Results: In normal hearts (n = 7) QRS duration (measure of asynchrony of activation) was 47 ± 5 ms during sinus rhythm and increased to 110 ± 12 ms during pacing at the right ventricular (RV) apex. When pacing at the LV apex and LV base QRS duration was 8 ± 7%* and 15 ± 7%* longer than during RV apex pacing, respectively (* = $p < 0.05$). Stroke volume (SV) and LVdP/dtmax, however, were larger during LV apex (15 ± 16%* and 10 ± 12%*, respectively) and LV base pacing (11 ± 12%* and 3 ± 12%, respectively) than during RV apex pacing. Simultaneous pacing at RV apex+LV apex, RV apex+LV base and RV apex+LV base+LV apex decreased QRS duration by approximately 20% as compared with RV apex pacing and resulted in LVdP/dtmax and SV values similar to those during pacing at the LV apex alone. In hearts with LBBB (n = 5), QRS duration ranged from 82 to 100 ms. QRS duration could be reduced by as much as 19–30 ms when using AV sequential pacing at one or more LV sites and AV-intervals of 40–100 ms. However, optimal LV function was obtained when using AV intervals 20–50 ms shorter than used to obtain the shortest possible QRS duration.

Conclusions: During cardiac pacing in normal and LBBB hearts more synchronous electrical activation may improve LV function, but the best LV function is obtained by optimizing the sequence of electrical activat-ion, e.g. to activate the LV wall before or simultaneous with the RV wall.

2445 Haemodynamic improvement by transvenous left ventricular pacing with a new over the wire lead (Easytrak) in patients with congestive heart failure

S. Sack, S. Enger, N. Dagres, A. Auricchio[1], C. Stellbrink[2], J. Neuzner[3], P. Potty[4], A. Maarse[4], A. Golles, R. Erbel. *Dept. of Cardiology, Medical School, University of Essen, Essen; [1]Dept. of Cardiology, University of Magdeburg, Magdeburg; [2]Dept. of Cardiology, RWTH Aachen, Aachen; [3]Dept. of Electrophysiology, Kerckhoff Clinic, Bad Nauheim, Germany; [4]Guidant Europe, Brussels, Belgium*

Multisite pacing has been recently introduced to improve clinical outcome in patients (pts.) with end-stage cardiomyopathy. Benefit of right ventricular (RV), left ventricular (LV) or biventricular (BIV) pacing is still controversial, although acute data favour LV or BIV being superior to RV pacing.

Methods: In a new approach of stimulating the left ventricle through coronary branch veins emptying into the great cardiac vein and coronary sinus (CS), a new Over The Wire (OTW) coronary venous pacing lead ("Easytrak")was implanted in 30 patients with congestive heart failure (NYHA II-III) during EP study. After coronary venogram, OTW was advanced through a new designed guiding catheter for access to CS. In 6 pts., cardiac output (CO) was determined by thermodilution, and RV, LV and BIV pacing under VDD pacing with 4 different atrioventricular intervals (AVI) (40, 80, 120 and 160 ms) were compared to baseline.

Results: LV coronary veins could be reached in 23 of 30 pts (77%). Pacing threshold (PT) at apex was 2.8 ± 0.4 mV, at mid ventricular level 3.2 ± 0.5 mV and at base 5.0 ± 0.5 mV ($p < 0.05$ vs. apex). If more than one vein was tested best PT was 1.7 ± 0.5 mV. R wave amplitude was >7 mV in all cases. CO increased from 3.9 to 4.3 l/min at VDD pacing with AVI of 40 ($p < 0.03$), 80 ($p < 0.05$) and 120 ms ($p < 0.02$) under LV pacing only. With LV AVI 160 ms, RV, and BIV pacing, no significant increase was observed.

In conclusion, the new OTW pacing lead seems to be a useful tool for left ventricular multisite pacing. Access to different pacing sites was achieved with acceptable PT. Hemodynamic benefit for LV pacing could be demonstrated, promising improvement of LV performance in severe congestive heart failure.

BRUGADA'S SYNDROME: CLINICAL AND GENETIC ASPECTS

2446 Novel mutations in SCN5A causing long-QT and Brugada's syndromes and their functional consequences on human cardiac voltage-gated sodium channel

I. Deschênes, I. Barde[1], M. Berthet[1], T. Chalvidan[2], I. Denjoy[3], P. Guicheney[1], M. Chahine. *Department of Medicine, Laval University, Sainte-Foy, Canada; [1]INSERM U523, Groupe Hospitalier Pitié-Salpêtrière, Paris [2]Service de Cardiologie, Hôpital Sainte-Marguerite, Marseille [3]Service de Cardiologie, Hôpital Lariboisière, Paris, France*

Introduction: Familial long QT syndrome (LQTS) and Brugada syndrome are two distinct hereditary cardiac diseases causing ventricular tachyarrhythmias (torsade de pointes) or idiopathic ventricular fibrillation and sudden death.

In this study we report the electrophysiological characteristics of two novel mutations in SCN5A (the cardiac sodium channel gene) causing LQTS (E1784K) and Brugada syndrome (R1512W).

Method: The mutant channels were expressed in a mammalian expression system and studied using the patch clamp technique.

Results: The E1784K mutation found in LQTS patients is located in the C-terminal region of the sodium channel and showed a persistent inward sodium current (1.5% at −20 mV) and a faster recovery from inactivation, for example at −120 mV, the time constant of recovery from inactivation was 6.4 ± 0.6 ms (n = 4) compare to 12.7 ± 0.4 ms (n = 5)for wild-type hH1. No effect on steady-state inactivation parameters were observed.

The R1512W mutation found in a patient with Brugada syndrome is located in the III-IV linker of the sodium channel. The R1512W mutation produced a slowing of both inactivation and recovery from inactivation. For example, at a holding potential of −120 mV the time constant of recovery from inactivation was of 16.3 ± 1.8 ms compare to 12.7 ± 0.4 ms for wild-type hH1. This slowing of recovery from inactivation seen with this Brugada syndrome mutation could reduce the availability of sodium channels after each stimulation, and could change conduction velocity.

Conclusion: We conclude that the different clinical manifestations of these two mutations, originate most probably from the distinct electrophysiological abnormalities of the mutated cardiac sodium channels.

2447 A single SCN5A mutation causing both long-QT and Brugada's syndrome

A.V. Postma, C. Alshinawi, M.P. van den Berg[1], J.W. Viersma[1], I.M. van Langen[2], A.H. Van der Hout[3], M.M.A.M. Mannens[2], A.A.M. Wilde[4]. *Clin.Genetics & Clin./Exp. Cardiology, AMC, Amsterdam; [1]Cardiology Dept., AZG, Groningen; [2]Clinical Genetics Dept., AMC, Amsterdam; [3]Medical Genetics Dept., AZG, Groningen; [4]Clin. and Exp. Cardiology & Cardiology, AMC & AZU, Amsterdam & Utrecht, Netherlands*

SCN5A, the gene that encodes the human cardiac Na^+ channel a-subunit, is mutated in LQT3 and in Brugada syndrome. The two syndromes display readily distinguishable ECG patterns but share the clinical feature of a high incidence of nocturnal sudden cardiac death. We have screened SCN5A in a large 8-generation kindred (n = 209) characterized by a high incidence of nocturnal sudden death, QT-interval prolongation and the Brugada syndrome ECG occurring in the same subjects. ECGs could be obtained from 119 individuals of whom 79 adults ($\geq$16 y) had a definite genetic status (gene carriers n = 43, non-carriers n = 36). In affected individuals heart rate is relatively slow ($P < 0.02$), PR and QRS durations are slightly prolonged, right precordial R-wave amplitudes are low and QT intervals are markedly prolonged ($p < 0.0001$ for all parameters). ST-segment elevation in the right precordials leads was present as well ($p < 0.0001$). 25 family members died suddenly, 16 of them typically between 04:00 and 07:00 A.M.

