour flow Doppler imaging of the vena contracta

A. Abaci, A. Oguzhan, S. Unal, B. Kiranatli, N.K. Eryol, A. Ergin. *Department of Cardiology, Erciyes University School of Medicine, Kayseri, Turkey*

The vena contracta is the narrowest portion of the regurgitant or stenotic jet that occurs just downstream from the orifice and reflects the size of that orifice. Vena contracta width (VCW) as determined by doppler color flow mapping has emerged recently as a simple echocardiographic marker of the severity of mitral regurgitation. We hypothesized that this method also can be used to calculate stenotic orifices. Therefore, this study was performed to assess the accuracy of VCW in evaluating the severity of mitral stenosis (MS) and (2) compare mitral valve area determined by VCW with other more traditional echocardiographic methods.

Methods: We studied 38 patients (29 females, 41 ± 15 years) with MS. VCW was measured from the apical four chamber view by Doppler color flow mapping. The narrowest sector angle that allowed visualization of the MS vena contracta was used to maximize color flow imaging frame rate. In all pts, VCW was seen clearly, and its largest diameter during diastole was measured for at least three cardiac cycles and averaged. Mitral valve area was calculated from the following equation: constant pi × r^2, where r = VCW/2. Mitral valve area was also determined by planimetry, the pressure half time method, and by the Gorlin formula. The results for all methods were compared.

Results: Mitral valve area by VCW (1.31 ± 0.45 cm^2) showed good correlations and was not significantly different from three comparative techniques: 1)cross-sectional area by planimetry (1.33 ± 0.40 cm^2, p = 0.92, mean difference = 0.22, r = 0.79, SEE = 0.28 cm^2, p < 0.001); 2) area derived from the Doppler half-time (1.26 ± 0.36 cm^2, p = 0.26, mean difference = 0.22, r = 0.77, SEE = 0.29 cm^2, p < 0.001); 3) area derived from the Gorlin equation in the 18 patients who underwent catheterization (1.27 ± 0.35 cm^2, p = 0.63, mean difference = 0.19, r = 0.81, SEE = 0.25 cm^2, p < 0.001).

Conclusion: These findings suggest that Doppler color flow imaging of the vena contracta of the MS jet can provide an accurate estimation of mitral valve area and appears to be potentially applicable to the assessment of the severity of MS.

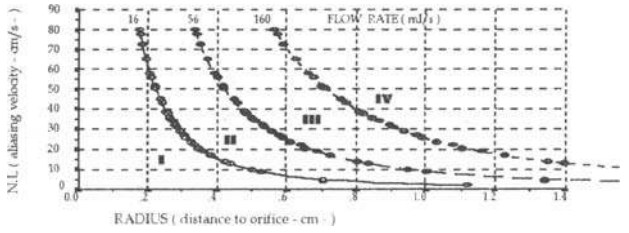
924 Validation of a simplified method based on the proximal flow convergence to estimate the severity of the mitral regurgitation

Jose L. Moya, Paz Catalán, Enrique Asín, Alberto García-Lledó, Jaime Pey, Francisco Barcia, Gonzalo Catalán, Celia Vaticón, Gabriela Guzmán. *Institute of Cardiology, Ramón y Cajal Hospital, Madrid, Spain*

Background: The proximal flow convergence (PFC) is an useful method in the cuantification of the mitral regurgitation (MR), even though its application in the daily clinical practice is not widespread due to its complex and time-consuming calculation.

Objectives: To simplify the cuantification of MR by the PFC, with the elaboration of a nomogram. Afterwards this method is validated through its application in the clinical practice.

Methods and results: We studied 58 patients (pats) with MR, which afterwards were going to be studied by angiography. The maximum regurgitation flow (MRF) was established by the method of the PFC { MRF = 2 × π × (radius obtained)^2 × Nyquist limit (NL) used}. The values of MRF that gave the best predictions of the degrees of angiographic severity from I to IV were estimated by ROC curves (cut points in 16, 56 and 160 ml/second). Maintaining those MRF values constant and applying in the ecuation the most used NL, we obtain the corresponding values of radius, that linked determine three curves. These curves define well-determined areas that represent the angiographic severity degrees.



We applied this nomogram in 24 new pats. with MR. Afterwards they were studied by angiography, with an excellent degree in agreement between PFC (nomogram) and angiography with a weighed kappa value (κ_p) of 0.93. The inter and intraobserver variability presented a κ_p = 0.89 and 0.91 respectively.

Conclusions: 1) The quick estimation of the severity of the MR by the PFC is possible in the daily clinical practice with the use of this simple nomogram. 2) This method has a very good degree in agreement with the angiographic severity of the MR. 3) The variability inter and intraobserver shows an appropiate reproducibility of the PFC method.

925 Direct calculation of regurgitant orifice area in patients with aortic regurgitation by omniplane transoesophageal echocardiography: comparison with angiographic data

A. Sciarra, M.T. Agricola, M.T. Mobily. *Div. di Cardiologia, Casa di Cura "Villa Serena", Spoltore, Italy*

Aim: The aim of the study is to determine the value of direct calculation of Regurgitant Orifice Area (ROA) by omniplane transesophageal echocardiography (OTE) in comparison with angiography (ANGIO). At our best knowledge this is the first clinical study in which is attempted the direct visualization of effective regurgitant orifice in patients with aortic regurgitation (AR).

Methods: We enrolled 28 consecutive pts in a prospective study, (14 men and 14 women, mean age 61.3 yrs, range 43–79, ±10 SD), with chronic AR; all patients underwent to OTE and ANGIO within 25 days. ANGIO was performed by the usual semi-quantitative grading (in four degrees). We calculated by OTE the ROA in oblique cross-sectional views, in order to detect the orifice by means of color Doppler signal; we also performed the color Doppler standard evaluation of AR. The analysis were performed blindly and by two experienced cardiologists for each method, in case of disagreement a third observer was introduced. ROA was calculated off-line on SVHS videotape.

Data Analysis: The pts were divided into four groups according to the angiographic grade of AR. We calculated ROA and the normalized value of ROA to body surface area (nROA).

Feasibility: We were able to perform ROA calculation in 22/28 pts (78%).

Results: ROA clearly detected pts with severe aortic regurgitation (ROA 2.25–2.72 mm^2, nROA 0.8–1.39 mm^2) with 0.8 mm^2 as cut-off value. Pts with trivial AR were also recognized by ROA (ROA 0.16–0.98 mm^2, nROA 0.144–0.058 mm^2) with 0.144 mm as cut-off value. We found an overlapping of ROA in pts with other grade of AR.

Conclusions: According to our results ROA allowed to a new quantitative evaluation of pts with AR and in our hands this method showed a good correlation with angiographic data.

LEFT VENTRICULAR LONG-AXIS FUNCTION

926 Tissue Doppler imaging, standard echo-Doppler and haemodynamic evaluation of left ventricular function in coronary artery disease patients with normal ejection fraction

R. Bolognesi, C. Manca, D. Tsialtas, P. Vasini, G. Tiberti, R. Zeppellini[1], F. Cucchini[1]. *Cattedra di Cardiologia, Università degli Studi di Parma; [1]Divisione di Cardiologia, Bassano del Grappa (VI), Italy*

Tissue Doppler Imaging (TDI) is a promising technique for non invasive evaluation of left ventricular (LV) function through the analysis of the mitral anulus lenghtwise movement; nevertheless data in healthy and diseased heart are still not conclusive. We performed a combined haemodynamic and echo-Doppler (standard and TDI) study of LV function in a group of 16 patients (mean age 52 ± 9) affected by coronary artery disease (CAD) without previous myocardial infarction, with preserved LV ejection fraction and in a control group of 7 age and sex matched subjects. In each subject we simultaneously recorded two main tracings: 1) the LV pressure curve through a micromanometer-tipped catheter, 2) the TDI tracing of the mitral anulus movement examined in four different sites around the mitral anulus, or alternatively with the standard Doppler signal of transmitral diastolic flow.

Mitral anulus displacement and peak Em (TDI) resulted significantly greater in control subjects than in CAD patients (1.6 ± 0.1 vs 1.3 ± 0.2 cm; p < 0.01 and 17 ± 1 vs 12 ± 2 cm/s; p < 0.01 respectively). Peak Em occurred earlier than peak E obtained with standard Doppler during diastole; in CAD patients time from peak Em to peak E was significantly shorter than in control subjects (9 ± 9 vs 23 ± 8 ms p < 0.005). In CAD patients the invasive indexes of isovolumic contraction (max dP/dt+ and dP/dt/P) and relaxation (max dP/dt−) were significantly lower (p < 0.05) whereas τ was significantly higher (p < 0.05) than in control. LV volumes and ejection fraction were similar in both groups.

In conclusion, subtle systolic and diastolic abnormalities in CAD patients can be detected through high fidelity haemodynamic as well as TDI (mitral anulus velocity) evaluations. The earlier occurrence of peak Em vs peak E supports the concept that a suction effect of the left ventricle promotes the blood inflow across the mitral valve. Such an effect was still evident but significantly reduced in our CAD patients in comparison to control subjects. Furthermore, the correlation we found in all subjects between mitral anulus displacement and invasive contractility indexes, was lacking when comparing mitral anulus displacement and relaxation indexes.

927 Left ventricular long-axis changes in early diastole are closely related to systolic function

G. Yip, Y. Zhang, P. Ho, M. Wang, J.E. Sanderson. *Medicine & Therapeutics Dept., The Chinese University of Hong Kong, Shatin, Hong Kong*

Measurement of movement of the mitral valve annulus either by tissue Dopler imaging (TDI)or by M-mode represents LV long axis (LAX) changes and this has been used to assess LV diastolic and systolic function. Frequently, there is discordance between mitral inflow velocities during early diastole (E and A wave) and those measured by long axis changes. We hypothesised that the long axis movement during early diastole (Em) may reflect more the recoil due stored forces from the previous systole and not the LV filling pressure gradient. Therefore, in a prospective within-patient study we have compared LV long axis changes in diastole with those in systole and with LV ejection fraction (LVEF)measured by 2D-echo in a large group of subjects with a wide range of LV function.

Methods: 265 subjects (106 normal) age range 20–89 yrs were studied with TDI and M-mode. mean LAX was measured from 4 positions (septal, lat.,inf.,and sup-basal);LVEF was measured by 2-D (Simpsons)and LV systolic LAX excursion. Mitral Doppler velocities were measured in the usual way.

Results: LVEF varied from 0.18 to 0.88. In diastole 51% had a normal mitral Doppler pattern, 36% an abnormal relaxation pattern, 7% restrictive, and 6% pseudo-normal. There was a strong correlation between LVEF and LAX E (Em) $r = 0.81$, $p < 0.0001$ by M-mode and $r = 0.63$ $p < 0.0001$ by TDI. There was no significant correlation bewteen Mitral E and LAX Em ($r = 0.88$, $p = 0.16$). Suprisingly LAX Am also correled with LVEF ($r = 0.74$, $p < 0.0001$).

Conclusion: There is a strong relationship between the early LAX changes in diastole and systolic function and probably the LAX Em is reflecting the stored energy from the previous systole and thus LV recoil. TDI LAX and mitral Doppler measurements are reflecting completely different processes in diastole.

928 Factors related to left atrioventricular plane displacement in a mixed population of patients with suspected or proven cardiac disease

R. Willenheimer, E. Rydberg, C. Cline, P. Gudmundsson, G. Ericsson. *Dept. of Cardiology, Malmö, Sweden*

Left atrioventricular plane displacement (AVPD) is an uncomplicated, highly reproducible, reliable, and clinically useful echocardiographic method for the determination of left ventricular function. AVPD is strongly related to the prognosis in patients with heart failure. AVPD reflects both left ventricular systolic and diastolic performance, and is a different measure of left ventricular function compared to ejection fraction. Factors influencing AVPD are insufficiently characterised, and we aimed to identify such factors.

Methods: We examined 357 consecutive patients with suspected or definite cardiac disease (age 67 (12) years, 33% women) by echocardiography/Doppler. Cardiac dimensions, left ventricular ejection fraction and filling, AVPD, and valvular function were assessed.

Results: We identified 10 factors explaining 68% of the AVPD variability, and these were included in a multiple regression analysis. AVPD correlated independently with left ventricular ejection fraction (standard coefficient (SC) 0.67, $p < 0.0001$), age (SC −0.20, $p < 0.0001$), body surface (SC 0.19, $p < 0.0001$), left ventricular end diastolic diameter/m^2 (SC 0.19, $p = 0.0004$), left ventricular mass/m^2 (SC −0.18, $p = 0.0001$), maximum velocity of early/atrial (E/A) transmitral diastolic flow (SC −0.10, $p = 0.004$), but not with left atrial end systolic diameter or degree of mitral, aortic, and tricuspid regurgitation.

Conclusion: AVPD was most closely correlated with systolic function expressed as ejection fraction, but also with age, body surface, left ventricular size and mass, and left ventricular filling. When aiming to assess left ventricular systolic function by AVPD, these factors must be considered. However, no adjustment for valvular regurgitation has to be made.

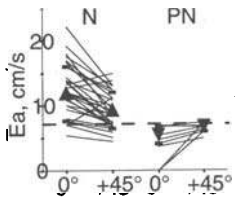
929 Accuracy and preload-dependency of diastolic mitral annular velocity parameters for the assessment of "pseudonormal" left ventricular relaxation

C. Seiler, K. Heule, S. de Marchi. *University Hospital, Cardiology, Berne, Switzerland*

Background: The purpose of this study using transesophageal echocardiography in 40 individuals with normal hearts (N, age 44 yrs), and in 13 patients with LV hypertrophy but normal, age-corrected transmitral Doppler flow pattern ("pseudonormal" group, PN, age 53 yrs) was to test the preload-dependency and the accuracy for the detection of PN of the following parameters: early (Ea) and late (Aa) diastolic mitral annular motion velocity and deceleration time (Ea-dt), mitral annular isovolumetric relaxation time (IVRTa), and the early transmitral flow velocity (E) to Ea ratio.

Methods: All mitral annular velocity parameters were measured using Doppler tissue imaging with the PW sample volume at the inferior annulus. Measurements were performed using a tilt-table during horizontal (0°) and upright (+45°) body position. Preload-dependency (f (prl)) was defined as a significant change of a variable following posture shift from 0° to +45°.

Results:



Variables determining PN	Sens	Specif	f (prl)
Ea < 7 cm/s	100%	90%	no
Ea/Aa < 0.8	100%	53%	yes
Ea-dt > 120 ms	67%	51%	yes
E/Ea < 8	69%	70%	yes
IVRTa > 75 ms	62%	55%	no

Abbreviations: Sens = sensitivity, Specif = specificity

Conclusions: Early diastolic mitral annular motion velocity is probably the most accurate of several annular velocity parameters for the correct detection of falsely normal transmitral flow velocity patterns. It also appears to be relatively insensitive to cardiac preload changes.

930 Strain rate imaging by ultrasound in diastolic function of the left ventricle

A. Stoylen, A. Heimdal[1], G. Skjelvan[2], T. Skjaerpe. *Cardiology Dept., University Hospital of Trondheim, Trondheim; [1]Physiology and Biomedical engineering, University of Trondheim, Trondheim[2]Trondheim Heart Center, Trondheim, Norway*

Aims: Strain rate in the left ventricle can be assessed by mapping of longitudinal velocity gradients obtained by colour Doppler; Strain Rate Imaging. Regional diastolic function by this, during early (E) and late (A) filling is characterised both by peak strain rate and propagation velocity of the wave of stretching from base to apex. The aim of this study was to establish normal values and to study the changes with minimal diastolic dysfunction.

Methods: 20 normal subjects (mean BP 119/75, mean HR 61 and mean EF 55%) and 23 hypertensive patients (mean BP 154/80 on treatment, mean HR 61 and mean EF 55%) were studied. Deceleration time of mitral flow was measured as an index of diastolic function.

Real-time SRI colour cine-loops were obtained with a GE Vingmed system 5 scanner in apical 2- and 4-chamber and long axis views. Peak early (PESR) and peak late (PASR) diastolic strain rate were measured in all 16 segments of the left ventricle. Propagation velocity of early (PVE) and late (PVA) diastolic strain were measured off-line in the six walls.

Results: Results are summarised in table I. There were no differences between apical, midwall or basal segments in PSR, and no significant differences between walls in PVE or PVA in normals. When the patients were separated by HR, to see the effect of betablockade, there were no significant differences in PVE, PVA or PESR, but PASR was significantly lower in the group with HR < 60; 1.42 vs. 1.82 Hz, P < 0.02.

Table I

	Age	IVSd (mm)	dec-t (ms)	PESR (Hz)	PASR (Hz)	PVE (cm/s)	PVA (cm/s)
Normals	37	8	175	2.30 (0.86)	1.39 (0.66)	57.8 (16.8)	94.5 (35.4)
Patients	66	11	258	1.43 (0.56)	1.64 (0.70)	28.2 (9.6)	66.9 (19.0)
P:	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	

Group characteristics and results. P values are T-test for differences between patients and normals, SD in parenthesis.

Conclusion: The present study shows that diastolic function is a result of peak strain rate, a measure of local relaxation, and the propagation of this relaxation. This gives new information about the physiology of diastole. Even for very moderate hypertrophy and diastolic dysfunction, changes are profound, with decrease in both peak E and E/A ratio, increase in peak A, but most profound reduction in propagation velocity of E. Changes are partly due to differences in age, but this does not alter the pathophysiologic implications.

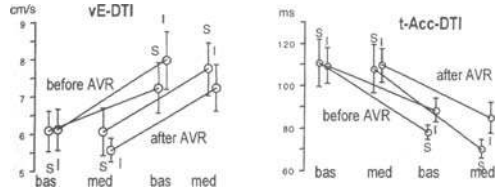
931 Doppler tissue imaging for the assessment of regional myocardial function after aortic valve replacement

Markus Schwerzmann, Beat C. Aeschbacher. *Cardiology, University Hospital, Berne, Switzerland*

Background: With regression of left ventricular hypertrophy (LVH) changes in global diastolic and eventually systolic function take place. Little is known about the range of these adaptations and their possible regional distribution. Doppler Tissue Imaging (DTI) allows regional evaluation of diastolic and systolic myocardial function, mitral inflow (MIF) and pulmonary venous flow (PVF) are surrogates of global diastolic function. The aim of this study was therefore 1. to evaluate the usefulness of DTI in the assessment of regional relaxation and 2. to look for possible regional differences in patients with regressive LVH after surgery for aortic stenosis (AS).

Methods: In 15 men with sinus rhythm, undergoing elective aortic valve replacement (AVR) for isolated AS, echocardiography including DTI was performed the day before AVR and one month thereafter. In DTI the sample volume was placed on the mitral annulus (bas) and 2 cm beyond the annulus (med) in septal (S) and inferior (I) wall segments.

Results: One month after surgery reduction in LVH took place (from 200 g/m^2 to 162 g/m^2), mainly due to reduction of septal wall thickness (from 18 to 15 mm). Left ventricular ejection fraction improved from 62% to 68% ($p = 0.04$). In MIF, isovolumetric relaxation time (IVRT) shortened form 93 to 70 ms ($p = 0.03$), PVF remained unchanged. In DTI E-wave velocity (vE-DTI) increased in all regions, acceleration time of contraction (tAcc-DTI) decreased in all regions (all $p < 0.05$, two-tailed): cf. graphic.



Conclusions: DTI shows early regional changes in systolic and diastolic function in patients with decreasing LVH. Especially the velocity of early passive relaxation (vE-DTI) and systolic acceleration time (tAcc-DTI) can be used as indicators. Using conventional surrogates of global diastolic function, MIF was superior to PVF in detecting early changes.

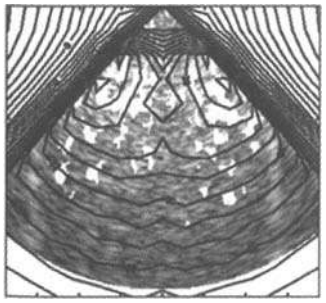
PROGRESS IN ULTRASONIC PERFUSION IMAGING

937 A parametric study of peak negative acoustic pressure field distribution and its implications for contrast echocardiography

J. D'hooge, M. Schrooten, B. Bijnens, J. Thoen[1], P. Suetens[2], F. Van de Werf, G.R. Sutherland. *Cardiology Dept, University Hospital Gasthuisberg, Leuven; [1]Department of Physics, Laboratorium voor Akoestiek, Leuven[2]Department of Electrical Engineering, Medical Image Computing, Leuven, Belgium*

Aim: To determine the relation between peak negative acoustic pressure (PNAP) across an acoustic field and bubble destruction.

Methods: The PNAP distribution occurring within the elevation- and scan planes of a phased array transducer was calculated by computer simulation. The influence of the following parameters on PNAP distribution was investigated: central frequency and bandwidth of the transmitted pulse, position of both axial and elevation focus and number and pitch of the crystals in the phased array. Bubble destruction was studied by scanning contrast-containing phantoms with a 2.5 MHz phased array transducer. Radio-frequency data was acquired for post-processing.



PNAP map vs bubble destruction (white).

Results: Simulations showed that both amplitude of PNAP and its homogenicity within the image increased with decreasing frequency but were independent of transmitted bandwidth. Highest PNAP's were located laterally at 4–5 cm depth. PNAP's were not directly related to propagation distance, being higher in the lateral image lines at the same distance from the transducer. Reflectivity analysis showed that bubble destruction increased with decreasing transmit frequency. Correlation analysis showed that bubble destruction was highest in lateral image regions. The distribution of bubble destruction (white) and PNAP (solid lines) agreed well (cf. figure).

Conclusions: PNAP's have a direct influence on bubble destruction: by decreasing the transmitted frequency the average field PNAP increases. Thus the average rate of bubble destruction within the acoustic field will increase but because of the non-uniform delivery of PNAP across the field bubble destruction is greater in the lateral regions. This has major implications on methods of quantifying contrast images based solely on bubble destruction.

938 Is pulse inversion technique or harmonic power Doppler more tolerant to attenuation-induced reduction of transmission power?

H. von Bibra, J.U. Voigt[1], M. Frörman, A. Juhlin-Dannfelt. *Clinical Physiology Dept., Karolinska Hospital, Stockholm, Sweden; [1]Medical Clinic II„ University Hospital, Erlangen, Germany*

Objective: In the clinical setting of myocardial perfusion studies, tissue attenuation (AT) is a major factor limiting the nonlinear microbubble response to insonation with a constant mechanical index (MI). Little is known about the relation of the latest imaging modalities to the nonlinear microbubble effect and their tolerance for AT. We studied this relation in an in vitro experimental setting using 3 different contrast agents and varying degrees of MI and AT for the comparison of harmonic power Doppler (HPD) and pulse inversion technique (PIT).

Methods: With a beaker model and a magnetic stirrer, the acoustic energy delivered to the microbubbles at 9 cm depth was reduced incrementally to −42 dB by using increasing layers of castoroil (0, 2, 4, 6 and 8 cm) and reducing MI (1.3, 0.9, 0.6, 0.4, 0.2 and 0.1). Levovist (0.7 ml, 300 mg/ml), Sonovue (0.3 ml) and Optison (0.03 ml) were studied with intermittent imaging at 0.5 Hz using an ATL HDI 5000 with a broadband transducer. Signal intensities (SI) in the digital data sets were measured in dB with a research tool analysis program (HDI lab).

Results: As expected, SI increased with increasing acoustic energy in all imaging modality data sets and contrast agents ($r = 0.87$). HPD demonstrated less tolerance for AT with the onset of SI response to increasing acoustic energy at −25 dB (Levovist) and −29 dB (Sonovue and Optison) compared to PIT: −27 dB (Levovist), −32 dB (Sonovue) and −30 dB (Optison).

Conclusion: These data suggest that the pulse inversion technique is inherently more tolerant for tissue attenuation than harmonic power Doppler. The extent of this effect is modified by the specific bubble composition.

939 Accurate quantification of absolute flow rate by contrast echocardiography using harmonic power imaging combined with dual triggering

S. Lafitte, J.M. Perron, S. Garrigue, P. Dos Santos, R. Roudaut. *Bordeaux, France*

Ultrasound pulsing variation turns out to be promising for myocardial blood flow assessment by contrast echocardiography. Since it has been suggested that contrast agent detection is improved by Harmonic Power Imaging (HPI), we hypothesized that HPI combined with contrast agent and dual triggering provide accurate quantification of absolute flow rate.

Methods: A myocardial tissue mimicking phantom was perfused by a saline solution at flow rates (range: 2–15 ml/min). Trans-sectional echocardiography was performed by using an HDI3000 system with a P3-2 probe. NC100100 was continuously injected in the system. ECG was simulated at 60 bpm by an external device. The first trigger (the destruction pulse) was increased from 550 to 900 ms before the subsequent q wave (second fixed trigger) for each flow rate. Images were digitized and analyzed from the fixed trigger. Pixel intensities were plotted with the delay (TD) between the two triggers (8 configurations from 550 to 900 ms) and the curve slope was calculated for each flow rate. Correlation analysis was performed between slopes and flow rates.

Results: For each flow rate, we observed a highly significant signal decrease always associated with a TD decrease ($R = 0.91$). As long as the flow rate was increased, the corresponding curve slope decreased (table). Most importantly, there is a high relationship between the flow rate value and curve slope changes ($R = 0.98$), providing an accurate quantification of the flow rate from the pixel intensities.

Flow rate (ml/min)	2	5	8	10	12	15
Slope	8.44	7.92	6.34	5.7	4.07	2.82
R	0.95	0.97	0.92	0.91	0.89	0.84

Conclusion: Dual trigger combined with contrast HPI is a reliable indirect method to quantify absolute flow rate.

940 Protection of microvascular reflow by endothelin antagonist treatment: evaluation with fluorescent microspheres and myocardial contrast echocardiography

L. Galiuto, A.N. DeMaria[1], U. del Balzo[2], K. May-Newman[2], S.F. Flaim[2], M. Kirchengast[3], S. Iliceto[4]. *Cardiology Dept, Catholic Univ. of the Sacred Heart, Rome, Italy; [1]Cardiology Dept, University of California at San Diego, San Diego CA[2]Alliance Pharmaceutical Corp, San Diego CA, USA; [3]Knoll AG, Ludwigshafen, Germany[4] Cardiology Dept, University of Cagliari, Cagliari, Italy*

Background: A progressive deterioration of microvascular flow has been observed after ischemia-reperfusion. We hypothesized that an endothelin ETA selective receptor antagonist, administered at the time of reperfusion, improves post-ischemic microvascular reflow. Also, we tested the efficacy of myocardial contrast echo (MCE) in detecting pharmacologically-induced changes in microvascular flow.

Methods: In 16 dogs, the LAD was occluded for 90 min and then reperfused for 180 min. Five min before LAD reopening, 5 mg/kg of LU-135252 (Knoll-AG) were infused intravenously in 8 dogs and vehicle was infused in 8 control dogs. Microvascular blood flow (BF) was assessed by fluorescent microspheres at baseline (BSL), during occlusion (OCC), 5, 90 and 180 min of reperfusion (RP). At the same time-points, MCE was performed with Imagent® (Alliance) infused i.v. (4 mg/min). The heart was imaged in short axis in ECG-gated harmonic mode. Background-subtracted videointensity and BF were expressed as LAD/LCx ratio and presented as% of baseline values.

Results: No differences in flow between the two groups were observed at BSL, OCC, 5 and 90 min of RP. At 180 min RP flow was decreased in controls (70 ± 7.4% of bsl) and remained stable LU-135252 treated animals (89 ± 4% of bsl, *p < 0.05 vs control). MCE followed closely the changes in flow observed in the two groups and significantly correlated with BF, r = 0.74, p < 0.0001).

Conclusions: The intravenous administration of LU-135252 at the time of reperfusion limited the progressive decrease in post-ischemic microvascular reflow. MCE with intravenous Imagent® allowed a reliable evaluation of pharmacologically-induced changes in microvascular flow. These data hold promises in the treatment of reperfusion injury and its non-invasive assessment by MCE.

941 ST-segment changes in patients with acute myocardial infarction treated with PTCA are less predictive for functional recovery than myocardial contrast echocardiography and coronary flow reserve

W. Lepper, A. Franke, R. Hoffmann, H.P. Kuehl, C.C. de Cock[1], G.J. Siesverda[1], O. Kamp[1], C.A. Visser[1], P. Voci[2], P. Hanrath. *University Hospitals of Aachen, Germany; [1]Amsterdam, Netherlands; [2]Pisa, Italy*

In 25 patients (pts) with acute first myocardial infarction (11 anterior, 14 inferior) myocardial contrast echocardiography (MCE) was performed prior to primary PTCA and 24 h later, using i.v. NC100100 (Nycomed-Amersham). The endocardial border length corresponding to the contrast defect was measured for each MCE in the apical views. The sum of ST-segment elevation (in mm) in 12-lead ECG was measured pre PTCA, at 1, 2 and 4 hours after PTCA. Coronary flow reserve (CFR) was measured in the infarct related artery using a Doppler guidewire and intracoronary adenosine immediately after PTCA and 24 h later. Depending on the CFR at the 24 h follow-up two groups were defined: Group A (CFR > 1.5, n = 17) and Group B (CFR ≤ 1.5, n = 8). Regional wall motion score index (RI) was calculated pre PTCA and after 4 weeks.

Results:

	Group A	Group B	P
CFR early after PTCA	1.62 ± 0.42	1.51 ± 0.37	NS
CFR after 24 h	2.11 ± 0.46	1.40 ± 0.21	P < 0.0001
MCE defect pre PTCA (cm)	6.0 ± 5.3	6.5 ± 4.5	NS
MCE defect at 24 h (cm)	4.1 ± 5.8*	9.2 ± 6.2	P = 0.058
ST-elevation pre PTCA (mm)	9.3 ± 6.4	13.5 ± 10.1	NS
ST-elevation after 1 hour (mm)	2.7 ± 2.6	6.5 ± 5.6	P < 0.05
ST-elevation after 2 hours (mm)	2.1 ± 1.9	4.4 ± 4.8	NS
ST-elevation after 4 hours (mm)	2.1 ± 1.8	3.1 ± 3.2	NS
RI pre PTCA	2.7 ± 0.5	2.8 ± 0.1	NS
RI after 4 weeks	2.0 ± 0.5#	2.6 ± 0.4	P < 0.05

#p < 0.0001 vs. RI prePTCA, *p < 0.05 vs. MCE defect prePTCA

Conclusion: Pts with reduced CFR 24 h after PTCA showed no reduction or even an increase in MCE defect size at 24 h follow-up and an impaired functional recovery. Reduction of ST-elevation was comparable for both groups. Thus, i.v. MCE may be more precise to predict success of reperfusion therapy in comparison to routine ECG-recordings.

COMPUTER DEMONSTRATIONS

D945 Analyzation of clinical or experimental vascular section with a relational database

C. Vogel-Wiens, F. Breger, P. Gonschior. *I. Medizinische Klinik, Klinikum rechts der Isar und Deutsches Herzzentrum, Technische Universität MünchenMunich, Germany*

Clinical and experimental vascular sections from online (IVUS, MR angiography) or offline analyzation methods are performed increasingly. Digital relational analysis enable enhanced studies of various parameters.

Methods: To compare different parameters adequately a relational digital image analysis procedure was developed and used that allows easy-to-use digital data transfer. The system files all clinical and histological data and all calculated data after acquisition. Microscopic or macroscopic images are scanned with a 3-chip CCD camera and digitally transferred to the processor. Using a sufficient software environement, digital analyzation of morphometric parameters and image processing is performed (NIH Image). A database (Cumulus, Canto Software Inc.) connected to a spreadsheat developed in a 4th Dimension environment (ACIUS, France) combines an easy to use interface with powerful analyzation features. This allows the relational analysis of nearly all clinical, experimental, macro- and microscopical features. All parameters can be used for further analysis and several calculations with correlated values.

In conclusion: Digitally assisted image analyzation and comparison in referal centers can be performed by several blinded experts after digital data transfer. This allows to bild a net of experimental and clinical data for research and education that is affordable, easy-to-use and standardized.

D946 Myocardial tissue characterization by echocardiography: a new totally digital method using the grey level histograms, the co-occurrence matrix and the fractal dimension

E. Donal, D. Coisne, S. Ragot, L. Christiaens, D. Herpin, J. Allal, R. Barraine. *Cardiologie, CHU La Milétrie, 86021 Poitiers, France*

There are two methods for quantitative approach of myocardial texture (T); one based on the radiofrequency signal analysis and the other one called "videodensitometry", needs a video interface for analysis.

Aims: presentation of a original new tool and a home made software for tissue characterization. We try to prove that it is possible to describe the T with the grey level histogram and with methods of quantifiication of the heterogeneity of the T: the cooccurrence matrix and the fractal approach.

Methods: the study population was composed of 34 normal volunteers. The conventional echocardiography was optimized with a 2.5 Mhz phased array transducer. The texture analysis was done in parasternal long axis; without zoom, ROI of 10*12 pixels, and with zoom, ROI of 20*10 were manually positioned in the interventricular myocardial region. Ten measures were done for each patient over the cardiac cycle. To describe the myocardial texture 9 values from 3 treatments were tested:

(1) the grey level histogram (parameters: mean, median, variance, skweness)
(2) A orthogonal biplane cooccurrence matrix (parameters: mean, variance, energy, contrast).
(3) The fractal approach (fractal dimension)

Results: there was a good intra-observer reproducibility except fractal dimension (intra-classe correlation coefficient ICCC > 80, results confirmed by Bland and Altman graphics). There was cyclic variation of each parameter over a cardiac cycle. The normalization of each measure by the value of the left ventricle cavity was not totally correlated with results without normalization.

Conclusion: tissue characterization by echocardiography is a difficult challenge. Our new tool is homemade, easy to use with images treated by the echo machine like in this study but also with radio-frequency signals.

CORONARY INTERVENTIONS: MISCELLANEOUS

P947 Value of the American College of Cardiology/American Heart Association coronary artery stenosis morphology classification for predicting acute outcomes in the era of coronary stent angioplasty

E. Jorgensen, H. Kelbæk, J. Kastrup, K. Saunamäki, S. Helqvist, L. Clemmensen, J.K. Madsen. *Cardiac Catheterisation Laboratory, Rigshospitalet, Copenhagen, Denmark*

Background: The American College of Cardiology/ American Heart Association (ACA/ AHA) stenosis morphology classification was developed for transluminal coronary balloon angioplasty in the 1980s. The aim of our study was to assess the value of this classification to predict the in-hospital outcomes in the era of stent angioplasty.

Methods: From June 1998 to January 1999 we classified 1220 coronary lesions during 807 consecutive angioplasty procedures into ACC/AHA type A, B and C. Angiographic success was defined as <50% residual stenosis after balloon angioplasty and <25% residual stenosis after stent angioplasty. In-hospital major adverse cardiac and cerebral events (MACCE) were registered at discharge.

Results: Of the 731 patients (74% males) 69% were treated because of stable and 31% because of unstable ischemic coronary syndromes. The lesion morphology distribution was as follows: type A 15%, type B1 20%, type B2 42% and type C 23%. Of the latter 46% constituted chronic total occlusions. Stents were implanted in 73% of type A, 81% of type B and 88% of recanalised type C lesions. Angiographic success rates were significantly lower for lesions with complex morphology: type A 100%, type B 96% and type C 81% (55% for chronic total occlusions). MACCE occurred in 17 patients (2.1%): 2 deaths, 4 Q-myocardial infarctions, 1 patient developed disabling stroke and 1 cardiac tamponade due to guidewire perforation, acute bypass surgery was performed in 6 patients and acute re-angioplasty in 3. The MACCE rate in single lesion procedures (n 480), two lesion procedures (n 232) and multi lesion procedures (n 86) were 1.5%, 3.4% and 2.2%, respectively (NS). Freedom from MACCE in single lesion procedures with morphology type A (n 67), B (n 293) and C (n 118) was 100%, 99% and 97%, respectively (NS). The procedural success rates (combined angiographic success and freedom from MACCE) of the lesions were 100%, 95% and 66% ($p < 0.001$, type A and B vs. type C).

Conclusions: 1) The ACA/AHA lesion morphology classification predicts angiographic success after coronary angioplasty even in the era of stenting, 2) stent use increases with lesion complexity, 3) the frequency of major adverse in-hospital clinical events is not related to the number of lesions treated per procedure and only tends to increase with lesion complexity, 4) a high procedural success for morphology type A lesions encourages to consider out-patient angioplasty treatment of these lesions.

P948 American College of Cardiology/American Heart Association stenosis morphology classification is a strong predictive factor of procedural success and late angiographic and clinical outcome after coronary stent implantation

A. Kastrati, J. Dirschinger, J. Mehilli, J. Pache, H. Schühlen, F.J. Neumann, A. Schömig. *Deutsches Herzzentrum; 1. Med. Klinik rechts der Isar, TU München, Munich, Germany*

ACC/AHA lesion morphology is predictive of success rates after PTCA but little is known on its value in predicting the procedural and late angiographic and clinical outcome after coronary stenting.

Methods: The study includes 2944 consecutive patients (pts) who underwent coronary stenting. Only pts with acute myocardial infarction before stenting were excluded. There were 264 pts (9%) with type A, 634 (22%) with type B1, 1152 (39%) with type B2 and 894 (30%) with type C lesions. Lesions of type B2 and C were combined to form the group of complex lesions. All pts had a 1-year clinical follow-up; death, myocardial infarction (MI) and target lesion revascularizations were recorded as adverse events. Six-month angiography was performed in 2296 pts (82% of the eligible pts). All angiograms were assessed with QCA.

Results:

	B2/C type (n = 2046)	A/B1 type (n = 898)	P
Procedural success, %	97.6	98.9	0.02
Thrombosis rate (30-day), %	2.7	1.3	0.02
Death or MI (30-day), %	2.6	1.2	0.02
Angiographic late lumen loss, mm	1.19 ± 0.83	0.99 ± 0.73	<0.001
Angiographic restenosis rate, %	33.2	24.9	<0.001
Event-free survival (1-year), %	75.6	81.1	0.001

In multivariate analysis, B2/C pts had an increased risk of restenosis with odds ratio of 1.33 [95% CI, 1.07–1.64] and of adverse clinical events at 1 year with hazard ratio of 1.27 [1.06–1.52] compared to A/B1 pts.

Conclusions: ACC/AHA lesion morphology classification has a strong predictive value not only for the procedural success rate but also for early and late angiographic and clinical outcome after coronary stent placement.

P949 Prolonged balloon inflations decrease elastic recoil during coronary angioplasty: a quantitative angiographic and intracoronary ultrasound study

O. Yeşildağ[1], U. Deligönül[2], T. Porter[2], H. Oskarson[2], A. Karim[2], S. Shurmur[2]. *[1]University of Ondokuz Mayıs Faculty of Medicine Samsun, Turkey; [2]University of Nebraska Medical Center, Omaha NE, USA*

To determine the angiographic, procedural and intracoronary ultrasound (ICUS) factors related to elastic recoil during balloon angioplasty (PTCA), 36 coronary arterial narrowings in 35 patients (pts) were analyzed. Reference diameters (RD) and minimum lumen diameters (MLD) were measured by edge detection method before and after PTCA. Angiographic balloon diameters (BD) were measured along the length of the balloon and average value was utilized for calculation of stretch (BD-pre MLD/RD) and recoil BD-postMLD/RD).

Morphologic characteristics of the dilated lesion (length, eccentricity, Ambrose morphology, calcification, thrombus, postprocedure dissection, bend > 45°) were evaluated visually. ICUS images were obtained using a 3.5 F, 30 mHz catheter. Plaque area, total vessel area (TVA) at the reference and stenotic site, eccentricity index and calcification were recorded before and after PTCA.

The average BD was 2.97 ± 0.43 mm and the balloon/artery ratio was 0.94 ± 0.16. The average stretch was 0.62 ± 0.18 (1.97 ± 0.53 mm) and the recoil was 0.29 ± 0.15 (0.92 ± 0.46 mm). Smaller MLD correlated to higher stretch ($r = 0.66$, $p < 0.01$) but not to recoil. Higher BA ratio was associated with more stretch ($r = 0.79$, $p < 0.01$) and recoil ($r = 0.65$, $p < 0.01$). Discrete (≤5 mm) lesions showed less recoil ($p = 0.04$). The length of the inflation, but not the inflation pressure, was inversely correlated to recoil ($r = -0.49$, $p < 0.01$). No ICUS characteristics including calcification, eccentricity or TVA diminution at the stenosis site were correlated to recoil.

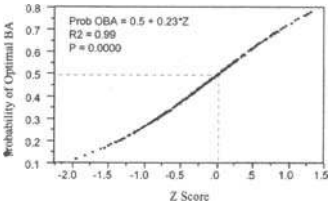
In conclusion, longer lesions are more prone to elastic recoil. Elastic recoil could be reduced by prolonged balloon inflations.

P950 A logistic regression model to determine the probability of achieving an optimal angiographic and physiologic result with balloon angioplasty alone

Moussa[1], A. Colombo[2], L. Di Francesco[2], C. Di Mario[2], T. Anderson[3], R. Bonan[4], T. Muremetsu[5], E. Lawrence[1], A. Rombolotti[2], J.W. Moses[1]. *On Behalf of the DESTINI-CFR Study group; [1]Lenox Hill Hospital, New York NY, USA; [2]Centro Cuore Columbus, Milan, Italy; [3]University of Calgary, Calgary AB; [4]Montreal Heart Institute, Montreal PQ, Canada; [5]Kawesaki, Japan Central hospital*

The DESTINI trial is a prospective randomized evaluation of primary stenting (PS) compared to Doppler-guided balloon angioplasty with conditional stenting (G-BA). The population of this analysis consisted of patients with a single lesion who were randomized to the G-BA arm (n = 301). Of this population, 138 pts (46%) achieved an optimal balloon angioplasty (OBA) result (DS < 35% and CFR > 2.0) and 163 pts (54%) had suboptimal result and proceeded to conditional stenting (CS).

Results: Among all clinical, angiographic and procedural variables, only the following was predictive of OBA by logistic regression: reference diameter (RD)(smaller vessels), lesion length (LL) (shorter lesions), and lesions that yielded at a lower inflation pressure (Pres). The regression equation {$Z = 3.59 - 0.546 * (RD) - 0.061 * (LL) - 0.12 * (Pres)$, $P < 0.0001$} was used to calculate the probability of achieving an OBA result using the formula ($Prob = 1/1 + e^{(-z)}$). As shown in the figure below, a Z score = 0 predicts a 50/50 chance of obtaining OBA; for every 0.2 increase in Z score there is a 5% absolute increase in the probability of achieving OBA.



Conclusions: Optimal balloon angioplasty, as defined angiographically and physiologically, depends primarily on lesion substrate. This is more likely to be achieved in pts with shorter lesions located in smaller vessels that yield at lower inflation pressure.

P951 Prognostic implication of concomitant non-critical stenosis in patients with single vessel coronary disease

A. Giusti, A. Scirè[1], P.S. Saccaggi, L. Angoli, P. Valentini, G. Specchia. *Dept. of Cardiology, Policlinico S.Matteo, Pavia; [1]Division of Cardiology, Esine, Italy*

Patients with a single critical vessel disease may or may not have additional non critical stenosis on the same vessel or in other coronary arteries. The prognostic implications of presence or absence of these non critical stenosis is currently unknown. We have studied 275 patients who underwent coronary angiography because of stable or unstable angina pectoris. The affected coronary artery was the LAD in 156 (57%), the right coronary artery in 78 (28%), the circumflex coronary artery in 41 (15%). Of the 275 patients 224 (81%) were treated with PTCA. In 200 (73%, group A) of them no additional lesions, beside the single critical one, were observed. The remaining 75 (group B) patients had one or more non critical lesions within the same vessel (n = 32, 43%) or on other coronary arteries (n = 43, 57%).

During the follow-up of 45 ± 8 months occurrence of major lethal and non lethal myocardial infarction (MI) and minor (revascularization) events were recorded. Seventy-two (26%) patients had events and group B had a higher incidence of total events when compared with group A ($c2 = 6.8$), resulting primarily from minor events. Of interest, is the fact that in LAD lesion group the presence of additional non critical stenosis was associated with a higher incidence of major events ($p < 0.05$) when compared with the patients who had LAD lesion without other concomitant non critical stenosis.

In conclusion, in patients with single vessel disease the concomitant presence of non critical lesions within the same vessel or on other coronary arteries is associated with a higher risk for MI or need of revascularization in the follow-up. Furthermore, the coexistence of additional no critical lesions with a critical stenosis on the LAD identifies a subgroup of patients at higher risk for lethal and non lethal MI.

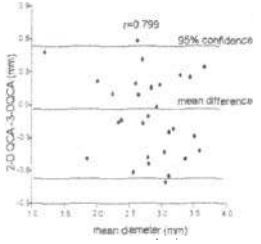
P952 Quantitative coronary angiography: a three-dimensional as compared to the two-dimensional approach

E. Wellnhofer, A. Wahle[1], I. Mugaragu, J. Gross, H. Oswald, E. Fleck. *Dept. of Int. Med./Cardiol., Campus Virchow, Charité, HU & DHZB, Berlin, Germany; [1]University of Iowa, Dept of Electrical and Computer Engineering, Iowa City IA, USA*

Goals: 1. Validation of an accurate method for 3-dimensional quantitative assessment of volumes, lengths and diameters of coronary vascular branches and segments from biplane angiographic projections (3-D QCA). 2. Comparison of diameter measurements using 3-D QCA as compared to 2-dimensional QCA (2-D QCA).

Methods: The accuracy was tested in a complex phantom. In-vivo, inter- (n = 31) and intraobserver agreement (n = 31) were assessed by analysis of routine angiograms. The sensitivity was evaluated using angiograms of patients having diagnostic vasoactive pharmacological intervention. 2- D QCA and 3-D QCA were compared concerning the accuracy of diameter evaluation.

Results: 3-D QCA yields accurate results (<3% error) even based on non-orthogonal views, provided that projections parallel to the object are avoided. Inter- and intraobserver variability is <5%. Significant ($p < 0.01$) changes of the volume (36%–39%) and the diameter (19%–21%) are detected following pharmacological intervention. 2-D QCA and 3-D QCA agree only in short matched segments without foreshortening (see Bland-Altman plot).



Conclusion: 3-D QCA permits an accurate, reproducible and sensitive comprehensive 3-dimensional geometric analysis of the coronaries and is superior to 2-D QCA with respect to diameter evaluation in foreshortened segments.

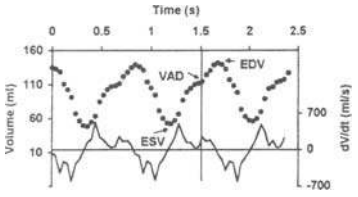
P953 Left atrial pump function in patients with coronary artery disease assessed by digitized cineangiography

J. Dernellis, C. Stefanadis, L. Diamandopoulos, P. Toutouzas. *Department of Cardiology, University of Athens, Athens, Greece*

Left atrial (LA) contribution to left ventricular (LV) filling in patients with LV dysfunction due to coronary artery disease was studied in 75 patients (pts) with single vessel disease (43 pts with left anterior descending (LAD), 15 pts with left circumflex (LCx) and 17 pts with right coronary artery (RCA) disease). Furthermore, 15 subjects with normal coronary arteries served as controls (C).

Methods: A computerized technique for the calculation of instantaneous LV volume from digitized cineangiographic data which was developed in our institution was used. LA contribution was estimated by LA filling fraction (LAFF = [LVEDV − LVVAD]/LVVAD, where LVVAD = LV volume at the end of atrial diastasis and LVEDV = LV end-diastolic volume)

Results: LV ejection fraction was decreased in all patients compared with controls ($p < 0.01$). LA contribution was augmented in 39 pts with lesion of LAD, in 7 pts with distal lesion of LCx and in 13 pts with distal lesion of RCA compared with controls, as indicated by increases in LAFF (LAD: 23.1 ± 3.3, LCx: 20.8 ± 3.6, RCA: 19.5 ± 4.6, vs C: 12.7 ± 2.4%). In 8 pts with proximal lesion of the LCx and 4 pts with proximal lesion of RCA, LA ischemia depressed LA contribution, as indicated by decreased LAFF (LCx: 4.5 ± 0.7, RCA: 5.5 ± 1.1%). In 4 pts with lesion of LAD who had severely impaired LV ejection fraction (28.8 ± 7.5%) and symptoms of congestive heart failure LA contractility was also decreased (LAFF: 2.2 ± 0.5%).



Conclusion: Ischemia renders LV performance dependent on augmented LA transport. LA contribution to LV filling may be depressed by LA ischemia. Furthermore, LA contribution was compromised in patients with advanced heart failure.

P954 Angiographic predictors for coronary dissection after coronary stening

Xiangdong Wang, Emily Lawrence, Matthew Oetgen, Issam Moussa, Sriram Iyer, Edward Kreps, Michael Collins, Gary Roubin, Antonio Colombo, Jeffrey Moses. *Lenox Hill Hospital, New York NY, USA*

Coronary artery dissection is an unavoidable complication in coronary stenting. Dissection following stent implantation may increase the number of devices used and total procedural time, resulting in an increased procedural cost. We reviewed the incidence of post stent dissection in 1678 patients (2215 lesions) from September 1996 to January 1999. This cohort consisted of de novo, non occlusive lesions only. Dissection occurred in 250 lesions (11.29%) after initial stent implantation, of which 200 lesions (9.03%) received at least one additional stent. Using univariate and multivariate analysis, we evaluated the eight possible baseline angiographic characteristics including calcifications, bifurcation, vessel tortuosity, tandem lesion, lesion shape (eccentric, concentric), vessel size, diameter stenosis and lesion length. Results are as shown below:

Variable	Univariate p value	Multivariate p value
Calcifications	0.08	0.12
Bifurcated Lesion	0.003	0.005
Tortuosity	0.08	0.03
Tandem Lesion	0.05	0.22
Lesion Shape	0.69	0.74
Smaller vessel size	0.0025	0.0007
Diameter Stenosis	0.97	0.88
Longer Lesions	0.026	0.03

Conclusion: Patients with tortuous vessels, smaller vessels, longer lesions, or bifurcated lesions are at higher risk of sustaining dissections after stent implantation.

P955 Comparison of the extent of revascularization and event free survival in the angioplasty arms of two randomized trials of coronary angioplasty versus surgery for multivessel coronary artery disease

M.J.B.M. van den Brand, A. Breeman, B. Rensing, E. Boersma, P. van den Heuvel, I. Penn, C. Ilsley, T. Toftegaard-Nielsen, F. Kiemeneij, P.W. Serruys. *Cardiology Dept., Thoraxcenter, Rotterdam, Netherlands*

The CABRI trial (Coronary Angioplasty Bypass Revascularization Investigation) randomized patients (pts) with multivessel disease (MVD) to surgery (CABG) or angioplasty (PTCA). Less than 1% of pts were treated with stented angioplasty (SA). In the ARTS trial (Arterial Revascularization Therapy Study) SA was the per protocol treatment in the angioplasty cohort. CABRI was conducted from 1988 to 1992 and ARTS from 1997 to 1998. We sought to determine the influence of completeness of revascularization (CR) on subsequent event free survival (EFS) (absence of death, myocardial infarction (MI), cerebral event or re-revacularization).

Methods: In CABRI as opposed to ARTS equivalence of revascularization between CABG and PTCA was not obligatory. In both studies inclusion was based on consensus between cardiologist and surgeon. We compared the number of diseased vessels (>50% diameter stenosis, reference diameter > 1.75 mm), CR and EFS at 1 month follow-up in the angioplasty cohorts of both trials.

Results: Baseline demographics were not different in both study populations. The table summarizes angiographic data, procedural outcome and EFS at 1 month and 6 month (CABRI).

Outcome in angioplasty arms ARTS/CABRI

	N	Segments diseas-dilated	CR	EFS	Death	MI	Rerevasc	FU
CABRI	541	1815–983	26%	90.2%	1.2%	2.1%	6.5%	1 m
				69.5%	3.3%	3.3%	24.0%	6 m
ARTS	600	1782–1636	73%	92.1%	1.6%	2.5%	3.3%	1 m

diseas = diseased, FU = follow-up, rerevasc = repeat revascularization

Conclusion: Although the extent of disease did not differ between both studies, revascularization was much more complete in ARTS, this was not reflected in a higher EFS at 1 month f-up. There was a trend towards more re-revascularizations in the CABRI trial, reflecting the lower rate of CR. Six month follow-up data from the ARTS will be available soon.

P956 Overlapping coronary stents result in an increased neointimal hyperplasia response: insight from a porcine coronary stent model

I. De Scheerder, K. Wang, X.R. Zhou, Q. Bei Ping, H. Yanming, H. Jianhua, L. Xiaoshun, M. Szilard, E. Verbeken, X. Zhu, F. Van de Werf. *University Hospitals Leuven, Leuven, Belgium*

Clinical experience suggests that overlapping coronary stents result in an increased in-stent restenosis. This study investigates the underlying mechanisms in a porcine coronary model. Single or two overlapping self-made stainless steel single wire sinusoidal helical coil stents were randomly deployed in the right coronary artery of 20 crossbred pigs (weight 20–25 kg). The pigs underwent a control angiogram at 6 weeks and were then sacrificed.

Quantitative coronary analysis before, immediately after stent implantation and at 6 weeks, was performed using the semi-automated Polytron 1000™ system. Morphometry was performed using a computerized morphometric program.

Angiographic analysis revealed a decreased recoil in the overlapping group (1% vs. 4%: $p < 0.02$) and a significantly larger minimal stent lumen diameter at follow-up in the single stent group (2.87 ± 0.16 vs. 2.58 ± 0.22 mm: $p = 0.005$). Histopathology showed a significantly increased injury (1.27 ± 0.43 vs. 0.83 ± 0.44, $p = 0.042$) and a significantly increased inflammatory reaction surrounding the stent filaments (1.51 ± 0.11 vs. 1.09 ± 0.54: $p = 0.035$) in the overlapping stent group. Morphometric analysis showed a significantly higher neointimal hyperplasia (3.34 ± 0.68 vs. 2.16 ± 1.48 mm^2: $p = 0.034$) in the overlapping stent group.

Conclusion: Overlapping stents result in more pronounced coronary vessel injury resulting in more inflammation and neointimal hyperplasia compared to single stents.

P957 A new unique low-pressure coronary stent design in a porcine model

P. Barath, A. Popov, S. Kaul, N. Sinaii, P.K. Shah. *Cardiology Dept, Cedars-Sinai Medical Center, Los Angeles CA, USA*

We tested a new unique low pressure stent (LP Stent, InterVenventional Technologies, Inc.) in a minipig model (62 stents in 26 arteries: 22 LAD, 21 Cx and 18 RCA normal coronary arteries; average diameter: 2.52 mm) using standard QCA, angioplasty/stenting and histomorphometric techniques. The device is a stainless steel tubular stent with a configuration of interconnected multiple circumferential serpentine elements and trapezoid strut cross tensile section, fabricated with photomask/chemical etching/electropolishing technique. Mechanical characteristics: tensile strength 120K psi, crush resistance 60.3 g, plasticdeformity 50 psi. We delivered the stent over non-compliant PET balloons. Hypothesis: the trapezoid strut facilitates the stent deployment at lower pressures and this may reduce intimal proliferation.

Results: All stents on the balloon were successfully deployed with a maximum inflation pressure of 6 or 8 atm within 30 sec. The stent on the balloon easily tracked the normal coronary arteries. No stent migration or side branch occlusions were observed.

Follow-up time	Overdilatation	QCA	Histomorphometry	*
24 hours (n = 17)	19.0 ± 6.5	3.9 ± 3.2	8.7 ± 10.5	0
5 days (n = 8)	16.5 ± 9.4	8.8 ± 4.6	9.4 ± 8.5	0
3 weeks (n = 6)	17.0 ± 12.7	7.1 ± 11.3	32.5 ± 16.2	1
1 month (n = 19)	13.0 ± 11.9	14.0 ± 12.4	43.5 ± 13.2	5
6 months (n = 12)	6.9 ± 18.7	6.0 ± 9.1	28.3 ± 15.7	2

Overdilation: mean ± SD of angiographic overdilation in%; QCA: mean ± SD angiographic diameter renarrowing in%; Histomorphometry: mean ± SD histomorphometric area stenosis in%. The highest angiographic restenosis was 45%. The numbers in the * column indicate the number of arteries where the area restenosis was >50%.

The highest histomorphometric restenosis was 69.77% after a 29% overdilation.

Conclusions: 1) LP Stent has outstanding mechanical characteristics; 2) It can be fully deployed with 8 atm inflation pressure with 30 sec; 3) It induced no angiographic restenosis; 4) The histological proliferation primarily correlates with the original overdilation.

P958 Emergency coronary artery bypass grafting for failed percutaneous transluminal coronary angioplasty: changes with the evolution of coronary stenting

N. Corvaja, M. Ferraro, M. Adamian, T. Nishida, M. Sallam, C. Briguori, L. Di Francesco, M. Vaghetti, G. Martini, B. Castiglioni, R. Albiero, C. Di Mario, A. Colombo. *Centro Cuore Columbus, Milan, Italy*

Acute or subacute vessel closure have been the most common complications requiring emergency coronary artery bypass graft surgery (eCABG) following PTCA. The introduction of coronary stenting and its developments have the potential of changing the need of eCABG for failed PTCA. The purpose of this study was to evaluate the impact of technical and procedural evolutions in stenting on the need and reasons to perform eCABG following PTCA.

Methods and results: From January 1993 through December 1998, at our institution, 58 out of 4213 (1.38%) patients undergoing PTCA required eCABG because of failed PTCA. Stent were used in 2775/4213 (65.8%) of the procedures. Overall indications for eCABG were: 1) coronary, dissection with threatened closure or acute closure in 40/58 (69%) patients; 2) coronary perforation in 12/58 (20.7%) patients; 3) mechanical device failure (device trapping or rupture) in 6/58 (10.3%) patients. The study population was divided in two groups according to the date of procedure: Group A from 1993 to 1996 and Group B from 1997 to 1998.

Results:

	Group A PTCA	Group B PTCA
Total patients w/PTCA	2497	1716
Total procedures w/Stent	1586/2497 (63.5%)	1189/1716 (69.3%)
Overall eCABG rate	52/2497 (2.1%)	6/1716 (0.35%)
eCABG for acute or threat. closure	38/52 (73.1%)	2/6 (33.3%)
eCABG for coronary perforation or device trapping or device rupture	14/52 (26.9%)	4/6 (66.7%)

Conclusions: 1) There has been a decrease in the incidence of emergency CABG for failed PTCA, likely related to the widespread use of coronary stenting and in particular stents of second generation which have made "untreatable" dissection treatable. 2) Presently the indication for emergency CABG has been mainly due to procedural mechanical complications not solvable by transcatheter therapeutics.

P959 Do coronary stents improve clinical outcomes? A retrospective study comparing stent device utilization and adverse outcomes

R.R. Heuser[1], F. Houser[2], S.D. Culler[3], E.R. Becker[3], S.L. Battaglia[2], L. Tarkington[2], A.W. Simon[4]. *[1]Phoenix Heart Center, Phoenix AZ; [2]Columbia HCA, Nashville TN; [3]Rollins School of Public Health, Atlanta GA; [4]BSM Consulting, Tucker GA, USA*

We compared outcomes in two groups of patients who had single and multivessel revascularization (n = 6.671) during 1997 as follows: 1) those who had PTCA (n = 3.097), and 2) those who received stents (n = 3.574) in all treated vessels. Consecutive patients from 32 hospitals in 16 states were studied. Stent patients were significantly less likely to have emergency CABG (p = 0.001) or die during the initial procedure (p = 0.034), but they were more likely than PTCA patients to be treated for hematoma (p = 0.002) and bradycardia (p = 0.004). Further analysis focusing only on stent patients indicated that those patients with adverse outcomes used more devices (including stents) and had smaller stent diameters. Among patients with any adverse events in the 6 months after their initial procedure, the following statistically significant findings were revealed: 1) the total number of devices used were greater in patients who died, underwent CABG, or had an MI, 2) the total number of stents used were greater in patients who underwent CABG or had an MI, 3) the total length of stents used were greater in patients who underwent CABG or had an MI, and 4) the diameter of the stent(s) used were smaller in patients who underwent CABG.

Parameter	No Adverse Outcome	Any Adverse Outcome	p
Total Device Count	6.17 ± 2.38	6.76 ± 2.81	>0.001
Stent Count (only)	1.37 ± 0.71	1.46 ± 0.78	0.014
Total Stent Length	22.50 ± 15.13	25.33 ± 15.13	>0.001
Stent Diameter	3.41 ± 0.41	0.17% ± 4.09	0.005

Our results suggest that device use does, in fact, have an impact on long-term clinical outcomes and that the relationship between device use and adverse outcomes needs additional study.

P960 Mid-term clinical and angiographic outcomes of the España and Portugal NIR stent registry (ESPORT-NIR)

R. Seabra-Gomes[1], E. García[2], P. Bordés[3], A. Iñiguez[4], A. Bethencourt[5], J. Rigla[6]. *For the ESPORT-NIR Registry Investigators; [1]Santa Cruz, Lisbon, Portugal; [2]H. Gregorio Marañon, Madrid; [5]H. General de Alicante; [4]Fundación Jiménez Díaz, Madrid; [5]H. Son Dureta, Mallorca; [6]Clinical BSC, Barcelona, Spain*

Introduction: Coronary stenting has played a major role on coronary angioplasty outcomes. Despite the great development of new types of stents, there is little information about their clinical performance. To assess the efficacy and safety of NIR stent in the treatment of coronary lesions, we undertook a prospective multicenter registry (ESpaña and PORTugal NIR stent registry).

Metods: From Aug 97 to Oct 98, 1004 pts (1136 lesions) were recruited by 50 centers. Inclusion criteria were de novo lesion or first restenosis after balloon angioplasty located in native vessels of ≥2.75 mm reference diameter. Patients with left main disease, recent myocardial infarction (MI), and left ventricular ejection fraction (LVEF) < 25% were excluded. All significant lesions had to be treated with a NIR stent. Primary end-points were major adverse cardiac events (MACE) at 7 months. Angiographic restenosis rate was evaluated from 213 randomly selected patients (237 lesions. Quantitative coronary angiographic analysis was performed in a central core lab by expert technician not involved in the study.

Results: Patients mean age was 61 years, 82% were male, 17% had diabetes. The target lesion was located in the LAD (47%), RCA (32%), LCX (21%). Mean LVEF was 59%. Indication for revascularization was unstable angina in 64%. Clinical success was 99% (angiographic success without in-hospital events). Angiografic restenosis (>50%) rate was 17.3% (12.5%–22.1%). Ranking scale of MACE are summarised below.

	Death	MI	TVR	MACE
1st month	2/1004; (0.2%)	8/1004; (0.8%)	5/1004; (0.5%)	15/1004; (1.5%)
7th month	9/996; (0.9%)	12/996; (1.2%)	66/996; (6.6%)	87/996; (8.7%)

Conclusion: In the wide clinical and anatomical setting of the population included in these registry, NIR stent implantation resulted in a highly effective procedure with a good midterm clinical and angiographic outcome.

P961 Clinical and angiographic results from the Austrian Multilink Duet Stent Registry (AMULET)

P. Yang, G. Heyer[1], J. Aichinger[2], E. Maurer[3], J. Sykora[4], N. Moes[5], O. Pachinger[3], G. Bonner[6], H. Prachar[7], D. Glogar. *On behalf of the AMULET Investigators; Dept. of Cardiology, Univ. of Vienna; [1]AÖLK Salzburg; [2]KH Elisabethinen Linz; [3]KH Wels; [4] AÖLK Klagenfurt; [5]Univ. of Innsbruck; [6]KH Rudolfstiftung, Vienna; [7]KH Lainz, Vienna, Austria*

A prospective multicenter registry was conducted to determine the safety and efficacy of coronary stenting with a new, flexible, balloon-expandable, radiopaque stainless steel stent (ACS Multilink Duet™) and its delivery system.

Methods: The immediate clinical and angiographic results and 30-day follow-up outcomes from 272 pts (62 ± 11 y, 73% male) with 322 Multilink Duet stents in 299 lesions (1.1 stent/lesion) are analyzed. Thirty percent of pts had unstable angina, and 26% had a recent myocardial infarction. Vessel distribution was LAD in 113 (38%), LCx in 52 (17%), RCA in 126 (42%), and SVG in 8 (3%) target lesions, 251 (84%) of which were de novo, 18 (6%) restenotic lesions, and 30 (10%) chronic total occlusions. Lesion morphology was type A in 69 (23%), B1 in 110 (37%), B2 in 69 (23%), and C in 51 (17%) lesions. Median lesion length was 8.08 mm (range 0 to 46.8). Stent indication was elective (68%), suboptimal PTCA (31%), or bailout (1%). Balloon pressure was 13.3 ± 2.3 atm, and the balloon to artery ratio (by QCA) was 1.09 ± 0.12.

Results: Stent deployment was successful in 99% of lesions, with delivery failure in 3 (1%) lesions due to inability to cross the lesion with the stent. Core-laboratory QCA results are summarized in the table below:

	MLD (mm)	Reference (mm)	% Diameter Stenosis
Pre	0.94 ± 0.50	2.79 ± 0.45	66.9 ± 24.6
Post	2.70 ± 0.40	3.02 ± 0.36	10.7 ± 7.6

Acute gain (MLD pre-MLD post) was 1.77 ± 0.56 mm, relative gain (acute gain/reference diameter) 0.64 ± 0.20. Vessel size < 2.75 mm was found in 49% of treated lesions. In-hospital and 30-day clinical follow-up is available in 248 (91%) pts so far, with stent thrombosis in 2 (0.8%) pts and intercurrent re-angio (without re-PTCA) in 3 (1.2%), revealing a 30-day event-free survival of 98%.

Conclusions: Coronary implantation of the Multilink Duet™ stent was associated with a high procedural success rate. Immediate and 30-day outcomes are very promising, despite relatively unfavorable baseline patient demographics and angiographic lesion characteristics.

P962 Cerebral protection for carotid angioplasty and stenting: first clinical experience with new techniques

M. Henry, M. Amor, I. Henry, I. Masson, K. Tzvetanov, A. Polydorou, M. Hugel. *U.C.C.I., Polyclinique, Essey-les-Nancy, France*

Purpose: To study feasibility, safety, indications of cerebral protection during carotid angioplasty with stenting.

Methods: Study of 247 carotid angioplasties performed in 229 high-risk patients with appearance of 11 cerebral embolizations (4.5%) (TIA: 4, minor strokes: 4, major strokes: 3). No death. 90 procedures were performed with cerebral protection. We tried to determine the time of occurrence of neurological accident, to assess its origin and risk factors (age of the patient, severity of the lesion, angiographic and echographic aspect), and the ways to prevent them. 2 main types of stents were used: the Palmaz and the Wallstent stents. 3 cerebral protection devices were used: Theron's technique (n = 47), the PercuSurge GuardWire™ technique (n = 35), and a new technique we developed (n) 8). Angioplasty + stenting were performed under cerebral protection and the dilated area was aspirated and cleaned.

Results: Embolic particles may be created at any time of the procedure. Patients' selection, medication (aspirin, ticlopidin), and the technique itself may reduce embolic risks. The stent is not as sufficient protection. With Theron's technique: neurological complications: 4/47. No complication with the 2 other devices. Advantages and disadvantages of these techniques of cerebral protection will be discussed.

Conclusion: Cerebral embolization remains the major problem of carotid angioplasty. Cerebral protection techniques should reduce its frequency. The 2 new techniques seem easy to use, safe and efficient, and should probably be developed in the near future to enlarge carotid angioplasty indications and render the procedure safer, and an alternative to surgery. Larger studies are expected.

P963 Early symptom-limited treadmill stress testing after intracoronary stenting

Marco Roffi, Giovanni Pedrazzini, Ali Garachemani, Bernhard Meier. *Department of Cardiology, University Hospital Bern,Berne, Switzerland*

Background: Due to concerns of subacute stent thrombosis, early exercise testing is rarely performed following intracoronary (i.c.) stenting. To assess the safety and feasibility of early exercise testing following i.c. stenting, we conducted a prospective trial randomizing patients (pts) to early treadmill stress testing after i.c. stenting or discharge without stress testing.

Methods: A total of 280 pts (232 males, 48 females) undergoing i.c. stenting at the University Hospital of Bern without contraindications to stress testing, were randomly assigned to one of two groups. Pts in group 1 underwent a symptom-limited exercise test the day after stent implantation, whereas pts in group 2 were discharged without prior stress testing. The clinical endpoints were subacute stent thrombosis and vascular access complications. Follow up was done by telephone contact 14 days after the procedure and was complete in all pts.

Results: The two goups were comparable and there was no statistically significant differerence in baseline characteristics or endpoints.

	Group 1 (stress test)	Group 2 (no stress test)	Total
No. of pts	139	141	280
Age (years ± SD)	61 ± 10	61 ± 11	61 ± 11
No. of stents (mean ± SD)	1.3 ± 0.5	1.3 ± 0.3	1.3 ± 0.7
Totall stent length (mm ± SD)	21 ± 12	19 ± 10	20 ± 12
Multivessel PTCA	41 (29%)	32 (23%)	73 (26%)
GP IIb/IIIa antagonist	19 (14%)	13 (9%)	32 (11%)
Subacute stent thrombosis	2 (1.4%)	3 (2.1%)	5 (1.8%)
Vascular access complications	2 (1.4%)	2 (1.4%)	4 (1.4%)

Conclusion: Early symptom-limited stress testing following i.c. stenting is sate and feasible in a general patient population without evidence of an increased incidence of subacute stent thrombosis or complications at the access site.

P964 Differences in restenosis rate in arterial segments with hinge motion points: comparison of different stent designs

J. Cortes, P.S. Phillips, J. Escaned, J. Goicolea, F. Alfonso, M. Alcocer, A. Fernandez-Ortiz, C. Bañuelos, R. Hernandez, C. Macaya. *San Carlos Hospital Interventional Cardiology Unit, Madrid, Spain; Scripps Mercy Medical Center San Diego CA, USA*

Arterial hinge points, defined as coronary segments with angle change > 15° between systole and diastole, have been associated with increased restenosis rate, with independence of the degree of straightening introduced by the stent. It is unclear whether stent desing influences restenosis at hinge points. With this aim, baseline artery angulation, hinge, and their modification by stenting were measured in segments treated with 3 stent designs: Multilink (MLK) n = 107, Bard-XT (XT) n = 71 and Palmaz Schatz n = 121. All patients had angiographic follow-up at 6 months. According to standard definitions of angulation and hinge motion MLK, XT and PS were placed on segments with angle > 45° in 20%, 48% and 33% cases respectively. Arterial angulation was reduced in 3.1 ± 15° by MLK, 8° ± 18 by XT and 11° ± 10° by PS. Relative risk (RR) for restenosis in the presence of each morphologic criterion and p values are shown below.

Morphology	MLK (n = 107)		XT (n = 71)		PS (n = 121)	
	RR	p	RR	p	RR	p
Baseline angle > 45°	0.15	NS	2.32	NS	0.87	NS
Angle change > 15°	0.28	NS	1.75	NS	0.72	NS
Baseline hinge	0.63	NS	2.68	p = 0.03	3.37	p < 0.01
Hinge change > 15°	2.66	NS	2.12	NS	2.42	NS

Conclusions: Stent design influences restenosis rate in coronary segments with hinge motion. Continuous, multicellular designs may be the design of choice in this situation.

P965 Antrin photoangioplasty: results of a phase I trial of a novel therapeutic modality in patients with lower extremity arterial atherosclerosis

P. Kramer, S. Rockson[1], M. Razavi[1], D. Adelman[2]. *MidAmerica Heart Institute, Kansas City MO; [1]Stanford University Medical Center, Stanford CA[2]Pharmacyclics, Inc., Sunnyvale CA, USA*

Lutetium Texaphyrin (Antrin) is a photesensitizing expanded porphyrin that is avidly taken up by atheromatous plaque. The safety, tolerability, and preliminary efficacy of Antrin photoangioplasty (PA) was assessed in a Phase I dose-ranging clinical trial in patients with claudication due to atherosclerotic stenosis of the iliac or superficial femoral arteries. Antrin was given IV over 5 min at doses of 1, 2, 3, 4, or 5 mg/kg. Photoillumination with laser-generated far-red light at 732 nm was performed using an optical fiber with a 3 cm diffusion tip centered over the target lesion at fluence rates of 425, 531, 664, or 830 mW/cm. Pharmacokinetics were assessed with timed plasma sampling. Quantitative angiography and intravascular ultrasound (IVUS) of the target lesions were performed at baseline and 28 days after treatment. Doses of drug and light were escalated in cohorts of 3 pts. In the absence of dose-limiting toxicity, drug or light doses were increased in subsequent cohorts. To date, 34 pts have been enrolled, and follow-up angiography and IVUS have been completed and analyzed in 23. In 15 (65%) of these 23 pts, there was >10% improvement in MLD or cross-sectional area by quantitative angiography and IVUS, respectively. There have been no major symptomatic, angiographic, or biochemical adverse effects of Antrin PA.

Conclusions: These preliminary results strongly suggest that Antrin photoangioplasty is a novel, safe, well-tolerated, nontraumatic, and effective treatment for atherosclerotic obstruction of the iliac and superficial femoral arteries. The results of the completed trial will be presented.

P966 Influence on stent design in restenosis rate: randomized comparison between the ACS multilink stent and the new AVE-stent (GFX)

Y. Yoshitomi, S. Kojima, M. Yano, T. Sugi, Y. Matsumoto, M. Saotome, M. Endo, M. Kuramochi. *Cardiology, Tohsei National Hospital, Shizuoka, Japan*

Background: Several new designs have been developed to improve reliability, flexibility and visibility. It is not known, however, whether the specific stent design affects reduction of restenosis rate. We have been evaluated the angiographic and clinical outcomes of the AVE-Stent (GFX) and the Multilink stent (ACS).

Methods: Consecutive patients with new and restenotic lesions underwent stent implantation under IVUS guidance were randomly assigned to either GFX (n = 51) or ACS (n = 50) from Jan. 1998. Restenosis was defined as a > 50% diameter stenosis at follow-up.

Results: Stable angina was 72% and acute coronary syndrome was 28%. Baseline and clinical characteristics were similar between the 2 groups. QCA showed similar reference vessel diameter (GFX; 3.15 ± 0.58 vs ACS; 3.14 ± 0.46 mm), pre-procedural MLD (0.45 ± 0.39 vs 0.50 ± 0.38 mm), post-procedural MLD (2.94 ± 0.52 vs 2.94 ± 0.44 mm), pre-procedural%DS (85 ± 12 vs 82 ± 12%), post-procedural%DS (8 ± 12 vs 7 ± 10%), and acute gain (2.49 ± 0.56 vs 2.37 ± 0.48 mm) (all p = NS). Delivery failure was 0%. Patients were treated with ASA (243 mg/day) and Cilostazol (200 mg/day). Acute and subacute closure occurred in 1 patient in GFX group and 1 patient in ACS group. Until Feb. 1999, early FU QCA was available on the first 68 patients. FU MLD was larger in ACS group than in GFX group (2.50 ± 0.61 vs 2.12 ± 0.81 mm, p = 0.03). Late loss was larger in GFX group than in ACS group (0.99 ± 0.78 vs 0.50 ± 0.39, p = 0.001). Restenosis rate was higher in GFX group than in ACS group (8/32; 25% vs 1/36; 3%, p = 0.01).

Conclusion: We demonstrate that post angiographic results with GFX are comparable to ACS. Stent design, however, affects intimal hyperplasia and restenosis rate.

P967 Magic5I study: a prospective multi-center study to evaluate the safety and influence of 5 different stent lengths of the Magic Wallstent on the occurrence of restenosis

David Foley[1], Michael Pieper, William Wijns, Harry Suryapranata, Gilles Grollier, Victor Legrand, Ivan De Scheerder, Claude Hanet, Jeroen Kleijne, Patrick W. Serruys. [1]*Thoraxcenter Rotterdam, Netherlands*

The purpose of this study was to evaluate the safety and efficacy of 5 different lengths of the self-expanding Magic Wallstent in native coronary lesions up to 45 mm in length, in terms of freedom from MACE and angiographic restenosis at 6 months. Also influence of actual stent length on outcome would be studied. Between 17 Sept 1997 and 23 Oct 1998, 277 pts with 312 lesions were included, 36 treated by MiniMagic[Mini] (10 mm), 67 by Extra-short[ES] (15 mm), 74 by short[S] (24 mm), 59 by medium[M] (32 mm), 49 by long[L] (48 mm) and 27 by a combination of these stents or other stents. Data collection and analysis was carried out at an independent core-laboratory. Mean age was 61 years, 79% of pts were male, 42% had prior MI, 14% were diabetic. Indication for stenting was unstable angina in 49%. Target vessel was LAD in 31%, CFX in 15% and RCA in 53%. Lesion type was 82 or C in 70%. Stenting was successful (reduction of stenosis to <20% by on-line quantitative angiography) in 98.6%. Mean vessel diameter was 3.02 ± 0.53 mm, lesion length (LL) 11.9 ± 9.07 mm, minimal luminal diameter pre 0.92 ± 0.38 mm, increasing to 2.62 ± 0.32 mm post, giving a mean diameter stenosis post of 17 ± 6%. In-hospital MACE occurred in 5.7% (0.8% q, 3.0% non-q MI and 1.9% re-PTCA). Post-stent therapy was aspirin and ticlopidine 250 mg daily for 1 month. There were no major bleeding events. Mean hospital stay was 1.7 days. At this time, 264 pts (96%) have completed 6 month clinical follow up and 25.4% have experienced MACE (1.9% death, 1.1% q and 3.8% non-q MI, 1.1% CABG and 17.4% re-PTCA (of whom 53% during routine follow up angiography). In single stent procedures a Mini was implanted in 28 pts (mean LL = 7.80 mm), ES in 47 pts (mean LL 9.29 mm), S in 57 pts (mean LL = 13.45 mm), M in 49 pts (mean LL = 24.0 mm) and L in 41 pts (mean LL = 33.36 mm). Event free survival at 6 months was respectively 86%, 83%, 83%, 71% and 66% (Fisher exact, p = 0.014). Angiographic follow up will be completed April 1999.

Conclusion: The Magic Wallstent may be safely implanted with excellent acute and in-hospital results in patients with unstable as well as stable angina, in lesions from 4.44 mm to 54.27 mm in length and vessels from 1.84 mm to 4.27 mm in diameter. At 6 months, infarct free survival was 97% and survival free of all MACE was 74.6%. MACE were more frequent in pts with longer stents, partly related to more adverse lesion characteristics.

P968 A randomised comparison of the handcrimped Palmaz-Schatz and NIR stents: the DANSTENT study

H. Kelbæk, E. Jørgensen, J. Kastrup, K. Saunamäki, S. Helqvist, L. Thuesen, L. Kløvgaard, G. Jensen, J.K. Madsen. *Rigshospitalet and Skejby Sygehus, for the DANSTENT study group, Copenhagen, Denmark*

Background: The Palmaz-Schatz (PS) is the only stent that has been shown to be superior to balloon angioplasty with regard to clinical outcome and development of restenosis in larger trials.

Methods: The DANSTENT study is a randomised, multicenter trial comparing the procedural, clinical and angiographic outcome of implantation of the PS 153 and the 16 mm NIR stents in de novo coronary artery lesions. All stents were handcrimped onto the balloons and deployed at high pressures in 232 patients, 73% men, aged 59 (40–82) years with predominantly stable (80%) angina pectoris.

Results: Approximately 10% of the patients had diabetes, 24% hypertension and 75% were current or previous smokers. CCS class 1–2 and 3–4 stable angina pectoris were recorded in 55% and 25%, respectively, while 13% had unstable angina and 7% silent ischemia. Thirty percent of the patients had multivessel disease, and 78% of the lesions were type B and C (47% located in LAD). Deployment success was 98% and 100% for the PS and NIR stent, respectively, at similar mean pressures, 15.1 and 15.7 atm (NS).

	PS	NIR	P
Pre-PTCA, n = 232			
Reference diameter, mm	3.02 (0.58)	3.09 (0.57)	NS
Minimal luminal diameter, mm	0.94 (0.45)	0.87 (0.50)	NS
Diameter stenosis, %	68.4 (14.0)	71.4 (15.4)	NS
Post-PTCA, n = 232			
Reference diameter, mm	3.35 (0.54)	3.38 (0.51)	NS
Minimal luminal diameter, mm	2.88 (0.47)	3.01 (0.49)	0.07
Diameter stenosis, %	14.3 (5.8)	11.3 (5.7)	0.01
Follow-up (6 months), n = 150			
MACE (death, AMI, TLR), %	15.5	17.7	NS

Conclusion: Although deployed at the same pressure the immediate minimal luminal diameter in coronary artery lesions treated with a PS 153 stent tended to be smaller and the residual stenosis was slightly but significantly more pronounced. This difference does not seem to affect the clinical outcome. Core lab quantitative coronary angiography at 6 months will be available in approximately 90% of the patients.

P969 The STOP study: a randomized multicenter Israeli study for Stents in Total Occlusion and restenosis Prevention – final report

C. Lotan, A. Hendler, Y. Turgeman, O. Ayzenberg, R. Beyar, E. Disegni, Y. Almagor, I. Tamari, Y. Ben-Horin, A. Bakst, B. Peled. *Israel Working Group for Interventional Cardiology; Cardiology, Hadassah Hospital, Jerusalem, Israel*

Background: Several studies have noted an increase in restenosis and re-occlusion rates in-patients undergoing balloon angioplasty for chronic total occlusion. To assess whether stent implantation decreases restenosis rates, we organized a multi-center randomized study to assess the benefit of additional coronary stenting in chronic (≥10 days) occluded coronary arteries.

Methods: After obtaining optimal PTCA results, patients were randomized either to no further treatment or additional stent implantation. The AVE Microstent was used in all patients and all were expected to undergo 6-month angiographic follow-up to assess restenosis.

Results: Ninety-six patients have been enrolled in this study. The mean age was 59.3 ± 10.3 years and 16 were females. Forty-eight patients were randomized to the stent arm, receiving 51 stents (lengths 18–39 mm) with no procedure related major complications. Sixty-nine patients (72%) were catheterized at 6 months. Restenosis rate in the PTCA group was 71% with MLD of 1.01 ± 0.79 mm compared to 42.1% in the stent group with MLD of 1.63 ± 1.02 mm (p = 0.03).

Reocclusion occurred in 7.9% in the stent group compared to 16.1% in the PTCA group. Interestingly, in 90% of the patients, restenosis occurred exactly at the point of total obstruction (within 5 mm).

Conclusion: Coronary stenting can significantly decrease the rate of restenosis and reocclusion in total occlusions. Care should be taken to implant short stents at the occlusion site.

P970 Randomized comparison of four different stent designs in 1,000 stenoses

P. Sick, G. Zindler, R.J. Zotz, H. Krankenberg, A. Kuhn, K.W. Diederich, B. Lauer, R. Hambrecht, O. Brosteanu[1], G. Schuler. *University of Leipzig, Heart Center; [1]Institute for Medical Informatics, Statistics and Epidemiology; Leipzig, Germany*

Background: Primary success rate, incidence of early complications (myocardial infarctions (MI), CABG, death, stent thrombosis) and long term results may be influenced by stent design.

Methods: In a prospective randomized trial four different stent designs (Micro II, AVE; Sito, Sitomed; Pura vario (PuVa), Devon Medical; Inflow Inflow Dynamics) were compared in 1000 stenoses of 926 patients with respect to primary success rate, incidence of complications and angiographical long term results after 6 months. A total of 1345 stents were implanted. Increase of %-stenosis was analyzed by quantitative coronary angiography (QCA) after stent implantation and at follow up.

Results:

	Micro	Sito	PuVa	Inflow	p-value
Primary success rate	98.9	98.1	96.7	95.2	0.08
Stent loss rate	0	0.7	0	1.8	0.04
Multiple stents	21.1	23.4	28.9	26.7	0.21
Stent thrombosis	0	1.1	1.5	1.1	0.47
MI, CABG	0	0.7	1.1	1.8	0.26
Death	0.5	0.7	2.6	2.2	0.19
Δ% stenosis [median]	33.2	29.1	29.5	27.1	0.40
restenosis rate	27.2	30.3	33.3	29.6	0.64

Conclusion: Irrespective of design, a very high rate of primary success with few early complications was achieved with all stents employed in this study. Although there was a tendency to less restenosis and less complications with the sine wave design (AVE Micro II), the difference was not significant. Thus the design of these 4 stents has no influence on procedural success rate, early complications and long term results.

P971 Can we use only one stent design in order to treat all types of coronary stenosis? In-hospital and 6-month results

Y. Chalet, J.R. Kieny, J.M. Sommier, D. Legutke, Y. Pagano, P. Lang, C. Sussmann, G. Courdier, C. Leiber, P. Arnold, J. Diesel. *Fondation Lucien Dreyfus, Fondation du Diaconat, Mulhouse, France*

The aim of this study was to evaluate the polyvalence of the DUET coronary stent in real practice.

Methods: we have prospectively evaluated the safety and efficacy of 400 DUET coronary stent which were consecutively implanted in 263 pts (61 ± 13 years, 28% women) including 381 lesions. All pts received ticlopidin and aspirin.

Results: clinical indications were acute coronary syndrome in 69% (unstable angina and myocardial infarction), stable angina in 19% and silent ischemia in 12% of pts. Revascularization was complete in 67% of pts. Lesions were type B/C in 68%, collateral branches were included in stent cells in 31%, bifurcation lesions were treated in 9.2% and ostial lesion in 12.8% of cases. The mean lenght of stent was 17.9 ± 6.1 mm, the mean diameter was 3.25 ± 0.31 mm and the mean inflation was 12 ± 2 atm. Technical success rate was 99.2%. Major adverse cardiac event occurred in 2.2% of pts (2 death in the setting of acute MI and 4 non Q-wave MI). There was no stent-related death, Q-wave MI, CABG or repeated PTCA. At 30 days there was one episode of stent thrombosis (0.38% of pts). Clinical 6-month follow-up was complete for the first 114 pts (173 stents) recurrence of angina and/or a positive stress test occurred in 13 pts (11.4%), 11 were treated by repeated PTCA and 2 by CABG.

Conclusion: a specific design give to the DUET coronary stent a polyvalence which allow, in real practice, to treat all types of coronary lesions with safety and efficacy.

P972 Clinical and angiographic outcome after implantation of the new coronary C1-stent in patients with coronary heart disease

W. Haberbosch, A. Rolff[1], M. Rau[1], M. Maikowski[1], H. Tillmanns. *University Giessen, Dpt. of Internal Medicine, Cardiology; [1]Kerckhoff-Klinik Bad Nauheim, Germany*

Introduction: The purpose of this study was to randomly compare the effect of low (8–10 atm) and high (14–16 atm) pressure implantation of C1-stents in 150 patients with single- or multivessel disease. In addition we planned to perform directional coronary atherectomy (DCA) of each in-stent restenosis (ISR) to compare tissue characteristics of the different lesions.

Methods and Results: QCA was performed using the Cardiovascular Measurement System, Medis, NL. Unpaired t-test was used for statistical evaluation. Until now, follow-up angiography was available in 84 pts. treated with high (HPI, n = 42) or low (LPI, n = 42) pressure stent implantation. Risk factors and angiographic parameters of the treated lesions were equally distributed in the two groups. Angiographic re-evaluation was performed 6 months after the intervention. In the total study population 20 pts. (23.8%) had ISR, 13 (31%) in the LPI group and 7 (16.7%) in the HPI group (p = 0.059). Acute results and in-hospital complications were the same in both groups.

	Low pressure	High pressure
Minimal luminal diameter before stent (mm)	0.66 ± 0.71	0.77 ± 0.63
Minimal luminal diameter at follow-up (mm)	1.79 ± 1.06	2.00 ± 0.79
Acute gain (mm)	2.39 ± 0.63	2.50 ± 0.78
Late lumen loss (mm)	1.33 ± 0.92	1.09 ± 0.86

(All values are given in number ± standard variation), all differences were not significant.

Conclusion: Implantation of the new C1-stent is safe and results in an excellent angiographic and clinical outcome. High pressure implantation is recommended.

P973 NIR stenting registry: retrospective observation on immediate results and clinical follow-up in 709 patients

Alberto Cremonesi[1], Alessandro Alberti[2], Fausto Castriota[1], Enrico Ricci[1], Bilal El Jamal[1], Chiara Grattoni[1], Raffaella Manetti[1], Cristina Nannini[2], Claudia Filippini[3]. *[1]Villa Maria Cecilia Int. Cath. Lab., Cotignola (Ravenna); [2]Villa Maria Pia Int. Cath. Lab., Torino; [3]Centro studi cardiologia interventistica, Torino, Italy*

Background and Objectives: The NIR stent is an expandable cellular coronary prosthesis with high flexibility and excellent trackability. The very low crossing profile, associated to the high flexibility, makes this stent suitable for complex and distal lesions. The aim of this study was to evaluate the feasibility, safety and long term (clinical follow-up) efficacy of elective and/or urgent deployment of the NIR stent in a broad patient group with coronary artery disease.