Linkage analysis in a subset of the family revealed complete linkage between 8 affected, 3 possibly affected and 12 unaffected sibs and SCN5A-linked markers, generating an estimated LOD score of $\geq$6 at 0% recombination. SSCP analysis of the complete coding region of SCN5A identified an aberrant conformer in exon 28 which co-segregated with the ECG abnormalities. The aberrant conformer was absent in unaffected family members and in 100 alleles from unrelated controls. DNA sequencing of exon 28 of affected family members revealed a TGA insert at position 5537, predicted to cause an insertion of aspartic acid (1795insD) in the C-terminal domain of the protein. The insertion was linked to the phenotype and was identified in all electrocardiographically affected family members.

Conclusions: LQTS3 and Brugada syndrome are allelic disorders but may share a common genotype.

2448 Incomplete penetrance and variable response to sodium channel blockade in Brugada's syndrome

S.G. Priori, C. Napolitano, L. Terreni, L. Crotti, R. Bloise[1], C. Pappone[2], M. Brignole[3], G. Gaggioli[3], M.L. Loricchio[2], P.J. Schwartz[1]. *Molecular Cardiology Dept., Fondazione Salvatore Maugeri, Pavia; [1]Dept.of Cardiology, Policlinico S Matteo, Univ. Pavia, Pavia; [2]San Raffaele Hospital, Milan; [3]Cardiology Dept., Lavagna Hospital, Lavagna, Italy*

The Brugada syndrome is an inherited cardiac disease characterized by a typical electrocardiographic pattern of ST segment elevation and right bundle branch block, and by a high incidence of ventricular fibrillation occurring in the absence of structural heart disease. Recently, mutations in SCN5A gene, encoding for the cardiac sodium channel protein, have been demonstrated to underlie the disease in approximately 10% of families. It has been suggested that the Brugada Syndrome is associated with high recurrence of cardiac arrest, implying an almost complete penetrance (i.e. the ratio between clinically versus genetically affected individuals) and that that pharmacological challenge with sodium channel blockers unmasks the typical abnormality in 100% of the gene carriers with normal ECG (concealed Brugada Syndrome).

Two families were referred to our attention after sudden cardiac death of two young males (23 and 30 yrs respectively). DNA samples were obtained from 29 family members and screened for mutations in the SCN5A gene. Two novel missense mutations were identified in exon 18 (family 1) and exon 17 (family 2). Nine asymptomatic gene carriers were identified among the 16 members of family 1. Nine gene carriers were identified among the 13 members of family 2: a deceased patient, in whom the mutation was demonstrated using the DNA extracted from paraffin-embedded tissue from a cardiac biopsy, seven asymptomatic individuals, and a young man with history of three aborted cardiac arrests. Among 18 gene carriers only the symptomatic patient of family 2 (1/18, 5.5%) presented the typical ECG pattern at rest. The flecainide test (2 mg/kg) was performed in 10 gene carriers (5 in family 1 and 5 in family 2) and a positive electrocardiographic response was observed only in 2/10 (20%) cases.

Our data demonstrate for the first time a very low penetrance in the Brugada syndrome and a lack of correlation between the genetic status and the response to flecainide test in asymptomatic gene carriers.

2449 Evaluation and follow-up of patients with right bundle-branch block and ST-segment elevation in right precordial leads

M.V. Pitzalis, M. Anaclerio, G. Luzzi, A. Lopedote, C. Forleo, F. Massari[1], F. Mastropasqua[1], P. Rizzon. *Institute of Cardiology, University of Bari, Bari; [1]Cardiology Dept., S. Maugeri Foundation, Cassano M, Italy*

The etiology of the syndrome characterized by right bundle branch block (RBBB) and persistent ST segment elevation in V1-V3, and the mechanism of the ventricular arrhythmias are controversial. Although the syndrome is classicly considered to be associated with no structural heart disease, several authors found few patients with the same ECG pattern and a right ventricular cardiomyopathy involving the specialized conduction system. The aim of this study was to prospectively assess the clinical characteristics and follow-up of patients with RBBB and ST elevation in V1-V3 admitted to our Institute. Between 1997 and 1998 we identified 7 consecutive patients with this ECG pattern (all males; age 55 $\pm$ 15). The first patient died suddenly because of a VF. The second had syncope. The third patient was resuscitated from a VF. The others had lipothymia and/or thoracic pain. The last 6 patients were prospectively analysed. They underwent 2-D echo, coronary angiography, left ventricular angiography, right ventricular angiography and endomyocardial biopsy (all but one), electrophysiological study, signal-averaged ECG and baroreflex sensitivity (BRS) evaluation. A right ventricular cardiomyopathy was found in 4 patients. One of them also had a dilated cardiomyopathy and a mitral valve prolapse and 2 of them also had left ventricular hypertrophy. Mitral valve prolapse or left ventricular hypertrophy were the only abnormalities in the remaining 2 patients. Fibrosis was found in all the 5 patients in whom the endomyocardial biopsy was performed. One of them also had hypertrophy and atrophy of myocardial cells and another had only hypertrophy of myocardial cells. VF was induced in 4 patients. Sick sinus syndrome was found in 1. Three patients had a supra-His conduction defect. One patient had prolonged His potential and HV interval. Late potentials were positive in 4 patients. No patient had a depression of BRS. A defibrillator (ICD) was implanted in 3 patients; 2 of them and another 2 patients were treated with betablockers; one patient did not receive any therapy. During a follow-up of 10 $\pm$ 6 months, no patient had arrhythmic events.

In conclusion, in all our patients with RBBB and ST elevation in V1-V3 we found a structural heart disease. Long-term follow-up is needed to assess whether patients with RBBB, ST elevation in V1-V3 and an organic cardiac disease are at risk for malignant ventricular arrhythmias as those without any structural heart disease.

2450 Novel mutations in the cardiac Na^+-channel α subunit gene (SCN5A) in patients with Brugada's syndrome

P. Guicheney, I. Deschênes[1], L. Nicolas, M. Berthet, T. Chalvidan[2], J.M. Davy[3], A. Leenhardt[4], P. Coumel[4], I. Denjoy[4], M. Chahine[1]. *Institut de Myologie, INSERM U523, Paris, France; [1]Laval University, Dept. of Medicine, Ste-Foy, Canada; [2]Service de cardiologie, Hôpital Cantini, Marseille[3]Service de Cardiologie, Hôpital Saint Eloi, Montpellier[4]Service de Cardiologie, Hôpital Lariboisière, Paris, France*

Brugada syndrome is characterized by a distinct electrocardiographic (ECG) pattern consisting of right bundle branch block (RBBB) with persistent ST-segment elevation in the right precordial leads, and sudden death by ventricular fibrillation. Mutations in SCN5A, the gene encoding the cardiac Na^+ channel alpha subunit, have been shown to cause this syndrome.

Methods: DNA analysis was performed on 8 patients with typical Brugada syndrome (ECG pattern and resuscitated sudden death). The 28 exons of SCN5A were analyzed by PCR-SSCP and abnormal conformers were sequenced. Mutant proteins were expressed in a mammalian cell line and Na^+ current kinetics were evaluated to confirm the pathogenicity.

Results: Mutations in SCN5A was evidenced in 4 of the 8 patients. A 1-bp insertion at position 2849 resulted in an in-frame stop codon that eliminates the domains DIII and DIV, and the carboxy-terminal portion of the channel. Two missense mutations (T632M and R1512W) were found in the cytoplasmic loops linking two domains, DI-DII, a region involved in protein kinase activation, where no mutation has been identified so far, and DIII-DIV, a loop important for the fast inactivation where the delKPQ has been identified in LQT3 patients. The third missense mutation (R1432G) induced the substitution of a highly conserved arginine by a glycine in the extracellular loop between transmembrane segments S5 and S6 of domain III. When expressed, the mutant proteins altered the Na^+ current kinetics. There was no evident phenotypic difference between the patients with identified mutations and the others.