Method: Between June 1996 and May 1997, n. 986 NIR STENTS were implanted in 781 vessels (de novo or restenotic lesions in native vessels, saphenous vein grafts and internal mammary conduits) of 709 consecutive patients (498 men, 211 women) undergoing coronary angioplasty in two Villa Maria Group Catheterization Laboratories.

Results: Procedural angiographic success was achieved in 98.4% of all the lesions treated, ranging from 100% success rate in type A lesion to 97.6% in type C lesions (overall procedural success 98.4%). Major cardiac complications (MACE) were considered from PTCA/stenting time to the patient discharge. The in-hospital MACE were limited and occurred in 15 patients: urgent CABG 0.8%, death 0.7%, sub-acute stent thrombosis 0.5% (overall in-hospital MACE rate 2.1%). Clinical follow-up data were obtained at 8.6 ± 2.8 months in 645 (92.4%) of the eligible patients. The event free survival rate was 88.3%. The late MACE rate evaluation showed death 1.2%, AMI 0.6%, TVR 9.8% (overall late MACE rate 11.7%).

Conclusion: The NIR stent performances in this broad patient population were excellent, showing very high procedural success rate both in normal and complex coronary anatomy. On the basis of the previous data, we can define NIR stent a safe multifunctional device suitable both for easy and complex situations. The clinical late results are very promising in term of event free survivals and late MACE.

P974 Multicenter evaluation of the ACS RX MULTI-LINK DUET™ coronary stent system in native de novo coronary lesions: the DUET study

J.A.M. te Riele[1], J.J. Piek, H. Mudra, J. Schofer, M. Bertrand, W. Rutsch, P.W. Serruys[2], J.A. Beekman, S. Veldhof. *On behalf of the DUET Study investigators; [1]Medisch Centrum 'De Klokkenberg', Breda; [2]Thorax Center, Rotterdam, Netherlands*

The DUET Study is a multi-center prospective efficacy and safety evaluation of the ACS MULTI-LINK™ coronary stainless steel, balloon expandable stent.

Aim: Primary objectives were to determine the one-month incidence of MACE (Major adverse cardiac events). The secondary objectives were the acute success rate, the restenosis and reocclusion rates (assessed by QCA) at six months and the occurrence of MACE in hospital and at six months.

Methods: 210 patients were enrolled between February and June 1998 in 18 European centers. Successful stent placement was achieved in 209 patients. All patients were treated with ticlopidine 250 mg/day for one month and with aspirin ≥100 mg/day. To allow the investigators to gain familiarity with the stent system, the first one to three patients per center formed a separate lead-in population leaving an intention-to-treat population of 157 patients.

Results: 79% of the intention-to-treat population was male, 28% had unstable angina, 69% had stable angina, 44% had a previous MI, 15% had a previous PTCA, and 3% had an history of stroke. The target vessel was 39.7% LAD, 20.6% LCX and 39.7% RCA. All of the intention-to-treat patients but one were effectively stented (17 required multiple stenting). Minimal lumen diameter (MLD) post-procedure was 2.61 ± 0.33 mm, with a residual diameter of stenosis of 16%. Preliminary follow-up data showed a MLD of 1.88 ± 0.55 mm with a residual diameter stenosis of 36%. The binary interpolated restenosis rate (≥50% residual stenosis) was 14.7%. Mean in hospital stay was 3 ± 4 days. Up to discharge 3.8% of the patients experienced any MACE (all MI). In addition there was one incidence of subacute occlusion. Up to one month two additional patients underwent revascularisation, resulting in a MACE-free population of 94.9%. 86% of the patients were angina free at one month. Final six-month angiographic and clinical data will be available by April 1999.

P975 Determinants and Implications of late expansion in coronary wallstents: an intravascular ultrasound study

M. Sanmartin, J. Goicolea, F. Alfonso, J. Escaned, R. Hernandez, C. Bañuelos, A. Fernandez-Ortiz, C. Macaya. *Unidad de Hemodinámica y Cardiología, Intervencionista, Hospital Clínico San Carlos, Madrid, Spain*

The self-expandable nature of the Wallstent (WS) has been shown to result in late Stent expansion (LE) and a greater neointimal growth. However, the determinants and final implications of LE have not been established. Accordingly, we have reviewed all our native coronary WS implanted in our Unit in which an intravascular ultrasound (IVUS) study with automatic pullback was available both at baseline, at the end of the procedure and at follow-up (FU). Each WS was divided in cross-sections at 2 mm intervals, which were considered independently and carefully matched at each situation, using both the aorto-ostial junction and fixed landmarks. IVUS dimensions as well as plaque and procedural data were included in the analysis. A total of 11 WS in 11 patients were studied (5 LAD, 2 LCX, 4 RC), with diameters from 4 to 5.5 mm (mean = 4.5), and lengths from 17 to 33 mm (mean = 23 mm), allowing for a total of 166 cross-sections to be compared. Multiple linear regression analysis was performed.

At FU, LE was present in 93% of the sections analysed, with a mean of 2.0 $mm^2 \pm 1.9$ (post-implantation Stent area 7.1 ± 1.2 and FU Stent area 9.1 ± 2.1; $p < 0.001$), and a corresponding decrease in the total Stent length from 29 ± 9 to 27 ± 8 mm, $p < 0.001$. LE was greater in non calcified segments. LE was larger in the proximal portion with a stepwise decrease to the mid and distal thirds, and was positively and independently associated with Stent oversizing. Neointimal proliferation at FU was positively associated with LE ($r = 0.63$; $p < 0.001$), even after adjusting for plaque area, minimal area or area gain. Late loss in luminal area, however, showed an inverse relation to LE (β [adjusted] = −0.3, 95% CI: −0.451/−0.15).

Conclusions: LE is a common phenomenon after WS, especially in non-calcified segments, and is mainly determined by Stent oversizing. Despite the fact that it is associated with greater neointimal proliferation it seems to have a net beneficial effect on luminal loss.

P976 Arterial wall stretch due to stent implantation: an additional predictor for major adverse cardiac events

M. Gyongyosi, P. Yang, D. Glogar. *The Austrian Wiktor Stent Study Group and the Paragon Stent Trial Investigators; Division of Cardiology, 2nd Department of Internal Medicine, University Medical School of Vienna, Austria*

Stent deployment on tortuous vessel straightens the artery, and consequent arterial wall stretch may contribute to major adverse cardiac events (MACE).

Methods. Clinical (age, sex, coronary risk factors, unstable angina, restenotic, type C and LAD lesions) and angiographic data (stent diameter, maximal stent-balloon pressure, balloon/artery ratio, stenosis length, acute lumen gain /ALG/, late lumen loss /LLL/; pre-, post-stent and follow-up /FUP/ minimal lumen diameter /MLD/, reference diameter, %diameter stenosis /%DS/ and vessel angulation /determined as the angle defined by the tangents of proximal and distal parts of the stenosis or stents/) on 404 patients with single stent implantation were analysed to multivariate nominal logistic regression analysis for prediction of MACE. The predictive accuracy, sensitivity and specificity values and cut-off points of the continuous variables were determined by using receiver operating characteristics curves.

Results The best predictive accuracies and sensitivities/specificities of factors indicating MACE were found for MLD-FUP ≤ 1.7 mm (0.9305, 86.6%), post-stent MLD ≤ 2.63 mm (0.773, 77.2%), %DS-FUP ≥ 42.2% (0.9432, 87.1%), ALG ≤ 1.523 mm (0.6280, 60.9%), LLL ≥ 0.99 mm (0.7680, 69.4%), pre-stent vessel angulation ≥ 33.5° (0.6797, 68.2%) and post-stent changes in vessel angulation ≥ 9.1° (0.6279, 62.2%). Multivariate analysis demonstrated post-stent MLD, MLD at FUP, %DS, acute lumen gain, late lumen loss, pre-stent vessel angulation and post-stent changes in vessel anqulation as significant predictors for MACE (table).

	p (multivariate)	Odds ratio	95% CI (odds ratio)
Post-stent MLD	0.0376	2.116	1.242–3.605
MLD-FUP	0.0021	20.286	10.447–39.394
%DS-FUP	0.005	41.795	19.57–89.258
Acute lumen gain	0.0402	1.743	1.026–2.963
Late lumen loss	0.0064	8.186	4.483–14.95
Pre-stent vessel angulation	0.0327	1.721	1.013–2.925
Post-stent changes in vessel angulation	0.0319	1.774	1.043–3.017

Conclusions. Permanent arterial stretch due to changes in vessel angulation after stent implantation contributes significantly to the occurrence of MACE, and this finding may have an impact on the future stent design.

P977 Value of signal-averaged electrocardiogram to predict the state of patency of the infarct related artery

A. Barragán, A. Dominguez, M. García, J. Lacalzada, F. Marrero, I. Laynez, F. Bosa, A. Lara, A. Duque, M. Rodriguez, M. Rayo, D. de Armas. *Hospital Universitario de Canarias; La Laguna; Tenerife; Canary Islands, Spain*

After myocardium infarct (MI) the presence of ventricular late potentials determines a major risk of ventricular arrhythmias, and it has been documented that an effective thrombolysis limits its development. This low amplitude and high frequency signals presents in the last 40 mseg. of the QRS are generated in small areas of myocardium that had different electrophysiological properties than the surrounding tissue. The changes in the electrical conditions are related with the state of permeability of the responsible artery after a MI and could be an important prognostic factor. In our study we trayed to evaluate the test for the determination of late potentials as a method to predict the state of patency of the infarct relatect artery.

In 106 patients with acute MI, three determinations of late potentials where performed with time domain averaging technique and with the filters of 25, 40 and 80–250 Hz, at 24, 72 and 144 hours of the beginning of the symptoms. In all patients coronarigraphy was done, that let to classify them in two groups. Group I includes patients with TIMI 0–1 (obstruction completes or minimum flow in the responsible artery), group II includes patients with TIMI 2–3 (open artery with filling complete and rapid).

The group I had a longer filtered QRS and duration of the terminal potential under 40 uV and lower root mean square voltage of the last 40 msec with all the filters employed. This correlation was stronger with the later studies.

The signal-averaged electrocardiogram has the ability to predict whose patients had a patent vessel post MI and it could be used to predict the thromboysis therapy success.

P978 Reuse of intracoronary ultrasound catheters in the age of cost containment: safety and efficiency study

R. Babic, M. Ostojic[1], G. Stankovic[1], S. Stojkovic[1], B. Beleslin[1], M. Nedeljkovic[1], J. Saponjski[1], V. Vukcevic[1], A. Djordjevic-Dikic[1], J. Stepanovic[1]. *Cardiovascular Research Center, Dedinje Cardiovascular Institute, Belgrade; [1]Cath Lab, Institute for Cardiovascular Diseases, Belgrade, Yugoslavia*

Reuse of medical devices labeled for single use, such as electrophysiology, angioplasty and diagnostic catheters, is known to be performed in numerous institutions. However, potential reuse of intracoronary ultrasound (ICUS) catheters is still controversial. Thus, purpose of the study was to evaluate whether reuse of ICUS catheters is feasible, safe and efficient.

Methods: 15 new ICUS catheters (3.5F, 20 MHz, mechanically rotating) were applied in consecutive pts for up to 3 times each, comparing results of brand-new devices with reused ones. On angiography all pts had nonocclusive coronary lesions of simple morphology. Following the use, ICUS catheters were decontaminated in ultrasound chamber, rinsed, dried by compressed air and sterilized with ethylene oxide. Prior to reuse, physical testing and quality assurance was performed. Informed consent for catheter reuse was provided from all pts.

Results: By described reuse strategy, 41 pts could be successfully studied overall, applying 15 new ICUS catheters (2.7 pts/catheter). For the new devices successful positioning at desired vessel site was achieved in 15/15 pts; acquired image quality was classified as optimal in 15/15 pts. For the first reuse 14/15 catheters were selected, since 1 failed to pass mechanical performance testing; successful positioning was in 14/14 pts; image quality was optimal in 13/14 pts and suboptimal in 1/14 due to the moderate image degradation (particular catheter was withdrawn from subsequent use). For the second reuse successful positioning was in 12/13 pts; image quality was optimal in 12/12 pts. Unsuccessful vessel negotiation in 1 case was due to decreased ICUS shaft pushability, requiring introduction of new device. There were no acute procedure related complications in all studies. None of pts developed fever, chills or hypotension following the procedure.

We conclude that, by meticulous cleaning, sterilization and testing, ICUS catheters can be safely reused in patients with noncomplex coronary lesions, retaining proper imaging characteristics. For communities with limited resources such approach may further expand utilization of this high tech procedure.

EXPERIMENTAL ISCHAEMIA AND REPERFUSION

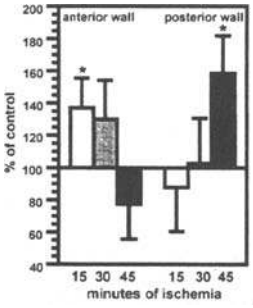
P979 Acute myocardial infarction: regulation of protein kinase C in the non-ischaemic area of the infarcted heart

M. Kirrstetter, M.U. Braun, R. Ihl-Vahl, S. Schön, R.H. Strasser. *Department of Cardiology, Medical Center, University of Heidelberg, Germany*

It is not known if regional myocardial infarction may modulate cell signaling in the non-ischemic area of the infarcted heart. Such mechanisms in the remote area might contribute to remodelling processes involving proliferation and hypertrophy. Protein Kinase C (PKC), a central enzyme in cell signaling which mediates hypertrophy, has been shown to be activated and subjected to an increased subtype-selective expression in the ischemic zone after acute myocardial infarction.

To address the question if regional infarction may promote an enhanced expression of PKC also in the remote area, the mRNA expression of one of the dominant isoforms of PKC, PKC-ε was investigated at various times (15, 30, 45 min) after LAD ligation in rat hearts in situ and compared to sham-operated controls. Quantification was performed using quantitative RT-PCR with internal and external standards.

Results: In the ischemic zone (anterior wall, fig.), a rapid increase of PKC-ε mRNA already after 15 and 30 minutes of ischemia was observed (n = 7, *p < 0.05, fig.). An even more pronounced increase of mRNA for PKC-ε was characterized in the non-ischemic zone of the infarcted heart. In contrast to the ischemic zone, this increase occurred significantly later (after 45 min, fig.).



Conclusions: These data characterize for the first time a subtype-specific regulation of PKC expression in the remote zone of the infarcted heart, suggesting a modulation of cell signaling even at a distance to the infarcted area which may contribute to remodelling processes.

P980 Differential gene regulation in early myocardial infarction: analysis of complex expression patterns using PCR-select cDNA-subtraction

S. Gielen, V. Adams, R. Hambrecht, C. Lenk, H. Jiang, G. Schuler. *Heart Center, University of Leipzig, Dept. of Cardiology, Leipzig, Germany*

Until recently the analysis of gene regulation in myocardial infarction was focused on a limited number of gene products. However, it is generally accepted that ischemia induces complex patterns of gene expression involving more than one signaling pathway. We tested the new method of PCR-select cDNA-subtraction in an animal model of myocardial infarction to assess the potential of in vivo analysis of differential gene expression.

Methods: In 3 male Wistar-Kyoto rats (250 g) the proximal LAD was ligated to induce an anterior myocardial infarction (MI). Three age and sex-matched sham-operated animals served as controls (C). Sixty minutes after coronary artery ligation the heart was removed and samples from the non-infarcted posterior left ventricular wall (PW) and from the same area of sham-hearts were snap-frozen. Messenger RNA was isolated from pooled MI- and C-tissue and reverse transcribed into cDNA. MI- and C-cDNAs were marked with different cDNA-adapters. After two hybridisation steps and PCRs differentially expressed sequences were amplified, sequenced, and identified using the NIH-Gene Bank.

Results: In the non-infarcted PW 53 differentially regulated genes have been identifed so far -24 were upregulated, 29 downregulated. In addition to sequences of proteins of the JAK-Stat-pathway, heat shock related protein, myosin light chain, and the adenin nucleotide translocator other proteins with so far unknown functional significance during ischemia have been identified: i.e. Annexin and zinc-finger proteins.

In conclusion, the new method of PCR-select c-DNA subtraction permits the in vivo analysis of complex pathogenic gene expression patterns and has the potential to identify new unkown co-regulated proteins.

P981 The inhibition of the extracellular-regulated kinases by PD 098.059 creates a complete cancellation of the ischaemic preconditioning-induced cardiac protection

C. Strohm, M. Barancik[1], S.A.R. Kilian, W. Schaper. *Max-Planck-Institute, Bad Nauheim, Germany; [1]Institute for Heart Research, Slovak Academy of Science, Bratislava, Slovakia*

There is a protective role of the the extracellular-regulated-kinases (ERK) on ischemic preconditioning (IP), which is indicated through our previous results. We studied the influence of ERK inhibitor PD 098.059 in IP, to test the hypothesis.

Methods: The experiments were carried out in 11 anesthetized, ventilated, open chested, male castrated pigs using the specific MEK1/2-inhibitor (PD 50 μM in KHB and DMSO 1 μl/ml). An intramyocardial infusion (20 μl/min), via three pairs of needles, injected the substance in the risk area (RA) during 15 min. The experimental design included 2 cycles of 10 min LAD occlusion and 10 min reperfusion as IP and followed by a 40 min occlusion/60 min reperfusion cycle, as Index ischemia. In each experiment a parallel infusion of the solvent was performed as a control. In an additional control group with no drug application the infarct size was determined. Biopsies of the area of infusion were taken after the second reperfusion. With western-blot analysis the phosphorylation of the ERK and Elk-1 was ascertained and with in-gel-phosphorylation (IGP) the activity of the ERK was tested.

Results: No infarcts were detected in the control group with the experimental design of IP using 40 min index ischemia. In the area of the PD-infusion significant wedge-shaped infarcts could be seen. In the rest of the RA no infarcts occurred, even in the area of solvent infusion. The western-blot analysis showed a decrease of the phosphorylation of ERK as well as their substrate Elk-1 after PD infusion. The result of IGP showed, that PD inhibited the ERK-1 activity (49.9 ± 6.5%) and ERK-2 (56.2 ± 4.3%) refer to DMSO as control.

Conclusion: Our experiments demonstrate that the use of the MEK1/2-inhibitor PD 098,059 results in a blockade of IP in vivo. These datas prove the important role of the ERK in IP.

P982 Ebselen protects the heart against ischaemia-reperfusion injury in rabbits

S. Hoshida, J. Tanouchi, Y. Yamada, N. Yamashita, T. Kuzuya, M. Hori. *Division of Cardiology, Osaka Rosai Hospital, Sakai, Osaka; First Department of Medicine, Osaka University School of Medicine, Suita, Osaka, Japan*

Ebselen is a selenoorganic compound that has exhibited multifunctional actions such as antioxidant capacity and anti-inflammatory effects. We previously reported the cardioprotective effects of this agent in canine ischemia-reperfusion injury but the treatment was started before coronary occlusion (Am J Physiol 267: H2342, 1994). In the present study, we evaluated the effects of ebselen on infarct size using a rabbit coronary artery occlusion-reperfusion model of myocardial infarction when treated immediately before coronary reperfusion.

Methods: In male Japanese white rabbits (n = 29), the branch of left coronary artery was occluded for 30 minutes and was reperfused for 48 hours. Rabbits were randomized for treatment with ebselen (n = 19) or its vehicle (n = 10); ebselen was administered 5 minutes before coronary reperfusion (1 mg/kg bolus + 1 mg/kg iv for 60 minutes, n = 10, Ebselen-L; 2 mg/kg bolus + 4 mg/kg iv for 60 minutes, n = 9, Ebselen-H). Infarct size was assessed by a dual staining method using triphenyltetrazolium chloride and Evans blue dye.

Results: Plasma selenium level during coronary reperfusion was increased in ebselen-treated groups dose-dependently. Infarct size did not differ significantly between the control (482 ± 6.8%) and the Ebselen-L (36.6 ± 8.2%). However, the infarct size in the Ebselen-H (22.0 ± 3.9%) was significantly smaller ($p < 0.05$) than the control. The anatomic area at risk did not differ significantly among the three groups. There were no differences in hemodynamic parameters among the three groups during coronary occlusion and reperfusion for 1 hour.

In conclusion, ebselen treated immediately before coronary reperfusion significantly reduced myocardial ischemia-reperfusion injury in a dose-dependent manner in rabbits.

P983 Specific relocation of the S100A1 Ca^{2+}-binding protein during cardiopulmonary bypass

A. Mandinova, W. Brett[1], U. Aebi, C.W. Heizmann[2], D. Atar[3]. *Biocenter, Maurice Mueller Institute, Basel; [1]Cardiothoracic Surgery Dept, University Hospital, Basel[2]Clinical Chemistry, University Children's Hospital, Zurich[3]Div of Cardiology, University Hospital, Zurich, Switzerland*

Background: Myocardial ischemia during cardiopulmonary bypass terminated by reperfusion generally leads to damage of the cardiomyocytes induced by transient cytosolic Ca^{2+}-overload. Recently, much attention has been paid to the role of heart-specific Ca^{2+}-binding proteins in the pathogenesis of myocardial ischemia-reperfusion injury. S100A1 is a heart specific EF-hand Ca^{2+}-binding protein which is directly involved in a variety of Ca^{2+}-mediated functions in muscle cells.

Aim and Methods: The aim of our study was to investigate the ultrastructural localization of S100A1 in the human heart under normal (baseline) conditions and after prolonged ischemia and reperfusion of the myocardium. We utilized confocal laser scanning microscopy to study cardiac biopsies from patients undergoing cardiopulmonary bypass.

Results: In control tissue samples obtained from patients before initiation of the extracorporal circulation S100A1 was localized to the cytoplasm of cardiomyocytes where it appears in strong association with actin contractile filaments. Prolonged ischemia of the heart (30 min) induced specific relocation of S100A1 to the cell membrane and extracellular space. However, this relocation was reversible after prolonged reperfusion (>30 min) of the heart.

Conclusion: Our data suggest that S100A1 is directly involved in the transient perioperative myocardial damage conferred by cardioplegia during corrective heart surgery in humans. Given its role in the contractile function of muscle cells, this S100 protein could be an important "intracellular link" in ischemia-reperfusion injury of the heart.

P984 Ischaemia-induced Stat-1 expression modulates apoptosis in cardiac cell

A. Stephanou, B.K. Brar, T. Scarabelli, R.A. Knight[1], D.S. Latchman. *Dept. of Molecular Pathology, Windyer Inst. of Medical Sciences, UCL; [1]Dept of Cystic Fibrosis, National Heart and Lung Institute, Imperial College London, UK*

Loss of cardiac myocytes by programmed cell death (apoptosis) is an important mechanism in the development of cardiac failure during injury due to ischaemia/reperfusion and myocardial infarction. Siganal transducer and activator of transcription-1 (STAT-1) is a transcription factor that is activated by interferon-γ (IFN-γ) via the Janus kinases (JAKs). STAT-1 has recently been implicated in playing a role in apoptosis. In the present study we assessed the role of STAT-1 in ischaemia/reperfusion-induced apoptosis.

Methods: Primary cardiomyocytes were isolated from 2-day old neonatal rats and subjected to simulated ischaemia in media buffer consisting of 137 mM NaCl, 3.58 mM Kcl, 0.49 mM $MgCl_2$, 0.9 mM $CaCl_2$. 2 H_2O, 4 mM HEPES supplemented with 0.75 sodium dithionite, 10 mM deoxyglucose, 20 mM lactate and 12 mM hydrogen ion (pH 6.5) concentration to inhibit glycolysis and placed in an atmospheric chamber of 5% CO_2 and 95% argon at 37°C for 4 hours. The ischaemic buffer was removed and cells were place back with minimal media and cells were returned to 37 o C. 21% O_2 and 5% CO_2. Cells were harvested and analysed by Western blotting for STAT-1. Experiments were also performed in which cell death was assessed in cardiac cells that were transiently transfected with an expression vector to over-express STAT-1. We also analysed a target gene for STAT-1, caspase 1 that may be involved in promoting apoptosis. Ex-vivo ischeamia/reperfusion studies were performed on isolated rat hearts using the Langerdoff perfusion apparatus and sections were analysed by immunofluorescence for both TUNEL labeling to assess apoptosis and STAT-1 immuno-staining.

Results: Exposure of cardiac cells to hypoxia/ischaemia results in apoptosis and is accompanied by phosphorylation and increased expression of STAT-1. To determine whether the increase in STAT-1 expression in cardiac myocytes was sufficient to induce apoptosis, cardiac cells were induced to over-express STAT-1 by transfection with a constitutive STAT-1 expression vector and then exposed to hypoxia. STAT-1 transfected cells were more susceptible to hypoxic-induced apoptosis than cells transfected with a control plasmid lacking the STAT-1 cDNA.. Expression of caspase-1, a cysteine protease enzyme involved in the final effector arm of the cell death pathway is also increased in response to hypoxia. IFN-γ which is known to to activate the STAT-1 pathway, also increases the expression of caspase-1 and also transactivated a caspase-1 reporter constract in cardiac myocytes. Moreover, IFN-γ-induced apoptosis was inhibited by yVAD-CHO, an inhibitor of the caspase-1 protease. Finally, ischaemia/hypoxia reperfusion also induces STAT-1 and caspase-1 expression in ventricular myocytes ex-vivo. Immunofluorescent staining also demonstrated an increase in STAT-1 positive staining in cardiac myocyte cells which also parallelled the incraese in TUNEL positive staining in response to ischaemia/reperfusion injury.

Conclusion: These results suggest that STAT-1 might play a critical role in the regulation of ischaemia/hypoxia-induced apoptosis via a caspase-1 activation dependent pathway in cardiac cells.

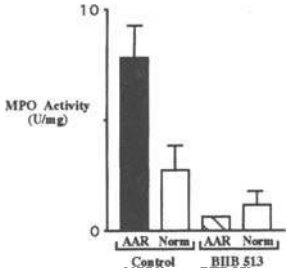
P985 Sodium-hydrogen exchange inhibition provides cardioprotection, attenuates neutrophil activity, but does not effect platelet aggregation *in vitro* or *in vivo*

R.J. Gumina[1], E. Buerger[2], J. Daemmgen[2], G.J. Gross[3]. *[1]Resident, Department of Internal Medicine, Mayo Clinic and Foundation, Rochester MN; [2]Boehringer Ingelheim Pharma KG; [3]Department of Pharmacology and Toxicology Medical College of Wisconsin, Milwaukee WI, USA*

Background: Numerous studies have demonstrated the cardioprotective efficacy of sodium-hydrogen exchange inhibition. Earlier studies using less specific inhibitors of NHE-1 suggested both anti-platelet and anti-neutrophil activity. To data the effect of NHE-1 inhibition on platelet and neutrophil activity in vitro has been limited and in vivo has not been reported.

Methods: Using a canine model of ischemia-reperfusion injury and platelet mediated cyclic flow the selective NHE-1 inhibitor BIIB 513 was used to determine the *in vitro* and *in vivo* effects on ischemia-reperfusion injury as well as platelet and neutrophil activity.

Results: *In vitro* up to 1 mM of BIIB 513 did not attenuate collagen, ADP, or thrombin induced platelet aggregation. *In vivo,* up to 9 mg/kg (3× the previously determined cardioprotective dose) did not attenuate platelet mediated cyclic flow. In contrast, both PMA- and PAF-induced neutrophil oxidative burst were attenuated by 1 μM BIIB 513. Furthermore, *in vivo* administration of 3 mg/kg of BIIB 513 not only significantly decreasedmyocardial infarct size but also significantly attenuated neutrophil accumulation within the myocardium-at-risk during ischemia, as measured by MPO activity.



Conclusions: NHE-1 inhibition affords cardioprotection not only via direct cardiomyocyte protection but also via attenuation of neutrophil activity. However, NHE-1 inhibition does not inhibit platelet aggregation *in vitro* or *in vivo* and thus would not be expected to interact with currently employed antiplatelet agents.

P986 Cardioprotection by ischaemic preconditioning is disturbed in the remodeled heart after myocardial infarction

T. Miki, T. Miura, A. Tsuchida, K. Shimamoto. *2nd Dept. of Internal Medicine, Sapporo Medical University, Sapporo, Japan*

Studies using normal myocardium have indicated a crucial role of protein kinase C (PKC) during ischemic insult in the mechanism of ischemic preconditioning (PC). However, intracellular signals to PKC and activity of this kinase are modified in the process of ventricular remodeling after myocardial infarction (MI). Therefore, we tested whether the PC mechanism is unchanged in the remodeled ventricular myocardium.

Methods: Using echocardiography, we confirmed that ventricular hypertrophy and dilation reach near maximal levels at 2–3 weeks after coronary ligation (COL) in the rabbit. Based on these results, the rabbit heart was excised 2 weeks after COL or sham operation, perfused with Krebs buffer and subjected to 30-min global ischemia (I)/2 h-reperfusion (R) to induce acute MI in vitro. The heart received either no pretreatment, PC with 2 cycles of 5-min I/5-min R, angiotensin II (AT-II, 100 nM), or diazoxide (100 μM), an opener of mitochondrial KATP channels (mito-KATP). The drugs were infused for 10-min before the global ischemia. Infarct size was determined by tetrazolium staining and expressed as a% of the left ventricle (%I/LV). The area of old MI induced by COL was excluded from infarct size measurement.

Results: Infarct size in the sham-operated hearts with no pretreatment (%I/LV = 47.9 ± 11.2) did not differ from that in the remodeled hearts with no pretreatment (%I/LV = 48.5 ± 6.8). Although PC and pharmacological PC with AT-II limited infarct size in sham-operated hearts (%I/LV = 9.2 ± 3.4 and 25.3 ± 4.5,respectively), they failed to protect the remodeled myocardium from infarction (%I/LV = 53.4 ± 0.8 and 46.0 ± 4.4,respectively). An opener of mito-KATP, which is a probable effector of PC, reduced infarct size in both sham-operated and remodeled hearts (%I/LV = 13.3 ± 3.3 and 11.7 ± 4.2,respectively).

Conclusion: The endogenous protective mechanism of PC is lost during ventricular remodeling after MI. This dysfunction in PC might be due to failure of signals elicited by PKC-linked receptors during PC to reach mito-KATP in the remodeled myocardium.

P987 Female gender and hypertension independently reduce tolerance to ischaemia-reperfusion injury post-myocardial infarction

F.R. Eberli, R. Liaoh[1], B.K. Podesser[1], S. Ngoy[1], C.S. Apstein[1], M. Jain[1]. *Cardiology Dept, University Hospital Berne, Berne, Switzerland; [1]Cardiac Muscle Research Lab, Boston University, Boston MA, USA*

Background: Females (F) and hypertension (HTN) have both been associated with increased mortality following myocardial infarction (MI). We have shown that in F, relative to males (M), HTN increased compensatory left ventricular hypertrophy (LVH) post-MI. Increased LVH might decrease tolerance to ischemia-reperfusion (Isch+Reper) injury and thus contribute to worse prognosis in F and HTN patients post-MI. We therefore examined if gender and HTN influence susceptibility to Isch+Reper injury post-MI.

Methods: Male (M) and F salt-sensitive (SS) and salt-resistant (SR) Dahl rats underwent coronary ligation. Post-MI, 4 wks of high salt diet resulted in similar levels of HTN in MSS and FSS rats (>170 mmHg), with no HTN (NHTN) in MSR and FSR rats. Isolated, red-cell perfused, isovolumically beating hearts underwent an Isch-Reper protocol consisting of 30 min low-flow Isch (15% of baseline flow) followed by 30 min Reper (100% baseline flow). Four post-MI groups were examine in this study: M+NHTN (n = 12), M+HTN (n = 8), F+NHTN (n = 11), F+HTN (n = 12).

Results: Infarct size was similar in all four groups (46–48% of LV). HTN increased heart weight/tibia length similarly by 20% in M+F ($p < 0.05$ vs NHTN). With identical coronary flow, lactate production, and oxygen consumption, F gender independently resulted in increased diastolic dysfunction during Isch versus M (39 ± 2 vs 32 ± 2 mmHg, $p < 0.05$), but not during Reper (16 ± 1 vs 14 ± 2 mmHg, p = ns). HTN, however, when compared to NHTN, caused worse diastolic dysfunction during Isch (40 ± 3 vs 32 ± 1 mmHg, $p < 0.01$) and Reper (18 ± 2 vs 12 ± 1 mmHg, $p < 0.01$), independent of gender. All four groups had similar percent recovery of developed pressure at the end of Reper.

Conclusion: Both female gender and hypertension independently increase susceptibility to Isch-Reper injury in post-MI hearts and may adversely affect prognosis following myocardial infarction.

P988 Time-dependent expression of cardiac bradykinin receptors in experimental left ventricular myocardial infarction

C. Tschöpe, S. Heringer-Walther, M. Koch, F. Spielmann, M. Wendorf, K. Schulze, C. Seeligmann, T. Walther[1], H.-P. Schultheiss. *Dept. of Cardiology, Univ.-Hospital Benjamin Franklin, Berlin; [1]Hypertension Dept., Max-Delbrück Center, Berlin, Germany*

An increase in cardiac bradykinin (BK) might be a mechanism to protect the heart during acute myocardial infarction (MI). To characterise the regulation of myocardial B1 and B2 receptors during MI, we studied the expression of both BK receptors in the left ventricle (LV) 6 h, 24 h and 6 days after left coronary ligation. Experiments were performed in male Spraque Dawley rats and compared with sham operated animals (n = 5, each group). After total RNA extraction, the myocardial expression of B1 and B2 receptors was analysed by a RNase-protection assay, using specific probes from the coding regions of both receptor genes and the GAPDH gene (as a house-keeping gene). Under basal conditions the B2 receptor – but no B1-receptor expression was detectable, although GAPDH, as an internal control, was detectable in all groups. Rats with MI were normotensive and showed an impaired left ventricular function. After MI no B1-receptor expression was detectable to any investigated time points. In contrast, we revealed a 3-fold increase of the B2-receptor expression 6 h after induction of MI. After 24 h and 6 days this upregulation was 10 fold increased compared to sham operated rats. Our data clearly show that the described increase in BK after MI is accompanied with a rapidly upregulation of the B2-receptor expression, which stays stable for at least 1 week. In contrast, the B1-receptor axis of the kallikrein-kinin system seems not to be involved under this pathophysiological circumstance.

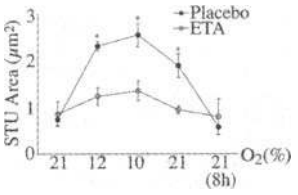
P989 Myocardial infarction mediated by endothelin receptor signalling in hypercholesterolemic mice

G. Caligiuri, B.I. Levy[1], P. Thorén[2], G.K. Hansson[3]. *INSERM U 460, Hospital CHU Xavier Bichat, Paris; [1]INSERM U 141, Paris, France[2]Physiology and Pharmacology, Karolinska Institute, Stockholm[3]Cardiovascular Research Unit, Karolinska Hospital, Stockholm, Sweden*

Endothelin (ET), a powerful vasocontrictor, is present in unstable coronary plaques and increases in patients with acute myocardial infarction (AMI). We tested the hypothesis that ET-mediated vasoconstriction precipitate AMI in a mouse atherosclerotic model.

Methods: 57 anesthetized apoE° LDL receptor° (E°/LDLR°) mice and 15 C57Bl6 control mice, aged >7 months, were subjected to acute hypoxia, as vasoconstrictor stimulus, by reducing oxygen (O_2) to 16, 14, 12 and 10%, (2' each step), followed by reoxygenation. E°/LDLR° mice were randomized to receiving placebo (Placebo, n = 30) or an endothelin receptor A antagonist (ETA, n = 17) just before hypoxia. STU area changes on the electrocardiogram (ECG) were considered as signs of ischemia. AMI was ascertained by serum Troponin T measurement, 14 days later, at autopsy.

Results: A total of 31/57 E°/LDLR° mice (54%) developed ischemic ECG changes. STU area changes were significantly greater in Placebo than in ETA group (figure, *$p < 0.01$).



Troponin T was higher in Placebo than in ETA group ($p < 0.5$). ECG and Troponin T were normal in controls.

Conclusion: E°/LDLR° mice develop coronary atherosclerosis and myocardial infarction. Hypoxic stress causes endothelin mediated acute myocardial infarction in atherosclerotic mice.

P990 Cariporide, a new selective Na^+/H^+-exchange inhibitor, improves postischaemic recovery by attenuating Ca^{2+}-overload and prolonging acidosis upon reperfusion

H. Strömer, M. de Groot, M. Horn, C. Faul, J.P. Morgan[1], S. Neubauer. *Medizinische Universitätsklinik, Würzburg, Germany; [1]Beth Israel Hospital, Harvard Medical School, Boston MA, USA*

Na^+/H^+-exchange inhibition improves mechanical recovery after ischemia. Despite an ongoing trial with Cariporide in patients with acute coronary syndrome (GUARDIAN trial), the mechanism of action remains speculative. Since Na^+/H^+-exchange is activated upon reperfusion, it has been hypothesized that its inhibition reduces Na^+- and (via Na^+/Ca^{2+} exchange) Ca^{2+}-overload. Attenuated Ca^{2+}-overload and prolonged acidosis are known to be cardioprotective.

Methods: To test this hypothesis, developed (DevP) and diastolic pressure (P_{dias}) were measured in isovolumic Langendorff rat hearts subjected to 30 min of ischemia and 30 min of reperfusion (T = 37°C) without (*Untreated*) or with 1 μM *Cariporide* (= HOE642) (*HOE*) added to the perfusate 30 min prior to ischemia. Intracellular $[Ca^{2+}]_i$ or pH_i were measured with aequorin or ^{31}P-NMR spectroscopy, respectively (n = 2 × 12).

Results (*$p < 0.05$): *Cariporide* did not affect mechanical function, Ca^{2+}-transients or pH_i under normoxic conditions. Mechanical recovery was substantially improved in *HOE* compared to *Untreated:* DevP (% of preischemic values) 92 ± 3 vs. 49 ± 7*, P_{dias} = 16 ± 3 vs. 46 ± 5* mmHg. No difference was found for ischemic contracture. $[Ca^{2+}]_i$ at end ischemia was significantly lower in *HOE:* 1.04 ± 0.06 vs. 1.84 ± 0.02* μM. $[Ca^{2+}]_i$ peaked in the first 30 sec of reperfusion and was significantly attenuated in *HOE:* 2.0 ± 0.3 vs. 3.2 ± 0.3* μM. pH_i was not different at end-ischemia (≈6.1). After reperfusion, pH_i was similar at 30 sec (≈6.5) and 60 sec (≈6.85) and ≥7 min (≈7.01) but acidosis was prolonged from 2 to 6 min in *HOE* compared to Untreated (e.g. 6.7 ± 0.05 vs. 7.3 ± 0.05* at 5 min).

Conclusion: The Na^+/Ca^{2+}-exchange inhibitor *Cariporide* improves postischemic recovery by reducing Ca^{2+} overload during ischemia and in the first minute of reperfusion and by prolonging acidosis in the following 5 minutes of reperfusion.

P991 Protection by mitochondrial ATP-sensitive potassium channel opener diazoxide of globally ischaemic cold-stored hearts

E. Kevelaitis, S. Kevelaitiene[1], A. Oubenaissa[2], C. Mouas[2], J. Peynet[3], P. Menasché[4]. *Dept. of Physiology; [1]Clinic of Cardiology, Kaunas, Lithuania Medical University; [2]INSERM U-127; [3]Dept. of Biochemistry; [4]Dept. of Cardiovascular Surgery, Hôpital Lariboisière, Paris, France*

There is increasing evidence that the cardioprotective effects of ischemic preconditioning are mediated by an opening of mitochondrial ATP-sensitive potassium channels (K_{ATP}). The objective of this study was to assess whether the K_{ATP} opener diazoxide could produce the protection of isolated hearts subjected to prolonged ischemic cold storage simulating the situation of cardiac allografts.

Methods: 34 isolated buffer-perfused rat hearts were arrested with and stored in Celsior (a new heart preservation solution) for 10 hr at 4°C. Reperfusion was then initiated for 2 hr. In the first group, hearts served as controls. In group 2, diazoxide was tested as a pharmacological preconditioning agent. After baseline functional assessment, hearts were subjected to a 15-min infusion of diazoxide (Hyperstat®, 30 μmol/l), followed by a 5-min washout period before arrest. In group 3, diazoxide was given as an additive to Celsior (100 μmol/l) and hearts were thus exposed to the drug during both arrest and storage. End points included recovery of left ventricular (LV) systolic and diastolic function (including pressure-volume (P-V) curves assessed by linear regression analysis of the end-diastolic pressure data to calculate a slope), total release of creatine kinase (CK) over the first 45 min of reperfusion, endothelium-dependent coronary vasorelaxation to 5-hydroxytryptamine ($5{\cdot}10^{-6}$ mol/l) under constant perfusion pressure conditions or to acetylcholine (10^{-6} mol/l) under constant flow conditions and myocardial water content.

Results: Baseline functional parameters were not different among the three groups. Main reperfusion data (mean ± SEM) are summarised below:

Group	Slope of P-V curve (mm Hg/ml)	LV max + dP/dt (mm Hg/s)	CK release (IU/g dry weight)	Water content (%)
1 (n = 12)	1212 ± 32	1061 ± 59	1013 ± 138	83.22 ± 0.26
2 (n = 12)	943 ± 55*	1068 ± 59	782 ± 55	81.86 ± 0.27*
3 (n = 10)	989 ± 86*	1577 ± 73**	780 ± 107	82.22 ± 0.23*

*$p < 0.05$ vs group 1; **$p < 0.01$ vs groups 1 and 2

Conversely, the endothelium-dependent coronary vasorelaxation to 5-hydroxytryptamine or acetylcholine was not different among the three groups.

Conclusion: Diazoxide-induced opening of mitochondrial K_{ATP} is an effective means of improving myocardial recovery after an extended period of cold global ischemia. The clinical relevance of these data stems from the availability of diazoxide for human use.

P992 Expression and protective effects of urocortin in cardiac myocytes

R.A. Knight, B.K. Brar[1], A. Okosi, A. Stephanou[1], K.M. Lawrence[1], T.M. Scarabelli[1], L. D'Souza, G. Santilli, D.S. Latchman[1]. *Department of Cystic Fibrosis, National Heart and Lung Institute, Imperial College; [1]Department of Molecular Pathology, University College London, UK*

Urocortin (Ucn) is a member of a family of peptides which includes hypothalamic corticotropin releasing hormone (CRH). We have previously shown that Ucn, but not CRH, is expressed in primary cultures of neonatal rat cardiac myocytes. In this study, we have assessed the role of cardiac Ucn in cell death induced by simulated ischaemia.

Methods: Neonatal rat cardiac myocytes were cultured in an atmosphere of 95% argon, 5% CO_2 for 6 hours. Ucn expression was assessed by PCR. Necrotic and apoptotic cell death was assessed in the absence and presence of Ucn and CRH. Four hour ischaemia-preconditioned medium was tested, both in the absence and presence of α helical CRH. Expression of transcription factors in control and ischaemic myocytes was evaluated by Western blotting. A fragment of the Ucn promoter containing an NF-IL6 consensus element ligated into a luciferase vector was transfected into cardiac myocytes, the cells exposed to ischaemia and luciferase activity measured on a luminometer.

Results: Ucn expression is increased by ischaemia and exogenous Ucn is roughly 10 × more potent than CRH in reducing both necrotic and apoptotic death induced by ischaemia, consistent with the higher affinity for Ucn of the type 2 CRH receptor expressed in the heart. The cardioprotective effects of ischaemia-conditioned media are also abrogated by the Ucn antagonist α helical CRH. For example, after 6 hours simulated ischaemia, 72% of cells were trypan blue positive; in the presence of ischaemia conditioned medium this fell to 44% but reverted to 70% with the Ucn antagonist. Ischaemia also produced a 10 fold increase in expression of the transcription factor, NF-IL6. Reporter activity of a Ucn promoter construct containing an NF-IL6. consensus site was doubled by ischaemia.

Conclusion: These data suggest that ischaemia increases expression and release of Ucn, an endogenous cardioprotrective agent.

P993 Effect of ischaemic preconditioning on mitochondrial function in perfused hearts after prolonged ischaemia

E. Ruuge, O. Korkina, A. Khatkevich. *Institute of Experimental Cardiology, Cardiology Research Center, Moscow, Russian Federation*

The protective effect of ischemic preconditioning against myocardial ischemia may partially come from the improved energy metabolism. The aim of this study was to examine the protective effects of preconditioning on the physiological parameters of cardiac muscle, functional characteristics of mitochondrial respiratory chain and oxygen radical production by cardiac mitochondria.

Methods: Isolated perfused rat hearts were either subjected or not subjected to preconditioning before 30 min of global ischemia and 30 min of reperfusion. Preconditioning was achieved with four cycles of 5 min of ischemia followed by 5 min of reperfusion. In both groups, mitochondria were isolated from the myocardial tissue after initial perfusion, 30 min of ischemia or 30 min of reperfusion. The rate of superoxide radical production was determined from the EPR spectra of 4,5-dihydroxy-1,3-benzene-disulfonic acid (Tiron), an oxygen free radical scavenger.

Results: An ischemic contracture appeared earlier in preconditioned group, but its level by the end of prolonged ischemia, as well as after 30 min of reperfusion, was significantly lower than in control group. In control group, the product of developed pressure and heart rate was restored only to 16 ± 10% of its initial value, while in preconditioned group this parameter was restored to 73 ± 5%. Preconditioning protected the mitochondrial membranes during prolonged ischemia. In preconditioned group, the respiratory control of mitochondria isolated from the postischemic myocardial tissue remained as good as 2.3 ± 0.1 even after 30 min of ischemia. At the same time, the prolonged ischemia induced entire respiratory impairment in the control group. However, the mitochondrial oxygen consumption was essentially higher (148 ± 8%) in control group than in preconditioned group. After 30 min of ischemia, the rate of superoxide radical generation was higher in mitochondria isolated from the hearts of both groups, but it was significantly lower in mitochondria isolated after prolonged ischemia from the preconditioned hearts. The rate of superoxide radical production by the mitochondria in preconditioned group was equal to 56 ± 7% of its value in control group.

Conclusion: The results suggest that preconditioning preserves the normal mitochondrial function and reduces the rate of oxygen radical production by cardiac mitochondria after prolonged ischemia. It may play an important role in improvement of postischemic contractile function and energy metabolism.

P994 Extracellular leakage of annexin V and inhibitory effects of propranolol in myocardial ischaemia followed by reperfusion

M. Kikuchi, N. Kaneko[1], K. Hiramori. *Second Department of Internal Medicin, Iwate Medical University, Morioka; [1]First Dept of Internal Medicine, Dokkyo University, Shimotsuga-Gun, Japan*

Background: Annexin V (AnV) is a calcium-dependent phospholipid-binding protein present in the myocardium. It is a new biochemical marker of myocardial injury. The purpose of this study is to evaluate the nature of AnV in myocardial ischemia followed by reperfusion, and the effects of propranolol to AnV.

Methods: In this experiment, 40 isolated rat hearts perfused by Langendorff's method were prepared. Thirty min of reperfusion was performed following global ischemia (GI) of 3 min, 10 min and 30 min in each eight rat hearts. Of 10^{-6} M propranolol was administered at 1 min before GI of 10 min and 30 min in each eight rat hearts. Haemodynamic parameters were obtained. We measured AnV concentration in perfusate by ELISA, and examined AnV localization in the reperfused heart by immunohistochemistry.

Results: Among various indices of cardiac fuction, LV developed pressure and coronary flow deteriorated after reperfusion following both 10 min and 30 min GI. LV diastolic pressure increased after reperfusion following 30 min GI. However, in reperfused isolated rat hearts with propranolol, cardiac performance was improved compared with that without propranolol.

AnV concentration in perfusate of before-GI was 0.6 ± 0.3 ng/ml. It did not increase after reperfusion following 3 min GI, but increased after reperfusion following 10 min GI. When GI lasted for 30 min, AnV concentration increased to 20.0 ± 3.4 ng/ml immediately after reperfusion, compared with before-GI level ($p < 0.0001$). Pretreatment with propranolol was effective for inhibiting the increase of AnV concentration immediately after reperfusion following 30 min GI (3.8 ± 0.6 ng/ml, $p < 0.0001$). Immunohistological examination revealed a significant staining of AnV in the cell membrane and intracellular space after 30 min reperfusion following 10 min GI, and the intracellular aggregation of AnV after 30 min reperfusion following 30 min GI. Propranolol inhibited both extracellular leakage and intracellular aggregation of AnV.

In conclusion, AnV leakage occurs by a reperfusion following GI, and propranolol inhibits the AnV leakage and the deterioration of cardiac function after reperfusion in this experimental setting.

P995 Ischaemic preconditioning preserves VEGF mRNA expression in rat infarcted myocardium

H. Kawata, A. Kawamoto, Y. Takeda, Y. Kobayashi, K. Nasu, E. Takase, H. Kurioka, Y. Sakaguchi, T. Hashimoto, K. Dohi. *First Department of Internal Medicine, Nara Medical University, Kashihara, Japan*

Background: Ischemic preconditioning reduces infarct size following acute myocardial infarction (AMI). We have demonstrated that serum vascular endothelial growth factor (VEGF) concentration was greater in patients with AMI who had preinfarction angina than those who didn't have. However, exact mechanism of this phenomenon is unclear. In the present study, we investigated the effect of ischemic preconditioning on VEGF mRNA expression in rat left ventricle following AMI. Methods and Results: We used 12 male SD rats aged 8 weeks. We performed the operation of ischemic preconditioning (4 series of 5 min-ischemia and 30 min-reperfusion, IP operation) in 3 rats (group R), the operation of left coronary artery ligation for 5 hours in 3 rats (group M), the operation of left coronary artery ligation for 3 hours after the IP operation in 3 rats (group RM), and sham operation in 3 rats (group S). After the operation, the cardiac tissue was harvested and separated at the point of ligation into two portions; apical portion including the infarcted area and basal portion not including infarct. Northern blot analysis was performed to quantificate the levels of VEGF mRNA, and immunohistochemical examination was performed to detect the distribution of VEGF protein in each portion. The VEGF mRNA levels of the apical portions were significantly higher in group RM (237.6 ± 22.1% expression compared with group S), not in group R (109.6 ± 4.5%) and group M (102.9 ± 4.3%), than in group S (100%) ($p < 0.0001$). The VEGF mRNA levels of the apical portions were significantly greater in group RM than in group R or group M ($p < 0.0001$). The VEGF mRNA levels of the basal portions were similar among the 4 groups. The levels of VEGF mRNA in group RM were significantly higher in the apical portions than in the basal portions (103.7 ± 9.2%) ($p < 0.05$). In group R, group M, and group S, the VEGF mRNA levels in the apical portions were not different from those in the basal portions. Immunohistochemical examination revealed that VEGF protein was not detected in group S. VEGF protein was expressed in endocardial myocytes of the apical portion in group R, myocytes in the non-infarcted area in group M, and myocytes in the infarcted area in group RM.

Conclusions: Ischemic preconditioning may preserve the expression of VEGF mRNA in the infarcted myocardium following AMI.

P996 Serine protease inhibitor (Aprotinin®) attenuates myocardial necrosis and apoptosis following ischaemia and long-term reperfusion in rats

M. Buerke[1], D. Prüfer[2], M. Dahm[2], H. Oelert[2], H. Darius[1], J. Meyer[1]. *[1]II. Department of Medicine; [2]Cardiac Surgery, Johannes Gutenberg-University, Mainz, Germany*

Although early coronary reperfusion of the ischemic myocardium is a desired therapeutic goal, evidence indicates that reperfusion itself contributes to additional myocardial injury. This has been in part attributed to neutrophil released mediators like oxygen derived radicals and proteases.

The cardioprotective effects of the serine protease inhibitor Aprotinin (APR) were examined in a murine model of myocardial ischemia and long-term reperfusion (i.e., 20 min. + 24 hours). Aprotinin (20.000 U/kg) administered 5 min. prior to reperfusion significantly attenuated myocardial injury compared to vehicle treated rats (79 ± 18 vs 890 ± 65 CK difference, $p < 0.01$). 5000 U/kg of APR resulted only in partial inhibition of reperfusion injury. Further, cardiac myeloperoxidase (MPO) activity, a marker of neutrophil accumulation was significantly reduced following Aprotinin treatment (0.34 ± 0.2 vs 1.34 ± 0.15, MPO difference, $p < 0.05$). Histological analysis of ischemic-reperfused myocardium of vehicle treated animals demonstrated increased neutrophil infiltration compared to the protease inhibitor treated rats (68 ± 15 vs 24 ± 8 PMN/mm^2, $p < 0.05$). Further, induction of apoptosis following myocardial ischemia and reperfusion could be significantly reduced following APR administration.

Thus, inhibition of neutrophil released proteases with Aprotinin appears to be an effective mean to preserve ischemic myocardium from reperfusion injury even following 24 hours of reperfusion. The cardioprotective effect appears to be at least in part due to reduced PMN infiltration with subsequent diminished myocardial necrosis.

P997 Soluble L-selectin levels decrease following dipyridamole administration in patients with ischaemic heart disease but not with syndrome X

T. Siminiak, D. Rogacka, J. Rzeźniczak[1], M. Słomczynski[1], R. Parucki[1], M. Kaźmierczak, R. Kalawski[1], H. Wysocki. *University of Medical Sciences; [1]J. Strus Hospital, Poznan, Poland*

Background. Activation of leukocytes during myocardial ischaemia contributes to the development of ischaemic myocardial injury. Increased leukocyte adhesion to endothelium as a result of myocardial ischaemia occurs via adhesion molecules and is known to be involved in the "no-reflow" phenomenon with impairment of coronary capillary flow. L-selectin, an adhesion molecule expressed by neutrophils, is known to contribute to increased leukocyte-endothelial adhesion during ischaemia.

Aim. The purpose of this study was to evaluate whether myocardial ischaemia produced during administration of dipyridamole results in release of soluble adhesion molecule L-selectin (sL-selectin) in patients with ischaemic heart disease (IHD) and with syndrome X (defined as ischaemic- like chest pain, positive exercise ECG and angiographically normal coronary arteries).

Methods. Plasma samples were obtained from 7 patients with syndrome X and 7 age-matched subjects with IHD before and 7 min. after i.v. administration of dipyridamole (0.56–0.84 mg/kg). Soluble L-selectin levels were measured by a sensitive ELISA assay.

Results. Dipyridamole decreased plasma levels of sL-selectin in patients with IHD from 1381 ± 246 to 999 ± 137 ng/ml ($p < 0.02$, mean ± SEM) but had no effect on sL-selection levels in patients with syndrome X (846 ± 13 and 966 ± 105 ng/ml, respectively).

Conclusion. Dipyridamole induced myocardial ischaemia results in a decrease of plasma levels of sL-selectin in patients with IHD but not in subjects with syndrome X. We speculate, that the decrease in sL-selectin levels as a result of dipyridamole infusion may be related to stimulation of expression of cellular L-selectin counter-receptors with subsequent "trapping" of soluble L-selectin. High basal concentrations of sL-selectin in patients with IHD may be a result of systemic leukocyte activation.

P998 Vulnerability of the aged rat heart to ischaemia and reperfusion

P. Assayag[1,2], S. Tanguy[1], J. de Leiris[1], F. Boucher[1], B. Swynghedauw[3], S. Besse[1]. *[1]ESA CNRS 5077, Université Joseph Fourier, Grenoble; [2]Service de Cardiologie Hôpital Bichat; [3]INSERM U127, Paris, France*

Myocardial aging is associated with contractile dysfunction and higher sensitivity to ischemia. However, the respective part of ischemia (I) and reperfusion (R) in the post-ischemic recovery of the aged heart remains unclear. Isolated hearts from 4 and 24 month old rats were subjected to paced low flow ischemia (60 min at 15% of initial coronary flow (CF); 4 mo-I and 24 mo-I groups) or to no-paced low flow ischemia (45 min at 15% CF) followed by 30 min of reperfusion (4 mo-IR and 24 mo-IR groups). Active tension (AT) and coronary resistance (CR) were recorded at baseline and after 1, 5 and 15 min of paced low flow ischemia, and AT and CF were recorded at baseline and after 15 and 30 min of reperfusion.

Results: mean ± SEM (in % of baseline value). $^*p < 0.05$ vs 4 mo groups.

	AT I 1 min	AT I 5 min	CR I 5 min	CR I 15 min
4 mo-I (n = 10)	74 ± 5	52 ± 6	157 ± 28	248 ± 62
24 mo-I (n = 11)	49 ± 5*	36 ± 4*	424 ± 101*	521 ± 95*

At the end of no-paced ischemia, CR and cardiac work (AT*heart rate product; 27 ± 3 vs 32 ± 3% of baseline value respectively) were similar in 4 mo-IR and 24 mo-IR groups.

	AT R15 min	AT R30 min	CF R15 min	CF R30 min
4 mo-IR (n = 9)	78 ± 6	73 ± 5	78 ± 10	71 ± 7
24 mo-IR (n = 8)	57 ± 7*	45 ± 7*	52 ± 9*	43 ± 9*

Conclusion: Myocardial function and vascular tone are impaired in senescent heart as soon as the first 15 min of ischemia, indicating a higher sensitivity to paced low flow ischemia during aging. After no-paced ischemia, which induces the same decline in cardiac work in both groups, the myocardial reperfusion however induces lower recovery of myocardial function and coronary flow in senescent hearts. These results indicate specific sensitivity of aged heart to reperfusion.

P999 Urodilatin limits acute reperfusion injury in the isolated rat heart

J. Inserte, D. Garcia-Dorado, L. Agullo, A. Paniagua, J. Soler-Soler.
Cardiology Dept, Hospital Universitary Vall d'Hebron, Barcelona, Spain

Hypercontracture is an important mechanism of myocyte injury during reperfusion. cGMP modulates the sensitivity of contractile myofilaments to Ca^{2+}, and increasing its concentration during the last minutes of anoxia prevents reoxygenation-induced hypercontracture in isolated cardiomyocytes. The purpose of this study was to determine whether stimulation of particulate guanylyl cyclase with the natriuretic peptide urodilatin, given at the time of reperfusion, reduces myocardial necrosis in the intact rat heart submitted to transient ischemia. Isolated rat hearts (n = 53) were submitted to either 40 or 60 min of non-flow ischemia and 2 hours of reperfusion, and allocated to receive either no drug (Control) or urodilatin 0.05 μmol/L during the first 15 min of reperfusion. A marked reduction in cGMP release was observed in control hearts during reperfusion after 40 or 60 min of ischemia (21 $\pm$ 6% and 11 $\pm$ 6% of preischemic values respectively). Urodilatin increased cGMP release to levels close to pre-ischemic values (135 $\pm$ 23% of preischemic values at 15 min of reperfusion after 40 min of ischemia and 92 $\pm$ 17% after 60 min ($p < 0.001$ respect to controls). This increase in cGMP was associated to a markedly improved contractile recovery after 40 min of ischemia ($p = 0.0309$), and attenuated reperfusion-induced increase in left ventricular end-diastolic pressure ($p = 0.0139$), LDH release ($p = 0.0263$), and contraction band necrosis ($p = 0.0179$) after 60 min of ischemia. Stimulation of a separate set of hearts with different concentrations of urodilatin demonstrated a sharp correlation ($r2 = 0.96$) between myocardial cGMP content and release.

These results indicate that reduced cGMP concentration may impair myocyte survival during reperfusion. Modulation of particulate guanylyl cyclase activity appears as a new therapeutic strategy to prevent immediate lethal reperfusion injury.

STABLE ANGINA: CLINICAL PRESENTATION, EVALUATION AND TREATMENT

P1000 Variability of angina symptoms: correlates and consequences

F.C. Lampe, P.H. Whincup, A.G. Shaper, S.G. Wannamethee, M.K. Walker.
Primary Care & Population Sciences, British Regional Heart Study, London, UK

Objective: To describe the variability associated with reported angina symptoms from one occasion to another, and to examine the effect of this variability on ischaemic heart disease outcome.

Methods: 7108 middle-aged men completed two chest pain questionnaires five years apart: the first (Q1) in 1978–80 and the second (Q5) in 1983–85. At each time point men were classified into one of four groups: definite angina (WHO angina meeting all criteria), possible angina (exertional chest pain without all other criteria), non-exertional chest pain or no chest pain. All men were followed up from Q5 to December 1995 (10.5–13 years) for major ischaemic heart disease events (fatal and non-fatal).

Results: Although age-specific angina prevalences were similar at Q1 and Q5, there was considerable variability in response. A minority (39%) of the 310 men with definite angina at Q1 reported definite angina at Q5, with 22% reporting possible angina, 11% reporting non-exertional chest pain and 29% reporting no chest pain. Of the 211 men with possible angina at Q1, 25% reported definite angina at Q5. Indicators of severe disease such as evidence of previous myocardial infarction, recall of a CHD diagnosis, and an abnormal ECG at screening were much more common in men who reported angina (definite or possible) at both Q1 and Q5 than those with angina on one occasion only. Persistence of angina was also strongly associated with subsequent ischaemic heart disease outcome. Compared to men without angina on either occasion, the age-adjusted relative hazard (95% CI) of a major ischaemic heart disease event from the time of Q5 was 1.5 (1.1, 2.2) for angina at Q1 only, 2.6 (2.1, 3.2) for angina at Q5 only and 3.4 (2.8, 4.3) for angina on both occasions. Persistent possible angina was associated with as poor a prognosis as persistent definite angina.

Conclusion: Angina symptoms elicited by questionnaire in population studies show substantial variability from one occasion to another. Persistence of reporting of symptoms is an important indicator of disease severity and prognosis.

P1001 European Survey on Circadian Variation of Angina Pectoris (ESCVA) – wake-time adjusted morning risk

S.N. Willich. *Social Medicine and Epidemiology, Charite Hospital Berlin, Berlin, Germany*

A circadian variation has been observed for acute coronary syndromes (myocardial infarction, sudden cardiac death, myocardial ischaemia) with a peak during the morning and a trough during the night. The previous reports, however, were based primarily on selected patients in clinical studies. The present study has been designed to determine the timing of attacks of angina pectoris in an out-of-hospital setting, the association of wake time and possible external triggers with angina attacks, and the influence of cardiac medication.

Methods: The ESCVA Study (European Survey on Circadian Variation of Angina Pectoris) is a multicenter international cross-sectional survey of patients in general medical practice of 7 European countries. Inclusion criteria are stable angina pectoris for at least three months, average frequency of two or more attacks per week, and treatment with on demand nitrates. Standardised self-administered questionnaires are provided to all consecutive patients of the participating physicians.

Results: From January to July 1998, 1,087 patients (61% male, 64 $\pm$ 9 years, 39% female, 67 $\pm$ 10 years) have been enrolled in 196 centers. A total of 3,453 angina pectoris attacks were reported, on average 3.2 per patient per week (range 0–48). The occurrence of angina pectoris attacks demonstrates a significant circadian variation ($p < 0.001$) with a primary morning peak from 9:00 to 12:00 (relative risk 3.0 compared to other times of day) and a secondary afternoon peak from 15:00 to 18:00. 50% of all attacks occurred within 6 hours after awakening. 75% of all patients reported possible external triggers of angina such as physical activity or anger.

Conclusions: A multicenter survey in general medical practice demonstrates marked wake time related circadian variation in angina pectoris attacks. To improve preventive strategies, type, dosage and particularly timing of cardiac medication are important, as may be behavioural approaches.

P1002 Diastolic and systolic function as predictors of exercise capacity in patients with stable angina

S.V. Eriksson, N. Rehnqvist[1], C. Held, L. Froslund[2], I. Björkander. *Department of Medicine, Danderyd Hospital, Danderyd; [1]National Board of Health and Welfare, Stockholm[2]Dept of Medicine, Trelleborgs Hospital, Trelleborg, Sweden*

Background: Data regarding relationships between exercise capacity and left ventricular systolic and diastolic function are conflicting. We therefore examined such relationships in patients with stable angina pectoris, participating in the Angina Prognosis Study In Stockholm (APSIS).

Methods: Measurements of left ventricular (LV) systolic and diastolic function at rest were examined as predictors of maximum exercise capacity in 675 patients with stable angina. Diastolic function was assessed by early (E) to late (A) mitral flow ratio (E/A-ratio) in 365 patients.

Results: In univariate analyses, maximum exercise time was more significantly related to patients height, E/A-ratios and left ventricular fractional shortening (FS) in men. E/A ratios among women were more closely related to exercise capacity. In contrast, FS was significantly related to exercise capacity in men ($r = 0.26$, $p < 0.001$), but not in women ($r = 0.05$, ns). In multivariate analyses, female sex ($p < 0.001$), height ($p < 0.001$) and E/A ratio ($p < 0.001$) all made independent contributions to exercise capacity.

Conclusion: Maximum exercise capacity of patients with stable angina is more closely related to indices of diastolic function than systolic function, especially among women. Exercise testing and evaluation of cardiac function with echocardiography and Doppler may be regarded as complementary procedures in patients with stable angina pectoris.

P1003 Prognostic implications of ambulatory ischaemia and relationships to ischaemia on exercise in patients with chronic stable angina pectoris: a report from APSIS

L. Forslund, P. Hjemdahl[1], C. Held[2], S. Eriksson[2], I. Björkander[2], N. Rehnqvist[3]. *Dept of Medicine, Trelleborg's Hospital, Trelleborg; [1]Dept of Clinical Pharmacology, Karolinska Hospital, Stockholm[2]Dept of Medicine, Danderyd Hospital, Stockholm[3]National Board of Health and Welfare, Stockholm, Sweden*

Aim: To assess the prognostic significance of ambulatory ischaemia, alone and in relation to ischaemia on exercise in patients with chronic stable angina pectoris, and to evaluate effects of treatment with metoprolol or verapamil.

Material, methods: We investigated 673 (302 men) out of 809 patients taking part in the Angina Prognosis Study In Stockholm (APSIS), who had satisfactory 24 h ambulatory ECG registrations and exercise tests at baseline.

Results: During a median follow-up of 40 months, 29 patients died of cardiovascular causes (CV death), and 27 suffered a non-fatal myocardial infarction (MI). Patients suffering CV death had more episodes with signs of ischaemia (5 vs 1; $p < 0.01$), and a longer median duration of ST-segment depression (23 vs 2 min; $p < 0.01$). There were no differences for patients with non-fatal MI. In a multivariate Cox model, including sex, previous MI, history of hypertension and diabetes, the duration of ST-segment depression showed an independent prognostic impact. When assessed together with results from exercise testing, ambulatory ischaemia carried additional prognostic information only among those patients with ST-segment depression $\geq$2 mm on exercise. Treatment significantly reduced signs of ambulatory ischaemia. However, when the treatment given and treatment effects on ischaemia were added to the Cox model, no significant impact on prognosis was found.

Conclusion: Ischaemia detected during ambulatory monitoring in patients with stable angina pectoris showed independent prognostic importance regarding CV death, but not the combined end-point of CV death+MI. Ischaemia on exercise testing and ambularoty monitoring are to some extent complimentary, but only in patients with marked ST-segment depression on exercise. One clinical implication of this finding is that when the exercise test is negative, little additional information is obtained from the ambulatory monitoring. Treatment reduced signs of ischaemia, but the short-term treatment effects did not influence the prognosis.

P1004 Value of continuous ambulatory pulmonary artery pressure monitoring in comparison to ECG holter monitoring in detecting ischaemia

S. Jasek, P. Podolec[1], C. Droste[2], Z. Sadowski, W. Tracz[1], H. Roscamm[2]. *Coronary Artery Disease, National Institute of Cardiology, Warsaw; [1]Institute of Cardiology, Dept. of Cardiac and Vascular Disease, Kracow, Poland[2]Rehabilitationszentrum, Inst. für Herz- und Kreislaufkranke, Bad Krozingen, Germany*

In group of 19 patients (pts) with angiographically proven coronary artery disease, 9 hours continuous pulmonary artery diastolic pressure (PADP) monitoring was performed by means of Gealtec (type 7 MPR) system concomitantly with Holter ST monitoring. All pts revealed ST depression of at least 1 mm together with pathological PADP increase >13 mm Hg (resting values within normal range) while exercised in supine cycloergometrer. All patients continue their normal daily activity and additionally were put to two tests – counting and interview in front of TV camera. Changes in PADP, ST deviation and HR in response to stress were compared. Excluding exercise test period, total number of 45 ST episodes and 68 episodes of pathological PADP increasing were recorded. In 13 pts both ST segment and PADP changes were found: 38 episodes of concomitant ST and PADP changes, 23 episodes of exclusive PADP and 5 solitude ST segment changes. Only in 1 pt ST segment changes run without PADP increase. On contrary, 4 of 5 pts revealed at least one episode of PADP increase without accompanying ST changes. In 31 of 38 episodes of concomitant PADP and ST changes, the former preceded ST changes by 64 ± 42 seconds. During interview 7 (36.7%) pts revealed PADP increase, in 6 cases associated with both pain and ST changes and in 1 case with pain only. During counting only in 3 of 6 pts PADP increase was accompanied by ST segment changes. During exercise stress test maximal increase of PADP was almost by 10 mm Hg higher and ST depression 0.25 mm dipper then that during the rest of ambulatory monitoring.

Conclusions: Ambulatory monitoring of pulmonary artery diastolic pressure detects ischemia more frequently then Holter ST monitoring. Pathological increase of pulmonary artery diastolic pressure precedes ST segment changes by about one minute.

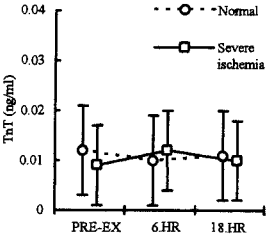
P1005 Does exercise-induced severe ischaemia result in elevation of plasma troponin T level in patients with chronic coronary artery disease?

M. Gürsürer, M. Aksoy, M. Çakmak, A. Emre, N. Çakmak, D. Ünal, B. Ersek. *Siyami Ersek Thoracic and Cardiovascular Surgery Center, İstanbul, Turkey*

It has been reported that a loss of cell-membrane integrity during severe ischemia results in elevation of plasma troponin T (TnT) in unstable angina. We investigated whether TnT is released into circulation during exercise-induced severe ischemia in patients (pts) with chronic coronary artery disease (CAD).

Methods: 212 pts with angiographically documented CAD and 54 normal subjects underwent exercise Tl-201 SPECT imaging. Blood samples were obtained before, 6 and 18 hours after exercise for TnT measurements. SPECT images were divided into 20 segments. Pts with $\geq$5 redistribution defects were considered to have severe ischemia.

Results: 48 pts had severe ischemia on SPECT images. The mean TnT were 0.009 ± 0.010, 0.012 ± 0.009, 0.010 ± 0.010 ng/ml in pts with severe ischemia and 0.012 ± 0.009, 0.010 ± 0.009, 0.011 ± 0.010 ng/ml in normal subjects before, 6 and 18 hours after exercise, respectively. There was no significant difference between the 2 groups and also in pre-, post-exercise TnTs in each group. All TnTs were normal (<0.1 ng/ml). Additionally, There was no significant difference with respect to TnT levels among pts with increased lung uptake and transient left ventricular dilatation which are indicators of severe ischemia and those without.



Conclusion: Exercise-induced severe ischemia does not result in elevation of plasma TnT level in patients with chronic CAD.

P1006 Aspirin reduces transient ischaemia in stable angina by reducing increased cytokine plasma levels and platelet activation

I. Ikonomidis, F. Andreotti[1], C. Stefanadis, C. Pitsavos, E. Economou, P. Toutouzas, P. Nihoyannopoulos[1]. *Cardiology Ippocration Hospital, Athens, Greece; [1]Hammersmith Hospital London, UK*

Macrophage colony stimulating factor (MCSF) causes macrophage/monocyte activation and thus release of vasoactive substances, interleukins 1b (IL1b) and 6 (IL6), platelet chemoattractants and tissue factor. We investigated whether platelet activation, thrombin generation or high cytokine levels are related to transient ischaemia in stable angina (SA) and whether reduction of the above factors by aspirin is associated with reduction of ischaemia.

Methods: We measured prothrombin fragments (PF1 + 2, nmole/l), MCSF, IL1b, IL6 (pg/ml) plasma levels and 24 h urine excretion of 11 dehydrothromboxane B2 (DTXB2, ng/mg creatinine) in 60 patients with SA and in 24 matched controls. Samples and urine collections were obtained at the end of a 48 h Holter (HM). Patients had angiographically documented disease. Fourty had ischaemia at HM and were randomly treated with ASA 300 mg, o.d. or placebo for 3 weeks in a double blind, cross-over trial.

Results: PF1 + 2, MCSF, and IL6 were increased in patients compared to controls (table). MCSF and IL1b increased according to the number of diseased (1–2–3) vessels ($p < 0.05$). Patients with ischaemia on HM had higher MCSF and DTXB2 but similar PF1 + 2 levels compared to those without (MCSF: 1124 ± 651 vs 528 ± 417, DTXB2: 4.2 ± 3.2 vs 2.3 ± 1.9, $p < 0.05$). MCSF was related to DTXB2 before and after aspirin administration ($r = 0.47$ and $r = 0.50$, $p < 0.01$). Aspirin reduced cytokine levels, PF1 + 2, DTXB2, the number and duration of ischaemic episodes (IE) at HM.

	SA	ASA	Controls	p
MCSF	1076 ± 613	950 ± 567	479 ± 287	<0.05
IL6	4.2 ± 1.3	3.5 ± 0.8	2.0 ± 0.9	<0.05
PF1 + 2	2.26 ± 1.8	1.73 ± 1.2	0.93 ± 0.5	<0.01
DTXB2	4.4 ± 2.8	2.2 ± 2.1	3 ± 3.3	<0.05
IE (no)	8.9 ± 1.1	6.6 ± 1.1		<0.01

Conclusion: Daily life ischaemia in patients with SA is related to increased platelet activation induced by high cytokine levels and not to thrombin generation and is reduced by aspirin possibly due to the antiplatelet and antiinflammatory effect of the drug.

P1007 Aspirin reduces procoagulant activity and thrombin generation in patients with stable angina

I. Ikonomidis, F. Andreotti[1], S. Loizou[1], C. Stefanadis, C. Pitsavos, E. Economou, P. Toutouzas, P. Nihoyannopoulos[1]. *Cardiology Ippocration Hospital, Athens, Greece; [1]Hammersmith Hospital London, UK*

Cytokines, C-reactive protein (CRP) and antiphospholipid antibodies (aPL) demonstrate significant procoagulant activity. aPL also induce thrombocytopenia. We investigated whether these factors are a) related to platelet activation and thrombin generation b) reduced by aspirin in stable angina.

Methods: We measured a) prothrombin fragments (PF1 + 2, nmole/l) b) IgG, IgM, IgA-aPL titers (Units) c) macrophage colony stimulating factor (MCSF), interleukin 1b (IL1b) and 6 (IL6) (pg/ml) and CRP (mg/l) plasma levels d) 24 h urine excretion of 11-dehydrothromboxaneB2 (DHTXB2, ng/mg creatinine) in 60 patients with stable angina (SA) and in 24 controls. Patients had angiographically documented disease and were randomly treated with aspirin (ASA) 300 mg, o.d. or placebo for 3 weeks in a double blind, cross-over trial.

Results MCSF, IL6, CRP, IgA-aPL and PF1 + 2 were increased in patients compared to controls (table, $p < 0.01$). IgA-aPL was inversely related to patelet count and DHTXB2 ($r = -0.39$ and $r = -0.32$, $p < 0.01$). Conversely, MCSF was related to DHTXB2 ($r = 0.40$, $p < 0.01$) No relation between aPL and CRP or cytokine levels was found. MCSF was related to IL1b and CRP ($r = 0.40$ and $r = 0.40$ $p < 0.05$). MCSF, IL6, CRP, IgA, IgG-aPL, DHTXB2 and PF1 + 2, levels were significanly decreased by ASA (table)

	Placebo	ASA	p	Controls	p
MCSF	991 (459–1476)	843 (501–1357)	<0.05	370 (265–770)	<0.01
IL6	3.9 (3.2–4.6)	2.9 (2.5–3.4)	<0.01	1.7 (1.3–2.5)	<0.01
CRP	1.4 (0.54–4.05)	1.0 (0.5–3.1)	<0.05	0.23 (0.17–1.4)	<0.05
IgA-aPL	3.4 (2.6–5.4)	2.9 (1.8–5.1)	<0.01	2.4 (1.5–3)	<0.01
DHTXB2	3.3 (2.3–5.4)	1.3 (0.8–3.1)	<0.01	2.9 (1.6.8–3)	NS
PF1 + 2	1.5 (1.1–2.7)	1.2 (1.1–1.8)	<0.01	0.82 (0.65–0.97)	<0.01

Conclusion: Elevated cytokine, CRP and aPL levels suggest an increased inflammatory and procoagulant activity that may partly explain the presence of increased thrombin generation in SA. Increased platelet activation is related to high MCSF levels whereas low platelet activity is associated with high aPL titers. Reduction of the above factors by ASA may represent an additional mechanism of its therapeutic action in coronary artery disease.

P1008 Long-term anti-ischaemic effects of spinal cord stimulation: a 48-hour ambulatory electrocardiogramme monitoring study

G. Zuin, F. Di Pede, F. Giada, G. Turiano, G.P. Pinato[1], M. Bevilacqua[1], R. Cazzin[2], A. Raviele. *Cardiology, Umberto I°, Mestre-Venice[1] Pain Center, Umberto I°, Mestre-Venice[2] Cardiology, Portogruaro-Venice, Italy*

Spinal cord stimulation (SCS) has anlgesic properties and may be used to treat the anginal pain in patients with refractory angina not candidates to myocardial revascularization. Some studies shoved also antiischemic effects. The aim of this study was to evaluate the long term persistence of the antiischemic effect of SCS.

Methods: Fifteen patients (9 male, 6 female, mean age 76 ± 8 yrs, range 58–90) treated with SCS for a mean follow up of 39 ± 27 months (range 9–92) with severe refractory angina pectoris (Canadian Class III-IV, optimal pharmacologic therapy not candidates to myocardial revascularization) were included in the study. Eleven patients had a previous myocardial infarction, 5 previous CABG, the mean EF was 0.54 ± 0.07 (range 0.36–0.65). All patients underwent a 48 hrs ambulatory electrocardiogram monitoring and were randomly assigned to 24 hrs without SCS (OFF period) and 24 HRS with SCS (ON period): The following parametners were evaluated: mean HR (bpm), number of ischemic episodes, total duration of ischemic episodes (min), total ischemic burden (mV.min).

Results: The Canadian Class improved during the follow up from a median value of 4.0 before SCS to 2.0 after implant ($p < 0.05$). The HR detected during ambulatory electrocardiogram monitoring was similar during the OFF period and the ON period (mean value 62.3 ± 4 and 63.1 ± 6 bpm, respectively). The number of episodes of ischemia decreased from a median value of 6 (range 0–29) during the OFF period to a median value of 3 (range 0–24) during the ON period ($p < 0.05$). The total duration of ischemia decreased from a median value of 29 min (range 0–186) during the OFF period to a median value of 16 min (range 0–123) during the ON period ($p < 0.05$). Total ischemic burden decreased from a median value of 2.5 mV.min (range 0–19.5) during the OFF period to a median value of 0.8 mV.min (range 0–13) during the ON period (p NS).

Conclusion: This study showes that SCS has antiischemic properties persisting over time.

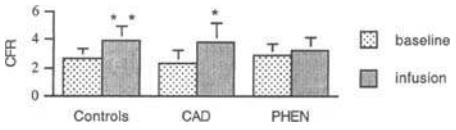
P1009 Nitric oxide synthase inhibition improves coronary microcirculatory function in patients with coronary artery disease

P.A. Kaufmann[1,2], T. Gnecchi-Ruscone[1], P.G. Camici[1]. *[1]Hammersmith Hospital, ICSM, London, UK; [2]Cardiology, Zurich, Switzerland*

Nitric oxide (NO) release in response to shear stress modulates coronary artery diameter. However, its impact on the coronary microcirculation and coronary flow reserve (CFR) particularly in patients with coronary artery disease (CAD) is unclear.

Methods: Myocardial blood flow (MBF, ml/min/g) at rest (R) and during iv adenosine (Ado; 0.14 mg/kg/min) was measured in 21 healthy males and 7 CAD patients using positron emission tomography and oxygen-15 labeled water. CFR was calculated as Ado-/R-MBF. Both measurements were repeated 15 minutes later during iv infusion of: 10 mg/kg NG-Monomethyl-L-arginine (L-NMMA) in 13 controls and 7 CAD patients; phenylephrine (PHEN) to increase blood pressure as with L-NMMA in 8 controls.

Results: Hemodynamics were similar in all groups at baseline. Mean arterial pressure (MAP) increased (+10%) and hear rate decreased (−10%) in all controls an patients (both $p < 0.05$) during the respective infusion. CFR increased significantly vs. baseline in controls (+59%, ** $p < 0.001$) and CAD (+56%, *$p < 0.05$) with L-NMMA but not with phenylephrine.



Conclusions: L-NMMA increases CFR, an this is not explained by the increase in MAP. Although the mechanisms remain unclear, this study proves that a further reserve is available on top of that achieved with standard doses of Ado in controls and in CAD patients.

P1010 Lesser inotropic reserve in response to dobutamine than to calcium in short-term hibernating myocardium

H. Post, R. Schulz, A. Jalowy, H. Dörge, M. Behrends, S. Belosjorow, G. Heusch. *Department of Pathophysiology, University of Essen, Germany Medical School*

We have previously shown in a porcine model of short-term hibernation that the β-adrenoceptor density during 90 min ischemia (I) remains unchanged and that the myocardium responds to dobutamine (Dob) and calcium (Ca) with an increase in contractile function. The increase in contractile function to Dob during I, however, is attenuated compared to normoperfusion (NP). It is not clear, whether this attenuated response to Dob is a consequence of alterations in the signal transduction pathway downstream of the β-adrenoceptor – as demonstrated to occur in heart failure – or a result of alterations in calcium handling of the myofibrils. We therefore compared the extent of inotropic reserve during Dob and Ca in 5 enflurane-anesthetized pigs, both during NP and I. During NP, Dob and Ca were infused into the cannulated LAD at increasing doses until an anterior wall work index (WI, mm·mmHg, sonomicrometry and micromanometry) did not increase further. To induce I, coronary inflow was reduced for 90 min to decrease WI from 343 ± 107 (SD) to 172 ± 44 mm·mmHg. Transmural blood flow (microspheres) was decreased from 0.69 ± 0.32 to 0.40 ± 0.19 ml/min/g. Dob and Ca infusions were repeated at 80–90 min I. The maximal increase of WI (ΔWI_{max}) during Ca was higher than during Dob, both during NP and I. Moreover, ΔWI_{max} with Dob, but not with Ca was lower during I than during NP. The doses of Dob (ng/ml blood) and Ca (mg/ml blood) at which ΔWI_{max} was recruited were not different during NP and I.

	Normoperfusion		Ischemia	
	ΔWI_{max}	dose	ΔWI_{max}	dose
Dob	92 ± 22*	187 ± 60	50 ± 27*#	192 ± 76
Ca	150 ± 48	261 ± 43	136 ± 39	270 ± 26

*: $p < 0.05$ vs Ca; #: $p < 0.05$ vs Normoperfusion; 2-way ANOVA

Since the β-adrenoceptor density and the Ca-mediated increase in WI remain unchanged, these results suggest an alteration in the signal transduction pathway between the β-adrenoceptor and the myofibrils in short-term hibernating myocardium.

P1011 Acute myocardial ischaemia lessens the potential protection afforded by ischaemic preconditioning

M.M. Awan, S. Makaula, D.M. Yellon[1], L.H. Opie. *Cape Heart Centre, University of Cape Town, Cape Town, South Africa; [1]University College Hospital, Hatter Institute, London, UK*

Background: Acute myocardial ischaemia is known to sensitize adenylate cyclase through a receptor-independent mechanism, which may lead to cell damage via activation of cAMP-dependent protein kinase (PKA). HYPOTHESIS: There is both a deleterious and a protective role of the trigger ischaemia in preconditioning (PC). The detrimental effects are mediated through activation of cAMP-dependent protein kinase (PKA).

Methods: Using the isolated rat heart, control hearts were subject to an ischaemia/reperfusion protocol of 30 min global normothermic ischaemia and 30 min reperfusion (index I/R). PC hearts were subjected to one episode of 10 min global normothermic ischaemia ending 10 min prior to the I/R phase. The work was repeated in the presence of 2 μM H89, the specific PKA antagonist (uM Ki values PKA = 0.048, PKC = 31.7). PC + H89 hearts were perfused with the antagonist for 3 min and antagonist perfusion stopped at the commencement of the PC ischaemia. After 5 min drug-free perfusion hearts were subjected to the index I/R. Control + H89 hearts were perfused with the antagonist for 3 min then subjected to 15 min drug-free perfusion followed by the index I/R protocol. The functional recovery after the index I/R was measured in all groups.

Results: See table.

PKA inhibition enhances PC

Expt	% Functional recovery (rate-pressure product)
Control	14.8 (2.9)*
Control + H89	36.7 (2.1)
PC	44.8 (4.3)
PC + H89	60.0 (3.0)*

* $P < 0.05$ v PC/Control + H89

Conclusion: PKA activation contributes to I/R damage. The ischaemic stimulus of PC affords protection and paradoxically limits this protection through PKA activation.

P1012 Conditioning myocardium via mechanical transmyocardial channeling provides protection for ischaemia

M. Slepian, P.N. Le Prince, B. Toporoff, K.B. Kern, R.W. Hilwig, V. Saadat, W.R. Roeske, J.G. Copeland. *Sarver Heart Center, University of Arizona, Tucson AZ, USA*

Background: Transmyocardial revascularization (TMR) has emerged as a promising modality for the treatment of chronic refractory myocardial ischemia. Recently we described a new non-laser means of TMR in which transmural myocardial channels are created via mechanical coring and vacuum tissue extraction. In this study we tested the hypothesis that the process of mechanical transmyocardial channel formation (TMC) followed by sixty day healing will lead to an altered myocardial substrate better able to support function in the setting of acute ischemic challenge.

Methods: In 12 pigs (female, 30 kg.) left thoracotomy was performed and the heart was exposed. In 6/12 pigs channels (1 mm, 5 mm inter-channel spacing, 31 ± 2/pig) were created mechanically in the left ventricular anterior wall (AW), from the level of the second diagonal to the apex (TMC group). 6/12 pigs, w/o TMC, served as controls (non-TMC group). All animals were allowed to recover. Sixty days post-TMC the LAD was ligated at the level of the second diagonal in all 12 pigs. ST elevation V4-V6 (mm.), heart rhythm, regional wall motion (2D Echo-AW segments, scoring: 1 NML, 2 hypokinetic, 3 akinetic, 4 dyskinetic, 5 aneurysmal) and microsphere retention ((blood inflow index) spheres/g tissue) were assessed at 60 min post LAD occlusion and were compared to non-TMC controls.

Results: ST elevation V4-V6 was reduced with TMC pre-channeling versus control (1.8 ± 2.0 vs 5.9 ± 2.0, p = 0.017). The # of VFib episodes (0.63 ± 0.7 vs 1.9 ± 1.0, p = 0.03) was significantly less for TMC than non-TMC control. Regional AW motion was more preserved in the TMC group versus control (1.4 ± 0.7 vs 2.25 ± 0.5 p = 0.02). Microsphere retention was increased with TMC versus control (1229 ± 678 vs 51 ± 27, $p < 0.001$).

Conclusion: Mechanical transmyocardial channeling combined with a sixty period of myocardial healing provides significant protection to the left ventricular myocardium in the setting of acute ischemic challenge. Conditioning the myocardium via the process of TMC and subsequent healing may be a useful adjunct therapeutic approach for the treatment of advanced ischemia not amenable to conventional therapies.

P1013 Correlation between heart rate variability and segmental left ventricular motion in patients with coronary artery disease before and after successful PTCA

M. Olszowska, T. Przewłocki, W. Tracz. *Jagiellonian University, Collegium Medicum; Institute of Cardiology; Department of Cardiac and Vascular Diseases, Krakow, Poland*

Heart rate variability (HRV) is a noninvasive index of the neural activity of the heart. HRV is frequently reduced in patients (pts) with coronary artery disease. We evaluated the correlation between parameters of HRV and segmental left ventricular motion in pts with coronary artery disease before and after successful percutaneous transluminal coronary angioplasty (PTCA). 152 pts (114 men, 38 women age range 40–68) underwent 24 hour Holter monitoring and echocardiographic examination before and 2 weeks after PTCA. Echocardiographic segmental left ventricular (LV) motion, parameters of time domain (SDNN, SDANN, SD, RMS-SD, p-NN50) and of frequency domain (LF band, HF band) were analysed.

All the pts were divided into Three groups before PTCA: 59 with normal segmental LV motion (group I), 51 with hypokinetic segments (group II), and 42 with akinetic segments (group III). All the parameters of time domain were similar in pts in group I and II, while HF band were lower in group II than in group I. In group III the parameters of HRV were significantly ($p > 0.01$) lower than in group I. The improvement of segmental LV motion after PTCA was observed in group II and III. All analysed parameters of HRV were not significantly changed in group I and II, although in group III following parameters significantly ($p > 0.01$) increased after PTCA: SDNN from 112.01 ± 17.0 to 140.02 ± 10.5, SDANN from 98.2 ± 17.2 to 126.1 ± 13.2, pNN50 from 5.8 ± 2.8 to 10.3 ± 4.3, LF band from 902.4 ± 473.2 msec^2/Hz to 1326.4 ± 519.4 msec^2/Hz, HF band from 392.4 ± 200.4 msec^2/Hz to 918.2 ± 491.1 msec^2/MHz.

Conclusion: HRV is correlated with left ventricular function. Abnormal segmental LV motion, especially akinetic segments, influense on diminished HRV parameters. The reversal of left ventricular dysfunction by successful PTCA improved heart rate variability.

P1014 Assessment of resting myocardial perfusion using sonovue myocardial contrast echocardiography using triggered pulse inversion harmonic imaging: a comparison to SPECT sestamibi imaging

E. Avelar, T. Kolias, M. Portis, E. Bossone, S. Batra[1], M. Vannan. *Cardiology Dept, University of Michigan-Ann Arbor, Ann Arbor MI; [1]Bracco Diagnostics Inc.,, Princeton, USA*

Background: We have previously shown in experimental studies that Pulse Inversion Detection is a sensitive technique for detection of microbubbles in the myocardium. We examined the efficiency of Pulse Inversion Harmonic (PIH) imaging for clinical myocardial contrast echocardiography (MCE).

Methods: 12 pts with a clinically indicated nuclear sestamibi scan and an adequate quality TTE identifying a resting wall motion abnormality (RWMA) were included in the study. The single view in which the wall motion abnormality was most evident was used for MCE using end-systolic triggered (1:1 and 1:4 cardiac cycle) PIH imaging (min 3 frames per trigger) on an ATL 5000 HDI machine. Each pt received a 3.0-ml bolus of IV SonoVue. The transmit focus was placed in the distal field and the mechanical index varied between 0.9 and 1.3 (average 1.1). MCE and nuclear images were interpreted independently for myocardial perfusion using identical regional scoring system. Data were analyzed for agreement between nuclear and MCE for 1) presence or absence of perfusion abnormalities, and 2) regional concordance in a given view.

Results: The apical 4 chamber (AP4C) view and the parasternal short-axis view, at the level of the papillary muscle (SAX-PM) were selected for imaging in 8 and 4 pts respectively. All pts had at least one abnormally perfused region on nuclear imaging. There was 100% agreement in the AP4C view and 95% agreement in SAX-PM view between SonoVueä PIH MCE imaging and nuclear sestamibi for the presence or absence of perfusion abnormalities. Regional concordance in the AP4C view was: apex 100%, mid septum 89%, basal septum 78%, mid lat wall 85%, basal lat wall 74%. In the SAX-PM view regional concordance was: ant septum 96%, ant wall 92%, ant lat wall 88%, post lat wall 78%, inf wall 88%, inf septum 94%.

Conclusion: SonoVue MCE when combined with triggered Pulse Inversion Harmonic Imaging shows excellent concordance to nuclear imaging for delineation of resting myocardial perfusion patterns in patients with resting wall motion abnormalities.

P1015 Preinfarction angina as a prognostic factor of new coronary events in patients after first acute coronary syndrome: one year follow-up

Z. Bednarkiewicz, M. Kurpesa, E. Trzos, W. Religa, M. Krzemińska-Pakuła. *Department of Cardiology, Medical University, Łódź, Poland*

The effect of preinfarction angina on prognosis after first acute coronary syndrome [ACS] is unclear. The aim of the study was to assess the role of preinfarction angina [PA] as the prognostic factor of new coronary events [NCE]: sudden cardiac death [SCD], unstable angina [UA] and myocardial infarction [MI] in patients after first ACS. Study population consisted of 234 patients [pts]; mean age 48.7 yrs [range 42–76 yrs]; male-167, with first ACS. PA was defined as chronic stable angina present for more than 1 month before ACS. At discharge patients were divided into two groups according to the presense or absence PA. Group I – 133 pts with ACS and PA, Group II – 101 pts with ACS and without PA. Before discharge in all patients left ventricular function [assessed as ejection fraction [EF]] was evaluated using Echo-2D and Doppler method. During two years follow-up frequency of new coronary events: sudden cardiac death [SCD], unstable angina [UA], infarction [MI] and total cardiac mortality [CM] were assessed.

Results:

	Group I [PA+] n = 133 pts	Group II [PA–] n = 101 pts	p
Mean EF [%]	45	54	<0.001
SCD [%]	7.5	4.9	<0.05
MI [%]	17.3	10.9	<0.001
UA [%]	28.5	13.8	<0.001
CM [%]	11.3	8.9	<0.01

Conclusions: New coronary events during two year follow-up occurred more often in patients with preinfarction angina. Angina before acute coronary syndrome – PA – seems to suggest more extensive coronary artery disease.

P1016 External counterpulsation increases capillary density during experimental myocardial infarction

Wei Huang, Yi-Ci Chen, Zhen-Sheng Zheng, Wei-Feng Zhong, Sun Yat-Sen, William E. Lawson, John C.K. Hui. *University of Medical Sciences, Guangzhou, China; State University of NY, Stony Brook NY, USA*

The mechanism(s) by which enhanced external counterpulsation (EECP) improves myocardial perfusion and relieves angina in coronary disease has been postulated to be due to recruitment or development of collaterals. An experimental acute dog infarction (MI) model was used to test this hypothesis.

Method: Acute MI was induced in 14 dogs [6 controls (C) and 8 EECP treated] by ligating the apical branch of the LAD. The EECP group was treated immediately after occlusion for 80 minutes, and again for 60 minutes prior to sacrifice of both groups at 6 hours. Frozen sections of myocardium were prepared using Bell's alkaline phosphatase and sectioned at 75 micron thickness. Capillary density (CD-capillaries/cm^2) and diameter (μm) were measured in both groups in infarct and non-infarct zones at three levels: subendocardium, intramyocardial, subepicardium. Statistical analysis was performed using the unpaired t test with a significance level of $p < 0.05$.

Results: Significant increases in CD were observed after EECP in the infarct zone (table). However, there were no significant differences in CD after EECP treatment in the non-infarct zone (average 6,066 ± 1,003 in C versus 6,659 ± 715 in EECP) and no differences in capillary diameters in either infarct or non-infarct zones (average 6.58 ± 0.20 μm in C versus 6.65 ± 0.24 μm in EECP).

Infarct Zone	Control	EECP	Significance
Subendocardial	4,578 ± 501	5,938 ± 502	p < 0.01
Intramyocardial	5,312 ± 916	7,138 ± 972	p < 0.01
Subepicardial	4,990 ± 686	6,586 ± 916	p < 0.01

These results demonstrate that CD in areas of acute MI can be significantly increased after EECP treatment. This finding may provide some insights into the mode of action for the use of EECP during acute and chronic ischemia.

P1017 Does exercise-induced hypotension necessarily predict adverse outcomes in patients with coronary artery disease?

S. Jabbourvv, R.Y.S. McLean, T.B. Graboys, Y. Young-Xu, R.J. Goldberg, C.M. Blatt, B. Lown, S. Ravid. *Lown Cardiovascular Center, Brookline MA, USA*

Purpose: Exertional hypotension (EH) is generally thought to portend severe CAD and/or myocardial ischemia and is an indication, as per AHA guidelines, for coronary angiography. The predictive utility of this criterion, however, has not been examined in an ambulatory outpatient population.

Methods: We studied 591 consecutive patients (mean age 67 yrs, 85% males) undergoing ETT in a cohort of patients with known CAD. EH was defined according to AHA criteria: EKG evidence of ischemia along with A) a sustained decrease of >10 mm Hg OR B) flat blood pressure response (<130 mm Hg) at peak exercise. Primary endpoints were MI or death.

Results: We found EH in 195 subjects (33%). There were no significant differences in baseline characteristics between those with and without EH. In a multivariate regression model, triple anti-anginal therapy (nitrates, B-blockers and Ca-antagonists) was the most significant factor associated with presence of EH. Rates of subsequent revascularization were equal in the two groups. During a mean f/u of 37 months, event rates were as follows: EH group [196 subjects, 21 (11%) MI, 10 (5%) death], non-EH group [395 subjects, 35 (9%) MI, 22 (5.7%) death). The differences were not significant ($p > 0.2$ for both). In univariate analysis, EH was not statistically associated with primary endpoints [hazard ratio = 1.3, 95% CI = 0.8–2.0, p = 0.3]. In multivariate Cox regression model, after adjusting for potential confounders, EH remained non-significant (HR 1.36, 95% CI 0.8–2.3, p 0.3)

Conclusions: We conclude that EH, as defined by AHA criteria, is not a significant predictor of worse outcomes in subjects with chronic CAD. EH is multifactorial and decisions regarding its management need to be individualized.

P1018 Increase of spatio-temporal beat-to-beat variability in coronary heart disease patients using magnetocardiography

K. Czerski, R. Agrawal, P. Goedde, S. Behrens, M. Oeff, H.-P. Schultheiss. *Cardiology Dept, Klinikum Benjamin Franklin, Berlin, Germany*

Magnetocardiographic (MCG) mapping provides an excellent tool to investigate the beat-to-beat variability (BBV) of electric heart activity. By solving the inverse problem the current source can be localized and consequently, the spatio-temporal BBV can be carried out. For patients with coronary heart disease (CHD) we expect an enhancement of BBV for the time instants of the heart cycle which correspond to disturbed electrical polarization in diseased regions of myocardium.

Method: The MCG-mapping (49-channel gradiometer in a shielded environment) was performed in 33 patients with angiographically documented CHD (16 post-myocardial infarction (PMI) patients and 17 patients with sustained ventricular arrhythmias (VA)) and in 19 healthy controls. Acquisition time amounted to 100 s at a sampling rate of 1 kHz. In the frame of our turbulence analysis the moving current dipole model was used to determine the time dependent location and strength of the current source. To measure spatio-temporal BBV we introduced a parameter, electrical Circulation (EC), which expresses a correlated shift of electrical activity in the time and space domain for consecutive heart beats.

Results: EC was significantly enhanced in the last phase of QRS-complex for all CHD patients compared to values for healthy controls. The investigated patient groups could be distinguished by means of the EC value within the T-wave, normalized on the amplitude of the current dipole vector. We achieved the following values: 2.2 ± 2.1, 6.2 ± 3.6 and 11.4 ± 3.4, for healthy controls, PMI patients and VA patients, respectively ($p < 0.005$ for all groups).

Conclusion: Significantly increased Circulation throughout the final part of the QRS-complex was observed in all CHD patients which can be correlated to the arrhythmogenic substrate. Additionally, an enhancement of Circulation within the repolarization provides a useful risk parameter for malignant cardiac arrhythmias.

REPERFUSION STRATEGIES

P1019 The influence of female gender on PTCA results and clinical outcome in the "Prague" study: national multicenter randomized study on patients with acute myocardial infarction presenting to community hospital

M. Aschermann, P. Widimský, L. Groh, M. Želízko, J. Vojáček, V. Mrázek.
University Hospitals Prague; Brno, IKEM Prague, Czech Republic

Several studies have shown unfavorable short-term outcome of women with respect to men after acute MI, even after adjusting for age. We assessed the influence of female gender on the short-term (30 days) prognosis after MI in randomized trial focused on evaluation of the best reperfusion strategy for patients with AMI admitted to the community hospital without cath-lab.

A total 255 patients were included (179 men, 76 women) and randomized to one of the following treatment: thrombolysis (TL) in the community hospital (group A, 70 patients), TL during transport to PTCA (group B, 71 patients) and direct transport to primary angioplasty (group C, 69 patients). All patients received aspirin and heparin, there were no death or VF during transport. Combined end-point at 30 days was death, re-MI and stroke.

Results:

	Group A		Group B		Group C	
	male	female	male	female	male	female
Mean age [years]	61	64	62	65	60	64
Door/reperfusion [min.]	115	115	120	128	98	105
PTCA success [%]	-	-	96	94	91	90
TIMI 2 + 3 pre [%]	-	-	48	39	28	33
TIMI 2 + 3 post [%]	-	-	96	95	94	95
30 d mortality [%]	12	21	15	13	7	13
30 d re-MI [%]	14	14	8	8	2	0
30 d urg. revasc. [%]	16	11	8	8	7	0
Comb. end-point [%]	25	29	19	21	8	13

Conclusions: Intermediate results of ongoing study shows a trend to benefit from transport to primary PTCA in the combined end point as well as in 30 days re-MI and urgent revascularization procedures. There were no significant differences between males and females in our study.

P1020 Thrombolisis versus PTCA in patients with recent acute myocardial infarction: exercise stress echocardiographic study

C. Auguadro, F. Buzzetti, M. Grillo, M. De Salvo, C. Falcone, E. Bramucci.
Cardiology Dept, Policlinico San Matteo, Pavia, Italy

Background: Intravenous thrombolitic therapy reduces mortality in patients (pts) with acute myocardial infarction (MI). More recently, catheter-based reperfusion for achieving infarct vessel patency and reducing the incidence of death or non-fatal MI has been introduced.

Objective: The aim of this study was to assess the left ventricular function during exercise stress echocardiography (EST-Echo) in pts who underwent primary percutaneous coronary angioplasty (PTCA) and in those who received fibrinolytic therapy.

Methods and patients: EST-Echo was performed in 146 pts 5 ± 3 days post MI. Medical therapy was not discontinued at the time of the test. The study population was divided into two groups: group 1 (G1) included 62 pts (51 Males, age 57 ± 10 yrs) who underwent PTCA at hospital admission and group 2 (G2) 84 (71 Males, age 58 ± 10 yrs) pts who received traditional thrombolytic therapy (rTPA).

Results: In basal conditions left ventricular ejection fraction (LV-EF), end-diastolic volume (LV-EDV), and end-systolic volume (LV-ESV) were similar between the two groups (G1: 49 ± 6, 141 ± 46 and 71 ± 29 respectively; G2: 48 ± 12, 142 ± 51 and 74 ± 42 respectively). Myocardial ischemia was induced by EST-Echo in 10/62 (16%) pts of G1 and in 34/84 (40.5%) of G2 ($p = 0.001$). In pts with ischemia during exercise, LV-EF, LV-EDV and LV-ESV were unchanged in comparison to baseline. In pts without ischemia during EST-Echo LV-EF increased in response to exercise (from 49 ± 6 to 54 ± 8 in G1, $p = 0.0002$; from 50 ± 14 to 58 ± 22 in G2, $p = 0.001$), the LV-EDV did not change from baseline whereas the LV-ESV decreased (from 66 ± 29 to 60 ± 28 in G1, $p = 0.02$; from 70 ± 43 to 68 ± 44 in G2, p = ns).

Conclusion: The echocardiographic parameters on baseline were similar between the two groups. The left ventricular function in response to effort, in both subgroups with and without ischemia during EST-Echo, did not differ between pts who underwent PTCA and pharmacological reperfusion. By contrary, this finding supports that the incidence of exercise-induced ischemia was significantly lower in pts who underwent PTCA than in those who received thrombolytic therapy.

P1021 Emergency revascularization and hybrid approaches in cardiogenic shock

F. Hernandez, P. Hernandez, J.C. Tascon, A. Albarran, M. Alonso, J. Andreu, R. Gascueña, M. Lazaro, J.E. Rodriguez[1]. *Cardiology Dept, Hospital 12 de Octubre, Madrid; [1]Cardiac Surgery, Hospital 12 de Octubre, Madrid, Spain*

Acute myocardial infarction (AMI) complicated by cardiogenic shock (CS) is still associated with a high mortality rate. Previous studies suggest that immediate revascularization with primary percutaneous angioplasty (PTCA), bypass surgery (CABG) or both can improve prognosis in this setting.

Methods: Between May 1996 and January 1999 36 patients (32 male), mean age 60 ± 10 years (44–80), were referred to our cath-lab with the diagnosis of CS complicating AMI. Intraaortic balloon counterpulsation (IABP) was used as adjunctive hemodynamic support in 89%. PTCA of the culprit lesion was always attempted if coronary anatomy was suitable, and multivessel PTCA was performed whenever there was no hemodynamic improvement. Left-main stenosis and non-suitable lesions for PTCA were considered an indication for surgery, as well as associated mechanical complications.

Results: 27 patients (32 lesions) were successfully revascularized with PTCA, and seven of them were immediately transferred to the operating room for CABG (hybrid revascularization in 3 patients) or repair of a mechanical complication (3 mechanical valves in mitral position and a left ventricle free-wall patch). Five patients underwent emergency CABG without previous PTCA, because left-main or multivessel disease made surgical revascularization a better option. Only four patients were not eligible for any kind of revascularization. Successful PTCA was achieved in 89% of lesions, and coronary stenting was performed in 84% of them. Mean time of IABP was 39 ± 32 hours, and no severe complications were related with counterpulsation. Survival rate at 30 days was 72%.

Conclusions: Successful direct early revascularization and hybrid surgical approaches in patients with AMI complicated by CS significantly reduce in-hospital mortality. Coronary stenting and IABP support may also contribute to this improved survival rate.

P1022 Serial coronary flow reserve in the successfully recanalized coronary artery and non-infarct artery in patients with acute myocardial infarction: the role of collateral circulation

Carel C. de Cock, Jean G.F. Bronzwaer, Koen Marques, Martin G. Stoel, Cees A. Visser. *Medical Center VU, Amsterdam, Netherlands*

Coronary flow reserve (CFR) in the infarct related artery (IRA) immediately after successful revascularization is frequently increased although not normalized in patients with acute myocardial infarction (MI). In addition, CFR in the normal contralateral vessel (non-IRA) is decreased immediately after successful revascularization. To assess the time course and the role of collateral circulation, 24 consecutive patients with acute myocardial infarction were studied. In all normal TIMI 3 flow was established after stent implantation. Distal coronary flow reserve was monitored in the infarct and non-infarct coronary artery immediately after stent implantation and after 24 hours. Patients were divided into 2 groups according to the presence (Rentrop 2 and 3) or absence (Rentrop 0–2) of collateral circulation.

		t = 0	t = 24
CFR (non-IRA)	Total group	2.01 ± 0.71	2.35 ± 0.79*
	R 0–2	2.25 ± 0.76	2.45 ± 0.81*
	R 2–3	1.59 ± 0.63	2.55 ± 0.84#
CFR (IRA)	Total group	1.41 ± 0.62	1.93 ± 0.69*
	R 0–2	1.42 ± 0.65	2.11 ± 0.70*
	R 2–3	1.45 ± 0.72	1.88 ± 0.81*

* $p < 0.05$ compared to t = 0, # $p < 0.05$ compared increase IRA R 2–3

Conclusion: both IRA and non-IRA have impaired CFR immediately after successful recanalization in patients with acute MI, which is significantly increased after 24 hours. In addition, the increase in CFR of the non-infarct IRA giving collateral circulation is significantly higher as compared to non-infarct IRA without collateral flow.

P1023 Heparinized stents in acute myocardial infarction: first results from the BESSAMI (Berlin Stent Study In Acute Myocardial Infarction) trial

P. Schwimmbeck, S. Spencker, C. Hohmann, D. Horstkotte, S. Behrens, M. Pauschinger, A. Morguet, C. Piper, B. Kuersten, H.-P. Schultheiss.
Department of Internal Medicine/Cardio, Benjamin Franklin Hospital, Berlin, Germany

BESSAMI is an ongoing single center prospective randomized trial to assess the combined complication rate of reintervention, CABG, reinfarction and death after primary PTCA alone versus IVUS-guided implantation of heparinized Wiktor-i stents in acute myocardial infarction (AMI).

Inclusion citeria are clinically and angiographically confirmed AMI with a vessel size of >2.5 mm. Excluded are patients with severe 3-vessel disease and urgent need of CABG. So far 52 consecutive patients are included. Patients with dissection after initial recanalization by PTCA as evidenced by flouroscopy and/or IVUS and/or TIMI-flow < 3 were randomized to group A (with stent; n = 26) or group B (without stent; n = 23). If no dissection was obvious and TIMI 3 reestablished, patients were allocated to group C (control; n = 3). All patients were treated with ticlopidine 500 mg/die for 4 weeks.

Results: There were no major differences in the baseline characteristics (see table). The procedural details are also given in the table.

	Group A (n = 26)	Group B (n = 23)	Group C (n = 3)
Sex	female 5 (22%)	female 7 (27%)	female 2 (66%)
Age	61 ± 4.9	62 ± 2.7	59 ± 10.7
3 vessel disease	5 (22%)	7 (27%)	0 (0%)
1 vessel disease	8 (35%)	11 (42%)	1 (33%)
Dissection after PTCA	21 (81%)	18 (78%)	0 (0%)
% Stenosis after PTCA#	49.1 ± 9.1	45.9 ± 3.9	39.0 ± 11.0
% Stenosis after stent#	–	17.9 ± 5.3*	–

*p < 0.001 for reduction of residual stenosis; #measurements by IVUS

The combined endpoint was reached in 2/26 patients of group A (2x urgent CABG) and 14/23 in group B (12x stenting for imminent vessel closure, 2x urgent CABG, p < 0.02). No endpoint was observed in group C. There was no in-hospital-mortality in either group.

In conclusion: IVUS-guided implantation of heparinized Wiktor-i stents in AMI is a safe procedure assosiated with few complications.

P1024 Abciximab associated with primary angioplasty and stenting in acute myocardial infarction: the ADMIRAL study, 30-day results

G. Montalescot, P. Barragan[1], *O.* Wittenberg[2], P. Ecollan[3], S. Elhadad[4], P. Villain[5], J.M. Boulenc[6], L. Maillard[7], P. Pinton[8]. *Cardiology Dept., Pitié-Salpêtrière, Paris[1] Cardiac Catheterization Dept., Polyclinique Les Alpilles, Marseille[2] Cardiology Dept., Clinique les Franciscaines, Nîmes[3] MICU, Pitié-Salpêtrière, Paris[4] Cardiology Dept., Lagny-Marne la Vallée Hospital, Lagny-sur-Marne[5] CRCVI, Polyclinique les Fleurs, Ollioules[6] Cardiology Dept., Clinique Saint-Joseph, Colmar[7] Cardiology A Dept., Trousseau Hospital, Tours[8] Paris, France*

Primary angioplasty is a validated procedure in the treatment of acute myocardial infarction (ami) and intracoronary stenting has been proposed to improve both the immediate results and the restenosis rate. Through its effects on platelet aggregation and on the vitronectin receptor of abciximab might be effective in further reducing complications in ami patients undergoing stent implantation. ADMIRAL is a phase 3 multicenter double blind placebo controlled randomized trial in patients undergoing primary PTCA and intracoronary stent implantation. 300 adult patients with a clinical diagnosis evolving ami within the first 12 hours and referred for urgent primary PTCA were included after obtaining written informed consent. Patients were randomized in equal probability to one of the following treatment groups: placebo or abciximab 0.25 mg/kg bolus followed by a 0.125 mcg/kg/min 12-hour infusion. Treatment was administered either during the pre-hospital phase, in the emergency room or in the catheterization laboratory before sheath insertion. All patients received aspirin (6 months) and ticlopidine (1 month) for stent implantation. Unfractionnated heparin was administered according to EPILOG criteria. Angiographic images were obtained prior to and immediately after PTCA and stenting, 24 hour after the procedure and at 6 months. Clinical follow up at 24 hours, 30 days and 6 months was carried out in all patients. The primary objective was to evaluate the incidence of a combined endpoint including death, recurrent myocardial infarction and urgent revascularization in the 2 groups at 30 days post randomization. Baseline characteristic of patients included and randomized are the following: median age (61.3 ± 12.8 years), male (81.6%), median weight (76.7 ± 15.2 kilos), Killip class I (91.3%), Diabetes (42.7%), Hypertension (45.3%), Dyslipidemia (39.0%), Previous unstable angina (8.2%), Previous infarction (11.5%), Previous PTCA (8.3%), Previous CABG (1.5%), target vessels (RCA in 38.4%, LAD in 37.9%, LCx in 8.0%), AMI diagnosis (anterior in 40.1% and Inferior in 49.3%); Initial TIMI 3 Flow (16.9%). Median presentation delay is 184 ± 147 minutes, median time to treatment is 210 ± 141 minutes and median time to cath'lab is 237 ± 144 minutes. Abciximab bolus was administered in 100.0% and bolus plus infusion in 99.5%. Initial coronary angiograms were performed in 99.5%, PTCA in 93.1% and Stent implemented in 85.8%.

P1025 Primary coronary angioplasty vs. thrombolytic therapy for treatment of acute myocardial infarction (MI). Findings from the PCAT collaboration

C.L. Grines, S. Ellis[1], M. Jones[2], L. Grinfeld, F. Zijlstra[3], F. Akhras, E. Garcia, F. Ribichini[4], R. Gibbons[5], E. Ribeiro[6], J. Simes[2], W.D. Weaver[7].
Cardiovascular Research, William Beaumont Hospital, Royal Oak MI; [1]Cardiology Dept., Cleveland Clinic, Cleveland OH, USA; [2]On behalf of the PCAT Collaboration, NHMRC Clinical Trials Centre, University of Sydney, Sydney, Australia[3] Cardiology Dept, Ziekenhuis De Weezenlanden, Zwolle, Netherlands[4] Cardiology Dept, Ospendale Santa Croce, Cuneo, Italy[5] Cardiovascular Diseases, Mayo Clinic, Ohmstead MN, USA; [6]Interventional Cardiology, Unicor Hospital, Sao Paulo, Brazil[7] Cardiovascular Medicine, Henry Ford Heart & Vascular Institute, Detroit MI, USA

We combined the individual case findings from 10 randomised trials of percutaneous transluminal coronary angioplasty (PTCA) vs thrombolysis (2635 patients) to determine the effects of each treatment on 30-day and long-term outcomes and to evaluate any differences in treatment effect sizes in subsets of patients. PTCA was associated with a lower risk of death or non-fatal MI at 30 days (odds ratio 0.46, 95%CI 0.35–0.61) and at 6 months (odds ratio 0.55, 95%CI 0.43–0.7). There was a similar relative treatment effect for defined subgroups, including those based on gender, diabetes, prior MI, site of MI and age. The absolute risk, however, of death or MI at 30 days was higher for women than men (16.7% vs. 12.3% in the lytic group), for patients with diabetes than without (19.3% vs 12.0%) and for patients with a prior history of MI than without (22.7% vs 11.6%), with greater absolute treatment effects of PTCA therefore expected in the higher risk groups. For patients aged over 60 years, death or MI at 30 days was reduced from 17.1% in the lytic group to 9.3% in the PTCA group; while for patients less than 60 years, the rates were reduced from 8.7% to 4.5%.

Conclusions: The benefit associated with PTCA therapy at hospital discharge is maintained at 30 days and at 6 months. While some variability in treatment effect was noted across the trials, the relative treatment effect was similar among all risk subsets. However, the magnitude of absolute benefit was greatest in patients at greater risk, such as those with diabetes, women, those with prior MI and older patients.

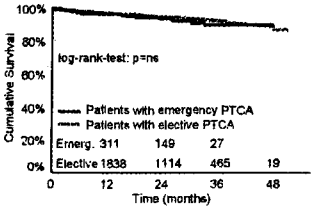
P1026 Long-term outcome after emergency PTCA

E. Frantz, A. Ellmer, P. Pfautsch, M. Baumann, W. Bocksch, C. Butter, S. Dreysse, J. Hug, E. Fleck. *Int. Med./Cardiology, Charité, Campus Virchow, Humboldt University; Deutsches Herzzentrum Berlin, Germany*

Whether performing PTCA in an emergency setting is detrimental to the long-term outcome has not yet been compared to elective PTCA.

The outcomes of all consecutive patients undergoing PTCA for AMI or unstable angina (target sample, n = 634) and of all patients with elective PTCA (control sample, n = 2684) during 1994–1996 were compared. In the target sample, 5.2% of patients were in cardiogenic shock. Among 30-day survivors, follow-up at 21.1 ± 11 (1–48) months of 94.0% of patients in the target sample, and at 24.8 ± 13 (1–53) months of 89.7% of patients in the control sample, respectively, was completed.

At follow-up 21/564 (3.72%) patients in the target sample and 117/2657 (4.40%) patients in the control sample had expired, p = ns. The rate of subsequent catheterizations (19.5% versus 20.9%, p = ns), interventions (27.0% versus 34.2%, p = ns), CABG surgery (20.9% versus 18.4%, p = ns), and left ventricular performance, functional status and drug intake at follow-up did not differ between samples. Differences were found with regard to repeat interventions that were performed earlier, and more frequently as emergency interventions themselves in the target sample, than in the control sample.



Performing PTCA as an emergency procedure is not detrimental to the long-term outcome of patients who survive the acute cardiac event. These results encourage all reasonable efforts to stabilize the emergency situation in order to enable patients survival unaffected from the acute coronary event.

P1027 Impact or reperfusion modality after acute myocardial infarction on reestablishing coronary blood flow

A. Vrachatis, G.A. Lazaros, V. Georgoulas, N. Michelakakis, E. Petropoulou, I. Lakoumentas, L. Stergiou, A.A. Zacharoulis. *Athens General Hospital 'G. Gennimatas', Athens, Greece*

Although thrombolysis (TH) and primary angioplasty (PA) are both effective in establishing reperfusion after acute myocardial infarction (AMI), various flow disturbances have been reported and seem to be related with adverse prognosis. In the present study we have examined the difference in the quality of coronary blood flow after AMI, in relation to the perfusion modality (either PA or TH).

Methods: 51 patients (pts) admitted for AMI within 3 hours from symptoms onset were randomized to TH (n = 25) and PA (n = 24). All pts underwent coronary angiography (CA) 90–120 min. after the beginning of TH or PA. Unsuccessful cases (TIMI grade flow < 2) were excluded and consequently 44 pts were randomized either to TH group (20 pts) or to PA group (24 pts). CA was repeated 18–36 hours later. The cTFC (corrected TIMI frame count) was used as coronary flow index and was measured in all (culprit or not) coronary arteries.

Results: cTFC values in culprit vessels, 90–120 min. after the beginning of TH or PA,. were significantly lower and near normal in PA group compared with those of TH group (27.4 ± 7.7 vs 39.8 ± 10, p < 0.001). After 18–36 hours cTFC values in TH groups, although decreased, still exceeded the normal ones (30.6 ± 7.9, p < 0.001). In addition, while in TH group cTFC was significantly higher (abnormal) in culprit arteries than normal ones (39.8 ± 10 vs 27 ± 8.1, p < 0.001), in PA group the above difference was not significant (27.4 ± 7.7 vs 25.7 ± 6.3, p = NS). In non culprit arteries cTFC 18–36 hours after reperfusion decreased in both groups. These variations, however, were insignificant in both the TH group (from 27 ± 8.1 to 23.7 ± 5.1, p = NS) and the PA one (from 25.7 ± 6.3 to 21 ± 3, p = NS).

In conclusion, in successfully reperfused coronary arteries after acute myocardial infarction, primary angioplasty reestablishes normal basal coronary flow faster as compared with thrombolysis.

P1028 "Open artery" theory: how will it affect the management of patients with myocardial infarction?

C.S. Stroumbis, L.K. Michalis, C.S. Katsouras, C. Economides, N. Kazakos, D. Doukas, D.A. Sideris. *University hospital of Ioannina, Ioannina, Greece*

Revascularization after myocardial infarction (MI) is conventionally reserved for patients with residual ischaemia. Given that normal flow in infarct related arteries (IRA) is an independent prognostic factor in these patients, possible verification that both early and late "opening" of occluded arteries is advantageous might have a dramatic effect on future management of such cases. The aim of this study was to estimate the consequences that acceptance of this theory would have in clinical practice

Methods: All patients hospitalized in our clinic with MI during a 2 month period (Feb–Mar 1998) underwent coronary angiography (CA) before discharge as well as a treadmill stress test which was repeated in 1 month. Subsequent treatment was based on conventional guidelines and only those with positive stress tests underwent myocardial revascularization.

Results: 49 patients with MI were studied. 11/49 underwent early revascularization because of contra-indication to or failure of thrombolysis (4) and post-infarct angina (7). CA in the remaining 38 revealed 3 vessel disease in 14, 2 vessel in 11 and 1 vessel in 13 patients. 17 patients had occluded infarct related arteries (2/17 also had 3 vessel disease). Revascularization would have been indicated in 29/38 patients based on the open artery theory of which 26/38 were anatomically suitable. Non invasive testing was positive for residual ischaemia in 15/38 of whom 13 were suitable for revascularization. Thus, based on the open artery theory 49/49 (100%) would have undergone CA (de facto, to determine occluded IRA) and 37/49 (76%) revascularization (to open IRA) whereas current indications (patients in need of early revascularization and those with residual ishaemia) call for 26/49 (53%) and 24/49 (49%) respectively (χ^2 test: p < 0.001 and p < 0.001).

Conclusion: Confirmation of the open artery theory would radically modify MI management strategies, which would become more invasive. Whether or not this novel approach will change the natural history of the disease remains to be seen.

ACUTE MYOCARDIAL INFARCTION: FROM BASICS TO PRACTICE

P1029 Estimation of apoptosis in acute myocardial infarction by Fas–Fas ligand system

H. Tomoda, M. Yoshitake, N. Aoki. *Department of Cardiology, Tokai University, Kanagawa, Japan*

The presence of myocardial apoptosis in addition to overt necrosis after ischemia and reperfusion has been demonstrated in experimental and post-mortem studies of acute myocardial infarction (MI) using the methods of detecting DNA fragmentation. The methods, however, indicate overlap positivity with necrosis, and the time course of possible apoptosis following ischemia could not be assessed by the methods. Thus, evaluation of changes in Fas-Fas ligand system, which is the representative system of apoptosis-signaling receptor molecules and initiates the apoptotic death program, was attempted in MI.

Methods: A total of 13 patients with MI who underwent primary percutaneous transluminal coronary angioplasty (PTCA) were studied. They consisted of 7 anterior MI and 6 inferior MI, and 4 of them indicated the signs and symptoms of heart failure, but there was no in-hospital death. All of them underwent primary PTCA without thrombolytic therapy at 5 ± 1 hours after the onset. Left ventriculography and coronary angiography were repeated before discharge. Blood samples were obtained before and after PTCA, and before discharge. Plasma soluble Fas (sFas) and soluble Fas ligand (sFas-L) were measured by enzyme-linked immunosorbent assay (ELISA).

Results: Plasma level of sFas was 2.03 ± 0.34 ng/ml before PTCA, decreased to 1.65 ± 0.24 ng/ml after PTCA (p < 0.05) and increased to 2.80 ± 0.30 ng/ml before discharge (p < 0.02). Plasma sFas-L did not change significantly; 0.04 ± 0.02 ng/ml before PTCA, 0.03 ± 0.02 ng/ml after PTCA and 0.03 ± 0.01 ng/ml before discharge. There were no significant changes in left ventricular end-diastolic volume (from 154 ± 9 ml to 151 ± 7 ml) and ejection fraction (from 46 ± 3% to 49 ± 4%) from pre-PTCA to pre-discharge periods.

Conclusions: The underlying conditions prone to induce apoptosis in MI estimated by Fas-Fas ligand system appear to decrease transiently by primary PTCA and increase thereafter gradually, suggesting that apoptosis might be playing a role for a balance between myocardial repair and remodeling during the convalescent phase of MI.

P1030 Effects of acute or chronic nitric oxide synthesis inhibition on mortality, haemodynamics and remodelling in rats with myocardial infarction

K. Hu, P. Gaudron[1], J. Weißmann, J. von Schrader, D. Fraccarollo, G. Ertl. [1]*Medizinische Universitätsklinik Würzburg; II. Medizinische Universitätsklinik, Klinikum Mannheim; Universität Heidelberg, Mannheim, Germany*

The role of endogenous nitric oxide (NO) post myocardial infarction (MI) is unclear. We studied the acute (3 hour to 3 weeks) or chronic (3 to 8 weeks) NO synthesis inhibition by L-NAME (L, 67 mg/L drinking water) on mortality, hemodynamics and left ventricular (LV) volume in rats with MI. Separate groups of rats were treated with hydralazine (H, 80 mg/L) plus L or placebo (P). Mortality were similar among various groups. After 3 or 8 weeks, mean arterial pressure (MAP, mmHg), LV end-diastolic pressure (LVEDP, mmHg), dP/dtmax (mmHg/s × 10^3) and cardiac index (ml/min/kg) were measured by Millar-tip catheter and electromagnetic flowmeter and total peripheral resistance index (mmHg/ml/kg) calculated. LV volume (Vol, ml/kg) was obtained by passive pressure-volume curves. Results for sham rats and rats with large MI (>35% of LV) are shown below:

	Sham + P	MI + P	MI + L	MI + L + H
		Acute		
N	13	11	17	20
MAP	113 ± 4	102 ± 3	94 ± 4*	88 ± 3*†
LVEDP	5.4 ± 1.0	15.6 ± 3.1*	25.2 ± 2.2*†	22.0 ± 2.1*†
DP/dtmax	16 ± 0.6	11 ± 0.8*	8 ± 0.5*†	7 ± 0.7*†
CI	327 ± 13	310 ± 18*	190 ± 17*†	260 ± 124*‡
TRPI	0.3 ± 0.0	0.3 ± 0.0	0.5 ± 0.1†	0.3 ± 0.1‡
Vol	1.6 ± 0.1	2.1 ± 0.1*	2.2 ± 0.1*	2.3 ± 0.1*
		Chronic		
N	11	6	19	22
MAP	112 ± 5	101 ± 2*	115 ± 3*†	102 ± 3‡
LVEDP	5.0 ± 1.0	14.4 ± 2.2*	17.3 ± 2.8*	13.0 ± 2.2*
DP/dtmax	15 ± 0.8	12 ± 0.5*	11 ± 0.7*	11 ± 0.7*
CI	310 ± 19	261 ± 12*	224 ± 14*†	280 ± 13‡
TRPI	0.3 ± 1.0	0.3 ± 0.0	0.4 ± 0.0†	0.3 ± 0.0‡
Vol	1.5 ± 0.1	2.4 ± 0.1*	2.5 ± 0.1*	2.5 ± 0.1*

(mean ± sem; *p < 0.05 vs. Sham; †p < 0.05 vs. MI + P; ‡p < 0.05 vs. MI + L)

Thus, acute NO inhibition post MI aggravated LV dysfunction (LVEDP, dP/dtmax, CI). Afterload normalization through H improved CI but had no effect on LV dysfunction (LVEDP, dP/dtmax). Chronic NO inhibition did not aggravate LV dysfunction. In the acute phase post MI, NO plays a role in LV function beyond afterload reduction in this model.

P1031 Differential effects of carvedilol on ischaemia-based or post-infarction ventricular remodelling in rats

A. Sakabe, H. Yaoita, H. Sato, K. Yoshinari, K. Watanabe, K. Maehara, Y. Maruyama. *First Department of Internal Medicine, Fukushima Medical Univercity, Fukushima, Japan*

Remodeling after myocardial infarction (MI), and remodeling of non-infarcted but ischemic myocardium due to coronary stenosis would be pathophysiologically different. Thus, the effect of carvedilol on these two different states might be different. To clarify it, we compared the effects of carvedilol on remodeling in the chronic ischemic state by fixed coronary stenosis and that after MI by coronary ligation in rats.

Methods: Coronary stenosis was made by ligating proximal portion of the left coronary artery together with a thread, followed by thread removal. An inert vehicle [group (Gr)-1A, n = 15], carvedilol 10 mg/kg/day (Gr-2A, n = 15) was orally administered for 12 wks starting from 6 hrs after operation. The same treatments were performed (vehicle, Gr-1B, n = 12; carvedilol, Gr-2B, n = 12) in rats with coronary ligation. Remodeling was assessed at 12 wks by echocardiography.

Results: At 12 wks compared with 6 hrs after stenosis, LV end-diastolic (EDV) and end-systolic volumes (ESV) increased ($p < 0.01$) and ejection fraction (EF) decreased ($p < 0.05$) in both of Grs-1A and -1B, compared with baseline values before coronary stenosis or occlusion. However, in Gr-2A compared with -1A, EDV (367 ± 36 vs 464 ± 62 μL, $p < 0.05$) and ESV (74 ± 17 vs 143 ± 47 μL, $p < 0.05$) were smaller and EF (75 ± 3 vs 68 ± 5%, $p < 0.05$) was greater. Heart rates and systemic blood pressure in Grs-2A and -2B were lower ($p < 0.01$) compared with Grs-1A and -1B respectively. In Grs-1B and -2B, EDV and ESV were greater and EF was lower ($p < 0.01$, each) than Grs-1A and -2A. These values tended to be greater in Gr-2B than Gr-1B, but did not reach to significant differences.

Conclusion: Carvedilol exerted an anti-remodeling effect in rat hearts with fixed coronary stenosis, but was not effective in attenuating remodeling after MI. These results indicate that carvedilol attenuates remodeling of non-infarcted but ischemic myocardium due to coronary stenosis rather than that developed after MI.

P1032 Pre-myocardial infarction angina has an arrhythmo-suppressive effect on reperfusion therapy: substudy of a prospective randomized JIMI trial

T. Itoh, T. Suzuki, H. Aoki, K. Ohira, N. Satoh, M. Shibata, M. Ohsawa, K. Fukami, T.Y. Suzuki, K. Hiramori. *The 2nd Dept. of Internal Medicine, Iwate Medical University, Morioka, Japan*

Background: It has not been concluded whether there is a relationship between pre-myocardial infarction angina pectoris (pre-MI AP) and reperfusion arrhythmia, although it has been reported that pre-MI AP has a beneficial effect in preserving left ventricular function. Moreover, determinants of reperfusion arrhythmias in patients with acute myocardial infarction (AMI) who have been successfully reperfused by reperfusion therapy are unknown.

Objective: To determine the predictive factors of reperfusion arrhythmias in patients with AMI who are successfully reperfused.

Methods: The Japanese Intervention Trial in Myocardial Infarction (JIMI) study (n = 123) is a prospective randomized trial that compares intracoronary thrombolysis with primary coronary balloon angioplasty. One hundred and ten consecutive patients with AMI who had been successfully reperfused in the JIMI study were studied. Multivariate logistic regression analysis was performed using ten clinical factors. Reperfusion arrhythmias were defined as all arrhythmias that occur within one hour after successful reperfusion therapy.

Results: 1) Reperfusion arrhythmias developed in 65 patients (59%). 2) Multivariate logistic regression analysis confirmed that inferior AMI and pre-MI AP were independently associated with reperfusion arrhythmia. 3) The odds ratio predicting reperfusion arrhythmias was 2.37 (95% CI; 1.06–5.31, p = 0.02) for inferior AMI. On the other hand, the odds ratio was minimal at 0.24 for pre-MI AP (95% CI; 0.09–0.65, p = 0.0036). 4) The method of reperfusion was not independently associated with reperfusion arrhythmias.

Conclusion: Pre-myocardial infarction angina pectoris suppresses reperfusion arrhythmia, while inferior AMI is an independent promoting factor for the arrhythmia.

P1033 Glucose-insulin-potassium infusion as adjunctive therapy to primary angioplasty for acute myocardial infarction

A. Liem, J.P. Ottervanger, J.C.A. Hoorntje, H. Suryapranata, M.J. de Boer, F. Zijlstra. *Cardiology Dept, Isala Clinics – Weezenlanden Hospital, Zwolle, Netherlands*

Background: Treatment with Glucose-insulin-potassium (GIK) infusion during the acute phase of myocardial infarction (AMI) has been proposed to support the ischemic myocardium. Until now, GIK therapy has mainly been tested in the pre-thrombolytic era.

Methods: 238 patients (pts) with AMI and <75 years were included. They were allocated to receive GIK in addition to standard medication or only standard medication, prior to reperfusion therapy. GIK therapy consisted of 2 ml/kg/h glucose 20%, 4 ampuls of KCL and 20 units insulin per liter, given at admission for 6 h. Standard medication consisted of aspirin, heparin and nitroglycerin. Enzymatic infarct size was determined by measurements of LDHQ72, ejection fraction (EF) by radionuclide technique at day 4.

Results: The majority of pts were treated with primary angioplasty (91%), 3% underwent CABG and 6% were treated conservatively. GIK therapy was given in 124 pts, whereas 114 pts received only standard medical therapy. No difference was observed in hospital mortality, GIK pts: 5%, control pts; 4%, enzymatic infarct size; GIK pts 1214 IU (± 1125 IU), control pts: 1192 IU (± 914 IU) or EF; GIK pts 43%(± 11%), control pts 42% (± 11%).

Conclusions: No benefit of GIK therapy was observed in patients treated with primary angioplasty for AMI. Further studies are required with a higher dosage of GIK or with longer duration of treatment.

P1034 Protective effects of preinfarction angina are not evident in acute myocardial infarction treated by primary coronary angioplasty and stenting

H. Tomoda, M. Yoshitake, N. Aoki. *Department of Cardiology, Tokai University, Kanagawa, Japan*

Preinfarction angina occurring shortly before the onset of acute myocardial infarction (MI) has been shown to have protective effects against ischemia, but the impact of primary percutaneous transluminal coronary angioplasty (PTCA) and stenting on this phenomenon is not known.

Methods: We studied 613 patients with transmural MI. Group I (n = 306) was treated by conventional medical therapies and coronary thrombolysis, and group 2 (n = 307) was treated by primary PTCA supported by stenting (success; 99%, stenting; 35%). Each group was subdivided into those with and without preinfarction angina within 24 hours before the onset of MI. There was no significant difference between the subgroups of groups 1 and 2 in clinical characteristics.

Results: In group 1, there were differences between patients with preinfarction angina (n = 84) and those without (n = 222) in in-hospital mortality (11% vs. 18%), pump failure (Killip classes 3 and 4) (11% vs. 21%, $p < 0.05$), left ventricular ejection fraction (LVEF) at discharge (52 ± 1% vs. 48 ± 1%; $p < 0.05$), and peak creatine kinase (CK, 2106 ± 179 U/L vs. 2764 ± 144 U/L, $p < 0.02$). In group 2, however, there was no significant difference between those with preinfarction angina (n = 82) and those without (n = 225) in mortality (6% vs. 6%), pump failure (12% vs. 12%), LVEF (50 ± 1% vs. 50 ± 1%), and peak CK (3285 ± 254 U/L vs. 3291 ± 151 U/L). Multivariate analysis indicated that preinfarction angina was an independent determinant of in-hospital death and pump failure in group 1, but not in group 2. Moreover, five year survial was significantly higher in those with preinfarction angina (85%) than in those without (74%, $p < 0.05$) in group 1, but there was no difference between those with and without angina in group 2 (88% vs. 88%).

Conclusions: We conclude that the protective effects of preinfarction angina in MI are not evident in those treated by primary PTCA and stenting, possibly because of the overwhelming protective effects of complete coronary recanalization provided by primary PTCA and stenting.

P1035 Effects of trimetazidine administration before thrombolysis in patients with anterior myocardial infarction: short-term and long-term results

S. Patema, P. Lo Verso[1], M. D'Amato[1], S. Zizzo[1], M.G. Vitrano[1], A.G. Giubilato[1], A. Giamporcaro[1], G. Spataro[1], P. Di Pasquale[1]. *Internal Medicine Dept, University, Palermo; [1]Cardiologia, Ingrassia, Palermo, Italy*

Reperfusion may prevent or reduce the development and extent of necrosis, but may also lead to an increase in reperfusion damage. Experimental studies performed in various animal models of myocardial ischemia have demonstrated the anti-ischemic properties of trimetazidine (TMZ) and have suggested that TMZ has antioxidant properties without any direct hemodynamic effects. Our study was aimed at investigating the effects of TMZ before thrombolysis in acute anterior myocardial infarction and included 81 patients, hospitalized within 4 h of the onset of symptoms. Patients were randomly (double blind) subdivided in two groups. The first group (40 patients, Group A, TMZ pretreatment) received 40 mg TMZ orally about 15 min before thrombolysis and subsequently 20 mg every 8 h. The second group (41 patients, Group B) received placebo before thrombolysis. Ventricular arrhythmias (VA) due to reperfusion were evaluated in the first 2 h. VA occurred in 15 of patients in group A versus 29 in group B ($p < 0.05$). CK peak normalization time was achieved after 55.7 ± 12.5 h in group A versus 61.2 ± 12.1 h in group B ($p = 0.048$). CK peak was 1772 ± 890 in group A vs 2285 ± 910 UI/l in group B ($p = 0.012$). In the follow-up (range 6–22 months), there were 4 deaths, two patients in each group. After 180 days from treatment, the TMZ group showed a smaller ESV than in placebo group (echocardiographic data), 46.2 ± 12 and 52.8 ± 13 m/m^2 respectively ($p = 0.037$). Our data suggest that TMZ probably reduces reperfusion damage and/or infarct size in patients with anterior AMI subjected to thrombolysis and affects the post AMI remodelling. Our data must be interpreted with caution because of the selection of patients. These findings require a much more extensive studies.

P1036 Low-dose continuous infusion of the synthetic glycolipid RC-552 provides sustained cardioprotection against infarction in dogs

G.T. Elliott, P.A. Weber[1], K. Przyklenk[2]. *[1]Ribi ImmunoChem Research, Inc., Hamilton MT; [2]Heart Institute, Hospital of the Good Samaritan, Los Angeles CA, USA*

As has been demonstrated with the first generation glycolipid cardioprotectant monophosphoryl lipid A, a new cardioselective synthetic glycolipid (RC-552) can reduce infarction within 10 minutes of administration to dogs and pigs. Bolus plus infusion dosing protocols were evaluated in the canine infarct model to determine if the brief, acute protective effect observed with bolus dosing could be maintained for hours with drug infusion.

Methods: Forty-one dogs received either: 1) RC-552 (70 μg/kg bolus); 2) RC-552 (70 μg/kg bolus plus 40 μg/kg/hr × 5 hours); 3) RC-552 (35 μg/kg bolus plus 4 μg/kg/hr × 5 hours); 4) Injection Vehicle (high dose volume equivalent). Three hours after bolus dosing, dogs experienced 1 hour LAD occlusion followed by 3 hours reperfusion. Radiolabled microspheres were administered during ischemia and at 1 hour reperfusion to determine myocardial blood flow. Infarct size (IS) as a percent area at risk (AAR) was determined by triphenyltetrazolium chloride-Unisperse® counterstaining.

Results: As expected bolus only administration of RC-552 was not effective against infarction 3 hours after dosing. In contrast, administration of either a high or low dose drug infusion after the bolus resulted in similar (50%) reduction in infarct size 3 hours after bolus dosing.

Treatment Groups	IS (% AAR)	Midmyo Coll Flow** (mL/min/g)
Vehicle (high dose bolus + infusion volume)	22 ± 4	0.06 ± 0.02
RC-552 (70 μg/kg bolus)	22 ± 3	0.09 ± 0.02
RC-552 (70 μg/kg bolus + 40 μg/kg/hr × 5 hr)	11 ± 4*	0.13 ± 0.04
RC-552 (35 μg/kg bolus + 4 μg/kg/hr × 5 hr)	9 ± 4*	0.16 ± 0.06

Values are Mean ± SEM *$p < 0.05$ ANOVA **at 30 minutes ischemia, p = NS

Conclusion: Combination of drug infusion following bolus dosing with RC-552 reduced infarct size to ischemic challenge beginning 3 hours post bolus dose, while bolus dosing alone was ineffective. Clinical use of this dosing protocol should allow RC-552 administration immediately prior to and throughout cardiopulmonary bypass without immunostimulation or deleterious effects on peripheral hemodynamic function.

P1037 Early versus later use of ACE inhibitors in acute myocardial infarction: a meta analysis

L. Melilli, R. Arora. *Interventional Cardiology Dept., Columbia University, Katonah NY, USA*

Background: Early use of ACE inhibitors in treatment of acute myocardial infarction (AMI) has remained controversial given inconsistent findings on appropriate left ventricular ejection fraction (LVEF) and systolic blood pressure (SBP) level. This meta analysis was conducted to determine indicators of therapeutic success with early (within 48 hours of chest pain onset) versus late use (72 hours) of ACE inhibitor therapy.

Methods: A meta analysis was conducted of all randomized placebo-controlled double-blind clinical trials published from January 1988 to June 1998 that assessed cardiovascular (CV) morbidity/mortality and tolerability in AMI patients who received ACE inhibitors within 24 to 72 hours of chest pain onset.

Results: Early use of ACE inhibitors reduced risk of CV-related mortality (RR 0.81, 95% CI 0.60, 1.02) and heart failure (RR 0.36; 95% CI 0.12, 0.60) regardless of baseline LVEF or SBP. Late use provided no additional benefit. Patients with anterior wall MIs were most likely to benefit from the survival advantage of early ACE inhibitor therapy ($p = 0.04$). Hypotension was significantly associated with anterior wall infarction ($p = 0.005$) and other medications with BP-lowering effects ($p = 0.02$), and was unrelated to start time or baseline SBP. Risk of renal dysfunction was lower with late (RR 0.36; 95% CI 0.09, 0.81) versus early use (RR 0.45; 95% CI 0.15, 1.05), and was significantly associated with anterior wall infarction ($p = 0.01$), elevated wall motion index ($p = 0.03$), and prior CV disease ($p = 0.02$).

Conclusion: Early use of ACE inhibitors within 48 hours of chest pain onset, particularly in anterior wall infarction, provides significant reduction in CV morbidity and mortality, independent of LVEF or SBP. Careful BP monitoring and titration of medications with BP-lowering effects can help avert hypotention. Careful monitoring of renal function in patients with prior CV morbidities is also warranted.

P1038 Paradoxical effects of smoking on the severity of myocardial infarction

S. Kennon, A. Suliman[1], P. MacCallum[2], K. Ranjadayalan[1], P. Wilkinson[3], A.D. Timmis. *Cardiology Dept., London Chest Hospital, London; [1]Cardiology Dept., Newham Healthcare Trust, London[2]Haematology dept., Royal Hospitals trust, London[3]Dept. of Public Health and Policy, School of Hygeine and Tropical Med., London, UK*

Background: The electrocardiogram remains the most useful tool for diagnosis of myocardial infarction and provides a simple means of monitoring the evolution of injury. Regional ST elevation occurs within seconds of coronary occlusion but early recanalisation accelerates its resolution and may protect against Q wave development.

Methods: Prospective analysis of 1399 patients with a first myocardial infarction in order to identify factors affecting the electrocardiographic evolution of injury.

Results: Smoking increased the odds of ST elevation (odds ratio (OR): 1.61; 95% confidence intervals (CI): 1.08–2.36) but reduced the odds of Q wave development (OR: 0.69; CI: 0.49–0.96). Prior aspirin therapy reduced the odds of ST elevation (OR: 0.57; CI: 0.35–0.94) and Q wave development (OR: 0.53; CI: 0.34–0.84). Admission within 2 hours of pain onset more than doubled the odds of ST elevation (OR: 2.44; CI: 1.65–3.59) but did not influence Q wave development. ST elevation and Q wave development were both associated with an adverse prognosis with estimated 6 month survival rates of 83.3% (81.0–85.6%) and 81.9% (79.5–84.3%), respectively, compared with 89.7% (84.9–94.5%) and 94.3% (91.4–97.2%) for patients without these ECG changes.

Conclusion: The thrombogenicity of the blood at the time of a plaque event may be a major determinant of infarct severity. Smoking, which increases thrombogenicity, has complex effects, increasing the likelihood of ST elevation while providing a substrate for successful thrombolysis which reduces the risk of Q wave development. The net effect, in prognostic terms, may be beneficial. Prior aspirin therapy, by reducing thrombogenicity, may reduce infarct severity, protecting against ST elevation and Q wave development more effectively than aspirin given after hospital arrival.

P1039 Early changes in neutrophil CD18 adhesion molecule expression predict infarct size in a rabbit model of myocardial infarction

Graham S. Hillis[1], William C. Dalsey[1], Antoinette Mangione[1], Xianliang Ma[2]. *Departments of Emergency Medicine; [1]Albert Einstein Medical Center; [2]Thomas Jefferson University Hospital, Philadelphia PA, USA*

CD18 integrins mediate leukocyte adhesion to vascular endothelium following myocardial necrosis. We hypothesised that changes in the expression of these rapidly activated and readily measured adhesion receptors on circulating neutrophils (PMN) would reflect the extent of cardiac damage.

Methods: Myocardial infarction was induced in anaesthetized adult male New Zealand white rabbits (n = 8) using a standard protocol. After 45 min the heart was reperfused for 3 h and the absolute and relative infarct size were calculated. Whole blood was collected before the induction of ischaemia, after 20 and 45 min of ischemia, and after 20, 60 and 180 min of reperfusion. Samples were immediately incubated with anti-CD18 and anti-IgG1 control monoclonal antibodies. Cells were lyzed, stabilized and fixed, after which flow cytometry was used to assess PMN CD18 expression. Absolute and relative infarct size were correlated with absolute levels of, and changes in, CD18, using linear regression.

Results: Mean CD18 expression was 2.42 (SEM ± 0.20) at baseline (range 1.66–3.53) and increased to 4.43 (±0.34, range 3.44–6.20: $p < 0.01$) after 3 h reperfusion. Mean CD18 expression had increased to 3.07 (±0.29; $p < 0.05$) within 20 min of ischaemia. Absolute and relative infarct size did not correlate with absolute PMN CD18 expression at 3 h ($r = 0.12$ & 0.04 respectively). When corrected for baseline levels, the changes in CD18 expression were correlated with absolute and relative infarct size ($r = 0.85$ & 0.89 respectively, $p < 0.001$ for both)

Conclusions: In this model of myocardial infarction PMN CD18 expression increases rapidly following myocardial injury. It should be acknowledged, however, that a proportion of the observed increase may be due to surgical stress. Absolute and relative expression at 3 h does not correlate with infarct size. However, when changes in PMN CD18 expression are assessed, rather than absolute receptor levels, there is an excellent correlation with infarct size. Further work is required to assess whether this is replicated in humans.

P1040 Angiographic morphology in patients presenting with ST-segment elevation myocardial infarction in relation to prior angina history

A. Kini, S.K. Sharma, T. Jayasundera, S. Kini. *Division of Cardiology, Box 1030, Mount Sinai Hospital, New York NY, USA*

Background: Angiographic studies have shown that patients presenting with acute ST-segment elevation MI have a higher incidence of total coronary occlusions, one vessel disease and poorly developed collaterals. Patients with prior angina presenting with Q-wave MI may have different angiographic characteristics compared to those with recent onset of angina (<7 days) or no prior symptoms. We analyzed 108 consecutive acute MI patients with ST segment elevation divided into two groups: Group I included patients with either no prior symptoms or new onset of angina (n = 60). Group II included patients with prior stable or crescendo angina (n = 48).

Results: There were no significant differences between the two groups with regards to baseline clinical variables.

Angiographic characteristics	Group I (n = 60)	Group II (n = 48)	p
One vessel disease (%)}	56	12	<0.001
Three vessel disease (%)	2	30	<0.001
ACC/AHA B2/C lesions (%)	63/20	40/58	<0.001
Mod-heavy calcification (%)	6	62	<0.001
Lesion thrombus (%)	40	29	NS
TIMI flow 0–1 (%)	30	38	NS
Collaterals (%)	26	42	0.04
Peak CPK (U/L)	2458 ± 628	1199 ± 268	<0.01
Q-wave MI (%)	83	50	0.002

Conclusion: Patients with prior angina presenting with ST segment elevation had a higher incidence of multivessel disease, calcified lesions, ACC/AHA B2/C lesions, collaterals and lower incidence of Q-wave MI with lower peak CK values. The impact of these angiographic findings on long-term prognosis needs to be further evaluated.

P1041 Quality of life 4 years after myocardial infarction: are the physical and mental summary scales of the SF-12 as reliable and sensitive at measuring quality of life as those of the SF-36?

M. Melville, N. Brown, T. Young[1], D. Gray. *Cardiovascular Medicine Dept., University Hospital, Nottingham; [1]BHF Cardiovascular Statistics Unit, University of Nottingham, Nottingham, UK*

The Short Form 36 (SF36) is a widely used quality of life (QOL) tool. The scoring system provides detailed scores for 8 different "domains" of health, plus two individual physical and mental component summary scores (PCS and MCS) and a global QOL score. While the SF36 has proved acceptable to patients, the SF12, a shorter tool derived from the SF36, could be more useful. The SF12 produces summary scores only but should retain the reliability and sensitivity of the SF36. We compared the two QOL tools in patients with coronary artery disease.

Method: 475 four-year survivors of a myocardial infarction, identified from a heart attack register, were mailed the SF36, the Rose angina and dyspnoea questionnaires and a demographic questionnaire.

Results: Of the 424 (89.1%) responders, 421 (99.3%) had answered the SF36. The PCS and MCS could be computed for both the SF36 and SF12 in 278 (66.0%) cases. The characteristics of responders and non-responders were similar. For both the SF36 and SF12 the correlation coefficients of each of the 8 domains to the two component summary scores were found to be in the expected range or higher. Reliability estimates calculated for the PCS36 and MCS36 were at least as good as those published for general populations. There was no significant difference between the SF12 and SF36 PCS or MCS scores when compared as a group ($P = 0.750$ and 0.123 respectively). The table shows that the PCS and MCS scores of the SF36 were capable of detecting the impact on quality of life of breathlessness of differing severity and that the SF12 was just as sensitive at identifying these differences. Similar results were observed when comparing severity or frequency of chest pain.

Table 1

Dyspnoea score	n	%	Comparison	SF-36 PCS	SF-12 PCS	SF-36 MCS	SF-12 MCS
0	111	39.9	0 v 1	<0.001	<0.001	0.451	0.166
1	54	19.4	1 v ≥2	<0.001	<0.001	0.016	0.002
>2	108	38.8	0 v ≥2	<0.001	<0.001	0.012	0.005

Conclusions: The SF12 is a reliable and sensitive substitute for the SF36 in determining differences in symptom-related QOL for patients with coronary artery disease where summary scores alone suffice. Response rates are likely to be higher when it is issued alone rather than embedded in the SF36.

P1042 Influence of angiotensin-converting enzyme gene polymorphism on plasma natriuretic peptide levels after reperfusion in patients with acute myocardial infarction

H. Fujinaga, T. Nakayama, S. Morishita, S. Kato, S. Kujime, M. Kimura, K. Chikamori, T. Wakatsuki[1], T. Oki[1]. *Division of Internal Medicine, Kochi Red Cross Hospital, Kochi; [1]Second Department of Internal Medicine, The University of Tokushima, Tokushima, Japan*

Purpose: To investigate the relationship between the angiotensin-converting enzyme (ACE) gene polymorphism and the improvement of left ventricular (LV) function by measuring plasma A-type natriuretic peptide (ANP) and B-type natriuretic peptide (BNP) levels after direct coronary angioplasty in the patients with acute myocardial infarction (AMI).

Methods: ACE gene polymorphism was determined in 29 patients with AMI who underwent successful direct angioplasty and had no significant restenosis three weeks after angioplasty. The patients were classified as having the 190 bp deletion homozygous genotype (Group D/D, n = 7), the 490 bp insertion homozygous genotype (Group I/I, n = 12) or the 490 bp insertion 190 bp deletion heterozygous genotype (Group I/D, n = 10). Plasma ANP and BNP levels immediately after reperfusion and three weeks after reperfusion, LV ejection fraction (EF) three weeks after reperfusion and peak serum creatine kinase (CK) values were compared between the three groups.

Results: There was a significant difference in age between the three groups (Group I/I: 48 ± 10, Group I/D: 71 ± 6, Group D/D: 65 ± 8 yr, $p < 0.01$ vs. Group I/I, respectively), while there was no significant difference in male gender (Group I/I: 50 (6/12), Group I/D: 50 (5/10), Group D/D: 57 (4/7)%, NS). Plasma ANP and BNP levels [pg/ml] in the three groups were as follows:

	Immediately after angioplasty		Three weeks after angioplasty	
	ANP	BNP	ANP	BNP
Group I/I	178 ± 111	22 ± 4	27 ± 12	35 ± 8
Group I/D	90 ± 26	224 ± 139*	20 ± 3	87 ± 30*
Group D/D	97 ± 24	299 ± 371*	42 ± 40	168 ± 177*

*$p < 0.01$ vs. Group I/I.

As shown, plasma BNP levels were significantly lower in Group I/I than in Group I/D and D/D after reperfusion. There was no significant difference in LVEF (Group I/I: 72 ± 2, Group I/D: 74 ± 3, Group D/D: 73 ± 9%, NS) and peak serum CK (Group I/I: 2074 ± 546, Group I/D: 2498 ± 1672, Group D/D: 1301 ± 513 U/l, NS).

Conclusion: The improvement of LV systolic function after successful reperfusion is greater in patients with AMI who have genetic insertion of ACE gene polymorphism.

P1043 Late progression of mild residual stenosis in culprit lesions after myocardial infarction

J. Morales, A. Medina, J.R. Ortega, E. Hernandez, F. Melián, J. Marrero, M. Landín, F. Wangüemert, J. Suarez de Lezo[1], M. Pan[1]. *Cardiology Dept., Hospital Pino, Las Palmas; [1]Cardiology Dept., Hospital Reina Sofía, Cordoba, Spain*

Mid-term and long-term evolution of culprit lesions with mild coronary stenosis (<50%) after myocardial infarction (MI) and thrombolysis is not well known.

In a consecutive serie of 350 patients (p) with myocardial infarction treated with rtPA which were included in a serial angiographic study, we have found in a coronary angiogram performed before discharge (9 ± 5 days after MI) a culprit lesion with a non significative (<50%) residual stenosis in 65 p (19%) (mean: 31 ± 13%).

In this group of 65 p a second elective coronary angiogram was performed 11 ± 5 weeks after MI in 47 p (72%). A similar residual stenosis was documented in 42 p (90%). Only 5 p shown progression: 2 p (4%) developed reocclussion without reinfarction and 3 p (6%) had a stenosis 51–99%.

A third angiogram was done 40 ± 26 months after MI in 24/42 p with mild residual stenosis in the second angiogram, due to ischemic symptoms recurrence (18 p with severe angina and 6 p with a new MI in another territory). Progression was detected in 14/24 (58%) culprit lesions: 4 reocclussions and 10 severe stenosis.

To analyze the progression of coronary plaques we have divided the coronary tree in 15 segments. One segment in a p was eliminated from the analysis due to a previous balloon angioplasty. A progression over 70% stenosis was presented in 14/24 culprit lesion segments (58%) in contrast with only 29/335 non culprit lesion segments (9%) ($p < 0.001$).

In conclusion: Mild residual stenosis after myocardial infarction have a potencial evolution towards severe stenosis or reocclussion in a long-term follow-up.

P1044 Can heart rate identify patients at risk for ventricular remodelling after small to moderate myocardial infarction?

G.M. Costa, C. Pizzi, A. Borghi, L. Gabrieli, C. Chiodarelli, E. Cordioli, R. Bugiardini. *Service of Cardiological Intensive Care, University of Bologna, Italy*

Background: Neurohormonal activation largely depends on left ventricular dysfunction; moreover remodeling after myocardial infarction (MI) is related to MI size. Aim of the study: to evaluate the importance of heart rate variability (HRV), expression of autonomic unbalance, in predicting remodeling in pts with small to moderate MI.

Methods: We studied 140 pts with small to moderate size MI [wall motion index ≤ 1.79 measured at discharge (T1)]. The end-diastolic diameter (EDD, mm), end-diastolic volume (EDV, ml) and left ventricular ejection fraction (EF, %) were measured by 2D-echocardiogram (E) at T1 and every 3 months up to the end of a 12 month follow-up (T2). Time domain HRV indexes (SDNN, SDANN) were measured at T1 and T2 by 24 hour Holter monitoring. All pts were treated with β-blockers and ACE-inhibitors. Coronary angiography was performed in all pts within 1 month from MI.

Results: at T2 69 pts showed significant LV enlargment (G1) while the remaining 71 did not (G2). G1 and G2 pts did not differ in age, sex, site and size of MI and TIMI grade flow of the infarct related artery. Table shows the E results (*p < 0.001 T1 vs T2):

	EDD-T1	EDD-T2	EDV-T1	EDV-T2	EF-T1	EF-T2
G1	48 ± 0.4	52.8 ± 0.4*	115.8 ± 9	121.9 ± 9*	48.1 ± 5	44.9 ± 7*
G2	51.2 ± 0.7	48.2 ± 0.5*	116.7 ± 8	110.8 ± 5*	47.3 ± 4	51.1 ± 5*

At T1 HRV shows a significantly higher sympathetic activation in G1 than G2 (SDNN: 72 ± 13 vs 123 ± 8; p < 0.001. SDANN: 59 ± 12 vs 103 ± 12; p < 0.001).

Conclusions: 1) low HRV, expression of sympathetic activation, early predicts late development of ventricular remodeling; 2) further studies are necessary to investigate the influence of therapy on autonomic tone and ventricular remodeling in post MI pts.

P1045 Circulating platelet activation status in acute coronary syndromes: higher activation in unstable angina relative to myocardial infarction

H. El Gendi, A.G. Violaris, T.F. Ismail, R.A. Foale, D.J. Sheridan. *Division of NHLI, St Mary's Hospital, Academic Cardiology Unit, London, UK*

Background: Platelet-rich thrombus formation at fissured atherosclerotic plaques is a feature of both unstable angina and myocardial infarction. However, platelets are thought to play a more central role in the pathogenesis of unstable angina while fibrin deposition predominates the pathogenesis of myocardial infarction.

Aim: To determine the extent of systemic platelet activation in patients with acute coronary syndromes relative to healthy controls and to investigate if this differs between patients with unstable angina and myocardial infarction.

Method: Peripheral venous blood samples were obtained within the first 24 hours of onset of chest pain. Twelve patients with myocardial infarction and 14 with unstable angina admitted to the coronary care unit were included in the study. The diagnosis of unstable angina and myocardial infarction was confirmed on the basis of ECG changes, and CK levels. Blood samples were also obtained from 18 healthy control subjects. Platelets were stained with fluorochrome-conjugated monoclonal antibodies directed against CD42a (GpIb, a general platelet marker) and P-selectin (an activation-dependent marker). Flow cytometry was then used to quantify the degree of P-selectin expression only on cells (platelets) expressing the general marker. Data was acquired under logarithmic amplification with low flow to prevent coincidence in the laser beam. Circulating platelet activation status was thus determined as the percentage of cells staining for P-selectin.

Results: Platelet activation was significantly higher in patients with myocardial infarction (P-selectin positive platelets, Mean ± SEM = 5.1 ± 0.9%, P = 0.008) and unstable angina (9.1 ± 1.5%, P = 0.003) compared to the healthy control group (2.3 ± 0.5%). Unstable angina patients exhibited significantly higher platelet activation than myocardial infarction patients (P = 0.03).

Conclusion: Platelets are activated systemically in both acute myocardial infarction and unstable angina. The higher level of platelet activation in unstable angina compared to myocardial infarction suggests a more important role for platelet activation in such patients. This confirms the need for specific antiplatelet therapy in patients with unstable angina.

LIPIDS AND LIPID LOWERING: CLINICAL EFFECTS

P1046 Statins effects on plasma removal of chylomicrons and remnants in coronary artery disease: study with artificial emulsions

A. Spósito, R. Santos, R. Amancio, C. Vinagre, L.I. Ventura, L.A.M. Cesar, J.A.F. Ramires, R.C. Maranhão. *Lipid Laboratory, Heart Institute Univ. of São Paulo, Sao Paulo-SP, Brazil*

Defects on the plasma removal of chylomicrons and remnants have been implicated in atherogenesis. Plasma removal of a chylomicron-like emulsion labeled with ^{14}C-Cholesteryl oleate (^{14}C-CO) and ^{3}H-Triolein (^{3}H-TO) was determined in 43 patients (mean age 56 ± 13) with coronary artery disease submitted to statin treatment. The ^{3}HTO and ^{14}C-CO kinetics evaluate respectively, lipolysis and removal of chylomicrons and remnants. Atorvastatin (A), (10 mg/day, n = 16), pravastatin (P), (40 mg/day, n = 13) or placebo (pl) (n = 14) were given for a 6-week treatment period. After a 12 hour fast, the emulsion was injected intravenously in a bolus and blood samples were collected in predetermined intervals during 60 minutes to determine the decaying curves and the fractional clearance rate (FCR) of the labels. There were similar reductions in total cholesterol (A = 24 ± 16%; P = 21 ± 11%, p = 0.0001 vs. baseline) and LDL cholesterol (A = 31 ± 19%; P = 25 ± 18%, p = 0.0001 vs. baseline), with statin treatment. The effects of statins on emulsion removal are shown in the table.

^{3}H-TO-FCR (min^{-1})	Atorvastatin	Pravastatin	Placebo
Baseline	0.029 ± 0.012	0.034 ± 0.026	0.029 ± 0.019
6 Weeks	0.037 ± 0.02	0.024 ± 0.017	0.019 ± 0.07
^{14}C-CO-FCR (min^{-1})	Atorvastatin	Pravastatin	Placebo
Baseline	0.008 ± 0.007	0.014 ± 0.014	0.016 ± 0.006
6 weeks	0.013 ± 0.013*	0.02 ± 0.018*	0.009 ± 0.008

Data = mean ± SD; *p = 0.01 vs. baseline vs.placebo ANOVA

There was a significant correlation between LDL cholesterol reduction and ^{14}CO-FCR increase (r = 0.5;p = 0.01). The ^{14}CO-FCR was increased in those patients in which the LDL cholesterol reduction was greater than 30%. There were no effects on lipolysis. Chylomicron-like emulsion removal was accelerated after both statins treatments, indicated by CO-FCR increase, and the acceleration was proportional to LDL cholesterol reduction. Improvement in chylomicron and remnants clearance may be an anti-atherogenic effect of statins.

P1047 Reduction of serum cholesterol concentration with a diet consisting of common foods enriched with plant sterols

J. Tuomilehto, P. Högström, S. Keinänen-Kiukaanniemi[1], M. Tikkanen[2], H. Karppanen[3]. *Epidemiology and Health Promotion, National Public Health Institute, Helsinki; [1]Department of General Practice, University of Oulu, Oulu[2]Department of Pharmacology, University of Helsinki, Helsinki[3]Department of Medicine, University of Helsinki, Helsinki, Finland*

Plant sterols are natural components in edible vegetable oils and they have recently been used in the search for natural substances for hypercholesterolaemia. It has been also suggested that incorporation of calcium, magnesium and potassium to the diet may further enhance the cholesterol lowering effect of plant sterols. We explored the effects of a diet that included common food items such as bread, yoghurt and sausages enriched with non-esterified sitosterol and the above mentioned minerals on serum lipids.

Methods: 80 subjects with mild hypercholesterolaemia were included in this double-blind placebo-controlled parallel-group trial. Following the dietary stabilisation period and a 2-week placebo run-in phase patients fulfilling the randomisation criteria entered the 15-week double-blind diet period. Habitual dietary intakes during the trial were monitored using 3-day food diaries. Patients in the Enriched Diet Group (EDG) received a combination of bread, yoghurt and sausages enriched with plant sterols (75% b-sitosterol and 25% b-sitostanol) by 1.25, 2.5 and 5.0 g/day during the three 5-week periods, respectively. Patients randomised to the Placebo Group (PG) received matching placebo products. Compared with the baseline the net reductions in serum total cholesterol (TC) were 5% ($p < 0.05$), 6% ($p < 0.01$) and 6% ($p < 0.01$) during the three 5-week periods, respectively (trend test, $p = 0.0038$). The corresponding reductions in LDL cholesterol were 5% (n.s.), 7% ($p < 0.0.1$), and 7% ($p < 0.01$) (trend test $p = 0.0046$). The relative reduction in TC adjusted for changes in intake saturated fat in EDG compared with PG was 0.44 mmol/l ($p = 0.0016$), and that in LDL-C 0.42 mmol/l ($p = 0.0007$). There were no changes in serum HDL-C or triglycerides between the groups. The plant sterol concentrations determined from serum confirmed the dose increase, although the actual intakes were slightly (n.s.) lower than the prescribed ones. The initial plant sterol dose 1.25 g/day was as effective as higher doses in reducing TC or LDL-C.

In conclusion, plant sterol enriched diet combined with moderate changes in mineral composition of common foods will effectively reduce serum TC and LDL-C in hypercholesterolaemic subjects. Such a diet with a relatively low dose of plant sterols can be an important addition to the existing non-pharmacologic measures to lower high serum cholesterol.

P1048 Influence of lipid fractions on coronary flow reserve in asymptomatic males without coronary artery disease

P.A. Kaufmann[1,2], T. Gnecchi-Ruscone[1], T.F. Lüscher[2], P.G. Camici[1]. *[1]Hammersmith Hospital, ICSM, London, UK; [2]Cardiology, Zurich, Switzerland*

Coronary endothelial dysfunction has been reported in asymptomatic subjects with hypercholesterolemia. The aim of the present study was to evaluate the influence of total cholesterol and its subfractions on the coronary flow reserve (CFR), an index of the integrated function of the coronary circulation

Methods: Using oxygen-15 labeled water and positron emission tomography, myocardial blood flow (MBF, ml/min/g) was measured at rest and during iv adenosine (Ado, 0.14 mg/kg/g) in 80 asymptomatic males: group 1 ($n = 61$; age, 45 ± 7 years) had normal (≤ 6.5 mmol/l) and group 2 ($n = 19$; age, 48 ± 10 years) had elevated total cholesterol.

Results: Total cholesterol was 5.1 ± 0.8 and 7.2 ± 0.7 mmol/l in group 1 and 2 ($p < 0.001$), respectively; LDL was 3.2 ± 0.8 and 4.9 ± 0.7 mmol/l ($p < 0.001$), HDL was 1.1 ± 0.3 and 1.0 ± 0.4 (p = ns) and triglycerides were 1.8 ± 1.3 and 3.0 ± 1.8 mmol/l mmol/l ($p < 0.005$). Group 1 and 2 had comparable MBF-rest (0.87 ± 0.14 vs 0.84 ± 0.14), MBF-Ado (3.63 ± 1.02 vs 3.30 ± 0.86) and CFR (4.23 ± 1.29 vs 3.95 ± 0.93); p = ns for all 3 comparisons. A significant, but weak correlation was found between CFR and HDL in group 1 ($r = 0.29$, $p < 0.05$), but not in group 2. In contrast, a significant inverse correlation between LDL and CFR was found in group 2 ($r = -0.61$, $p < 0.05$), but not in group 1.

Conclusions: In contrast to previous reports we found no correlation between CFR and total cholesterol. This might be due to different selection criteria. However, LDL cholesterol subfraction correlated inversely with CFR in hypercholesterolemic subjects supporting a pathogenetic role for the LDL subfraction in microcirculatory dysfunction.

P1049 Lipoprotein a as an independent risk factor for coronary artery disease in patients with angina

E. Moreno, O. Baun, R. García, R. Melgares, A. Navarrete, B. Lamenca, A. Poyatos[1], R. Valenzuela[2], L.J. Baena[2], N. Ruiz[2]. *[1]Dept of Cardiology, Laboratory Dept.; [2]Nursing Unit, University Hospital Virgen de las Nieves, Granada, Spain*

There are few studies using a multivariate analysis about predictor factors of coronary artery disease (CAD) in patients with angina. Seldom they include Lipoprotein a.

For that purpose, we have designed a case-control study including patients who underwent a coronary arteriography, collecting clinical variables and analytical parameters focusing on the lipid profile.

Methods: From a total population of 869 consecutive patients who underwent a coronary arteriography between April 1997 and Dec 1997, we included 188, with the following inclusion and exclusion criteria: age > 18, indication of invasive study because of unstable angina or stable angina with high risk criteria on non invasive tests. Exclusion: creatinine ≥ 2.5 mg/dl, hyperthyroidism, hepatopathy, and previous hypolipemiant treatment.

We collected the following clinical variables: age, gender, hyperlipidemie, hypertension, diabetes, tobacco, ancient AMI, and hematologic and biochemical parameters; total CHO, triglycerids, LDL, HDL, apolipoproteins A and B, lipoprotein a, platelets, fibrinogen and hemoglobine.

Blood samples were obtained before coronariography, and frozen to −40 degrees. A blind analysis was performed. We took the mean of three different measures on each sample.

Coronariography was performed by an independent physician, and lesions of any severity were considered. 144 patients had CAD, and 44 had no lesions.

Variables were analysed by SPSS 8.0, with t-Student test. We found significance for the following variables: ancient AMI, hypertension, diabetes, smoking, masculine gender, total cholesterol, LDL, LDL/HDL ratio, apolipoprotein b, fibrinogen and lipoprotein a.

Subsequently, a regression logistic test was performed, with a CI of 95%, and we obtained as independent risk factors for CAD: ancient AMI ($p = 0.0001$), masculine gender ($p = 0.0014$), ratio LDL/HDL ($p = 0.0042$), and lipoprotein a ($p = 0.010$). This last parameter had a Sens of 50% and a Spec 93.6%, with an OR = 14.66 (7.38–28.87) (CI Fisher), p corrected by Yates of 0.00001.

Conclusions: 1. In our study, in patients with angina, masculine gender, LDL/HDL ratio, and lipoprotein a > 30 mg/dl were the only independent risk factors for CAD.

2. The relative risk for CAD in patients with lipoprotein a > 30 mg/dl is 14 times that in subjects with low levels.

P1050 Hypertensive middle-aged men have exaggerated and prolonged rise of plasma triglyceride values postprandially similar to coronary artery disease and diabetes mellitus patients

Genovefa Kolovou, Georgia Grapsa, Stela Iraklianou, Eleni Alexandratou, Evdokia Adamopoulou, Nikolaos Kafaltis, Alexandra Valaora, Panayota Kaperneka, Dennis V. Cokkinos. *1st Cardiology Department, Onassis Cardiac Surgery Center, Athens, Greece*

Objective: Previous studies have shown that patients with coronary artery disease (CAD) have an exaggerated rise and a delayed fall of plasma triglycerides (TG) after fat loading (FL). We designed this study since no data exist as regards the response to FL in patients (pts) with primary hypertension (HYP) compared to pts with CAD and non insulin dependent diabetes mellitus (DM)

Methods: A fat rich meal (83.5% fat, 1604 calories per m^2 body surface) was given to 21 pts with HYP without CAD, to 18 normotensive individuals without CAD and no risk factors (Controls), to 20 normotensive pts with proven CAD (CAD + No HYP) and 16 pts with DM without CAD or HYP, all with similar baseline TG values.

Results: Total and high density lipoprotein cholesterol did not change significantly in any group. The TG values increased % significantly 6 h after fat loading in HYP, CAD + NoHYP and DM pts compared to Controls ($137 \pm 79\%$ in HYP, $128 \pm 86\%$ in CAD + NoHYP pts, $91 \pm 67\%$ in DM, $76 \pm 54\%$ in Controls; $p = 0.001$, $p = 0.04$ and $p = 0.01$ respectively) and 8 h ($107 \pm 85\%$ in HYP, $81 \pm 66\%$ in CAD + NoHYP pts, $62 \pm 54\%$ in DM, $55 \pm 41\%$ in Controls; $p = 0.0003$, $p = 0.05$ and 0.004 respectively). The rise in TG values in HYP pts over that predicted from Controls was 82 mg/dl higher at 6 h ($p = 0.0009$) and 71 mg/dl ($p = 0.0008$) higher at 8 h than expected; in CAD + NoHYP pts the corresponding increases were 68 mg/dl at 6 h ($p < 0.05$) and 54 mg/dl ($p = 0.09$) at 8 h. In DM pts the corresponding increases were higher 63 mg/dl at 6 h, $p = 0.03$, and 50 mg/dl higher at 8 h than expected $p = 0.02$.

Conclusions: The study suggests that HYP and DM pts, have an exaggerated and prolonged rise of plasma triglyceride values after fat loading, similar to CAD + NoHYP pts compared to Controls.

P1051 Efficacy and safety of atorvastatin versus simvastatin in type II diabetes patients with coronary heart disease

W. März, H. Wollschläger[1], G. Klein[2], A. Neiss[3], M. Wehling[3]. *University of Freiburg; [1]Städtisches Krankenhaus Amberg; [2]Reha-Clinic, Bernried; [3]University of Heidelberg, Germany*

In type II diabetes, the atherogenic lipid trias contribute to the elevated risk of macrovascular disease. The Target Tangible study compared the effects of atorvastatin and simvastatin in a large cohort of coronary heart disease (CHD) patients in Germany. We conducted a subgroup analysis to assess the efficacy and safety of atorvastatin and simvastatin in patients with type II diabetes.

Methods: Patients with LDL-C levels ≥ 130 mg/dL (3.4 mmol/L) entered a 6-week washout. Those meeting the lipid entry criteria were randomized (2:1) to atorvastatin 10 mg or simvastatin 10 mg for 14 weeks. Dose was increased to 20 mg and 40 mg at weeks 5 and/or 10, respectively, if the target LDL-C level of <100 mg/dL (2.6 mmol/L) was not achieved. Primary endpoints were efficacy (responder rates) and safety (adverse events and laboratory measurements). Secondary endpoints were changes in lipid parameters including TGs.

Results: A total of 2856 patients met the lipid entry criteria; of whom 517 (18%) had diagnoses of type II diabetes. A greater percent of diabetic patients (67%) reached the goal than non-diabetic (61%). Significantly ($p < 0.001$) more patients achieved the LDL-C goal with atorvastatin (72% and 66% in diabetics and non-diabetics, respectively) than with simvastatin (57% and 52%). Furthermore, the median percent TG lowering on study completion was −29% on atorvastatin and −15% on simvastatin in diabetics vs −28% and −21%, respectively, in non-diabetics. There was no significant difference in adverse event rates between atorvastatin- and simvastatin-treated patients. Elevations of creatine kinase and liver enzymes > 3× ULN occurred in 0.4% and 0.2%, respectively, of diabetics and 0.3% and 0.1% of non-diabetics with no significant difference in these parameters between atorvastatin- and simvastatin-treated patients.

Conclusions: Benefits of statin treatment were significantly greater in diabetic than in non-diabetic patients. Atorvastatin was more effective than simvastatin in lowering LDL-C and TGs, and more type II diabetes patients reached LDL-C goals with atorvastatin than with simvastatin.

P1052 Cost-effectiveness of statin therapy against mild to moderate hypercholesterolemia in patients with coronary artery disease

L. Melilli, R. Arora. *Interventional Cardiology Dept., Columbia University, Katonah NY, USA*

Background: The recent Lipoprotein and Coronary Atherosclerosis Study (LCAS) demonstrated that fluvastatin significantly slowed coronary artery disease (CAD) progression compared to placebo, with less need for revascularization procedures and fewer deaths over a 2-year follow-up period. This cost analysis was conducted to determine the long-term cost-effectiveness of fluvastatin based on these findings.

Methods: Wholesale drug costs and mean 1996 New York State Medicare/Medicaid charges were applied to drug and procedure rates reported in LCAS. The cost effectiveness of fluvastatin was assessed for lives saved (including all drug- and procedure-related charges), and myocardial (coronary angioplasty, coronary artery bypass grafting, coronary stent, atherectomy, or transcatheter revascularization) and all (myocardial revascularization, carotid endarterectomy, peripheral angioplasty, or peripheral bypass fraft) revascularization procedures avoided for up to 2 years.

Results: Fluvastatin resulted in per patient cost savings of from $621.19 to $836.39 for myocardial revascularization procedures avoided, and from $946.58 to $1274.51 for all rescularization procedures avoided. Moreover, fluvastatin provided cost savings of from $1568.11 to $2111.24 per life saved over a 2-year period.

Conclusion: Fluvastatin provides significant cost-effectiveness benefits in treatment of mild to moderate hypercholesterolemia in patients with CAD. These cost benefits are related to fewer deaths and fewer required revascularization procedures over a 2-year follow-up period.