Conclusion: The complete screening of SCN5A led to the identification of mutations in only 4 of 8 patients. This confirms the involvement of SCN5A in Brugada syndrome, and suggests that other genes are probably responsible for this syndrome.

CLINICAL CHARACTERISTICS OF PATIENTS WITH ATRIAL FIBRILLATION

2451 Atrial fibrillation in the 1990s: a shift towards non-rheumatic cardiac causes

S. Lévy, M. Maarek[1], Ph. Coumel[1], J. Lekieffre[2], J.L. Medvedowsky, A. Sebaoun. [1]*The College of French Cardiologists Marseille-Aix, Paris;* [2]*Lille, Hospital Nord, Marseille, France*

The clinical presentation and causes of atrial fibrillation (AF) in the 1990's may differ from AF seen 2–3 decades ago. It was the objective of this prospective study to characterize the underlying conditions of patients with electrocardiographically documented AF, observed in general practice in France (The ALFA Study). This study started june 1st 1993. The work-up included thyroid function tests, 12 lead ECG and M mode and 2D echocardiogram. AF was subdivided into paroxysmal (<7 days), chronic (last episode > 1 month) and recent onset AF (persistent > 7 days and <1 month).

Results: The study population comprized 756 patients with a mean age of 68.6 ± 11.4 years (range 19 to 95 years). There were 436 men (57.7%) and 320 women (42.2%). The relative prevalences of paroxysmal, chronic and recent onset AF were 22.1%, 51.4% and 26.4% respectively. Symptoms were present in 670 (88.6%) patients. Cardiac disorders present in 534 patients (70.6%), included hypertension (39.4%), coronary artery disease (16.6%) and myocardial diseases (15.3%) as the most common disorders. Rheumatic valvular heart disease were present in 115 patients (15.2%) and non-rheumatic valvular disease (mitral valve prolapse) in 25 patients (3.3%). The paroxysmal group differed by a high incidence of palpitations (79.0%) and a low incidence of detectable heart disease (53.9%). The chronic group was characterized by an older age, a higher percentage of organic heart disease (76.9%) and of congestive heart failure (42.6%).

In conclusion, this large-scale study highlights some of the changes that have occurred in the past decades particularly a shift in cardiac causes towards non rheumatic AF and a large proportion with lone AF in the paroxysmal group.

2452 Influence of gender on the clinical characteristics of atrial fibrillation

S. Lévy, M. Maarek[1], Ph. Coumel[1], J. Lekieffre[2], J.L. Medvedowsky, A. Sebaoun[1]. [1]*The College of French Cardiologists Marseille-Aix; Paris;* [2]*Lille; Hospital Nord, Marseille, France*

Little is known on the influence of gender on the clinical presentation of AF. It was the objective of the ALFA Study to prospectively characterize the various subsets of patients with electrocardiographically documented AF, observed in general practice in France (The ALFA Study). This study started June 1st 1993. The work-up included thyroid function tests, 12 lead ECG and M mode and 2D echocardiogram. AF was subdivided into paroxysmal (<7 days), chronic (last episode > 1 month) and recent onset AF (persistent > 7 days and <1 month).

Results: The study population comprized 756 patients with a mean age of 68 ± 11.4 years (range 19 to 95 years). There were 436 men (57.7%) and 320 women (42.2%). The mean age was significantly ($p < 0.0001$) higher in the female population (71.4 ± 11.4 years) than in the male population (66.5 ± 11 years). Evaluated by decades, the male/female ratio decreased after 60 years of age. Symptoms were present in 670 (88.6%) patients and were slightly although significantly ($p < 0.004$) more frequent in the female population (92.5%) than in the male population (85.8%). Underlying heart disease was present in 534 patients (70.6%) and was significantly ($p < 0.001$) more common in women (76.9%) than in men (66.1%). Rheumatic heart disease represented a common cause in women (25.0%), but not in men (8.0%).

In conclusion, this large-scale study showed interesting differences between men and women regarding age distribution, symptoms and the prevalence and type of underlying heart disease in a population of patients with AF in general practice in France.

2453 Development of atrial fibrillation in patients with advanced chronic heart failure: clinical characteristics and prognostic significance during long-term follow-up

H.J.G.M. Crijns, G. Tjeerdsma, P.J. de Kam, F. Boomsma, M.P. van den Berg, D.J. van Veldhuisen. *Dept. of Cardiology, Thoraxcenter, University Hospital Groningen, Netherlands*

Atrial fibrillation (AF) in patients with chronic heart failure (CHF) leads to loss of atrial contribution to ventricular filling, inappropriate increases in ventricular responses, and tachycardiomyopathy. It could thus be speculated, that the onset or development of AF in patients with CHF would be related to an adverse prognosis, and that it would easier develop in patients with more advanced disease.

Methods: We studied 325 patients, who at baseline had sinus rhythm and moderate to severe CHF (mean age 67 ± 8 yr, 75% male, LV ejection fraction 0.23 ± 0.07, 73% in NYHA class III, 27% in NYHA class III/IV or IV). During a mean follow-up of 3.4 yr (range 2.0–5.4 yr), 30 patients (9%) developed AF. At baseline, patients who developed AF in the course of the study were older (mean age 70 yr for those who developed AF, vs. 66 yr for those who remained in SR throughout the study, $p < 0.007$), but LVEF, NYHA class, and etiology of CHF were the same. Further, onset of AF was related to a slightly lower systolic blood pressure (mean 120 mm Hg vs. 127 mm Hg, resp., $p = 0.049$), and lower plasma norepinephrine concentrations (median 403 pg/ml vs. 488 pg/ml, resp., $p = 0.038$), but the two groups were otherwise remarkably similar. On multivariate analysis, all these 3 factors, and N-terminal atrial natriuretic peptide, were significantly related to the development of AF. During follow-up, 14 of the 30 patients (47%) who had developed AF in the course of the study died, compared to 145 of the 295 patients (49%) who remained in SR throughout the study (p = NS between groups).

Conclusion: In CHF, elderly patients have a higher chance of developing AF, but this chance does not appear to be related to more severe CHF. In addition, the development of AF in the present study was not associated with a poorer outcome.

2454 A registry of chronic atrial fibrillation: an overview of epidemiology and prognosis in clinical practice in France

Jean-François Leclercq, Patrick Attuel, Franck Halimi, Pierre Fiorello, Stéphanie Manot, Nathalie Aufrère. *Département de Rythmologie B, Clinique Val D'Or, Saint Cloud, France*

The follow-up (F-U) of 250 patients (pts) with chronic documented atrial fibrillation (AF) consecutively enrolled in a prospective registry between Sept 1994 and July 1995 is evaluated. Only 7 pts were lost to F-U, which is ≥3 years in the remaining 243. Out of the 250 pts, 157 (63%) were males. Mean age was 70 years, and only 58 pts were ≤60 years. AF was paroxysmal in 122 pts, permanent in 89, and converted to sinus rhythm in 39. No etiology was found in 127 pts (51%), whereas 53 had hypertension, 31 a coronary heart disease, 24 a valvular disease, and 17 a cardiomyopathy. History of previous neurologic event (stroke or transient ischemic attack) was present in 24 pts, other embolic events in 2, heart failure in 36. Anticoagulant was given in 134 pts, aspirine or ticlopidine in 56, no antithrombotic agent in 60. An antiarrhythmic drug was used in 147 pts.