P1053 Treatment of mixed hyperlipidaemia in coronary artery disease patients with fluvastatin and bezafibrate in monotherapy and combination

P. Pauciullo[1], M. Mancini[1], M. Mariani[2], M. Cortellaro[3], R. Paoletti[3]. *On behalf of the FACT study centres; [1]University of Naples, Naples; [2]University of Pisa, Pisa; [3]University of Milan, Milan, Italy*

Purpose: The Fluvastatin Alone and in Combination Treatment (FACT) study was designed (a) to compare the long-term effects of fluvastatin and bezafibrate in monotherapy and in combination on plasma lipids and serum fibrinogen in patients with coronary artery disease (CAD) and mixed hyperlipidaemia; (b) to assess the safety and tolerability of the fluvastatin and bezafibrate combination.

Methods: In this multicentre, double-blind, parallel group study 333 patients (age 56 ± 8 years, LDL- cholesterol 135–250 mg/dL and triglycerides 180–400 mg/dL) were randomised to receive fluvastatin (F) 40 mg or bezafibrate (B) 400 mg or fluvastatin 20 mg plus bezafibrate 400 mg or fluvastatin 40 mg plus bezafibrate 400 mg for 24 weeks.

Results: Baseline (Base) lipids and fibrinogen values (mean ± SD) and mean % change (Δ) are reported:

Parameter (mg/dL)	F 40 mg		B 400 mg		F 20 mg B 400 mg		F 40 mg B 400 mg	
	Base	% Δ	Base	% Δ	Base	% Δ	Base	% Δ
LDL-C	190 ± 35	−23†	179 ± 32	−8	187 ± 34	−23†	191 ± 36	−25†
Triglyceride	264 ± 65	−7	256 ± 65	−24†	254 ± 57	−35†	261 ± 73	−38†‡
HDL-C	39 ± 8	1	42 ± 10	16†	40 ± 8	21†	42 ± 9	21†
Fibrinogen	352 ± 83	−4	322 ± 51	−9†	339 ± 69	−14†	319 ± 57	−16†τ

†$p \leq 0.001$, τ$p < 0.01$, ‡$p < 0.05$

No clinically relevant hepatic or muscular laboratory abnormalities were reported. Adverse events did not occur more frequently with combination than with monotherapy.

Conclusion: The combination of fluvastatin 40 mg and bezafibrate 400 mg was significantly more effective in reducing both LDL-C and triglycerides than bezafibrate alone in CAD patients with mixed hyperlipidaemia.

P1054 Is the beneficial effect of lipid-intervention in coronary artery disease related to both lowering of triglycerides and of LDL cholesterol?

U.F.E. Rensing, H. Roskamm, P. Betz, M. Spinder. *For the CIS-Investigators; Herz-Zentrum, Bad Krozingen, Germany*

It is well established that LDL-Cholesterol (LDL-C) promotes progression of coronary artery disease (CAD), and that lowering LDL-C will inhibit it. However, it is still a matter of debate wether lowering triglycerides (TG) also inhibits progression. This is what we studied.

Methods: The Coronary Intervention Study, CIS, is a multi-centre, randomized, double-blind, placebo-controlled study to investigate the *angiographic* effects of lipid-intervention on progression of CAD in 254 *young* men with hypercholesterolemia. LDL-C targeted treatment with up to 40 mg simvastatin or placebo o.d., and add-on medication (colestyramine), was pursued for a mean of 2.3 years and resulted in significant differences (Δ) of serum lipids between the treatment groups [e.g. ΔLDL-C = −5%, ΔTG = −6% by intention to treat analysis (ITT)].

Results: Two pre-defined primary end points had been chosen to assess for progression: the mean change in minimum lumen diameter ($MinLD_{1-2}$), and the visual global change score (GCS). These two parameters of progression developed differently between the treatment groups and in relation to treatment: the difference between the groups (Δ), amounted to 0.12 mm for the $\Delta MinLD_{1-2}$ ($p = 0.0000$), and to 0.61 for the ΔGCS ($p = 0.0001$), as determined in fully compliant patients by an analysis 'as treated' and, by ITT-analysis in all patients, Δ still amounted to 0.08 mm for the $\Delta minLD_{1-2}$ ($p = 0.0022$), and to 0.38 for the ΔGCS ($p = 0.02$). Upon multivariate analysis (ITT) of all patients in both treatment groups, TG and LDL-C turned out to be independently correlated to the quantitative criterion of progression, the $MinLD_{1-2}$, whereas HDL-C, VLDL-C, and APOA did not:

Multilinear Regression Analysis: $MinLD_{1-2} = -0.109 + 0.0003TG + 0.0008LDL\text{-}C$ [mg/dl]

N = 201	$r_{univariate}$	$r'_{multivariate}$	F-ratio***	$R_{multiple}$	Mean# ± SD
TG	0.228*	0.228	10.9	0.228	186 ± 105
LDL-C	0.226*	0.205	8.7	0.303	139 ± 42
VLDL-C	0.187*	−0.041	<4		31 ± 24
HDL-C	−0.129°	−0.037	<4		47 ± 10

*$P \leq 0.01$; °n.s.; ** > 4 indicates multivariate significance; r, r', R = correlations; # on treatment

Conclusion: In young men, under the conditions of the CIS, lipid intervention inhibited progression of CAD in a treatment related manner, and of the lipids studied, only TG and LDL-C determined progression independently.

P1055 Mutations in the human paraoxonase gene: frequencies, allelic linkages and association with coronary artery disease

K. Stangl, I. Cascorbi[1], M. Laule, V. Stangl, G. Baumann, I. Roots[1]. *Med. Klinik, Kardiologie, Campus Mitte, Charité, Humboldt Universität, Berlin, Berlin[1] Klinische Pharmakologie, Charite, Humboldt Universität, Berlin, Germany*

Objectives: We sought to investigate the frequencies and linkages of paraoxonase 1 (PON1) mutations and their association to the risk of coronary artery disease (CAD).

Background: Oxidative damage is a major cause of atherosclerosis. Since human paraoxonase is suggested to play a role in protection from LDL-oxidation, recent studies have dealt with the impact of hereditary PON1 gene polymorphisms as risk factors for CAD. The results from these studies are conflicting.

Methods: In a case-control study, 1000 Caucasian patients with angiographically confirmed CAD were recruited and matched by age and gender to 1000 controls. PON1 mutations in codons 55 and 192 were evaluated by PCR/RFLP and allocated to defined haplotypes *1 (55L/192Q), *2 (55L/192R), and *3 (55M/192Q).

Results: Frequency of PON1 genotypes without any mutation (PON1*1/*1, wild-type) in cases was 16.9% vs. 17.1% in controls. PON1*2/*2 showed a frequency of 6.6% vs. 7.3% ($p = 0.68$ compared to wild-type), and PON1*3/*3 occurred in 11.8% in cases vs. 10.3% among controls ($p = 0.40$). There was also no difference in the distribution of carriers heterozygous for *2 or *3 among cases and controls. A haplotype containing both mutations 55M and 192R was not observed. None of the investigated genotypes showed association with early manifestation, severity of disease, acute coronary syndromes, or myocardial infarction. Logistic regression analysis adjusting for age, gender, diabetes, hypertension, hypercholesterolemia, and smoking revealed no evidence of increased coronary risk associated with PON1 genotypes.

Conclusion: These results suggest that PON1 polymorphisms are not major genetic determinants of CAD.

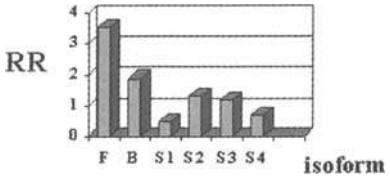
P1056 Lipoprotein(a) and apo(a) isoforms are prognostic markers for women with coronary heart disease

O. Wiklund, U. Lundstam, J. Herlitz[1], T. Karlsson[1], T. Lindén. *Wallenberg Laboratory, Sahlgrenska University Hospital, Gothenburg; [1]Department of Cardiology, Sahlgrenska University Hospital, Gothenburg, Sweden*

Lp(a) as a risk factor is controversial, and few studies have analyzed Lp(a) in relation to prognosis in established CHD. The Lp(a) level is genetically determined, and related to apo(a) isoforms. Low molecular weight isoforms are associated with high plasma levels. In this study lipoproteins, with focus on Lp(a) and apo(a) isoforms, was studied as prognostic markers for patients with CHD.

Subjects and methods: 964 patients (23% women) undergoing coronary angiography due to angina pectoris during 1985–1987. 814 of these had >50% stenosis of at least one vessel. Functional status, risk factors including serum-lipoproteins, Lp(a) and apo(a) isoforms was analyzed. Follow up regarding mortality and cause of death was done in 1998. Mean follow up time was 11.7 years.

Results: In univariate analysis death was related to age and cardiac function. Low HDL and apoA levels were related to increased risk. Surprisingly high cholesterol, LDL and apoB were associated with decreased risk for death. However, when only cardiovascular death was studied no association to cholesterol, LDL or apoB was seen. High Lp(a) was associated with increased risk only for women ($p < 0.02$).



Risk ratio for women in relation to apo(a) isoforms.

For women also the low molecular weight isoforms (F and B) were associated with increased risk for total as well as cardiovascular death. For men isoform F, but not B, was a risk marker.

Conclusion: For women with CHD high Lp(a) levels as well as low molecular weight apo(a) isoforms are associated with increased mortality. For men the results are inconsistent and not conclusive. The results are in accordance with earlier reported results from this study, where only female patients had higher Lp(a) levels compared with a random population sample.

P1057 Regression of atherosclerosis in patients with arterial occlusive disease in war time and post-war time in Sarajevo: a 6-year study

M. Dilic. *Institute of Vascular Diseases, Clinical Center Sarajevo, Sarajevo, Bosnia-Herzegovina*

It is well known that amelioration of multiple risk factors (MRF) can lead to regression of atheromatous plaques. During the war period, in the besieged city of Sarajevo, we have noticed a clear clinical improvement in the patients with previosly established diagnosis of arterial occlusive disease (AOD). They have prolonged their free walking distance (FWD) despite they were without any medication or medical treatment at all. The aim of this study was to asses potential regression of atherosclerosis by haemodynamic and Color Doppler measurements.

Methods: We followed a group of patients with arterial occlusive diseases (AOD) in Fontaine St. IIA (n = 53) and IIB (n = 76), which showed a clear clinical improvement of their vascular disease. We measured FWD and brachio-pedal index (BPI), as well as Color Doppler examination – pulsatility index (PI), resistive index (RI), average diameter of arterial lumen (ADAL), and regression of plaque (RP). The group was in high risk, with at least 4 out of 7 MRF. The study had three parts, Part I (1993–1994), Part II (1994–1996) and Part III 1996–1998).

Results: In Part I; we had improvement in FWD of 126.5% ($p < 0.001$), of BPI 36.9% and PI 26.4% ($p < 0.01$), and RI 9.2% ($p < 0.05$), of ADAL 11.2% ($p < 0.05$). Direct measurement of plaque regression (PR > 0.9 mm) was of no significance. In Part II; we had improvement of FWD of 58% ($p < 0.01$), of BPI 17.3% and PI 14.9% ($p < 0.05$), of RI 5.6% (NS), of ADAL 8.1% ($p < 0.05$), and RP non-significant. In Part III; improvement of FWD was just 8.5% (NS), of BPI 10.7% and PI 4.5% ($p = 0.02$), of RI −4.9%, and ADAL 1.9% (NS), and regression of plaque non-significant.

In conclusion: The results suggest that we have had initial clinical and flow improvement in Part I and II, which might be in correlation with complete change of life-style in war time (lack of food, body weight reduction, reduction of tobacco smoking). In Part III (post war period), we have improvement of life conditions, and FWD and haemodynamic parameters are going back to 1992.

P1058 Relation of serum C3 to fasting insulin and traditional risk factors in 1090 middle aged men

A. Muscari, G. Massarelli, L. Bastagli, G. Poggiopollini, V. Tomassetti, G. Drago, C. Martignani, P. Pacilli, P. Boni[1], P. Puddu. *Dept. Internal Medicine, S.Orsola Hospital – Univ. of Bologna, Bologna; [1]S.Orsola-Malpighi Hospital, Central Laboratory, Bologna, Italy*

Background: Serum C3, a powerful indicator of the risk of myocardial infarction (MI), is produced by activated macrophages, hepatocytes and adipocytes. C3 (the third complement component) is the precursor of C3a-des-Arg, the most potent stimulator of triglyceride synthesis and glucose transmembrane transport in the adipose tissue. C3 levels are known to correlate with body mass index (BMI), serum lipids, blood glucose and blood pressure. Aim of this study was to ascertain whether an association between C3 and fasting insulin, a recognized index of insulin resistance, may explain the above correlations.

Methods: The fasting serum levels of C3, insulin (INS), glucose (G), triglycerides (TG), total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), as well as systolic (SBP) and diastolic (DBP) blood pressure, BMI, history of diabetes or hypertension, smoking habit, alcohol consumption, physical activity, previous MI and family history of MI (FH-MI) were assessed in 1090 unselected men, aged 55–64 years.

Results: In a logistic regression model including all the study variables, only C3 ($P = 0.011$), FH-MI ($P = 0.018$), ex-smoker status ($P = 0.020$), age ($P = 0.025$), G ($P = 0.028$) and HDL-C ($P = 0.051$, inverse relation) were significantly associated with previous MI ($N = 51$). In univariate analysis serum C3 (1.11 ± 0.18 (1 SD) g/l) was associated with all the variables assessed, except FH-MI and cigarette smoking. The strongest simple correlations were with INS (rho = 0.46), TG (rho = 0.35) and BMI (rho = 0.35). The relation of C3 to physical activity, alcohol consumption and HDL-C was of inverse type. In multiple linear regression (MLR), C3 was independently assbciated with INS ($r = 0.27$, $P < 0.0001$), TC ($r = 0.18$, $P < 0.0001$), BMI ($r = 0.13$, $P < 0.0001$), G ($r = 0.12$, $P = 0.0001$), SBP ($r = 0.10$, $P = 0.0007$), TG ($r = 0.09$, $P = 0.002$) and HDL-C ($r = -0.06$, $P = 0.048$). The overall R^2 was 0.31. In MLR, without C3 among the independent variables, INS correlated with BMI, TG, HDL-C (inversely), DBP and G. When C3 was included in the model, INS correlated with BMI, C3, TG and HDL-C only.

Conclusions: Serum C3 strongly correlates with INS, but this does not explain entirely any of the independent correlations between C3 and traditional risk factors. Rather, the relation of INS to some variables seems to be mediated by C3.

P1059 Elevated plasma lipid peroxides in acute myocardial infarction and stable angina

D.A. Gorog, N. Jackson[1], C.M. Travill[1], G.J. Davies. *Cardiology Department, Hammersmith Hospital, ICSM, London; [1]Cardiology Department, Luton; Dunstable Hospital, Luton, UK*

The concept that oxidised low density lipoprotein (ox-LDL), not native LDL, plays a major role in atherogenesis is gaining support. The platelet-stimulating effect of ox-LDL may contribute to the pathomechanism of platelet hyper-reactivity observed in coronary artery disease (CAD). Lipid hydroperoxides in plasma are carried almost exclusively in LDL and reflect ox-LDL. Previously, elevated plasma ox-LDL was measured in patients with CAD after bypass surgery. As coronary bypass may contribute to generation of ox-LDL in the circulation, we measured plasma lipid hydroperoxides (ox-LDL) in acute myocardial infarction (AMI) and stable angina.

Methods and Results 24 patients with AMI and 29 patients with stable angina were compared with 21 age-matched controls. Lipids and lipoproteins were selectively removed from plasma by absorption to Liposorb® gel. Lipid hydroperoxide concentration in the washed gel was measured by a sensitive and specific triiodide spectrophotometric technique. Lipid hydroperoxide levels in patients with AMI and stable angina were significantly elevated (2.93 ± 0.21 μmol/L, p = 0.0218 and 3.18 ± 0.27 μmol/L, p = 0.066) compared to controls (2.28 ± 0.16 μmol/L). Previously, a plasma concentration > 3 μmol/L was considered pathological. Using this criteria, we detected pathological lipid hydroperoxide concentrations in 9.5% of controls, 37.5% of AMI and 55.2% of stable angina patients.

Conclusion Plasma levels of lipid hydroperoxides (ox-LDL) are significantly elevated in CAD presenting with AMI and angina. This increase is not attributable to a previous cardiopulmonary bypass procedure but to the presence of atherosclerotic disease. Raised levels of plasma ox-LDL may contribute to both atherogenesis and thrombogenesis in coronary artery disease.

GENETICS OF ATHEROSCLEROSIS – EXPERIMENTAL AND CLINICAL

P1060 Oligonucleotides anti-p50 and anti-p65 inhibit the nuclear factor-κB-mediated expression of ICAM-1 in human coronary vascular cells

R. Voisard[1], N. Huber[1], R. Baur[1], M. Susa[2], O. Ickrath[3], A. Both[3], W. Koenig[1], V. Hombach[1]. *[1]Department of Internal Medicine II (Cardiology); [2]Institute of Microbiology, University of Ulm; [3]Katharinen Hospital Stuttgart, Germany*

Activated coronary vascular cells express adhesion molecules after angioplasty. We investigated whether an inhibition of the two subunits of nuclear factor-κB (NF-κB), p50 and p65, can reduce the expression of the intercelluar adhesion molecule-1 (ICAM-1) in human coronary vascular cells.

Methods: Smooth muscle cells from human coronary plaque material (HCPSMC, plaque material of 52 patients) and human coronary endothelial cells (HCAEC) were successfully cultured. The expression of adhesion molecules was stimulated by tumor necrosis factor-α (TNF-α, 20 ng/mL, 6 hrs). 12 hrs prior to the TNF-α stimulus anti-p65 and anti-p50 oligonucleotides (1, 2, 4, 10, 20, and 30 μM) were added to the cultures for a period of 18 hrs. The surface expression of ICAM-1 was analysed with monoclonal antibodies using an immunofluorescence microscope.

Results: In HCAEC the surface expression of ICAM-1 was inhibited in a dose dependent manner after adding of anti-p65 and anti-p50 in the concentrations of 2, 4, 10, 20, and 30 μM, reaching a maximal inhibition of more than 55% after 30 μM. In HCPSMC the first inhibition of ICAM-1 expression was seen after incubation with anti-p65 and anti-p50 in a concentration of 10 μM, a maximal inhibition of 31.8% was documented after incubation with 30 μM.

In conclusion: The presented data contribute important information for the development of therapeutic antisense strategies aiming at an inhibition of the surface expression of adhesion molecules in early restenosis.

P1061 Reduction of in-stent restenosis in porcine coronary arteries after local delivery of adenovirus encoding NOS3

O. Varenne, P. Sinnaeve[1], H. Gillijns, H.K. Gold[2], F. Van de Werf[1], R.D. Gerard, D. Collen, S. Janssens[1]. *Center for Gene Therapy, VIB, Leuven; [1]Department of Cardiology, University of Leuven, Leuven, Belgium[2]Department of Cardiology, MGH, Boston, USA*

In-stent restenosis caused by neointima (NI) formation remains a challenging problem for interventionnal cardiologists. To assess the ability of adenoviral gene transfer to inhibit restenosis, porcine coronary arteries were balloon-injured with three 30 sec inflations at 8 atm. Recombinant adenovirus (1.5x10e9 PFU) encoding endothelial nitric oxide synthase cDNA (AdNOS3, n = 22) or no transgene product (AdRR5, n = 22) was blindly injected at the site of PTCA using a local drug delivery catheter. After gene transfer, a 7 mm Palmaz Schatz stent was locally deployed in the center of each transduced area, using two balloon inflations at 14 atm for 30 seconds. Coronary angiograms were obtained after stent implantation (MLDd0) and at 28 days (MLDd28) to evaluate in-stent stenosis. Coronary arteries were harvested, pressure fixed and embedded in plastic. Five-μm sections were prepared every 200 μm and stained with hematoxylin and eosin for subsequent analysis. NI area (NA), vessel area (VA), and lumen area (LA) were measured at the site of maximal NI formation. MLDd0, MLDd28 and VA were similar in AdNOS3 and AdRR5. NA area was significantly reduced, and LA was significantly increased in stented arteries transduced with AdNOS3 by comparison to controls.

Table

	AdNOS	AdRR5	P value
MLDd0 (mm)	2.97 ± 0.06	2.87 ± 0.07	NS
MLDd28 (mm)	2.33 ± 0.12	2.03 ± 0.19	NS
VA (mm^2)	10.0 ± 0.34	9.85 ± 0.57	NS
LA (mm^2)	5.04 ± 0.53	3.60 ± 0.49	0.020
NIA (mm^2)	2.92 ± 0.47	4.56 ± 0.69	0.046

These results suggest a beneficial action of NOS3 gene transfer in stented porcine coronary arteries and may represent an attractive alternative for the treatment of in-stent restenosis.

P1062 Adenoviral gene therapy with a novel dCK/ara-C suicide system for vascular smooth muscle cell proliferation after arterial injury

K. Iwano, Y. Manome[1], Y. Gotoh, T. Ohno[1], S. Mochizuki[2]. *Cardiology Dept, Saitama Cardiovascular Center, Saitama; [1]Microbiology 1, Jikei University School of Medicine, Tokyo[2]Internal Medicine 4, Jikei University School of Medicine, Tokyo, Japan*

Percutaneous transluminal coronary angioplasty (PTCA) has become a popular treatment for ischemic heart disease. However, restenosis of the treated lesion occurs in one third of the patients. Because of that, prevention of restenosis is one of the urgent subjects for treatment of ischemic heart disease.

Methods and Results: In this study, we demonstrated the potent inhibition of vascular smooth muscle cell proliferation after arterial injury by adenoviral gene transfer with a novel suicide gene system, called deoxycytidine kinase (dCK) /arabinofuranosyl cytosine (ara-C) system. Our system has a significant potential advantage for treatment of restenosis, because vascular smooth muscle cell were extremely sensitive to the metabolite of ara-C. Feasibility of this system for vascular restenosis was greater than the previously reported systems such as HSV thymidine kinase or bacterial cytosine deaminase gene. We first demonstrated adenoviral vector efficiently transduced the dCK gene into the vascular smooth muscle cell. The dCK converts a prodrug, ara-C, to the toxic form. Thus, expressed dCK transgene conferred the sensitivity on the vascular smooth muscle cell to the ara-C in vitro. Next, we performed an in vivo gene therapy experiment. A 2F Fogarty balloon catheter was inserted from the right femoral artery of the rats and the intima of the left carotid artery was injured. With this arterial injury model, we could easily reproduce the vascular stenosis by smooth muscle cell proliferation and the Intima/Media ratio (%) reached up to 136.4 ± 29.8 after two weeks. After the carotid arterial injury, we transferred the dCK gene by adenoviral vector and then the rats were treated with ara-C or saline. Thickness of the carotid arterial wall was assessed and we observed the dCK/ara-C treated group exhibited a significant lower Intima/Media ratio (= 18.1 ± 36.2) than other control groups (= 140.6 ± 59.1) ($p < 0.01$).

Conclusion: These data suggest that adenoviral mediated dCK gene transduction and ara-C treatment prevent the smooth muscle cell proliferation after arterial injury and may present a promising approach for restenosis after PTCA.

P1063 Isolation/characterization of canine heart nitric oxide synthase III complementary deoxyribonucleic acid and promoter region

M. Schwemmer, E. Bassenge. *Albert-Ludwigs-University, Institute of Applied Physiology, Freiburg, Germany*

The endothelial nitric oxide synthase (NOS-III) is the main source for endogenous production of nitric oxide (NO) in the vasculature (e.g. endothelial cells, platelets). It is critically involved in the regulation of vascular tone and platelet function and altered expression of NOS-III is implicated in a variety of cardiovascular diseases with concomitant endothelial or platelet dysfunction (e.g. atherosclerosis, dyslipidemia, hypertension).

Aim of the study: to isolate and characterize canine NOS-III cDNA and regulatory (promoter) sequences with reference to known sequences in other species.

Methods: The complete coding sequence of NOS-III cDNA in conjunction with untranslated regions (5'- or 3'-UTR) and promoter region was identified by homologous (RT-)PCR cloning strategy. Primer sequences were derived from bovine or human NOS-III cDNA or gene (5'- or 3'-UTR) sequences to obtain 7 successful and overlapping (RT-)PCR amplifications on canine heart total RNA or genomic DNA (for promoter region) that were cloned and verified by sequencing. Sequence analysis was performed using the ENTREZ and BLAST programs.

Results: A NOS-III sequence contig of 5134 nucleotides length was established using homologous PCR cloning of canine heart RNA/DNA. An open reading frame (ORF) comprising 3609 nucleotides (1203 amino acids) with 253 bp 3'-UTR (distal to TGA codon) and 1272 bp 5'-UTR (proximal to ATG codon; promoter region) was identified. ORF sequence pair comparisons to the human and bovine NOS-III sequences at the nucleotide or amino acid level yielded 90% and 88% or up to 84% and 86% homologies, respectively. Sequence analysis of the canine NOS-III promoter regions revealed a stretch of 310 nucleotides with 83% homology to the human sequence that contains a cluster of binding sites for several regulatory elements (AP-1, cAMP, GATA-box, acute phase reactant...).

Summary and Conclusions: Isolation and characterization of the canine heart NOS-III cDNA with adjacent UTRs was readily achieved by homology PCR cloning. Canine NOS-III cDNA and promoter sequences are highly homologous to known human and bovine sequences. The homology PCR cloning strategy is presented as an alternative to common library cloning approaches. The obtained canine NOS-III sequences might serve to further analyze structure, regulated function (promoter region consensus sites), and expression of NOS-III in different pathophysiological conditions and in other species, too.

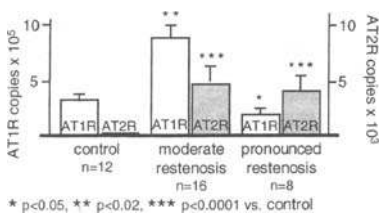
P1064 Angiotensin II receptor subtype gene expression after stent implantation in a pig model

I. Haehnel, U. Pfeifer, A. Resch, B. Märkl, R. Herrmann, A. Schömig, E. Alt. *I. Med. Klinik, Klinikum rechts der Isar; Deutsches Herzzentrum, Technische Universität München, Munich, Germany*

Background: Angiotensin II has been attributed as a potent growth factor on promoting proliferation of vascular smooth muscle cells. Reports on the association of ACE and AT1 receptor gene polymorphisms to restenosis after PTCA or stenting implicate an important role for this process. This study was designed to investigate the nature and magnitude of changes in the levels of the AT1R and AT2R gene expression in the proliferative response to coronary stent implantation.

Methods: Twelve pigs were implanted with slotted tube stents in the LAD and LCx. After 10 days the stented vessels were removed and snap frozen. Samples were cut in half to compare the direction and magnitude of changes in ATR subtype expression levels with histomorphometric analysis. Non-competitive RT-PCR was utilized to measure expression levels utilizing synthetic internal standard mRNAs. β-actin expression was used to correct for variation in sample size.

Results: Samples were divided in 2 groups according to the mean lumen diameter (MLD) stenosis in the histomorphometric analysis: moderate with an MLD of 19.1 ± 3.1% (n = 16) and pronounced with an MLD of 33.6 ± 5.2% (n = 8).



Conclusion: The shift in ATR gene expression levels indicates the importance of the RAS for stent restenosis. The decrease of AT1R in samples with pronounced stenosis could be due to a desensitation at the receptor level. Further studies are warranted with local ACE inhibitors/ATR antagonists applied with local delivery systems, such as biodegradable stent coatings, for reducing in-stent restenosis.

P1065 Antisense oligonucleotide *c-myb*: effects on apoptosis of porcine vascular smooth muscle cells and aortic endothelial cells

D.L. Lambert, S.E. Francis, J. Gunn, D.C. Crossman, D.C. Cumberland, C.M. Holt. *Cardiovascular Medicine Group, Division of Clinical Sciences (NGHT), Northern General Hospital Site, University of Sheffield, UK*

Introduction: Local delivery of antisense oligonucleotide (AS-ODN) *c-myb* at the time of angioplasty decreases neointima formation in a number of animal models via suppression of vascular smooth muscle cell (VSMC) proliferation and migration. Recently, c-*myb* has been reported to be involved in the control of apoptosis in some cell types. We tested the effect of AS-ODN *c-myb* on apoptosis of porcine VSMC and aortic endothelial cells (PAEC) *in vitro*.

Methods: Cultures were washed and incubated with media containing 0.5% porcine serum (PS) with; vehicle sham, 5 μM AS-ODN c-*myb* or 5 μM sense (SN)-ODN c-*myb* for 24 hrs. Cultures were analysed with a commercial cell death ELISA; or filmed by time lapse video microscopy (TLVM). Apoptosis was confirmed with electrophoresis of fragmented DNA.

Results: By ELISA, apoptosis was increased 2.2 ± 0.4 fold in AS-ODN c-*myb* treated PVSMC ($p < 0.005$) compared to sham treated cultures, whilst SN-ODN *c-myb* decreased apoptosis 0.7 ± 0.1 fold (p = n.s.). By TLVM, apoptosis increased from; 1.8 ± 0.4% sham, to 6.8 ± 0.8% AS-ODN *c-myb* ($p < 0.001$) and 2.2 ± 0.4% SN-ODN c-*myb* (p = n.s.).

In PAEC, via ELISA AS-ODN c-*myb* treatment decreased apoptosis 0.8 ± 0.1 fold (p = n.s.). SN-ODN c-*myb* treatment decreased apoptosis 0.7 ± 0.2 fold (p = n.s.). Using TLVM, AS-ODN c-*myb* treatment had no effect on PAEC apoptosis; 1.4 ± 0.2% sham, 1.4 ± 0.5% AS-ODN *c-myb* (p = n.s).

Conclusions: AS-ODN *c-myb* treatment of VSMC increased apoptosis 2–3 fold whereas SN-ODN c-*myb* showed no effect. Neither AS-, or SN-ODN treatment affected apoptosis of PAEC. Local delivery of AS-ODN *c-myb* at angioplasty may modify the VSMC apoptotic profile.

P1066 The *fms*-like tyrosine kinase-1 promoter drives high-level, endothelium-restricted transgene expression in isolated cell cultures and in human saphenous vein in situ, using adenoviral-mediated gene transfer

S.A. Nicklin, S.J. White, A.H. Baker. *Bristol Heart Institute, University of Bristol, Bristol, UK*

Background: The utility of recombinant adenoviruses (Rad) for vascular gene therapy is limited by the promiscuous tropism of the virus, and the use of non-specific viral promoters, resulting in high level transgene expression in all tissues. As an initial step in addressing this problem, we have evaluated two endothelial cell specific promoters, [*fms*-like tyrosine kinase-1 (*FLT*-1) and von Willebrand factor (*vWF*)], for their ability to drive endothelial cell-restricted transcription from recombinant adenoviruses, RAdFLT-1 and RAdvWF respectively. We have compared this to expression from the cytomegalovirus (CMV) promoter in RAdCMV in both isolated cell cultures and in the human saphenous vein model of organ culture.

Methods: Using a chemiluminescent assay, production of β-galactosidase was quantified in primary human endothelial cells (EC) from umbilical vein (HUVEC) and saphenous vein (HSVEC), and a number of non-endothelial cell types, infected with recombinant adenoviruses. Following this, either RAdCMV or RAdFLT-1 at 1.2×10^{10} plaque forming units (pfu)/ml were exposed to the lumenal surface of segments of human saphenous vein (either endothelium denuded or endothelium intact) for 1 hour. Vein segments were cultured for 7 days and infection efficiency determined by *en face* staining for β-galactosidase. Cell types producing β-galactosidase were determined using immunofluorescent cytochemistry and cell-specific markers.

Results: Levels of β-galactosidase from RAdFLT-1 and RAdvWF were 80% and 1% of RAdCMV in HUVEC and 40% and 0.05% of RAdCMV in HSVEC, respectively. In addition, β-galactosidase production from RAdFLT-1 (as a percentage of RAdCMV) was 0.5% in human primary vascular smooth muscle cells (VSMC), 0.01% in primary fibroblasts, 0.5% in HepG2 and 0.01% in HeLa. *En face* staining of infected veins revealed that RAdCMV produced transgene expression in both endothlium intact and endothelium denuded veins. However, RAdFLT-1 produced high level transgene expression in endothelium intact veins only. Immunofluorescence confirmed that transgene expression from RAdFLT-1 was restricted to endothelial cells.

Conclusion: High level, endothelium-restricted expression of therapeutic genes from the *FLT-1* promoter may be possible for use in vascular gene therapy.

P1067 Transgenic mouse model of positive vessel remodelling and smooth muscle cell proliferation

J. Sindermann, P. Babij[1], K.L. March[2]. *Indiana University, Indianapolis IN; [1]Wyeth-Ayerst Corp., Princeton NJ [2]Roudebush VA Medical Center, Indianapolis IN, USA*

We developed a transgenic mouse with augmented SMC proliferation in vivo by targeted expression of a simian virus 40 T antigen (TAg) under control of a 2.3 kb smooth muscle-myosin heavy chain (SM-MHC) promoter derived from rabbit. This promoter effectively restricted TAg expression to SMC in vasculature, gastrointestinal and genitourinary tract as well as to SMC of spleen capsula and stroma. TAg was not detected in skeletal and cardiac muscle. The mice displayed spontaneous neointima formation in the aorta and major branch vessels, which was accompanied by an age-dependent enlargement of vessel circumferences up to 3.1-fold in comparison with age matched non-transgenic sibling mice. Aortic neointima formation started at the age of five weeks and increased to form a neointima: media ratio of 0.62:1 at the age of eight weeks and 1.13:1 at 13 weeks. Despite this marked neointimal formation, vessels of transgenic animals conserved their luminal area by outward remodeling, with a 1.9-fold diameter increase of the aortic lumen compared with controls. This concomitant thickening and outward remodeling of the transgenic vessel wall in the context of the hyperplasia results in the maintenance of vessel wall stress as a constant parameter. These data suggest that this model of augmented SMC proliferation induces vessel remodeling via signalling mechanisms sensitive to vasuclar wall stress, thus avoiding luminal occlusion. Further manipulation of these mice will shed light on the molecular coupling between proliferation and therapeutic remodeling.

P1068 Cyclic strain stress-induced MKP-1 expression in smooth muscle cells is regulated by Ras/Rac-MAPK pathways

C. Li, Y. Hu, M. Mayr, Q. Xu. *Institute for Biomedical Aging Res., Austrian Academy of Sciences, Innsbruck, Austria*

Recently, we demonstrated that mechanical stress results in rapid phosphorylation or activation of platelet-derived growth factor (PDGF) receptors in vascular smooth muscle cells (VSMCs) followed by activation of mitogen-activated protein kinases (MAPKs) and AP-1 transcription factors (Hu et al., FASEB J. 1998; 12: 1135–1142). Here we provide evidence that VSMC responses to mechanical stress also include induction of MAPK phosphatase-1 (MKP-1), which may serve as a negative regulator of MAPK signaling pathways. When rat VSMCs cultivated on a flexible membrane were subjected to cyclic strain stress (60 cycles/min, 5–30% elongation), induction of MKP-1 proteins and mRNA was observed in time- and strength-dependent manners. Concomitantly, mechanical forces evoked rapid and transient activation of all three members of MAPKs, i.e. extracellular signal-regulated protein kinases (ERKs), c-Jun NH2-terminal kinases (JNKs) or stress-activated protein kinases (SAPKs) and p38 MAPKs. Suramin, a growth factor receptor antagonist, completely abolished ERK activation, significantly blocked MKP-1 expression, but not JNK/SAPK and p38 MAPK activation in response to mechanical stress. Interestingly, VSMC lines stably expressing dominant negative ras (N17) or rac (N17) exhibited a marked decrease in MKP-1 expression; the inhibition of ERK kinases (MEK1/2) by PD 98059 or p38 MAPKs by SB 203580 in VSMCs resulted in a downregulation of MKP-1 induction. Furthermore, overexpressing MKP-1 in VSMCs led to the dephosphorylation and inactivation of ERKs, JNKs/SAPKs and p38 MAPKs and inhibition of DNA synthesis. Taken together, our findings demonstrate that mechanical stress induces MKP-1 expression regulated by two signal pathways, including growth factor receptor-ras-ERK and rac-JNK/SAPK or -p38 MAPK, and that MKP-1 inhibits VSMC proliferation via MAPK inactivation. These results suggest that MKP-1 plays a crucial role in mechanical stress-stimulated signaling leading to VSMC growth and differentiation.

P1069 Overexpression of the catalytic domain of cGMP-dependent protein kinase Iβ reduces proliferation and migration of vascular smooth muscle cells

P. Sinnaeve[1,2], N. Van Pelt[1], H. Gillijns[2], J.D. Chiche[3], D. Collen[2], K. Bloch[3], S. Janssens[1,2]. *[1]Cardiac Unit; [2]Center for Transgene Technology and Gene Therapy, University of Leuven and V.I.B., Belgium; [3]Cardiovascular Research Center, Harvard Medical School, Charlestown MA, USA*

Nitric oxide (NO) directly modulates smooth muscle cells (SMC) proliferation and migration which contribute to the neointimal response to arterial injury. These NO effects on SMC functions appear to be dependent on the second messenger cGMP and its cGMP-dependent Protein Kinase (G-Kinase). We have reported reduced soluble guanylate cyclase expression after vascular injury and we hypothesize that this contributes to neointima formation by mitigating the activation of G-Kinase. To confer constitutive cGMP-independent G-Kinase activity to vascular SMCs, an adenoviral vector carrying the Flag epitope-tagged catalytic domain of GK Iβ was constructed (AdGKcd). Expression in explanted rat aortic SMCs was confirmed using specific anti-Flag antibodies and enzyme activity in extracts from infected cells was demonstrated in a phosphorylation assay using a synthetic G-Kinase substrate. Proliferation, assessed by 5'-BrdU incorporation, was reduced in AdGKcd-infected cells but not in control AdRR5-infected cells (68 ± 10 vs 101 ± 11% of incorporation in uninfected cells, n = 3, <0.05). Transwell migration (8 μm pores) was similarly reduced in AdGKcd-infected cells but not in AdRR5 cells (67 ± 6 vs 102 ± 11% of migration of uninfected cells, n = 5, $P < 0.05$). 8-Br-cGMP (1 mM) was used as a positive control, and reduced migration by 19% ($P < 0.05$, n = 3).

Thus, overexpression of a mutant, constitutively active G-Kinase significantly reduces proliferation and migration of vascular SMCs, and may hold promise as a gene-based therapy for vasculoproliferative disease.

P1070 The cytoskeletal-associated protein moesin is re-expressed in the neointima and media of carotid-arteries after balloon angioplasty: a new approach to comprehension of the molecular biology during the process of restenosis

R. Blindt, K. Hoffmeister, K. Seifert, J. vom Dahl, P. Hanrath. *Medical Clinic I, University Hospital Aachen, Germany*

Background. Migrating cells like myofibroblasts in restenosis change their cell shape and form cellular protrusions like filopodia. A prerequisite for filopodia formation is the rearrangement of actin cytoskeleton. An essential role of moesin (78 kD) is described for Rho-and Rac-dependant assembly of actin filaments. In vivo moesin is not observed in mature smooth muscle cells. The hypothesis is that during the process of restenosis moesin is reexpressed in transformed, migrating myofibroblasts in order to form cellular protrusions.

Methods. 12 hours after balloon angioplasty pig carotid arteries were embedded in paraffin after methanol/ethanol-fixation. Carotid cryosections from the rat-restenosis were obtained after 1 day, 7, 14 and 28 days. Sections were stained with specific antibodies against moesin and smooth muscle cell actin. Anti-moesin antibodies were achieved by immunisation of chickens with isolated moesin.

Results. 12 hours after angioplasty moesin expression was observed in myofibroblasts as well as in dividing cells within the media of the pig carotid artery. To determine the start of moesin expression in the rat-restenosis model immunfluorescence with antibodies against moesin and smooth muscle actin at 1 day, 7 days and 28 days after angioplasty. Even in the early period (1 day) angioplasty tissue staining was positive for moesin and smooth muscle cell actin whereas in the non-dilated control tissue no specific moesin staining could be observed.

Conclusion. These findings demonstrate for the first time a de novo expression of moesin within the arterial media after arterial injury and indicate that moesin may be important for migration and proliferation of myofibroblasts. This indicates a possible role of moesin in the pathogenesis of restenosis after angioplasty and stent implantation.

P1071 Gene transfer of the antisense RNA to 18 kDa isoform of basic fibroblast growth factor inhibits coronary smooth muscle cell proliferation

A. Skaletz-Rorowski, K. Peters, H. Eschert, A. Thormann, C. Naus[1], G. Breithardt[2]. *Inst. f. Arteriosclerosis Research, University of Münster, Münster; [2]Dept. of Cardiology and Angiology, University of Münster and Inst. f. Arteriosclerosis Research, University of Münster, Germany; [1]Dept. of Anatomy, University of Western Ontario, London ON, Canada*

Restenosis with coronary smooth muscle cell (cSMC) proliferation remains a major problem in PTCA. Recent data suggest that the secreted/non-nuclear targeted 18 kD isoform of basic fibroblast growth factor (bFGF) expressed by cSMC plays a prominent role in the autocrine/paracrine proliferative response to vascular injury. To investigate the possibility of (non-viral) plasmid/liposome (PL)-mediated gene transfer in the treatment of restenosis, we transfected bovine cSMC with bFGF cDNA coding for the 18 kD isoform in both the sense and antisense orientation. The plasmid pCI-neo includes the CMV promotor region and a dominant selectable marker, the neomycin phosphotransferase II (NPTII) gene. By using the pCI-neo plasmid, NPTII expression was observed in ca. 20% of cSMC 36 hr posttreatment (immunofluorescence staining). After selection with the antibiotic G418 stably transfected cSMC cultures were characterized with respects to endogenous bFGF expression, proliferation and cell cycle progression. Expression of antisense bFGF RNA (pCI-neo-AS-bFGF) markedly reduced cellular 18 kD bFGF content, whereas overexpression of the sense bFGF coding sequence (pCI-neo-S-bFGF) resulted in high 18 kD bFGF levels (Western Blot). pCI-neo-AS-bFGF cSMC showed a significant decrease in cell number (up to 30% inhibition) compared to pCI-neo transfected cells (control). Growth curves of pCI-neo-S-bFGF cSMC demonstrated an enhanced proliferation (ca. 53%) compared to control. Propidium iodid staining and FACS analysis of transfected cSMC, demonstrated that in contrast to pCL-neo-S-bFGF cSMC the most of the pCI-neo-AS-bFGF cSMC and control cells were in the G_0/G_1 phase, and there was an increase in the proportion of the cells in the S phase from 15% (pCI-neo-AS-bFGF cSMC) to 39% (pCL-neo-S-bFGF cSMC). Our data show, that i) primary cSMC could be transiently and stably transfected using a PL-mediated gene transfer and that ii) the 18 kD isoform of bFGF play an important and potent role in cSMC proliferation.

P1072 The atrial natriuretic peptide gene ScaI polymorphism and history of non-fatal myocardial infarction among males in the north region of Poland

M. Gruchała, D. Ciećwierz, R. Targoński, W. Dubaniewicz, W. Sobiczewski, R. Rotkiewicz-Woźniak, B. Wasag, P. Romanowski, A. Rynkiewicz. *I Dept. Cardiology, Dept. Invasive Cardiology and Dept. Biology and Genetics, Medical University of Gdańsk, Poland*

Atrial natriuretic peptide is one of important hormones responsible for maintenance cardiovascular system homeostasis.

The purpose of this study was to determine potential association between ANP gene polymorphism and incidence of coronary heart disease (CHD), myocardial infarction, arterial hypertension and familial history of CHD among men in the North region of Poland.

We performed a case-control study including 244 male patients with CHD confirmed by coronary angiography (mean age 55 ± 12) and 227 controls (negative history and normal ECG, mean age 46 ± 5). The genotype frequencies were not signifcantly more frequent in both study groups (CHD subjects: A2A2 63%, A1A2 34%, A1A1 3%, controls: A2A2 72%, A1A2 26%, A1A1 2%; p = 0.06). However we have found statically significant difference in genotype distribution between CHD subjects with and without history of survived myocardial infarction. A2A2 genotype was more frequent in males with positive history of myocardial infarction (69% vs. 49%; p = 0.003). There was no association between ANP gene polymorphism and arterial hypertension, familial history of CHD and coronary artery atherosclerosis. Segregation of the ScaI ANP genotypes was independent of common risk factors: body mass index, plasma lipoproteins, triglicerydes, diabetes, arterial hypertension and smoking habits.

In conclusion the A2A2 Sca1ANP genotype seems to be a risk factor for myocardial infarction among males with angiographically confirmed coronary artherosclerosis.

P1073 Functional relevance of atherosclerosis-associated Ser128Arg and Leu554Phe E-selectin mutations

K. Wenzel, R. Stahn[1], C. Glaeser[2], G. Baumann, S.B. Felix. *Department of Internal Medicine I, Charité, Berlin; [1]Max-Delbrück-Center Berlin; [2]University Halle, Germany*

The cellular adhesion molecule E-selectin is expressed on activated endothelial cells and is involved in the process of adherence of blood cells to the vessel endothelium in inflammatory events like atherosclerosis. In a recent study we found a Ser128Arg and a Leu554Phe mutation in the E-selectin gene, as well as increased frequencies of both mutations in young patients with severe coronary atherosclerosis. In this study we investigated the influence of these mutations on the cell adhesion and release of soluble E-selectin.

Methods: Mutants were created by site directed mutagenesis and COS cells transfected with E-selectin wild-type or mutants. Using transfected COS cells and interleukin-1 beta stimulated HUVECs we performed antibody binding studies and cell adhesion assays. Soluble E-selectin in supernatants of wild-type and Leu554Phe mutant transfected COS cells was estimated by ELISA.

Results: Significant differences were found in the strength of HL-60 cell adhesion for the Ser128Arg mutant: Adhesion strength to the mutant was reduced compared to wild-type on transfected COS cells ($P < 0.01$) as well as on stimulated HUVECs ($P < 0.01$). Significantly diminished release of soluble E-selectin was detected for the Leu554Phe membrane domain mutant compared to the wild-type.

In conclusion, the Ser128Arg and Leu554Phe mutations influence the E-selectin function in vitro. The results indicate a contribution of both analysed mutations for dysregulation in inflammation and thereby in the complex pathogenesis of atherosclerosis.

P1074 No association between M235T polymorphism of the angiotensinogen gene and risk of coronary heart disease

B. Klein, M. Kempf, R. Gök, M. Vater, M. Nauck, M. Hoffmann, W. März, J. Senges, B.R. Winkelmann. *Herzzentrum Ludwigshafen; Institute für Klinische Chemie, Universitätsklinikum Freiburg, Germany*

Background: The point mutation M235T of the human angiontensinogen gene is known to be associated with an increase of the plasma angiotensinogen level. Several studies found a correlation between the T-allele and arterial hypertension and others have reported an association with CAD.

Methods: LURIC is a prospective case control study on environmental and genetic risk factors for CAD in patients undergoing a coronarangiography. A standardized patient history was obtained and blood samples were drawn in the morning. Bloodpressure was measured by oscillometric device (average between three measurements). Angiotensinogen M235T polymorphism was determined in isolated DNA. Plasma angiotensinogen was measured by radioimmunoassay.

Results:

	Angiotensinogene genotype		
	MM	MT	TT
Number	328	454	191
pl. Angiotensinogen (nmol/L)*	1224 ± 636	1219 ± 670	1310 ± 697
Age (years)	61 ± 10	61 ± 11	62 ± 10
Blood pressure syst. (mmHg)	142 ± 23	141 ± 23	142 ± 24
Blood pressure diast. (mmHg)	81 ± 11	81 ± 11	80 ± 12
Hypertension (%)	59	60	58
Pos. family history (%)°	36	37	32
Myocard. Infarction (%)	45	44	43
Control	19	20	21
Stenosis 11–49%	8	8	7
Stenosis ≥ 50%	72	72	72

*p = 0.25, °p = 0.37 pl. = plasma

Conclusion: In this patient group there was no correlation between the M235T polymorphism of the angiotensinogen gene and the risk for cardiovascular disease, neither manifest CAD nor myocardial infarction, and for other risc factors like hypertension and positive family history.

P1075 Association of G-33A mutation in the promoter region of thrombomodulin gene with coronary artery disease

Y.H. Li, J.H. Chen, H.L. Wu, G.Y. Shi, T.H. Chao, W.C. Tsai, L.M. Tsai, H.R. Guo, W.S. Wu, Z.C. Chen. *Departments of Internal Medicine and Biochemistry, National Cheng Kung University Hospital; Department of Internal Medicine, Chi-Mei Foundation Hospital, Tainan, Taiwan, China*

Background: Thrombomodulin (TM) is an important endothelial anticoagulant protein. The aim of the study was to investigate the frequency of G-33A mutation in the promoter region of TM gene in patients (pts) with coronary artery disease (CAD) and to determine whether the mutation contributes a risk for CAD or myocardial infarction (MI).

Methods: We analyzed 320 pts (mean age 63 years) with CAD proven by angiography and 186 controls (mean age 54 years) without clinical or angiographic evidence of CAD. Screening for TM G-33A promoter mutation was conducted using polymerase chain reaction, single-strand conformation polymorphism, and direct DNA sequencing.

Results: The frequency of the G-33A mutation (GA+AA) was significantly higher in the CAD group (23.8% vs 15.6%, odds ratio [OR] = 1.69, p = 0.039). Multiple logistic regression analysis showed that the mutation was an independent risk factor (OR = 1.96, p = 0.019) for CAD, as was age (OR = 1.06, p < 0.001), male (OR = 2.38, p = 0.003), hypertension (OR = 3.15, p < 0.001) and diabetes mellitus (OR = 2.19, p = 0.005). There was no significant association between the G-33A mutation and the number of diseased vessels in pts with CAD (24.5% of 86 pts with 1-vessel disease, 22.9% of 92 pts with 2-vessel disease and 23.9% of 142 pts with 3-vessel disease, p = NS). There was also no significant difference of the mutation frequency in CAD pts with (n = 154) or without (n = 166) a history of MI (19.4% vs 27.7%, p = NS). However, in all MI pts, younger subjects (age ≤ 55 years, n = 43) tended to have higher incidence (30.2% vs 15.3%, p = 0.061) of TM G-33A mutation than those with age > 55 years (n = 111).

Conclusions: Our observations suggest that there is a significant association of the G-33A mutation in TM gene with CAD in a Chinese population and this mutation may be related to the occurrence of MI in younger pts with CAD.

P1076 Plasma soluble thrombomodulin level is genetically influenced by G-33A promoter mutation of thrombomodulin gene in patients with coronary artery disease

Y.H. Li, J.H. Chen, H.L. Wu, T.H. Chao, W.C. Tsai, L.M. Tsai, H.R. Guo, P.S. Yeh, W.S. Wu, Z.C. Chen. *Departments of Internal Medicine and Biochemistry, National Cheng Kung University Hospital, and Department of Internal Medicine, Chi-Mei Foundation Hospital, Tainan, Taiwan*

Thrombomodulin (TM) is an important endothelial anticoagulant protein. Increased plasma soluble TM level was found in patients (pts) with coronary artery disease (CAD), and was a clinical marker for the progression of CAD. The aim of the study was to investigate the influence of G-33A promoter mutation of TM gene on the plasma soluble TM level.

Methods and Results: The plasma soluble TM levels were determined with ELISA in 280 consecutive pts undergoing coronary angiography. Screening for TM G-33A promoter mutation (GA + AA) in these pts was conducted using polymerase chain reaction, single-strand conformation polymorphism, and direct DNA sequencing. In all, the soluble TM level was significantly higher in pts with CAD (n = 206) than that with normal coronary artery (45.6 ± 25.3 vs 39.0 ± 18.7 ng/mL, p < 0.05). In pts without CAD, there was no significant difference (38.8 ± 17.1 vs 40.0 ± 25.1 ng/mL, p = NS) in the soluble TM level between pts with (n = 14; age 59.0 ± 11.9 years; male 64.3%) or without (n = 60; age 58.4 ± 13.8 years; male 63.3%) G-33A mutation. However, in CAD group, the soluble TM level was higher (47.0 ± 27.4 vs 39.0 ± 17.2 ng/mL, p < 0.05) in pts with normal genotype (n = 53; age 63.8 ± 10.7 years; male 73.2%) than that with G-33A mutation (n = 53; age 63.2 ± 11.3 years; male 66.0%). Furthermore, the soluble TM level increased with the extent of CAD (36.1 ± 14.9 vs 46.6 ± 18.4 vs 54.8 ± 35.9 ng/mL in 1-, 2-, and 3-vessel disease, p < 0.001) in pts with normal genotype. But in pts with G-33A mutation, there was no difference of soluble TM in 1-, 2- or 3-vessel disease (38.6 ± 17.2 vs 37.0 ± 15.3 vs 42.0 ± 18.4 ng/mL, p = NS).

Conclusions: The results suggest that G-33A promoter mutation in TM gene contributes to plasma levels of soluble TM in pts with CAD. For those CAD pts with normal TM genotype, the plasma soluble TM level is indeed a clinical marker for the extent of CAD.

P1077 Juvenile myocardial infarction: prognostic role of genetic polymorphisms at medium-term follow-up

E. Brscic, S. Bergerone[1], A. Gagnor, E. Colajanni[2], S. Guarrera[2], L. Scaglione, M. Cassader, G. Gaschino[3], M. Di Leo[4], G.P. Trevi. *Medicina Interna, A.O.S.Giovanni Battista Di Torino, Torino; [1]Medicina Interna, A.O.S.Giovanni Battista di Torino, Torino[2]Genetica, Biologia e Biochimica, Torino[3]Divisione di Cardiologia, Ospedale M. Vittoria, Torino[4]Divisione di Cardiologia, Ospedale SS Annunziata, Savigliano, Italy*

Aim of this study was to investigate the influence of different genetic factors, compared to that of conventional risk factors, on follow-up events in a sample of Italian patients with juvenile myocardial infarction.

The studied population consisted of 106 young patients (mean age 40 ± 4, range 23–45 years) with diagnosis of acute myocardial infarction (AMI). Clinical, epidemiological, biochemical and genetic data from the group of patients with events during follow-up were compared with those from patients without events. The genetic polymorphisms tested were: ACE I/D, Angiotensin II receptor A/C, ApoE e2/e3/e4, Nitric Oxide Synthase VNTR, and platelet GP IIIa A1/A2.

Coronary angiography (performed in 94 patients) showed coronary artery disease in 93% of the patients. During follow-up (46 ± 12 months, range 25–72) the overall combined end-points (cardiac death, myocardial infarction and revascularizations procedure) accounted for 21 events. Family history of coronary artery disease, smoking, and the presence of the e4 allele of the apoE polymorphism were significantly more prevalent at univariate analysis in the group of patients with events. At logistic procedure analysis Apo E polymorphism (p = 0.004, OR 6.8, 95% confidence interval 2 to 22), family history (p = 0.005, OR 8.3, 95% confidence interval 2 to 35), smoking post-AMI (p = 0.008, OR 10.9, 95% confidence interval 2 to 62) and significant stenosis of the left anterior descending at coronary angiography (p = 0.02. OR 6.6, 95% confidence interval 1.3 to 33) were independent predictors of adverse events.

Conclusions: AMI at young age is commonly characterised by multiple cardiovascular risk factors and by a favourable prognosis in short and medium-term follow-up. Evidence of significant disease at coronary angiography suggests the presence of a premature atherosclerotic process. ApoE polymorphism (e4 allele) seems to be a strong independent predictor of adverse events, suggesting a remarkable influence in the accelerated coronary disease.

P1078 3-Deazaadenosin inhibits diet-induced atherosclerotis in C57/Bl/6J mice

G. Walker, R.C. Braun-Dullaeus, A. Langheinrich, L. Dennhauser, R.M. Bohle[1], J. Kreuzer[2], H. Tillmanns, W. Haberbosch. *University Hospital Giessen, Dpt. of Cardiology Giessen; [1]Institute of Pathology; [2]University Hospital Heidelberg, Dpt. of Cardiology, Heidelberg, Germany*

Background Adhesion of leukocytes to the activated endothelium and their migration into the subendothelial space play an important role in the pathogenesis of atherosclerosis. The adenosine analog 3-Deazaadenosine (c^3Ado) has been shown to inhibit the expression of adhesion molecules in cultured endothelial cells. Therefore we hypothised that c^3Ado is able to prevent diet-induced atherosclerosis in C57/BL/6J mice.

Methods and results The animals were placed on a regular or high cholesterol (chol) diet with or without c3Ado (10 mg/kg/die) for 9 weeks (n = 10, respectively). Total chol level rose from 66 ± 13 in the control group to 474 + 34 mg/dl in mice fed the atherogenic diet. c3Ado treatment did not influence chol concentrations. Anti-von-Willebrand, anti-CD-11b, anti-VCAM-1 and anti-ICAM-1 monoclonal antibodies were used for immunohistochemical staining of endothelial cells, macrophages and endothelial ICAM-1 and VCAM-1 expression respectively. Untreated mice on atherogenic diet showed typical aortic lesions and an increase of intimal thickness up to 35% (83 ± 3 vs. 61 ± 2.0 μm in comparison to animals on control diet, (p < 0.001). c3Ado totally inhibited the expression of endothelial VCAM-1 and ICAM-1 and completely prevented lesion formation in the animals given the atherogenic diet (60 ± 2.2 μm). Mice on atherogenic diet alone showed marked endothelial expression of ICAM-1 and VCAM-1 and mild infiltration and adhesion of monocytic cells. In contrast, no expression of ICAM-1 and VCAM-1 and no infiltration or adhesion of monocytic cells was observed in c3Ado-treated mice despite atherogenic diet.

Conclusions These data demonstrate that c3Ado efficiently inhibits diet-induced atherosclerosis and the endothelial expression of VCAM-1 and ICAM-1 in C57/BL/6J mice.

P1079 Promoter dependence of persistence of the effect of the human apo E enhancer on human apolipoprotein A-I expression after adenoviral gene transfer is explained by promoter attenuation

Sophie Van Linthout, Bart De Geest, Désiré Collen, Paul Holvoet. *Center for Molecular and Vascular Biology, University of Leuven, Leuven, Belgium*

Stable elevation of HDL cholesterol, induced by apo A-I gene transfer, may have a dramatic impact on ischemic cardiovascular disease. We previously demonstrated that the effect of apo E enhancer(s) inserted 3′ of adenoviral constructs containing both the CMV promoter and the apo A-I promoter (CMV/A-I.gA-I adenoviruses) on human apo A-I expression in C57BL/6 mice was copy dependent and transient (≤14 days) whereas the effect of 4 apo E enhancers 3′ of constructs containing only the apo A-I promoter (A-I.gA- I.4xapoE) persisted for at least 1 month. We investigated whether this effect persisted after 1 month and whether CMV promoter shut-off may explain differences in persistence of the apo E enhancer(s) effect.

Results: Compaired with gene transfer with 5 × 108 p.f.u. of a virus containing the apo A-I promoter without enhancers (A-I.gA-I), human apo A-I levels after gene transfer with the same dose of A-I.gA-I.4xapoE were 6.0-fold ($p < 0.0001$) higher at 1 month (104 ± 8.4 mg/dl), 4.3-fold ($p = 0.009$) higher at 2 months (86 ± 31 mg/dl), 3.1 fold ($p = 0.01$) higher at 3 months (58 ± 16 mg/dl), 3.9-fold ($p = 0.006$) higher at 6 months (40 ± 7.7 mg/dl), 4.1-fold ($p = 0.006$) higher at 7 months (21 ± 5.1 mg/dl) and were below 10 mg/dl at 8 months. Compared with CMV/A-I.gA-I adenoviruses, human apo A-I levels induced by A-I.gA-I.4xapoE were on average 3.9-fold higher between 1 and 7 months. Human apo A-I copy number at 1 month was not significantly different between CMV/A-I.gA-I adenoviruses (1.2 ± 0.14), A-I.gA-I (1.1 ± 0.24) and A-I.gA-I.4xapoE (1.4 ± 0.20). In contrast, the human apo A-I mRNA signal at 1 month was 21-fold higher ($p = 0.0004$) for A-I.gA-I.4xapoE compared with CMV/A-I.gA-1 adenoviruses.

Conclusion: The enhancer effect of 4 apo E enhancers on human apo A-I expression after gene transfer with A-I.gA-I.4xapoE persists for 7 months. The human apo A-I mRNA/human apo A-I DNA copy number ratio at 1 month is significantly lower for CMV/A-I.gA-I adenoviruses compared with A-I.gA-I.4xapoE, indicating that CMV promoter attenuation is the predominant mechanism of the rapid decline of human apo A-I levels.

P1080 Rare promoter variants in the human bradykinin B2-receptor gene alter gene expression in vitro

A. Weidemann, J. Erdmann[1], H. Kallisch, E. Fleck, V. Regitz-zagrosek. *Internal Medicine/Cardiology, Charite, Virchow-Clinic, HU and DHZB, Berlin; [1]Internal Medicine/Cardiology, Berlin, Germany*

There is increasing evidence that the human bradykinin B2-receptor (B2-R) is a promising candidate gene for hypertension.

In recent studies we detected polymorphic sites in the promoter of the B2-R gene. Electrophoretic Mobility Shift Assays (EMSA) revealed destruction or reduction of transcription factor binding ability of three of these mutations. In this study we tried to ascertain if these variants (−704 C/T, −412 C/G, −78 C/T) could alter the B2-R gene expression in vitro.

The WT and mutant alleles of the patients' B2-R promoter (−1057 to +10) were cloned into a reporter vector (pGL3Basic). Using electroporation these constructs were transiently transfected into COS-7 cells. After 48 h the luciferase-expression could be measured and normalized with the simultaniously transfected β-galactosidase.

We report here that the −412 C/G variant, which according to EMSA destroys a SP1 consensus sequence, reduces the luciferase expression to 58% ± 18% (n = 6). The nucleotide substitution at position −704 (CT) is capable of increasing the gene expression by 17% ± 18% (n = 7), while the mutation at position −78 C/T does not influence the promoter activity (93% ± 11%, n = 5). The mutation −412 C/G was only detected in a patient with dilated cardiomyopathy, his brother and an anonymous blood donor. One patient with HCM and one further with DCM beared the −704 T allele and the −78 T allele, respectively. Thus the frequencies of these polymorphisms are below 0.5%.

In this study we were able to show that the rare mutation −412 C/G reduces the transciptional activity of the promoter of the B2-R gene because it destroys the binding site for the ubiquitous transcription factor SP1. This leads to the conclusion that SP1 is involved in the regulation of transcription of the B2-R gene. The slightly enhanced gene expression caused by the −704 T allele might be because of the loss of a repressor binding site in the distant regulatory region.

P1081 Fine mapping of a quantitative trait – measured haplotype analysis of the angiotensin-1 converting enzyme gene

B. Keavney, C. McKenzie[1], J.M.C. Connell[2], C. Julier[1], P.J. Ratcliffe[1], E. Sobel[1], M. Lathrop[1], M. Farrall. *Cardiovascular Medicine Dept, Oxford University, Oxford; [1]Wellcome Trust Genetics Centre, Oxford University, Oxford; [2]MRC Blood Pressure Group, University of Glasgow, Glasgow, UK*

Background: Linkage and segregation analysis have shown that circulating ACE levels are influenced by a major quantitative trait locus mapping within or close to the ACE gene. The D allele of the I/D polymorphism is associated with higher ACE levels and possibly with cardiovascular risk, but this polymorphism is unlikely to be the causative variant. Multiple variants in linkage disequilibrium with the I/D polymorphism have been described, but it is unknown if any of these are directly implicated in the determination of plasma ACE. We have used a novel technique utilising evolutionary information to more precisely localise the causative variant at this locus.

Methods: Analysis of 10 polymorphisms spanning 26 kb of the ACE gene using PCR methods in 83 extended British Caucasian families comprising 555 individuals. Measurement of plasma ACE using an HPLC method. Haplotype assignment using the SIMWALK program followed by measured haplotype analysis using the PAP package.

Results: A limited number of haplotypes existed in these families owing to strong linkage disequilibrium over the region. A haplotype tree (cladogram) was constructed with three main branches, accounting for >90% of the observed haplotypes; one branch is most likely to be derived from an ancestral recombination event between the other branches. This evolutionary information was then used to direct measured haplotype analyses which excluded upstream sequences, including the ACE promoter, from harbouring the major ACE-linked variant which explains 36% of the total trait variability. Residual familial correlations were highly significant, suggesting the influence of additional unlinked genes.

Interpretation: These results demonstrate that this analytic approach has power to localise genetic variants that directly influence a quantitative trait of likely cardiovascular significance in a human population.

P1082 Association of angiotensin I gene polymorphism with coronary atherosclerosis

V.A. Stepanov, M.G. Spiridonova, V.P. Puzyrev, T.V. Kosyankova, R.S. Karpov[1]. *Inst. for Medical genetics, Tomsk; [1]Institute of Cardiology, Tomsk, Russian Federation*

Angiotensin I (AGT) plays the key role within the renin-angiotensin system and is an attractive candidate as the risk factor for cardiovascular disease. Several polymorphisms of the AGT gene have been described including a methionine for a threonine substitution at residue 174 (T174M). The aim of this study was to investigate the relation between T174M polymorphism and coronary atherosclerosis in Russian population. 94 unrelated patients with coronary artery disease (CAD) proven by angiography and 131 healthy individuals were involved in the case-control study. The frequency of M174 allele was significantly higher among CAD patients than in control group (22.4% vs. 7.6%, $p < 0.001$). Genotype frequencies were 59% (T174), 38% (T174M), and 3% (M174) in the patients group; and 85%, 15%, and 0% in control population, respectively. T174M polymorphism was not associated with the serum triglycerides, total cholesterol, HDL-, LDL, and VLDL-cholesterol levels. No statistical difference in the systolic and diastolic blood pressure in the individuals with different AGT genotypes was found. Our results suggest that AGT gene could be a important risk factor for cardiovascular disease in Russians.

LIPIDS AND LIPID LOWERING: EFFECTS ON ENDOTHELIUM

P1083 Short-term atorvastatin therapy improves endothelial adhesiveness and carotid artery geometry

T. Sampietro, C. Palombo, R. Licitra, M. Kozàkovà, A. Patricelli, C. Morizzo, G. Bigalli, S. Fusaro[1], M. Tuoni[1], A. Bionda[1]. *Cardiology Dept., Institute of Clinical Physiology, Pisa; [1]Department of Internal Medicine, Pisa, Italy*

Hypercholesterolemia is associated with endothelial dysfunction, and cholesterol (CH) lowering seems able to restore, at least partly, coronary and peripheral arterial function. We studied the effects of short term atorvastatin (A) therapy on critical atherogenic events, such as the adhesion and transendothelial migration of circulating leukocytes, and on large artery geometry. Twenty pts, 7 F and 13 M (age 48.69 ± 8.years) with primary hypercholesterolemia (PH), with or without clinical cardiovascular disease (8 and 12 pts, respectively), and without other risk factors were enrolled to A monotherapy (10–20 mg once daily) after a 3-month dietary phase and at least 4-week lipid lowering therapy washout. Soluble endothelial leukocytes adhesion molecule (sELAM1), intercellular adhesion molecule (sICAM1) and vascular adhesion molecule (sVCAM1) were determined at baseline, and after 1- and 3-months of A therapy. Phlogosis indexes, acute phase reactant proteins, tumor necrosis factor alpha and interleukin 6 were also measured at the same times. Common carotid artery (CCA) was examined by high resolution B-mode ultrasound: diameter and far wall intima-media thickness (IMT) of CCA were measured on digitized zoomed 2D images, one cm proximal to flow divider.

After 12-weeks of A therapy, total CH decreased from 332 ± 76 to 215 ± 23 mg/dl ($p < 0.0001$), apoprotein-B (apoB) from 214 ± 55 to 144 ± 27 mg/dl ($p < 0.0001$) and LDL-CH from 254 ± 81 to 145 ± 25.5 mg/dl ($p < 0.0001$). Triglycerides, lipoprotein(a) and HDL-CH were unchanged. Baseline sELAM1, sICAM1 and sVCAM1 were 23.5 ± 3.6 ng/ml, 275.5 ± 35 ng/ml and 770 ± 216 ng/ml respectively. After 3-month therapy sELAM1, which is found only on activated endothelium, was significantly reduced ($p < 0.03$). Before and after treatment, mean CCA IMT was 0.71 ± 0.11 mm, and 0.59 ± 0.14 mm ($p < 0.0002$), mean CCA diameter was 6.35 ± 0.86 and 6.71 ± 0.89 mm ($p < 0.0004$). By multiple regression analysis, CCA diameter correlated inversely ($p < 0.005$), and IMT directly ($p < 0.2$) to CH and LDL-CH.

Conclusions: in pts with PH, 3-month Atorvastatin therapy significantly reduces CH, LDL-CH, and apoB, and is capable to induce significant reduction of endothelial adhesiveness and large artery remodeling in absence of changes in other clinical chemical parameters.

P1084 A triglyceride-rich fat emulsion and free fatty acids but not triglyceride-rich lipoproteins impair endothelium-dependent vasorelaxation

P. Lundman, P. Tornvall, L. Nilsson[1], J. Pernow. *Department of Cardiology, Karolinska Hospital, Stockholm; [1]Atherosclerosis Research Unit, King Gustaf V Research Institute, Stockholm, Sweden*

Objective: It has been shown that Intralipid®, a triglyceride-rich fat emulsion, impair endothelium-dependent vasorelaxation. The present study was performed in order to further investigate the effects of triglycerides and their metabolites free fatty acids on endothelium-dependent and endothelium-independent vasorelaxation.

Methods: Femoral arterial rings from rats were studied in organ baths. The vascular segments were constricted with prostaglandin F2 alpha or phenylephrine after 20 minutes of preincubation with the triglyceride-rich fat emulsion Intralipid®, free fatty acids (palmitic acid (16:0), oleic acid (18:1) and linolenic acid (18:3)), bound to bovine serum albumin, or very low density lipoproteins. Endothelium-dependent and endothelium-independent relaxation was determined by administration of acetylcholine and nitric oxide donors (sodium nitroprusside or S-nitroso-N-acetyl-D,L-penicillamine (SNAP)), respectively.

Results: Preincubation with Intralipid® caused a concentration-dependent impairment of endothelium-dependent but not endothelium-independent relaxation. Very low density lipoproteins did not affect vascular function. Incubation with all free fatty acids impaired endothelium-dependent relaxation, while endothelium-independent relaxation was unaffected. Administration of the antioxidant vitamin C reversed the impairment of endothelium-dependent relaxation induced by Intralipid®.

Conclusion: Free fatty acids and Intralipid®, but not very low density lipoproteins, impair endothelium-dependent relaxation. This effect is reversed by vitamin C, which indicates involvement of oxidative mechanisms.

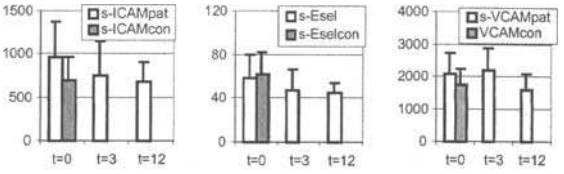
P1085 Long-term effect of lipid lowering therapy on soluble markers of endothelial cell dysfunction

P.L. van Haelst, J.J. van Doormaal, R.O.B. Gans, H.J.G.M. Crijns, J.W. Cohen Tervaert. *Dept. of Cardiology and Internal Medicine, University Hospital Groningen, Groningen, Netherlands*

An early pathophysiological role in atherosclerosis is attributed to endothelial cell dysfunction (ECD). Levels of soluble forms of various cell adhesion molecules (CAMs) reflect ECD. Previously, it has been shown that CAMs are elevated in patients with atherosclerosis and in short-term studies it has been demonstrated that HMGCoA-inhibitors decrease CAM. We questioned whether this short term effect is sustained during long-term follow-up.

Materials and methods: In a group of 10 non-diabetic, normotensive patients (9 males) with established atherosclerosis and hypercholesterolemia, we determined the levels of s-VCAM, s-ICAM and s-Eselectine before, and after 3 and 12 months of treatment with fluvastatin 80 mg. For baseline comparisons, 28 age- and sex-matched healthy volunteers were studied.

Results: At baseline, s-ICAM ($p < 0.05$), but not s-VCAM and s-Eselectin were significantly higher in patients compared to controls. s-VCAM remained unchanged at three months and decreased after one year (2079 versus 2181 versus 1568 ng/ml; $p < 0.05$), whereas s-ICAM and s-Eselectin diminished continuously during follow-up (s-ICAM: 956 versus 745 versus 675 ng/ml [$p < 0.01$] and s-Eselectin: 59 versus 47 versus 45 ng/ml [$p = 0.05$]). Total cholesterol levels and LDL cholesterol levels also decreased during treatment (chol: 6.4 versus 4.5 versus 4.5 mmol/L; LDL 5.1 versus 3.5 versus 3.5 mmol/L) and were not related to CAMs. Triglycerides and HDL did not change



Conclusions: Soluble markers of endothelial cell dysfunction in patients with atherosclerosis improve during long-term follow-up. The decrease in CAM was differential, suggesting stages in restoring ECD. Further studies are needed to determine whether CAMs are better predictors of clinical events than total or LDL cholesterol.

P1086 LDL-apheresis and atorvastatin significantly reduce (plasma and urinary) isoprostanes

H. Sinzinger, A. Ferlitsch, H. Schmidinger, A. Oguogho. *Institute for Diagnosis and Treatment of Lipid Disorders and Atherosclerosis (ATHOS), Vienna; Department of Nuclear Medicine, University of Vienna, Austria*

Isoprostanes (IP) among them the vasoconstrictory and mitogenic 8-epi-$PGF_{2\alpha}$ are formed by the free radical catalyzed actions on membrane fatty acids may serve as an in-vivo measure of oxidation injury. We examined the influence of severe lipid lowering (atorvastatin [AT; 40 mg/d] therapy [n = 12; 8 m, 4 f; 27–46 a] and [dextran sulphate] LDL-apheresis [n = 9; 7 m, 2 f; 43–68 a]) in patients with familial heterozygous hypercholesterolemia (FH) on plasma and urinary 8-epi-prostaglandin ($PG)F_{2\alpha}$ (after extraction and purification) as compared to healthy controls using a specific immunoassay. In-vitro Cu^{++}-induced LDL-oxidation and thiobarbituric acid reactive substances (TBARS) were determined in parallel. AT (−16%/−19%) and LDL-apheresis (−28%/−34%) are significantly ($p < 0.01$) reducing 8-epi-$PGF_{2\alpha}$ (TBARS −44%, lag-time of oxidation +83%). Smokers show higher values of 8-epi-$PGF_{2\alpha}$ (plasma: 54.3 ± 9.6 pg/ml vs. 34.6 ± 6.2; controls: <20; urine: 481 ± 86 pg/mg creatinine vs. 336 ± 65; controls: <300). Similar kinetics are observed in all the subgroups. There is no significant age- and sex-difference. Repeated LDL-apheresis therapy shows an identical response.

These data suggest, that severe (LDL-)cholesterol lowering significantly diminishes oxidation injury. This may essentially contribute to the clinical benefit seen.

P1087 Cerivastatin prevented tumour necrosis factor-α-dependent downregulation of endothelial nitric oxide synthase: role of endothelial cytosolic proteins

F. González-Fernández, I. Galán, M.M. Arriero, I. Millás, M. Montón, P. Marcos-Alberca, A. Celdrán, J. Farré, S. Casado, A. López-Farré. *Nephrology, Hypertension and Cardiovascular Research Laboratory, Fundación Jiménez Díaz, Madrid, Spain*

Cardiovascular disease is accompained by an impaired endothelium-dependent vasodilatory response and an increased production of tumor necrosis factor alpha (TNF-α). Loss of endothelial nitric oxide synthase (eNOS) expression may contribute to endothelial dysfunction. The aim of the present study was to analyze the effect of Cerivastatin, a novel HMG CoA reductase inhibitor, on TNF-α-related downregulation of eNOS protein expression in bovine cultured endothelial cells (EC). TNF-α (10 ng/ml)- incubated EC showed a reduced expression of eNOS protein and reduction in eNOS mRNA stabilization. This effect was associated with the binding of EC cytosolic proteins to the 3′-unstranslated region (3′UTR) of eNOS mRNA. The EC cytosolic proteins bound specifically a C-rich region (126 bases) within 3′-UTR eNOS mRNA. Cerivastatin prevented TNF-α-induced downregulation of eNOS protein expression. The effect of Cerivastatin on eNOS protein expression followed a dose-dependent manner (10^{-8} mol/l to 10^{-5} mol/l). Furthermore, Cerivastatin prevented the binding of the cytosolic protein to the C-rich region of 3′-UTR eNOS mRNA.

In conclusion: TNF-α reduced eNOS protein expression and stimulated the binding of cytosolic proteins to 3′-UTR eNOS mRNA. Cerivastatin upregulated eNOS protein expression and reduced the binding of cytosolic proteins to 3′-UTR eNOS mRNA reversing the effects of TNF-α. These findings suggest that Cerivastatin may have beneficial effects in endothelial dysfunction associated to cardiovascular diseases beyond its effect on the cholesterol.

P1088 Effects of atorvastatin treatment on endothelial dysfunction and vascular structural associated with dyslipidaemia in rabbits

V. Cachofeiro, R. Maeso, J. Navarro-Cid, G. Hernández[1], C. Díaz[1], L.M. Ruilope, V. Lahera. *[1]R & D Dept Parke Davis, Barcelona; Dept of Physiology, School of Medicine, UCM, 28040 Madrid, Spain*

We evaluated aortic endothelial function and structural changes induced by a diet containing 0.5% cholesterol + 14% coconut oil for 14 weeks in NZ rabbits untreated or treated with atorvastatin (2.5 mg/kg/day). Plasma cholesterol and triglyceride concentrations were higher in rabbits fed the experimetal diet than control group ($p < 0.05$). Relaxing responses to Ach (10^{-9}–10^{-5} mol/L) were blunted in dyslipidemic rabbits. Incubation of aortic rings with either the thromoxane A_2 receptor antagonist, Ifetroban or with the endothelin-1 (ET_A) receptor antagonist BQ123, increased Ach-response in dyslipidemic and control rabbits. Constrictor responses to Ach in presence of the NO synthase inhibitor LNAME (10^{-4} mol/l) were higher in dyslipidemic rabbits than in control ones ($P < 0.05$), and were reduced by either ifetroban or BQ123. Atorvastatin treatment reduced lipid levels only in dyslipidemic rabbits. Atorvastain enhanced the relaxing response to Ach and reduced the contracting response to Ach + LNAME in rabbits fed with experimental diet. Incubation with either Ifetroban or BQ123 did not further increase relaxing responses to Ach or reduce constrictor responses to Ach + LNAME in atorvastatin-treated rabbits. Increased ($P < 0.05$) lesion area, degree of stenosis and media thickness were observed in dyslipidemic rabbits as compared to controls. Atorvastatin treatment markedly reduced ($P < 0.05$) these changes. In conclusion: 1) TXA_2 and ET seem to participate in the endothelial dysfunction observed in dyslipidemic rabbits. 2) the amelioration on endothelial dysfunction produced by Atorvastatin treatment in dyslipidemic rabbits could be partially due to a reduction in thromboxane A_2 and endothelin-1 availabilities. 3) the beneficial effects of Atorvastatin treatment on aortic structural alterations could contribute to the observed improvement of endothelial function.

P1089 Regulation of endothelial nitric oxide synthase by Rho-dependent actin stress fiber formation

U. Laufs[1], J.K. Liao[2]. *[1]Klinik III für Innere Medizin, Universität zu Köln, Cologne, Germany; [2]Brigham and Women's Hospital, Harvard University, Boston MA, USA*

Inhibition of isoprenoid synthesis by HMG-CoA reductase inhibitors (statins) upregulates endothelial nitric oxide synthase (eNOS) in human endothelial cells via inhibition of geranylgeranylation and membrane-translocation of the small GTPase Rho. The anchoring of specific mRNAs to the cytoskeleton and their co-localization with ribosomes and RNA-binding protein complexes are necessary for their translational expression and stability. Since Rho plays an important role in cytoskeletal reorganization, we hypothesized that Rho-induced myosin light chain (MLC) phosphorylation and focal adhesion complexes may affect eNOS mRNA translation and stability. Inhibition of Rho activity by *Clostridium botulinum* C3 transferase (50 μg/ml) or by overexpression of a dominant-negative Rho mutant, N19RhoA, decreased focal adhesion complexes and actin stress fiber formation. These inhibitory effects on Rho correlated with increases in eNOS mRNA stability and expression. To determine whether the increase in eNOS expression was mediated by inhibition of Rho-induced MLC phosphorylation, endothelial cells were treated with specific inhibitors of MLC kinase, H-7 (100 μM) and ML-7 (0.5–5 μM). Both H-7 and ML-7 caused a 4- and 3-fold increase in eNOS mRNA and protein levels, respectively. Since MLC phosphorylation is required for the formation of focal adhesion complexes and actin stress fibers, we disrupted these cytoskeletal processes directly with cytochalasin D (0.1–10 μM) which resulted in a concentration-dependent increase in eNOS expression. Cytochalasin D, however, did not inhibit the geranylgeranylation, membrane translocation, or activity of Rho, but produced a compensatory 3-fold increase in membrane-associated Rho. The cytoskeletal effects of cytochalasin D on eNOS expression were specific since disruption of microtubule formation by nocodazole (5–500 nM) had no effect on eNOS expression. Our findings indicate that Rho-mediated actin stress fiber formation negatively-regulates eNOS mRNA stability and expression. We propose that the dynamic status of the cytoskeleton plays an important role in regulating eNOS expression via the transportation, localization, and compartmentalization of eNOS mRNA. It remains to be determined how eNOS mRNA stability is affected by its localization.

P1090 HMG-CoA reductase inhibitor, pravastatin, reduces the levels of tissue factor and plasminogen activator inhibitor-1 in human cultured monocytes

Toshiyuki Ishibashi, Kenji Nagata, Yoshitane Seino, Kazuhiko Nakazato, Joji Shindo, Keiko Yokoyama, Yukio Maruyama. *First Department of Internal Medicine, Fukushima Medical University, Fukushima, Japan*

Macrophage accumulation and activation in plaques play an important role in pathogenesis of acute coronary syndromes. Recent clinical trials of HMG-CoA reductase inhibitor, pravastatin, have shown the benefits in the treatment of coronary artery disease. In the present study, we investigated the beneficial effects of pravastatin on macrophage functions in addition to the cholesterol-lowering.

Methods: Human monocytes were obtained from peripheral blood of healthy volunteers by gradient centrifugation and adherent method. Monocytes (1×10^5/ml) were cultured in the presence of oxidized LDL and lipoprotein deficient serum in RPMI 1640 medium. Pravastatin (1–10 μg/ml) was added to this culture system. The levels of tissue factor (TF) and plasminogen activator inhibitor-1 (PAI-1) in culture medium were measured by ELISA. The levels of mRNA for TF and PAI-1 were assessed by reverse-transcriptase polymerase chain reaction (RT-PCR) in the cultured monocytes.

Results: There were no changes in the levels of TF or PAI-1 in the medium between pravastatin-treated group and control after 1 day of culture. However, after 3 days of culture, pravastatin decreased the protein levels of TF and PAI-1 by 23.8 ± 14.3% ($n = 5$, $P < 0.05$) and 20.5 ± 11.5% ($n = 9$, $P < 0.001$) in the medium, respectively. Similar reductions by pravastatin (TF; 20.7 ± 14.1%, $n = 5$, $P < 0.05$, PAI-1; 18.7 ± 4.3%, $n = 6$, $P < 0.001$) were observed after 7 days of culture. RT-PCR revealed a decrease in the mRNA levels of TF in the monocytes after 3 days of culture, but not the PAI-1 levels.

In conclusion, we demonstrate that pravastatin reduced the production of TF and PAI-1 in cultured monocytes, suggesting that pravastatin may affect the procoagulant state induced by the accumulation and activation of macrophages in plaques and that this may contribute to the prevention of coronary events in patients taking pravastatin.

P1091 Influence of atorvastatin and cerivastatin on proliferation, apoptosis rate, and expression of fibronectin, MMP-1, 3, TIMP-1, -2 in human VSMC

M. Neuß, M. Gräfe, M. Schartl, K. Graf, E. Fleck. *Med. Klinik/Kardiologie, Charite, Campus Virchow Hospital, HU Berlin; DHZB, Berlin, Germany*

Inhibitors of the HMG-CoA reductase lead to a reduction of cardiovascular and total mortality in patients with CAD. To investigate the influence of statins on biochemical events related to plaque-stability, we isolated VSMC from human saphenous vein (s.v.) and coronary arteries and analysed the effect of atorvastatin and cerivastatin on proliferation, apoptosis rate, expression of fibronectin, tenascin, MMP1, MMP3, TIMP-1 and 2.

Methods: VSMC were isolated by outgrowth of samples from the media and used in passage 3–5. Proliferation was determined by use of an MTT-test, apoptosis by use of the tunel-method. Expression of fibronectin and tenascin was determined by western-blot of culture supernatants, expression of MMP1, 3, TIMP-1, and 2 by ELISA.

Atorvastatin and cerivastatin led to a dose-dependent inhibition of the proliferation of VSMC from coronaries (n = 5) and s.v. (n = 7) in response to PDGF and induced apoptosis in a dose-dependent manner (n = 4).

	Control	10 μM ator	1 μM ator	1 μM ceri	100 nM ceri
Rate of apoptosis	2.2 ± 1.3%	8.5 ± 2.6%*	4.2 ± 2.1%*	12.3 ± 1.8%*	6.3 ± 2.2%*

The expression of fibronectin, tenascin, MMP1, and TIMP-1 remained unchanged in VSMC from coronaries or s.v. after incubation with cerivastatin (10 nM) or atorvastatin (500 nM), while both substances led to a significant down-regulation of MMP-3- and TIMP-2.

	Control	PDGF 10 ng/ml	PDGF + Ator	PDGF + Ceri
MMP3 (μg/ml)	6.75 ± 3.29	25.5 ± 15.07	4.8 ± 3.54*	3.5 ± 1.83%*
TIMP-2 (μg/ml)	6.6 ± 5.5	5.5 ± 3.28	3.0 ± 2.25*	4.5 ± 3.17*

*p < 0.05 vs. control.

In conclusion atorvastatin and cerivastatin influence important events related to plaque stability.

ENDOTHELIAL AND PLATELET FUNCTION

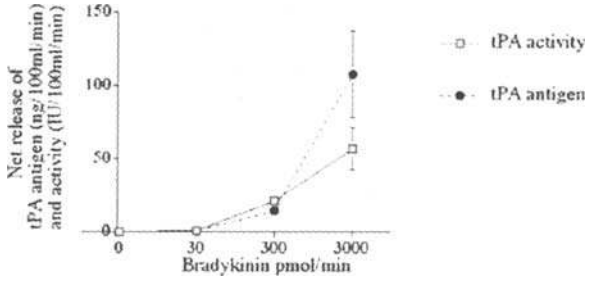
P1092 Bradykinin is a potent dose-dependent stimulus for release of tissue plasminogen activator (tPA) in the human forearm circulation

C. Labinjoh, D.E. Newby, S. Mattison, N.A. Boon, D.J. Webb. *Clinical Pharmacology Unit, University of Edinburgh, Edinburgh, UK*

Background: A reduction in coronary thrombotic events is seen with the use of angiotensin-converting enzyme (ACE) inhibitors in ischaemic heart disease. The mechanism for this may involve an increase in tPA release which, in turn, may be mediated by mediated by bradykinin. We examined the effects of intra-arterial infusion of bradykinin on blood flow, fibrinolysis and coagulation in the human forearm circulation.

Methods: Bradykinin at 10–3000 pmol/min was infused into the brachial artery of the non-dominant forearm in 8 healthy non-smoking men. Blood flow measurements were made using venous occlusion plethysmography, the non-infused arm acting as a contemporaneous control. Venous blood samples for tPA, plasminogen activator inhibitor (PAI) and von Willebrand factor (vWF) were obtained from both forearms during saline and bradykinin infusions.

Results: Bradykinin caused a dose-dependent local increase in forearm blood flow, tPA antigen and tPA activity ($p < 0.01$ for all) in the infused arm without changes in PAI-1 or vWF ($p > 0.05$ for both).



Relationship between bradykinin and tPA.

Conclusions: Intra-arterial bradykinin causes a substantial dose-dependent release of tPA in the forearm vascular bed. This has potentially important implications for the understanding of the mechanism of action of ACE inhibitors and their role in ischaemic heart disease.