During the F-U, death occurred in 24 pts (9.6%), a neurologic event in 18 pts: 16 embolic (6.4%) and 2 haemorragic, and signs of heart failure in 29 pts. Permanent AF was predictive of death or heart failure (17 & 18% vs 4 & 7.6%, $p < 0.01$ & <0.05) but not of neurologic event. Lone AF gived much less death or heart failure (4 & 3%) than valvular or coronary heart disease (22 & 39%, $p < 0.01$). The only etiology associated with a higher risk of neurologic event is hypertension: 9/53 = 17% vs 4.5% in normotensive pts ($p < 0.05$). Previous heart failure is associated with a higher risk of death or heart failure in the F-U, but not of neurologic event. Sex, previous neurologic event or therapy have no significant impact on the F-U in this registry.

2455 Atrial fibrillation – compliance with national guidelines

V. Frykman-Kull, M. Rosenqvist. *Cardiology Department, Karolinska Hospital, Stockholm, Sweden*

Atrial Fibrillation(AF) is the most common arrhythmia and is associated with increased risk for stroke, congestive heart failure and increased mortality. Recent audits showed that there are significant differences in attitudes regarding anticoagulation treatment in patients with AF. National guidelines have been recommended to ensure a more uniform approach to this group of patients.In Sweden, National guidelines for management of AF were published in 1992.

Aims: To explore the compliance between National guidelines and clinical practice in management of AF according to anticoagulation treatment.

Methods: The medical records of 160 consecutive hospital treated patients with AF 5 yrs after the national guidelines were published. The records were reviewed with respect to indications and contraindications for chronic anticoagulation treatment and risk factors for stroke.

Results: The following clinical variables were considered as risk factors for stroke: Age > 65 yrs, previous ischemic attack/stroke, hypertension and diabetes. 23 patients had contraindications for anticoagulation treatment and 31 patients had no previous record of AF. Out of the 110 patients with riskfactors for stroke, previously known AF and no contraindications only 30 (27%) were treated with warfarin/coumadine and 46 (42%) received aspirin. All patients prescribed aspirin had doses below the recommended (320-mg a day). Although 34 patients(31%) had a moderate or high risk of stroke and no known contraindication to anticoagulation treatment they did not receive warfarin or aspirin. There was no difference in treatment between genders.

Risk factors	Anticoagulation	Aspirin	Untreated	Total
1	14	26	22	62
2	13	16	10	39
3	3	4	1	8
4			1	1
Total	30 (27%)	46 (42%)	34 (31%)	110

Conclusions: Clinical practice for patients with AF vary significantly despite published national guidelines. In addition there seems to be an underuse of anticoagulation treatment in the presence of risk factors for stroke.

2456 Prevalence, associated factors and mortality of atrial fibrillation in a large French cohort

L. Guize, F. Thomas, T. Lavergne, X. Copie, K. Bean, A. Bénétos, J.-Y. Le Heuzey. *Centre d'Investigations Préventives et Cliniques (IPC) and Hôpital Broussais, Paris, France*

We studied the prevalence of AF according to age, in men and women, in a large French cohort. Factors associated with AF were also considered. We analyzed the relation between AF and CV and non-CV mortality.

Methods: The cohort was composed of 116384 men and 78805 women aged 30 to 95 years, who had a routine medical examination at the IPC Center from 1972 and 1988. Mean follow-up period was 14.5 years. 235 men and 63 women had an AF at the time of the examination.

Results: In both sexes, prevalence of AF increased with age. Before the age of 50 years the prevalence of AF was 0.05% in men and 0.01% in women, reaching 6.2% and 5.6%, respectively, after 80 years. Factors positively associated with the presence of AF, after adjustment for age, were myocardial infarction, ischaemia on ECG, hypertension, diabetes, obesity, alcohol, gamma-GT, and diuretics. Factors negatively associated with AF were vital capacity, expiratory volume, cholesterol, and the ratio of serum albumin/globulins. In men, AF increased the risk of cardiovascular mortality independently of the presence of cardiopathy and other factors. The risk ratio (RR) for cardiovascular mortality was 2.8 (1.7–4.8) ($p < 0.0001$) in presence of AF among men with cardiopathy. This was due to an increased risk of coronary mortality [RR: 3.5 (1.6–7.4)] and cerebrovascular mortality [RR: 2.7 (1.0–7.5)]. Among men with a lone AF, the risk of CV mortality was not significant. In women, the risk of cerebrovascular mortality tends to increase in presence of AF [RR: 3.5 (0.7–17.2)]. AF was not associated with non CV mortality in both sexes.

In conclusion, among the independent associated factors, alcohol and respiratory insufficiency are significant. In women, AF only seems to increase the risk of cerebrovascular mortality. In men, AF was found to be an independent risk factor for CV mortality only, due to an independent effect on coronary and cerebrovascular mortality.

EUROPEAN EXPERIENCE WITH SURGERY OF ATRIAL FIBRILLATION

2457 Long-term results of Maze surgery for drug-refractory paroxysmal atrial fibrillation without structural heart disease

E.R. Jessurun, N.M. van Hemel, J.A.M. Defauw, A. Brutel de la Rivière, M.A.M. Stofmeel, J.C. Kelder. *St Antonius Hospital, Nieuwegein, Netherlands*

Background. If drug-refractoriness of paroxysmal atrial fibrillation (PAF) occurs, His bundle ablation followed by chronic pacing is frequently done, but this is an indirect therapy. Surgical channeling and exclusion of atrial areas inhibits PAF without damage of sinus node function.

Objectives. To examine the effectiviness and safety of MAZE surgery to abolish symptomatic drug-refractory PAF.

Methods. MAZE III surgery was applied on selected patients (pts) with symptomatic long-standing, drug-refractory PAF after exclusion of structural heart disease. These pts were candidates for His bundle ablation. Clinical characteristics, quality of life and follow-up results were collected to determine long-term surgical results.

Results. MAZE surgery was applied in 41 pts with a mean age of 49 ± 8 years. Death or stroke did not occur during a mean follow-up of 31 ± 16 months. At discharge 35/41 (85%) pts were free of PAF, and 6/41 (15%) had PAF or atrial tachycardias. During follow-up 39/41 (95%) pts remained free of PAF. Two of 41 (5%) underwent His bundle ablation and pacing for drug-refractory postoperative PAF. Three of 41 (7%) pts showed sinus node incompetence: 1 pt with persisting nodal rhythm after surgery, 2 with sinus pauses arising late after discharge. Pacing was needed in 1 patient. Quality of life, determined in the most recently operated pts (n = 9), improved significantly. Also the averaged maximal workload and peak VO_2 increased clearly after surgery.

Conclusion. This pilot study demonstrates safety and usefulness of MAZE III surgery in selected pts who are candidates for His bundle ablation and chronic pacing.

2458 Intraoperative radiofrequency ablation of atrial fibrillation in patients with structural heart disease

H.T. Sie, W.P. Beukema, A.R. Ramdat Misier, J.J. Ennema, J.L. Smeets[1], H.J.J. Wellens[1]. *Cardiology Dept, Isala klinieken, De Weezenlanden, Zwolle; [1]Cardiology Dept, Academic Hospital, Maastricht, Netherlands*

In patients (pts) with chronic atrial fibrillation (AF) and structural heart disease, radiofrequency (RF) ablation was used to compartmentalize both atria, as a modification of the MAZE III procedure. The primary indication for surgery was mitral valve (MV) disease. MV repair was performed in 30 pts, MV replacement in 45 pts, ASD closure in 2 pts and tricuspid valve (TV) replacement in 1 pt. In 15 pts combined MV surgery and aortic valve replacement was carried out, 24 pts needed TV repair and 24 pts underwent concomitant CABG. There were 48 females and AF (>1 yr) was documented in all pts. The mean (± SD) values for age and left atrial dimension were 68 ± 9 yr and 48 ± 8 mm. The extra corporal circulation time was 230 ± 69 min, and the aortic cross clamp time 114 ± 37 min including 17 ± 5 min to perform the left sided MAZE. There were 4 in-hospital deaths (D). During a follow-up (FU) of 21 ± 9 months 9 pts died (3 cardiac D), 4 non-cardiac D, 2 unclassified D. 50 pts were in sinus rhythm, 8 pts in atrial flutter and 3 in AF. In 4 pts a DDD pacemaker was implanted. Echodoppler measurements in 65 pts showed biatrial transport in 50 pts and only right sided atrial transport in 1 pt.

Conclusion: 1. The RF modified MAZE simplifies the MAZE and is safe; 2. RF ablation can eliminate AF and reestablish atrial transport; 3. The RF-MAZE should be considered in all pts with chronic AF undergoing MV surgery.

2459 Surgical radiofrequency ablation for atrial fibrillation: effectiveness of the epicardial approach

S. Benussi, C. Pappone[1], S. Nascimbene, A. Blasio, A. Caldarola, P.L. Stefano, F. Maisano, O. Alfieri. *Cardiochirurgia, San Raffaele Hospital, Milan; [1]Aritmologia, San Raffaele Hospital, Milano, Italy*

Chronic atrial fibrillation (AF) in pts with mitral valve disease has a poor rate of conversion to sinus rhythm (SR) if not treated. Surgical incisions, endocardial cryoablation and endocardial radiofrequency (RF) have proven effective. We here report our experience with epicardial RF ablation of the left atrium during mitral surgery.

Methods: Since February 1998, 26 pts underwent mitral valve surgery and concomitant surgical treatment of chronic AF using an original technique with a RF multipolar catheter. Right and left pulmonary veins encirclings are performed epicardially usually before CPB. After cardioplegic arrest the valve procedure is carried out. Two endocardial linear lesions, between the two encirclings and from the left encircling to the mitral anulus, are then performed. In 12 pts having suture of the left appendage, the last ablation line involved the base of the auricle. Mean duration of the ablation procedure was 12 minutes, but most of it was performed before aortic cross clamping (ACC).

Results: Mean AF duration was 39.1 ± 52.1 months, mean left atrial diameter and mean cardio-thoracic index were 53.2 ± 18.7 cm and 0.58 ± 0.03 respectively. No significant prolongation of CPB (124.4 ± 24.1 min) and ACC time (76.2 ± 22.2 min) was needed. Bleeding was not increased (252 ± 136 ml). After operation sinus rhythm was present in 25/26 pts. Ten pts (38.5%) underwent electrical cardioversion for atrial flutter or other SV tachycardias in 6 cases, for AF in 4. No pt died. No procedure-related complication was recorded. Mean postoperative hospital stay was 7.6 ± 5.9 days. At follow-up (7.4 ± 3.5 months), 19/26 pts (73%) were in SR, and 17/19 pts (89.5%) recovered biatrial contractility (at 2.9 ± 3.2 months).

Conclusion: Epicardial radiofrequency catheter ablation of the left atrium during mitral valve surgery is a safe and effective approach to treat chronic AF. These findings may suggest a widening of the indications for AF surgery.

2460 Curative ablation of chronic permanent atrial fibrillation by the induction of contiguous left atrial lesion lines between the mitral annulus and the pulmonary veins: results, complications and long-term follow-up in 25 patients

G. Hindricks, F.W. Mohr, H.H. Scheld[1], M. Borggrefe[1], D. Hammel[1], R. Autschbach, G. Schuler, H. Kottkamp. *University Leipzig, Heart Center; [1]University Münster, Heart Center, Leipzig, Germany*

A new left atrial approach for intraoperative catheter-guided radiofrequency (RF) ablation of permanent atrial fibrillation (AF) was performed in 25 pts. (age: 63 ± 7 yrs) during operative mitral valve repair or replacement. AF was documented in all pts. for 1–14 yrs. (mean 4.3 ± 2 yrs.) Left atrial size measured 47–63 mm. Linear lesions in the left atrium were induced temperature-guided with a specially designed hand-held electrode probe (10 mm tip, Sulzer Osypka). from the posterolateral mitral annulus to the left inferior pulmonary vein and continued via the upper left pulmonary and the upper right pulmonary vein to the lower right pulmonary vein.

Results: The antiarrhythmic part of the surgical procedure was completed in 21 ± 4 minutes (total bypass time: 107 ± 12 min.). Postoperatively, all patients had sinus rhythm. Between days 2 and 6 after surgery 13 of 25 pts. relapsed to AF (n = 5) or developed atypical atrial flutter (n = 8). Treatment with sotalol (80 mg tid for three months) and/or electrical cardioversion restored sinus rhythm or DDD-pacing in all but 1 pt.. During long term follow-up (1–21 mo., median: 6 mo.) 18/24 pts. (75%) were in sinus rhythm or DDD-pacing, 2 pts. in AF and 4 pts. in atypical atrial flutter. One pt. died on the first day after surgery due to recurrent ventricular fibrillation, 1 pt. developed stroke 4 weeks after surgery despite sinus rhythm and effective anticoagulation.

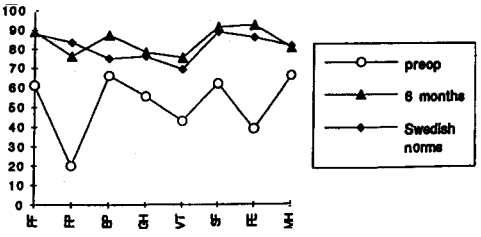
Conclusions: Curative treatment of chronic permanent AF can be achieved by the induction of continuous left atrial lesion lines using intraoperative radiofrequency application (freedom from AF during long term follow-up: 22/24 pts). Because of the high efficiency of the procedure and the short intervention times, the technique may deserve widespread use. The results of this study may also have implications for the development of a curative percutaneous treatment strategy.

2461 Quality of life after Maze surgery for atrial fibrillation

Per Blomström, Carina B-Lundqvist, Lena Jidéus, Leif Nilsson, Stefan Lönnerholm, Tomas Andén, Sten Oxelbark. *Thoracic Centre, University Hospital, Uppsala, Sweden*

In 45 patients (33 male, 12 female) with paroxysmal (P) (n = 28) or chronic (C) (n = 17) atrial fibrillation (AF) undergoing maze surgery, the quality of life were evaluated pre- and six months postoperatively by using SF 36. The mean duration of PAF and CAF was 10.2 years (2–25 years) and 2 years (1–6 years), respectively.

Results: Preop., all scores were significantly lower compared to the general Swedish population (GSP) ($p < 0.0001$). The lowest score was obtained for RP (20 ± 36) and RE (39 ± 44) i.e. problems with work or other daily activities. Six months postop. the level of all items were significantly increased ($p < 0.001$) and did not differ significantly compared to the norms for GSP.



Conclusion: Patients with idiopatic PAF or CAF has a very low quality of life. Already six months after maze surgery, the patients resume the same level of quality of life as the general population.

2462 Value of the electrophysiological evaluation of sinus and atrial activity after the Maze surgery: prediction of atrial fibrillation recurrences

J.G. Rebollo, A.H. Madrid, L. Arabia, M.L. Zea, E. Oliva, I.G. Andrade, T. Centella, A. Epeldegui, L. Novo, C. Moro. *Arrhythmia and Cardiac Surgery Units, Ramón y Cajal Hospital, Alcalá University, Madrid, Spain*

The maze procedure may restore sinus rhythm (SR) in those patients with atrial fibrillation (AF) who undergo cardiac surgery. However, some patients may develop sinus dysfunction and interatrial conduction disturbances after surgery, and further recurrences of AF.

Methods: we have studied 23 patients (15 female, 8 male), mean age of 61 ± 22 years during a 10 months mean follow up. The underlying cardiopathy were: reumathic heart disease (70%), degenerative (22%), neoplasic (4%) and congenital (4%). The duration of the AF was <1 year in 8 patients (30%) and >1 year in 15 (70%). We performed an electrophysiological study (EPS) previously to discharge and another second EPS at the end of the follow up period.