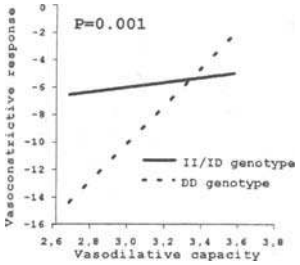
P1093 The Intervention Cardiology Risk Stratification (ICARIS) study: ACE-polymorphism genotype and coronary endothelial function

S.H.J. Monnink, R.A. Tio, A.J. van Boven, P.J. de Kam, N.J.G.M. Veeger, L. Pont[1], W.H. van Gilst[1], H.J.G.M. Crijns. *Departments of Cardiology; [1]Clinical Pharmacology University Hospital Groningen, Netherlands*

An important determinant for cardiovascular disease is the endothelial function, determined by intracoronary infusion of acetylcholine (i.e. paradoxical vasoconstriction if endothelial dysfunction is present). ACE-DD receptor genotype negatively interferes with atherosclerotic progression. In the present ICARIS study we correlated ACE-polymorphism genotype DD or II/ID with coronary acetylcholine response and maximal vasodilative capacity after nitroglycerin.

Methods: Using off-line quantitative coronary angiography, the response on intracoronary acetylcholine infusion (left main stem concentration 10^{-8}–10^{-6} molar) was determined in 91 patients with angina pectoris. After univariate analysis, multiple regression was performed for the maximal vasoconstrictive response on acetylcholine (% from baseline) with the predictors vasodilative capacity after nitroglycerine (mm), ACE- genotype and their interaction.

Results: Univariate analysis for all potential risk factors demonstrated a vasoconstrictive circumflex response in patients with DD-genotype compared to II/ID-genotype ($p = 0.001$). ST-T abnormalities at rest or on exercise, total cholesterol and previous myocardial infarction were detected via multiple regression as confounding factors. After correction for these factors in these patients (n = 76, 63% males, mean age 58), the difference between the ACE-genotypes remained borderline ($p = 0.050$).



Conclusion: These data demonstrate that ACE-DD genotype is associated with abnormal endothelial function in smaller coronary arteries.

P1094 Are ACE-inhibitors antioxidants? Effect of chronic ACE-inhibition on endothelium-mediated vasodilation and ICAM-1 plasma levels in patients with coronary artery disease

Burkhard Hornig, Naoshi Arakawa, Ulf Landmesser, Christoph Kohler, Dorothe Ahlersmann, Helmut Drexler. *Department of Cardiology and Angiology; Medical School of Hannover, Germany*

Impaired flow-dependent, endothelium-mediated vasodilation (FDD) and increased expression of adhesion molecules, both induced by oxidative stress, are early findings in patients with coronary artery disease (CAD). Since angiotensin II (AII) can induce radical formation within the vessel wall, we hypothesized that chronic ACE-inhibition may reduce oxidative stress by reduction of AII thereby leading to improvement of FDD and reduction of adhesion molecules. Accordingly we determined the acute effect of the antioxidant vitamin C (25 mg/min; i.a.) on FDD of the radial artery in 30 patients with angiographically documented CAD at baseline and after 4 weeks of ACE-inhibition with ramipril (5 mg bid). Diameter was measured by high-resolution ultrasound (10 Mhz; precision 2 μm), blood flow (BF; ml/min) calculated from BF-velocity (8 Mhz Doppler) and cross-sectional area. Diameter changes (D%, representing FDD) and BF were determined at rest and after wrist occlusion (8 min). To determine the portion of FDD inhibited by radicals (i.e. normalized by vitamin C) the Delta-value (FDD after vitamin C minus FDD control) was calculated. In addition, plasma concentration of soluble intercellular adhesion molecule 1 (sICAM-1) and urine concentration of isoprostanes (systemic parameter of oxidative stress) were measured at baseline and after 4 weeks of ACE-inhibition.

	FDD	FDD vit.C	Delta-FDD	Isoprostane	sICAM-1
Control	7.6 ± 0.5	12.5 ± 0.6	4.5 ± 0.5	803 ± 21	317 ± 14
4 weeks	11.9 ± 0.6*	12.3 ± 0.6	0.4 ± 0.5*	632 ± 22*	274 ± 13*

(all data ± SEM; *p < 0.01 vs control).

Conclusion: Chronic ACE-inhibition concomitantly leads to improvement of endothelium-mediated vasodilation and reduction of the adhesion molecule ICAM-1 and urinary isoprostanes. The antioxidans vitamin C improved FDD at baseline but not after 4 weeks of ramipril, suggesting an antioxidant effect of the ACE-inhibitor.

P1095 High-resolution magnetic resonance imaging of the brachial artery – a novel method for assessing vascular function

M.B. Sorensen, P. Ong[1], C.S. Hayward[1], P. Gatehouse, D. Pennell, P. Collins[1]. *Cardiovascular MR Unit, Royal Brompton Hospital, London; [1]Cardiac Medicine, National Heart and Lung Institute, London, UK*

Background: Measurement of changes in brachial artery (BA) diameter by external ultrasound (EXUS) in response to reactive hyperaemia (RH) or GTN is widely used to assess vascular function. Magnetic Resonance Imaging (MRI) is extensively used for non-invasive assessment of cardiovascular function. Compared to EXUS, MRI is less observer-dependent and measures cross-sectional area (CSA) rather than solely diameter.

Methods: The CSA of the BA was measured by MRI in 16 subjects and compared to CSA from intravascular ultrasound (IVUS) in 8 patients with coronary artery disease (CAD) and BA dimensions from EXUS in 8 healthy male volunteers. The MRI was performed at 1.5 Tesla with high resolution (field of view: 100 mm) segmented FLASH. Reactive hyperaemia was induced by 5 minutes circulatory forearm cuff-occlusion. Imaging of the BA was performed over 12 cardiac cycles at baseline, following cuff release and 3 minutes after GTN challenge in the CAD patients. MRI was also used to measure BA diameter perpendicular to the skin surface at baseline and following RH, similar to EXUS.

Results: Data from the invasive IVUS measurement of brachial artery dimensions correlated strongly with the MRI measurement both at baseline ($r = 0.89$, $p = 0.003$) and after vasodilation ($r = 0.78$, $p = 0.007$). CSA by IVUS was consistently greater (24.1 ± 6.6 vs 19.0 ± 4.3 mm^2, $p = 0.004$). MRI measurement of BA diameter correlated significantly to EXUS diameter ($r = 0.69$, $p = 0.003$). BA diameter was significantly smaller by MRI compared to EXUS (4.1 ± 0.3 vs 4.9 ± 0.5, $p < 0.001$).

Conclusion: MRI diameters and areas correlate well, though are smaller than ultrasound measurements. These differences most likely relate to MRI detecting blood signal rather than the vessel wall. Measurement of CSA by MRI provides increased information compared to that from EXUS as the vessel lumen is frequently non-circular. MRI is a promising technique for non-invasive determination of vascular function.

P1096 Inverse relationship between carotid intima-media thickness and brachial artery ischaemic-mediated dilatation in healthy young subjects with history of parental myocardial infarction

G. Gaeta, S. Cuomo, P. Guarini[1], M.C. Foglia[2], M. De Michele[1], F. Scotto di Uccio, A. Boccalatte, M. Trevisan[3]. *Cardiologia, Antonio Cardarelli Ospedale, Naples; [1]Cardiologia, S. Maria di Loreto, Naples[2]Laboratorio Analisi Cliniche, Antonio Cardarelli, Naples, Italy[3]Social and Preventive Medicine Dept, State University of New York, Buffalo, USA*

Background: Increased intima-media thickness (IMT) of the distal common carotid artery and brachial artery endothelial dysfunction may be early manifestations of the atherosclerotic process. However, little is known about the possible association between carotid IMT and brachial artery flow-mediated dilatation (FMD). The aim of this study was to evaluate the relationship between carotid IMT and brachial artery FMD.

Methods: Fifty-eight healthy young subjects with history of parental myocardial infarction [41% males; age 21 ± 5 years; 27% current smokers; body mass index (BMI) 22.7 ± 2.9; total cholesterol 171 ± 33 mg/dl; HDL cholesterol 51 ± 13 mg/dl; Lp(a) 26 ± 34 mg/dl; apo A1 144 ± 23 mg/dl; apo B 92 ± 26 mg/dl; systolic blood pressure 121 ± 10 mmHg; diastolic blood pressure 64 ± 8 mmHg] underwent: 1. carotid ultrasonography to measure the sum of IMT (SIMT) at four sites of the left and the right common carotid artery and carotid bifurcation; 2. brachial artery ultrasonography to measure the percent brachial artery diameter change (BADC) to reactive hyperemia induced by 4-min blood flow occlusion to the distal limb.

Results: SIMT correlated directly with BMI ($r = 0.36$, $p = 0.005$) and inversely with percent BADC ($r = -0.31$, $p = 0.02$). Multivariate analysis demonstrated that SIMT was an independent predictor of percent BADC.

Conclusions: In healthy young subjects with history of parental myocardial infarction increased carotid IMT is therefore associated with reduced brachial artery FMD, independent of the effects of age, BMI, blood pressure, smoking status, lipids. These combined changes in vascular structure and function may play an important role in the development of atherosclerosis and may become an useful surrogate in assessing the predisposition to atherosclerosis in healthy subjects with well known risk factors.

P1097 Brachial artery intima-media thickness measured with high-resolution (13 MHz) ultrasound: relation to coronary artery disease and endothelial function

M. Frick, H. Hügel, S. Schwarzacher, O. Pachinger, F. Weidinger. *Dept. of Cardiology, University of Innsbruck School of Med., Innsbruck, Austria*

Background: High-resolution ultrasound allows accurate measurement of brachial artery (BA) diameter, which is used for the assessment of endothelial function (flow-mediated vasodilation, FMD). Whether BA wall thickness (WT) measured in vivo is related to coronary artery disease (CAD) and/or FMD is unknown.

Methods: In 40 patients (pts) undergoing coronary angiography, BA-FMD and WT were measured with ultrasound (13 MHz) by an observer blinded to the diagnosis. 19 pts (age 51 ± 10 years) had CAD (* 30% diameter stenosis in 1 major branch), 21 pts (age 50 ± 8 years) had smooth coronaries. The number of risk factors per patient was similar in both groups (1.8 ± 0.9 vs. 1.4 ± 0.9). Within 2 days after angio, FMD and BA wall thickness were measured: Media-to-media (MDM) minus Intima-to-intima diameter (IDM)/2 (calculated WT) and direct intima-media measurement of the BA wall (direct WT). Measurement error is <0.05 mm.

Results: CAD pts showed significantly greater WT than controls, both using calculated WT (0.35 ± 0.06 vs. 0.31 ± 0.05 mm, $p < 0.02$) and direct WT (0.4 ± 0.05 vs. 0.35 ± 0.05 mm, $p < 0.01$). Calculated and direct WT showed close correlation ($r = 0.8$, $p < 0.01$). A wall index [(MDM-IDM)/MDM)x100] was also larger in CAD pts. than in controls (13.8 ± 2.1 vs. 12.5 ± 1.7, $p < 0.05$). FMD and WT showed no correlation.

Conclusion: BA-WT is measurable in vivo with high-resolution ultrasound and is greater in CAD pts than in controls with similar risk factor profile. These findings are in accordance with recent postmortem histologic data, suggesting atherosclerotic involvement of the BA. High-resolution ultrasound measurement of WT, in addition to FMD, may help to assess atherosclerotic risk non-invasivly.

P1098 Coronary endothelial function and renin-angiotensin system-related receptor polymorphism genotype: the Intervention Cardiology Risk Stratification (ICARIS) study

S.H.J. Monnink, R.A. Tio, A.J. van Boven, P.J. de Kam, N.J.G.M. Veeger, L. Pont[1], W.H. van Gilst[1], H.J.G.M. Crijns. *Departments of Cardiology; [1]Clinical Pharmacology University Hospital Groningen, Netherlands*

An important function of the endothelium is the presence of the angiotensin converting enzyme (ACE). ACE activates the potent vasoconstrictor angiotensin-II (ATII) and inactivates the vasodilator bradykinin (BK). ACE-dd and ATII-cc receptor genotypes interfere negatively with atherosclerotic progression and endothelial function. In the present ICARIS study we correlate the coronary response on intracoronary infusion of acetylcholine with the ACE, ATII and BK-2 receptor genotypes.

Methods: Acetylcholine was infused intracoronary (left main stem concentration 10^{-8}–10^{-6} molar) in 91 patients with angina pectoris accepted for diagnostic coronary angiography. The proximal LAD and LCX coronary response was determined using off-line quantitative coronary angiography. Multiple regression analysis was performed for all potential risk factors and first-order interactions towards the maximal vasoconstrictive response on acetylcholine (MAX%).

Results: Multiple regression analysis of these patients (n = 76, 63% males, mean age 58) showed that ATII genotype is an independent determinant of the acetylcholine response. The MAX% was −5.9% for ATII-aa genotype and −9.9% for ATII-ac genotype; $p = 0.049$. Receptor genotype of these patients was: ATII-aa 50% and ac 50%; ACE-dd 28% and id 44% and ii 28%; BK-cc 71% and ct 29%. No significant relation could be demonstrated for BK genotype, whereas ACE genotype was only a borderline predictor in combination with the maximal vasodilative diameter ($p = 0.050$).

Conclusion: ATII-ac receptor genotype is related with coronary endothelial dysfunction. This relationship was independent from the presence of clinical risk factors. No interactions with ACE or BK receptor polymorphism genotype could be demonstrated.

P1099 Tamoxifen improves endothelium-dependent vasodilatation in men with angiographically proven three-vessel coronary artery disease

S.C. Clarke, J.M. Rigley, H.L. Kirschenlohr[1], J.C. Metcalfe[1], P.M. Schofield. *Cardiac Unit, Papworth Hospital, Cambridge; [1]Department of Biochemistry, University of Cambridge, Cambridge, UK*

Tamoxifen, a triphenylethylene with oestrogenic and anti-oestrogenic properties, has been shown to have a major effect on cardiovascular protection in women but has not been extensively studied in men. Endothelial function declines with age and is impaired in patients with risk factors for and proven atherosclerosis. We studied the effects of tamoxifen on endothelial function in men with three vessel coronary artery disease (TVD).

Methods: 31 men with angiographic TVD, stabilised on a statin for at least 6 weeks pre-study, were randomised to tamoxifen 40 mg/day for 28 days or no additional therapy. Using high resolution ultrasonography of the brachial artery, flow-mediated endothelium-dependent vasodilatation (EDVD) was measured following reactive hyperemia. Endothelium-independent (EIVD) vasodilatation was measured after administration of sublingual glyceryl trinitrate. Results were expressed as percentage change in brachial artery diameter compared to baseline diameter. Endothelial function was studied at days 0, 7, 14 and 28.

Results: Tamoxifen significantly improved EDVD by day 7. There was no significant change in EDVD in the control group.

	EDVD (% ± SEM)			
	Day 0	Day 7	Day 14	Day 28
Control	1.6 ± 0.4%	1.9 ± 0.5%	1.8 ± 0.4%	2.0 ± 0.4%
Tamoxifen	2.0 ± 0.3%	*2.8 ± 0.4%*	*4.9 ± 5.8%*	*7.5 ± 0.7%*

$p < 0.05$ compared with day 0.

Tamoxifen had no effect on EIDV in either group.

Conclusion: Tamoxifen improves EDVD in men receiving statins with angiographic TVD. Tamoxifen may have cardioprotective effects in men mediated in part by improvement of endothelial function.

P1100 Exercise perfusion scintigraphy positivity is associated with peripheral vascular endothelial dysfunction in patients with normal coronary arteries

A. Varga, L. Pratali, E. Fabian[1], E. Pacetti[2], B. Nemes[1], M. Morelos, I. Stock[1], P.C. Rossi[2], E. Picano. *Institute of Clinical Physiology, Pisa, Italy; [1]Cardiology department, BM Korhaz, Budapest, Hungary[2]Regional Hospital, Fivizzano, Italy*

Background: Patients with chest pain and angiographically normal coronary arteries often have a positive thallium-201 myocardial perfusion scintigraphy, hypothetically linked to coronary microvascular disease and endothelial dysfunction. High resolution brachial ultrasound provides a noninvasive assessment of systemic endothelial function.

Aim: To determine the endothelium dependent vasodilator function in the brachial artery of patients with chest pain, angiographically normal coronary arteries and different response during thallium-201 perfusion scintigraphy.

Methods: Forty-two patients (33 males, mean age: 59 ± 8 years) with chest pain syndrome and angiographically normal coronary arteries underwent exercise stress thallium-201 scintigraphy. The scintigraphy was considered positive in case of a transient perfusion defect. Endothelium dependent vasodilation was assessed by measuring the change in brachial artery diameter in response to hyperemic flow by vascular ultrasound.

Results: On the basis of the associated scintigraphic response, 2 groups were identified: I. (n = 14) with negative and II. (n = 28) with positive perfusion scintigraphy. Brachial artery flow mediated vasodilation was decreased in patients with positive thallium-201 scintigraphy (I. = 11.4 ± 5.9% vs II. = 5.9 ± 5.4%, $p < 0.01$).

Conclusion: In patients with angiographically normal coronary arteries, a stress induced perfusion defect is an "anatomic lie" ("false-positive" versus the angiographic standard) but a "physiologic truth" (true positive versus the physiologic assessment of systemic endothelial function).

P1101 Effect of circuit weight training on functional capacity and vascular function in non-insulin-dependent diabetes

A. Maiorana, J. Collis, C. Cheetham, G. O'Driscoll[1], C. Goodman, R. Taylor[2], D. Green. *Human Movement and Exercise Science, The University of Western Australia, Perth; [1]Cardiac Transplant Unit, Royal Perth Hospital, Perth[2]Department of Cardiology and Medicine, Royal Perth Hospital, Perth, Australia*

Background: Exercise training programs are often recommended for patients with NIDDM to improve physical conditioning and glycaemic control. We investigated the effect of a program of combined aerobic and resistance exercise on measures of functional capacity, strength, body composition and vascular function.

Methods: After familiarisation sessions, 16 patients (53 ± 2 yrs, 89 ± 4 kg; mean ± SE) undertook a randomised, cross-over design study of the effect of 8 weeks of supervised CWT. VO_2peak, sum of 7 maximal voluntary contractions and the sum of 8 skinfolds were determined at entry, cross-over and 16 weeks. Endothelium-dependent and -independent vascular function were determined by forearm strain-gauge plethysmography and intrabrachial infusions of acetylcholine (ACh) and nitroprusside (SNP). Conduit vessel endothelial function was assessed using high-resolution ultrasound and the brachial artery flow mediated response to reactive hyperaemia (FMD); nitroglycerine (GTN) being used as a non-endothelium-dependent dilator.

Results: VO_2peak significantly increased as a result of CWT (23.1 ± 1.2 v 24.8 ± 1.4 ml/kg/min; $P < 0.05$, paired t-test) as did exercise test duration (12.6 ± 1.2 v 14.8 ± 1.3 min; $P < 0.01$). Muscular strength (396 ± 29 v 456 ± 30 kg; $P < 0.01$) also increased with training. Skinfolds significantly decreased (149 ± 11 v 141 ± 10 mm; $P < 0.05$), whilst body weight was unchanged. Glycated haemoglobin decreased from 8.5 ± 0.4 to 7.9 ± 0.3 ($P < 0.05$). The forearm blood flow ratio responses to three incremental doses of ACh significantly increased after exercise training ($P < 0.05$, two-way ANOVA), as did the FMD response to hyperaemia ($P < 0.001$). In contrast, CWT did not influence the response to SNP or GTN.

Conclusions: An individually prescribed, structured and supervised CWT program improved objective measures of functional capacity and muscular strength in patients with NIDDM. In addition, anthropometric and strength data suggest that lean body mass increased, with a corresponding decrease in adiposity. CWT exercise also enhanced endothelium-dependent vasodilation in forearm vessels of patients with NIDDM, indicating that clinically relevant exercise training programmes may reverse the endothelial dysfunction which is associated with this disease.

P1102 Oleic acid, a prominent component of the Mediterranean diet, exerts direct vascular antiatherogenic properties by modulating endothelial activation through effects on intracellular reactive oxygen metabolites

Marika Massaro[1], Maria Annunziata Carluccio[2], Evelina Lorenzini, Aldo Paolicchi, Roberto Tongiani, Raffaele De Caterina[1]. *[1]CNR Institute of Clinical Physiology, Pisa; [2]Lecce; Department of Experimental Pathology, the University of Pisa, Pisa, Italy*

Endothelial cell activation plays an important role in the pathogenesis of atherosclerosis by allowing monocyte recruitment through the expression of adhesion molecules and chemoattractants. Intracellular production of reactive oxygen species is crucial for the trascriptional activation of these genes through the induction of Nuclear Factor-κB (NF-κB), consensus sequences for which are present in the promoters of all these genes. We stimulated human vascular endothelial cells with interleukin-1 (IL-1) and lipopolysaccaride (LPS) with or without preincubation with 50–100 μM oleic acid for 48–72 hours. This concomitantly reduced VCAM-1 and E-selectin surface expression, mRNA levels at Northern analysis and NF-κB activation at electrophoretic mobility shift assay. We subsequently investigated the possible influence of oleic acid on the oxidative status of endothelial cells, by measuring the activity of glutathione (GSH)-related antioxidant enzymes glutathione peroxidase (GSH-Px) and glutathione transferase (GSH-T), and the concentration of intracellular glutathione (GSH) and ascorbic acid. Exposure to 1μg/mL LPS caused a significant decrease of intracellular GSH (−38 ± 23%) and ascorbic acid (−60 ± 30%). When cells were grown for 48 h in the presence of 100 μM oleic acid before the exposure to LPS, the depletion of GSH and ascorbic acid were prevented. Neither LPS nor oleic acid caused changes in the activity of GSH-related antioxidant enzymes. Measurement of oleic acid incorporation in total cell lipids indicated a preferential incorporation of oleate at the expenses of saturated fatty acids. These results indicate that a prominent component of olive oil and the Mediterranean diet exerts direct vascular atheroprotective effects by inhibiting endothelial activation through a quenching of stimulus-related increase in intracellular reactive oxygen species.

P1103 Differential gene expression in canine platelets following chronic administration of non-intermittent glyceryl trinitrate

M. Schwemmer, J. Zipfel, E. Bassenge. *Institute of Applied Physiology, Albert-Ludwigs-University, Freiburg, Germany*

Nonintermittent therapy with nitrovasodilators may induce tolerance (upregulation of platelet activity/reduced vasodilation). During 5 day infusion of glyceryl trinitrate (GTN; 1.5 μg/kg/min) into dogs we analyzed differential gene expression in the megakaryopoietic lineage. Platelet RNA (ribonucleic acid) from day 0 (control) or days 1, 3, and 5 of GTN treatment was subjected to differential display reverse transcription polymerase chain reaction. For each day 40 different PCR reactions (160 total reactions) were resolved by denaturing polyacrylamide gel electrophoresis. For cloning and sequencing, differentially expressed bands were reamplified. Out of the 40 PCR reactions, 16 showed differential banding patterns between different days of analysis (24 differentially expressed bands). Development of tolerance was related to quantitative (enhanced or diminished gene expression) and qualitative changes in gene expression: either the expression of a specific RNA was restricted to control platelets, or it was only detectable during GTN administration. For some RNAs, expression could be observed only on day 1 of GTN administration or was completely absent. Reamplified PCR products of interest are now being cloned for further characterization. Thus chronic administration of the nitrovasodilator glyceryl trinitrate induces profound alterations of gene expression in the megakaryopoietic lineage during development of nitrate tolerance.

Conclusion: Differentially expressed genes could be intimately implicated in nitrate dependent signal transduction or in tolerance development. Differential display of platelet RNAs during long-term administration of NO donors is an adequate approach to identify mechanisms involved in the pharmacodynamics of nitrates and in the development of tolerance.

P1104 Inhaled nitric oxide does not influence bleeding time or platelet function in healthy volunteers

J. Albert, M. Norman[1], N.H. Wallén[2], C. Frostell[3], P. Hjemdahl[2]. *Section of Anesthesiology, Karolinska Hospital, Stockholm; [1]Dept. of Women and Child Health, Stockholm[2]Dept. of Lab. Med., Div. of Clin. Parmacol., Stockholm[3]Pediatric Intensive Care Programme, Stockholm, Sweden*

Bleeding time has been reported to increase during NO inhalation and it has been speculated that inhaled NO inhibits platelet function, but we have been unable to document any effects on circulating platelets. However, an effect on platelet-vessel wall interactions, or vasodilator response in the skin circulation might also increase bleeding time.

Methods: Because all earlier studies have been open, we performed a double-blind, placebo controlled cross-over study in which healthy volunteers (n = 15) inhaled NO (30 ppm) or air. Aspirin (640 mg orally, n = 14) was used as positive control on a third occasion. Bleeding time was measured, and platelet function was determined by measuring the expression of P-selectin on circulating platelets and locally activated platelets in wound blood using flow cytometry in whole blood. Local skin perfusion was assessed by laser Doppler flowmetry.

Results: Bleeding time was unaffected by NO, as there were slight increases during both NO and control inhalation (+20% and +14% respectively, $p = 0.9$). Similarly, NO inhalation had no effect on the time-dependent increase in P-selectin expression of platelets in wound blood or on the skin perfusion. Aspirin pre-treatment, on the other hand significantly prolonged bleeding time ($p < 0.001$) and the platelet activation in wound blood (P-selectin expression) was attenuated after aspirin compared to baseline ($p < 0.01$).

In conclusion: This first placebo-controlled study demonstrates that NO inhalation has no significant effect on bleeding time, platelet function or skin perfusion. It has previously been feared, that treatment with NO inhalation to critically ill patients will aggravate the disturbances in haemostasis that these patients often display by a direct effect on platelets. This is unlikely on the basis of present findings.

P1105 A simple point of care method for assessment of platelet function at the bedside using the ICHOR device

N. Lakkis[1], A. McNeal[2], A. Babukuty[2], J. Farmer[1]. *[1]Department of Medicine, Section of Cardiology, Baylor College of Medicine; [2]Section of Cardiology, Ben Taub General Hospital; Houston TX, USA*

There is a current clinical need for a point of care device to assess platelet function in patients receiving platelet Gp IIb/IIIa receptor blocker therapy for better safety and efficacy. Unfortunately, the traditional methods are suboptimal. The purpose of this study is to assess the feasibility of assessing platelet function as measured by platelet aggregation inhibition, using the ICHOR hematology analyzer in patients undergoing coronary angioplasty and were treated with tirofiban.

Methods: The study was conducted at Ben Taub General Hospital, an affiliated hospital of Baylor College of Medicine. Twelve patients undergoing coronary angioplasty for acute coronary syndromes and treated with tirofiban (0.4 μg/kg/min loading dose for 30 minutes and 0.1 μg/kg/min for 12–24 hours maintenance infusion) were recruited. Blood samples were collected from the arterial sheath while in place and from a peripheral intravenous catheter after sheath removal. Platelet aggregation was tested before tirofiban infusion, after completion of the bolus infusion, at 4 hours, before discontinuation and 2 hours after the infusion was discontinued. Four different platelet agonists were used: ADP, ristocetin, epinephrine, and collagen.

Results: The mean age of the patients enrolled was 52 ± 3 years. Coronary angioplasty of the LAD was performed in 6 patients, RCA in 4 patients and of the circumflex in 2 patients. Baseline studies showed a mean platelet aggregation of 65%, 86%, 88%, and 70% in response to ristocetin, ADP, epinephrine and collagen, respectively. The percentage of aggregable platelets decreased to 10%, 24%, 15% and 24% when stimulated with ristocetin, ADP, epinephrine and collagen following the tirofiban bolus infusions. This effect was maintained at 4 hours and before the discontinuation of the infusion at a mean of 17 hours. Platelet function recovered partially 2 hours after discontinuation of tirofiban with mean percent platelet aggregation of 46%, 55%, 49% and 57% as measured with the same agonists. A heterogenous response was noted when testing platelets from different patients with the same agonists in the presence or absence of tirofiban.

Conclusion: The ICHOR hematology analyzer is a simple, rapid bedside method that may have clinical utility in assessing platelet aggregability in patients undergoing coronary angioplasty who are treated with Gp IIb/IIIa receptor blockers.

P1106 Flow cytometer model markedly affects the measurements of platelet P-selectin in patients with chest pain

V.L. Serebruany, S.R. Murugesan, D.J. Kereiakes[1], M.R. Dalesandro[2], P.A. Gurbel. *Sinai Center for Thrombosis Research, Baltimore MD; [1]Lindner Center for Cardiovascular Research, Cincinnati OH; [2]Centocor. Inc., Malvern PA, USA*

Surface expression of P-selectin is known to be a marker of platelet activation in patients with acute coronary syndromes. However, direct comparisons of flow cytometry data may be obscured by differences in methodology, artifactual platelet activation during washing procedures, and choice of antibodies. We sought to test the hypothesis that the model of flow cytometer represents another variable affecting P-selectin measurements.

Methods: Platelet P-selectin in whole blood was measured by FACScan™ (Beckton Dickinson, Inc., San Diego, USA) or EPICS XL® (Coulter Corporation, Miami, USA) flow cytometry in 338 patients presenting with chest pain to the emergency departments of three community hospitals as part of a multicenter diagnostic trial.

Results: Platelet expression of P-selectin (% of cell positivity) was consistently higher for each discharge diagnosis when measured with FACScan™ flow cytometer (13.2 ± 4.1 for myocardial infarction, 10.0 ± 3.6 for unstable angina, 9.9 ± 3.5 for heart failure, 4.7 ± 0.1 for gastrointestinal illness, and 6.3 ± 0.7 for patients with non-cardiac chest pain) when compared with results obtained from the EPICS XL® instrument (2.4 ± 0.2, 2.5 ± 0.2, 2.5 ± 0.1, 1.8 ± 0.1, and 2.3 ± 0.1 respectively, $p = 0.0001$ for all groups).

In conclusion, this study reveals that the level of platelet P-selectin detected depends upon the model of flow cytometer used. If P-selectin is to become a diagnostic tool for assessing platelet hyperactivity in vascular disease, it is mandatory that standard measurements be defined for each model of flow cytometer.

P1107 The central role of the platelet ADP (P_{2T}) receptor in amplification of platelet secretion in human whole blood

R.F. Storey, A. White, S. Heptinstall. *Division of Cardiovascular Medicine, University Hospital, Nottingham, UK*

Background: ADP released from platelet dense granules amplifies responses to other agonists. AR-C69931MX is an intravenous direct platelet ADP receptor (P_{2T}) antagonist currently being investigated in patients with acute coronary syndromes. We compared the effects of this agent and aspirin (ASA) on platelet secretion.

Methods: Whole blood was venesected from healthy human volunteers before and 2.5 hours after ingestion of ASA (600 mg). Hirudin was used as anticoagulant to maintain physiological divalent cation levels. Either saline (control) or AR-C69931MX 100 nM was added to aliquots of blood. P-selectin expression (a marker of alpha granule release) and ^{14}C-5HT release (a marker of dense granule release) were measured, using flow cytometry and ^{14}C-labelled platelets respectively, in response to different agonists, including ADP, TRAP, the thromboxane A2 mimetic U46619, platelet activating factor (PAF) and collagen.

Results: P-selectin median fluorescence; mean data (n = 6) ± SD:

Agonist	Control		AR-C69931MX	
	−ASA	+ASA	−ASA	+ASA
Baseline	8.2 ± 1.1	7.7 ± 1.1		
ADP 30 μM	14.1 ± 2.2	13.6 ± 2.6	9.7 ± 4.2*	9.2 ± 1.1
TRAP 30 μM	100.9 ± 22.8	100.1 ± 14.3	83.0 ± 15.1*	76.4 ± 14.4
U46619 1 μM	67.4 ± 29.3	58.2 ± 17.7	14.8 ± 2.9*	14.3 ± 2.5
PAF 1 μM	14.1 ± 1.7	13.6 ± 1.6	10.6 ± 1.7*	10.7 ± 1.6
Collagen 8 μ/ml	20.6 ± 14.4	9.0 ± 1.5*	9.2 ± 1.4*	8.3 ± 1.0

* $p < 0.05$ for AR-C69931MX or ASA effect (ANOVA for repeated measures)

Data for ^{14}C-5HT release showed an identical pattern of inhibition for both agents with all the agonists shown, with AR-C69931MX inhibiting responses to all the agonists but ASA only inhibiting collagen-induced 5HT-release. There were significant additive effects of both agents on collagen-induced 5HT-release. AR-C69931MX, but not ASA, also inhibited 5HT- and adrenaline-induced release. Concomitant aggregation studies showed the same patterns of inhibition also.

Conclusion: AR-C69931MX is a potent inhibitor of platelet secretion indicating a central role for the P_{2T} receptor in amplification of platelet secretion. In contrast, the effects of ASA are much more limited but the two agents have additive effects on collagen-induced 5HT-release.

P1108 Heparin-induced thrombocytopenia type II: incidence and outcome in 1,000 consecutive medical patients

U. Janssens, R. Khanduja, N. Lorenz, J. vom Dahl, P. Hanrath. *Medical Clinic I, University Hospital of Aachen, Aachen, Germany*

Heparin induced thrombocytopenia type II (HIT) is a life-threatening side-effect of heparin therapy. Patients (pts) with HIT may subsequently develop severe arterial and venous thromboembolic complications (TECs). The reported frequency of HIT varies widely and ranges from 0% to 30%. Therefore we carried out a prospective study to evaluate the incidence of HIT in pts admitted to a cardiology department.

Methods: All consecutive pts who received subcutaneous (sc) or intravenous (iv) heparin were included in the study. Platelet counts were obtained on admission and thereafter every second day. Clinical signs of thrombosis were screened daily. HIT was defined as a) a drop of platelet counts more than 50% of baseline values and b) a positive heparin induced platelet activation assay (HIPA) and/or c) clinical signs/proof of arterial and/or venous thromboembolism. Heparin therapy was discontinued in all pts with a significant thrombocytopenia and replaced by danaparoid sodium or lepirudin when necessary and in all serologically proven HIT pts or pts with thrombocytopenia and TECs.

Results: Between 12/96 and 6/97 1000 pts (63.6 ± 32.1 years, 71% male, 270 pts sc heparin, 730 pts iv heparin) were included in this study. 33 pts (3.3%) developed a thrombocytopenia with a nadir of 95 Giga/l on day 10 (3–20). HIPA was positive in 7 of these pts (0.7%). Lowest platelet counts in HIPA positive pts were 55 ± 18 Giga/l on day 12 ± 6.7. 4/7 HIPA positive pts exhibited venous TECs, two of them pulmonary embolism. There was no arterial thrombosis nor limb amputation or even death in HIT pts.

In conclusion: Incidence of HIT in 1000 consecutive medical pts was 0.7%. The low rate of disabling or life-threatening complications and no HIT related death in our patient series may be attributed to the close monitoring of platelet counts and early recognition of this adverse event of heparin therapy.

P1109 Fibrinogen deposition to the postischaemic endothelium initiates platelet adhesion in vivo

S. Massberg, G. Enders, F.C. de Melo Matos, L.I. Domschke, R. Leiderer, S. Eisenmenger, K. Messmer, F. Krombach. *Institute for Surgical Research, University of Munich, Munich, Germany*

Background: During ischemia-reperfusion (I/R), platelets are among the first cells recruited to the postischemic microvasculature. The molecular mechanisms underlying platelet adhesion during I/R in vivo have not been completely identified. In the present study, we evaluated whether fibrinogen deposition during I/R might promote platelet accumulation to the postischemic microvasculature.

Methods and Results: The deposition of fluorescent 488-fibrinogen and the accumulation of rhodamine 6G-tagged platelets were assessed in vivo in a mouse model of intestinal I/R (90 min/60 min) using video fluorescence microscopy (n = 30). Following ischemia, fibrinogen accumulated in both arterioles and venules within minutes after the onset of reperfusion. The deposition of fibrinogen co-localized with adherent platelets (647 ± 138 and 347 ± 81 platelets/mm^2 in arterioles and venules, respectively). Following pre-treatment with an anti-fibrinogen antibody, platelet adhesion was dramatically reduced (135 ± 79 and 61 ± 22 platelets/mm^2 in arterioles and venules, respectively). Furthermore, platelet adhesion was found to involve Arg-Gly-Asp-recognition sequences, and platelets isolated from a patient with Glanzmann's disease showed decreased interaction with the postischemic endothelium. The latter indicates that the platelet alpha IIb/beta 3 integrin mediates fibrinogen-dependent platelet accumulation in I/R.

Conclusion: In I/R, the deposition of fibrinogen promotes the recruitment of platelets to postischemic microvessels. By initiating platelet adhesion, the association of fibrinogen with the endothelium might represent an important event leading to postischemic reocclusion and remodeling of the microvessels.

P1110 Endogenous nitric oxide and prostaglandins act synergistically to counteract thromboembolic processes in arterioles but not in venules

M.A.W. Broeders, G.-J. Tangelder[1], D.W. Slaaf[2], R.S. Reneman, M.G.A. Oude Egbrink. *Physiology Dept, Maastricht University, Maastricht; [1]Physiology Dept, Free University, Amsterdam[2]Biophysics Dept, Maastricht University, Maastricht, Netherlands*

In vitro, nitric oxide (NO) and prostacyclin (PGI2) released by endothelial cells act synergistically to inhibit the aggregation of blood platelets. It is unknown whether this synergistic interaction is also effective in vivo and whether this interaction, if any, differs between vessel types.

Methods: in the present study the combined effect of NO and PGI2, on thromboembolism was investigated in an in vivo model. Vessel walls of rabbit mesenteric arterioles and venules (diameter: 18–40 micron) were punctured with a micropipet (tip size: 6 micron). The ensuing thromboembolic reaction was followed by intravital videomicroscopy and the effects of NO and PGI2, alone or in combination, were studied. Besides, the influence of wall shear rate was investigated.

Results: in arterioles, combined inhibition of NO synthase with Ng-nitro-L-arginine (L-NA; 0.1 mM local superfusion) and of cyclooxygenase with aspirin (ASA; 100 mg/kg; i.v.) resulted in a dramatic, significant prolongation of the duration of embolization (duration on the average >600 s) as compared to control (median: 153 s; no L-NA and ASA), or treatment with either L-NA (234 s) or ASA (314 s). In 7 out of the 10 arterioles (70%) of the L-NA + ASA group embolization duration continued for 1 to 3 hours after vessel wall injury. In contrast, in venules combined treatment with L-NA and ASA (209 s) had no additional effect on embolization duration as compared to the effect of L-NA alone (230 s); treatment with ASA had no significant effect at all (122 s; control: 72 s). Only, in the L-NA + ASA arterioles ($r = 0.547$; $p < 0.041$), the duration of embolization positively correlated with wall shear rate.

Conclusion: In conclusion, this study provides evidence for an inhibitory synergistic, (inter)action of endogenous NO and PGI2 in ongoing thromboembolism in arterioles, but not in venules and for a protective effect of NO combined with PGI2 protecting the vessel wall against shear rate induced thromboembolic processes.

P1111 Identification of persistent procoagulant activity in patients with unstable angina by troponin T measurements

M. Müller-Bardorff, E. Giannitsis, S. Schweikart, U. Wiegand, M. Kampmann, H.A. Katus. *Med. Klinik II, University of Lübeck, Germany*

The present study sought to determine the incidence of persistent thrombin generation in patients (pts) with unstable angina (UAP) despite antithrombotic therapy, and to evaluate the correlation of elevated cardiac troponin T (cTnT) with procoagulant activity.

Procoagulant activity was studied in 111 pts with UAP (n = 44), acute myocardial infarction (AMI) (n = 27) and stable angina (n = 40). Pts with UAP were further categorized by plasma cTnT concentrations $\geq$ 0.1 μg/L. All pts with UAP and AMI received antithrombotic therapy consisting of therapeutic doses of unfractionated heparin and acetylsalicylic acid. Quantitative cTnT levels and plasma concentrations of fibrin monomers, prothrombin fragments, thrombin antithrombin III complexes, plasminogen and α-2 antiplasmin were sampled serially within the first 48 hours.

18 of 44 pts (40.9%) with UAP had concentrations of cTnT $\geq$ 0.1 μg/L. In these pts mean plasma concentration of fibrin monomers were significantly higher (5.09 $\pm$ 7.03 vs 2.07 $\pm$ 1.8 μg/l, p = 0.01), and a substantially higher proportion of these pts were found to have elevated levels of fibrin monomers (13 of 18 vs 7 of 26 pts, p = 0.003). The sensitivity, specificity and positive predictive value of cTnT for the identification of increased thrombin activity as reflected by elevated fibrin monomers was 65, 79 and 72%, respectively. In the cTnT positive pts with UAP, a significant correlation (r = 0.74, p < 0.004) was found between levels of cTnT and fibrin monomers and for prothrombin fragments F1 + 2 (r = 0.71, p = 0.046) and thrombin antithrombin III complexes (r = 0.42, p = 0.055). No significant correlation was found with markers of the fibrinolytic system (plasminogen, α-2 antiplasmin).

There is ample evidence that increased thrombin generation may persist despite administration of therapeutic doses of unfractionated heparin and acetylsalicylic acid in pts with UAP. Pts with increased procoagulant activity may be identified by cTnT.

P1112 Cutaneous microcirculation during HELP-LDL-apheresis in cardiac allograft recipients with severe hypercholesterolaemia

J.-W. Park, C. Mrowietz[1], G. Lässig, F.M. Wagner, S. Schueler, F. Jung[1]. *Cardiovascular Institute, University Dresden; [1]Clinical Hemostaseology and Transfusionmedicine, University Homburg, Germany*

In hypercholesterolemic patients with coronary artery disease impaired cutaneous microcirculation can be reversed by HELP-LDL-apheresis treatment (**H**eparine-induced **E**xtracorporeal **L**DL **P**recipitation; HELP). The study aim was to proof if this is also true for heart transplant patients (HTX) with cardiac allograft vasculopathy (CAV) and hypercholesterolemia.

Patients and Methods: Cutaneous microcirculation was examined before, during, and 60 minutes after a single HELP in 8 HTX (all males, 51 $\pm$ 9 years, 8–36 months post transplantation) with CAV (IVUS, modified Stanford-class IV) and hypercholesterolemia. Mean erythrocyte velocity was measured during continuous registration of perfusion in nail-joint capillaries of patients' left hand by using an intravital capillary microscope.

Results: The mean erythrocyte velocity before HELP was tremendously lower in HTX (0.13 $\pm$ 0.07 mm/s) than in healthy controls (reference range 0.48 $\pm$ 0.72 mm/s). During and after HELP the mean erythrocyte velocity increased significantly, 60 minutes after the end of HELP the mean erythrocyte velocity was still 130.7% of baseline value (0.17 $\pm$ 0.11 mm/s; p < 0.05). Before, during, and after HELP the skin temperature was constantly at 28.1°C.

Conclusions: The mean erythrocyte velocity in nail-joint capillaries of HTX with CAV and hypercholesterolemia is tremendously reduced indicating a markedly impaired cutaneous microcirculation. This impairment can be reversed in part by HELP-LDL-apheresis.

P1113 The influence of thrombin generation on severity and prognosis of congestive heart failure

M. Iida, Y. Ichie, I. Kodama[1], H. Honjo[1], R. Niwa[1], M. Yamamoto[1]. *Cardiology Dept, Mitsubishi Nagoya Hospital, Nagoya; [1]Department of Circulation, RIEM, School of Medicine, Nagoya University, Nagoya, Japan*

Aim: V-HeFT trial revealed that patients with congestive heart failure(CHF) experiencing thromboembolism had a lower left ventricular(LV) function. Thrombin has been shown to enhance atrial natriuretic peptide(ANP) secretion from in vitro ventricular myocytes. Therefore thrombin generation may be related with severity and prognosis of CHF.

Methods: Prothrombin Fragment 1+2 (PT F1+2), a marker of thrombin generation, and von Willebrand factor (vWF), a marker of endothelial dysfunction, were measured in the CHF patients deteriorated by non-ischemic events(n = 30), in the unstable angina patients with normal LV function(n = 28), and in the healthy individuals (n = 17). For the patient groups, blood samples were collected both at admission and at discharge. We investigated the relations of these hemostatic factors and the indices of CHF such as neuroendocrine factors (ANP and brain natriuretic peptide(BNP)), left ventricular mass index (LVMI) and percent fractional shortening (%FS) obtained by echocardiography. Theses patients were prospectively followed for recurrence during subsequent 6-month period after discharge.

Results: In CHF patients, PT F1+2 (nmol/L) increased remarkably at admission (1.5 $\pm$ 0.12) and decreased at discharge(0.95 $\pm$ 0.08). These concentrations were significantly higher than those of healthy individuals (0.77 $\pm$ 0.44). In angina patients, PT F1+2 levels disclosed the similar changes as those of CHF. PT F1+2 significantly correlated with ANP (r = 0.55, p < 0.01) and BNP (r = 0.48, p < 0.01) in CHF at admission, and with ANP (r = 0.54, p < 0.01) and LVMI (r = 0.38, p < 0.05) in CHF at discharge. In contrast, PT F1+2 did not correlate with any indices of CHF in angina patients. Multivariate logistic regression analysis of the variables at discharge indicated significant predictors of recurrence were BNP and PT F1+2 in CHF, however, vWF in angina.

Conclusion: PT F1+2, a marker of thrombin generation, positively correlated with neuroendocrine factors and was revealed to be an independent predictor of recurrence in CHF patients.

P1114 Endocardial damage is common in the left atrial appendage of patients with mitral valve disease: implications for left atrial thrombogensis

I.R.A. Goldsmith[1,2], G.Y.H. Lip[2], A.D. Blann[2], P. Kumar[3], P. Carter[3], R.L. Patel[1]. *[1]Cardiothoracic Unit, Walsgrave, Coventry; [2]University Department of Medicine, City Hospital, Birmingham; [3]Manchester Metropolitan University, Manchester, UK*

The process of thrombogenesis and sequence of changes in the development and progression of left atrial thrombus in patients with mitral valve (MV) disease has not been precisely described. To document endocardial changes in the left atrial appendage (LAA) and right atrial appendage (RAA) of patients with MV disease and the differences between patients with atrial fibrillation (AF) and sinus rhythm (SR), LAA and RAA biopsies were obtained immediately following commencement of cardiopulmonary bypass from 35 patients (18 males; mean age 61 years) who underwent MV surgery. The specimens were fixed in 2.5% glutaraldehyde solution, stored in phosphate buffer and examined using scanning electron microscopy. The most advanced lesion in each specimen was documented by 2 independent observers. Plasma levels of von Willebrand factor (vWf, marker of endothelial dysfunction) were measured using ELISA on all patients and in age and sex-matched controls. Changes of endothelial cell damage were seen in all LAA and RAA specimens. Advanced changes were more frequently seen in the LAA as compared to the RAA (31% v 6%; p = 0.002) whilst early minimal changes were more frequently seen in the RAA compared to the LAA (23% v 6%). Similarly, LAA of patients in AF had more advanced changes as compared to patients in SR (39% v 27%; p = 0.003). Plasma vWf levels were significantly higher in patients with MV disease compared to controls (132 $\pm$ 33 v 99 $\pm$ 37 IU/dL; p = 0.0004) and in patients with advanced LAA changes compared to earlier changes (149 $\pm$ 34 v 121 $\pm$ 31 IU/dL; p = 0.04).

Conclusions: Endothelial cell damage occurs in all atrial appendages of patients with mitral valve disease, with more advanced changes occurring in the LAA compared to RAA and in patients in AF compared to SR. The raised vWf levels in patients with MV disease and with more advanced endocardial damage is in keeping with the recognised association of vWf with endothelial damage.

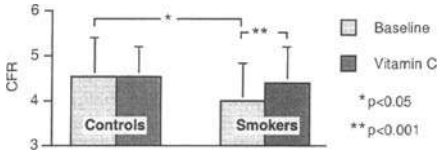
P1115 Oxidative stress impairs coronary microcirculatory function in asymptomatic smokers: reversal by vitamin C

P.A. Kaufmann[1,2], T. Gnecchi-Ruscone[1], P.G. Camici[1]. [1]*Hammersmith Hospital, ICSM, London, UK;* [2]*Cardiology, Zurich, Switzerland*

Coronary endothelial function and vasomotion are impaired in smokers without coronary disease and this is thought to be due to increased oxidative stress due to prooxidant substrates present in cigarette smoke. To test this hypothesis, we measured the coronary flow reserve (CFR) in smokers and non smoking controls before and after administration of the anti-oxidant vitamin C.

Methods: Myocardial blood flow (MBF, ml/min/g) at rest (R) and during iv adenosine (Ado; 0.14 mg/kg/min) was measured in 8 healthy non smoking males and 11 age-matched asymptomatic male smokers using positron emission tomography and oxygen-15 labeled water. Both measurements were repeated 15 minutes later following a 10 minutes iv infusion of 3 g vitamin C. CFR was calculated as Ado-/R-MBF.

Results: Heart rate and mean arterial blood pressure were similar in both groups at R and during Ado before and after vitamin C. At baseline, CFR was reduced by 21% in smokers compared to controls, but was normalised after vitamin C.



Conclusions: CFR is decreased in asymptomatic smokers and is improved by Vitamin C. This provides evidence that increased oxidative stress contributes to coronary endothelial dysfunction in smokers.

P1116 Leukocyte-platelet adhesion parallels increased platelet activation in patients with acute coronary syndromes

H.M. Hoffmeister, E. Büttcher, R. Ehlers, S. Kazmaier, H.P. Wendel, U. Helber, W. Heller. *Medical Department III, University of Tübingen, Germany*

To investigate whether leukocyte-platelet adhesion (LPA) is associated with platelet stimulation and consecutive release of inflammatory mediators in acute coronary syndromes, we prospectively examined 30 patients with unstable angina pectoris (UAP) vs. 16 age-matched controls. Flow-cytometry (FACS) with FITC-antibodies against the GPIIb/IIIa receptor (CD41) on monocytes (MONO) and granulocytes (GRANU) was used to identify thrombocytes adherent to these leukocytes at admission (0 d) and 2 d later. The soluble P-selectin adhesion molecule was determined as marker of platelet activation.

	UAP (0 d)	UAP (2 d)	Controls
MONO- (%)	41 ± 5**	19 ± 5	15 ± 3
LPA (MC)	9.1 ± 0.6**	7.7 ± 0.6	6.8 ± 0.4
GRANU- (%)	20 ± 2	8 ± 2	21 ± 3
LPA (MC)	7.6 ± 0.3	6.3 ± 0.4	7.9 ± 2.9
P-selectin (ng/ml)	43 ± 1.6*	36 ± 1.4	36 ± 2.7

Means ± SEM; % = positive/total cells; MC = mean channel value; * = $p < 0.05$; ** = $p < 0.01$.

Monocyte-thrombocyte conjugates are markedly enhanced during the acute phase of UAP compared with granulocyte-thrombocyte conjugates. Increased P-selectin levels prove the associated platelet activation.

Conclusion: Monocyte-platelet adhesion is transiently increased in parallel to platelet activity (as evidenced by P-selectin) during the acute phase of unstable angina and may trigger inflammation-coagulation associated pathway activity.

P1117 Patients with total coronary occlusions have a higher mean platelet volume and glycoprotein IIb/IIIa expression than patients with stenoses

H. El Gendi, A.G. Violaris, T.F. Ismail, R.A. Foale, D.J. Sheridan. *Division of NHLI, St Mary's Hospital, Academic Cardiology Unit, London, UK*

Background: Successfully dilated coronary occlusions have a higher risk of restenosis compared to non-occlusive stenoses. Patients with elevated mean platelet volume are also at increased risk of restenosis following percutaneous transluminal coronary angioplasty, possibly due to increased platelet aggregability. To investigate whether these two risk factors are related and to identify possible therapeutic targets, we studied mean platelet volume and platelet GPIIb/IIIa expression in patients with stenotic and occlusive coronary disease.

Methods: Mean platelet volume and platelet count were prospectively assessed in 30 patients undergoing successful left coronary system intervention, using an automated full-blood counter (Coulter technique). GPIIb/IIIa expression was assessed by staining platelets with a fluorochrome-conjugated monoclonal antibody directed against the integrin and quantifying the degree of binding by flow cytometry. Blood samples were collected prior to the intervention in EDTA tubes for mean platelet volume and platelet count determination. Citrated tubes were used for flow cytometric studies.

Results: Nineteen patients (15 males, mean age 63) had non-occlusive stenoses (66 ± 5% (mean ± SD) stenosis), 11 patients (4 males, mean age 62) had chronic total occlusions. There was no significant difference between the platelet counts of patients with occlusions (254 ± 19) versus those with stenoses (243 ± 17, P = 0.44). However, there was a significantly higher mean platelet volume in patients with occlusions compared to those with stenoses (mean ± SEM = 9.16 ± 0.3 fL versus 8.4 ± 0.17 fL, $P < 0.05$) and GPIIb/IIIa expression measured as mean channel fluorescence (58.32 ± 4.2 versus 45.7 ± 3, P = 0.02).

Conclusion: Our data show that patients with occlusions have higher mean platelet volume and platelet GPIIb/IIIa expression compared to those with stenoses. These findings provide direct evidence that angiographic indicators of restenosis risk may be related to thrombotic risk and support the use of GPIIb/IIIa antagonists in such patients.

P1118 Evidence for prothrombotic effects of exercise and limited protection by aspirin

N. Li, N.H. Wallén, M. Daleskog, M.-C. Johansson, P. Hillelson, P. Hjemdahl. *Department of Clinical Pharmacology, Karolinska Hospital, Stockholm, Sweden*

Exercise may activate platelets and leukocytes and promote thrombosis. Effects of aspirin treatment on prothrombotic effects of exercise have not been established.

Methods: 15 healthy males performed exhaustive exercise (bicycle ergometry) without and with one week's pre-treatment with aspirin (500 mg/day). Before and immediately after exercise, platelet aggregability ex vivo was measured by filtragometry and venous blood samples were obtained. Whole blood flow cytometry was used to determine platelet and leukocyte activation and platelet-leukocyte aggregates.

Results: Exercise increased platelet P-selectin expression, and enhanced the expression of CD11b in neutrophils and lymphocytes. Exercise also enhanced platelet and leukocyte activation elicited by thrombin, ADP, PAF, and fMLP in vitro. Consistent with enhanced platelet and leukocyte activation, their interaction was also enhanced, as flow cytometry detected more circulating platelet-platelet and platelet-leukocyte aggregates after exercise ($P < 0.001$ for both). Filtragometry readings were shortened, and the plasma levels of soluble P-selectin, von Willebrand factor, and F1+2 were elevated. Aspirin treatment reduced the urinary excretion of 11-dehydro-thromboxane B2 markedly, decreased P-selectin expression in single platelets at rest ($P < 0.05$), and inhibited fMLP-induced neutrophil CD11b expression. However, aspirin did not influence exercise-induced increases in platelet aggregability, platelet P-selectin expression, leukocyte CD11b expression, or platelet-leukocyte aggregate formation. Furthermore, aspirin failed to counteract exercise-induced elevations of soluble P-selectin, von Willebrand factor, and F1+2.

Conclusions: Exercise induces platelet and leukocyte activation and platelet-leukocyte aggregation in vivo, and increases their responsiveness to in vitro stimulation. Aspirin treatment attenuated certain signs of platelet activity in vivo at rest and fMLP-induced neutrophil activation in vitro, but did not attenuated the prothrombotic effects of exercise.

P1119 Enhanced antiplatelet effects of clopidogrel versus aspirin in patients following myocardial infarction

K. Moshfegh, M. Redondo[1], F. Julmy[2], W.A. Wuillemin[1], B. Lämmle[1], B.J. Meyer[2]. *Division of Cardiology, University Hospital Bern, Bern; [1]Division of Hematology, University Hospital, Bern[2]Division of Cardiology, University Hospital, Bern, Switzerland*

To compare the importance of thromboxane A2 (TxA2)- versus adenosine diphosphate (ADP) pathway of platelet inhibition we determined the relative antithrombotic effects of clopidogrel (C), a selective ADP pathway inhibitor, and aspirin (A), a TxA2 pathway inhibitor, alone and in combination.

Methods: Nineteen patients who survived a myocardial infarction were consecutively given 7-days treatments with 100 mg A, 75 mg C combined with 100 mg A, and 75 mg C alone after a washout period. We measured the antithrombotic effects of clopidogrel and/or aspirin on platelet aggregation and platelet P-selectin expression following stimulation with various agonists using light transmission aggregometer and flow cytometry, respectively.

Results:

Platelet activation (P-Selectin)	ADP (10 μM) (%)	Thrombin (0.1 U/l) (%)
A 100	20.1 ± 1.9	54.8 ± 3.2
C 75	7.1 ± 0.7 *	39.9 ± 3.6 *
A 100 + C 75	6.8 ± 0.9 *	36.4 ± 4.9 *
Platelet aggregation	ADP (6 μM) (%)	Collagen (4 μg/ml) (%)
A 100	44.4 ± 3.9	35.7 ± 6.0
C 75	17.6 ± 3.4 *	53.4 ± 7.4
A 100 + C 75	21.9 ± 3.3 *	13.1 ± 2.3 *#

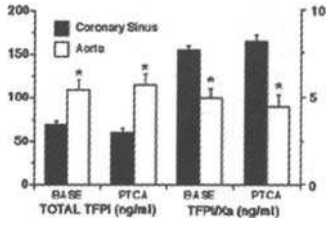
Wilcoxon signed rank: $p < 0.05$; *A vs C or A+C, #C vs A+C

Conclusion: Clopidogrel compared to aspirin produces a reduction of platelet activation except for collagen where the combination of clopidogrel and aspirin is more effective than the monotherapies suggesting additive antiplatelet effects. Ongoing clinical trials are further exploring the benefits of these combined antiplatelet therapies.

P1120 Plasma levels of tissue factor pathway inhibitor are decreased in the coronary sinus of patients with acute myocardial infarction

A. Ravera, P. Golino, F. Piscione, D. D'Andrea, P. Cirillo, M. Ragni, M. Ezban[1], M. Chiariello. *Division of Cardiology, University of Naples Federico II, Naples, Italy; [1]Novo Nordisk, Copenhagen, Denmark*

Tissue Factor Pathway Inhibitor (TFPI) is a naturally-occurring inhibitor of the extrinsic coagulation pathway. We have shown that TFPI plasma levels decrease during thrombus formation in a rabbit model of carotid artery stenosis and endothelial injury. To determine whether a similar decrease in plasma TFPI also occurs in patients with acute myocardial infarction (MI), 10 patients undergoing primary PTCA for an acute MI were included in the study. Blood samples were obtained from the coronary sinus (CS) and the ascending aorta at baseline and after balloon dilation, placed in chilled test tubes containing sodium citrate, immediately centrifuged, and stored at −70°C. Total TFPI plasma levels, as well as the complex TFPI/factor Xa, an index of factor Xa generation, were measured using ELISA kits commercially available (American Diagnostica). At baseline, all patients had a complete occlusion of either the LAD (n = 6) or the CX (n = 4) coronary artery (TIMI flow 0), and showed antegrade TIMI flow 3 after PTCA. A significant decrease in total TFPI plasma levels was observed in the CS as compared to those measured in the aorta, both at baseline and after PTCA (figure; $p < 0.05$ vs CS). In contrast, plasma TFPI/Xa levels were significantly higher in the CS than in the aorta, indicating active generation of factor Xa at the site of thrombus formation (figure).



We conclude that: 1) In patients with acute MI an increased generation of factor Xa occurs, presumably via activation of tissue factor-dependent coagulation cascade; 2) Plasma TFPI levels are decreased across the coronary circulation, indicating consumption of TFPI at the site of thrombus formation; 3) TFPI plays an important pathophysiological role as a modulator of tissue factor-dependent coagulation in patients with MI.

P1121 Regulation of ADP- or thrombin-induced platelet aggregation via AT_1 receptors

O. Sommer, B. Fink, E. Bassenge. *Institute of Applied Physiology, Albert-Ludwigs University, Freiburg, Germany*

Background: The AT_1 receptor present in heart, liver, kidney, brain, platelet and in most of vascular tissues, is a highly potent regulator of blood pressure. AT_1 receptors trigger the activation of phospholipase A_2, a key enzyme in prostanoid formation.

Methods: We investigated the AT_1 receptor inhibition (losartan) of ADP or thrombin-induced platelet aggregation and intracellular Ca^{2+} in washed platelets or in platelet rich plasma of dogs and human volunteers. Calcium was measured with FURA-1 and platelet aggregation by PACKS4 (from Helena Diagnostika Instruments).

Results: AT_1 receptor inhibition decreases ADP or thrombin induced aggregation in a dose dependent manner as shown in the table (Δ% values are mean ± SEM, n = 5, all are significantly different from control, $p < 0.05$).

Losartan (M)	10^{-6}	10^{-5}	10^{-4}
Thrombin (0.1 U/ml)	−20 ± 5	−48 ± 10	−80 ± 5
ADP (3 μM)	−37 ± 5	−54 ± 13	−70 ± 9

AT_1 receptor inhibition abolishes thrombin (0.1 U/ml) induced intracellular calcium concentration (basal: 96 ± 6 nM, thrombin: 702 ± 23 nM) at a comparable magnitude as shown for the platelet aggregation.

Conclusions: AT_1 receptor inhibition decreases intracellular free calcium, impairs thereby (e.g. inflammatory) prostanoid formation and aggregation and finally reduces the risk for enhanced thrombosis.

P1122 Renin-angiotensin system and its pathophysiological role in human monocytes and macrophages

Kenji Nagata, Toshiyuki Ishibashi, Kazuhiko Nakazato, Yoshitane Seino, Keiko Yokoyama, Yukio Maruyama. *First Department of Internal Medicine, Fukushima Medical University, Fukushima, Japan*

Increased expression of angiotensin-converting enzyme (ACE) by macrophages has been shown in human coronary atherosclerotic lesions, suggesting the presence of renin-angiotensin system (RAS) in macrophages. In the present study, we investigated the expression and regulation of angiotensin II type 1 receptor (AT1), type 2 receptor (AT2) and ACE in human monocytes and macrophages, and attempted to elucidate its pathophysiological role.

Methods: Human monocytes were obtained from peripheral blood of healthy volunteers by gradient centrifugation and adherent method. Monocyte-derived-macrophages were prepared by culture of 7 days. The levels of mRNA for AT1, AT2, ACE, tissue factor (TF) and plasminogen activator inhibitor-1 (PAI-1) were assessed by transcriptase polymerase chain reaction. The levels of TF and PAI-1 in culture medium were measured by ELISA.

Results: Human monocytes expressed AT1, AT2, and ACE mRNAs. The levels of mRNA for AT1 and AT2 decreased in macrophages compared with monocytes, whereas macrophages expressed increased levels of ACE mRNA. Monocyte chemoattractant protein-1 or oxidized LDL decreased the AT1 and AT2 mRNA levels and increased the ACE mRNA levels in monocytes after 18 hours of culture. To determine the pathophysiological role of RAS in these cells, an ACE inhibitor (captopril, CPT) was added to cultured monocytes. CPT (10^{-9} ~ $^{-8}$ M) decreased significantly the protein levels in the medium of TF and PAI-1 by 51% (n = 4, $P < 0.05$) and 17% (n = 7, $P < 0.05$) after 3 days of culture. Similar reductions by CPT (TF; 34%, n = 6, $P < 0.05$, PAI-1; 17%, n = 8, $P < 0.01$) were observed after 7 days of culture. In addition, CPT reduced the levels of mRNA for TF and PAI-1 after 1 day of culture.

In conclusion, our results suggest that RAS of monocytes and macrophages may play a role in atherogenesis and procoagulant state of plaques in acute coronary syndromes.

P1123 Local delivery of a new bispecific antibody to improve retention of glycoprotein IIb/IIIa receptor antagonist at the angioplasty site

K. Hogrefe, R.S. Foo, D. de Bono, A.H. Gershlick. *Department of Cardiology, Glenfield General Hospital, Leicester, UK*

Targeting of an anti-GPIIb/IIIa antibody to the angioplasty site might improve its local concentration and retention following local delivery, which may optimise its effects on platelets and SMCs without significant systemic side-effects. In this experiment we used an anti-tissue factor antibody as the targeting agent. Tissue factor is a membrane-bound polypeptide normally not exposed to the blood stream, but is expressed after balloon injury at the angioplasty site.

Methods: A new bispecific F(ab')2 was contructed combining the antigen binding sites of two murine anti-rabbit IgGs, which are specific to the platelet GPIIb/IIIa receptor and tissue factor, respectively. Segments of rabbit aorta were removed and balloon dilatation with an angioplasty balloon (8 atm for 60 s, three times) performed. The segments were then mounted in a perfusion circuit (0.9% Saline, 37°C, flow-rate 20 ml/min). Radio-labelled bispecific F(ab')2 or anti-GPIIb/IIIa antibody as a control was delivered through a microporous infusion catheter (Cordis Corporation, US). The radioactivity of the segments was measured in a gamma-counter after 1 ml Saline flushing and at pre-set time intervals. To compare the relative radioactivity the initial gamma-counter result of each segment was defined as 100% and subsequent counts converted.

Results: The overall delivery efficiency was low for both groups (<2%), but the retention of the bispecific F(ab')2 was significantly greater than that of the anti-GPIIb/IIIa IgG (see table).

Time interval	Bispecific Ab	Anti-GPIIb/IIIa Ab	p value (t-test)
2 hours	28.2	16.2	0.03
3 hours	23.6	14.3	0.02
12 hours	21.8	10.6	0.05

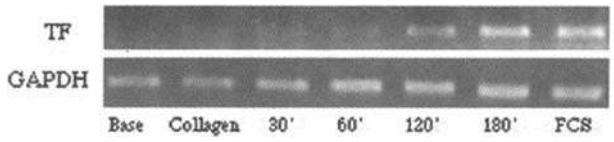
Percentage of retention at the damaged vessel wall after local delivery (N = 8)

Conclusion: These results support the concept of targeting damaged vessel wall to increase local retention of GPIIb/IIIa antagonists at the angioplasty site.

P1124 Tissue factor mRNA is up-regulated in rabbit smooth muscle cells stimulated with activated platelets

M. Ragni, P. Golino, P. Cirillo, A. Scognamiglio, F. Botticella, F. Pacifico[1], S. Formisano[1], M. Chiariello. *Division of Cardiology, University of Naples Federico II, Naples; [1]Cell. and Mol. Biology and Pathology, University of Naples Federico II, Naples, Italy*

Tissue Factor (TF)-induced activation of the coagulation plays a key role in acute coronary thrombosis. We have recently demonstrated an increase in TF expression in the media of rabbit carotid arteries with recurrent thrombosis. To determine the role of platelet-derived mediators in this phenomenon, cultured rabbit smooth muscle cells (SMCs) were stimulated with activated platelets and specific TF mRNA expression was measured by RT PCR. Rabbit SMCs from thoracic aorta were grown in DMEM + 10% fetal calf serum (FCS) and made quiescent by FCS withdrawal. Human platelet rich plasma (300,000/μl) was placed into transwell cylinders, at the bottom of which a microporous membrane allowed only the passage of platelet-derived mediators. Transwells were placed into SMCs culture wells and platelets were stimulated with collagen. Activated platelets were removed after 30 min and SMCs were processed for total RNA isolation at baseline (no stimulation), and after 30, 60, 120, and 180 min following stimulation. Two μg of total RNA was retrotrascribed and specific TF mRNA was amplified by PCR. Housekeeping GAPDH mRNA was also simultaneously amplified as internal control. PCR products were run on 1% ethidium bromide-agarose gel. A progressive increase in TF mRNA, peaking at 180 min, was evident in SMCs stimulated with activated platelets with respect to baseline (figure).



Positive control included SMCs stimulated with FCS. Collagen per se had no effects on SMCs TF mRNA levels, whereas no differences were seen in GAPDH mRNA levels among various time points. In conclusion, activated platelets induce TF mRNA expression in cultured SMCs; in vivo, this platelet-induced up-regulation of TF may be responsible for sustaining thrombus formation following the initial thrombogenic stimulus.

STROKE DIAGNOSIS, THERAPY AND CONSEQUENCES

P1125 Morphological evaluation of plaques of the aortic arch in patients with acute ischaemic stroke. the diagnostic impact of transoesophageal echocardiography

C.M. Schannwell, F.C. Schoebel, R. Marx, G. Plehn, M. Schmitz, S. Heggen, L. Schmitz, Ch. Perings, M. Leschke, B.E. Strauer. *Clinic of Cardiology, Heinrich Heine University, Düsseldorf, Germany*

Background: The presence of large atherosclerotic plaques in the aortic arch has been shown to be an independent risk factor for ischemic stroke (IS). The importance of the plaque morphology as an independent risk factor for ischemic strokes has not been evaluated yet.

Methods: We performed transesophageal echocardiography in 62 patients (P) with acute ischemic stroke (age: >60 years) and in 62 age and sex matched subjects (C). The following plaque classification was used: small (thickness of 2–3 mm); large and uncomplicated (thickness > 4 mm; no detection of plaque ulceration and mobility) and large and complex (detection of plaque ulceration and mobility).

Results: Plaques could be proved in 69% (n = 43) of the patient group (P) and 27% of the control group ($p < 0.001$). Complex plaques were more common in the patient group than in the control group (32.4% versus 2.6%; $p < 0.001$). Furthermore there was a higher frequency of uncomplicated plaques in the patient group compared to the control group (23.7% vs 12.3%). Referring to small plaques no significant differences could be detected. Multiple logistic regression analysis showed that complex plaque morphology is the strongest independent risk factor of acute ischemic stroke (odds ratio: 16.8). Large and uncomplicated plaques represent a mild elevated risk (odds ratio: 2.4). No risk elevation could be shown for small plaques in both groups. All complex plaques were larger than 4 mm in diameter. Furthermore 65% of the large plaques showed complex morphology.

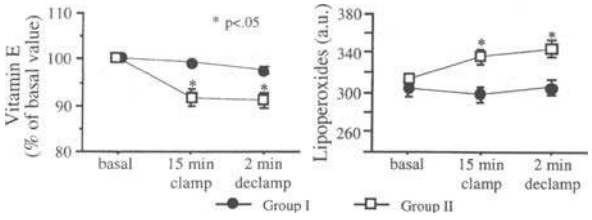
Conclusion: Transesophageal echocardiography offers the opportunity of morphological evaluation of atherosclerotic plaques within the aortic arch. Complex morphology seems to be a stronger risk factor for ischemic stroke than thickness. Diagnostic importance has been shown by multiple logistic regression analysis proving complex plaque morphology as the strongest independent risk factor of acute cerebral ischemia.

P1126 Antioxidant effect of oral dipyridamole during cerebral ischaemia associated with human carotid endarterectomy

C. Petersen, C. Kusmic, C. Busceti, G. Parenti, F. Laghi Pasini[1], R. Barsacchi[2], E. Picano. *Insitute of Clinical Physiology, CNR, Pisa; [1]Department of Physiology and Biochemestry, Pisa University; [2]Internal Medicine Department, Siena, Italy University*

Acute cerebral hypoperfusion/reperfusion may pose an oxidative stress on human brain, detectable through a decrease in antioxidant physiologic systems (such as vitamin E) and an increase of oxyradical species (such as lipoperoxides). Dipyridamole has antioxidant properties of uncertain clinical relevance.

In order to clarify an antioxidant effect of dipyridamole in vivo in a model of controlled cerebral hypoperfusion, 21 patients (65 ± 10 years, 11 males) undergoing carotid endarterectomy were allocated in 2 groups (group I = 10 with dipyridamole 200 mg p.o. 3–4 h before surgery, group II = 11 with placebo) in a double-blind placebo controlled randomized design. Plasma vitamin E and – in a subset of 12 patients – lipoperoxides were assayed from ipsilateral jugular bulb before, at 15′ of clamp and 2′ after declamp. Dipyridamole treated (Group I) patients showed lower increases in lipoperoxides and less depletion of vitamin E plasma concentration versus untreated (Group II) patients.



In conclusion, cerebral oxidative stress associated with human carotid thromboendarterectomy can be attenuated by pre-treatment with oral dipyridamole.

P1127 Influence of acute brain infarction on sympathovagal balance

D.C. Karatza, A.G. Manolis, C.K. Arvaniti, A.T. Anastassopoulou, P.A. Chaikos, G.K. Kazamias, R. Divari, A. Papadimitriou, N.E. Louvros. *Department of Cardiology and Neurology, Hellenic Red Cross Hospital, Athens, Greece*

Cardiovascular and cerebral functions are strongly related (Neurocardiology). Cerebrovascular diseases frequently cause a cardiovascular autonomic dysregulation. Aim of the study was to evaluate prospectively the sympathovagal balance during the acute phase of brain infarction in relation to infarct localization.

Methods: In the present study we evaluated the autonomic nervous system activity, using heart rate variability (HRV) indices, in time domain analysis, during 24 hour Holter recordings (Marquette 8000 V. 5.8) in 22 consecutive pts (12 M, 10 F, mean age 65 ± 8.5 year) with hemispheric brain infarction. 15 age and sex matched healthy subjects (HS), constituted the control group. 10 pts had right sided (RS) and 12 pts had left sided (LS) lesions. The HRV indices studied were: mean NN, SDNN, r-MSSD and pNN50. Pts with a history of symptoms suggesting cardiac or vascular disease or with a history of neurological disease, diabetes or other endocrinological disorders, as well as those with cardiac arrhythmias, were excluded from the study. The above referenced indices were evaluated during the first 24 hours from symptoms' onset. All pts underwent CT-scan during their hospitalization. The non-parametric anova Kruskal-Wallis and Scheffe test, were used for the statistical analysis.

Results:

n	Mean NN (ms)	SDNN (ms)	r-MSSD (ms)	pNN50 (%)
RS (n = 10)	686.2 ± 88.6	47.14 ± 3.89	16.14 ± 4.56	8.3 ± 4.2
LS (n = 12)	1009 ± 130	135 ± 18.24	42.7 ± 6.44	13.45 ± 7.95
HS (n = 15)	890 ± 100	152 ± 10.4	49.5 ± 2.25	21.7 ± 4.36

RS group is highly statistically significant at a = 0.01 compared to the LS and HS groups (all p-values were equal to 0.000 < 0.01). The difference of the means between LS and HS group is weakly statistically significant at a = 0.1.

Conclusions: These findings indicate that there is an autonomic dysregulation after ischemic infarction of either cerebral hemisphere. However, right sided lesions cause a greater parasympathetic hyponfunction compared to the left-sided lesions. A possible explanation is that brain lesion itself, damages structures regulating neurohumoral functions.

P1128 Hypo-osmolar, but not hyper-osmolar fluid intake reduces the risk of stroke: findings from the Adventist Health Study

S. Knutsen, J. Chan. *Epidemiology & Biostatistics Dept, Loma Linda University SPH, Loma Linda CA, USA*

Objective: To investigate the effect of fluid intake on the risk of stroke.

Methods: In 1976, a total of 34,198 white, non-hispanic California Seventh-day Adventists were enrolled in a cohort study and followed for 6 years. Information on diet, water and other fluid intake was assessed at baseline. The risk of fatal stroke was analyzed according to fluid intake in persons with prevalent CHD, stroke or diabetes using Cox Proportional Hazards Model.

Results: A total of 3,809 reported having CHD, stroke or diabetes at baseline and among them, 184 persons died of stroke during follow-up. After adjusting for age, sex, hypertension, smoking, BMI and education, the risk of fatal stroke showed an inverse dose-response relationship to reported daily intake of water and hypo-osmolar fluids (see Table 1). No association was found with intake of hyper-osmolar fluids.

Table 1

Water		Hypo-osmolar		Hyper-osmolar	
Intake*	RR (95% CI)	Intake*	RR (95% CI)	Intake*	RR (95% CI)
<2	1.00	<2	1.00	<2	1.00
3–4	0.67 (0.42–1.08)	2–5.5	0.59 (0.32–1.10)	2–4	1.31 (0.82–2.09)
5+	0.47 (0.30–0.76)	5.5+	0.42 (0.22–0.76)	4+	1.24 (0.71–2.16)
	p (trend) = 0.002		p (trend) = 0.005		p (trend) = 0.41

*Glasses/day

Conclusion: Our data suggest that good hydration may be important in preventing stroke among those who already have signs of CVD or diabetes. Water and hypo-osmolar fluids, but not hyper-osmolar fluids, are associated with decreased risk. Further studies are needed to investigate the effect of intake of different fluids on risk of incident stroke.

P1129 Retrograde and rotational flow in the thoracic aorta in patients with systemic emboli: a transoesophageal echocardiographic evaluation of mobile plaque motion

A. Tenenbaum, M. Motro, M.S. Feinberg[1], E. Schwammenthal[1], Z. Vered[1], E.Z. Fisman. *Cardiac Rehabilitation Institute; [1]Heart Institute, Chaim Sheba Medical Center, Tel-Hashomer, Israel*

Blood flow in the thoracic aorta is complex and incompletely characterized. Mobile aortic plaques (MAP), moving freely back and forth with the pulsatile aortic flow, in fact represent natural tracers which reflect the flow pattern itself. The purpose of the present study was to use MAP motion on transesophageal echocardiography (TEE) to characterize flow patterns in the atheromatotic thoracic aorta of elderly patients with stroke and systemic emboli.

Methods. The study group was recruited from 211 patients referred for TEE to evaluate recent embolism. Among them, 17 patients (11 men, 6 women; mean age 66.8 ± 7.7 years; 12 with cerebrovascular and 5 with peripheral emboli) with MAP of ≥3 mm length formed the study group. The longest amplitudes of three spatial components of mobile lesion motions were measured: x (*antegrade/retrograde, A/R*), y (*up/down, U/D*) and z (*right/left, R/L*).

Results. A total of 27 mobile lesions were detected: 3 (one patient) in the ascending aorta, 11 (8 patients) in the arch and 13 (8 patients) in the descending aorta. The length of mobile plaque components ranged from 3 to 13 mm; amplitudes of A/R, U/D, R/L and retrograde flow (RF) motions ranged (respectively) from 3 to 26 mm, from 1 to 16 mm, from 1 to 17 mm, and from 1 to 13 mm. Rotational components in MAP motions were detected in all patients. Systolic rotation was clockwise in 5 (29.4%) of them, counterclockwise in 4 (23.5%), incomplete (semicircle) in 5 (29.4%) and alternate clockwise/counterclockwise in 3 (17.6%). Diastolic rotation was clockwise in 3 (17.6%), counterclockwise in 6 (35.3%) and incomplete (semicircle) in 8 (47.1%) patients. In addition, periodically chaotic irregular multidirectional MAP motions were registered in all patients. There were 16 multiple MAP in 6 patients: in all these cases simultaneous rotations of MAP in different directions (highly suggestive for the presence of multiple vortices) were found.

Conclusions. Retrograde and rotational blood flow in the thoracic aorta exist in all patients with systemic emboli and mobile protruding aortic atheromas. Therefore, retrograde cerebral embolism from distal aortic plaques is theoretically possible. It may have significant implications in the study of pathogenesis of embolic events.

P1130 Transcatheter closure of 100 patent foramina ovalia in patients with unexplained stroke and suspected paradoxical embolism: a comparison of five different devices

P. Keppeler, S. Rux, J. Dirks, D. Krüger, U. Krumsdorf, H. Sievert, R. Schräder. *Herzkatheterlabor, Cardiovascular Center Bethanien, Frankfurt am Main, Germany*

Background: Interventional closure of patent foramen ovale (PFO) has been proposed to prevent recurrence of presumed paradoxical embolism in patients with unexplained stroke. Over the past years, several devices for transcatheter PFO-occlusion have been developed.

Patients: Between 08/94 and 01/99 transcatheter closure was attempted in 100 patients aged 17–77 years (mean ± SD: 46 ± 14). The PFOs were suspected to have caused between one and four paradoxical embolic events. In all cases, right-to-left-shunt through the PFO was proven by transoesophageal contrast echocardiography and other embolic sources were excluded. The PFO-size measured by balloon-passage ranged from 6–24 mm (12 ± 3).

Results: PFO-closure was successfully performed in 23/26 patients with SIDERIS-Buttoned-Devices, in 11/11 patients with the ASDOS-double-umbrella, in 20/20 patients with ANGEL-WINGS-device, in 20/20 patients with the Cardio-Seal-occluder and in 23/23 with the PFO-star. The primary overall success rate was 97%.

During follow-up one SIDERIS-Device was surgically explanted because of partial unbuttoning and two patients with an incomplete defect-closure suffered recurrent embolism. Asymptomatic Arm-fractures occurred in 10 cases (at least one per device), thrombus-formation was diagnosed after implantation of one ASDOS-, two ANGEL-WINGS- and one Cardio-Seal-system.

During 172 patient-years only two patients, treated with the SIDERIS-Buttoned-Device, suffered a recurrent embolic event. After use of the ANGEL-WINGS-, Cardio-Seal- and PFO-star-system no severe complications were observed.

Conclusion: All systems are suitable for transcatheter PFO-occlusion. In comparison to the older devices the ANGEL-WINGS-, the Cardio-Seal- and the PFO-star-system seem to be more stable and reliable in preventing recurrent embolism.

P1131 Takayasu's arteritis as risk factor for early development of vascular atherosclerosis

A. Sugraliev, G. Arabidze, Ye. Nassonov, G. Domba. *Kazak Postgraduate Institute of Medical Training, Almaty, Kazakhstan; Cardiology Research Center, Moscow, Russian Federation*

Lipid metabolism disturbances have been described in some inflammatory diseases. In patients with acute infections hypertriglyceridemia has been found but in chronical inflammations lipid abnormalities remain poorly known.

This study is based on an analysis of data obtained during long-term observation on 38 patients (pts) with Takayasu's Arteritis (TA) (37 female, 1 male; mean age 36 + 4.5 years).

The duration of the disease from the moment of establishing diagnosis of TA is from 1 to 25 years. A diagnosis of TA was established by the Criteria of the American College of Rheumatology 1990 and confirmed by angiography.

28 (74%) pts of TA have arterial hypertension (AH). 7 pts received glucocorticoid therapy in their anamnesis but not at the period of this examination, 7 pts have received b-blokers, 1 pt has hypothyroidism, 2 pts have diabetics.

Increasing of levels of total cholesterol (Tchol) in the range of 5.2–6.4 mmol/l was discovered in 18 (47%) pts; >6.5 mmol/l in 9 (23%); only 11 (30%) of TA had normal levels of Tchol. Increasing of levels of triglycerids >2 mmol/l is observed only in 2 pts. It is important to note, that we didn't observe any lipid abnormality in patients at the initial stage of TA. However, increasing levels of Tchol were discovered in pts with long duration of disease (>10 years) of TA with high activity of inflammation processes (ESR > 25 mm per hour) in long time period.

In conclusion, the findings suggest that lipid abnormalities in TA with vascular inflammation may lead to an early development of atherosclerotic processes of main vessels.

P1132 Regulation of angiotensin II AT2 receptor gene expression after stroke in rats

Y.Z. Zhu. *Pharmacology Dept, National University of Singapore, Singapore, Singapore*

Regulation of angiotensin II AT2 receptor gene expression after stroke in rats.

Previously, we reported that both AT1 and AT2 receptor gene expression was transiently increased after myocardial infarction (MI). The increased angiotensin II (ANG II) receptor gene expression suggests that ANG II is involved in the process of cardiac remodeling after MI. It is still far being understood whether or not ANG II could contribute any beneficial effects after stroke. Therefore, it would be useful to know how ANG II receptor gene expression is regulated in stroke. We used a rat model of occlusion of the middle cerebral artery (MCA) in male Wistar rats. The MCA was occluded by electro-cauterization and the artery was then cut to complete the permanent occlusion. Rats (n = 5) were sacrificed 1 day and 3 days after surgery. Total RNA from infarct and non-infarct cortex of the brain was extracted and reverse transcribed. cDNA was amplified by the polymerase chain reaction (PCR) with specific primers of angiotensin-converting enzyme (ACE), AT1 and AT2 receptor. PCR products were analyzed and quantified by the Vilber Lourmat Imaging system. Both ACE and AT1 receptor gene expression was very weakly expressed and there was no significant difference between infarct and non-infarct cortex. Interestingly, AT2 receptor gene expression was increased in the infarct cortex 2.65-fold (1 day) and 1.72-fold (3 days) after stroke, respectively. Our results demonstrated that the up-regulation of AT2 receptor may serve as an enhancer of the tissue repairing after stroke.

MYOCARDIAL FUNCTION AND HEART FAILURE

P1133 Does high-density lipoprotein act as an endotoxin-binding protein with a potential regulatory impact for immune activation in chronic heart failure?

M. Rauchhaus, V. Koloczek, M. Kemp, K. Werdan[1], P.A. Poole-Wilson, A.J.S. Coats, S.D. Anker. *Cardiac Medicine Dept., National Heart & Lung Institute, London, UK; [1]Klinik Innere Medizin III/Kardiologie, Martin Luther Universität, Halle, Germany*

Background: Tumor necrosis factor-alpha (TNF-alpha) and other cytokines are elevated in severe chronic heart failure (CHF). It has been reported in animal experiments that blood lipids, such as high-density lipoprotein (HDL), have the ability to act as endotoxin (LPS) binding proteins, thereby influencing the LPS-mediated release of TNF-alpha and other cytokines. Recently, we have shown that concentrations of LPS are elevated in decompensated CHF patients.

Methods and Results: We studied 26 patients with CHF (age 67 ± 2 y, NYHA 2.9 ± 0.2, LVEF 32 ± 4%, all mean ± SEM) and 7 healthy control subjects (age 71 ± 2 y). Venous blood samples were taken to analyse plasma concentrations of LPS (LAL test) and total TNF-alpha (high sensitivity Quantikine kit, R&D Systems). Additionally, we measured serum LDL and HDL levels as well as liver function (ASAT, total protein and albumin) and kidney function (creatinine, urea, all routine hospital techniques). In CHF patients, concentrations of LPS and TNF-alpha were higher (0.47 ± 0.03 EU/ml and 6.0 ± 0.7 pg/mL, respectively) than in healthy volunteers (0.33 ± 0.03 EU/ml, $p < 0.05$ and 3.4 ± 0.5 pg/ml, $p = 0.07$, respectively), whereas HDL and LDL levels were lower ($p = 0.008$ and $p = 0.06$). LPS correlated positively with TNF-alpha ($r = 0.71$, $p < 0.0001$) and inversely with HDL ($r = -0.54$, $p = 0.006$). The degree of immune activation (TNF-alpha) was inversely related to levels of HDL ($r = -0.37$, $p = 0.046$). CHF patients with the most abnormal LPS values (mean of controls + 2 SD) had the lowest HDL levels (1.3 ± 0.1 vs 1.6 ± 0.1 mmol/l, $p = 0.04$). These relationships were all independent of liver and kidney function parameters.

Conclusion: Our data suggest that in CHF patients, high concentrations of LPS are related to decreased HDL levels and increased concentrations of TNF-alpha. This finding supports the hypothesis of an involvement of lipoproteins, particularly HDL, in the modulation of immune activation and subsequent cytokine release in CHF. Thus, HDL may have beneficial effects other than protecting against atherosclerotic lesions.

P1134 Congestive heart failure does not affect nuclear DNA content in human cardiac myocytes

C. Lagrasta, R. Maestri, D. Corradi, N. Bertani, G. Graiani, E. Cigola, F. Quaini, G. Olivetti. *Pathology Dept., University Medical School of Parma, Parma, Italy*

It has repeatedly been shown that DNA synthesis occurs in adult ventricular myocytes and quantitative studies have demonstrated an increased number of nuclei and mitotic figures in hypertrophied hearts in humans. However, since DNA ploidy and multinucleation are present in cardiac myocytes, whether activation of DNA synthetic machinery leads to cell proliferation or DNA accumulation in each nucleus remains to be determined. Thus, a DNA cytophotometric study was performed on enzymatically dissociated cardiac myocytes collected at autopsy from 9 individuals who died for causes different from cardiovascular diseases and from two groups of patients with congestive heart failure (CHF). The first group consisted of 5 females and 4 males with severe cardiac hypertrophy (54%, $p < 0.001$) and the second of 11 males affected by hypertrophic ischemic cardiomyopathy (39%, $p < 0.001$) with large infarcts documented by the presence of scarred tissue in the left ventricle and severe coronarosclerosis. The average age was similar among the three groups ranging from 37 to 88 years. The mean values of the different classes of ploidy were obtained for mononucleated and binucleated myocytes of the left (LV) and right ventricles (RV) and in the interventricular septum (IS). A minimum of 350 to a maximum of 600 myocytes in each sample were evaluated and the amount of DNA present in each nucleus determined with an image analyzer after Feulgen reaction. The system was calibrated with chicken erythrocytes collected and stained on each slide together with ventricular myocytes. Different fractions of nuclei with 2C, 4C, 6C, 8C and >8C DNA content were found in isolated cells from normal and pathologic hearts. Compared to controls, DNA content per nucleus did not change in mononucleated and binucleated myocytes of LV and IS of ischemic and hypertrophied hearts. In contrast, mono- and binucleated myocytes of RV in ischemic cardiomyopathies were characterized by a 2-fold increase in diploid class and a 50% decrease in the fractions of 8C and >8C. No statistical significant correlation was seen between the different classes of ploidy in myocytes of both ventricles and corresponding myocardial weights. The percent of mononucleated (76 ± 9%) and binucleated myocytes (24 ± 9%) did not vary among the three groups of hearts. In conclusion, since DNA content per nucleus did not increase in cardiac myocytes of LV and IS of the hypertrophied and ischemic failing human hearts, DNA synthesis has to be regarded as an index of cell cycle progression and myocyte proliferation.