Results: At hospital discharge 13 patients (57%) were in SR, 8 (35%) in AF and 2 (8%) were not studied. The EPS before hospital discharge showed a cycle length of 780 msec (530–1000), a Sinus Node Recovery Time (TRNS) of 985 msec (880–1200). All the patients showed intraatrial conduction disturbances and 3 of them interatrial conduction disturbances. At the end of the follow up period, 8 patients (36%) were in sinus rhythm. The EPS showed these mean data: a cycle length of 1000 msec, a TRNS of 1200 msec, a Sinoatrial Conduction Time (TCSA) of 250 msec, an Interatrial Conduction Time (TCIA) of 200 msec.

In Conclusion: The number of patients in SR at hospital discharge (57%) decreases during the follow up to 36%. The duration of the AF is a determinant factor in these results, because no patient with a duration of AF > 1 year persisted in SR. The data of the PES at discharge was not useful to predict the recurrence of AF.

ADVANCES IN PHYSIOLOGICAL PACING

2463 The registry of the European working group on cardiac pacing

H. Ector, A.F. Rickards[1], L. Kappenberger[1], P. Vardas[1], A. Oto[1], M. Santini[1], R. Sutton[1]. *Cardiology Dept, Univ Hospital Gasthuisberg, Leuven, Belgium; [1]Royal Brompton & Harefield NHS Trust, London, UK*

In 1996 a total number of 190,189 pacemakers (PM) (first implants 130,957) were registered in 2,774 hospitals of 20 European countries for a population of 442.95 million(M): an implantation rate per M population: total 429, first implants 296.

The PM implantation rate per M varies considerably from country to country: for the total number of PM: median 355; first implants median 283. For 1996 the rate of first implants per M was: Austria 444; Belgium 626; Croatia 157; Czech R 467; Denmark 301; FR Yugosl 67; France 528; Germany 423; Greece 286; Italy 346; Lithuania 94; Moldova 13; Netherlands 275; Norway 235; Poland 196; Slovak R 280; Spain 262; Sweden 382; Switzerland 328; UK 263.

For the number of PM implanting hospitals per M, we have obtained the following figures: median 4.34 min 0.23 max 19.5.

The% of PM modes in the different countries gives the following values: VVI-VVIR pacers: median 51.3 min 28.1 max 91; AAI-AAIR: median 2.4 min 0.28 max 13.7; DDD-DDDR: median 39.2 min 6 max 61.8. The%VVI(R) pacing in SSS was: Austria 44.7; Belgium 29; Croatia 70; Czech R 38.7; Denmark 16; FR Yugosl 16; France 27.5; Germany 49.7; Italy 35.1; Moldova 60; Netherlands 41.3; Poland 44; Slovak R 88; Spain 58; Sweden 27; UK 38.6.

For 1996 15 countries have reported on ICD's. The total number of ICD's per M was: Austria 13.3; Belgium 24.1; Croatia 0.8; Czech R 8.2; Denmark 24; FR Yugosl 0.4; Germany 23.8; Italy 10.5; Netherlands 10; Norway 14.6; Poland 0.9; Slovak R 4.3; Spain 7.4; Switzerland 14..4; UK 6.

The number of ablations per M in 1996 is known for 9 countries: Belgium 130.6; Croatia 2.5; Czech R 25.3; FR Yugosl 5.3; Norway 59.3; Poland 5.2; Slovak R 38.1; Switzerland 67.2; UK 42.1.

2464 The effects of long-term right ventricular apical pacing on cardiac sympathetic innervation: an I-123 metaiodobenzylquanidine cardiac scintigraphic study

E.N. Simantirakis, V.K. Prassopoulos[1], S.I. Chrysostomakis, S.I. Koukouraki[1], M.K. Kanakaraki, N.S. Karkavitsas[1], P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete; [1]Nuclear Medicine Department, Heraklion University Hospital, Heraklion, Crete, Greece*

The aim of this study was to investigate whether there are MIBG scintigraphic abnormalities in paced patients where the ventricular stimulus originates from the apex of the right ventricle and is fully paced.

Methods: We studied 11 patients, mean age 68 ± 8 years, who had been paced in DDD mode for a long period (3.6 ± 1.1 years) (Group A) and 8 patients, mean age 69 ± 9 years, with a recent pacemaker implantation (40 ± 17 days) (Group B). Twelve healthy individuals, aged 63 ± 11 years, served as a control group. None of the patients had any condition that might affect myocardial adrenergic innervation. All patients underwent planar and SPECT myocardial imaging 4 hours after intravenous infusion of 5 mCi I^{123}-MIBG. The heart to mediastinum (H/M) ratio was calculated in order to quantify cardiac MIBG accumulation, while the SPECT study was performed in order to investigate the regional distribution of adrenergic innervation (AI). All Group A patients underwent a SPECT Tl^{201} myocardial study during the same week as the I^{123}-MIBG study.

Results: The H/M ratio was smaller in Group A than in Group B ($p < 0.01$) or the controls ($p < 0.001$). In Group A, 9/11 patients had a regional alteration in adrenergic innervation, compared with 0/8 from Group B ($p < 0.01$). Also, 9/11 patients in Group A had abnormal MIBG SPECT studies (inferior apical and inferior-lateral wall), while only 3/11 had a positive Tl^{201} SPECT study in the same two areas ($p < 0.05$).

Conclusions: Long term stimulation from the apex of the right ventricle appears to lead to disturbances of adrenergic innervation of the ventricular myocardium. This provides another reason to seek alternative pacing sites which could ensure a more normal activation sequence.

2465 Chronic right ventricular apex pacing can suppress hypertrophy in the septum of hypertrophying dog hearts

M.F.M. van Oosterhout, T. Arts[1], R.S. Reneman, F.W. Prinzen. *Physiology Dept., Maastricht University, Maastricht; [1]Biophysics Dept., Maastricht University, Maastricht, Netherlands*

Asynchronous electrical activation, induced by ventricular pacing (VP), causes enhanced mechanical load in late activated and diminished mechanical load in early-activated regions. We have recently shown that these conditions ultimately lead to reduced wall thickness in early-activated regions and increased wall thickness in late-activated regions of normal hearts. Because pacing is advocated as therapy in hypertrophic cardiomyopathy we investigated whether VP induces a similar remodeling in canine hearts with pressure overload hypertrophy (POH).

Methods: POH was induced by aortic banding in puppies. At age 9 months 7 dogs were paced for 6 months at physiological heart rate (DDD, AV-interval 25 ms) at the right ventricular (RV) apex (POH-pace group). Four POH dogs remained in sinus rhythm and served as control (POH-control group). 2D-echocardiography and X-ray marker detection were used to measure left ventricular (LV) cavity and wall volume and the relative changes in volume of 5 LV wall sectors (apical and basal septum and LV anterior, posterior and lateral wall).

Results: During the last six months of the protocol LV wall volume increased in the POH-control group, varying from 27 ± 9% in the apical septum to 30 ± 5% in the LV lateral wall (mean ± S.D.). In the POH-pace group the increase in regional wall volume in 4 out of 5 sectors ranged from 31 ± 16% in the basal septum to 35 ± 17% in the LV anterior wall. In the apical septum, however, this increase was significantly smaller (17 ± 21%). In these hearts also myocyte diameter was smaller in the apical septum than in the LV lateral wall.

Conclusions: In hypertrophying hearts chronic pacing at the RV apex suppresses the development of hypertrophy specifically in the apical septum. In contrast to normal hearts VP does not lead to excess hypertrophy in late activated regions, suggesting different sensitivity of normal and hypertrophic myocardium to mechanical load.

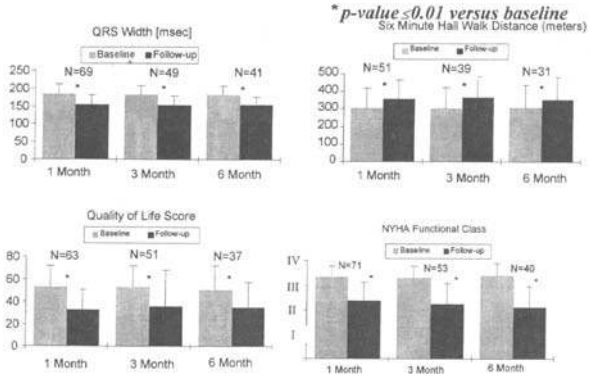
2466 Long-term results with cardiac resynchronization for heart failure: the InSync™ trial

D. Gras[1], S. Cazeau[1], A. Lazarus[1], P. Mabo[2], C. Bucknall[3], T. Tang[4], H. Oude Luttikhuis[5], A. Kirstein-Pedersen[6]. *For the InSync Investigators, [1]Clinique du Val d'Or, Paris; [2]Dep. de Cardiologie et Maladies, Rennes, France; [3]Ottawa Heart Institute, Ottawa ON, Canada; [4]St. Thomas Hospital, London, UK; [5]St. Sophia Ziekenhuis, Zwolle, Netherlands; [6]Skejby Sygehus, Aarhus, Denmark*

The InSync™ trial is a prospective, multicenter evaluation of Cardiac Resynchronization for patients with advanced Heart Failure (HF) and ventricular conduction delays. Patients with advanced dilated cardiomyopathy (NYHA class III/IV, EF < = 35%, LVEDD = > 60 mm) and conduction disturbances (QRS = > 150 ms) were included.

Methods: 71 patients (77% male, average age 67 ± 9 years) were enrolled in this global study. QRS width, 6 minute Hall Walk Distance (HWD), Quality of Life (QoL) questionnaire (Minnesota Living with HF score) and NYHA Class were examined at baseline, 1, 3 and 6 months after implantation and compared to baseline.

Analysis: Statistically significant improvements were observed for each endpoint at 1, 3 and 6 months.



Conclusion: These data from the InSync trial suggest that Cardiac Resynchronization may provide an effective additional therapy in symptomatic HF patients with ventricular conduction disturbances.

2467 Profile of cardiovascular mortality in the CTOPP study

M. Sami, H. Abdollah, S. Connolly, L. Bonilla, C. Kerr. *For the CTOPP Study Investigators; Royal Victoria Hospital, Quebec PQ; Kingston General Hospital, Kingston ON; Hamilton Civic Hospital, Hamilton ON; Vancouver General Hospital, Vancouver BC, Canada*

The Canadian Trial of Physiologic Pacing (CTOPP) randomized 2568 patients about to receive a pacemaker to either "physiologic" pacing (AAI, DDD, AAIR, DDDR) or "non-physiologic" (VVI, VVIR) pacing. Patients with chronic atrial fibrillation or significant co-morbidity were excluded. 1094 patients received the former and 1474 the latter. Over an average follow up of 3 years, all cause mortality was similar in the 2 groups. The aim of this sub-study was to examine the profile of cardiovascular (CV) mortality in our population.

Results: Total CV deaths were 15% of those randomised to VVI, VVIR vs 13% of those randomised to physiologic pacing. The percentages of patients dying of heart failure (HF), presumed arrhythmic death, myocardial infarction, stroke and pulmonary embolism, respectively, were similar in both groups. Of the 284 CV deaths noted among patients aged 70 or more, 68 (24%) were due to HF and 125 (44%) were presumed arrhythmic. Of the 75 deaths noted in patients aged less than 70, 15 (20%) were due to HF and 36 (48%) were presumed arrhythmic deaths.

Conclusion: At an average follow-up of 3 years, the CV mortality profile was similar for those patients receiving "physiologic" and "non physiologic" pacemakers. Furthermore, this profile was similar for those over or under the age of 70.

EFFECTS OF GENDER ON PROGRESSION OF CORONARY ARTERY DISEASE AND RESPONSE TO TREATMENT

2484 Disturbances of vascular endothelial function in pre-eclampsia

J. Chambers, L. Fusi, M. De Swiet, J.S. Kooner. *National Heart and Lung Institute, Imperial College School of Medicine, Hammersmith Hospital, London, UK*

Women who have experienced an episode of pre-eclampsia are susceptible to recurrent pre-eclampsia, and hypertension, in later life. The mechanisms which underlie this risk have not been identified. We hypothesised that vascular endothelial function is defective in women with previous pre-eclampsia, and may influence their future risk of hypertension related disorders.

We studied 103 consecutive women aged 18–43 yrs, with recent (>3 months) pre-eclampsia, and 48 age matched controls. Brachial artery flow-mediated (FMD, endothelium dependent), and glyceryl trinitrate-induced (GTN, endothelium independent) dilatation, were measured using high resolution ultrasound. Subjects were characterised for major vascular risk factors.

FMD was reduced in women with previous pre-eclampsia compared to controls (2.2 ± 0.4 vs 4.7 ± 0.6%, $p < 0.001$). In contrast, there were no significant differences in GTN induced dilatation (21.0 ± 1.3 vs 20.5 ± 0.7%, $p = 0.74$). Compared to controls, brachial artery diameter was higher in women with previous pre-eclampsia (3.49 ± 0.04 vs 3.28 ± 0.07 mm, $p = 0.01$), but there were no differences in brachial artery flow either at rest, or during reactive hyperaemia, between the two groups. Women with previous pre-eclampsia had higher diastolic and systolic blood pressure, and body mass index ($p < 0.01$), but similar total and HDL cholesterol, and smoking rates (p = ns) compared to controls. In a multivariate model, reduced FMD in women with previous preeclampsia was independent of vascular risk factors ($p = 0.01$), and differences in brachial artery diameter.

In summary, endothelium dependent dilatation is impaired in healthy young women with a previous episode of pre-eclampsia. Our findings support the hypothesis that basal endothelial nitric oxide activity is impaired in women with previous pre-eclampsia, and may contribute to their future risk of vascular disorders.

2485 Intracoronary 17β-oestradiol reduces plasma endothelin-1 levels in postmenopausal women with coronary artery disease

C.M. Webb, M. Ghatei[1], J.G. McNeill, P. Collins. *ISCM at the National Heart & Lung Institute, and Royal Brompton Hospital, London; [1]Hammersmith Hospital, London, UK*

Oestrogen (E) beneficially affects coronary reactivity by an endothelium-dependent mechanism in postmenopausal women with coronary artery disease, at least in part via nitric oxide. Postmenopausal E therapy is known to decrease systemic plasma levels of the potent vasoconstrictor endothelin-1 (ET), however the effects of intracoronary E administration on ET production is unknown. We therefore investigated the effects of a 20 min intracoronary 17β-oestradiol (E2; 60 ng/min) or vehicle control (VC; 0.001 ml 15% ethanol/min) infusion on ET-1 levels in 20 postmenopausal women [14 patients (mean ± SEM; aged 65 ± 2 years) and 6 controls (63 ± 3 years)] with coronary artery disease (CAD). Immediately before and after the E2 infusion, 2-minute intracoronary infusions of substance P (10 and 25 pmol/ml; SP10 and SP25 respectively) were given. A catheter was positioned the ostium of an irregular coronary artery for the infusions, and another into the coronary sinus for blood sampling. Blood sampling for analysis of plasma ET-1 levels took place at baseline, then at 5 minute intervals during the infusion of E2. Plasma ET-1 levels in the coronary sinus were significantly decreased after 20 min of E2 infusion compared to baseline (0.86 ± 0.16 vs 1.12 ± 0.18 pmol/l, $P = 0.05$; coronary sinus vs baseline). In the control group there was no significant change in ET-1 levels after VC compared to baseline. Levels of coronary sinus ET-1 after SP10 and SP25 were decreased after the E2 infusion (1.29 ± 0.17 vs 1.03 ± 0.15 pmol/l ($P = 0.04$) and 1.3 ± 0.15 vs 0.99 ± 0.17 pmol/l ($P = 0.024$); SP10 and SP25 before vs after E2 respectively). We conclude that intracoronary E may beneficially affect endothelium-dependent coronary reactivity in postmenopausal women with CAD at least in part via a decrease in ET-1 production.