P1135 Early detection of anthracycline-induced cardiotoxicity in asymptomatic patients with normal left ventricular systolic function: autonomic versus echocardiographic parameters

G. Tjeerdsma, M.T. Meinardi[1], D.J. van Veldhuisen. *Cardiology/Thoraxcenter, University Hospital, Groningen; [1]Internal Medicine Dept., University Hospital, Groningen, Netherlands*

Backgrounds: Anthracyclines are widely used in patients with breast cancer, but bear the risk of inducing left ventricular (LV) dysfunction. Although both diastolic and systolic dysfunction have been well recognised, there are indications that autonomic abnormalities precede these changes and thus are a more sensitive marker for monitoring cardiotoxicity. Heart rate variability (HRV) analysis is a reliable tool to assess autonomic tone.

Methods: Autonomic function was compared with LV diastolic function in twenty asymptomatic females with normal systolic function (left ventricular ejection fraction (LVEF) > 0.50), treated for breast cancer with high-dose anthracycline-based chemotherapy, and twenty age-matched healthy females. LV diastolic function was echocardiographically assessed by measuring early peak flow velocity/atrial peak flow velocity ratio, isovolumetric relaxation time and deceleration time. HRV analysis was assessed for time domain and frequency domain parameters.

Results: The mean (SD) age of the patients was 45 (7) years and the mean (SD) LVEF 0.59 (0.06). The mean (SD) time interval after the end of chemotherapy was 29 (27) months. One or more diastolic parameters were abnormal in 50% of the patients. HRV frequency parameters were abnormal in 85% of patients. Mean values of both time domain and frequency domain parameters were decreased ($p < 0.05$), in particular the parasympathetic indexes.

Conclusions: Autonomic impairment occurs in a large proportion of asymptomatic patients with normal systolic LV function after high-dose anthracycline-based chemotherapy. Especially HRV analysis may potentially be a sensitive tool to identify first signs of cardiotoxicity in these patients.

P1136 Soluble and surface-bound P-selectin reveal heightened platelet activity in patients with decompensated heart failure: is aspirin therapy enough?

P.A. Gurbel, C.M. O'Connor[1], W.A. Gattis[1], V.L. Serebruany. *Sinai Center for Thrombosis Research, Baltimore MD; [1]Duke Clinical Research Institute, Durham NC, USA*

Selectins may participate in the pathogenesis of congestive heart failure (CHF) by modulating platelet – leukocyte – endothelial interactions in the deteriorating myocardium. P-selectin is an important marker of platelet and endothelial activation and may be up-regulated in patients with CHF. However, no data are available on the simultaneous determination of plasma levels and platelet expression of P-selectin in patients with CHF. We sought to prospectively compare platelet and soluble P-selectin in patients with CHF and in healthy controls.

Methods: Matched soluble levels by ELISA, and platelet-bound expression by whole blood flow cytometry of P-selectin were determined in 34 patients with decompensated CHF and compared with fourteen healthy controls. Fifteen patients were aspirin-free and nineteen patients were using aspirin (81–500 mg/daily).

Results: Patients with CHF exhibited significantly elevated soluble P-selectin (189.5 ± 68.0 ng/ml, $p = 0.014$) and more than two-fold increased expression of platelet-bound P-selectin (9.31 ± 4.12% positive platelets, $p = 0.027$) compared to the P-selectin profile in controls (102.6 ± 29.0 ng/ml plasma, and 4.06 ± 1.21% positive platelets). Aspirin therapy did not affect the P-selectin profile in patients with CHF.

In conclusion, despite antecedent aspirin therapy and interindividual variability of the P-selectin profile, soluble and platelet P-selectin were elevated in the majority of patients with severe CHF, suggesting persistent platelet activation. The present data provide evidence that more potent adjunctive antiplatelet regimens deserve further study in the heart failure population.

P1137 Oxidative stress is less in non-ischaemic chronic heart failure

G.R. Ellis, R.A. Anderson, D.J. Blackman, J. Morris-Thurgood, S.K. Jackson, M.J. Lewis, M.P. Frenneaux. *Cardiovascular Sciences Research Group, Welsh Heart Research Institute, University of Wales College of Medicine, Cardiff, UK*

Increased oxidative stress may play an important role in the pathophysiology of chronic heart failure (CHF). Coronary artery disease (CAD) is also associated with increased oxidative stress. In this study, we compared oxidative stress assessed by plasma lipid-derived free radicals in patients with CHF due to underlying CAD versus patients with CHF due to dilated cardiomyopathy (DCM).

Methods: The study group consisted of 30 patients with NYHA class II–IV symptoms of CHF, LV ejection fractions < 35% on optimal medical therapy, 15 of whom had underlying CAD, and 10 age and gender matched healthy controls. The patients were matched for age and NYHA class. Lipid-derived free radicals from plasma samples were measured by electron paramagnetic resonance (EPR) spectroscopy using the spin trap α-phenyl tert-butylnitrone with peak spectral heights recorded in arbitrary units (u).

Results: (Data expressed as mean ± SD). The mean magnitude of EPR spectra obtained from the DCM group was significantly greater than controls (0.33 ± 0.18 u vs. 0.21 ± 0.03 u, $p < 0.05$). Plasma lipid-derived free radical levels were greater in the CHF patient group with underlying CAD than both the control group and those patients with DCM (0.54 ± 0.28 u vs. 0.21 ± 0.03 u, $p < 0.05$ and vs. 0.33 ± 0.18 u, $p < 0.05$ respectively).

Conclusion: This study has demonstrated that free radical levels in venous blood are elevated in CHF patients regardless of the underlying aetiology. We have also shown that CHF patients with underlying CAD have higher levels of oxidative stress than those with DCM confirming the pro-oxidant nature of atherosclerosis. Further studies are now needed to establish the main source of free radicals in CHF, the pathophysiological mechanisms underlying this process and the potential therapeutic role of antioxidants.

P1138 Lung water content and alveolar-capillary diffusion impairment in severe heart failure

G. Marenzi, P.G. Agostoni, M. Guazzi, M. Musmeci, G. Lauri, M. Grazi, E. Assanelli, F. Lavarra, M. Bussotti, G. Cattadori, M.D. Guazzi. *Institute of Cardiology, University of Milan, Centro Cardiologico "Monzino", IRCCS, Milan, Italy*

We investigated the relationship between lung water (LW) and alveolar-capillary diffusion for carbon monoxide (DLco) in severe HF. LW, lung volumes and DLco were evaluated in 15 normal subjects and in 28 patients with severe HF (NYHA III–IV), in the latters before and after fluid removal by extracorporeal ultrafiltration (UF, 3973 ± 2205 ml; weight reduction = 5.8 ± 3.7 kg). In particular, we measured vital capacity (VC), alveolar volume (Va), LW (single breath expiratory decay of CH4, C2H2 and CO), DLco and its two components: diffusing membrane resistance (Dm) and capillary volume content (Vc).

	Controls	Before UF	After UF
VC (L)	4.7 ± 1	$2.1 \pm 0.7^{*}$	$2.5 \pm 0.7^{*\#}$
Va (L)	6.3 ± 1.3	$4.1 \pm 1.6^{*}$	$4.6 \pm 1.4^{*\#}$
LW (ml)	420 ± 13	$640 \pm 180^{*}$	$550 \pm 170^{*\#}$
DLco (ml/min/mmHg)	29 ± 5	$17 \pm 4^{*}$	$17 \pm 5^{*}$
Dm (ml/min/mmHg)	47 ± 11	$23 \pm 7^{*}$	$25 \pm 8^{*}$
Vc (ml)	102 ± 20	100 ± 38	87 ± 39
DLco/Va	4.5 ± 1	4.3 ± 0.8	$3.8 \pm 1^{\#}$
Dm/Va	7.1 ± 3	$6.0 \pm 2^{*}$	6.8 ± 2

Data are mean ± SD. * = $p < 0.01$ vs. Controls; # = $p < 0.01$ vs. Before UF.

Conclusions. In severe HF: 1) LW increase is associated with reduction in lung volumes (VC, Va) and DLco (due to its component Dm); 2) DLco, but not Dm, is normal when related to Va. After UF, LW decrease is associated with lung volumes increase but with no change in DLco. Several hypothesis may account for this finding: a) LW removal is from the perivascular, peribronchial and alveolar spaces, rather than from the alveolar-capillary membrane; b) the tendency of Vc to reduce after UF counterbalances the effect of lung volume and Dm increases on DLco.

P1139 Clinical correlates of granulocyte-macrophage colony-stimulating factor in advanced heart failure

J. Parissis, S. Adamopoulos, K. Venetsanou, D. Mentzikof, M. Kalantzi, S. Karas, D. Kremastinos. *Amalia Fleming Hospital and Onassis Cardiac Surgery Center, Athens, Greece*

Background: It has been reported that cytokine activation is implicated in the pathophysiology of congestive heart failure (CHF). Granulocyte – macrophage colony – stimulating factor (GM-CSF) is an inflammatory mediator which stimulates a range of functional activities of monocytes, including regulation of monocyte adhesion and induction of cytokine production. We investigated whether serum GM-CSF is increased in advanced CHF, and we sought to determine the relationship between serum levels of GM-CSF and other clinical or neurohormonal parameters in CHF patients.

Methods: Serum GM-CSF and soluble intercellular adhesion molecule-1 (sICAM-1) were measured in 23 patients with advanced CHF (LVEF: 25 ± 4%; NYHA III: 13/23, NYHA IV: 10/23; Ischemic Heart Failure: 15/23, Dilated Cardiomyopathy: 8/23) and 15 healthy age-matched controls by Elisa assays. Furthermore, plasma norepinephrine was determined in study population by HPLC. Patients with infections, malignancies and other acute or chronic inflammatory diseases were excluded from our study.

Results: Serum levels of GM-CSF and sICAM-1 in CHF patients with ischemic heart failure did not differ significantly from those of CHF patients with dilated cardiomyopathy. CHF patients had significantly higher serum GM-CSF (25.8 ± 5.1 vs 2.1 ± 0.9 pg/ml, $p < 0.001$) and sICAM-1 (392.7 ± 34.3 vs 183.5 ± 13.1 ng/ml, $p < 0.001$) than healthy controls. Additionally, serum GM-CSF and sICAM-1 were more elevated in NYHA IV patients as compared with NYHA III patients (GM-CSF: 28.3 ± 3.9 vs 23.2 ± 3.1 pg/ml, $p < 0.05$; sICAM-1: 407.6 ± 21.7 vs 371 ± 17.1 ng/ml, $p < 0.01$). In the CHF group, GM-CSF levels were significantly correlated with sICAM-1 levels ($r = 0.72$, $p < 0.001$), plasma norepinephrine ($r = 0.52$, $p < 0.05$), right atrial pressure ($r = 0.45$, $p < 0.05$) and LVEF ($r = -0.48$, $p < 0.05$). Finally, no significant correlation was found between GM-CSF values and the age, sex or body mass index of CHF patients.

Conclusions: We have detected an increased serum activity of GM-CSF in patients with advanced CHF. This increase represents an abnormal stimulation of immune system and may be related with neurohormonal activation and haemodynamic deterioration which accompany the advanced CHF.

P1140 Regular cycle ergometer training improves endothelial function of the radial artery in patients with chronic heart failure

N. Schoene, R. Hambrecht, J. Hofer, S. Erbs, A. Wolf, G. Schuler. *Universität Leipzig, Herzzentrum, Klinik für Innere Medizin/Kardiologie, Leipzig, Germany*

In congestive heart failure (CHF) agonist-induced endothelium-dependent vasodilation is impaired. Local forearm training corrects endothelial dysfunction of the radial artery in these patients. The objective of this study was to investigate the effects of regular bicycle exercise on endothelial function of the upper extremity.

Nineteen male patients with stable CHF were prospectively randomized to a training group (T) ($n = 9$) or an inactive control group (C) ($n = 10$). At baseline (B) and after 4 weeks (4 wks) the internal diameter (ID) [mm] of the radial artery was measured using a high-resolution ultra-sound system (NIUS-02) with a 10 MHz probe. For assessment of endothelium-dependent and -independent vasodilation acetylcholine (ACH) (7.5; 15; 30 μg/min) and nitroglycerin (NITRO) (0.2 mg/min) were infused into the brachial artery. Flow-dependent vasodilation was determined after 5 minutes of upper arm occlusion (RH).

After 4 weeks of regular bicycle exercise there was a significant increase in endothelium-dependent vasodilation (ΔID 0.23 ± 0.07 at B vs. ΔID 0.43 ± 0.06 after 4 wks, $p < 0.05$ vs. B and C) (ACH 30 μg/min) as well as in flow-dependent vasodilation (ΔID 0.38 ± 0.06 at B vs. ΔID 0.57 ± 0.08 after 4 wks, $p < 0.05$ vs. B and C). Patients in the control group showed no significant change in respone to acetylcholine (ΔID 0.18 ± 0.07 at B vs. ΔID 0.16 ± 0.07 after 4 wks) (ACH 30 μg/min) or upper arm occlusion (ΔID 0.33 ± 0.03 at B vs. ΔID 0.35 ± 0.05 after 4 wks). There was no difference in the response to nitroglycerin in both groups at B and after 4 wks.

Conclusions: Regular cycle ergometer training improves endothelial function of the upper extremity in patients with stable CHF, possibly by enhanced endothelial release of nitric oxide (NO) and/or reduced degradation of NO due to intermittent increases in shear stress.

P1141 Increased soluble platelet/endothelial cellular adhesion molecule-1 and osteonectin levels in patients with severe congestive heart failure

V.L. Serebruany, S.R. Murugesan, D. Atar[1], C.M. O'Connor[2], W.A. Gattis[2], P.A. Gurbel. *Sinai Center for Thrombosis Research, Baltimore MD, USA; [1]Div. of Cardiology, Zurich University Hospital, Zurich, Switzerland[2] Duke Clinical Research Institute, Durham NC, USA*

Platelet-endothelial interactions modulated by adhesion molecules, may play an important role in the pathogenesis of congestive heart failure (CHF). Soluble levels of these molecules and platelet-derived substances are reportedly elevated in patients with CHF. However, no data are available on the plasma levels of Platelet/Endothelial Cell Adhesion Molecule-1 (PECAM-1), and platelet-derived osteonectin in this growing population.

Methods: Soluble levels by ELISA were prospectively determined in patients with severe CHF ($n = 37$) and correlated to etiology and antecedent aspirin use, and compared with fourteen healthy controls. Left ventricular dysfunction was attributed to idiopathic dilated cardiomyopathy in 18 and coronary artery disease in 19 patients. Twenty-one patients were aspirin-free and sixteen patients were using aspirin (81–500 mg/daily).

Results: Elevated soluble PECAM-1 (51.31 ± 2.44 ng/ml, $p = 0.0001$), and osteonectin (826.27 ± 22.37 ng/ml, $p = 0.0001$) were observed in patients with CHF, as compared to healthy controls (32.56 ± 1.21 ng/ml, and 478.02 ± 31.32 ng/ml, respectively). Neither etiology of CHF, or antecedent aspirin therapy significantly affected the levels of PECAM-1 or osteonectin.

In conclusion, despite long-term aspirin therapy, soluble PECAM-1 and osteonectin were elevated in the majority of patients with severe CHF irrespective of disease etiology, thus, suggesting persistent platelet-endothelial activation. The present data provide additional evidence that more potent anti-platelet and endothelial preservation regimens deserve further study in the heart failure population.

P1142 Immune activation in chronic heart failure: the possible functional and prognostic importance of lipoproteins

M. Rauchhaus, V. Koloczek, M. Kemp, A.J.S. Coats, S.D. Anker. *Cardiac Medicine Dept., National Heart & Lung Institute, London, UK*

Increased concentrations of tumor necrosis factor-alpha (TNF-alpha) have been reported in severe chronic heart failure (CHF), but the regulatory mechanisms of immune activation remain unclear. The relationship between lower blood lipid levels and subsequent mortality in CHF is poorly understood. Based on the ability of lipoproteins to bind endotoxin, we hypothesised them to have beneficial immuno-regulatory effects in CHF.

Levels of cholesterol (CHOL), LDL, HDL, TNF-alpha and soluble TNF receptors 1 and 2 (sTNF-R1/2) were measured in 58 CHF patients (age 60 ± 1 y, peak VO_2 16 ± 1 ml/kg/min, NYHA class 2.7 ± 0.1, ejection fraction 26 ± 3%, all mean ± SEM) and 18 healthy controls (age 59 ± 2 y). Patients with CHF had raised concentrations of sTNF-R1 ($p = 0.005$), but TNF-alpha and sTNF-R2 were not increased. In cachectic CHF patients (cCHF, $n = 19$), the highest concentrations of TNF-alpha ($p < 0.0001$), sTNF-R1 ($p = 0.0006$) and sTNF-R2 ($p = 0.12$) were found. There was a correlation between TNF-alpha and body mass index ($r = -0.52$, $p < 0.0001$), age ($r = 0.43$, $p < 0.002$), CHOL ($r = -0.40$, $p = 0.003$) and LDL ($r = -0.30$, $p = 0.03$), independently of kidney function and CHF aetiology. In cCHF patients who had the strongest immune activation, TNF-alpha correlated with CHOL ($r = -0.55$, $p < 0.02$), HDL ($r = -0.49$, $p < 0.04$), sTNF-R1 ($r = -0.72$, $p = 0.0008$) and sTNF-R2 ($r = -0.56$, $p = 0.054$). Additionally,% weight loss was related to TNF-alpha concentrations ($r = 0.63$, $p = 0.005$) and HDL levels ($r = -0.54$, $p < 0.02$). Over a 1-year follow-up, 15 CHF patients experienced major events, defined as death ($n = 9$) and heart transplantation ($n = 6$). When the event-free survival was analysed, independent predictive values were found for peak VO_2 ($p = 0.001$), the lowest tertile of CHOL (<5.2 mmol/l, $p = 0.009$) and NYHA class ($p = 0.03$). In multivariate analysis, a lower CHOL level significantly predicted a poor 1-year clinical outcome ($p = 0.006$, RR 4.6, 95% CI 1.5–13.4) independently of peak VO_2, NYHA class, age and the presence of cardiac cachexia. When outcome was restricted to mortality, again, CHOL levels < 5.2 mmol/l significantly predicted 1-year mortality ($p < 0.05$, RR 5.6, 95% CI 1.1–29.4), independently of peak VO_2, NYHA class, body wasting and age. In patients who died, the correlation between TNF-alpha and CHOL was strongest ($r = -0.62$, $p < 0.02$).

In conclusion, serum CHOL may be involved in the regulation of immune activation in clinically stable CHF patients. These results could provide a potential explanation for the observed relationship between lower CHOL levels and impaired prognosis in CHF. This study may suggest a beneficial functional and prognostic importance of predefined lipid levels in established CHF.

P1143 Left ventricular function improvement during permanent left ventricular-based pacing in congestive heart failure

Y. Etienne, M. Gilard, J. Mansourati, O. Simon, C. Le Rest, P. Guillo, Y. Jobic, J.J. Blanc. *University Hospital of Brest, France*

Some studies showed acute hemodynamic and sustained clinical improvement during left ventricular (LV) or biventricular pacing in pts with severe congestive heart failure (CHF) and intraventricular conduction delay. Whether this new therapeutic option affects LV function has not already been reported.

Methods: In order to evaluate this hypothesis a radionuclide ventriculography and an echocardiographic study were performed at baseline, 1 month, 6 months and every 6 months after permanent LV-based pacing in 19 pts (68.2 ± 6 years; 17 males) with severe but stable CHF (NYHA class III: 6 pts; class IV: 13 pts) and left bundle branch block (LBBB, mean QRS duration = 182 ± 33 ms). The following data were collected: radionuclide-derived LV ejection fraction (EF), LV end-diastolic (EDD), end-systolic (ESD) diameters and fractional shortening (FS) assessed by M-mode echo, systolic pulmonary artery pressure (PAP) by continuous wave Doppler and mitral regurgitation (MR) jet area evaluated by color Doppler. After a mean follow-up (FU) of 10 ± 8 months, the following results were observed (mean ± SD):

	EF (%)	EDD (mm)	ESD (%)	FS (%)	PAS (mmHg)	MR (cm^2)
Baseline	24.8 ± 9	72.6 ± 7	63.5 ± 8	12.9 ± 4	44.2 ± 12	11.9 ± 6
FU	32.4 ± 10*	69.4 ± 8*	57.7 ± 9**	17.6 ± 6**	38.9 ± 9	7.4 ± 6**

*p < 0.05; **p < 0.01 FU vs baseline

Conclusion: LV based permanent pacing induces significant improvement in LV systolic function and significantly decreases the mitral regurgitation in pts with severe CHF and LBBB.

P1144 Haemodynamic and circulatory response to extracorporeal ultrafiltration in refractory congestive heart failure

G.C. Marenzi, G. Lauri, M. Grazi, E. Assanelli, F. Lavarra, R. Monticchio, M. Musmeci, P.G. Agostoni, M.D. Guazzi. *Institute of Cardiology, University of Milan, Centro Cardiologico "Monzino", IRCCS, Milan, Italy*

In rCHF, extracorporeal ultrafiltration (UF) allows clinical improvement and restores diuretic efficacy. In the course of a UF session patients are exposed to rapid variations of body fluid composition so that, as fluid is withdrawn from the intravascular compartment, hypotension or even shock could occur if compensatory mechanisms do not minimise blood volume reduction. We investigated the hemodynamic and circulatory adjustments during UF in 21 patients with rCHF, anasarcatic oedema, and oligo-anuria undergoing UF (4.1 ± 1.5 L, weight reduction of 5.3 ± 1.8 kg). Hemodynamics, plasma volume changes (ΔPV) and plasma refilling rate (PRR) were measured after every liter of plasma water removed. ΔPV and PRR were calculated by considering hematocrit and ultrafiltrate volume. Data are mean ± SD.

	Pre-UF	1 L	2 L	3 L	4 L	End-UF
CO (L/min)	3.2 ± 1	3.1 ± 1	3.4 ± 1	3.5 ± 1	3.6 ± 1*	3.8 ± 1*
PWP (mmHg)	28 ± 8	25 ± 7	24 ± 8*	22 ± 7*	21 ± 8*	19 ± 9*
RAP (mmHg)	17 ± 6	15 ± 5	14 ± 6*	11 ± 9*	11 ± 8*	9 ± 7*
MSAP (mmHg)	81 ± 15	80 ± 14	80 ± 13	82 ± 15	83 ± 12	83 ± 14
ΔPv (%)	–	−2 ± 4	−1 ± 2	1 ± 2	−2 ± 1	−3 ± 2
PRR (ml/min)	–	14 ± 4	12 ± 3	10 ± 5	8 ± 4*	7 ± 3*

* = p < 0.01 vs. Pre-UF.

The maximal PRR value observed not affecting plasma volume was 18.3 ml/min.

Conclusions. In rCHF patients, subtraction of plasma water by UF is associated with hemodynamic improvement. Refilling from the overhydrated interstitium is the major compensatory mechanism to intravascular fluid removal and hypotension does not occur when PRR is adequate to prevent hypovolemia. The upper PRR limit of 18 ml/min suggests that UF might be a safe procedure up to a fluid removal velocity of 1100 ml/hour. However, non invasive surveillance of hematocrit and body fluid balance during UF has to be done to monitor circulatory changes and to prevent hypovolemia.

P1145 Metoprolol treatment reduces sympathetic nerve activity in patients with heart failure

B. Rundqvist, P. Friberg[1], B. Andersson, M. Elam[2], Y. Bergmann-Sverrirsdottir[2], G. Eisenhofer[3], F. Waagstein. *Cardiology Dept., [1]Clinical Physiology, [2]Clinical Neuroscience Dept., Sahlgenska Univeristy Hospital, Gothenburg, Sweden; [3]Clinical Neuroscience Dept., National Institutes of Health, Bethesda, USA*

Activation of the sympathetic nervous system is considered to have pathophysiological and prognostic impact in heart failure. The aim of this study was to assess the effect of 6 months metoprolol treatment on cardiac,renal,muscle and overall sympathetic function in patients with mild to moderate heart failure.

Methods: In a doubleblind design 22 patients (NYHA II-III) were randomly assigned to placebo or metoprolol (150 mg) treatment. Cardiac and renal vein catheterisation were performed at baseline and after 6 months. Regional sympathetic function was assessed by means of isotope dilution of tritiated Norepinephrine (NE) and microneurography in the peroneal nerve (MSA). Left ventricular ejection fraction (LVEF) was determined by radionuclide ventriculography.

Results: (mean ± SE) see table.

	Baseline metoprolol	Baseline placebo	6 months metoprolol	6 months placebo
LVEF(%)	32 ± 3	31 ± 3	42 ± 4*	33 ± 3
MSA (b/min)	58 ± 3	60 ± 5	43 ± 4*	58 ± 5
Cardiac NE so	357 ± 67	222 ± 83	235 ± 64	196 ± 79
Renal NE so	1033 ± 114	893 ± 115	846 ± 129	734 ± 134
Systemic NE so	4905 ± 622	4145 ± 565	3485 ± 505	4458 ± 652

*denotes a statistically significant difference p < 0.05, b/min denotes bursts/min and so denotes spillover (pmol/min)

Conclusions: Metoprolol treatment significantly reduced sympathetic nerve activity and improved LVEF in patients with mild/moderate heart failure. The decrease in nervetraffic was paralleled by trends towards lower regional and systemic NE release. Reducing the sympathoexcitation that prevails in heart failure may be one mechanism underlying the favorable effects of betablockade in this disorder.

P1146 Accurate non-invasive estimation of systolic pulmonary artery pressure by Doppler echocardiography in chronic heart failure

P.L. Temporelli, F. Scapellato, U. Corrà, E. Eleuteri, P. Giannuzzi. *"S. Maugeri" Foundation, IRCCS, Division of Cardiology, Veruno, Italy*

Systolic pulmonary artery pressure (sPAP) can be estimated by Doppler echocardiography by summing right atrium-ventricular pressure gradient (ΔP) to right atrial pressure (RAP). ΔP is easily derived from maximal velocity (Vmax) of tricuspid regurgitation (TR) by applying the modified Bernoulli equation. Therefore, accuracy in estimating sPAP depends mostly on the accuracy of RAP measurement. To date however, no model for noninvasive estimation of RAP has been applied in clinical practice. In chronic heart failure (CHF) patients (pts) we recently demonstrated a strong correlation between acceleration rate (Ac) of early tricuspid flow and RAP. In this study we sought to verify the accuracy of summing ΔP and Doppler-derived RAP in the prediction of sPAP.

Method: 40 pts (55 ± 7 yrs) with CHF and LV systolic dysfunction (mean EF 23 ± 8%), in NYHA class II to IV, underwent simultaneous right heart catheterization and Doppler echocardiography. All but 3 pts had TR and 42% of them had a moderate to severe regurgitation. By continuous-wave Doppler of TR profile we measured Vmax and calculated ΔP. By pulsed-wave Doppler we measured Ac of early tricuspid flow to derive RAP on the basis of the equation: RAP = −1.263 + 0.01116*Ac. Doppler-derived sPAP was the sum of ΔP and RAP.

Results: Adequate Doppler recordings were obtained in all pts. Mean sPAP was 45 ± 18 mm Hg. In 3 pts without TR hemodynamic sPAP was below the 25 mm Hg normal limit. Mean ΔP and Doppler RAP were 47 ± 16 mm Hg (range 15 to 79) and 5 ± 4 mm Hg (range 0 to 17), respectively. At linear regression analysis there was a very high correlation between hemodynamic and Doppler-derived sPAP (r = 0.98). Doppler sPAP accurately predicted hemodynamic sPAP in 100% of the pts in the range of 15 to 30 mm Hg, in 92% of pts in the range of 30 to 50 mm Hg, in 92% of pts in the range of 50 to 65 mm Hg, and in 90% of pts with >65 mm Hg.

In conclusion, this study demonstrates that accurate noninvasive estimation of sPAP is possible. The sum of Doppler-derived ΔP from TR jet and RAP from diastolic tricuspid flow represents a reliable tool for predicting sPAP.

P1147 Autonomic heart rate control and JT interval during night sleep stages in coronary disease patients with congestive heart failure

G. Varoneckas, D. Žemaitytė. *Institute Psychophysiology and Rehabilitation, Palanga, Lithuania*

Introduction. Night sleep, due to modification of autonomic heart rate (HR) control over individual sleep stages, might be seen as a natural testing condition of cardiovascular function and reflects an ability for restoration of the latter during sleep, especially for coronary artery disease patients (CAD pts) with congestive heart failure (CHF).

The goal of the study was an investigation of autonomic HR control and JT interval during the shifts of sleep stages during the night in CAD pts with CHF.

The contingent was 184 CAD pts, aged 52.9 (SEM 1.24) yrs. CHF was evident in 125 pts.

Methods: An analysis of HR, HR variability, hemodynamics (stroke volume – SV, cardiac output – CO and total peripheral resistance – TPR), were performed during all stages of night sleep. JT interval and JT dispersion (JT_d), measured from 12 leads of electrocardiogram recording, was analyzed during sleep stages in 23 CAD pts. Hemodynamics was measured by means of impedance cardiography. Active orthostatic test (AOT) was performed before and after sleep, maximal HR response to AOT (ΔRR_B) evaluated. Analysis of HR power spectrum (σRR) with dividing into very low, low, and high frequency components was performed.

Results: CAD pts with CHF, as compared with pts without CHF, demonstrated reduced HR variability at wakefulness (σRR_W = 25 vs 42 ms, ΔRR_B = 209 vs 261 ms) and sleep ($\sigma RR_{non\ REM}$ = 19 vs 38 ms and σRR_{REM} = 37 vs 52 ms) in parallel to depressed hemodynamics ($SV_{non\ REM}$ = 67.4 vs 89.2 ml), especially during REM sleep (SV_{REM} = 65 vs 79 ml). CAD pts with CHF shown two different patterns of cardiovascular function restoration during sleep: positive (an increase of ΔRR_B and a decrease of TPR) and negative – with opposite changes. A group of CAD pts with CHF, displaying myocardial ischemia and PB's during REM sleep was characterized by the lowest level of hemodynamics and HR variability in this sleep stage. Pts with CHF, as compared with pts without CHF, demonstrated increased baseline level of JT dispersion (JT_d = 60 vs 48 ms), followed by a tendency for further increase during REM sleep. CAD pts with CHF demonstrated reduced level of autonomic HR control, especially parasympathetic one, increased JT dispersion and depressed hemodynamics. This is true particularly for REM sleep. Such combination of negative symptoms might be responsible for more frequent appearance of dangerous dysrrhythmias during REM sleep in CAD pts with CHF.

In conclusion: CAD pts with CHF demonstrated lower level of autonomic HR control and hemodynamics, increased JT dispersion at both, wakefulness and sleep. Mostly reduced parasympathetic control, hemodynamics and increased JT dispersion might be responsible for more frequent appearance of ventricular dysrrhythmias during REM sleep.

P1148 Is age a contributory factor of mitochondrial bioenergetic decline and DNA defects in congestive heart failure?

J. Marin-Garcia, R. Ananthakrishnan, M.J. Goldenthal, M.E. Pierpont[1]. *The Molecular Cardiology Institute, Highland Park NJ; [1]Department of Paediatrics, U. Minnesota, Minneapolis MN, USA*

While mitochondrial abnormalities are increasingly recognized in cardiac diseases including hypertrophic cardiomyopathy, their presence in congestive heart failure (CHF) and the role that age plays in their incidence and severity have yet not been assessed. Levels of cardiac respiratory enzyme activities and mitochondrial DNA (mtDNA) were examined in 60 patients (pts) with CHF (due to either ischemic or dilated cardiomyopathy), who were sub-divided into 3 age-groups (age range from 1 month to 60 years). Respiratory enzyme activity levels were significantly lower in 39 pts (65%) compared to age-matched controls and increased activity levels were noted in 12 (20%). Decreased activities were found in complex I (n = 11), III (n = 21), IV (n = 12) and V (n = 15) but not in II, the only respiratory complex entirely nuclear-encoded. No age-specific differences were found in the overall frequency of enzymatic abnormalities. However, older pts had significantly increased multiple enzyme activity defects as well as increases in the abundance and frequency of the 7.4 kb deletion. Interestingly, 3 pts had marked reduction in mtDNA levels. None of the pathogenic mtDNA mutations previously associated with hypertrophic cardiomyopathy were found, nor was there any relationship that could be established between levels of specific mtDNA deletions and enzyme activities. In summary, specific mitochondrial abnormalities are heterogenous and frequent in both adults and children with CHF. Older pts are more likely to have mtDNA deletions and multiple enzyme activity defects. The molecular basis for these abnormalities remains undefined.

P1149 Increased expression of CD32 on monocytes despite unchanged leukocyte apoptosis in patients with chronic heart failure

N.V. Ulrich, M. Möllgaard, W. Döcke[1], M. Möckel[2], G. Baumann. *Cardiology Dept., Charité/Campus Mitte, Berlin[1]Immunology Dept., Charité/Campus Mitte, Berlin[2]Charité/Campus Virchow-Klinikum, Nephrology/Intensive Care Medicine, Berlin, Germany*

Inflammation processes mediated by proinflammatory cytokines and varied circulating blood cells play a significant role in the pathogenesis of chronic heart failure (CHF). It is unknown if increased TNF production by myocardial macrophages and cardiac myocytes in patients with CHF is reflected by immunological changes of circulating blood cells.

Patients and Methods: We examined 10 male patients with chronic heart failure (62.8 years, ejection fraction < 40%, NYHA III) and 11 healthy controls (30.8 years). Morning blood was drawn from a peripheral vein and leukocytes were separated immediately. Fluorescein-isothiocyanate (FITC)-labeled human annexin V and phosphatidyl inositol (PI) were used to detect early stages of apoptotic cell death in lymphocytes by flow-cytometry. Expression of CD14, CD32 and CD36 on polymorphnuclear blood cells (PMN) and monocytes was measured to determine their potential scavenger role in the phagocytosis of apoptotic cells. Plasma levels of IL-6 and TNF-alpha were measured additionally.

Results: Annexin V binding of PI negative lymphocytes was not different between patients and healthy controls (1o.65% vs 6.44%). CD32 expression on monocytes was significantly higher in patients (94.75 vs 68.54 mean fluorescence intensity, $p < 0.05$). IL-6 and TNF-alpha were significantly higher in patients but did not correlate with annexin V binding. CD14 and CD36 were not different between the groups.

Conclusion: CHF patients show increased expression of CD32 as an unspecific marker of inflammation, but even in patients with extremely high TNF production there is no effect on apoptosis of circulating lymphocytes as well as on expression of scavenger receptors.

MYOCARDIAL FUNCTION AND GENE EXPRESSION

P1150 Myocardial hypertrophy elicited by blocking G protein-coupled receptor kinases in cardiomyocytes

J. Carlsen, J. Theilade[1], T.E.H. Christoffersen[1], T. Kümler[1], S. Haunso, S.P. Sheikh[1]. *Medical Dept. B 2142, The Heart Center, H:S Rigshospitalet, Copenhagen; [1]The Cardiovascular Research Institute, Copenhagen University, Copenhagen, Denmark*

Background: Activation of the angiotensin II receptor (AT1) induces a hypertrophic response in cardiomyocyte cell cultures. The AT1 is a serpentine receptor, that couples to heterotrimeric G proteins (Galpha and Gbetagamma). Here we ask whether G protein-coupled Receptor Kinases (GRK's) may contribute to the hypertrophic phenotype in cardiomyocytes?

Methods: Primary cell cultures were prepared from the ventricles of neonatal 1–2 days old Wistar rats. Overexpression of the Gbetagamma sequestering protein, betaARKct, was achieved using an adenovirus construct kindly provided by Walter J. Koch. hBNP (human Brain Natriuretic Peptide)promotor linked to luciferase was used as a reporter gene assay for cardiomyocyte hypertrophy. Immunoprecipitation was performed with phophotyrosine and AT1 antibodies.

Results: betaARKct activates the hypertrophic response as evidenced by a 2–3 fold increase in the hBNP promotor activity, which is similar to the increase elicited by angiotensin II (AII). Furthermore, betaARKct results in constitutive activation of AII signaling. Accordingly, Losartan was able to partially block both the hypertrophic response and second messenger activation by betaARKct. In addition, betaARKct reduced phosphorylation of the AT1 receptor by 3–4 fold.

Conclusion: We suggest, that the activity level of GRK's in cardiomyocytes is an important element in the hypertrophic response. betaARKct downregulates GRK activity, resulting in increased AT1 signaling, inducing cardiomyocyte hypertrophy independently of agonist addition.

P1151 Unaltered mRNA levels and function of calcium/calmodulin-dependent protein kinase in endstage failing and non-failing human myocardium

W. Schillinger, A. Xu[1], J. Prestle, G. Hasenfuss, N. Narayanan[1]. *Kardiologie und Pneumologie, Georg-August-Universität Göttingen, Göttingen, Germany[1] Health Sciences, Dept. of Physiology, University of Western Ontario, London, Canada*

In cardiac muscle Calcium/Calmodulin-dependent kinase (CaM kinase) was shown to regulate sarcoplasmic reticulum (SR) calcium uptake and release by phosphorylating the major SR proteins including ryanodine receptor (RyR), Phospholamban (PLN), and SR Ca^{2+}-ATPase (SERCA). In failing human myocardium intracellular calcium handling is impaired.

Accordingly, we investigated mRNA levels of the cardiac CaM kinase II isoform and functional consequences of CaM kinase-dependent phosphorylation on SR calcium uptake in failing and nonfailing human myocardium. Northern blot analysis of the delta2-isoform was performed in hearts from 12 patients with endstage heart failure undergoing cardiac transplantation, and from 10 brain-dead organ donors. Relative densitometric units of CaM kinase II relative to glyceraldehyde-3-phosphate dehydrogenase were 1.17 ± 0.14 and 1.17 ± 0.15 in failing and nonfailing hearts, respectively (no significant differences). SR membranes were isolated from failing and nonfailing myocardium and phosphorylated by endogenous CaM kinase after addition of [gamma32]ATP. Membranes were subjected to SDS-PAGE, gels were dried and autoradiographed. Significant phosphorylation of RyR, PLN, and SERCA only occurred when both calcium and calmodulin were present in the reaction medium. Phosphorylation was markedly enhanced after the addition of exogenous CaM kinase II. The identity of phosphorylated proteins was verified by Western Blotting, and for SERCA by immunoprecipitation of phosphorylated SERCA with a monoclonal antibody (IID8F6). Oxalate-facilitated calcium uptake of phosphorylated and dephosphorylated membranes was investigated in 4 failing and 4 nonfailing hearts. In both types of myocardium, CaM kinase-dependent phosphorylation significantly increased calcium uptake by 108% ($p < 0.004$) and 181% ($p < 0.06$) in failing and nonfailing myocardium, respectively.

We conclude that the expression of CaM kinase II is not altered in failing myocardium. CaM kinase was shown to phosphorylate RyR, PLN, and SERCA in failing and nonfailing human myocardium. Functional implications of CaM kinase-dependent phosphorylation on cardiac performance could be preserved during heart failure.

P1152 Effect of endothelin converting enzyme inhibition on NO synthases in hypertrophied and non-hypertrophied postischaemic myocardium

H.M. Hoffmeister[1], B.K. Krämer[2], K. Wolf[2], M. Fischer[1], T. Hövelborn[1], M.E. Beyer[1]. *[1]Medical Department III, University of Tübingen; [2]Medical Department II, University of Regensburg, Germany*

Endothelin is the most potent vasoconstrictor, blockade of its receptors or of its converting enzyme has been shown to be beneficial in ischemia/reperfusion injury. In an isolated rat heart model with 3 h of hypoperfusion (15% coronary flow) and 1 h of reperfusion we determined NO-synthase (NOS)-mRNA expression. We measured mRNA expression of eNOS, bNOS, and iNOS in hypertrophied (SHR) and non-hypertrophied (WISTAR) left ventricles. Additionally a group received the endothelin converting enzyme (ECE) inhibitor phosphoramidon (2 μmol/l; PHOS) during hypoperfusion and reperfusion. The latter regimen resulted in a 20% improvement of functional recovery. All data are mean ± SEM in CPM/μg total RNA.

		Control	Hypoperf.-NaCl	Hypoperf.-PHOS.
Wistar	eNOS	0.68 ± 0.26	1.54 ± 0.42(*)	2.56 ± 0.62#
	iNOS	0.14 ± 0.05	0.13 ± 0.02	0.16 ± 0.04
SHR	eNOS	0.70 ± 0.26	1.62 ± 0.35*	1.69 ± 0.62(*)
	iNOS	0.05 ± 0.01	0.49 ± 0.11#	0.35 ± 0.09#

(* = $p < 0.05$; # = $p < 0.01$)

Hypoperfusion/reperfusion resulted in a significant induction of eNOS mRNA expression. bNOS did not increase in either group. In SHR-rats a marked increase in iNOS mRNA was observed in contrast to WISTAR. ECE-inhib. had no effect on these changes.

Conclusion: In hypertrophied LV hypoperfusion/reperfusion results in an increased induction not only of eNOS but also of iNOS. Inhibition of ECE has a beneficial functional effect, but does not influence NO on the level of mRNA expression.

P1153 The ryanodine-channel-binding protein FKBP12.6 is increased in human heart failure

B. Bölck, G. Münch, R.H.G. Schwinger. *Klinik III für Innere Medizin, University of Cologne, Germany*

Background: Disturbed intracellular calcium handling has been suspect to play a pathogenic role in cardiac hypertrophy and heart failure. Alterations in the function of the Ca^{2+}-release channel (ryanodine receptor; RyR2) of the sarcoplasmic reticulum may contribute to this impaired Ca^{2+}-handling. Recently, a little protein, the FKBP12 has been found to be tightly bound with the RyR. FKBP12 modulates the ryanodine receptor and may contribute to decreased Ca^{2+}-release.

Aim: The purpose of the study was to evaluate the protein expression of FKBP12.6 in hearts from patients with terminal heart failure due to idiopathic dilated cardiomyopathy undergoing cardiac transplantation (DCM, n = 8) in comparison to control hearts from organ donors without any signs of heart failure (NF, n = 8). The protein expression of FKBP12.6 and RyR2 from left ventricle myocardium was detected with monoclonal (RyR2) and polyclonal (FKBP12.6) antibodies in Westernblot-technique.

Results: The protein expression of FKBP12.6 was significantly increased in DCM (FKBP12.6: DCM 14.6 ± 2.0 vs. NF: 7.5 ± 1.03 densitometric units/μg protein, $p < 0.02$). In contrast RyR2 was identical in DCM (16.4 ± 2.2 densitometric units/μg protein) and NF (17.3 ± 4.3, $p = 0.88$).

Conclusions: This results predict to the impaired Ca^{2+}-homeostasis. The altered expression of FKBP12.6 in failing human myocardium may contribute to alterations in Ca^{2+}-release behavior of sarcoplasmic reticulum in spite of unchanged Ca^{2+}-release channel density.

P1154 Increased expression of glyceraldehyd 3-phosphate dehydrogenase in end-stage heart failure

S. Lutz, D. Baltus, R. Mura, F. Niroomand. *Dep of Cardiology, University of Heidelberg, Germany*

Glyceraldehyd-3-phosphate dehydrogenase (GAPDH) catalyzes the formation of glycerate-3-phosphate, the first ATP-forming step in the Embden-Meyerhof pathway. Based on its ubiquitous expression and the constitutive promoter, GAPDH is considered to be a housekeeping gene and is therefore used as a marker for cytosolic proteins and transcripional regulation of many genes. However, recent studies indicate, that the promoter of the GAPDH gene has positive regulatory elements. Under certain conditions, e.g. increased proliferation, the expression of GAPDH is up-regulated.

In studies of gene expression, we found a 109% increase in mRNA levels in explanted hearts from patients with end-stage heart failure, who underwent cardiac transplantation (n = 6) compared to non-failing human heart (n = 12). Signals of GAPDH were normalized against ribosomal 18 S RNA. The increased transcription resulted in an increased expression of GAPDH. Cytosolic fractions from 5 explanted failing hearts and a pool of 3 non-failing human hearts were prepared by centrifugation of supernatants from the homogenate at 100 000 g * 60 min. The cytosolic fractions were seperated in sodium dodecylsulfate polyacrylamide gelelectrophoresis and immunoblotted. Detection of GAPDH was carried out using a monoclonal antibody. Cytosolic fractions from failing human hearts showed a 92 ± 18% increase in GAPDH expression. Furthermore, GAPDH activity was increased by 102 ± 10.5% in failing human hearts, compared to non-failing hearts.

The influence of increased GAPDH expression for the energy household in end-stage heart failure remains to be resolved. However, GAPDH should not be used as a marker for comperative studies of failing and non-failing hearts.

P1155 Uniform reduction in SERCA2a content and metabolic enzyme activities in left ventricles with asymetric hypertrophy due to chronic ventricular pacing

M.F.M. van Oosterhout, M. Peschar, L.H.E.H. Snoeckx, T. Arts[1], R.S. Reneman, F.W. Prinzen. *Physiology Dept., Maastricht University, Maastricht; [1]Biophysics Dept., Maastricht University, Maastricht, Netherlands*

Recently studies from our laboratory showed that chronic ventricular pacing leads to asymmetric hypertrophy. In general, global hypertrophy is associated with diminished myocardial activities of various metabolic enzymes and sarcoplasmic reticulum calcium ATPase (SERCA2a).

Methods: We investigated activities of SERCA2a and metabolic enzymes in the left ventricular (LV) free wall (FW) and septum (S) from canine hearts after 6 months of pacing at the LV FW pacing at physiological heart rate (DDD, AV interval 25 ms, PACE, n = 8). These data were compared with those from hearts with global LV pressure overload hypertrophy (POH, aortic banding, n = 4) and from sham operated dogs (SHAM, n = 5). Wall mass of the LV FW and S was determined echocardiographically, myocyte diameter histologically, activities of fructose-6-phosphate kinase (PFK), citrate synthase (CS), 3-hydroxy-acyl-CoA dehydrogenase (HAD) and creatine kinase (CK) using biochemical techniques and SERCA2a contents via Western blotting.

Results: In PACE animals FW mass did not change but S mass increased by 39 ± 13%. Myocyte diameter in the S was 18 ± 7% larger than in the FW and was similar to that in POH hearts. SERCA2a content and activities of PFK, CS, HAD and CK were not significantly different between FW and S in any group. SERCA2a content (58%) and activities of PFK (52%), CS (32%), HAD (17%) and CK (17%) were significantly lower in PACE than in SHAM hearts. No significant differences in SERCA2a content and metabolic enzyme activities were found between PACE and POH hearts.

Conclusions: Chronic ventricular pacing induces localized hypertrophy in combination with generalized reductions in SERCA2a content and activities of metabolic enzymes. This indicates that expression of these proteins is not directly dependent on the local degree of hypertrophy, but rather to some systemic factor. The similar biochemical changes suggest involvement of the same factor in PACE and POH.

P1156 Opposite regulation of brain and C-type natriuretic peptides in the streptozotocin-diabetic cardiopathy

T. Walther, S. Heringer Walther[1], H.P. Schultheiss[1], C. Tschöpe[1]. *Hypertension Dept., Max-Delbruck Center, Berlin; [1]Cardiology Dept., University Hospital Benjamin Franklin, Berlin, Germany*

C-type natriuretic peptide (CNP), a recent addition to the family of natriuretic peptides including atrial and brain natriuretic peptide (ANP, BNP), is thought to be an endothelium-derived vasodilator and to have an antimitotic effect. While ANP and BNP levels are increased in conditions such as congestive heart failure, cardiac CNP levels have not been investigated in this connection. Diabetes mellitus also involves myocardial dysfunctions without coronary artery disease or systemic hypertension. We investigated the cardiac expression of CNP versus BNP mRNA in streptozotocin (STZ)-diabetic rats. Male Wistar rats with STZ-induced diabetes (n = 4) were studied in comparison to control rats (n = 4). The animals were characterised by their mean arterial blood pressure and plasma glucose levels. After extraction of total cardiac RNA, a specific cDNA probe of BNP was used for Northern blot analysis. Myocardial CNP expression was analysed by RNase protection assay using a specific probe from the coding region of the rat CNP gene. Twelve weeks after diabetes induction, the rats were normotensive (97.3+2.1 vs. 96.1+1.7 mmHg) and hyperglycaemic (820+65 vs. 160+23 mg/dl; $p < 0.001$). STZ-diabetic rats had a 3.2-fold increase of cardiac BNP expression compared to controls. In contrast, cardiac CNP mRNA levels were decreased 2.6-fold. In agreement with others, we found an increased BNP expression in STZ-diabetic hearts. Furthermore, our data show firstly that the gene expression of CNP is downregulated in this diabetic model. Thus, CNP seems to be regulated like other peptide systems with antimitotic and vasodilatory activities (nitric oxide, prostacyclin, kinins). This may contribute to cardiac dysfunction in diabetes mellitus and suggests that stimulation of CNP expression could provide cardiac protection in such cases.

P1157 Regulation of mitochondrial biogenesis during early human cardiac development

J. Marin-Garcia, R. Ananthakrishnan, M.J. Goldenthal. *Molecular Cardiology Institute, Highland Park NJ, USA*

Previous studies in our laboratory demonstrated marked changes in bovine heart mitochondrial bioenergetics during fetal growth and development. To further understand the regulation of mitochondrial biogenesis in early human development, we examined fetal and neonatal heart tissues, for the activity and subunit content levels of specific mitochondrial enzymes. Comparing early fetal (EF, 45–65 day post conception) to later fetal (LF, 85–105 day post conception) and neonatal (birth-1 month) stages, we found:

- A 1.8 fold increase during EF to LF transition in specific activity of Krebs cycle enzyme, citrate synthase (CS), and an overall 4–5 fold increase in EF to neonatal transition.
- A 1.3 fold increase in COX/CS activity ratio during EF to LF indicating increased COX (cytochrome c oxidase) activity, and no increase in activity ratio from LF to neonatal stage.
- A 1.5–2 fold increase in peptide content of COX subunits (COX2 and COX4) as determined by immunoblot analysis during EF to LF with an overall 4–10 fold increase noted during EF to neonatal stage.
- Levels of peptide content of specific transcription factor, mt-TFA were relatively unchanged in development.
- A 1.7–2 fold increase in mitochondrial DNA (mtDNA) levels (EF to LF), and a 3.5–4 fold increase (EF to neonatal).

These data suggest that mitochondrial number doubles during early fetal cardiac development with coordinate regulation of some nuclear-encoded (COX4, CS) and mitochondrial components (COX2, mtDNA), and reveal a different pattern of regulation of mt-TFA. In the transition from LF to neonate, a further mitochondrial increase is indicated by more than 2 fold increases in CS and COX activities, COX peptides and mtDNA levels. These data are critical for identifying the regulatory events mediating mitochondrial biogenesis in early cardiac development.

P1158 The role of mitochondrial gene expression in ventricular fibrillation in isolated ischaemic and reperfused rat hearts

P. Kovacs, Z. Szilvassy[1], C. Csonka[2], I.E. Blasig[2]. *First Department of Internal Medicine, School of Medicine, Debrecen; [1]Department of Pharmacology, School of Medicine, Pecs, Hungary; [2]Institute of Molecular Pharmacology, Berlin, Germany*

In the present study we investigated the up- and down-regulation of mitochondrial genes [ATP synthase subunit 6 (ATP6) and cytochrome oxidase III (COX III)] related to ventricular fibrillation (VF) in ischemic/reperfused nondiabetic and diabetic myocardium.

Methods: We carried out subtractive screening, Northern blotting, and reverse transcription polymerase chain reaction (RT-PCR) of mitochondrial genes expressed after 30 min ischemia followed by 120 min of reperfusion in isolated rat hearts (n = 6 in each group) showed VF or did not develop VF. Cardiac function was also recorded in the nonfibrillated myocardium.

Results: ATP6 and COX III (selected out of 40 mitochondrial genes) showed an expression after 30 min of ischemia in both nondiabetic and diabetic myocardium. Upon reperfusion, using Northern blotting, the down-regulation of ATP6 (by 86% in nondiabetics and 100% in diabetics) and COX III (by 92% in nondiabetics and 100% in diabetics) mRNA was only observed in the fibrillated myocardium. A reduction in the expression of these genes was not seen in nonfibrillated hearts. Cardiac function showed no correlation between the up- and down-regulation of ATP6 and COX III genes in ischemic/reperfused myocardium. RT-PCR confirms the same expression in ATP6 mRNA and COX III mRNA after 30 min ischemia, and a decline throughout an additional two-hour period of reperfusion in both fibrillated nondiabetic and fibrillated diabetic myocardium.

Conclusion: Our data suggest that ATP6 and COX III may play a critical role in arrhythmogenesis and the stimulation of the expression of ATP6 and COX III may prevent the development of VF in both ischemic/reperfused diabetic and nondiabetic myocardium. Furthermore, the results show that the mechanism(s) of VF, in this respect, does not show any difference between the nondiabetic and diabetic myocardium.

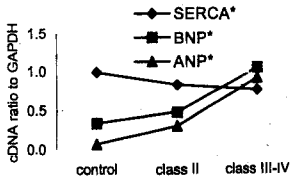
P1159 Increased expression of atrial and brain natriuretic peptides in human myocardium is related to clinical severity of left ventricular dysfunction

R.A. de Boer[1], D.J. van Veldhuisen[1], R.H. Henning[2], Y.M. Pinto[1,2], W.H. van Gilst[2], H.J.G.M. Crijns[1]. *Department of [1]Cardiology; [2]Clinical Pharmacology, University of Groningen, Netherlands*

Cardiac expression of natriuretic peptides (ANP and BNP) is a well established marker in the study of left ventricular dysfunction. However, such studies are usually performed in animal models and there are few data on the relative expression of ANP and BNP in human left ventricular dysfunction. Therefore, we evaluated the ANP and BNP expression in human left ventricular dysfunction.

Methods. Total RNA was isolated from right ventricular tissue biopsies from 27 patients with idiopathic dilated cardiomyopathy (14: NYHA class II, 13: class III–IV) and 13 controls. Expression of Atrial Natriuretic Peptide (ANP), Brain Natriuretic Peptide (BNP), and Sarcoplasmic Reticulum Ca^{2+}-ATPase (SERCA) was determined by semi-quantitative PCR, expressed as a ratio to the co-amplified glyceraldehyde-3-phosphate dehydrogenase (GAPDH).

Results. ANP, BNP, and SERCA mRNA are depicted according to NYHA class. ANP and BNP mRNA increased according to NYHA class, and according to down-regulation of SERCA (figure, *: $p < 0.05$, linear trend analysis).



Conclusion. This study demonstrates that in human left ventricular dysfunction the expression of ANP and BNP is related to the clinical severity of the disease, and is already present at the early stages of LV dysfunction. This suggests that they are useful markers in the study of molecular changes in human left ventricular dysfunction.

CARDIAC FUNCTION

P1160 Genetic polymorphisms of the ACE and AT1R genes and left ventricular function in subjects with angiographically proven coronary heart disease

D. Ciećwierz, W. Dubaniewicz, L. Mierzejewski, M. Gruchała, R. Targoński, A. Koprowski, P. Romanowski, A. Rynkiewicz. *I Dept. Cardiology, Dept. Invasive Cardiology and Dept. Biology and Genetics, Medical University of Gdańsk, Poland*

Several studies have suggested that genetic polymorphism of the renin-angiotensin system (RAS) have been associated with CHD. The aim of the present study was to estimate the potential association between ACE I/D polymorphism, and A1166C angiotensin II type 1 receptor (AT1R) genotype and left ventricular volumes and function in patients with CHD.

The study was performed in 93 patients with CHD confirmed by coronary angiography, all were younger than 50 years of age. Left ventricular volumes and function were measured during cardiac catheterisation. The polymerase chain reaction, restriction enzymes digestion and agarose gel electrophoresis were used to determine the ACE I/D and A/C AT1R genotypes.

	DD (n = 33)	ID (n = 42)	II (n = 18)
EF (ml)**	52 ± 14	57 ± 12	61 ± 12
LVEDP (mmHg)NS	17 ± 8	17 ± 7	13 ± 8
SVI (ml/m²)NS	39 ± 13	45 ± 17	60 ± 21
EDVI (ml/m²)NS	88 ± 40	78 ± 32	87 ± 29
ESVI (ml/m²)*	50 ± 37	28 ± 14	27 ± 16
	CC (n = 3)	AC (n = 23)	AA (n = 50)
EF (ml)NS	58 ± 5	58 ± 12	56 ± 16
LVEDP (mmHg)NS	17 ± 13	18 ± 14	15 ± 6
SVI (ml/m²)NS	42 ± 19	44 ± 12	44 ± 15
EDVI (ml/m²)NS	97 ± 69	79 ± 28	83 ± 35
ESVI (ml/m²)NS	27 ± 11	37 ± 18	39 ± 35

Significance was calculated as the difference between DD vs ID + II genotype and AA vs AC + CC genotype **-$p < 0.05$, *-$p < 0.03$

In conclusion, the DD genotype of the I/D ACE polymorphism is associated with significantly worse left ventricular function in younger patients with coronary heart disease. There is no association between the A/C AT1R polymorphism and left ventricular function in the study group.

P1161 Contrast echocardiography versus harmonic imaging in ejection fraction quantification

M.T. Gonzalez, M. Mateos, A. Evangelista, H. García del Castillo, J. Angel, J. Soler-Soler. *Cardiology, H Vall d?hebron, Barcelona, Spain*

The aim of this study was to assess whether the use of contrast and/or harmonic echocardiography improves results obtained by fundamental imaging. Twenty-four consecutive patients (age: 63 ± 8 y) with ischaemic heart disease underwent echocardiography and contrast ventriculography within a <24 hours period. Ejection fraction (EF) was determined by fundamental imaging, 2nd harmonic, 2nd harmonic with contrast (Levovist©, 8 ml ev, 400 mg/ml)) and after 5–10 min in wash-out phase. Interobserver variability was assessed.

EF by angiography was 54 ± 21%, range 24 to 82%. Mean values and correlation with angiography were

	Fundamental	Harmonic	Contrast	Wash-out
Mean	55 ± 13	54 ± 15	61 ± 17	54 ± 13
r	0.60	0.81	0.85	0.88
SEE	17.5	12.8	11.6	9.6

Absolute and percentual differences in interobserver variability were:

	Fundamental	Harmonic	Contrast	Wash-out
Absolute	1.3 ± 12.7	1.4 ± 12.6	0.5 ± 10.1	1.7 ± 3.9
Differences	5.7 ± 29%	1.1 ± 24%	0.1 ± 16%	3.1 ± 8%

Conclusions: Contrast agents, particularly in the wash-out phase, facilitates ejection fraction quantification by echocardiography, improves correlation with angiography and decreases interobserver variability.

P1162 Effect of left ventricular filling pattern on cardiopulmonary exercise response in patients with left ventricular systolic dysfunction

F.I. Parthenakis, E.M. Kanoupakis, N.E. Mezilis, E.I. Skalidis, E.N. Simantirakis, I. Savopoulos, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

We evaluated the relationship between transmitral flow filling pattern, assessed by Doppler echocardiography, and exercise tolerance during cardiopulmonary exercise testing, in pts with left ventricular (LV) systolic dysfunction.

Methods: The study included 32 pts (18 men, age 56 ± 13 years) in sinus rhythm, with angiographic LV ejection fraction < 40%. Idiopathic (17 pts) and ischaemic (15 pts) cardiomyopathy were the causes of heart failure according to coronary angiography. All pts underwent 2-D and Doppler echocardiography examinations and were classified, on the basis of early (E) to late (A) transmitral peak flow and/or peak A velocity criteria, as having a nonrestrictive (E/A < 2 or A > 35 cm/s, Group I, 15 pts) or restrictive (E/A > 2 or A < 35 cm/s, Group II, 17 pts) pattern. A modified Naughton treadmill exercise protocol was used, with gas exchange analysis, and the exercise duration and the oxygen consumption at peak exercise (peak VO_2) and at the anaerobic threshold (VO_2AT) were recorded.

Results: There were no differences between Groups I and II in the resting EF (29 ± 7 vs. 28 ± 4%, p:NS) or in exercise duration (378 ± 54 vs. 376 ± 33 s, p:NS). Group I had significantly higher values of peak VO_2 and VO_2AT than Group II (15.6 ± 1.8 vs. 12.6 ± 1.3 ml/kg/min and 12.1 ± 0.9 vs. 9.7 ± 1 ml/kg/min, respectively, $p < 0.05$ in each case). There was a good correlation between both the maximum velocity of A and the deceleration time of E and peak VO_2 (r = 0.79, r = 0.85, respectively) and VO_2AT (r = 0.8, r = 0.66, respectively), while no correlation was found for E velocity.

Conclusions: In pts with left ventricular systolic dysfunction the restrictive diastolic filling pattern, by Doppler echocardiography, is a powerful noninvasive marker for diminished exercise performance during cardiopulmonary exercise testing.

P1163 Restrictive left ventricular filling in dilated cardiomyopathy is accompanied by marked neurohumoral imbalance

Friedrich M. Fruhwald, Astrid Fahrleitner, Norbert Watzinger, Robert Maier, Harald Dobnig, Martin Schumacher, Sonja Fruhwald, Robert Zweiker, Werner Klein. *Karl-Franzens-University of Graz, Austria*

Background: Patients with idiopathic dilated cardiomyopathy (IDC) show different types of left ventricular (LV) filling on Doppler echocardiography. Restrictive filling pattern is defined as an E/A ratio ≥ 2 or by the combination of an E/A ratio between 1 and 2 with a deceleration time > 140 msec. The nonrestrictive pattern is defined as E/A ratio ≤ 1 or E/A ratio between I and 2 with deceleration time > 140 msec. Patients with the restrictive LV-filling pattern show an impaired prognosis.

Methods: We investigated 32 patients (26 male, 6 female; mean age 55 ± 2 years) with IDC. Patients were divided into a restrictive group according to the above mentioned criteria (13 male, 3 female; mean age 55 ± 3) and into a nonrestrictive group (13 male, 3 female; mean age 52 ± 4). After echocardiography was done blood samples were taken and the following parameters were measured using a RIA: N-terminal pro-ANP (NT-ANP), B-type natriuretic peptide (BNP), big endothelin 1 (big-ET), norepinephrine, epinephrine.

Results: There was no statistically significant difference between the two groups in left ventricular enddiastolic diameter and left ventricular ejection fraction. Restrictive patients had greater left atrial diameters (49 mm) than nonrestrictive patients (40 mm, $p < 0.001$). Neurohumoral parameters are given in table 1 (mean ± SEM):

	Restrictive	Nonrestrictive	p-value
NT-ANP (<0.6 nmol/l)	2.14 ± 0.31	0.50 ± 0.07	<0.001
BNP (<18.4 pg/ml)	452 ± 83	43 ± 12	<0.001
Big-ET (<0.7 fmol/ml)	1.88 ± 0.33	0.82 ± 0.33	0.002
Norepinephrine (<600 pg/ml)	325 ± 65	48 ± 6	<0.001
Epinephrine (<100 pg/ml)	83 ± 12	39 ± 5	0.007

During a follow-up period of 24 months 7 patients died and 3 underwent heart transplantation. All but one patient were from the restrictive group.

Conclusion: Patients with IDC and a restrictive LV filling pattern showed a marked neurohumoral activation. They revealed significantly higher levels of NT-ANP, BNP, big endothelin, norepinephrine and epinephrine compared to nonrestrictive patients. Furthermore, restrictive LV filling pattern and neurohumoral activation were markers of an impaired prognosis.

P1164 Correlation of end-diastolic pressure and myocardial elasticity with wave reflections

J. Demellis, C. Stefanadis, E. Tsiamis, A. Michaelides, C. Tentolouris, P. Toutouzas. *Department of Cardiology, University of Athens, Athens, Greece*

Left atrial (LA) systolic pressure waveform was studied in 11 normal subjects (NLS), 7 patients with congestive heart failure (CHF) and 8 patients with mitral stenosis (MS) who underwent retrograde non-transseptal balloon mitral valvuloplasty (RNBMV).

Methods. LA and left ventricular (LV) pressure were simultaneously recorded from a double-tip micromanometer introduced retrogradely into the LA using a steerable cardiac catheter developed in our institution (Cordis Europa 5RE-699). We have applied real-time two-dimensional echocardiographic imaging with automatic boundary detection (HP Sonos 2500) for the estimation of LA and LV area changes. The LV chamber stiffness constant (α) was calculated by fitting the pressure (P) and the area (A) data during diastole to the exponential function $P = bxe^{\alpha A}$. In NLS and in CHF measurements were repeated at baseline, and after right atrial pacing and dobutamine infusion at equal heart rates. In MS, measurements were obtained at baseline and after RNBMV at equal pacing rates.

Results. The LA systolic pressure curve consisted of two positive waves: a first wave (A) and a second wave (A_r) influenced by wave reflection from the left ventricle.

		A (mmHg)	A_r (mmHg)	A_r/A	α (cm^{-2})	LVEDP (mmHg)
NLS	Baseline	11.8 ± 3.8	8.7 ± 2.4	0.74 ± 0.15	0.21 ± 0.11	8.7 ± 2.5
	Pacing	13.8 ± 2.7	12.1 ± 2.2	0.88 ± 0.17$^{\$}$	0.25 ± 0.14$^{\$}$	10.1 ± 3.1$^{\$}$
	Dobutamine	15.1 ± 2.8	10.3 ± 2.5	0.69 ± 0.14*	0.15 ± 0.01*	7.2 ± 1.8$^{\$}$
CHF	Baseline	15.1 ± 6.3	16.9 ± 3.1	1.12 ± 0.25	0.33 ± 0.10	16.3 ± 4.2
	Pacing	17.6 ± 2.5	21.0 ± 3.4	1.19 ± 0.21$^{\$}$	0.38 ± 0.18$^{\$}$	17.1 ± 3.1
	Dobutamine	16.2 ± 3.1	15.3 ± 2.6	0.94 ± 0.19*	0.28 ± 0.09*	15.0 ± 2.2$^{\$}$
MS	Baseline	27.0 ± 3.1	30.6 ± 4.1	1.13 ± 0.26	0.24 ± 0.38	9.0 ± 3.1
	RNBMV	16.5 ± 2.2$^{\$}$	14.8 ± 3.3	0.90 ± 0.21*	0.16 ± 0.22$^{\$}$	9.4 ± 4.1

LVEDP = left ventricular end-diastolic pressure. $^{\$}p < 0.05$, $^{*}p < 0.01$ and $^{*}p < 0.001$ for comparisons between baseline and pacing and between pacing and dobutamine in NLS and in CHF and between baseline and RNBMV in MS.

Mitral valve area was significantly increased after RNBMV in MS (from 0.9 ± 0.2 to 2.1 ± 0.5 cm^2). The A_r/A was linearly related with a and LVEDP in all circumstances.

Conclusions. The second (A_r) wave might be attributed to the increased reflection associated with increased LVEDP and intrinsic LV stiffness. The primary determinant of the A_r/A is the elasticity of the LV myocardium.

P1165 Effects of valsartan and enalapril on left ventricular diastolic function in patients with mild to moderate essential arterial hypertension

A. Cuocolo[1], R. Izzo[1], G. Iovino[1], G. Storto[1], M. Damiano[1], F. Bertocchi[2], J. Mann[2], B. Trimarco[1]. [1]*University Federico II, Naples, Italy;* [2]*Novartis Pharma, Basle, Switzerland*

This study investigated the effects of valsartan, a new AT1 angiotensin II receptor blocking agent, on left ventricular (LV) diastolic function assessed by a radionuclide ambulatory monitoring system (Vest) in comparison with those of the ACE-inhibitor enalapril. The study involved 24 patients (16 men, mean age 47 ± 8 yrs) with mild to moderate essential arterial hypertension and with no evidence of LV hypertrophy at echocardiography. All of the patients underwent Vest under control conditions at rest and during an upright bicycle exercise test before and at the end of each 4-week treatment period during which valsartan (80–160 mg/die p.o.) and enalapril (20–40 mg/die p.o.) were given according to a double-blind, cross-over design. At baseline, LV peak filling rate (PFR) at rest was normal (>2.5 EDV/s) in 12 patients (group A) and impaired (<2.5 EDV/s) in the remaining 12 (group B). The two groups of patients did not differ with respect to age, sex, heart rate, blood pressure and LV systolic function at baseline. In both groups, valsartan and enalapril induced a significant and comparable reduction in systolic and diastolic blood pressure. In group A, neither valsartan nor enalapril induced any significant change in PFR at rest and or peak exercise. In group B, valsartan induced a significant increase of PFR at rest (from 2.0 ± 0.3 to 2.4 ± 0.3 EDV/s, $p < 0.01$) and at peak exercise (from 4.0 ± 1.0 to 4.4 ± 20.3 EDV/s, $p < 0.05$), but PFR remained unchanged after enalapril at rest (2.0 ± 0.4 EDV/s, p = ns vs baseline and $p < 0.01$ vs valsartan) and peak exercise (3.7 ± 1.1 EDV/s, p = ns vs baseline and $p < 0.05$ vs valsartan). In conclusion, valsartan-induced renin angiotensin system blockade improves LV filling in patients with mild to moderate essential arterial hypertension and impaired diastolic function. These findings support the hypothesis that the renin-angiotensin system plays a role in the control of diastolic function in these patients.

P1166 Acute improvement in diastolic function with DDD pacing in hypertrophic obstructive cardiomyopathy

J.C. Tascon, A. Albarran, F. Hernandez, M. Alonso, J. Andreu, R. Coma[1], J. Rodriguez[1], R. Gascuena, M. Lazaro, P. Hernandez. *Cardiology Dept, Hospital 12 de Octubre, Madrid;* [1]*Coronary Care Unit, Hospital 12 de Octubre, Madrid, Spain*

Objective: Evaluate the hemodynamic and angiographic patterns of diastolic function in hypertrophic obstructive cardiomyopathy during DDD pacing.

Methods: 36 patients (13 male), mean age 64 ± 12 years, in NYHA functional class III-IV despite medical therapy, were treated with sequential DDD pacing. The hemodynamic study basally and after pacing evaluated left ventricle (LV) outflow tract peak and mean gradients, LV and RV end-diastolic pressures, mean capillary wedge, pulmonary and right atrial pressures, as well as cardiac output. The angiographic study analyzed the early LV filling at 30% and at 50% of diastole, the final LV filling (late 50%) and the presence of mitral regurgitation. Results are shown in the table.

Results

	Basal	DDD Pacing	P
Peak gradient	94 ± 37	37 ± 26	<0.001
Mean gradient	52 ± 22	19 ± 16	<0.001
LV end-diastolic	22 ± 6	15 ± 5	<0.001
Mean wedge	20 ± 7	15 ± 6	<0.001
Pulmonary diastolic	21 ± 7	16 ± 7	<0.001
RV end-diastolic	8 ± 4	7 ± 4	<0.01
Mean right atrium	7 ± 3	6 ± 4	<0.01
Cardiac output	3.8 ± 1.2	4.1 ± 1.1	<0.05
30% early filling	42 ± 11	52 ± 11	<0.001
50% early filling	64 ± 10	76 ± 9	<0.001
50% late filling	36 ± 10	24 ± 9	<0.001
Mitral regurgitation	1.5 ± 1.2	0.8 ± 1	<0.001

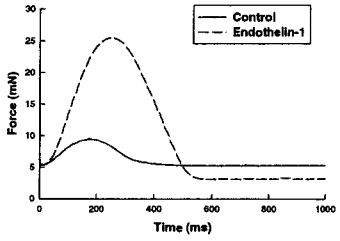
Conclusions: Sequential A-V pacing improves LV diastolic function and achieves a decrease in biventricular filling pressures. Cardiac output is not reduced during pacing. These hemodynamic and angiographic patterns and the associated decrease in LV outflow tract gradients and mitral regurgitation do suggest a beneficial effect in NYHA functional class.

P1167 Endothelin-1 increases myocardial distensibility in conditions of cardiac overload

A.F. Leite-Moreira, A. Rocha-Sousa. *Laboratory of Physiology, Faculty of Medicine, Porto, Portugal*

Endothelin-1 (ET-1) has vasoconstrictor, growth promoting and positive inotropic properties, with increased plasma levels in heart failure. The present study investigated the less well-known effects of ET-1 on the diastolic properties of the myocardium.

The effects of ET-1 (10 nM) were tested in isolated rabbit papillary muscles (Krebs-Ringer; 1.25 mM Ca^{2+}; 35°C) in the absence (n = 9) and in the presence (n = 5) of a non-selective endothelin receptor antagonist, PD145065. Isotonic, afterloaded and isometric twitches were recorded and analysed. Parameters for isometric contractions included: resting tension at the beginning and at the end of the twitch, active tension (AT) and peak rates of tension development (+dT/dt) and tension decline (−dT/dt). Significant results (mean ± SE, $p < 0.05$) are given, expressed as% change from baseline.



In isometric twitches (figure) ET-1 induced an increase of AT (147 ± 33%), +dT/dt (154 ± 39%) and −dT/dt (145 ± 38%). In addition, after ET-1, resting tension at the end of the isometric twitch decreased by 19 ± 3%, when compared to control and to its value at the beginning of the twitch. This effect was observed in all afterloaded twitches. It increased with afterload and was maximum in the isometric twitches. All these effects of ET-1 were abolished by PD145065.

In conclusion, this study showed that ET-1 has a novel effect on the diastolic properties of the myocardium. It decreases resting tension, or conversely increases myocardial distensibility, when afterload is elevated. Based on these results it is tempting to suggest that, in addition to hypertrophy, ET-1 might play a role in ventricular remodelling by contributing to cardiac dilatation, as for instances, in heart failure, where cardiac overload is known to be present.

P1168 Right and left ventricular diastolic function in systemic lupus erythematosus: the influence of antiphospholipid antibodies

I. Moyssakis, F. Triposkiadis, K. Boki, T. Doduras, P. Vlahoyannopoulos, M. Gofa, G. Anastasiades, M. Kyriakidis. *University of Athens, Medical School, Department of Pathologic Physiology; Department of Cardiology, "Laikon" Hospital, Athens, Greece*

Background: Cardiac associations of the antiphospholipid (APL) antibodies include valvular abnormalities, coronary occlusion and cardiomyopathy. The present study examined whether right ventricular (RV) and left ventricular (LV) diastolic dysfunction precedes LV systolic dysfunction in APL(+) patients (pts) with systemic lupus erythematosus (SLE) and no clinically apparent heart disease.

Methods: Twenty four APL(+) (22 female, 2 male, age 41 ± 12 years) and 31 APL(−) (30 female, 1 male, age 43 ± 16 years) with cardiac asymptomatic SLE and preserved LV function (LV fractional shortening > 33%) were echocardiographically evaluated. Parameters measured included LV dimensions, early and late atrioventricular (AV) flow velocities (E and A wave respectively), E/A ratio, deceleration time (DT), and isovolumic relaxation time (IVRT-time from semi-lunar valve closure to AV valve opening).

Results (unpaired t-test): Heart rate (beats/min) was similar in the two groups (81 ± 9 vs 78 ± 11, p = NS). RV E/A was lower (0.9 ± 0.18 vs 1.05 ± 0.2, $p < 0.05$) while RVDT (155 ± 13 vs 141 ± 23 msec, $p < 0.01$) and RVIVRT (59 ± 11 vs 50 ± 15 msec, $p < 0.05$) were greater in APL(+) compared to APL(−) pts. Likewise, the LV E/A ratio was lower (1 ± 0.25 vs 1.2 ± 0.32, $p < 0.05$) while LVDT (163 ± 24 vs 150 ± 20 msec, $p < 0.05$) was prolonged in APL(+) compared to APL(−) pts. The LVIVRT was similar in the two groups (82 ± 11 vs 79 ± 13 msec, p = NS).

Conclusions. APL antibodies in cardiac asymptomatic SLE pts with preserved LV systolic function are associated with redistribution of AV flow from early to late diastole and prolongation of RV and LV DT as well as RV isovolumic relaxation. These findings indicate that RV and LV diastolic dysfunction may precede LV systolic dysfunction in APL(+) patients with SLE.

P1169 Decreased Ca,ATPase activity: supposed mechanism of left ventricular diastolic dysfunction and possibility of its pharmacological correction

G.V. Simonia, N.I. Tatishvili, I.M. Jashi[1]. *Department of Internal Medicine, State Medical University, Tbilisi; [1]Institute of Clinical and Experimental Cardiology, Tbilisi, Georgia*

Left ventricular diastolic dysfunction is thought to be associated with impaired intracellular Ca homeostasis. The study was designed to determine membrane Ca,ATPase activity in patients with diastolic dysfunction and to assess the effect of lisinopril therapy on Ca pump.

Methods: A total of 28 patients (21 males, 7 females, mean age 59 ± 6 yrs) with left ventricular diastolic dysfunction were examined. Age matched control group included 16 healthy subjects. Diastolic dysfunction was detected Doppler-Echocariographically (E/A, deceleration time). All of examined patients were found to have normal systolic function. Ca,ATPase activity was measured in red blood cell membrane by the method of Raess and Vincenzi, before and after 4-week lisinopril therapy (10–20 mg/24 h).

Results: Baseline levels of Ca,ATPase activity in patients with diastolic dysfunction were significantly decreased compared to that of healthy subjects (0.81 ± 0.07 mcmol Pi/mg*h vs 1.22 ± 0.08 mcmol Pi/mg*h, $p < 0.01$) and positively correlated to the level of diastolic filling ($r = 0.64$, $p < 0.01$). After lisinopril administration Ca,ATPase activity significantly increased (0.92 ± 0.06 mcmol Pi/mg*h vs 0.78 ± 0.06 mcmol Pi/mg*h, $p < 0.05$) and was related to the improvement of diastolic filling, however did not achieve normal level.

Conclusion: Ca,ATPase activity could be considered as a marker for left ventricular dysfunction and indicates the possible role of this enzyme in the impairment of diastolic filling. Lisinopril may be a valuable medicine for correction of Ca,ATPase dysfunction.

P1170 L-NAME-induced hypertension: novel adaptation to systolic load in the absence of hypertrophy due to enhanced contractility and left ventricular concentric remodelling

J. Bartunek[1,2], E.O. Weinberg[2], P.S. Douglas[2], B.H. Lorell[2]. *[1]Cardiovascular Center, Aalst, Belgium; [2]Cardiovascular Division, Beth Israel Deaconess Medical Center, Boston MA, USA*

L-NAME, which inhibits nitric oxide synthesis, causes hypertension and is associated with a blunted LV growth response to pressure overload. This would be expected to cause heart failure. We utilized L-NAME-induced hypertension to test the hypothesis that successful adaptation to pressure overload occurs even when hypertrophy is suppressed.

Male rats were treated with L-NAME 50 mg/kg/day or no drug (C) for 6 weeks. The systolic wall stress (WS), relative wall thickness (RWT) and hypertrophy were also compared with aortic stenosis (AS) rats 6 weeks after the banding. LV calcium-dependent contractile reserve was measured in perfused hearts and isolated myocytes.

Systolic WS and RWT (LV diameter/2× posterior wall thickness) were increased and similar in L-NAME and AS rats. Despite of that, L-NAME rats showed a blunted increase in LV/body weight (BW) ratio ($^*p < 0.05$ vs C).

	C	L-NAME	AS
WS (kdyn/cm^2)	37 ± 4	85 ± 19*	92 ± 16*
LV/BW (g/kg)	2.1 ± 0.1	2.3 ± 0.1	4.3 ± 0.8*
RWT (mm/mm)	37.5 ± 5	51 ± 4*	51 ± 3*
LV EDD (mm)	8.9 ± 0.1	7.7 ± 0.3*	8.8 ± 0.5
LV devP/g (mmHg/g)	95 ± 6	143 ± 8*	113 ± 7

Nevertheless, L-NAME rats showed preserved LV developed pressure/g (LVdevP/g). This was maintained by a decrease of in vivo LV chamber dimension relative to wall thickness and augmented myocyte calcium-dependent contractile reserve. Thus, when the expected compensatory hypertrophic response is suppressed during L-NAME-induced hypertension, chronic pressure overload is associated with a successful adaptation to maintain systolic performance which depends on both LV remodeling and enhanced contractility.

P1171 Atrio-ventricular coupling in normals and in patients with left ventricular dysfunction: analysis based on pressure-volume relation

J. Dernellis, C. Stefanadis, N. Giatrakos, K. Tentolouris, A. Michaelides, P. Toutouzas. *Department of Cardiology, University of Athens, Athens, Greece*

Left ventricular (LV) input impedance is a definition of left atrial (LA) afterload, which is far less dependent on preload than are pressure and stress. LV input impedance can be calculated by the ratio of the LA end-systolic pressure to stroke volume (P_{es}/SV). With each ejection LA matches systolic force generation with the LV load. Thus, the atrio-ventricular coupling can be assessed by the effective LV elastance to LA end-systolic elastance ratio (E_{LV}/E_{es}). In a model heart, optimal transfer of work is predicted to occur when the E_{LV}/E_{es} ratio is equal to 1.

Methods: We performed echocardiographic assessment of LA volumes simultaneously with recordings of pulmonary wedge pressures in 30 patients. Ten patients had no structural or functional LV abnormalities, 10 had a recent myocardial infarction with LV dysfunction and 10 suffered from congestive heart failure (CHF). Pressure-volume loops were obtained at baseline and during increases in LA pressure produced by normal saline infusion. LA afterload was estimated by E_{LV} and atrioventricular coupling was calculated by E_{LV}/E_{es} ratio.

Results: The LA afterload was progressively increased in patients with myocardial infarction and in patients with CHF compared with controls ($p < 0.001$). E_{LV}/E_{es} ratio increased gradually as LV function deteriorated (controls: 1.01 ± 0.12, myocardial infarction: 1.41 ± 0.15 and CHF: 6.11 ± 0.84, $p < 0.001$).

Conclusions:. In normal subjects LA matched systolic force generation with the ventricular load. In contrast, in patients with myocardial infarction atrio-ventricular coupling was defective despite the increased stroke work. In patients with CHF there was a totally abnormal atrio-ventricular coupling associated with a considerable waste of energy. This could be another mechanism for LA lack of adaptation in this setting.

P1172 A quantitative analysis of nitrotyrosine in myocardium and serum in advanced human heart failure

E.J. Birks, D. Hunt, N.R. Banner, M.H. Yacoub. *National Heart and Lung Institute at Imperial College of Science, Technology and Medicine, London, UK*

We and others have previously reported iNOS expression in the myocardium of patients with severe heart failure. The functional significance of these findings and the relationship to myocardial dysfunction remain unclear. NO reacts with superoxide radicals to produce the highly toxic peroxynitrite which can result in tissue damage. In small amounts, however, peroxynitrite may be beneficial. Peroxynitrite nitrates tyrosine residues and can be detected by measuring nitrotyrosine. In an attempt to quantify nitrotyrosine levels in heart failure we developed a nitrotyrosine ELISA to quantitate nitrotyrosine in myocardium. Twenty two patients with end stage heart failure and 9 normal donors were studied. Donor hearts were assessed prior to retrieval by transoesophageal echocardiography and ejection fraction was determined to be >55%. Nitrotyrosine levels were also measured in the serum of 26 patients with end stage heart failure and 5 normal controls. Mean myocardial nitrotyrosine levels in end stage heart failure (0.47 ± 0.07 ng/ml) were significantly greater than in donor heart (0.32 ± 0.01 ng/ml), $p < 0.05$. Mean serum nitrotyrosine was lower in end stage heart failure (10.24 ± 0.03 ng/ml) than in normal controls (0.44 ng/ml), $p < 0.05$. In conclusion this study has demonstrated for the first time markedly elevated nitrotyrosine in the myocardium of patients with heart failure suggesting a role for peroxynitrite in the pathogenesis of heart failure. These findings need to be evaluated further.

P1173 Myocardial mRNA expression of insulin-dependent transmembrane glucose transporter is increased in human insulin-dependent diabetes mellitus and decreased in non-insulin-dependent diabetes mellitus

H. Brussee[1], S. Barth[3], W. Klein[1], I. Friehs[4], B. Rigler[2], R. Gasser[1]. *Depts. of [1]Cardiology; [2]Cardiac Surgery; [3]Medical Biochemistry, University of Graz, Austria; [4]Dept. of Cardiac Surgery, Harvard University, Boston MA, USA*

Transmembrane glucose transport and thus cellular high energy metabolism of the cardiovascular system depend largely on the insulin resposnsive GLUT 4 isoform of the transmembrane glucose transport molecule. Several authors have shown, that, in animals, myocardial GLUT 4 mRNA expression is decreased in experimental diabetes. There are no data on humans as yet.

Here we investigate probes (60–150 mg) of right atrial auricle from diabetic and non diabetic patients subjected to cardiac surgery which were snap frozen in liquid NO and stored at −70°C until homogenisation. Total RNA was isolated using guanidium thiocyanate, phenol-chloroform extraction and alcohol precipitation (for details see our earlier paper Mol Cell Biol 8: 2394–2400, 1988). Total RNA was hybridised with 32P labelled human GLUT 4 cDNA and re-hybridised with a human G3PDH cDNA probe to correct for equal amounts of RNA. Quantification was performed by a laser scanner and is expressed in optical densities.

Our results represent the first measurements of GLUT 4 mRNA in human myocardial tissue. Seven patients had NIDDM (determined by OGT, HbA1C, and insulin secretion), 7 had IDDM and 7 served as controls. GLUT 4 mRNA expression was 97.0 ± 10.4 ($\pm$ SEM) in the control group, 133.3 ± 15.2 in the IDDM group and 49.1 ± 6.2 ($\pm$ SEM) in the NIDDM group.

In summary, GTUT 4 isoform mRNA expression is increased in IDDM patients, but decreased in NIDDM patients. From these data, one can deduce that DM is initially associated with a decreased GLUT 4 expression, the latter then being upregulated by external application of insulin.

P1174 Inotropic effects of endothelin in isolated myocytes from human atrial and ventricular myocardium

S. Schmidt-Schweda, C. Rummer, H. Möllmann, S. Kamenzin, J. v. Burstin, S. Wollner, Ch. Holubarsch. *University of Freiburg, Germany, Dept. Cardiology & Angiology*

Endothelin (ET) and its blockade may play a major role in pathophysiology and therapy of congestive heart failure. We investigated the effect of ET on shortening of enzymatically isolated human myocytes ("chunck"-method) from right atrial myocardium (EF $57 \pm 2\%$, coronary bypass-surgery, n = 20, 16 patients) and ventricular myocardium (3 nonfailing donor hearts, n = 3; 27 explanted failing hearts, EF $22 \pm 1.5\%$, n = 48). The cells were electrically stimulated at 0.2 Hz (32°C, 1.25 mM extracellular calcium).

ET increased the fractional shortening in atrial myocytes from 3.7% to maximally $7.3 \pm 1.2\%$ at 10^{-8} M ($p < 0.05$ at 10^{-10} M). This effect was blocked by the ET_A-receptor-antagonist BQ 123 (10^{-7} M). In a small number of nonfailing left ventricular cells, ET seemed to have also a small inotropic effect (from $2.2 \pm 0.4\%$ to $3.5 \pm 0.7\%$ at ET 10^{-8} M). In contrast, ET exerts no inotropic effect in failing ventricular myocytes, neither at 2.5 mM, nor at 1.25 mM extracellular calcium. After lowering the pH-value from 7.4 to 7.0, ET was able to increase the shortening in failing left ventricular cardiomyocytes (from $4.7 \pm 0.7\%$ to $7.9 \pm 1.1\%$, $p < 0.05$). This effect was completely reversed by increasing the pH-value again and was blocked by preincubation with amilorid (10^{-6} M). Control experiments with 10^{-7} M isoproterenol (from $3.2 \pm 0.3\%$ to $7.9 \pm 0.4\%$) and increasing extracellular calcium-concentrations (from 3.7 ± 0.4 to $13.5 \pm 1.3\%$ at 15 mM) demonstrated the preserved β-receptor-function and contractile reserve. Whereas the efficiency and potency of ET in atrial myocytes is much higher than in intact muscle strip preparations, the inotropic effect in the intact ventricular preparations seems to be mediated by an acidosis of the core. Furthermore, therapeutical blockade of ET in congestive heart failure is thought to have no negative effect with respect to contractile function.