2486 Hormone replacement therapy and the incidence of acute myocardial infarction: a population-based nested case-control study

C. Varas, L.A. García-Rodriguez[1], S. Perez-Gutthann, A. Duque. *Global Epidemiology, Novartis Pharma, Barcelona; [1]Spanish Pharmacoepide. Research Center, CEIFE, Madrid, Spain*

Epidemiological studies have consistently shown an association between a marked reduction on the risk of coronary heart disease (CHD) and hormone replacement therapy (HRT). However, these studies provided only information on the effects of the oral route of HRT administration. Therefore, we conducted a population-based nested case-control study using the General Practice Research Database in the UK.

Methods: A cohort of 164,769 women aged 50–74 years was followed from January 1, 1991 to December 31, 1995. Women with history of myocardial infarction (MI), other cardiovascular and cerebrovascular disease, neoplasms, coagulopathies, vasculitis and alcohol-related diseases were excluded from the source population. 1,242 potential cases of MI were identified. After the review (blind to exposure status) of medical records and all available information related to each identified event (including autopsy reports and death certificates for fatal cases) 1.013 first episodes of AMI cases were confirmed, 791 non fatal AMI and 222 CHD deaths, using WHO adapted criteria. 5,000 controls frequency-matched by age were randomly sampled. Prescriptions of HRT filled during the study period were obtained from the database.

Results: Prevalence of HRT use was 22%. 13% of cases and 17% of controls used HRT during the last six months prior to the index date. The odds ratio (OR) of AMI for HRT-users compared to non-users was 0.7 (95% C.I.: 0.6–0.9) after controlling for age, coronary risk factors, comorbidity, current use of aspirin and type of menopause. A trend of greater benefit with longer duration of HRT use was observed: ≤1 year, 0.8 (95% CI: 0.6–1.1); >1–3 years, 0.7 (95%CI: 0.6–1.0); >3 years 0.6 (95% CI: 0.4–0.9). The ORs for unopposed and opposed therapy were 0.6 (95% CI: 0.4–0.9) and 0.8 (95% CI: 0.6–1.0). 79% of women used oral therapy and 21% transdermal therapy. The ORs associated with oral conjugated oestrogens was 0.7 (95% CI: 0.6–0.9) and with transdermal oestradiol was 0.8 (95% CI: 0.6–1.3). The protective use of HRT was associated with medium doses of oestrogens and, appeared to diminish after 2–3 years of the cessation of use. The overall absolute risk of AMI was 1.6 per 1,000 person-years. In our cohort, 61 AMI cases were estimated to be prevented per 100,000 person-years by current-recent HRT use.

In conclusion, these results are consistent with those previously reported for oral HRT and suggest that the use of transdermal therapy has a similar protective effect than that reported with oral preparations.

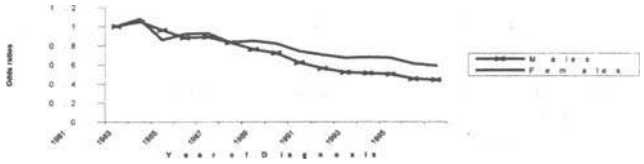
2487 Gender differences in survival following acute myocardial infarction 1981–1995

K. MacIntyre, S. Capewell, M. Livingston, J. Chalmers[1], J. Boyd, A. Finlayson[1], A. Redpath[1], J. Pell[3], C. Evans, J.J.V. McMurray[4]. *Department of Public Health, University of Glasgow; [1]Information and Statistics Division Edinburgh; [3]Greater Glasgow Health Board; [4]Department of Cardiology, Western Infirmary, Glasgow, UK*

Background: There has been much debate about whether or not women receive different management than men after acute myocardial infarction (MI) and have a worse prognosis than men. We have examined case fatality in *all* patients admitted to hospital with acute MI in Scotland between 1981–1995 to determine whether or not gender differences in survival after MI do exist and persist.

Methods: Scotland (population 5.1 million) has a national Morbidity Record Database holding comprehensive, high quality data, which links all hospitalisations and deaths. A Scottish wide, retrospective, cohort study of all 178,077 individual MI patients admitted between 1981–1995 was carried out. Mortality up to 10 years was calculated with Cox-modelling for the effects of age, sex, socioeconomic deprivation, co-morbidity and year of treatment.

Results: 83075 women and 95002 men were hospitalised with acute MI during the period of study. Unadjusted 30 day, 1 year, 5 year and 10 year case fatality rates in all patients were 24, 33, 50 and 65%. Adjusted case fatality rates fell significantly in both men and women between 1981–1995 (figure). Men however, had a greater fall in case fatality rate than women and this gender difference in prognosis persisted over the period of study.



Acute myocardial infarction: case fatality at 30 days.

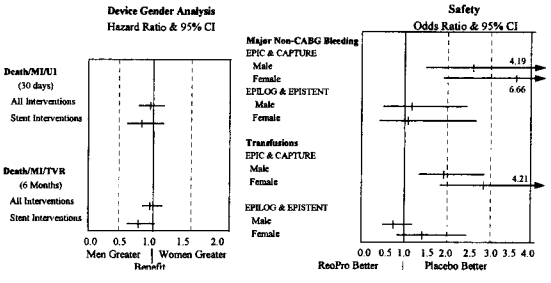
Conclusions: Women continue to have a worse survival than men after myocardial infarction. Further investigation and explanation of this alarming finding is required.

2488 Abciximab benefit in coronary intervention by gender and device: results of randomized trials

D. Kereiakes[1], A. Lincoff[2], M. Simoons[3], M.J. deBoer[4], J. Tcheng[5], A. Vahanian[6], R. Cook[7], R. Achenbach[7], C. Cabot[7], E. Topol[2]. *[1]The Lindner Center, Cincinnati OH; [2]The Cleveland Clinic, Cleveland OH; [5]Duke University, Durham NC; [7]Centocor Inc., Malvern PA, USA; [3]Erasmus University, Rotterdam; [4]Hospital de Weezenlanden, Zwolle, Netherlands; [6]Tenon Hospital, Paris, France*

Platelet GP IIb/IIIa inhibition with abciximab (AB) reduces ischemic complications of percutaneous coronary intervention (PCI). Adverse outcomes of PCI may be increased in women.

Methods: We analyzed results for women (n = 2116) and men (n = 5744) in EPIC, EPILOG, CAPTURE and EPISTENT placebo-controlled randomized trials of AB therapy during PCI. Results: Women were older, had more diabetes mellitus or unstable angina presentation and less prior myocardial infarction (MI) or coronary bypass surgery (CABG) than men. Hazard ratios and 95% confidence intervals (CI) for death, MI, or urgent intervention (UI) to 30 days; death; MI or target vessel revascularization (TVR) to 6 months (A) as well as major non-CABG bleeding or transfusion requirement (B) are shown.



In conclusion, prophylactic AB improves outcomes following PCI with similar benefit and safety profiles in both men and women. Device-gender analyses for other GP IIb/IIIa inhibitors need to be performed.

2489 Coronary intervention in women: how do they fare in the long term?

A. Bhaskaran, B. Barker, R. Siegel, Z. Yilma, P. Underwood, W. Breisblatt, A. Nuttall, J. Vermillion, S. Huemiller, D. Swanson. *Advanced Cardiac Specialists & Phoenix