P1175 The inotropic effect of endothelin-1 in human myocardium does not depend on Ca^{2+}-release from the sarcoplasmic reticulum

L.S. Maier, M. Zirnig, J. Weisser, B. Pieske. *Abt. Kardiologie und Pneumologie, Zentrum Innere Medizin, Göttingen, Germany*

The endothelin (ET) system seems to be of pathophysiological relevance for human heart failure. In isolated human myocardium, a positive inotropic effect of ET-1 was described but whether this depends on increased intracellular Ca^{2+}-transients or myofilament sensitivity is uncertain. We investigated the influence of ET-1 on twitch force and intracellular Ca^{2+}-transients.

Methods: Isolated muscle strips from end-stage failing human hearts and nonfailing rabbit hearts for comparison. Electrical stimulation, isometric contractions (1 Hz, 37°C). Simultaneous measurement of twitch force and intracellular Ca^{2+}-transients using Fura-2/AM for: 1.) ET-1 (0.1 μM), 2.) ET-1 after blocking sarcoplasmic reticulum (SR) Ca^{2+}-storage function with cyclopiazonic acid (CPA)/ryanodine (10 μM) and 3.) ET-1 after blocking L-type Ca^{2+}-channels with diltiazem (3 and 30 μM, respectively).

Results: 1.) In failing human myocardium ET-1 (n = 14) increased twitch force by $47 \pm 7\%$ and the Fura-signal slightly by $7 \pm 2\%$ ($p < 0.05$). 2.) CPA/ryanodine (n = 9) reduced basal twitch force by $25 \pm 4\%$ and the Fura-signal by $37 \pm 4\%$ ($p < 0.05$). Addition of ET-1 in the presence of CPA/ryanodine increased twitch force by $49 \pm 13\%$ ($p < 0.05$) without changes in the Fura-signal. 3.) Diltiazem (n = 5) decreased twitch force by $27 \pm 4\%$ and the Fura-signal by $17 \pm 5\%$ ($p < 0.05$). ET-1 in the presence of diltiazem increased twitch force by $23 \pm 7\%$ ($p < 0.05$) without changes in the Fura-signal. Similar changes were found in rabbit myocardium except for a stronger increase in twitch force by ET-1 after diltiazem.

Conclusions: The positive inotropic effect of ET-1 in human and rabbit ventricular myocardium does not depend on SR Ca^{2+}, but mainly results from increased Ca^{2+}-responsiveness of the myofilaments. Moreover, increased extracellular Ca^{2+}-influx may contribute to the positive inotropic effect in failing human but not in rabbit myocardium.

P1176 Activation of c-Jun N-terminal kinases and p38-mitogen-activated protein kinases in heart failure secondary to ischaemic heart disease

S.A. Cook, P.H. Sugden, A. Clerk[1]. *Cardiac Medicine, National Heart and Lung Insititute, London; [1]Division of Biomedical Sciences, Imperial College School of Medicine, London, UK*

Three mitogen-activated protein kinase (MAPK) subfamilies are expressed in rodent and rabbit hearts and are activated by pathophysiological stimuli. The role(s) of these MAPKs in the pathology of the heart is unclear, but they have been implicated in cardiac myocyte hypertrophy and apoptosis in the rat. We have determined and compared the expression and activation of these MAPKs in donor and failing human hearts.

Methods: Samples were taken from the left ventricles of 4 unused donor hearts and 12 explanted hearts from patients with heart failure secondary to ischaemic heart disease. Total MAPKs or dually-phosphorylated (activated) MAPKs were detected by Western blotting. MAPK activities were measured by in gel kinase assays. Bands were quantified using laser scanning densitometry.

Results: As in the rat heart, c-Jun N-terminal kinases (JNKs) were detected in human hearts as bands of 46 kDa and 54 kDa, p38-MAPK(s) was detected as a 40 kDa band, and extracellularly-regulated kinases, ERK1 and ERK2, were detected as 44 and 42 kDa bands respectively. The total amounts of 54 kDa JNK, p38-MAPK and ERK2 were similar in all samples, although 46 kDa JNK was reduced in the failing hearts. Mean activities of JNKs and p38-MAPK(s) were significantly higher in failing heart samples than in donor heart samples ($P < 0.05$). There was no significant difference in phosphorylated (activated) ERKs between the two groups.

Conclusions: These results demonstrate that JNKs, p38-MAPK(s) and ERKs are expressed in the human heart. The activities of the "stress-regulated" MAPKs (the JNKs and p38-MAPKs), but not the ERKs, were increased in heart failure secondary to ischaemic heart disease. These data indicate that JNKs and p38-MAPKs may be important in human cardiac pathology.

P1177 Cardiac functional changes to low- and high-dose dobutamine after anthracycline therapy in patients with acute leukaemia

S.S. Ogawa, Y. Katsube, T. Seki, T. Ohkubo, Y. Kuramochi, D. Fukumi, Y. Uchikoba, Y. Hino. *Department of Pediatrics, Nippon Medical School, Tokyo, Japan*

To test whether cardiotoxity could be detected by dobutamine (DOB) stress test, we measured and calculated left ventricular systolic and diastolic indices by findings of 2-D echo and pulsed doppler. 26 patients who had acute leukemia after therapy off, aged 7 y 6 m–19 y 8 m were divided into three groups; without ATC therapy group (N group) (n = 7), small ATC group (S group) (n = 7, ATC < 300 mg/m^2), moderate ATC group (M group) (n = 12, ATC ≥300 – ≤860 mg/m^2) based on our previous report that cardiac function reduced more ATC therapy dosed more than 300 mg/m^2. Test were performed 2–3 years later after therapy off. Left ventricular ejection fraction (EF), heart rate corrected mean velocity of the circumferential fiber shortening (mVcfc), and the ratio of left ventricular systolic wall stress and end-systolic ventricular volume index (ESS/ESVI) were measured and calculated as a systolic functional index by 2-D echo. The ratio of maximum early filling peak velocity and atrial contraction peak velocity (E/A) was measured and calculated as a diastolic functional index by echocardiac pulsed doppler. DOB was administered starting at 5 μg/kg/min (γ) for 3 minutes up to 30 γ. We considered that the ratio of values at rest and 5 γ represented as a inotropic changes of cardiac function, and ratio of values at rest and 30 γ represented as a cardiac functional reserve. All indices were calculated and compared among three groups.

Results:

	DOB 5 γ/rest			DOB 30 γ/rest		
	N group	S group	M group	N group	S group	M group
EF	1.1 ± 0.3	1.2 ± 0.1	1.1 ± 0.3	1.2 ± 0.3	1.2 ± 0.1	1.1 ± 0.1
mVcfc	1.1 ± 0.1	1.2 ± 0.1	1.1 ± 0.1	1.8 ± 0.3	1.9 ± 0.4	1.9 ± 0.5
ESS/ESVI	1.1 ± 0.1	1.2 ± 0.1	1.1 ± 0.1	1.7 ± 0.1	1.6 ± 0.2	1.2 ± 0.1*
E/A	1.0 ± 0.2	1.0 ± 0.1	1.1 ± 0.1	0.7 ± 0.1	0.6 ± 0.1	0.6 ± 0.1

*$p < 0.05$ vs. other groups

Conclusions: Changes of cardiac function to low dose DOB were no significant differences among 3 groups. On the other hand, cardiac functional reserve was significantly reduced after ATC therapy dosed more than 300 mg/kg/m^2. Thus, DOB stress test will be helpful for detection of cardiotoxity after ATC therapy.

P1178 Endogenous endothelin-1 causes a positive inotropic effect after selective endothelin$_A$ receptor blockade

M.E. Beyer, T. Hövelborn, H.M. Hoffmeister. *Medical Dept. III, University of Tübingen, Tübingen, Germany*

The vasoconstrictor endothelin-1 (ET-1) is involved in the development of atherosclerosis. Thus ET-receptor blockade may have an atheroprotective action. The effects of ET-1 are mediated by ET_A- and ET_B-receptors. We demonstrated in previous *in vivo* studies that activation of ET_B-receptors causes a positive inotropy while ET_A-receptors are mainly responsible for the vasoconstrictive effects of ET-1. Furthermore selective ET_A-blockade has a slight positive inotropic effect. This study examined whether this positive inotropic effect of a selective ET_A-blockade is mediated by endogenous ET-1 (via ET_B-receptors).

In open-chest rats the acute effects of the selective ET_A-antagonist BQ 610 (0.15 μmol/kg) were tested without and after inhibition of the ET-1 synthesis by 10 mg/kg phosphoramidon in comparison to NaCl-controls. Additionally to measurements in the intact circulation isovolumic measurements (isovol. LVSP, isovol. dp/dt$_{max}$) were performed for quantification of myocardial contractility.

	Without phosphoramidon		With phosphoramidon	
	BQ 610	NaCl	BQ 610	NaCl
Cardiac output	126 ± 3†	111 ± 1	116 ± 5	117 ± 5
Peripheral resistance	86 ± 2*	94 ± 1	93 ± 3	94 ± 3
Isovol. LVSP	100 ± 1*	96 ± 1	98 ± 1	98 ± 1
Isovol. dp/dt$_{max}$	106 ± 2*	100 ± 1	101 ± 2	98 ± 2

Mean ± SEM in % of preinfusion values; * = $p < 0.05$, † = $p < 0.01$ vs. NaCl.

BQ 610 causes vasodilatation with a consecutive increase of the cardiac output. Furthermore selective ET_A-blockade by BQ 610 causes a positive inotropic effect. These effects of BQ 610 are completely abolished after inhibition of the ET-1 synthesis by phosophoramidon.

Conclusions: The positive inotropic effect of selective ET_A-blockade is mediated by endogenous ET-1 via ET_B-receptors, since inhibition of endogenous ET-1 synthesis by phosphoramidon completely prevents this effect.

P1179 Influence of angiotensin II on the interaction of human cardiac fibroblasts with collagen I matrices

M. Neuß, K. Kappert, V. Regitz-Zagrosek, K. Graf, E. Fleck. *Charite, Campus Virchow Hospital, HU Berlin; DHZB, Berlin, Germany*

The healing process after a myocardial infarction entails the migration and proliferation of cardiac fibroblasts into the infarcted region. To investigate the role of angiotensin II (ang II) in this process we isolated human cardiac fibroblasts and analysed the effect of ang II. on adhesion and migration on collagen matrices.

Human cardiac fibroblasts were isolated from explanted, end-stage failing human hearts and used in passage 1 for the experiments. By immunochemistry and FACS-analysis fibroblasts were shown to express α1-, α2-, β1- and β3-integrins. By inhibition by previous incubation with P5D2 the adhesion of human cardiac fibroblasts on a collagen matrix (20 μg/ml) was shown to be β1-integrin mediated (n = 3, $p < 0.0001$ vs. control). For the analysis of the influence of ang II on the migration of human cardiac fibroblasts, cells were serum-deprived and seeded into collagen-coated (20 μg/ml), modified Boyden-chambers. Ang II stimulated in a dose- and time-dependent manner the migration of human cardiac fibroblasts (n = 5; 16 h: 10 nM 22.3 ± 7.1%, 100 nM 38.5 ± 6.4%, 1 μM 112.5 ± 8.7%). Pre-incubation with the map-kinase inhibitor PD 98059 (10 μM) or with the AT1-blocker irbesartan significantly inhibited the migration in response to angiotensin II (n = 3). By incubation with increasing concentrations of P5D2 the influence of ang II on the β1-mediated adhesion on collagen I (20 μg/ml) was analysed. Ang II was shown to increase dose-dependently via AT1 the β1-mediated interaction of human cardiac fibroblasts with a collagen I matrix.

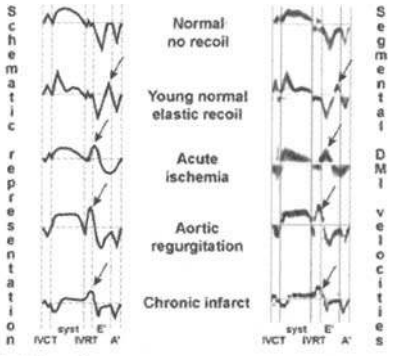
In conclusion angiotensin II influences via AT1-receptor the interaction of human cardiac fibroblast with collagen matrices via β1-integrins. The map-kinase is involved in the signal transduction cascade.

P1180 Abnormal segmental diastolic long-axis motion towards the apex – diastolic contraction, elastic recoil or induced by a haemodynamic event? The clinical role of strain rate imaging

B. Bijnens, F. Jamal, T. Kukulski, M. Szilard, J. D'hooge, F. Van de Werf, G. Sutherland. *Cardiology Dept., Univ. Hospital Gasthuisberg, Leuven, Belgium*

Doppler Myocardial Imaging (DMI) segmental velocity profiles can identify abnormal regional myocardial motion but cannot define the underlying pathologic mechanisms. Recent studies have shown acute ischaemia to produce early/mid diastolic contraction in the affected segment. This may be identified by DMI as a region of abnormal base apex motion during early diastole. However, abnormal diastolic base apex motion may occur passively due to a number of differing mechanisms. Potentially, Regional myocardial Strain Rate(RSR) derived from the Colour DMI data sets acquired at high frame rate (>140 f.p.s.) can be used to differentiate overall wall motion with no segmental contractile function from motion due to active contraction. To determine the potential clinical role of this new technique a series of in vivo closed chest acute segmental ischaemic animal studies and clinical studies involving both young and older normals (the latter without abnormal diastolic motion), patients (pts) undergoing routine PTCA, pts with chronic infarction and pts with aortic regurgitation were performed to study abnormal myocardial apical motion during diastole. Four different patterns and timing of abnormal diastolic segmental apical motion were identified (figure), each related to a differing pathologic mechanism. RSR values clearly differentiated passive segmental motion due to either elastic recoil, chronic infarction or motion induced by severe aortic regurgitation (low RSR) from active contraction present in diastole in acutely ischaemic segments in both the animal and PTCA patient groups.

Figure 1 Base-apex abnormal diastolic segmental motion



Abnormal segmental diastolic motion.

We conclude that RSR measurement would appear to be an important new technique to differentiate active diastolic contraction induced by acute ischaemia from passive induced segmental motion.

P1181 Evidence for an altered functional status of the Na^+/Ca^{2+}- exchanger in contracting failing human myocardium but unchanged activity in isolated vesicles

H. Diedrichs, J. Müller-Ehmsen, R.H.G. Schwinger. *Klinik III für Innere Medizin der Universität zu Köln, Cologne, Germany*

The Na^+/Ca^{2+}-exchanger (NCX) has been suggested to compensate the altered Ca^{2+}-homeostasis in failing human myocardium through functional and expressional upregulation.

The present study aimed to investigate the function of the Na^+/Ca^{2+}-exchanger in both contracting left ventricular papillary muscle strips (PAP) and myocardial vesicles of terminally failing (DCM, dilated cardiomyopathy, NYHA IV) as compared to nonfailing (NF) human myocardium. Therefore, the effect of decreasing extracellular $[Na^+]_e$ (140 to 25 mmol/l) on force of contraction (FOC) of PAP from DCM (n = 19) and NF (n = 6) was studied. In addition, the time and Ca^{2+} dependent NCX activity was measured as Na^+-dependent $^{45}Ca^{2+}$-uptake into myocardial vesicles (NF n = 8, DCM n = 8). Decreasing $[Na^+]_e$ (which exerts its effect through alteration of the NCX driving force to extrude Ca_{2+}) enhanced contractility in DCM with higher potency than in NF (EC_{50} 73.0 vs. 45.8 mM). However, the Na^+-dependent Ca^{2+}-uptake into isolated myocardial vesicles (NCX activity) was unchanged both at different times (1–60 s, $T_{1/2}$: DCM 2.4 ± 0.3 s vs. NF 2.5 ± 0.3 s) and at different Ca^{2+}-concentrations (0.3–3000 μmol/l, t = 3 s, $K_{1/2}$: DCM 39.2 μM vs. NF 38.3 μM).

The results show a higher sensitivity of DCM to NCX dependent increases in contractility, whereas the activity of the NCX in isolated vesicles is unchanged. This observation might be explained by increased intracellular Na^+-levels due to a decreased Na^+/K^+-ATPase activity.

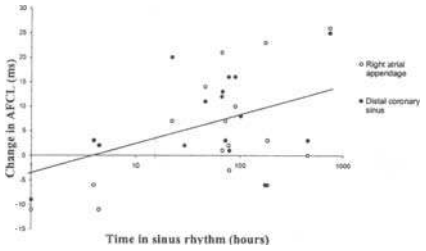
CARDIOVERSION OF ATRIAL FIBRILLATION

P1182 Magnitude of reversal of atrial effective refractoriness in man is related to duration of sinus rhythm post cardioversion

W.J.C. Hobbs, S.P. Fynn, D.M. Todd, C.J. Garratt. *Manchester Heart Centre, The Royal Infirmary, Manchester, UK*

Background: The reversability of atrial electrical remodeling in man, after termination of clinical AF has not been demonstrated. We aimed to examine this important question of reversibility using AF cycle length (AFCL) as a measure of atrial refractoriness.

Methods and Results: We measured (AFCL) at the right atrial appendage (RA) and distal coronary sinus (DCS) prior to attempted internal cardioversion in 39 patients with persistent AF. Seventeen patients were restudied acutely following recurrence of AF with repeat measurement of AFCL. There was an increase in AFCL from the initial cardioversion to that measured at the time of first AF recurrence at both the RA (161 ± 22 ms versus 167 ± 26 ms, p = 0.05) and DCS (162 ± 19 ms versus 168 ± 21 ms, p = 0.01). The magnitude of increase in AFCL was positively correlated with duration of sinus rhythm prior to AF recurrence (r = +0.524, p = 0.001).



Conclusions: These findings demonstrate that changes in atrial electrophysiology associated with chronic AF in man are reversible following cardioversion and that the extent of this reversal is dependent upon the duration of sinus rhythm post-cardioversion.

P1183 Effects of calcium-channel blockers on technical efficacy and early clinical efficacy of external cardioversion of persistent atrial fibrillation

G.L. Botto, R. Bonatti, G. De Nittis, M. Susta, F. Tettamanti, A. Politi, T. Broffoni, G. Ferrari. *Dep. of Cardiology, S. Anna Hospital, Como, Italy*

Background. Atrial fibrillation (AF) is self-perpetutating arrhythmia causes electrophysiological changes that are mediated by rate-induced intracellular calcium overload. Calcium channel blockers (CCBs) have been demonstrated to be effective in preventing atrial electrical remodeling

Aim. Was to evaluate the effect of the concomitant use of CCBs on technical efficacy of electrical cardioversion (EC) of persistent AF and on the occurrence of early relapses of the arrhythmia after successful EC.

Methods. From june '93 to december '98, 437 consecutive patients (pts) (mean age 62 ± 12 years), NYHA class I–II, experienced EC for permanent AF (mean arrythmia duration 96 ± 129 days). One-hundred-thirty-five pts (31%) were pre-treated with CCBs before EC and 48 hours after (Group A), while 302 pts (69%) didn't receive them (Group B). Pts with AD > 72 hours were anticoagulated for 3 weeks prior to EC and for 4 weeks after. We define EC technical failure (TF) the inability of interrupting AF, and EC clinical failure (CF) early relapse of AF 48 hour after successfull EC

Results. The two group were comparable in terms of age, gender, body weight, arrythmia duration, previous AF episodes, atrial dimension, left ventricular disfunction, concomitant use of antiarryhtmic or non-antiarrhythmic drugs. The prevalence of arterial ipertension (HTx) or coronary disease (CD) was higher in Group A compared to Group B (HTx 49/135 pts, 36% *vs* 74/302 pts, 25%; p < 0.05, CD 18/135 pts, 13% *vs* 15/302 pts, 5%: p < 0.0001)

	Technical Failure	Clinical Failure	Sinus Rhythm	Chi-square test p value
Group A (n = 135)	5 (4%)*	20 (15%)	110 (81%)	* = 0.047 *v* SR
Group B (n = 302)	30 (10%)	39 (13%) 233 (77%)	* = 0.043 *v* CF + SR	

Four pts (0.9%) experienced embolic events 2, 6, 8 and 13 days after successful EC while they were correctly anticoagulated.

Conclusions. The pre-treatment with CCBs is useful in reducing technical failure of persistent AF, while no effects are detectable on preventing early relapses of the arrhythmia after successful EC. More randomized studies are mandatory to confirm the present data.

P1184 Rate control versus electrical cardioversion for persistent atrial fibrillation: the RACE study design

K.A. Abhilakh Missier, I.C. Van Gelder, H.J.G.M. Crijns, J.H. Kingma, O. Kamp, H.A. Bosker, J.G.P. Tijsen. *On behalf of the RACE project group. University Hospital Groningen, Netherlands*

Persistent atrial fibrillation (AF) does not terminate spontaneously and may cause left ventricular dysfunction and thromboembolic complications. For restoration of sinus rhythm (SR) electrical cardioversion (ECV) is most effective. However, AF frequently relapses, necessitating re-ECV and institution of potentially harmful antiarrhythmic drugs. If AF is accepted, rate control and prevention of thromboembolic complications using negative chronotropic drugs and warfarin is pursued. These strategies have never been systematically compared. It is our hypothesis that serial ECV is a futile procedure in terms of reduction of morbidity and mortality, or enhancing quality of life. RACE is a randomized comparison of serial ECV (repeat ECV as soon as possible after relapse and institute serial drug therapy: sotalol, class Ic drug, amiodarone) and rate control (resting heart rate < 100 using digitalis, calcium antagonists and/or beta-blockade).

Morbidity (heart failure, side effects of drugs, thromboembolic complications, bleeding and pacemaker implantation), mortality, quality of life and cost-effectiveness are primary and secondary endpoints. Included are patients with recurrence of persistent AF, present episode < 1 year and a maximum of 2 previous successful ECVs during the last 2 years.

This study started in 1998 and aims to include 520 patients by June 1999 in approximately 35 centers across The Netherlands. All patients will be followed during during two years.

P1185 Is cardioversion for atrial fibrillation a realistic option in the elderly?

N. Lever, C.H. Davies, Y. Bashir. *Department of Cardiology, John Radcliffe Hospital, Oxford, UK*

Background: Atrial fibrillation (AF) in the elderly is associated with significant morbidity, both from increased risks of stroke and from a higher rate of bleeding complications on warfarin. However, the elderly are often not referred for DC cardioversion. Little is known about the success rates of cardioversion in this age group or the role of adjunctive amiodarone.

Method: Case note review of 162 consecutive elective admissions for first time cardioversion of AF during a 2 year period. Data was prospectively dichotomised by age equal to or greater than 75.

Results: 48 patients were ≥75 years (mean 79, range 75–87 years) whereas the remaining 114 were <75 (mean 63.5, range 33–74 years). There was no significant difference between the groups in duration of AF (5.5 Vs. 5.7 months), LA size (46 Vs. 42 mm), LV impairment, hypertension, heart failure or valvular disease.

All patients	Initial Success	6/52 Follow-up Success
<75 years old	90/114 (79%)	52/90 (58%)
≥75 years old	44/48 (92%)	29/44 (66%
Amiodarone	Initial Success	6/52 Follow-up Success
<75 years old	44/51 (86%)	29/44 (66%)
≥75 years old	30/31 (97%)	24/30 (80%)

Both acute and follow up rates of successful cardioversion were independent of age. The use of amiodarone significantly increased success at 6 weeks in both age groups ($P < 0.001$ χ-squared test).

Conclusions: Cardioversion should not be denied to patients on the grounds of age alone. Success at six weeks is significantly increased by the use of amiodarone.

P1186 Importance of the long-axis atrial dimension in patients with chronic non-valvular atrial fibrillation

H. Gurba, A. Kuch-Wocial, M. Szulc, G. Styczynski, P. Jedrusik, P. Pruszczyk, A. Torbicki[1]. *Internal Medicine and Hypertension, Medical University of Warsaw, Warsaw; [1]Internal Medicine, Lung Diseases and Tuberculosis, Warsaw, Poland*

Left atrial spontaneous echocardiographic contrast (LA SEC) indicates stasis and increased embolic risk. However, LA SEC should be searched for with transesophageal echocardiography (TEE). Therefore it would be desirable to establish a reliable indicator of LASEC which could be assessed during transthoracic echocardiografic examination (TTE).

We analyzed possible correlation between appearance or disappearance of SEC and changes of left atrial dimensions in patients after attempt of cardioversion of chronic non valvular atrial fibrillation (AF).

Sixty-one pts with chronic AF aged 60.2 ± 8.7 yrs underwent both TTE and TEE before and at least 12 month after direct current cardioversion (DCC). Initially and at follow up we evaluated dimensions of the left atrium and the presence of SEC. At follow up disappearance of SEC (+/−) occurred in pts in whom left atrium long axis diameter (LAlax) decreased while appearance of SEC (−/+) was accompanied by an increase of LA lax.

results

SEC	−/−	+/−	−/+	+/+
Pts	10	11	7	26
LAlax "0" (mm)	60.8 ± 8.3	62.0 ± 8.5	52.9 ± 8.2	63.7 ± 6.1
LAlax "12" (mm)	62.1 ± 6.5	57.5 ± 6.7	63.1 ± 4.5	67.0 ± 9.1
p	ns	<0.05	<0.05	ns

absence (−) or presence (+) of SEC (initially/at follow-up)

Conclusion: Appearance or disappearance of spontaneous echocardiografic contrast are related to the changes of left atrium long axis diameter. This may suggest that enlargement of the left atrium long axis diameter is a marker of tromboembolic risk.

P1187 Cardiac biochemical markers after cardioversion of atrial fibrillation

K. Vikenes, P. Omvik, M. Farstad, J.E. Nordrehaug. *Dept. of Heart Disease, Haukeland University Hospital, Bergen, Norway*

Cardiac biochemical markers are known to be released from necrotic myocardial orsceletal muscle after direct current (DC) shocks. The purpose of this study was to assess Troponin T and I among conventional markers after direct current cardioversion in patients with atrial fibrillation.

Methods: Fifty consecutive patients (mean age 66 range 33–81) underwent underanaesthesia 1–4 DC-shocks (mean cumulative energy 414 J, range 100–860 J). Blood samples were drawn prior to the procedure, 1–2, 6–8, and 20–24 hours after cardioversion.

Results: Table I shows that the troponins were completely unaffected by the DC-cardioversion while CK and myoglobin were considerably elevated. CK-MB mass and ASAT were elevated in 18% and 29% patients respectively 20–24 hours after cardioversion. There was a significant association between elevated CK, myoglobin and CK-MB mass and accumulated energy given; also when age and gender were adjusted for.

Table 1: Mean values of the biochemical cardiac markers before and after DC-cardioversion Numbers in brackets are the percentages of patients with values above reference value

Marker	Before	1–2 hours after	6–8 hours after	20–24 hours after	p-value for trend
Troponin I (≤0.4 ug/l)	0.11 (0)	0.12 (0)	0.11 (0)	0.10 (0)	0.935
Troponin T (≤0.4 ug/l)	0.27 (0)	0.27 (0)	0.30 (0)	0.30 (0)	0.773
CK-MB (≤5 ug/l)	1.9 (0)	2.0 (4)	3.5 (14)	3.6 (18)	<0001
Myoglobin (<90 ug/l)	35 (0)	266 (63)	448 (64)	120 (39)	<0.001
CK (male ≤ 200 U/l) (female < 150 U/l)	110 (0)	186 (18)	856 (67)	1517 (80)	<0.005
ASAT (male: 10–50 U/l) female: 10–35 U/l)	26 (0)	27 (2)	35 (7)	50 (29)	<0.001
LD (>70 yr: <650 U/l) (<70 yr: <450 U/l)	414 (0)	394 (2)	435 (2)	475 (2)	<0.001
Ratio CK-MB/CK*100 (reference value < 3)	1.85 (0)	1.45 (0)	0.91 (0)	0.71 (0)	<0.001

In conclusion, only the Troponin I and/or T are reliable markers of myocardial necrosis in patients undergoing direct current cardioversion of arrhytmias.

P1188 Does successful cardioversion favorably affects the left heart in chronic non-valvular atrial fibrillation? Long-term echocardiographic follow-up

H. Gurba, A. Kuch-Wocial, M. Szulc, G. Styczynski, P. Pruszczyk, A. Torbicki[1].
Internal Medicine and Hypertension, Medical University of Warsaw, Warsaw; [1]Internal Medicine, Lung Diseases and Tuberculosis, Warsaw, Poland

Successful cardioversion was reported to decrease left atrial (LA) dimensions and improve left ventricular (LV) function.

We checked the long-term effects of cardioversion (DCC) and compared them to changes occurring in patients who continued on atrial fibrillation (AF). Left heart dimensions could be reliably evaluated by echocardiography initially (0) and both after 1 and 3 yrs in 75 pts (aged 62.0 ± 8.7, 28 F, 47 M), while LV ejection fraction (LVEF) in 48 pts. In almost half of these pts sinus rhythm (SR) was maintained throughout the follow-up period. Initially the groups were similar clinically and echocardiographically except for LA short axis diameter (LA sax) which was slightly greater in pts who had AF at 3 yrs follow-up. During follow-up LA dimensions showed divergent trends in AF and SR. This resulted in highly significant differences between these groups in both LA long axis (LA lax) and LA sax. At 1 yr and at 3 yrs pts in SR had significantly higher LVEF than in AF.

Results:

	LA lax (mm)		LA sax (mm)		LVEF (%)	
	SR	AF	SR	AF	SR	AF
Pts	35	34	36	39	23	25
0	58.6 ± 7.3	61.8 ± 7.6	43.2 ± 5.4*	46.9 ± 4.7	63.4 ± 12.6	57.9 ± 12.3
1 yr	54.6 ± 7.5*	63.8 ± 7.4	43.0 ± 6.8*	48.8 ± 4.9**	65.5 ± 5.6*	59.4 ± 10.5
3 yrs	56.5 ± 7.2*	66.6 ± 6.8**	42.2 ± 6.0*	49.3 ± 4.6**	64.6 ± 6.8*	56.2 ± 10.3

*p < 0.05 compared with pts with AF, **p < 0.05 compared with initial value

Conclusion: Patients with chronic non-valvular atial fibrillation in whom it is possible to restore and maintain sinus rhythm keep their dimensions and LVEF on initial level for at least 3 years. This favorably compares to the deterioration of respective parameters in pts who continue to fibrillate, and occurs despite lack of initial differences between the two groups.

P1189 Left ventricle function after dc shock of atrial fibrillation compared to pharmacological treatment

Tomasz Zapolski, Andrzej Wysokiński. *Departament of Cardiology Medical University School of Lublin, Poland*

Introduction: Electrical cardioversion and chemical treatment are both methods of restoration of the sinus rhythm (SR) in patients with atrial fibrillation (FA). The purpose of this study was to compare this different methods in its influence on left ventricle (LV) function after reversion of FA to SR.

Material and methods: We studied 68 patients with nonrheumatic FA before and one hour after pharmacological (20 cases) and electrical (48 cases) reversion of FA to SR. LV function was assessed using following parameters recorded from transthoracical approach: LVEDs, LVEDd, EF, SF, Etime, Edcct, Eampl, Vmax, LVET. Consequently TEE was performed with Doppler probe at the opening of the left superior pulmonary vein to measure: PVS, PVD, PVS/PVD, PVDdcct. Then differences (diff) between values of each parameter before and after restoration of SR were calculated

Results:

Parameter	Transthoracical cardioversion n = 48	Pharmacological reversion n = 20	p
diff LvEDs (cm)	0.31 (± 0.04)	0.13 (± 0.03)	0.05
diff LvEDd (cm)	0.09 (± 0.05)	0.09 (± 0.02)	NS
diff EF LV (%)	4.7 (± 1.2)	1.1 (± 0.6)	0.03
diff SF LV (%)	2.4 (± 0.8)	0.5 (± 0.31)	0.04
diff E time LV (msec)	4.83 (± 0.87)	5.9 (± 0.91)	NS
diff E dcct LV (msec)	3.11 (± 1.32)	2.68 (± 1.21)	NS
diff E ampl LV (cm/s)	5.01 (± 1.23)	4.93 (± 1.28)	NS
diff V max LV (cm/s)	0.88 (± 0.53)	1.12 (± 0.49)	NS
diff LvET (msec)	26.3 (± 8.9)	23.7 (± 8.6)	NS
diff PVS (cm/s)	−1.41 (± 0.55)	0.88 (± 0.33)	0.002
diff PvD (cm/s)	2.86 (± 0.82)	3.29 (± 0.59)	NS
diff PvS/PvD	−0.01 (± 0.006)	0.01 (± 0.004)	0.006
diff PvD dcct (msec)	27.4 (± 6.54)	25.3 (± 6.54)	NS

Conclusions: There is significant impairment of left ventricle systolic function after transthoracical cardioversion of atrial fibrillation compared to pharmacological restoration of sinus rhythm.

PACING AND ATRIAL FIBRILLATION

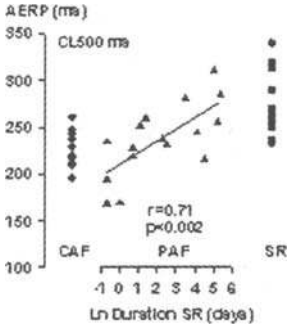
P1190 The intra-operative atrial refractory period in relation to the presence of chronic or paroxysmal atrial fibrillation or sinus rhythm

R.G. Tieleman, I.C. Van Gelder, A.E. Tuinenburg, J.G. Grandjean[1], B.A. Schoonderwoerd, P.J. De Kam, M.A. Allessie[2], H.J.G.M. Crijns.
Cardiology Dept., University Hospital Groningen, Groningen; [1]Thoracic Surgery, University Hospital Groningen, Groningen[2] Physiology Dept., University of Limburg, Maastricht, Netherlands

During recent years, the results from animal experiments have led to the concept of tachycardia-induced atrial electrical remodeling, in which prolonged episodes of AF induce shortening of the atrial effective refractory period (AERP) with loss of rate-related shortening at higher rates. After restoration of sinus rhythm (SR), these changes have proven to be reversible. Limited data exists on whether electrical remodeling plays an important role and is reversible in clinical chronic AF (CAF) or paroxysmal AF (PAF).

Methods: In the present study we measured the AERP at cycle lengths (CL) between 250 and 600 ms using epicardial pacing leads in 46 patients (15 SR, 16 PAF, 15 CAF) during cardiac surgery. Carefull history taking and patient file evaluation was performed to determine the duration of AF and the duration of SR after a last episode of PAF at the time of surgery.

Results: Patients with CAF and PAF had significant shorter AERPs ($p < 0.01$ at all CL>300 ms) and a reduced rate-adaptation compared to patients in SR. In patients with PAF, there was a significant logarithmic correlation between the duration of SR after the last episode of PAF and the AERP, with normal AERPs in the PAF patients with more than 4 days of SR (Ln{4} = 1.4 = median duration of SR, see figure). There was no relation between the duration of CAF or PAF and the AERP.



Conclusion: In humans, CAF and PAF are associated with short atrial refractory periods and a reduced rate adaptation of the atrial refractory period. Although the logarithmic correlation between the AERP and the duration of SR after the last episode of PAF does not provide absolute proof, it is in agreement with the concept of recovery from electrical remodeling of the atria after restoration of SR.

P1191 Different refractory period changes induced in the human atria by rapid high right atrial pacing and the effect of verapamil

P. Flevari, G.N. Theodorakis, E.G. Livanis, T. Mesiskli, E. Zarvalis, D. Leftheriotis, D.Th. Kremastinos. *2nd Dept of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

Rapid high right atrial pacing induces a shortening of the atrial effective refractory period (ERP), defined as atrial remodelling. This has been related to intracellular calcium overload. The purpose of this study was to assess a) rapid high right atrial pacing-induced ERP changes in the right and left human atrium, b) the effect of verapamil, an intracellular calcium lowering drug, on these changes. In order to exclude possible autonomic influences, pharmacological autonomic blockade preceded a) and b).

Methods: Ten patients without structural heart disease or history of atrial fibrillation were included in the study. Their mean age was 42 ± 19 years. After autonomic blockade (propranolol, 0.2 mg/kg IV, followed by atropine, 0.04 mg/kg IV), right and left atrial ERP were measured by electrode catheters placed in the high right atrium and distal coronary sinus respectively (drive cycle length 500 ms). For the first part of the study, ERPs were assessed before and after 5 mins of rapid high atrial pacing (pacing cycle length 200 ms). For the second part, similar ERP assessments were conducted following intravenous verapamil infusion (10 mg). ANOVAR followed by Scheffe's test were used for analysis.

Results: Significant results were obtained (ANOVAR F = 3.39, p < 0.03):

	Right atrial ERP		Left atrial ERP	
	before verapamil	after verapamil	before verapamil	after verapamil
Before pacing	220 ± 34	216 ± 30	211 ± 41	208 ± 30
After pacing	184 ± 26	205 ± 24	202 ± 41	201 ± 31
P value	<0.003	NS	NS	NS

Conclusions: Under autonomic blockade, 5 mins of rapid high right atrial pacing induce electrical remodelling only in the right atrium. Verapamil, possibly through its intracellular calcium lowering properties, attenuates this effect.

P1192 Long-term survival in 6326 patients with cardiac pacemakers – influence of gender on survival

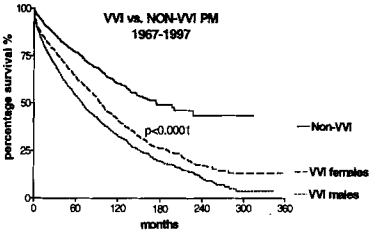
M. Brunner, Ch. Buechner, Ph. Baumgarten, A. Grom, T.S. Faber, M. Zehender. *Innere Medizin III, Kardiologie, Universitätsklinik, Freiburg, Germany*

Cardiac pacemakers (PM) are the treatment of choice for severe bradycardias. However there are few data on long-term surival of these patients with particular regard to gender.

Methods: In a multivariate analysis we investigated the influence of gender in comparison to other clinical factors on long-term survival in 6326 pts who received a PM in our hospital during the last 30 years and were followd by 6/12 months control intervals.

Results: 4569 pts received a VVI-PM (2134 females), the other 1757 pts received a NON-VVI PM (AAI, DDD). Despite a higher age of women with VVI-PM (73.2 vs. 71.6 y, P < 0.05) their median survival time was significantly longer (94 vs 68 months, p < 0.001, figure 1). Similar findings were made for NON-VVI-PM. The advantage in survival began as early as 20 months after the implantation.

Atrial fibrillation, past myocardial infarction and and type of pacemaker had an additional influence on the difference survival times of men and women.



Conclusion: Gender-specific differences in survival times are evident within the first 20 months after implantation and are enhanced by other clinical factors.

P1193 Does overdriving intrinsic rate at rest by atrial pacing prevent atrial fibrillation in patients with a pacemaker due to a symptomatic sinus node disease?

Rainer Schrepf, Rudolf Lindlbauer. *III. Medical Clinic of the Community Hospital Munich- Harlaching, Teaching Hospital of the University of Munich, Germany*

First retrospective data report a reduced incidence of atrial fibrillation in patients with sinus node disease and an overdrive stimulation of their rest rate by atrial pacemaker stimulation

The aim of our randomized prospective cross-over trial was to determine the risk for atrial fibrillation (AF) in patients with pre-existing paroxysmal AF pacing them at a rest rate of either 40 or 65 ppm. Thus comparing inter- and intra individually intrinsic rhythm to atrial pacemaker stimulation.

Ninety four patients were randomized to either 40 or 65 ppm for a one year follow-up with a consecutive cross-over. Every three months patients presented in our outpatient department. Cardiac rhythm was controlled by a holter-ECG, the data of the inherent holter function and a questionnaire. Statistical analysis was performed by SAS multivariate analysis.

Results: Episodes of paroxysmal AF were highly significant more often pacing at a basic rate of 40 than of 65 ppm (n = 164 vs. 49, p < 0.005). 66 of the 94 patients paced at 40 ppm and 23 paced at 65 ppm had a recurrence of paroxysmal AF (p < 0.005). The number of episodes and of patients with recurrence of AF was approximately three times higher with intrinsic rhythm, when compared to atrial overdrive stimulation at rest.

Conclusion: Patients with pacemaker implantation due to symptomatic sinus node disease with paroxysmal AF exhibited a significantly higher number of AF episodes being in intrinsic rhythm at rest when compared to an atrial overdrive stimulation under the same conditions. Increased basic rate in atrial pacing therefore should find a wider application in this patient population.

P1194 Ablate and pace is equally effective for treatment of paroxysmal recurrent and permanent fast response atrial fibrillation

S. Viani, T. Giujusa, R. Mantovan, F. Marton, C. Cavallini, F. Chirillo, E. Franceschini, L. Giommi, P. Stritoni. *Division of Cardiology, Treviso Hospital, Treviso, Italy*

The study investigated the impact of A-V junction ablation and PM implantation (A-P) for treatment of both highly symptomatic permanent fast response atrial fibrillation (PFAF) and paroxysmal recurrent atrial fibrillation (PRAF) not controlled by drug therapy.

Methods: Group A (G A) included 13 pts (8 M), aged 58–80 (mean 68 ± 6) with PFAF (mean ventricular rate at rest: 110 ± 5), while Group B (G B) included 7 pts (3 M), aged 54–87 (mean 65 ± 12) with PRAF (3 or more episodes in the previous 6 months). The two groups were comparable in respect to age, sex and specific heart disease distribution (hypertensive 9, valvular heart disease 7, CAD 2, cardiomyopathy 2). Persistence of A-V block, stimulation threshold (ST) and pacing impedance (PI) were evaluated at follow-up (FU). The Minnesota Living with Heart Failure Questionnaire (LHFQ), NYHA classification, a specific score for palpitations (P score = 0 to 5) and the number of tablets/pt (T/P) daily consumed were employed in both groups to compare quality of life before and after the procedure (7 ± 3 m).

Results: A-V junction was successfully ablated in all the pts by right-sided approach. No pt resumed A-V conduction at follow-up. VVIR pacing mode was reserved for all G A pts while G B pts were paced with VVIR (2) and DDD (5) mode-switching PMs. No PM failure occurred and ST and IP negligibly increased from implantation to FU visit in both groups. No death occurred in the study population. A significant clinical improvement was equally evident in both groups despite G B pts experienced many recurrences (asymptomatic) of pathological atrial rhythm, as detected by PM recordings, and two of them developed permanent AF.

	LHFQ			NYHA			P score			T/P score		
	pre		post	pre		post	pre		post	pre		post
GA	36 ±17	vs	7.2 ±6.9*	3.1 ±0.8	vs	1.7 ±0.4*	4.4 ±0.9	vs	0.2 ±0.4*	5.3 ±2	vs	2.8 ±1.4*
GB	32 ±24	vs	4.2 ±4.7°°	2.7 ±1	vs	1.5 ±0.5°	4.5 ±1.2	vs	0.3 ±0.8*	5.2 ±1.1	vs	2.8 ±1.5°°

°p < 0.05, °°p < 0.02, *p < 0.001. A decrease of LHFQ, NYHA, P and T/P scores ≥ 80%, 40%, 90% and 45% respectively was detected in both groups.

Conclusions: We conclude that 1) A-P is equally effective for treatment of both PFAF and PRAF not controlled by drug therapy when associated with structural heart diesease 2) In these pts a sensor-driven, regular, paced ventricular rhythm improves clinical status despite permanent or recurrent loss of atrial contribution to ventricular filling.

P1195 Factors predicting quality of life outcome following atrioventricular node ablation and DDDR mode-switching pacing for paroxysmal atrial fibrillation

H.J. Marshall, Z.I. Harris, E.W. Lau, M.J. Griffith, M.D. Gammage.
Cardiovascular Medicine Dept, Queen Elizabeth Hospital, Birmingham, UK

Atrioventricular node ablation and DDDR mode-switching pacing (A/P) usually improves quality of life (QOL) in patients with drug resistant paroxysmal atrial fibrillation. However, some patients do not respond as well as expected. This study assesses factors which may predict improvements in QOL and hence aid patient selection.

Methods: Patients undergoing A/P were prospectively assessed with a detailed history and echocardiography. The following parameters were recorded: age; sex; other heart disease or lone AF; number of antiarrhythmic drugs failed; length of history; number of episodes per month and average duration of episodes (multiplied to produce days of AF per month); left atrial size. Antiarrhythmic drugs were withdrawn 3 days before the procedure. QOL was assessed before and 3 months after ablation using the Psychological General Well Being questionnaire, the McMaster Health Index questionnaire and a visual analogue scale cardiac symptom score. At 3 months, patients were also assessed to see if they had developed chronic AF (absence of sinus rhythm on Holter monitor and >95% AF on pacemaker diagnostics). Association of preoperative factors with the percentage change in overall QOL score was assessed using multivariate, stepwise, linear regression.

Results: Forty-eight patients entered the study. Only the number of days spent in AF per month showed a significant association with percentage change in QOL score (regression coefficient 1.92; standard error 0.72; 95% confidence limits 0.43–3.3; p = 0.014). QOL was not significantly influenced by the development of chronic AF (17 patients).

Conclusions: In this study, a greater improvement in quality of life was seen in patients with a higher arrhythmia burden preoperatively. This supports the hypothesis that A/P should be considered preferentially for patients with frequent prolonged episodes of AF. However, the data also demonstrate that the transition to chronic AF after A/P does not necessarily result in a detrimental effect on QOL.

P1196 Predictors of chronic atrial fibrillation following atrioventricular node ablation and DDDR mode-switching pacing for paroxysmal atrial fibrillation

H.J. Marshall, E.W. Lau, Z.I. Harris, M.J. Griffith, M.D. Gammage.
Cardiovascular Medicine Dept, Queen Elizabeth Hospital, Birmingham, UK

Atrioventricular node ablation and dual chamber mode-switching pacing (A/P) is effective therapy in patients with drug resistant paroxysmal atrial fibrillation. About a third of patients develop chronic atrial fibrillation (CAF) soon after the procedure. This effectively results in VVIR pacing and may lead to symptoms of loss of atrial transport. It is not clear which factors predispose patients to develop CAF in this setting.

Methods: Patients undergoing A/P were prospectively assessed with a detailed history and echocardiography. The following parameters were recorded: age; sex; other heart disease or lone AF; number of antiarrhythmic drugs failed; length of history; number of episodes per month and average duration of episodes (multiplied to produce days of AF per month); left atrial size. It was also noted if patients were in AF at the start of their ablation procedure. Antiarrhythmic drugs were withdrawn 3 days before the procedure. Three months after the procedure, patients were assessed to see if they had developed chronic AF (absence of sinus rhythm on Holter monitor and >95% AF on pacemaker diagnostics). Association of preoperative factors with the development of CAF was assessed using multivariate, stepwise, linear regression.

Results: Forty-eight patients entered the study. 17 had developed CAF at the three month assessment. Pre-operative factors predicting CAF are shown in table 1: no other factors showed significant association with the development of CAF.

Table 1. Factors predicting transition to chronic AF

	Regression coefficient	Standard error	5% confidence limits	P
Lone AF	−0.295	0.125	−0.547 to −0.042	0.023
Days AF per month	0.023	0.011	0.002 to 0.045	0.036
AF at time of ablation	0.305	0.134	0.034 to 0.575	0.028

Conclusions: These data suggest that following A/P with antiarrhythmic drug withdrawal, atrial fibrillation is more likely to become permanent if it is secondary to other cardiovascular disease or is present at the time of the procedure. A higher arrhythmia burden also predisposes to the development of CAF. These findings may help target those patients who either require only a VVIR pacemaker or in whom other efforts to maintain sinus rhythm should be made.

P1197 Survival of patients with atrial fibrillation and VVI-pacemaker: a comparison of 30 years and 1670 patients

M. Brunner, A. Grom, T.S. Faber, R. Macharzina, Ch. Büchner, M. Zehender.
Innere Medizin III, Kardiologie, Universitätsklinik, Freiburg, Germany

Atrial fibrillation (AF) is the most common arrhythmia in adults, but data on long-term survival in these patients are rare. We analyzed the survival time of patients with chronic AF after implantation of a cardiac pacemaker (PM) for symptomatic or asymptomatic bradycardia over a period of 35 years.

Patients and Methods: Survival analysis was based on standardized control intervals of 6/12 months over a period from 1967–1997 and included other factors such as gender, symptoms and known coronary artery disease (CAD).

Results: During the 3 decades 6327 pts received a PM, 1670 (26%) had AF. Of these 915 were males, 761 females, (mean age: 72.9 y and 73.7 y, p = n.s.), 98% received a VVI-PM, 2%DDD-PM. Pts in the first decade (D1, 1967–1977, n = 401) were significantly younger (mean age 71.3 y ±10.2) than those in the second (D2, 1978–87, n = 704) (mean age 73.7 y, ±8.6) or third decade (D3, 1988–97, n = 565) (mean age 75.2 y, ±9.0) ($p < 0.003$). 50% mortality was reached in D1-pts at 39 months, in D2-pts at 86 months and in D3-pts at 94 months ($p < 0.0001$ D1 vs D2/D3) Prognosis of pts with chronic AF was not different for pts presenting between 1978–87 and 1988–97.

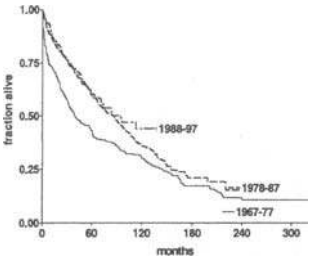


Figure 1 demonstrates Kaplan-Meier-survival plots of the three group of pts.

Conclusion: Despite advances in medical treatment, pts with chronic AF show nearly no difference in survival during the first 10 years after PM implantation.

EVALUATION OF ELECTROPHYSIOLOGY

P1198 Monitoring of initial changes of atrial fibrillation at multiple sites helps to define therapeutic options

A. Michelucci, P. Bartolini[1], L. Padeletti, A. Colella, A. Sabini, S. Morelli[1], R. Zipoli, G. Calcagnini[1], V. Barbaro[1], G.F. Gensini. *Istituto Clinica Medicae Cardiologia, Careggi Hospital, Florence;* [1] *Biomedical Engineering Laboratory, Istituto Superiore di Sanità, Rome, Italy*

Knowledge of the initial changes of atrial fibrillation (AF) could contribute to understand and justifie some therapeutic options.

Methods: A computerized method for continuous evaluation of AF intervals (f-f intervals: as an index of local refractoriness) at different atrial sites was utilized to study the beginning of induced human AF. In order to analyze the shortest and the longest f-f intervals, the 5th (P5) and the 95th (P95) percentiles were also calculated. 82 AF episodes were induced (atrial burst pacing: 400/min, parasinusal zone) in 22 pts (60 ± 14 yrs). Atrial activity was recorded (bipole: 5 mm) and continuously analyzed at 3 atrial sites (parasinusal zone, os and distal part of coronary sinus). Recordings were also subdivided according to Wells classification.

Results: Type I AF was observed for all the time in 51 episodes (range, 2–103 sec.) which terminated spontaneously. Disorganized AF was observed from the beginning in 13 episodes (range, 3–664 sec.) which terminated spontaneously, and in 4 episodes > 10 min. treated by propafenone (P) or low energy endocavitary cardioversion (LEEC). A progressive disorganization of AF (from type I to III) was observed in 6 episodes (range, 59–1800 sec.) which terminated spontaneously, and in 4 > 10 min treated by P or by LEEC. During progressive disorganization the value of mean f-f intervals and of P5 tended to continuously decrease at all atrial sites indicating an increase of circulating wavelets and a reduction of refractoriness. The duration of episodes with a progressive or immediate disorganization (1129 ± 2367 sec.) was significantly longer ($p < 0.0067$) than that of organized episodes (48 ± 181 sec.). Progressive disorganization always appeared initially at the coronary sinus os (interatrial septum) and supervened after different time legs which never exceeded 7–8 min.

Conclusion: Disorganization being rapid and prolonging AF justifies an early interruption of the arrhythmia (atrial defibrillation). The beginning of disorganization at coronary sinus os probably represents another clue to support atrial septal pacing for prevention of AF.

P1199 The virtual atria, a new model to study atrial flutter and atrial fibrillation

N. Virag[1], O. Blanc[1], O. Egger[1], J.-M. Vesin[1], J. Koerfer[2], L. Kappenberger[2]. *[1]Signal Processing Laboratory, EPFL; [2]Divison of Cardiology, CHUV, Lausanne, Switzerland*

Atrial fibrillation is the most frequent and costly arrhythmia, provoking heart failure and embolism. There is no biologic model to test therapeutic interventions, therefore we need to develop new research tools. Computer simulations offer the advantage of showing details difficult to study in nature and of being reproducible. Furthermore, the limited surface and thickness of atria compared to the ventricles allows us to develop a realistic 3D model of atria with today computer power.

Methods: Based on a 2D heterogeneous and anisotropic model of cardiac tissue we have developed a new 3D anatomic model of human atria which uses a modeling of the membrane ion kinetics given by Beeler-Reuter or Luo-Rudy. The simulated size of both atria is 3 cm × 3 cm × 7 cm with about 250'000 cardiac cells. Holes of adapted size have been placed to simulate the veins and the valves. The propagation of a normal sinus beat at 50 cm/s is initiated from the sino-atrial node (SA node).

Results: Experiments for initiation of atrial flutter and atrial fibrillation have been performed, using a programmed stimulation protocol similar to those of electrophysiological studies. S^2 and S^3 have been initiated from several locations, intensities and timings and different action potential duration have been tested by a modulation of the ionic channels. Most of the attempts have led to nonsustained arrhythmias proving the stability of the tissue. However, we have identified that some locations are more likely to generate atrial flutter: the region between the inferior vena cava and the tricuspid valve and the region of the pulmonary veins. This observation correlates with the observations made in humans. We have been able to induce in our computer model of atria sustained atrial flutter with a periodic pattern and atrial fibrillation with a random pattern containing up to 6 independent wavelets.

Conclusion: This new virtual model of the atria can reproduce clinical observations and it allows us to observe the evolution of the action potential and the underlying ionic currents in any point on the surface of the atria, before, at the onset and during the arrhythmia. The possibility to test anti-tachy pacing techniques, ablation, defibrillation and pharmacological interventions is given.

P1200 Left atrial activation from the right atrium through two septal inputs

D.C. Shah, M. Haïssaguerre, P. Jaïs, A. Takahashi, M. Hocini, J. Clémenty. *Hôpital du Haut-Lévêque, CHU de Bordeaux 33604 Pessac, France*

Introduction: Interatrial activation routes and left atrial (LA) endocardial activation have not been delineated in humans.

Methods: In 13 patients (11 M, 2 F, mean age 26 ± 8 years; WPW syndrome, n = 8; AVNRT, n = 1; PSVT, n = 1; atrial tachycardia, n = 3) with a patent foramen ovale, complete LA endocardial activation mapping was performed during sinus rhythm and lateral right atrium (RA) pacing (680 ± 80 ms) using the Cordis Biosense system after ablation. No patient had structural heart disease, atrial fibrillation or had undergone linear ablation.

Results: A mean of 71 ± 20 points was used to reconstruct endocardial LA maps with a volume of 34 ± 10 cc. During sinus rhythm and relatively high lateral RA pacing, the LA was activated craniocaudally in 71 ± 10 ms from a single high anterior septal breakthrough including the anterior aspect of the right superior pulmonary vein (PV) (in 8) correlating with an inferior P wave vector (58 ± 28°). Terminal LA activation occurred posterolaterally in the vicinity of the mitral annulus. During low lateral RA pacing (n = 9), the LA was activated caudocranially in 71 + 11 ms (no major anisotropy): in one case from a midseptal breakthrough and in 8 from a single inferior breakthrough 24 ± 12 mm below the breakthrough site in sinus rhythm. Terminal LA activation occurred near the left superior PV and correlated with a superior P wave vector (−25 ± 64°). In all but one case the posterior mitral annulus margin was activated from septal to lateral.

Conclusions: Two main inputs ('Bachman's bundle' and coronary sinus region) provide the route for RA to LA activation. Their spatial positions correlate with craniocaudal and caudocranial activation as well as the resulting P wave vector.

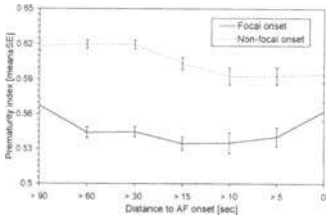
P1201 Trends in the prematurity of premature beats before atrial fibrillation onset: evidence for two distinct mechanisms

J.E.P. Waktare, K. Hnatkova, F.D. Murgatroyd, A.J. Camm, M. Malik. *St Georges Hospital Medical School, London, UK*

Previous studies from ourselves and others have documented that atrial premature beats (APB's) from a single focus are responsible for initiating paroxysmal atrial fibrillation (AF) episodes in some patients.

Methods: Holter recordings from 177 subjects with paroxysmal AF were analysed and AF episodes were identified by a previously validated technique. The distribution of coupling interval ratios (prematurity index, PI) of ABP's was calculated for successive time windows prior to AF onset. The distributions were classified as suggestive of focal onset or not based upon an automated analysis which detected whether a higher than expected proportion of all APB's with a uniform PI was present.

Results: 74 recordings in 39 pts (24 male, 62 ± 13 years old) were analysable. 15 (20%) were classified as having probable unifocal APB's. Subjects without unifocal APB's had a longer mean PI at 0.61 ± 0.11 vs. 0.55 ± 0.1 ($p = 1.3 \times 10^{-112}$, absolute values for mean coupling intervals of 512 ms and 483 ms respectively) but exhibited a progressive decline in PI towards AF onset (figure). There was no change in PI in subjects with presumed focal onset.



Conclusion: (1) Subjects with unifocal APB's prior to AF onset have more premature APB's than other paroxysmal AF patients. (2) Ectopics do not become more premature in subjects with the unifocal APB's, but do so in other patients. These data are consistent with there being two distinct mechanisms of AF; unifocal APB's and increasing atrial instability.

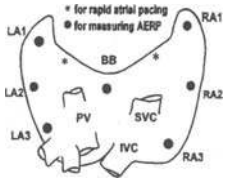
P1202 Regional differences in the recovery course of tachycardia-induced changes of atrial electrophysiological properties

S.H. Lee, J.J. Cheng, M.S. Chang, S.A. Chen. *Shin Kong Wu Ho-Su Memorial Hospital, and Veterans General Hospital-Taipei, Taiwan, China*

Background: Regional differences in recovery of tachycardia-induced changes of atrial electrophysiolgical properties have not been well studied.

Methods: In experimental group I (15 dogs), atrial effective refractory period (AERP) and inducibility of atrial fibrillation (AF) were assessed before and after complete atrioventricular junction (AVJ) ablation with 8-week rapid right atrial (RA) pacing (780 bpm) and VVI pacing. In experimental group II (7 dogs), AERP and inducibility of AF were assessed before and after 8-week rapid left atrial (LA) pacing and VVI pacing (fig).

Results: In the two experimental groups, recovery of atrial electrophysiological properties included a progressive recovery of AERP shortening, recovery of AERP maladaptation, and decrease of episodes of reinduced AF. However, recovery of shortening and maladaptation of AERP and inducibility of AF was slower at the LA than at the RA and Bachmann's bundle. The time with disappearance of the three events were shown in table (presented as hours after termination of pacing).



Site	Post-pacing AERP↓		Maladaptation of AERP		AF(+)	
	I	II	I	II	I	II
RA1	12	4	12	4	12	8
RA2	4	0	4	0	4	4
RA3	4	0	4	0	4	0
BB	4	0	4	0	4	0
LA1	24	20	24	20	24	20
LA2	24	20	24	16	24	20
LA3	28	20	28	20	28	20

Conclusions: The LA might play a critical role in initiation of AF.

P1203 Reduction in the susceptibility to atrial fibrillation by modification of atrial electrophysiology despite non-linear atrial ablations

J. Tebbenjohanns, M. Niehaus, T. Paul[1], F. Wibbelt, O. Meyer, T. Korte. *Cardiology Dept., Medical School Hannover, Hannover; [1]Pediatric Cardiology, Medical School Hannover, Hannover, Germany*

Background: I has been suggested that long linear lesions are mandatory for curative ablation in the setting of atrial fibrillation (AF). Even in non-trabecularized areas of the right atrium lesion continuity is often difficult to achieve over a long distance. We tested the hypothesis that atrial ablations may modify the electrophysiologic substrate and may decrease the susceptibility to AF.

Methods: Eight sheeps (75–86 kg) with rapid atrial pacing for 6 ± 2 months to produce chronic AF (>3 weeks of sustained AF) underwent this study. Three long lesions were created in the right and left atrium using a novel ablation catheter with coiled electrodes.

Results: Examination of the explanted hearts showed multiple, discontinuous lesions in both atria. Lesion continuity over the whole distance of preselected target sites were only found in the cavotricuspid isthmus. The mean AF cycle lengths increased from 105 ± 25 ms to 170 ± 35 ms ($p < 0.05$). The internal atrial defibrillation threshold was reduced from 7 ± 2 Joule to 2 ± 1 Joule ($p < 0.05$). Reproducible induction of AF was achieved by using one single extrastimulus before ablation in all animals. After ablation AF was induced with a single extrastimulus in only one animal ($p < 0.05$).

Conclusions: A decrease in the susceptibility to AF and a significant modification of atrial electrophysiology is possible despite predominant discontinuous lesions in both atria in a sheep model of chronic atrial fibrillation.

P1204 Repeated electrophysiological evaluation of sinus node function following internal electrical cardioversion of chronic atrial fibrillation

E.M. Kanoupakis, E.G. Manios, M.D. Kaleboubas, M.K. Zeaki, E.N. Simantirakis, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

In an era when the future of implantable atrial defibrillators is being evaluated, there is little information about the functional state of the sinus node in patients with chronic atrial fibrillation (AF) who have undergone electrical cardioversion. Here we present the preliminary results of an ongoing study of the functional state of the sinus node in cases of long lasting AF following internal current cardioversion.

Methods: We studied 32 consecutive patients, free of antiarrhythmic drugs, with chronic AF (>3 months), following successful internal electrical cardioversion. Each patient who remained in sinus rhythm underwent an electrophysiological study (EPS) immediately after cardioversion (t0), after 24 hours and after 30 days.

Results: The results of the 3 EPS examinations are given in the table below, where SNRTc = corrected sinus node recovery time, ERP500 = effective refractory period of right atrium at 500 ms pacing cycle length, d% SCL/A = percentage change in sinus node cycle length after atropine administration, P dur = duration of P wave.

Table

Time of study	SNRTc	ERP500	d% SCL/A	P dur.
t0	294 ± 109	203 ± 14	21.3 ± 10	155 ± 33
24 hrs	313 ± 104	249 ± 26#	23.8 ± 8	142 ± 27*
30 days	318 ± 112	255 ± 25#	20.6 ± 12	141 ± 24*
		#$p < 0.001$ vs. t0		*$p < 0.05$ vs. t0

Conclusion: These preliminary data indicate a change in atrial refractoriness and P wave duration during the first month after successful conversion of AF, with the main changes developing during the first 24 hours. In contrast, they do not confirm any changes in sinus node functional tests during the same period.

P1205 Electrophysiological characteristics of the human atria after cardioversion of persistent atrial fibrillation

C. Pandozi, L. Bianconi, M. Villani, G. Gentilucci, M.C. Scianaro, F. Lamberti, A. Castro, A.P. Jesi, M. Santini. *Department of Cardiology, San Filippo Neri Hospital, Rome, Italy*

Background: In animal models induced Atrial Fibrillation (AF) shortens the atrial Effective Refractory Period (aERP) and reverses physiological adaptation to rate. This could be related to changes in Monophasic Action Potential (MAP) behaviour. The aim of our study was to analyze aERP, MAP duration and rate adaptation in patients (pts) with persistent AF after cardioversion.

Methods and Results: With determined aERP and MAP90 at 5 paced cycle length (300–700 ms) and 5 atrial sites after internal cardioversion of persistent AF in 25 pts: 14 in wash-out (WO) and 11 on Amiodaron (A). the mean aERPs were 195.5 ± 18.8 ms in WO and 206.3 ± 17.9 ms in A, $p < 0.001$. The mean MAP90 duration was 220.8 ± 31.1 in WO and 240.8 ± 36.7 in A, $p < 0.0001$. The aERP/MAP90 ratio was 0.89 ± 0.15 in WO and 0.87 ± 0.10 in A, p = ns. Slope values indicating a normal (> 0.007) or nearly normal (0.005–0.006) adaptation of ERP to rate were found in 77% of the paced sites. Accordingly, MAP90 duration constantly increased from the shorter pacing cycle (300 ms) to the longer one (700 ms): 206.1 ± 24.9–237.3 ± 27.2, r = 0.95 in WO and 219.9 ± 25.5–257.3 ± 31.1, r = 0.94 in A.

Conclusions: After cardioversion of persistent AF: 1) aERP adaptation to rate was normal o nearly normal in the majority of the pts; 2) MAP90 duration showed a similar behaviour increasing at longer pacing cycle length; 3) no differences have been observed in aERP/MAP90 ratio between WO and A pts.

PREDICTING AND PREVENTING POSTOPERATIVE ATRIAL FIBRILLATION

P1206 Predictors of persistent atrial fibrillation following open heart surgery

G. Cioffi, G.F. Mureddu[1], M. Pozzoli[2], E. Traversi[3], C. Cemin, T.E. Russo, A. Pellegrini, F. Terassi. *Rehabilitation Center Eremo, Arco di Trento; [1]S. Giovanni Hosp. Rome; [2]Division of cardiology, Lecco; [3]Montescano Medical Center, Pavia, Italy*

Purpose. Although atrial fibrillation (AF) is the most common postoperative complication in patients (pts) undergoing open heart surgery (OHS), routine use of antiarrhythmic treatment is not recommended. In these pts AF usually converts spontaneously to sinus rhythm and farmacological interventions are often effective. However AF may persist. The aim of this study was to identify the factors that predict the persistence of AF after OHS.

Methods and results. We examined 121 consecutive pts who developed AF after OHS. Over a period of 30 ± 2 days, AF converted to sinus rhythm in 108 pts (89%), while persisted at discharge in 13 pts (11%). Variables associated with persistent AF to univariate analysis are listed below:

	Persistent AF	Converted AF	p
Age (years)	72 ± 8	63 ± 9	0.006
Female gender (%)	70	30	0.01
NYHA class (1–4 score)	2.5 ± 0.5	1.8 ± 0.6	0.004
Valvular procedure vs CABG (%)	90	10	0.0001
History of AF (%)	30	7	0.02
Left atrial diameter (mm)	51 ± 4	41 ± 6	0.0001
Left ventricular EF (%)	47 ± 4	53 ± 8	0.04

Multivariate analysis revealed that valvular procedure was the strongest indipendent risk factor of persistence of AF (OR 33.6, p 0.007) and older age and left atrial dilatation provided a small contibution in predicting events.

Conclusions: in pts undergone OHS followed by AF, valvular procedure, particularly when associated to advanced age and left atrial dilatation, identifies patients at high risk of persistence of arrhythmia who should particularly benefit of preoperative prophylactic treatment.

P1207 Single-day loading dose of oral amiodarone does not prevent atrial fibrillation after coronary artery bypass surgery

D. Maras, S.D. Boskovic, S. Kovacevic, P. Otasevic, Z. Popovic, L.J. Vuk, T. Jovanovic[1], M. Bojic, A.N. Neskovic. *Cardiovascular Research Center, Dedinje Cardiovascular Institute, Belgrade; [1]Institute of Physiology, Belgrade University School of Medicine, Belgrade, Yugoslavia*

It has been shown that one-week loading dose of oral amiodarone can reduce presence and severity of atrial fibrillation (AF) following coronary artery bypass surgery (CABS). However, there is no evidence whether single-day loading dose of oral amiodarone has beneficial effect in preventing AF after CABS.

In order to assess the effect of single-day loading dose of oral amiodarone in prevention of AF after CABS we conducted double-blind randomized study and evaluated 315 consecutive patients (pts). Pts received either amiodaron (159 pts) or placebo (156 pts) in a dose of 1200 mg one day before CABS, following with 200 mg daily during next 7 days, including the day of operation. All pts were monitored for AF during first 48 h in the ICU. After that serial electrocardiogram(twice daily routinely, and if heart rate (HR) was >100/min, or pt had angina, hypotension, dyspnea or sweating) and HR measurements (4 times daily routinely) were obtained in order to detect AF. Only episodes of AF that lasted more than 1 hour, or were shorter but associated with symptoms and/or hemodynamic disturbances, were taken into consideration. In addition, overall mortality, other rhythm disturbances, and duration of hospital stay were also evaluated.

Results: Pts with and without postoperative AF were similar regarding age, sex, preoperative EF and severity of coronary artery disease, operative data, and electrolyte status. The incidence and characteristics of AF, as well as mortality and duration of hospital stay are shown in table:

	Amiodarone (n = 159)	Placebo (n = 156)	P value
AF (pts,%)	31 (19.5)	33 (21.2)	NS
AF episodes	1.92 ± 1.2	2.27 ± 2.2	NS
AF duration (h)	28.4 ± 39.9	21.2 ± 29.0	NS
Total mortality (pts,%)	7 (4.4)	5 (3.2)	NS
Hospital stay (days)	10.3 ± 6.2	10.0 ± 3.6	NS
Other arrhythmias (pts,%)	48 (30.2)	45 (28.8)	NS

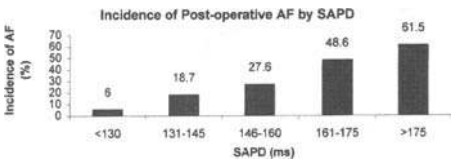
Conclusion: Single-day loading dose of amiodarone does not prevent occurrence, duration and number of episodes of AF in pts undergoing CABS and has no effect on overall mortality and duration of hospital stay.

P1208 Signal-averaged p-wave duration accurately stratifies risk for atrial fibrillation after coronary artery bypass grafting

R.A. Archbold, A.G. Zaman[1], N.P. Curzen, P.G. Mills. *Department of Cardiology, London Chest Hospital, London; [1]University Hospital of Wales, Cardiff, UK*

Atrial fibrillation (AF) occurs in 20–40% of patients after coronary artery bypass grafting (CABG). Signal-averaged P-wave duration (SAPD) has been proposed as a predictor for AF after CABG. We determined the influence of pre-operative SAPD on incidence of post-operative AF in 326 patients undergoing elective CABG.

Ninety two (28.2%) patients developed post-operative in-hospital AF. The mean SAPD was significantly longer in AF compared to non-AF patients (158 v 145 ms; $p < 0.0005$). The incidence of AF increased progressively with increasing SAPD such that 3/50 (6%) patients with a SAPD < 130 ms compared to 8/13 (61.5%) patients with a SAPD > 175 ms developed AF (figure). The odds ratio (95% confidence interval) for AF was 2.11 (1.62–2.74) for each increase of 15 ms in SAPD, and 4.95 (2.96–8.28) for patients with a SAPD > 155 ms. SAPD > 155 ms predicted AF with a sensitivity of 63%, a specificity of 74%, and positive and negative predictive accuracies of 49% and 82%, respectively.



There is a clear relationship between SAPD and incidence of AF after CABG which may be used to identify patients at high and low risk for the arrhythmia.

P1209 Atrial conduction changes after cardiopulmonary bypass and their relationship to the development of post-operative atrial fibrillation

W.P. Orr, P.J. Stafford, P. Braidley, R. Pillai, Y. Bashir. *Oxford Heart Centre, John Radcliffe Hospital, Oxford, UK*

Background Atrial fibrillation (AF) is common after cardiopulmonary bypass (CPB). The mechanism is unclear but may involve slowed intra-atrial conduction due to ischaemic injury. Prolongation of pre-operative P-wave duration appears to be a weak predictor of post-op AF, but no study has explained the changes in atrial conduction following CPB or their relationship to the development of AF.

Methods Signal-averaged P-wave duration was analysed in 97 consecutive patients undergoing first-time CABG with no prior history of AF, using a previously validated P-wave selective averaging system. Measurements were performed pre-operatively and at day 1, day 5 and week 6 post-operatively and compared in patients who developed AF (>30 mins or requiring treatment).

Results AF developed in 31 patients (32%).

P-wave duration	Pre-op (SEM)	1 day post-op (SEM)	5 days post-op (SEM)	6 weeks post-op (SEM)
AF	139 ms ± 2.7	129 ms ± 3.6*	130 ms ± 2.8	131 ms ± 2.8**
Non-AF	136 ms ± 1.8	129 ms ± 1.6*	127 ms ± 1.6	139 ms ± 2.5
Total	137 ms ± 1.5	129 ms ± 1.5*	128 ms ± 1.4	136 ms ± 1.9

*$p < 0.005$ cf pre-op; **$p < 0.05$ cf non-AF

Conclusion Contrary to expectation, intra-atrial conduction accelerates after CPB, indicating that the pro-fibrillatory effects must be mediated by shortening of atrial refractoriness to enable re-entry. Moreover, the failure of P-wave duration to return to baseline values in patients who developed AF suggests that they sustained persistent structural changes of atrial myocardium, possibly due to ischaemic injury. Further studies are needed to evaluate the nature and cause of these alterations in atrial electrophysiology

P1210 Exon 7 gene polymorphism as a risk factor for atrial fibrillation following surgical coronary artery revascularisation

R.W. Irvine, P. Johnson, M.H. Yacoub. *Cardiac Surgery Dept, Harefield Hospital, Uxbridge, UK*

Background and Methods: Atrial Fibrillation is a leading cause of morbidity post coronary artery bypass grafting and has an incidence of approximately 30% in most series. It is thought to be due to intraoperative myocardial ischaemia. Polymorphisms involving the gene encoding endothelial Nitric Oxide Synthase (eNOS) could indeed influence coronary flow. We have investigated the influence of the Glu298Asp polymorphism in the gene encoding eNOS in a group of 109 patients undergoing surgical coronary artery revascularisation with reference to postoperative atrial fibrillation.

Results: A new polymorphism (named E7II) was detected by SSCP-PCR in the exon 7 genomic amplicon that was apparently unrelated to the previously described Glu298Asp polymorphism (E7I). E7I was present in 67% of the patient population compared to 28.2% of controls and was homozygous in 8.8% of the patient population and none of the controls. ($P < 0.001$) (Gene frequency 0.379 vs 0.141). For E7II, the allele was present in 62.9% of the patient population and 50.5% of controls (Gene frequency 0.317 vs 0.258)($P = 0.06$). 13.6% of patients with the E7I gene experienced atrial fibrillation compared to none of the normal population. 9.1% of those with the E7I gene experienced other arrythmias while none of the normal population was affected (n = 67). Similarly, 18.2% of patients with the E7II gene experienced atrial fibrillation whilst 3.1% of the normals in this group were affected ($p = 0.05$). 12.7% of patients with the E7II gene experienced other arrythmias while none of the normals were affected(n = 87).

Conclusions: This study has documented for the first time an association between atrial fibrillation post CABG and eNOS gene polymorphisms at exon 7. These findings could have important prognostic and possibly therapeutic implications for patients undergoing coronary artery bypass grafting.

P1211 Preoperative low-dose intravenous amiodarone in preventing atrial fibrillation after coronary artery bypass grafting

S.H. Lee, C.M. Chang, C.R. Hung, J.J. Cheng, S.A. Chen. *Shin Kong Wu Ho-Su Memorial Hosp. & Veterans General Hospital-Taipei, Taiwan, China*

Background: Atrial fibrillation (AF) occurs commonly after coronary artery bypass grafting (CABG) and may result in hemodynamic compromise and severe symptoms. The purpose of this study was to assess the use of preoperative low-dose intravenous amiodarone as prophylaxis against AF after CABG in a prospective, randomized, placebo-controlled fashion.

Methods: One hundred and forty patients were given either intravenous amiodarone (66 patients) or placebo (74 patients) for three days before elective CABG. Therapy consisted of 150 mg amiodarone for loading and 0.4 mg/kg/hr for 72 hours.

Results: Postoperative AF occurred in 8 of the 66 patients in the amiodarone group (12%) and 25 of the 74 patients in the placebo group (34%) ($p = 0.02$). The maximal ventricular rate during AF was significantly lower in the amiodarone group than that in the placebo group (110 ± 23 vs 137 ± 26 bpm, $p < 0.01$). The amiodarone group had significantly shorter intensive care unit stay (104 ± 32 vs 138 ± 28 hours, $p < 0.01$). Nonfatal postoperative complications occurred in six amiodarone-treated patients (9%) and in eight patients receiving placebo (11%, p = NS). Fatal postoperative complications occurred in two patients who received amiodarone (3%) and in five who received placebo (7%, p = NS).

Conclusions: Preoperative low-dose intravenous amiodarone significantly reduced the incidence of postoperative AF. Furthermore, low-dose intravenous amiodarone did not increase the risk of intraoperative and postoperative complications in the patients receiving CABG.

P1212 How good is the pre-operative signal averaged p-wave for prediction of post-operative atrial fibrillation? – a prospective study in 465 patients

K.J. Ward, K.I. Roukas, C. Bucknall, J.S. Gill, P.J. Stafford[1]. *Cardiac Depts. of St Thomas' Hospital, London; [1]Glenfield Hospital, Leicester, UK*

Background: Analysis of the pre-operative signal averaged P wave (SAPW) is reported to be of variable utility as a predictor of atrial fibrillation (AF) after coronary bypass grafting (CBG). Many studies reporting high diagnostic accuracy are flawed by small numbers of patients and retrospectively derived diagnostic criteria. We report the results of a large prospective study that utilises a prospectively derived diagnostic criterion to predict AF after CBG.

Methods: SAPW recordings were made in 465 pts (363 M, mean age 62.6 yrs) before CBG in 2 UK centres. A P wave specific averaging system was used that has been previously described. Continuous electrocardiographic (ECG) monitoring was performed for 48 hrs after CBG with routine ECG recordings thereafter until hospital discharge.

Results: 130 (28%) pts developed AF > 1 hr duration (group AF). Mean P-wave duration was significantly longer in these pts than in those who remained in sinus rhythm (147 ± 13 ms vs 143 ± 15 ms $p < 0.002$). The positive predictive accuracy of a P-wave duration of ≥ 141 ms was 33% with a negative predictive accuracy of 80%. Specificity was 57% and sensitivity 71%.

Conclusion: We have found that when applied to a large number of patients with prospectively defined diagnostic criteria analysis of the pre-operative SAPW is a poor predictor of AF after CBG. However, a short P wave duration (< 141 ms) implies a low risk of postoperative AF which may be clinically useful. These findings confirm the results of previous moderately large investigations.

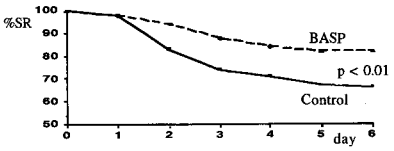
P1213 Bi-atrial synchronised pacing prevents atrial fibrillation after coronary artery bypass surgery

W.P. Orr, S.S.L. Tsui, P.J. Stafford, R. Pillai, Y. Bashir. *Oxford Heart Centre, John Radcliffe Hospital, Oxford, UK*

Background Atrial Fibrillation (AF) after coronary artery bypass surgery (CABG) is common and associated with increases in cost and morbidity. Pharmacological prophylaxis is of limited efficacy and often contra-indicated because of haemodynamic instability. We designed a prospective randomised trial to determine whether bi-atrial synchronised pacing (BASP) via epicardial wires can prevent AF after CABG.

Methods 230 patients undergoing first-time CABG, in sinus rhythm pre-operatively with no prior history of AF, randomised to post-operative BASP (using a standard SSI-generator programmed to AAT mode) or control. Pairs of epicardial wires placed on the right atrium and posterior aspect of the left atrium. Pacing commenced within 4 hours of surgery and continued for 96 hours with pacing parameters measured daily. Episodes of AF > 30 mins or requiring treatment noted.

Results BASP successfully maintained to 96 hours in 89% of cases, intermittent/total loss of capture or sensing at maximum settings occurring in 11%. BASP reduced the incidence of AF from 33.9% to 17.9% (RR 0.53) with no excess haemorrhage, infection or other morbidity.



Conclusion Bi-atrial pacing following cardiopulmonary bypass is technically feasible, safe, and effectively reduces the incidence of AF.

PACING FOR PREVENTION OF ATRIAL FIBRILLATION

P1214 Temporary left atrial pacing reduces atrial fibrillation incidence early after cardiac surgery

F. Anselme, F. Bouchart, A. Kasaï, M. Voglimacci, J.P. Bessou, A. Cribier, N. Saoudi. *Rouen university hospital, Rouen, France*

Acute electrophysiological studies have shown that left atrial pacing (LAP) could prevent atrial fibrillation (Afib) initiation. The early postoperative period of cardiac surgery (CSurg) is associated with a high incidence of Afib. Thus we evaluated the role of temporary LAP on Afib incidence following CSurg.

Methods: Temporary pacing leads were implanted on the roof of the LA during CSurg in 24 patients (pts) (Gr I). The atrial pacing rate was set either at 100 bpm for 3 days and decreased to 90 bpm for the 2 following days or at 10 bpm above the intrinsic sinus rate in order to obtain a permanent atrial capture. Incidence of Afib in Gr I was compared to that of an age-matched control group during the same period (Gr II, n = 21). In this group, pts were paced in the RA whenever clinically necessary. Chronic Afib, LA diameter (D) > 50 mm, thyroid dysfunction, and prior use of antiarrhythmic drugs were exclusion criteria. Presence of Afib was evaluated using 24 hour Holter monitoring (Day 1), ECG telemetry and a continuous loop recording system for the 5 days following CSurg. Aortic valve replacement was performed on 4 Gr I and 4 Gr II pts. The remaining pts underwent coronary artery bypass grafting. No pt received postoperative prophylactic beta blocker therapy.

Results are expressed as mean ± SD and number of pts.

	N	Age (y)	EF (%)	LAD (mm)	BB	Ao Cl. (mn)	I	Afib*
Gr I	24	60 ± 10	60 ± 14	41 ± 9	16	76 ± 36	9	5
Gr II	20	61 ± 7	64 ± 11	40 ± 7	12	82 ± 27	5	11

*$p \leq 0.05$. Ao Cl: Aortic clamp duration; BB: preoperative beta blocker therapy; I: postoperative inotropic drugs. No difference could be found between the two study groups except for the incidence of Afib.

Conclusions: These preliminary results suggest that in the early post operative phase after cardiac surgery temporary left atrial pacing may reduce atrial fibrillation incidence.

P1215 Long-term biatrial pacing. what happens with interatrial condiction disturbances?

A. Kutarski, K. Oleszczak, M. Wójcik, A. Głowniak. *Dept of Cardiology, University Medical Academy, Lublin, Poland*

IACD plays important role in pathogenesis of atrial arrhythmias and in some pts RA pacing can aggravate recurrence of arrhythmia; BiA pacing is accepted mode of non-pharmacological prevention of atrial arrhythmias in pts with IACD. In 91 pts with implanted split BP BiA pacing system we examined acute and chronic atrial timing values.

Examined Parameters	S(P)-Q	PII duration	IACT*	TAAT**
	Average (median)			
Sinus rhythm	210 (200)	157 (160)	117 (110)	183 (180)
RA pacing	245♣ (240)	178♣ (170)	154♣ (150)	214♣ (210)
BiA pacing	201♣ (190)	126♣ (125)		133♣ (135)

*IACT = S(PII)-outset A of opposite atrium; **TAAT (Total Atrial Activ. Time) = S(PII)-end A of opposite atrium; ♣ – Average difference significant in comparison to sinus rhythm

Values of TAAT were examined monthly (presented in ms):

Months	1	2	3	4	5	6
No of pts	54	36	34	23	17	32
Sinus rhythm	184	178	179	179	190	178
BiA pacing	127	123	127	124	120	119

RA pacing aggravates significantly IACD in comparison to sinus rhythm. BiA pacing normalise all atrial activation times. IACD seems to be stable during long term BiA pacing and its values (obtained with temporary reprogramming to sinus rhythm) do not change.

P1216 Intermittent or continuous overdrive atrial pacing significantly reduces paroxysmal atrial fibrillation recurrences in brady-tachy syndrome

R. Ricci[1], M. Santini, A. Puglisi[1], P. Azzolini[1], C. Pignalberi[1], A. Capucci[2], G. Boriani[3], A. Spampinato[11], F. Bellocci[1], G.L. Botto[4], A. Grammatico[5], F. de Seta[5]. *[1]Rome; [2]Piacenza; [3]Bologna; [4]Como; [5]Medtronic, Italy*

Overdrive Atrial Pacing (OAP) has been associated with a lower rate of recurrent paroxysmal Atrial Fibrillation (PAF).

Aim of the study was to evaluate the impact of intermittent or continuous OAP on PAF recurrences in a selected population of highly symptomatic brady-tachy patients implanted with a DDDR pacemaker. Study population included 35 patients (mean age 75 + 11, 12 M, 23 F) affected by brady-tachy syndrome with at least three symptomatic episodes of PAF during the last month before implantation. Intermittent OAP was obtained by programming the device in DDDR mode, continuous OAP through a dedicated algorithm, named *Consistent Atrial Pacing* (CAP), which updates beat by beat the Atrial Escape Interval to overdrive suppress spontaneous atrial activity (both sinus rhythm and premature atrial complexes (PAC). Patients were randomized in two groups, DDDR + CAP versus DDDR and followed for two months. After the first month the pacing modality was crossed over. 45% of patients were on antiarrhythmic treatment which did not change during the study period.

Results: 90% of patients in DDDR and 85% in DDDR + CAP were free from symptomatic PAF recurrences. 50% in DDDR and 35% in DDDR + CAP had no mode switching episodes stored in the pacemaker memory (p = n.s.)

	AP%	MS/d	Msd/d	PAC/d	PVC/d	ARP1	ARP2
CAP	97 ± 3	1.5 ± 2.8	117 ± 224	0.4 ± 0.7	375 ± 570	253 ± 48	250 ± 32
DDDR	87 ± 16	1.4 ± 2.9	98 ± 267	2.1 ± 4.3	521 ± 694	261 ± 53	247 ± 31
p	<0.01 n.s.	n.s.	<0.1	n.s.	n.s.	n.s.	

Legenda: AP = Atrial Pacing; MS = mode switching; d = day; MSd = MS duration (min); PAC = premature atrial complexes/1000; PVC = premature ventricular complexes; ARP1 = Atrial Refractory Period (600 ms); ARP2 = ARP (400 ms).

Conclusions: Both intermittent and continuous OAP strongly decrease PAF recurrences in selected highly symptomatic brady-tachy patients. Continuous OAP significantly increase AP percentage and decrease the number of PAC/day without a major impact on arrhythmia recurrences.

P1217 First occurrence of paroxysmal atrial fibrillation in patients inplanted with preformed vs non preformed atrial leads

A. Spampinato[1], M. Martelli[1], G. Bruni[1], C. Pignalberi[2], M. Pepe[3], F. De Seta[3], F. Bellocci[1]. *[1]Villa Tiberia Hospital, Rome; [2]Campus Biomedico Univ., Rome; [3]Medtronic Rome, Italy*

The **Aim** of this study was to evaluate if the primary occurrence of paroxysmal atrial fibrillation (PAF) in patients (pts) that had received a dual chamber pacemaker could be due to the shape of the atrial lead.

Methods: A population of 57 patients (pts) was divided into two groups: 26 pts (group 1) were inplanted with J-shaped screw-in bipolar atrial leads (Medtronic CapSure Fix 7.2 french, silicone, steroid eluting Model 5568, Medtronic CapSure Fix 7.5 french, polyurethan, steroid eluting Model 4568 and Medtronic 6.6 french, polyurethan, Model 4557 leads), 31 pts (group 2) were implanted with non preformed screw-in bipolar atrial leads (Medtronic 7.2 french, silicone, steroid eluting CapSure Fix Model 5068, Medtronic 7.2 french, silicone, steroid eluting CapSure Fix Model 5078 and Medtronic 7.2 french, polyurethan, steroid eluting CapSure Fix Model 4068 leads). There were no significant differences between the two groups in terms of age, sex, pathologies left atrial size and implant site. Follow up visits were performed at discharge and every 3 months for 1 year in both groups.

Results: Only 1 patient of group1 developed PAF at 12 months follow up (1/26 = 4%), while 8 pts belonging to group 2 (8/31 = 29%) developed PAF (3 of them were found in AF at 1st month follow up, 2 at 3th month follow up, 2 at 6th month follow up and 1 at 12th month). A significative difference between occurrences in two groups ($P < 0.05$, Fisher Exact Test) was found No adverse event occurred in either group during the study (dislodgement, infections, etc.).

Conclusions: Data collected seem to confirm significant AF proarrhythmicity with non preformed atrial pacing leads. This proarrhytmicity is probably due to the fact that this kind of non-preformed lead in the atrium results in a larger lead curve thus causing a mechanical stimulation of the right atrial wall that in turn could induce AF.

P1218 Is suppression of paroxysmal atrial fibrillation by synchronised bi-atrial pacing related to shortening of intra-atrial conduction delay?

W.P. Orr, T. Levy[1], P.J. Stafford, Y. Bashir, V. Paul[1]. *Department of Cardiology, John Radcliffe Hospital, Oxford; [1]Department of Cardiology, Harefield Hospital, Harefield, UK*

Background Multisite atrial pacing has been reported to prevent paroxysmal atrial fibrillation (PAF). Postulated mechanisms include the shortening of intra-atrial conduction times and alteration of atrial refractoriness. We investigated the effects of synchronised bi-atrial pacing on P-wave duration and energy using signal averaged electrocardiography (SAECG) and the relationship of these changes to the suppression of AF.

Methods 10 patients with refractory PAF (mean age 63, 8 male, 6 lone AF) were treated with bi-atrial permanent pacing (ELA Chorus RM, left atrial pacing via coronary sinus). P-wave SAECG was recorded using a previously validated P-wave selective averaging system. Patients were continuously monitored by the device for episodes of AF during three month periods in biatrial (DDDbi) and control (DDI) modes.**Results** P-wave duration was significantly reduced during bi-atrial pacing compared with control but this did not correlate with the degree of suppression of AF (r = 0.25, p = NS). No differences in P-wave energy were detected between pacing modes.

	DDI	DDDbi
P-wave duration (ms)	178 ± 5.6	147 ± 5.2*
% time in AF	22.5 ± 10.3	4.8 ± 4.1*
Median AF episodes (range)	151 (12–255+)	28 (0–255+)
P 30 (μV^2.s)	24.9 ± 4.1	22.1 ± 3.7
P 60 (μV^2.s)	3.8 ± 0.5	3.3 ± 0.5

*$p < 0.05$

Conclusion Bi-atrial synchronised pacing reduces P-wave duration and suppresses paroxysmal AF. However, the magnitude of the anti-arrhythmic effect did not correlate with the degree of reduction in intra-atrial conduction delay and may involve alternative electrophysiological mechanisms.

INITIATION OF ATRIAL FIBRILLATION

P1219 Characteristics of epicardial electrograms from the right atrial free wall distinguish patients in whom induced atrial fibrillation is sustained

P. Kanagaratnam, N.S. Peters. *Imperial College School of Medicine, St. Mary's Hospital, London, UK*

Background: It has been suggested that the functional properties of the crista terminalis (CT) have a central role in the atrial myocardial substrate for sustained atrial fibrillation (AF). We tested the hypothesis that the characteristics of epicardial atrial electrograms, particularly along the CT, distinguish atria in which induced AF is sustained.

Methods: Epicardial mapping was performed on 10 patients, with no history of AF, undergoing coronary artery bypass surgery before atriotomy or cardioplegia. The mapping plaque was made up of 112 unipolar electrodes at 3.5 mm spacing and was placed over the right atrial free wall such that the line of the CT traversed the middle of the array. Electrograms were recorded during steady state pacing from near the sinus node at cycle lengths of 500 ms and 660 ms. Electrogram duration and morphology (simple or complex) were determined. AF was induced by 7 Hz pacing for 5 sec up to four times and then twice for 10 sec. AF was defined as sustained if it lasted >30 sec. The electrogram data from the region of the CT (42 electrodes) and of the non-CT myocardium (70 electrodes) were then compared for each patient.

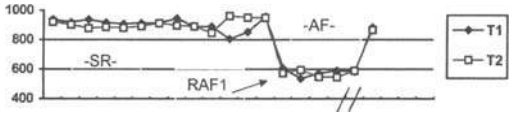
Results: Sustained AF was induced in 5 of the 10 patients. During 500 ms pacing, overall electrogram duration was greater in AF (42.15 ± 11.1 ms) than non-AF patients (25.7 ± 6.4 ms; $p < 0.001$). In the atria that sustained AF the electrogram duration was longer in the CT region compared to the non-CT myocardium when pacing at 500 ms ($p < 0.002$). By contrast, although at 660 ms pacing the overall electrogram duration was longer in patients with AF ($p < 0.03$), there was no significant difference between the CT and non-CT myocardium. Differences in electrogram complexity were not significant.

Conclusions: In atria that will sustain AF, electrogram duration, particularly in the region of the CT, is greater than in atria that will not. Only in atria that will sustain AF do epicardial electrograms in the region of the CT become distinctly different from surrounding myocardium and only at shorter cycle lengths. Interval dependent functional properties of the CT may, therefore, play a central role in the myocardial substrate maintaining AF.

P1220 Analysis of onset of paroxysmal atrial fibrillation during holter recordings

F. Lombardi[1], D. Tarricone[1], A. Colombo[1], R. Ravaglia[1], A. Bianchi[1], G. Corrado, M. Santarone, C. Fiorentini[1]. [1]*Cardiologia, Dipartimento di Medicina, Chirurgia e Odontoiatria, Ospedale San Paolo, University of Milan;* [2]*Cardiologia, Osp. Valduce, Como, Italy*

To evaluate the pattern of paroxysmal atrial fibrillation (PAF) onset and the relation between the preceding cycles and the coupling interval (RAF1), we studied 31 pts (71% males, 42–87 yrs) with 62 PAF lasting >30 sec on Holter recordings. These parameters were considered: RAF1, RR-1 (the last cycle before RAF1), RR-2, RR-3, RR-5, RR-10, RR-15, RR-30, RR-45, RR-60, RR-5 m, RR-10 m, RR-15 m and RR-30 m (the corresponding cycles before RAF1). The first three RR intervals and the mean cycle of first 100 RR intervals during AF (AFcl) as well as of 5 min after sinus rhythm recovery were also calculated. According to presence or absence of short-long sequence before arrhythmic events, PAF episodes were classified as Type 1 (T1; n = 25) and Type 2 (T2; n = 37).



The AFcl was similar in both type of PAF onset (581 ± 30 vs 589 ± 21 ms). In comparison to preceding cardiac cycles, a reduction in RR-3 was observed in T1 onset, whereas a slight increase was noticed in T2. Percentage of episodes without ectopic beats was significantly higher in T2 than T1 onset (65 versus 24%). By regression analysis, a significant correlation between RAF1 and preceding cardiac cycles was consistently evident only in T2 onset. These data suggest that an increase in heart rate is uncommon before T1 and T2 PAF onset. The major variations in cardiac cycles seem to be confined within a few beats before PAF onset.

CELLULAR, GENETIC AND BASIC MECHANISMS OF ATRIAL FIBRILLATION

P1221 Plasma atrial and brain natriuretic peptides in patients with lone atrial fibrillation

Mio Ebato, Yoshiko Nakamura, Bunken Ebato, Yukei Higashi, Takeshi Tsutsumi, Youichi Takeyama. *Division of Cardiology, Showa University Fujigaoka Hospital, Yokohama, Japan*

Background: Enhanced production of natriuretic peptides have been identified as a marker of left ventricular (LV) systolic dysfunction and hypertrophy. Only a few studies have investigated the influence of atrial fibrillation on plasma atrial and brain natriuretic peptides (ANP and BNP).

Methods: Plasma ANP and BNP levels were examined in 30 patients (male/female: 20/10) with chronic lone atrial fibrillation (group AF). The data were compared with those in age and sex matched healthy subjects with normal sinus rhythm (CONTROL, n = 30). Clinical characteristics, findings of echocardiography and Holter ECG were also analysed. All patients in groupAF attended at the out patient clinic regularly and attained heart rate (HR) at rest < 90 beats/min. Patients with LV ejection fraction (LVEF) < 55% were excluded from the study.

Results: ANP and BNP levels were significantly higher in groupAF than in CONTROL (ANP: 55 ± 32 vs 29 ± 13 pg/ml p = 0.004, BNP: 123 ± 80 vs 36 ± 20 pg/ml p < 0.001). No significant difference was found in mean blood pressure (MBP: 92 ± 10 vs 93 ± 10 mmHg), LV mass index (LVMI: 92 ± 13 vs 91 ± 15 g/m2), LV enddiastolic dimension (LVDd: 45 ± 5 vs 44 ± 4 mm), LV endsystolic dimension (LVDs: 28 ± 6 vs 26 ± 7 mm) and LVEF (62 ± 5 vs 64 ± 5%). In CONTROL, both ANP and BNP levels showed significant correlation with age (ANP: r = 0.70 p < 0.001, BNP: r = 0.81 p < 0.001). But in group AF, only BNP levels had significant correlation with age (r = 0.72, p < 0.001). MBP, LVMI, LVDd, LVDs, LVEF, average HR and maximum HR on Holter ECGs had no significant correlation with ANP and BNP levels in groupAF.

Conclusion: Plasma ANP and BNP levels were elevated even in patients with atrial fibrillation without LV systolic dyfunction and hypertrophy. Aging provided further increase in plasma BNP in patients with atrial fibrillation which might be the result of accelerated diastolic dysfunction.

P1222 Paroxysmal atrial fibrillation initiated from plurifocal pulmonary vein sources

M. Hocini, M. Haïssaguerre, P. Jaïs, D.C. Shah, A. Takahashi, S. Garrigue, J.T. Peng, J. Clémenty. *Hôpital du Haut-Lévêque, CHU de Bordeaux 33604 Pessac, France*

The pulmonary veins (PV) are the dominant source of ectopic beats (APB) initiating paroxysms of atrial fibrillation (AF). The extent of arrhythmogenic substrate has not been defined.

Methods: For the last 10 months, 35 patients (7 females, 28 males, 53 ± 10 years, 10 with heart disease) were successively referred for catheter ablation of drug resistant AF. In 13 patients, spontaneous APB were frequent enough to guide mapping whereas in 22 patients APB were rare or absent, requiring provocative manoeuvers. Two or 3 multielectrode catheters were used to map the PV simultaneously (when needed) and PV angiograms to define precisely the targetted sites.

Results: 71 foci were identified: 97% from the PV and 3% from the atrial tissue. Repetitive discharges were documented in 48 and AF initiation in 37. All foci discharging only in bursts inducing AF without producing isolated APB originated from the PV. There were 1, 2 and 3–4 arrhythmogenic PV in 40%, 26% and 34% of patients. In addition, 2 or 3 distinct APB sources were recognized to originate from the same PV (but from ostia of different branches) in 15 patients. These different foci could fire sequentially or simultaneously, produce conducted or non conducted spikes and required separate RF applications. In 4 patients, the ectopic source 'wandered' from within the PV to the atrial edge after ablation. A single ablation session was performed in 15 patients while in the remaining 20, 29 sessions were necessary owing to recurrent ectopy: 1) from the same source (7); 2) from a different part of the same PV (8); 3) from a different PV (14).

Conclusions: The PV are the dominant source of AF initiation even in patients with few or no APB. Multiple PV are involved in 60% of patients and the sources of AF are frequently plurifocal in a given PV, sometimes being displaced to the atrial edge after ablation. Multiple RF applications were necessary to abolish such plurifocal sources.

P1223 Variability of provocative manoeuvers for inducing pulmonary vein ectopy

D.C. Shah, M. Haïssaguerre, P. Jaïs, A. Takahashi, M. Hocini, J. Clémenty. *Hôpital du Haut-Lévêque, CHU de Bordeaux 33604 Pessac, France*

A significant problem in successfully ablating pulmonary vein (PV) ectopy initiating atrial fibrillation is the requirement for sufficient ectopy to allow precise mapping and localisation.

Methods: 80 consecutive patients with paroxysmal atrial fibrillation (63 M, 17 F, mean age 54 ± 10 years, 24 structural heart disease) underwent mapping and ablation of PV ectopy initiating atrial fibrillation. In the absence of sufficiently frequent spontaneous ectopics, various provocative manoeuvers were used to elicit enough ectopy to permit mapping and successful ablation. Usually in the following order they included carotid sinus massage, deep breathing and Valsalva, slow rate (100–200 bpm) pacing, Isuprel infusion, high rate pacing and combinations. IV Digoxine and Adenosine were also tried.

Results: Several manoeuvers were successful in eliciting ectopy from the same focus while different foci in the same patient exhibited varying sensitivity. If atrial fibrillation was induced, reinitiation was noted after cardioversion. All manoeuvers were unsuccessful in 2 patients.

Provocative manoeuvers	Positive responses (pts)
Slow rate pacing (100–200 bpm)	15
Isoproterenol infusion (2–4 μg/min)	37
Valsalva	14
Carotid massage	3
High rate pacing (200–300 bpm)	12
Adenosine triphosphate (20–80 mg in bolus)	5
Digoxin 0.5 mg intravenous	0
Propanolol 5 mg intravenous	0
Verapamil 10 mg intravenous	0
Post cardioversion	5

Conclusions: Isoprenaline infusion, respiratory manoeuvers and the pause following pacing (short-long sequence) were most effective. The response of PV ectopy suggests a (Ca++ mediated) mechanism sensitive to mechanical stimuli. Stretch mediated triggered activity is a likely possibility.

P1224 How does duration and dispersion of atrial refractoriness influence persistence of atrial fibrillation?

E. Leistad, S. Subudhayangkul[1], G.A.D. Ungab[1], B. Cotter[1], M. Wadhwa[1], G.K. Feld[1]. *Department of Medicine, Lovisenberg Hospital, Oslo, Norway; [1]Cardiovascular Division, UCSD Medical Center, San Diego CA, USA*

The electrophysiologic mechanisms of the persistence of atrial fibrillation (AF) after its initiation are not well understood. Therefore, the electrophysiological characteristics of the right atrium were evaluated in order to identify parameters associated with persistence of AF.

Methods: AF was induced by rapid atrial pacing in 30 anesthetized, open-chest, juvenile pigs. Activation mapping and programmed stimulation (S1S1 = 200 ms) were performed at 56 electrodes on the right atrial free wall. ERP (mean and minimum), dispersion of refractoriness, conduction velocity, wavelength, AF cycle length (mean of 10 beats) and AF cycle length/time (electrical remodeling) were determined.

Results: Sustained AF (AF lasting >30 min) was induced in 10 pigs, non sustained AF (NSAF) in 9 and no AF (AF duration < 30 s) in 11 pigs. AF cycle length was shorter in SAF and/vs NSAF vs no AF. Mean ERP (107 ± 9 and/vs 122 ± 5 vs 142 ± 9). and wavelength (7 ± 1 and/vs 9 ± 1 vs 11 ± 1) were shorter in SAF and/vs NSAF and no AF. Minimum ERP was shorter in SAF and NSAF vs no AF. Conduction velocity at cycle lengths of 200 and 150 ms was not different between groups. Dispersion of ERP was greater in SAF and/vs NSAF vs no AF. (8 ± 1 and/vs 11 ± 1 and 19 ± 4).

Conclusions: There was no correlation between duration of AF and conduction velocity. However, persistence of AF correlated with shorter ERP and wavelength, and greater dispersion of ERP and electrical remodeling. These findings may have important pharmacological and other therapeutical implications.

P1225 The degree and area of effective refractory period shortening required for occurrence of focal localized fibrillation in the canine right atrum

K. Sagara, H. Iinuma, A. Sekiguchio, H. Watanabe, K. Kato. *The Cardiovascular Institute, Tokyo, Japan*

It has been well known that atrial fibrillation (AF) occurs under the condition of conduction delay, shortening of atrial effective refractory period (ERP) and the dispersion of these factors. Recently important reports have been made, suggesting the presence of focal AF localized at the small area in the right/left human atrium, which made it possible to be ablated at a point. However, the substrate and electrophysiological properties of the local AF have not been clear. The purpose of this paper is to clarify the condition allowing the presence of regional AF, the degree and area of ERP shortening in the dog right atrium (RA).

Methods: We prepared thick filter paper disks with a variable diameter (D) of 6–10^{mm}, which could contain a liquid for a long time, having 6–8 bipolar electrodes to stimulate and record electrical activities of atrial tissues within and surrounding it. We sutured the disk of variable size to RA free wall of 15 anesthetized dogs. Before and after an administration of 10^{-4}–10^{-3} M acetylcholine (Ach), S_1S_2 programmed stimulation was applied to measure ERP and induce focal AF (continuous irregular electrical activity of variable amplitude with cycle length (CL) of 40–60^{ms}).

Results: 1) ERP shortening: Ach of 10^{-4} or 10^{-3} M shortened ERP from 131 ± 14 to 87 ± 10, 32 ± 10^{ms}, respectively, only beneath the disk. 2) Induction of focal AF: No focal AF was provoked in any size of disk at 10^{-4} M Ach. At 10^{-3} M Ach, focal AF occurred at a rate of 0, 25, 75% in the local area of RA beneath the disk of D = 6, 8, 10^{mm}, respectively. During focal AF, regular activity with CL of 100–150^{ms} was recorded on RA around the disk (2^{mm} apart), RA appendage and LA.

Conclusion: Thus, it was known that ERP shortening of a critical degree and area might allow the presence of focal localized AF.

P1226 Up-regulation of inositol 1,4,5-trisphosphate receptor (ip3r) in the atrial tissue of patients with chronic atrial fibrillation

J. Yamada, T. Ohkusa, M. Yano, Y. Saiki, Y. Fujimura, K. Esato, M. Matsuzaki. *Yamaguchi University School of Medicine, Ube-Yamaguchi, Japan*

Background We have previously reported the alterations in cardiac sarcoplasmic reticulum Ca^{2+} regulatory proteins (ryanodine receptor and Ca^{2+}-ATPase) in atrial tissue of patients with chronic atrial fibrillation (AF). The IP3Rs have been found to be intracellular Ca^{2+} release channels. Recently, the IP3R was detected in both intracellular and plasma membrane fractions and may be to play a possible role to modulate intercellular communication via the intercalated discs. The purpose of this study was to determine whether AF patients have alterations in IP3Rs in the atrial myocardium.

Methods We analyzed expression level of IP3R by Western blotting analysis in right atrial myocardium from 10 mitral valvular disease (MVD) patients with AF (MF), 3 MVD patients with normal sinus rhythm (NSR) (MN). As a control group (C), right atrial myocardium from 7 patients with NSR, obtained during cardiac surgery for coronary artery bypass or thoracic aortic aneurysm. Hemodynamic and echocardiogram data were obtained from preoperative cardiac catheterizations and echocardiograms.

Results The relative expression level of IP3R in MA was significantly increased as compared to MN (MA vs MN; 0.81 ± 0.26 vs 0.47 ± 0.06: $p < 0.05$). In both MA and MN, these levels were also significantly increased as compared to C (0.13 ± 0.07). There were positive correlations between the IP3R expression level and left atrial dimension, right atrial pressure, *or* pulmonary capillary wedge pressure. However, there were no significant differences in these parameters between MA and MN.

Conclusions This study shows that chronic mechanical overload to atrial myocardium increases the expression level of IP3R, and this level was more increased in patients with chronic AF. These results suggest that in patients with AF, up-regulated IP3R may play an important role to modulate intercellular communication.

P1227 Effects of chronic atrial fibrillation on calcium and sodium currents in humans

R.F. Bosch, X.R. Zeng, J.B. Grammer, K. Madic, C. Mewis, V. Kühlkamp. *Department of Cardiology, University of Tübingen, Germany*

Atrial fibrillation (AF) leads to a change in atrial repolarization and in intraatrial conduction properties. The underlying cellular mechanisms in humans are only poorly understood. We studied the effects of chronic AF on L-type calcium currents ($I_{Ca,L}$) and on sodium currents (I_{Na}) in humans.

Methods: Ionic currents were recorded in single atrial myocytes in the whole cell mode of the patch clamp technique. Patients in chronic atrial fibrillation (AF) (n = 8) were compared to those in normal sinus rhythm (SR) (n = 17).

Results: The presence of AF led to a strong reduction of $I_{Ca,L}$ densities at test potentials between −10 mV and +50 mV, i.e. at +10 mV, current densities were −6.97 ± 0.50 pA/pF (Mean ± SEM) in SR (n = 42) and −1.88 ± 0.19 pA/pF in AF (n = 18; $p < 0.001$ vs. SR). I_{Ca} voltage dependence was not altered by AF, peak current amplitudes occurred at +10 mV in both groups. Voltage dependence of activation and inactivation as well as recovery from inactivation of $I_{Ca,L}$ were not affected by AF. In AF, inactivation kinetics (biexponential fit) were slower than in SR. The fast inactivation constant τ_{fast} was 5.1 ± 0.6 ms in SR (n = 39) and 8.3 ± 0.9 ms in AF (n = 16; $p < 0.01$ vs. SR), whereas the slow time constant τ_{slow} was unaffected. I_{Na} current densities were identical in the 2 groups at all test potentials, i.e. at −40 mV: −50.2 ± 3.1 pA/pF in SR (n = 44) and −46.1 ± 4.5 pA/pF in AF (n = 25, p = ns). Voltage-dependent and kinetic properties of I_{Na} were also not altered by AF.

Conclusions: Electrical remodeling in human AF is associated with a marked decrease of $I_{Ca,L}$ densities and a slowing in the inactivation kinetics. A decreased calcium inward current in AF seems to contribute to accelerated repolarization and to the perpetuation of the arrhythmia. In contrast to the findings in animal models, I_{Na} is not affected in chronic human AF.

P1228 3-D endocardial spatial dispersion of atrial electrogram fragmentation during atrial fibrillation in the chronic goat model

L. Gepstein, G. Hayam, T. Wolf, A. Zaretzky, R. Shofty, S.A. Ben-Haim.
Faculty of Medicine, Technion, Haifa, Israel

Local electrogram fragmentation has been previously shown to be associated with slow conduction, tissue anisotropy, conduction block, reentry and activation wave collision. To test the hypothesis that there is regional variation in the complexity of endocardial atrial activation during atrial fibrillation (AF) we have utilized a non-fluoroscopic electroanatomic mapping (NFM) system to map the 3-D spatial dispersion of the degree of local electrogram fragmentation and cycle-length (CL) histograms in the chronically paced goat model.

Methods and Results: Experiments were carried out in 10 goats with sustained AF (>24 h). By sampling a plurality of endocardial sites at which 60 sec of local atrial electrograms were recorded, the 3-D geometry of the chamber was reconstructed, with the electrophysiologic information color-coded and superimposed on the anatomy. A fragmentation index (FI), defined as the average number of deflections in the local bipolar electrogram for each atrial activation, was calculated for each site. Significant spatial variations were noted with the RA high and low septum associated with significantly higher FI values (3.2 ± 0.1 and 3.4 ± 0.1, $p < 0.01$)) than the rest of the atrium (2.3 ± 0.1 to 2.5 ± 0.2). In the LA, significantly higher FI values ($p < 0.01$) were noted at the posterior and septal aspects (3.5 ± 0.6 and 3.7 ± 0.2 respectively). Similarly the RA septum and posterior walls were associated with the shortest median CL (112 ± 3 and 114 ± 2 ms respectively) with longer median CLs observed at the anterolateral free wall (125 ± 3 ms) and near the SVC, IVC and isthmus regions (129 ± 4, 131 ± 2 and 132 ± 6 ms respectively). The LA was characterized by a more homogenous dispersion of CL histograms with the septal area displaying slightly shorter median CLs (118 ± 3 ms).

Conclusions: 1) Significant spatial dispersion of different electrophysiological parameters can be observed in this chronic model of AF and may result from a combination of anatomical and electrophysiological factors. 2) The septum is associated with the most complex atrial activation patterns (highest FI) as well as by the shortest median CLs suggesting a critical role of this area in the perpetuation of AF.

P1229 Regional patterns of atrial fibrillation spatial organization in the chronic goat model as quantified by the endocardial spatial correlation index

L. Gepstein, G. Hayam, T. Wolf, U. Dror, A. Zaretzky, R. Shofty, S.A. Ben-Haim. *Faculty of Medicine, Technion, Haifa, Israel*

Previous studies have shown that quantitative measurement of the degree of similarity between atrial activation sequences (using the cross-correlation function) recorded from a number of bipolar electrodes can be used to assess the global spatial organization of AF. To test the hypothesis that regional disparities in the spatial organization of AF exist, we examined possible regional differences in the endocardial spatial correlation index (SCI).

Methods and Results: 6 goats with sustained AF (>24 h) induced by chronic rapid atrial burst pacing were studied using a 3-D electroanatomical mapping system (Carto). A special quadripolar catheter (with a distance of 15 mm between the two bipoles) was used to record 15 seconds of atrial electrograms during AF. The signals extracted from the two bipolar electrodes were processed and then cross-correlated. This process was repeated at a plurality of endocardial sites in the RA. Significant regional variation was noted in all animals. The septum and posterior walls were characterized by the lowest SCI values (0.25 ± 0.01 and 0.35 ± 0.03 respectively, mean $\pm$ SEM). The anterolateral free wall and tricuspid-IVC isthmus displayed a more organized activity (SCI values of 0.47 ± 0.02 and 0.48 ± 0.02). The highest SCI values were noted at the SVC-atrial junction (0.66 ± 0.02) and IVC-atrial junction (0.55 ± 0.03).

Conclusions: 1) Significant regional differences were noted in the spatio-temporal organization of AF as measured by the SCI values. 2) The smooth RA (RA septum and posterior wall) is characterized by low SCI values indicating uncoupling of atrial activation sequences between the two bipoles due the presence of simultaneous multiple neighboring wavefronts. In contrast the anterolateral free wall is relatively protected from this turbulent activity (most probably due to the presence of the cristae terminalis) and is activated mainly by broad wavefronts (high SCI values). 3) The ability to assess regional disparities in the spatial organization of AF may increase our understanding regarding the mechanisms underlying AF and may possibly aid in designing custome-made curative strategies.

P1230 Efficacy and safeness oral loading dose propafenone in paroxysmal atrial fibrillation

A. Capucci, G.L. Botto[1], G. Boriani[2], G.Q. Villani, D. Aschieri, M.F. Piepoli.
Cardiology Dept., Polichirurgico, Piacenza; [1]Cardiology, S. Anna Hospital, Como[2]Cardiologic Institute, University, Bologna, Italy

In 486 patients (pts) (226 M, 61 years) the efficacy and safety of a single oral loading dose of propafenone (PNF) (600 mg p.o. as a single dose) for converting recent onset (<48 hours) paroxysmal atrial fibrillation (AF) to sinus rhythm (SR) were assessed. All pts (lone AF, hypertension or mild organic heart disease) were in NYHA functional class I or II, but without signs or symptoms of heart failure and were hospitalised. They were randomly allocated to treatment with PNF or placebo. In case of persistent AF (>8 hours) they were DC cardioverted. A continuous Holter monitoring was recorded.

Results: With respect to placebo, PNF reduced conversion time to SR (7.8 vs 4.1 hrs, $p < 0.01$) and increased cardioversion rate both at 3 hours (19.3 vs 49%, $p < 0.01$) and at 8 hours (39 vs 77%, $p < 0.01$). However an higher percentage of adverse events was observed in the group of pts under PNF treatment (3.7 vs 2.5%, $p < 0.05$), but no major adverse events were observed. In PNF group minor side effects included slight transient hypotension (6 pts), junctional rhythm (2 pts) and QRS > 120 msec (3 pts). One case of atrial flutter with 1:1 AV conduction was observed but in the PI group.

Conclusion: A single oral loading dose of PNF is effective and safe in hospitalised pts with AF. Atrial flutter may be a common finding before conversion to SR, but without haemodynamic consequences. These observations can be the basis for a cost effective out of hospital therapeutic approach of pts with AF.

P1231 What are the limits for atrial fibrillation surgery in mitral patients?

J. Melo, P. Adragão[1], C. Aguiar[1], J. Neves, M. Ferreira, T. Santiago.
Cardiothoracic Surgery Department; [1]Cardiology Department, Santa Cruz Hospital, Carnaxide, Portugal

Background and Purpose: Different surgical approaches are available for the treatment of atrial fibrillation (AF). Some are complex, long and require surgical incisions on the posterior aspect of the heart. Radiofrequency (RF) catheter ablation has been used as an alternative to surgical incisions for creation of lesions in the atrial wall. We report our experience on electrosurgical treatment of AF using a new catheter conceived for intraoperative use.

Methods: Thirty-five Pts with mitral valve disease and AF were submitted to concommitant valve and AF surgery. AF was chronic in 27 Pts (77%) and paroxysmal in 8 (23%). Surgical approach was conventional sternotomy in 29 Pts, minithoracotomy in 5 and left thoracotomy in 1 Pt. AF surgery consisted of bilateral isolation of pulmonary veins (BIPV) using RF energy applied by a novel system specially designed for intraoperative use. It is a heptapolar catheter that allows 7 simultaneous applications of RF energy. Each set of applications aimed at a maximal duration of 60 sec and a maximal preset temperature of 70°C. Energy delivery (≤150 Watts) was controlled by thermosensors located on each electrode in order to optimize tissue warming. Mitral valve surgery consisted of valve replacement in 31 Pts, repair in 3 and leak suture in 1 Pt. Concommitant procedures were tricuspid valve repair in 9 Pts, atrial septal defect closure in 3 and LA volume reduction in 1 Pt.

Results: BIPV required two or three RF endocardial applications. Mean time dispended on the RF procedure was 7 ± 4 minutes. No mortality or myocardial infarction occurred and no bleeding was attributable to the RF procedure. At discharge, 21 Pts (60%) were off AF; 14 (40% of all Pts) of these presented sinus rhythm and bilateral atrial contraction. 4% had high atrial rhythm and bilateral atrial contraction, 8% were out of AF with the right atria contracting and 4% where out of AF with hemodynamically silent atria.

Conclusion: BIPV is a fast, safe and efficient procedure for electrosurgical treatment of AF in Pts submitted concommitantly to mitral valve surgery, precluding its use in other groups of Pts with less severe baseline characteristics.

P1232 Signal averaged P-wave energy increases after coronary bypass grafting in patients with postoperative atrial fibrillation

K.J. Ward, K.I. Roukas, C. Bucknall, J.S. Gill, P.J. Stafford[1]. *Cardiac Departments of St Thomas' Hospital, London; [1]Glenfield Hospital, Leicester, UK*

Background: A number of investigations have demonstrated that analysis of the signal averaged P-wave (SAPW) *before* coronary bypass grafting (CBG) is of limited predictive value for *post-operative* atrial fibrillation (AF). Analysis of the *post-operative* SAPW may be more helpful. We have therefore investigated the characteristics of pre- and post-operative SAPW in pts undergoing first elective CBG.

Methods: SAPW were prospectively collected before and 6 hours after CBG in 181 pts (135 M, mean age 64 yrs). P-wave duration and energies contained in frequency bands from 40 and 80 to 150 Hz of the P-wave spectrum were calculated. Continuous electrocardiographic (ECG) monitoring was performed for 48 hrs after CBG with routine ECG recordings thereafter until hospital discharge.

Results: 54 (30%) of pts developed AF (group AF). Post-operative P-waves were significantly shorter compared to pre-operative values in both AF pts and those who remained in sinus rhythm (group SR). In SR pts no changes in P-wave energy occurred, but in AF pts a significant post-operative increase in high frequency P-wave energy was observed:

	Group AF		Group SR	
	Pre	Post	Pre	Post
Duration (ms)	148 (2)	140 (2)**	144 (1)	138 (1)**
P60	1.2 (0.1)	1.6 (0.17)*	1.2 (0.06)	1.4 (0.09)
P80	0.49 (0.05)	0.71 (0.09)*	0.52 (0.03)	0.60 (0.03)

P60, P80: Energy from 60 and 80 to 150 Hz. **$p < 0.001$, *$p < 0.05$ vs preoperative value

Conclusion: All patients demonstrate reductions in the SAPW duration after CBG, implying an increase in conduction velocity that would reduce vulnerability to AF. However, pts who develop AF exhibit an acute increase in P-wave energy that may correlate with a reduction in atrial refractoriness. Our data suggest that this provides the substrate for post-operative AF.

ATRIAL FIBRILLATION: HOW TO PREVENT OR PREDICT RECURRENCES

P1233 Incidence of sudden cardiac death after atrioventricular node ablation and pacing: long-term follow-up

M. Gasparini, M. Mantica, P. Turco, M. Brignole, C. Menozzi, P. Delise, A. Proclemer, S. Tognarin, R. Ometto. *Cardiologia/Elettrofisiologia Dept, Istituto Clinico Humanitas, Rozzano/Milan, Italy*

The incidence of sudden cardiac death (SCD) after atrioventricular (AV) node ablation and permanent pacing has been focused mainly in patients early after ablation, and is reported to range between 2% per year to 8% per year in patients with congestive heart failure. Few data are available regarding the risk of SCD late after the ablation procedures in pts with paroxismal or chronic atrial fibrillation (PAF, CAF).

Methods and Results: From May 1987 to January 1997, AV node ablation was performed in 585 severely symptomatic patients (mean age 66 ± 11 years) with high-rate, drug-resistant paroxismal (n = 308) or chronic AF (n = 277). Lone AF was present in 133 patients, while the remaining 452 patients suffered from dilated, ischemic or valvular heart disease. Patients underwent VVIR (454 patients) or DDDR (131 patients) pacemaker implantation, after AV node ablation. During a mean follow-up of 33.6 ± 24.2 months 80 deaths were recorded (13.7%): 40 non-cardiac, 23 non-sudden and 17 SCD (3%, 1.04% per year). The actuarial occurrence rates of SCD were 0.8%, 1.5%, 2.8% and 6% after 1, 2, 3 and 6 years respectively.

Pts with or without SCD were not statistically different in mean age (64.8 ± 0.2 vs 66.3 ± 11 ys, NS) while LVEF (34.2 ± 10.1 vs 46.6 ± 18.8, $p < 0.04$) and NYHA class (3.1 ± 1 vs 2.3 ± 0.9, $p < 0.02$) were significantly different between the 2 groups.

Conclusions: Data from our large cohort of patients indicate a fairly low incidence of sudden cardiac death at a long term follow-up after AV node ablation and pacing for drug-refractory, high-rate AF. The presence of clinical signs of heart failure and low LVEF before AV node ablation and pacing are good predictors of the incidence of SCD in these patients.

P1234 Multilinear radiofrequency ablation of the atria for the suppression of paroxysmal atrial fibrillation

E.G. Vester, I. Dobran, M. Hennersdorf, V. Niebch, H. Dees, B.E. Strauer. *Department of Cardiology, Pneumology and Angiology, Heinrich-Heine-University, Düsseldorf, Germany*

Background: For the treatment of paroxysmal atrial fibrillation (pAFib) only palliative ablation techniques are established, newly developed more curative techniques are presently under evaluation. A novel method for AFib suppression by atrial compartmentalization (COM) due to multilinear ablation (ML-RFA) is introduced. 11 patients (pts) with missing or minor cardiac disease and highly symptomatic, medically refractory pAFib underwent a well defined ML-RFA protocol in a prospective study using the 8-polar Revelation™ and the 2-polar large tip Cosio flutter ™catheter. During sinus rhythm 4 contineous lines from VCS to VCI, VCS to Tricuspid annulus anterior resp. posterior and along the isthmus were drawn. Primary endpoints were 1) increasing pacing threshold and reducing the amplitude of the local ecg and 2) improving symptoms and reducing the frequency of AFib attacks. The intended lines could be accomplished in all cases. A second ablation in the isthmus became necessary in 3 cases because of the onset of "new" atrial flutter, a left atrial linear resp. focal ablation in 4 cases because of recurrence of AFib. The pacing threshold increased from 1.45 ± 0.70 to 3.19 ± 1.07 V, i.e. by 121% ($p < 0.01$). The amplitude of the local A-wave decreased by 47 ± 5% ($p < 0.01$) from 1.62 ± 1.53 mV to 0.76 ± 1.12 mV (53 ± 6%). During short term FU (1–6 mo) the event free interval increased from 1.6 to 11.1 days ($p < 0.01$), symptoms improved markedly in 9/11 pts (81%) and no recurrence at all had 5 pts (45%). There was no severe complication.

Conclusion: Primary right atrial COM by MA-RFA is effective, safe and successful in nearly 50% of cases. In 1/3 of pts new atrial flutter or AFib requires additional isthmus resp. left atrial RFA. Final success rate amounts to 45% for suppression and 80% for symptoms relief.

P1235 Analysis of left atrial appendage doppler flow rate in atrial fibrillation and its relationship with duration of the arrhythmia and response to chemical cardioversion

E. Antonielli, P. Trambaiolo, A. Pizzuti[1], A. Bassignana, M.E. Rovere, M. Tanga, G. Baduini[1], M. Di Leo. *Dept of Cardiology, SS. Annunziata Hospital, Savigliano; [1]Dept of Cardiology, Mauriziano Umberto I° Hospital, Torino, Italy*

Background. Persistence of atrial fibrillation (AF) and lower response rate to cardioversion (CV) have been associated with shorter wavelengths of reentry pathways. A direct and close correlation between atrial electrical activity and left atrial appendage (LAA) Doppler flow has recently been demonstrated.

Purpose. To characterize LAA Doppler flow, in order to define the cycle length of emptying waves and hence LAA rate and its relationship with 1) duration of AF and 2) response to attempts at chemical CV.

Methods. Transesophageal echocardiographic (TEE) studies were performed in 38 pts (27 males, mean age 63 ± 11 years) in AF (mean duration 12 ± 15 days, unknown in 9 pts) awaiting CV. Propafenone (30 pts) or flecainide (8 pts) were administered i.v. at a dosage of 2 mg/kg body weight in 10 minutes, during continuous TEE monitoring. LAA rate was averaged in basal conditions and at the end of drug infusion over at least 5 consecutive cardiac cycles.

Results. LAA rate could not be determined in basal conditions in 2 pts and at the end of drug infusion in further 8 pts because of the presence of very low or passive flow profiles. A weak but significant correlation between LAA rate and duration of AF was found ($r = 0.45$, $p = 0.003$). CV was successful in 18 pts (47%). Baseline LAA rate was significantly lower in pts with successful CV (380 ± 42 vs 438 ± 37 beats/min, $p < 0.001$). At the end of drug infusion, there was a highly significant decrease in LAA rate (409 ± 39 vs 280 ± 42 beats/min, $p < 0.001$) but no significant difference in the magnitude of slowing between successful and unsuccessful CV.

Conclusion. Analysis of LAA Doppler flow rate is feasible in the vast majority of pts with AF. A lower LAA rate seems to indicate pts with AF of shorter duration and more prone to successful chemical CV.

P1236 Echocardiographic assessment of diastolic left ventricular function is a valuable tool for predicting the risk of early recurrence of atrial fibrillation after successful cardioversion

C.M. Schannwell, F.C. Schoebel, G. Plehn, R. Marx, M. Leschke, E.G. Vester, Ch. Perings, B.E. Strauer. *Clinic of Cardiology, Heinrich-Heine University Düsseldorf, Germany*

Background: After successful cardioversion early recurrence of atrial fibrillation is documented frequently. The purpose of this study was to investigate whether left ventricular (LV) diastolic parameters are valuable to predict the risk of early atrial fibrillation after successful cardioversion.

Methods: In 58 consecutive patiens with atrial fibrillation (58 ± 6 years; 61% male; duration of atrial fibrillation > 28 days in 81%) who underwent successful cardioversion (electrical: 85%) to sinus rhythm, we performed an echocardiographic examination 24 hours after successful cardioversion. Following parameters of diastolic function were assessed: peak early (V_E) and peak late (V_A) diastolic flow velocity; early-to-late flow velocity ratio (V_E/V_A); acceleration (AT) and deceleration time (DT) of flow velocity in early diastole and isovolumetric relaxation time (IVRT). All patients were treated with anti-arrhythmic agents after cardioversion. Early recurrence was defined as documentation of atrial fibrillation during 30 days after cardioversion. Using multiple logistic regression, clinical and Doppler-echocardiographic parameters were tested for an association with recurrence of atrial fibrillation.

Results: 18 patients had recurrence of atrial fibrillation within 30 days after successful cardioversion. All patients (n = 11) with a restrictive diastolic filling pattern (V_E/V_A-ratio: 2.1 ± 0.8, DT: 158 ± 21 ms, IVRT: 51 ± 5 ms) and duration of atrial fibrillation > 28 days had early recurrence of atrial fibrillation. In 5 patients with restrictive diastolic filling pattern and atrial fibrillation < 28 days before successful cardioversion and 2 patients without restrictive filling pattern who had atrial fibrillation for more than 28 days also early recurrence of atrial fibrillation was documented. Multivariate analysis adjusted to clinical parameters as age, gender, presence of coronary artery disease and use of different antiarrhythmic agents after cardioversion demonstrated that just parameters of LV diastolic function were significantly associated with the recurrence of atrial fibrillation.

Conclusion: Assessment of LV diastolic function by Doppler-echocardiographic analysis of the diastolic transmitral flow 24 hours after successful cardioversion can predict the risk of early recurrence of atrial fibrillation. A restrictive diastolic filling pattern is associated with significantly increased risk of early recurrence of atrial fibrillation.

P1237 The value of Doppler derived mitral "a" wave in predicting maintenance of sinus rhythm after cardioversion

M.S. Kücükoglu, Z. Yigit, B. Ökcün, H. Mutlu, V. Sansoy, S. Üner, D. Güzelsoy. *Institute of Cardiology, University of Istanbul, Istanbul, Turkey*

The aim of this study was to assess the value of Doppler derived mitral "a" wave in patients with atrial fibrillation (AF) in predicting maintenance of sinus rhythm (SR) after cardioversion (CV).

One hundred and eighty-seven patients with nonvalvular AF (90 female, 97 male, mean age 65 ± 9) in whom SR had been restored with pharmacologically or with DC shock were enrolled in the study. Transthorasic echocardiography (TTE) is performed in all patients during the first 24 hours after CV. TTE variables evaluated included left ventricular ejection fraction (LVEF), left atrium diameter (LAD), and transmitral flow pattern. Patients were followed up for at least 1 year. The duration of the restored SR was less than 30 days in 20 patients, 31–90 days in 25 patients, 91–180 days in 43 patients, 181–365 days in 25 patients and more than 365 days in 74 patients.

Duration of SR was inversely correleted with age ($r = -0.97$, $p = 0.006$), duration of AF ($r = -0.93$, $p = 0.02$), and LA diameter ($r = 0.93$, $p = 0.02$). There was a direct correlation with the amplitude of the "a" wave, and the duration of maintenance of SR ($r = 0.96$, $p = 0.008$). The relation of age, AF duration and LAD to maintenance of SR was not influenced by the mode of CV, however mitral "a" wave was influenced by the mode of CV. There was a positive relation in the patients whom SR was restored pharmacologically ($r = 0.99$, $p < 0.00001$), but no relation in the patients DC shock was used for CV.

In conclusion, Doppler derived mitral "a" wave measured during the first 24 hours after CV may be used to predict 1 year outcome of CV.

P1238 Maintenance of sinus rhythm after cardioversion of chronic atrial fibrillation: sotalol versus bisoprolol

A. Plewan, G. Lehmann, E. Alt, C. Schmitt. *German Heart Center; 1. Medizinische Klinik, Klinikum rechts der Isar, Tech. Univ. München, Germany*

Aim: Purpose of the study was to compare the efficacy and safety of sotalol and bisoprolol for maintenance of sinus rhythm (SR) after electrical cardioversion (CV) of atrial fibrillation (AF).

Methods: 128 patients entered the trial and were randomized equally to sotalol (80 mg bid) or bisoprolol (5 mg/day). Patients with contraindications to β-blockers or class III antiarrhythmics drugs and prior treatment with study drug for prevention of AF were excluded. Follow up clinical evaluation was performed one day, one months and thereafter in 3 months intervals up to one year. Rhythm was documented by 12-lead surface ECG.

Results: There were no differences in baseline clinical characteristics between both groups. After a follow up of 12 months 59% of all patients were still in SR. The proportion of patients (pts) remaining in SR on each drug was calculated for the two groups by Kaplan Meier method. 41% of patients on sotalol and 42% on bisoprolol developed AF during follow up (n.s.), 49 ± 87 and 38 ± 74 days respectively after CV. Sinus heart rate was significantly decreased ($p < 0.001$) in both groups (n.s. between groups). Uncorrected QT duration was prolonged by sotalol and significantly longer than the uncorrected QT interval in the bisoprolol group. Under treatment the corrected QT duration (Bazett formula) was equally prolonged in both groups ($p < 0.001$), whereas uncorrected QT duration at similar heart rate levels were prolonged in sotalol pts only (mean increase 30 ms; 95% confidence interval 21–40 ms, $p < 0.01$). Proaarhythmias occurred in none of the pts in the bisoprolol and in 2 pts (3.1%) in the sotalol group. Both adverse effects were torsade de pointes tachycardias.

Conclusion: This study demonstrats that sotalol and bisoprolol are equally effective in maintaining sinus rhythm. An obvious class III effect under low dose sotalol treatment could be shown. Our data indicate that, due to the proarrhythmic side effects of sotalol, bisoprolol seems to be advantageous in treatment for maintenance of SR after CV of AF.

P1239 Recent onset paroxysmal atrial fibrillation: spontaneous conversion and the role of high-dose intravenous amiodarone

G. Cotter, A. Blatt, E. Kaluski, E. Metzkor-Cotter, M. Koren, R. Zaidenstein, Z. Vered, A. Golik. *Cardiology Institute and Department of Medicine "A", Assaf Harofeh Medical Center, Zerifin, Israel*

Objective: To compare the efficacy (conversion to sinus rhythm) of high dose amiodarone versus placebo, in patients with Paroxysmal atrial fibrillation (PAF).

Methods: One hundred patients with 2^{nd}–6^{th} episode of new onset PAF (lasting less than 48 hours) were randomized to receive placebo or high dose intravenous amiodarone (3 gr. over 24 hours).

Results: Spontaneous conversion (SC) to normal sinus rhythm (NSR) occurred in 64% of the patients in the placebo arm (mostly within 8 hours), and 92% of the amiodarone arm ($p = 0.0017$). Clinical EKG and echocardiographic parameters that were associated with reduced incidence of SC were: hypertension, ischemic heart disease, congestive heart failure, ST depression, left atrial enlargement, reduced ejection fraction, and moderate or severe mitral regurgitation. In patients without any of these markers SC to NSR occurred in nearly 90% of the patients.

Conclusions: 1) High dose amiodarone is superior to placebo in converting PAF to NSR. 2) Amiodarone most markedly improves conversion rates of patients with clinical and echocardiographic markers of reduced SC rates. 3) Anti-arrhythmic therapy with amiodarone, can be reserved for patients with markers associated with reduced incidence of SC, or for those failing SC within 8 h.

P1240 Verapamil could prevent atrial fibrillation recurrences if administred before conversion to sinus rhythm

G. Dan, A. Gonta, C. Stanescu, M. Vintila. *Cardiology Dept, University Hospital "N.G.Lupu", Bucharest, Romania*

It has been shown that atrial "electrical remodeling" (ER) which takes place shortly after the onset of atrial fibrillation (AF) is partly responsible for the maintenance of this arrhythmia. Sparse studies in man speculate that calcium channel blockers could prevent ER. The aim of this study was to assess if Verapamil could prevent AF recurrences after electrical conversion (EC) and if the timing of treatment with Verapamil is determinant in this action. We included 68 pts. with persistent AF successfully converted to sinus rhythm. They were divided in two groups on the basis of their previous treatment: group A (34 pts.) was treated with Verapamil before EC in order to maintain the heart rate below 100/min and group B (34 pts.) was treated with Digoxin before EC. In order to minimize the experimental error, the groups were chosen equal and matched for the baseline characteristics. After EC each group was divided in two subgroups: one received Verapamil (17 pts.) and the other did not (17 pts.). Neither antiarrhythmics nor beta-blockers were permitted. During the follow-up period (45 days) the rhythm was checked daily and the AF recurrence rate was determined; the results were analyzed using McNemar's test to calculate Chi-square. After the follow-up period 16 pts. in group A (47%) and 10 pts. in group B (29%) remained in sinus rhythm ($p < 0.05$). There were no statistical differences between the AF recurrence rates in the subgroups with or without Verapamil after EC in both group A (10 pts. vs. 8 pts.), and in group B (13 pts. vs. 11 pts.). We conclude that administration of Verapamil prior but not after EC could prevent AF early recurrences and that it could be a proof of influencing ER.

P1241 The effectiveness of amiodarone in spontaneous conversion of atrial fibrillation and maintenance of sinus rhythm in patients with heart failure

N. Karanovic, S. Salinger, M. Randjelovic, M. Pavlovic, B. Randjelovic, L. Todorovic, Z. Perisic. *Clinical Center, Clinic of Cardiovascular Diseases, Nis, Yugoslavia*

Patients and methods: In order to evaluate the effects of amiodarone and digitalis versus digitalis alone on AF in this study 54 patients with CHF (NYHA class II and III) and AF were followed up for six months. Twentysix of them were randomized to amiodarone and digitalis and 28 to digitalis alone. Both groups were comparable in clinical parameters and ejection fraction (Area Lenth – 43.56 ± 7.54% vs. 42.34 ± 5.67%, n.s.). Twelve-lead EKGs and 24-hour Holter monitoring were repeated at 2 weeks, 3 months and 6 months after the biginning of the study. At these enpoints, the average ventricular rate (VR) was also calculated.

Results: Of all patients involved in this study, four pts. (15.38%) of the amiodarone and digitalis and four pts.(14.39%) of the digitalis group, had intermittent AF on 24-hour Holter monitoring. Six of 26 patients on amiodarone and digitalis (23.08%) and none of 28 on digitalis converted to sinus rhythm during the study. The mean ventricular rate during AF over 24 hours was reduced by amiodarone at two weeks (23%, $P < 0.001$) and at 6 months (19%, $P < 0.001$). The difference was significant ($P < 0.005$).

Conclusions: In patients with CHF, amiodarone showed a significant potential to spontaneously convert patients with AF to sinus rhythm in comparison with patients who were treated only with digitalis. This drug prevented the development of new-onset AF and significantly reduced the VR in those patients with persistent AF.

MEDICAL MODULATION OF ATRIAL FIBRILLATION: HEART RATE AND THROMBOTIC RISK

P1242 Evidence for reduced electrical remodelling in patients with persistent atrial fibrillation taking calcium channel blockers

A. Bollmann, K. Sonne, I. Toepffer, H.D. Esperer, H.U. Klein. *Cardiology Dept, University Hospital, Magdeburg, Germany*

Background: Experimental and clinical studies have demonstrated a progressive shortening of atrial refractoriness during atrial fibrillaton (AF). Calcium channel antagonists (ca) of the verapamil type have been suggested to prevent a reduction in the atrial refractory period. Since (1) there is a close inverse correlation between atrial refractory period and the rate of electrical atrial activation (f) and (2) f be accurately estimated from the surface ECG, it was hypothesized that patients taking ca have a lower f recorded on the surface ECG.

Methods: Holter ECG recordings were made in 20 patients (14 male, 6 female, mean age 58 ± 11 years) during persistent AF. One minute ECG segments were used for analysis at 4 PM, 10 PM, 4 AM and 10 AM. In those segments f was determined by subtracting averaged QRST complexes and then a Fourier analysis was applied to the resulting signal.

Results: Mean f of the 4 recordings per patient was 6.8 ± 0.6 Hz (range 5.0 to 7.8 Hz). Ten patients with long-term ca use (group I) had a mean f of 6.4 ± 0.6 Hz, significantly lower than the 7.1 ± 0.4 Hz ($p = 0.028$) recorded in 10 patients without ca treatment (group II). f was constant over time in both groups. During all measurements group I patients had a lower f than group II patients ($p = 0.028$). No other variable including age, gender, AF duration, underlying heart disease, echocardiographic parameters or concomitant digoxin treatment affected f.

Conclusion: In patients with persistent AF, fibrillatory frequency assessed by spectral analysis of the surface ECG is lower in patients taking calcium channel blockers of the verapamil type, suggesting a partially suppressed electrical remodeling process.

P1243 Stroke prevention practices in patients with atrial fibrillation and pacemaker therapy: evidence for underutilization of anticoagulation

J. Carlsson, G. Dees, S. Miketic, E. Sorges, S. Haun, A. Cuneo, U. Tebbe. *Klinikum Lippe-Detmold, Detmold, Germany*

Background: Oral anticoagulation reduces the risk of thromboembolic events in patients (pts.) with atrial fibrillation (AF). However, there is evidence that anticoagulation is underutilized in a variety of clinical settings. The purpose of the study was to investigate anticoagulation rates in patients with AF and pacemaker therapy.

Methods: Between 11/98 and 12/98 all pts. of our pacemaker clinic were prospectively analyzed concerning heart rhythm, underlying disease, stroke risk factors, and antithrombotic medication.

Results: A total of 326 pts. with a mean age of 77.7 ± 9.6 years were analyzed. 52% were female and the mean pacing duration was 67.8 ± 53.4 months (1–225). 140 (43%) were diagnosed as being in AF, 153 (47%) were in sinus rhythm while 33 (10%) had other rhythms. While AF pts. had a mean age of 80.5 ± 7.1 years, pts. in sinus rhythm were 75.5 ± 11.4 years of age ($p = 0.014$). All pts. with AF had additional clinical risk factors for thromboembolic stroke. The ECG was insufficient to diagnose AF in 120 (86%) of the pts.. These pts. required temporary pacemaker reprogramming to low ventricular rates to diagnose the underlying rhythm. Of the pts. with AF 39 (28%) were on anticoagulation, 37% were on aspirin and the remainder did not receive any antithrombotic medication. Only 10.3% of the pts. not receiving oral anticoagulation had contraindications against this therapy.

Conclusions: The majority of AF pts. with pacemakers does not receive appropriate prophylaxis against thromboembolic stroke despite having no contraindications against anticoagulation. Therefore, cardiologists and electrophysiologists caring for pacemaker pts. should not only facilitate the diagnosis of AF but also encourage the referring physician to use anticoagulation in order to lower the stroke risk in this population.

P1244 Increased thrombogenesis and atrial fibrillation: effects of combination aspirin and warfarin therapy

F.L. Li-Saw-Hee, A.D. Blann, G.Y.H. Lip. *Haemostasis, Thrombosis and Vascular Biology Unit, University Department of Medicine, City Hospital, Birmingham, UK*

Atrial fibrillation (AF) is associated with an increased risk of thromboembolism and is known to have a hypercoagulable state. Aspirin and warfarin reduce the risk of stroke in patients with AF.

Methods. Prospective randomised study of chronic AF patients treated with warfarin 2 mg (group A, n = 23), aspirin 300 mg and warfarin 1 mg (group B, n = 21), and aspirin 300 mg and warfarin 2 mg (group C, n = 17). Effects on various haemostatic factors were looked at 2 weeks and 8 weeks, and subsequent full anticoagulation (for 8 weeks, INR 2–3).

Results. Patients with AF had higher baseline levels of D-dimer (533 ± 768 vs 173 ± 335 ng/ml), von Willebrand factor (vWF) (143 ± 37 vs 105 ± 30 IU/dL), plasminogen activator inhibitor 1 (PAI-1) (8.4 ± 7.5 vs 5.9 ± 3.6 ng/ml) and fibrinogen (3.1 ± 0.8 vs 3.1 ± 0.9 g/L) compared to age- and sex-matched controls ($P < 0.05$ for all).

		Baseline	2 weeks	8 weeks
Group A	vWF	144 ± 36	141 ± 40	148 ± 39
	D-dimer	625 ± 875	467 ± 451	482 ± 734
	Fibrinogen	3.0 ± 1.0	2.8 ± 1.0	2.5 ± 0.9
	PAI-1	8.3 ± 7.8	7.5 ± 4.8	8.8 ± 5.0
Group B	vWF	135 ± 33	136 ± 37	138 ± 36
	D-dimer	564 ± 840	247 ± 306	378 ± 1099
	Fibrinogen	3.0 ± 0.9	3.0 ± 0.7	2.5 ± 0.8
	PAI-1	9.7 ± 8.7	11.7 ± 9.0	14.1 ± 12.0
Group C	vWF	148 ± 42	154 ± 46	151 ± 33
	D-dimer	346 ± 447	385 ± 673	196 ± 187
	Fibrinogen	2.8 ± 0.7	2.9 ± 0.9	2.9 ± 0.8
	PAI-1	7.0 ± 4.7	10.8 ± 8.7	11.9 ± 11.3

P = NS (RMANOVA) *mean ± SD.

Both D-dimer and fibrinogen levels were significantly lower in dose-adjusted warfarin (INR 2–3) if compared to baseline levels in AF patients not on warfarin ($P < 0.05$).

Conclusion. Low-density warfarin and aspirin antithrombotic therapy results in improved reduction in haemostatic markers but the greatest reduction in thrombogenesis still was with full anticoagulation.

P1245 Atrial fibrillation and quality of life: do asymptomatic patients need treatment?

I. Savelieva, P. Dorian[1], B. Luderitz[2], M. Paquette[1], A.J. Camm. *Cardiological Sciences, St George's Hospital Medical School, London, UK; [1]Division of Cardiology, St Michael's Hospital, Toronto ON, Canada[2]Department of Cardiology, University of Bonn, Bonn, Germany*

Atrial fibrillation (AF) has been reported to be asymptomatic in 30% of patients (pts). Although AF is generally recognised to be associated with an increased morbidity and mortality, it is unknown to what extent asymptomatic AF affects quality of life (QL) and whether this condition needs treatment.

Methods: The aim of the study was to assess QL in 38 pts with the lowest quartile symptom scores from Bubien and Kay's Symptom Checklist (Group 1) and 118 pts from the remaining 3 quartiles (Group 2). Symptoms relevant for AF were selected, including palpitations, dyspnoea, exercise intolerance, dizziness, chest discomfort, and syncope. A control group comprised 50 healthy subjects.

Results: QL was significantly decreased in pts with AF, including those with and without symptoms, compared to control group ($p < 0.03$). Group 2 pts had significantly lower SF-36 scores than Group 1 pts ($p < 0.003$). Compared to controls, Group 1 pts had significantly decreased scores regarding vitality, mental health, and general health ($p < 0.03$). SF-36 scores are summarised in the table (data presented as mean ± SD, *$p < 0.03$ compared to controls).

SF-36 score in different groups

SF-36 score	Control	Group 1	Group 2	All AF
Role-Physical	88 ± 28	83 ± 26	35 ± 38*	48 ± 42*
Vitality	71 ± 14	63 ± 15*	42 ± 19*	49 ± 21*
Physical Fx	89 ± 19	89 ± 13	61 ± 26*	68 ± 27*
Social Fx	92 ± 14	87 ± 23	67 ± 27*	73 ± 27*
Mental Health	81 ± 11	75 ± 15*	65 ± 18*	69 ± 18*
Role-Emotional	92 ± 24	88 ± 22	58 ± 43*	65 ± 41*
Bodily Pain	77 ± 15	81 ± 14	65 ± 19*	69 ± 20*
General Health	78 ± 18	63 ± 17*	51 ± 21*	55 ± 21*

Conclusion: According to SF-36 scores, asymptomatic AF does not significantly deteriorate QL. However, several aspects of QL are lower in the asymptomatic patients compared to healthy subjects. Thus, consideration should be given to the treatment of this condition as sinus rhythm restoration may improve QL in some pts.

ECHO/DOPPLER AND ATRIAL FIBRILLATION

P1246 Long-term prognostic value of dobutamine stress echocardiography in patients with atrial fibrillation

D. Poldermans, P.M. Fioretti, E. Boersma, J.J. Bax, A. Elhendy, I.R. Thomson, J.R.T.C. Roelandt. *Erasmus Medical Center, Rotterdam, Netherlands*

Aim of the study: To assess the long-term prognostic value of dobutamine stress echocardiography [DSE] for late cardiac events [CE] [cardiac death [CD] and MI] in pts with atrial fibrillation [AF].

Background: The diagnostic accuracy of DSE may be reduced in pts with AF due to unpredictable heart rate response.

Methods: Clinical data and DSE results were studied in pts undergoing DSE between 1989 and 1997. Sixty-nine pts had AF at the time of DSE and were matched [age, gender, rest wall motion abnormalities] with a control group in sinus rhythm. Presence and extent and of stress induced ischemia [NWMA] was scored for every pt. Follow-up was 37 months [range 6–96]. Data are presented as hazards ratio [HR] with 95% CI.

Results: Heart rate during DSE at rest, low-dose, and peak dose dobutamine in pts with AF and sinus rhythm was respectively: 76/72*; 82/78*; and 124/125 bpm [*$p < 0.05$]. Peak rate pressure product [peak heart rate × peak systolic blood pressure] in pts with AF and sinus rhythm was respectively 17602/17169 [$p = 0.4$]. CD occurred in 5 and MI in 2 pts. NWMA were highly predictive for late CE in pts with AF. There was no difference in prognostic value of NWMA in pts with AF or sinus rhythm for late CE HR: 8.0 [1.5–45] respectively HR 4.2 [3.1–5.6] [$p = 0.45$]. The number of ischemic segments was also predictive for late CE in pts with AF and sinus rhythm.

Conclusions: The prognostic accuracy of DSE for late cardiac events was not influenced by atrial fibrillation.

P1247 Changes in coronary blood flow and flow reserve after induction of atrial fibrillation

E.I. Skalidis, G.E. Kochiadakis, S.I. Chrysostomakis, E.N. Simantirakis, E.G. Manios, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

The deleterious effects of atrial fibrillation (AF) on cardiac performance as well as the benefits from restoring sinus rhythm have been extensively studied, but the effect of AF on coronary blood flow remains unknown. The aim of this study was to assess the coronary blood flow changes with loss of atrial contraction in patients with a controlled heart rate to avoid the influence of rapid and irregular ventricular response.

Methods: Eight patients (5 men, mean age 57 ± 5 years) with a dual chamber pacemaker for complete atrioventricular block, no significant coronary artery disease and preserved ejection fraction were studied. During routine cardiac catheterization, coronary flow velocity were recorded using a 0.014" Doppler guide wire in the proximal left anterior descending coronary artery after intracoronary administration of 200 μg nitroglycerin. Time-averaged peak flow velocity (APV) was recorded at baseline (R) and after maximal vasodilatation (H) during atrioventricular sequential pacing at 100 bpm. Vasodilatation was achieved by intracoronary administration of 18 μg adenosine. The same measurements were repeated during ventricular pacing at the same heart rate, at least 5 minutes after induction of AF by programmed electrical stimulation. Intracardiac recordings were used to confirm the induction of AF. Coronary flow reserve (CFR) was calculated as the ratio of APV-H to APV-R.

Results: The values of the parameters measured during atrial pacing and AF are given in the table below.

Table

	APV-R cm/s	APV-H cm/s	CFR
Atrial paced rhythm.	19.1 ± 8.1	58.8 ± 25.6	3.1 ± 0.4
Atrial fibrillation.	16.2 ± 7.5*	57.5 ± 24.7	3.6 ± 0.5*
$p < 0.05$ vs. atrial paced rhythm			

Conclusions: In patients with well preserved ventricular function the induction of AF reduces baseline coronary blood flow without affecting hyperemic blood flow, leading to augmented CFR.

P1248 Role of direct measurement of left atrial volume on the result of electrosurgical treatment of atrial fibrillation

J. Melo, P. Adragão[1], C. Aguiar[1], J. Neves, M. Ferreira, R. Ribeiras[1], M. Rebocho, T. Santiago. *Cardiothoracic Surgery Department; [1]Cardiology Department, Santa Cruz Hospital, Carnaxide, Portugal*

Background and Purpose: Left atrial (LA) volume has been considered an important factor of success for atrial fibrillation (AF) treatment options. The aim of this study was to assess the influence of LA volume on the results of AF surgical therapy.

Methods: We studied 18 Pts submitted to simultaneous mitral valve and AF surgery. AF was chronic in 12 Pts and paroxysmal in 6 Pts. The surgical procedure for AF treatment was bilateral pulmonary veins isolation using radiobrequency energy. Before going on bypass, LA pressure was measured. After arresting the heart, a balloon was inserted in the LA and inflated with saline serum. LA volume was considered to be the volume of saline required to achieve the same mean LA pressure previously recorded during beating heart status. Pts were divided in two groups: group A – Pts with LA volume < 200 mL – and group B – Pts with LA volume ≥ 200 mL. At hospital discharge, cardiac rhythm and presence of atrial contraction were analysed for each Pt.

Results: Group A consisted of 11 Pts and group B of 7 Pts. In group A, 2 Pts were discharged in AF and 9 presented rhythm different to AF, whereas in group B, 6 Pts were discharged in AF and one presented rhythm different to AF ($p = 0.013$). Bilateral atrial contraction was present in 8 of the 9 group A Pts out of AF and in no group B Pt ($p = 0.004$).

Conclusion: In this population of Pts submitted to concommitant mitral and AF surgery using bilateral pulmonary veins isolation with radiofrequency energy, supression of AF and restoration of bilateral atrial contraction were achieved more frequently when LA volume was under 200 mL.

P1249 Recovery of left atrial function after conversion of non-rheumatic atrial fibrillation by echocardiographic automatic boundary detection

F.I. Parthenakis, G.E. Kochiadakis, E.I. Skalidis, N.E. Igoumenidis, M.K. Kanakaraki, E. Papakonstandi, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

In this study we evaluated left atrial (LA) function after chemical conversion of non-rheumatic atrial fibrillation (AF) using echocardiographic automatic boundary detection (ABD).

Methods: The study population consisted of 33 patients, 16 men, mean age 43 ± 11 years. Eighteen pts had brief duration AF (≤ 2 days, Group I) and 15 long duration AF (>3 weeks, Group II). All pts had normal left ventricular function. Changes in serial LA area wave forms were obtained from the apical 4-chamber view, using ABD with the LA as region of interest, on the first day and at 3, 7 and 30 days after conversion to sinus rhythm. LA end-systolic (ESA), mid-diastolic (MDA), end-diastolic (EDA) areas, diastolic emptying index (DEI = ESA − EDA/ESA) and atrial systolic emptying index (ASEI = MDA − EDA/MDA) were calculated.

Results: There were no differences in LA dimensions (40 ± 5.5 vs 41.5 ± 3 mm, p: NS) or in EF (59 ± 10 vs 61 ± 6, p: NS) between Groups I and II. In Group I there was a decrease in EDA (9.3 ± 1.5 vs 7.0 ± 1.3, $p < 0.005$), an increase in DEI (0.40 ± 0.004 vs 0.53 ± 0.005, $p < 0.001$) and ASEI (0.15 ± 0.001 vs 0.33 ± 0.004, $p < 0.001$) between the 1st and 3rd day, which persisted without significant change until day 30. In Group II, there was no significant change in EDA, DEI or ASEI between the 1st and the 3rd day. There was a decrease in EDA (9.3 ± 2 vs 8.1 ± 1, $p < 0.05$) an increase in DEI (0.36 ± 0.005 vs 0.42 ± 0.005, $p < 0.05$) and in ASEI (0.13 ± 0.001 vs 0.22 ± 0.001, $p < 0.05$) between the 3rd and 7th day which persisted until day 30. There were no significant differences in ESA or MDA in either group during the follow-up period.

Conclusions: Recovery of LA function is related to the duration of atrial fibrillation before restoration to sinus rhythm. Automatic boundary detection is a simple, noninvasive method for assessing the rate of recovery of LA function.

P1250 Comparison of left atrial appendage function in patients with idiopathic atrial fibrillation, valvular and non-valvular atrial fibrillation: impact on the thromboembolic risk

H. Omran, B. Rang, S. Illien, R. Rabahieh, R. Kubini, B. Lüderitz. *Department of Cardiology, University of Bonn, Germany*

Background: Patients with idiopathic atrial fibrillation (AF) have a lower thromboembolic risk than those patients with valvular and non-valvular AF. The aim of this study was to compare left atrial chamber and appendage function and the incidence of thrombi between those patient groups.

Methods: 130 patients with AF were investigated by transthoracic and multiplane transesophageal echocardiography The following parameters were measured: left atrial diameter (LAD), left ventricular ejection fraction (EF), incidence of left atrial thrombi and spontaneous echo contrast (SEC), maximal area of the left atrial appendage (LAA_F) and peak emptying velocity of the left atrial appendage (LAA_V). As controls served 30 patients in sinus rhythm (SR).

Results: 25 patients had idiopathic AF, 82 patients had non-valvular AF und 23 patients had valvular AF.

Comparison of patients with idiopathic, non-valvular and valvular AF

	Duration [weeks]	AF LAD [cm]	EF [%]	LAA_V [m/s]	LAA_F [m/s]	SEC [Grad]	Thrombi
SR	#3.6 ±	59 ± 0.4	0.6 ± 6	3.3 ± 0.18	0 1.3	0	
Idiopath. AF	159 ± 203*	4.1 ± 0.5*	54 ± 9*	0.52 ± 0.18*	4.3 ± 2*	0.4 ± 0.8*	0*
Non-valv. AF	463 ± 799	4.4 ± 0.6	49 ± 11	0.3 ± 0.13	5.4 ± 2.1	2.3 ± 1.4	11 [13%]
Valv. AF	2262 ± 2340	4.9 ± **	49 ± 0.7**	0.17 ± 14	6.4 ± 0.06**	3.2 ± 3.3**	6 [23%]** 1.1**

*p < 0.05 idiopathic AF versus non-valvular AF; **p < 0.05 valvular AF versus non-valvular AF

Conclusions: Patients with idiopathic AF have a lower incidence of left atrial thrombi and a better left atrial appendage function than those patients with an underlying heart disease. These data support the concept that patients with idiopathic AF have a lower thromboembolic risk than those patients with an underlying heart disease.

P1251 Comparison of TEE-detected risk markers for thromboembolism in patients with paroxysmal and permanent atrial fibrillation: a prospective study

C. Albo, C. Smadja, B. Buyukoglu, B. Benhalima, N. Lamisse, A. Cohen. *Saint Antoine University Hospital and Medical School, Paris, France*

Paroxysmal (par.) atrial fibrillation (AF) has been associated with a lower risk of thrombo-embolic complications. However, the presence of atrial markers using transthoracic and transesophageal echocardiography (TEE) has not been yet evaluated.

Methods: We studied with transthoracic and TEE 104 consecutive patients with par. AF (duration < 48 hours, n = 33), in sinus rhythm at the time of TEE examination and permanent (perm.) AF, (n = 71) who had no recent embolic event. We evaluated history of embolic events (T.E.), right (RA) and left (LA) sizes, shortening fraction (SF, %), spontaneous echo contrast (SEC), thrombus, low LA appendage emptying velocities (LAA vel.).

Results: The main results are summarized in the table.

	Par. AF (n = 33)	Perm. AF (n = 71)	P
Age (years)	65 ± 16	71 ± 11	0.028
History of T.E.	5 (15%)	13 (18%)	0.906
SF (%)	35 ± 9	31 ± 10	0.053
LA area (cm^2)	21 ± 13	26 ± 6	0.008
LAA area (cm^2)	4.6 ± 2.2	5.8 ± 2.2	0.011
RA area (cm^2)	15 ± 10	20 ± 6	0.001
LAA SEC	5 (15%)	36 (51%)	0.001
LAA thrombus	0	4 (6%)	0.001
LAA vel. (cm/s)	36 ± 19	34 ± 18	0.605

Conclusion: TEE-detected atrial abnormalities are less frequent in patients with paroxysmal AF, despite the fact that history of T.E. was equally frequent.

P1252 Left atrial appendage outflow is augmented during atrial fibrillation compared to sinus rhythm: insights from a pig model of pacing-induced atrial fibrillation

M. Zarse, M. Waldmann, G. Muehlenbruch, A.M. Sinha, R. Seipelt[1], F. Schoendube[1], B.J. Messmer[1], A. Franke, C. Stellbrink, P. Hanrath. *Department of Cardiology/Internal Medicine; [1]Department of Cardiothoracic Surgery, University of Technology, Aachen, Germany*

Maximal peak outward flow (V_{outmax}) of the left atrial appendage (LAA) is frequently measured to analyze its contractility. Decreased V_{outmax} of the LAA after cardioversion of atrial fibrillation (AF) is regarded as atrial stunning, without appreciating the hemodynamic effects of the atrial activation sequence. During sinus rhythm (SR) the main atrium is activated before the LAA thus creating a preload against whom the LAA has to contract. In contrast the chaotic activation pattern of AF prevents organised contraction in the main atrium, while the smaller LAA still contracts without preload, allowing higher V_{outmax}.

Methods: Transpericardial echocardiography (echo), using a 5.5 MHz echo probe was performed in five pigs (70–75 kg). Non-sustained AF (NSAF) was induced with burst pacing (20 Hz). Pulsed-wave doppler analysis of LAA-V_{out}, atrial E-wave (MV-E), A-wave (MV-A) and peak systolic and diastolic velocities of the left upper pulmonary vein (PV-sys and PV-dias) were recorded during AF and SR before and after NSAF episodes. Mean values were obtained in 3 consecutive cardiac cycles during SR, and 10 consecutive cycles during AF.

Results:

cm/s	LAA-V_{outmax}	PV-sys	PV-dias	MV-E	MV-A
SR pre AF	49 ± 6	60 ± 5	41 ± 7	63 ± 6	51 ± 4
AF	67 ± 14*	59 ± 11	38 ± 9	65 ± 13	24 ± 5*
SR post AF	48 ± 6	65 ± 11	47 ± 3	61 ± 5	61 ± 10

*p < 0.01 compared to SR

Compared to SR MV-A decreases, LAA-V_{outmax} increases significantly during NSAF. PV-sys, PV-dias and MV-E are not significantly affected. Values during SR before and after induction of NSAF do not change.

Conclusions: Altered electrical activation, resulting in decreased LAA afterload leads to an increased V_{outmax} at the onset of AF. Thus reduction of V_{outmax} after termination of AF may only represent the reversion of this phenomenon.

P1253 Exclusion of atrial thrombi by transesophageal echocardiography predicts low risk of embolic events after cardioversion of atrial fibrillation

R. Griebenow, L.I. Krämer, J. Wagner[1], G. Quinkler, P. Wacker, M. Zentani.
Kardiologie, Medizinische Universitätsklinik II, Cologne; [1]Med. Klinik II, Elisabeth-Hospital, Grevenbroich, Germany

The place of transesophageal echocardiography (TEE) in the strategy to prevent embolic events after cardioversion of atrial fibrillation is still debated.

Methods: In a prospective study we used TEE in 127 patients to exclude thrombi in the left atrium and atrial appendage before cardioversion of atrial fibrillation. We detected spontaneous echo-contrast in 53 of these patients. The patient group consisted of 75 men and 52 women, mean age 68.1 ± 10.5 y, 57 of them having hypertension, 25 valvular heart disease, 21 coronary heart disease, 21 heart failure, 21 diabetes, 6 hyperthyreodism and 12 having no underlying cardiac disease.

Sinus rhythm was achieved in 103 patients by direct current cardioversion (n = 91, 239 ± 75 J) or by medical treatment (12) within 5.06 ± 7.20 days after TEE, during which period patients received either heparin (67), phenprocoumon (22), both (4) or no antithrombotic therapy (10). Mean atrial diameter was 44.8 mm in patients with successful and 46.3 mm in patients without successful cardioversion.

Results: Within 72 hours after establishing sinus rhythm none of the 103 successfully treated patiens developed any clinically symptomatic embolic event, all of them still having sinus rhythm. According to the method of HANLEY and LIPPMAN-HAND (JAMA 1983;249:1743) and assuming a significance of 0.05 our result of no embolic event in 103 patients can be extrapolated to a maximal risk of embolic events in a representative population of 2.9%, whereas the risk of embolic events in populations without antithrombotic therapy reaches from 3.4% to 7.1%.

Conclusion: We conclude, that if the existence of thrombi in the left atrium and left atrial appendage is excluded by TEE, antithrombotic therapy immediately before cardioversion of atrial fibrillation is sufficient without need of a longer period of anticoagulation.

Day 3

Monday, August 30, 1999

CATHETER ABLATION FOR VENTRICULAR TACHYCARDIA

1254 Catheter ablation of ventricular tachycardia in patients with structural heart disease using the localisa non-fluoroscopic localization system

E. Wever[1], A. Elvan[2], H. Ramanna[2], R. Hauer[2], E. Robles de Medina[2], F. Wittkampf[2]. [1]*St Antonius Hospital Nieuwegein;* [2]*Heart-Lung Institute, University Hospital Utrecht, Netherlands*

Ventricular tachycardia (VT) in patients (pts) with structural heart disease may originate from extended areas. We hypothesized an increased success rate of VT ablation in such pts may by area ablation using multiple adjacent radiofrequency (RF) applications. The aim of this study was to clinically evaluate the new real-time nonfluoroscopic 3D localization and visualization system (LocaLisa) in guiding catheter mapping and delivery of multiple adjacent RF pulses for ablation of complex VT substrates.

Methods: We treated 14 consecutive pts (age 59 ± 14 years), with 20 clinical VT morphologies: 10 pts with coronary artery disease (CAD, LVEF 0.30 ± 0.09), 1 pt with an inferobasal aneurysm without CAD, and 3 pts with arrhythmogenic right ventricular dysplasia (ARVD). All pts had symptomatic episodes (>1/week) of sustained monomorphic VT, mean cycle length 390 ± 96 ms. The ablation target site was determined using activation and entrainment mapping. The LocaLisa system was used to provide a real-time 3D image of the ablation catheter, to mark ablation target sites, and to deliver RF pulses at and around target sites, only in areas with low-voltage and fractionated signals. Ablation outcome was assessed using conventional pacing techniques, one week continuous telemetry monitoring, and follow-up.

Results: Multiple (23 ± 13) RF pulses (maximal power 50W, temperature 60°C) were delivered in an area of 7.1 ± 4.3 cm^2 using various brands of standard ablation catheters with 4 mm tip electrodes. After catheter ablation, 19 of 20 clinical VT morphologies were noninducible. In one ARVD pt with two VT morphologies, one VT was still inducible postablation. During a median follow-up of 7 (range 1–10) months, all pts remained free of VT recurrences. Functional class improved or remained stable. Average fluoroscopy time was: RAO, 28 ± 11 min; LAO, 19 ± 9 min.

Conclusions: These data suggest that the use of LocaLisa allows for appropriate catheter positioning for mapping and ablation of a complex VT substrate, while reducing fluoroscopy exposure.

1255 Radiofrequency catheter ablation of iterative or incessant postinfarction ventricular tachycardia: is it worthwhile?

R. De Ponti, P. Della Bella[1], J.A. Salerno, C. Tondo[1], C. Storti, C. Carbucicchio[1], M. Zardini, S. Riva[1], C. Klersy[2], G. Fassini[1]. *Depts. Cardiol., Univ. of Insubria-Med. Sch. of Varese, "Mater Domini" Hosp. Castellanza (VA);* [1]*Univ. of Milano, Fondazione "Monzino" (MI);* [2]*Direzione Scientifica, IRCCS Pol. S. Matteo (PV), Italy*

To better define the role of radiofrequency catheter ablation (RFCA) in pts with incessant or frequently recurrent postinfarction ventricular tachycardia (iVT), 124 pts referred to both Institution for drug-refractory well-tolerated PIVT were considered and a comparison between 97 pts with paroxysmal VT (pVT) and 27 pts with iVT has been performed. Between the two groups, no significant difference as to age, sex distribution and number of VT morphologies/pt was observed. In iVT group, there was an higher prevalence of pts with an ejection fraction (EF) < 30% (63% in iVT pts vs 23% in pVT pts; p = 0.01); there was no difference in VT cycle length (407 ± 81 in pVT pts vs 412 ± 83 ms in iVT pts). When appropriate, myocardial ischemia was corrected prior to ablation. The site of ablation was identified during VT on the basis of EP criteria and standard RF energy delivery was used. As to the acute ablation result, there was a trend towards an higher success rate in pts with iVT as compared to pts with pVT (78% vs 72%; p = 0.6), but there was also an higher complication rate (including 1 death) in iVT group (18% in iVT pts vs 4% in pVT; p = 0.023). During follow up, as to death for congestive heart failure (CHF), cumulative survival probability (CSP) at 5 years was 98% in pVT pts vs 62% in iVT pts with a 20 fold increased risk of dying from CHF in the iVT group (p = 0.0006); the type of arrhythmia is an independent risk factor, even when EF is considered. As to VT recurrence, there is no significant difference in CSP between the two groups (69% in pVT vs 56% in iVT) at 5 years.

In conclusion: RFCA in pts with iVT should be individually considered, taking into account that, as compared to pVT pts, the acute success rate may be slightly higher, but the procedure-related complication and mortality rate for CHF during follow-up are higher.

1256 Mapping of ventricular tachycardia: the steerable high-density sector basket catheter

N.M.S. de Groot, L. van Erven, A.F.M. Kuijper, M. Schalij. *Cardiology Dept., Leiden University Medical Center, Leiden, Netherlands*

Identifying areas of slow conduction and early endocardial activity during ventricular tachycardia (VT) is mandatory for successfull radiofrequency catheter ablation (RFCA). The objective of this study was to evaluate the efficacy of a newly developed, steerable sector basket catheter during ablation of VT in pts.

Methods: Pts (n = 12, male, 63 ± 9 years) with drug refractory VT were studied during RFCA. The 8.5F steerable sector basket catheter with a 20-bipolar array was inserted percutaneously into the LV using the femoral approach. The 5 arms of the catheter are positioned close together, resulting in a spatial resolution of ± 1 cm. Color coded activation maps were reconstructed on-line using a computerized mapping system. After induction of VT and mapping of the region of interest, a standard ablation catheter was inserted and positioned within the region of interest.

Results: Sustained monomorphic VT (CL 322 ± 55 ms) was induced in all patients. During VT earliest endocardial activation was recorded 72 ± 19 ms prior to the onset of the QRS complex. Entrainment studies using the basket catheter electrodes to stimulate the heart were performed to localize the area of slow conduction during VT. Successful ablation of VT (non-inducible after ablation) was achieved in 83% of pts. No complications were observed.

Conclusion: The new steerable sector basket catheter facilitates RFCA of VT. Potentially fast and hemodynamically unstable VT can be mapped and treated using this approach.

1257 Radiofrequency catheter ablation of ventricular tachycardia in patients with coronary artery disease: relation between the inducibility of non-clinical tachycardias and clinical outcome after a long-term follow-up

M. Ortiz, J. Almendral, J. Villacastin, A. Arenal, N. Pérez-Castellano, S. Gonzalez, J. Garcia, E. Pérez-David, J.L. Delcan. *Hospital General Gregorio Marañon, Madrid, Spain*

It has been suggested that inducible non clinical ventricular tachycardia (NCVT) after radiofrequency (RF) catheter ablation of ischemic VT are clinically significant, based on the analysis of stored electrograms from ICD implanted in such patients (P). However, this information is seriously limited by the inability to determine the VT morphology of VT detected and treated by ICDs. We analyzed VT recurrences in 27 P (23 men, aged 62 ± 10 years, left ventricular ejection fraction 34 ± 12%) with ischemic sustained monomorphic VT (SMVT) who underwent successful RF ablation of the clinical VT and were discharged without ICD. In 13 of them (Group A) no other SMVT were induced after a complete stimulation protocol before hospital discharge. In the remaining 14 P (Group B), 18 NCVT were induced. Nine NCVT (338 ± 65 ms cycle length) were haemodinamically well tolerated in 7 P and treated with RF (6 of them were successfully ablated in 5 P). Nine NCVT (242 ± 66 ms cycle length) in 9 P required prompt termination. Antiarrhythmic drug (AAD) regimen was not changed in group B P (12 were discharged on no AAD and 2 on amiodarone that had been taking before the ablation).

Results: During a mean follow-up of 28 ± 18 months, VT recurred in 6 P (22%). The table considers the morphology of the VT that recurred classified as identical to the clinical VT, to an NCVT that was induced or had a different morphology (other VT). One P of group A and 3 P of group B died during follow-up, (2 of them from heart failure, one on each group, 1 from asystole and 1 from no cardiac death).

	n	Clinical VT	NCVT	Other VT
Group A	13	3	-	0
Group B	14	1	0	2

Conclusions: Despite a significant incidence of VT recurrence in this P population no spontaneous VT had the morphology of the non clinical induced VT, suggesting a lack of clinical significance of these tachycardias.

1258 Acute and long-term results of the radiofrequency-catheter ablation for monomorphic and ventricular tachycardia in the chronic post-myocardial infarction state

E.G. Vester, I. Dobran, Ch. Perings, M. Klein, H. Dees, M. Hennersdorf, B.E. Strauer. *Department of Cardiology, Pneumology and Angiology, Heinrich-Heine-University, Düsseldorf, Germany*

Background: We report on the short- and long-term results of RFA in patients (pts) who developed late after myocardial infarction drug refractory CRVT and try to identify predicting factors for ablation success.

Results: A total number of 45 pts (42 male, 3 female, age 66 ± 6 years, LVEF 32 ± 13%, localization of myocardial infarction: 50% anterior, 45% inferior, 5% posterolateral) received at least one, in 8 cases (18%) 2 and in 2 cases (4.4%) 3 RFA treatments. 4 pts underwent ablation with a "chilled" system. 23 pts showed only 1 morphology (morph), 16 pts 2 and 6 pts 3–4 morph. 7 pts presented with an incessant form of CRVT. The acute success rate amounted to 80% in the case of 1 morph, 57% in 2 morph and 33% in 3–4 morph ($p < 0.01$) and in the presence of the incessant form 86%. The cumulative recurrence rate during long-term follow-up (34 ± 20 months) was 29%. In total the ablation procedure was successful for 30 pts (67%). "Chilled" RFA led in 3/4 cases after 3 ± 2 RF applications to effective ablation (vs non chilled-RFA after 12 ± 9). After unsuccessful RFA 13 pts (29%) underwent implantation of a cardioverter/defibrillator and 4 pts (9%) an antitachycardiac surgery. Analyzing the mapping criteria, used for guiding the RFA, success rate was 86% in the presence of isolated middiastolic potentials followed by all other criteria showing together a success probability of 64% ($p < 0.05$). The rate of severe but reversible complications amounted to 8.7%, no pt died due to the procedure. During FU 8 pts died (20%). The cumulative survival rate after RFA was 87%, 80% and 73% at 1, 2 and 3 years.

Conclusion: RFA is relatively safe and for 2/3 of the pts a successful curative treatment modality for CRVT in the chronic post myocardial infarction state. The following factors predict a success rate of 80% or more: only one VT-morphology, incessant form and isolated middiastolic potentials. "Chilled" ablation might be more effective than conventional RF application.

1259 Ablation of ventricular tachycardia after Fallot repair: long-term experience on 11 cases

R. Frank, C.E. Guzman, L. Romero, S. Chabrak, J. Tonet, Y. Gallais, G. Fontaine. *Hôpital Jean Rostand, Ivry, France*

From 1983 to 1998, 11 patients with drug resistant ventricular tachycardia (VT) after Fallot surgery were submitted to catheter ablation. Surgery had been done at the age of 1 to 11 years (mean value 6 ± 2), and VT had developed from 3 to 13 years later (mean 12 ± 4)

They had from 1 to 5 VT morphologies (median 2), with a left bundle branch block pattern in all, and a frontal axis from −60 to 110. VT cycle length was 258 ± 54 ms.

VT origin was found just under the pulmonary valves, anterior in 3 and septal in 3, on the anterior wall of the infundibulum in 5, on the septum in 1, and I lower on the anterior RV wall. Two patients had 2 different VT origin, respectively below the pulmonary valves, anterior and posterior, and high and low on the anterior right ventricular wall.

The 3 first patients (1983–1991) had fulguration (DC shock), the 6 next (1993–1996) had DC after failure of RF ablation with a 50 watt generator, and the last 3 had only RF with an 8 mm electrode and high power (80 watts) generator.

Ablation was done in one (7) or 2 sessions (4). The procedure lasted from 180 to 240 mn, with 21 to 52 mn of fluoroscopy.

All were successful. However one needed surgery on a second VT site. Ten patients have an uneventful follow-up, from 1 to 8 years without any therapy. The first patient died of ventricular fibrillation 10 years after ablation and persisting non sustained VT.

VT ablation is an effective cure for VT occurring on the surgical scar of Fallot repairs, usually needing higher energies than other ablative procedure.

CLINICAL USE OF IMPLANTABLE DEFIBRILLATORS

1260 The U.S. national survey of implantable cardioverter defibrillator recipients: examining the global and specific aspects of quality of life

S. Sears, A. Eads, S. Marhefka, B. Sirois, G. Urizar, J. Todaro, W. Sotile[1], A.B. Curtis[2], J.B. Conti[2]. *Dept of Clinical & Health Psychology, University of Florida, Gainesville FL; [1]Cardiac Rehabilitation Program, Wake Forest University, Winston-Salem NC[2]Department of Medicine, University of Florida, Gainesville FL, USA*

Background: The implantable cardioverter defibrillator (ICD) provides a marked survival benefit over antiarrhythmic medications for patients with life-threatening arrhythmias. The purpose of this study was to examine quality of life and define specific ICD concerns in a large, random, U.S. sample of ICD recipients.

Methods: 450 ICD recipients (82% male, mean age 65+12) responded to a mail-in survey regarding 22 specific ICD concerns and four global health outcomes. This sample was randomly drawn from a biomedical device company database.
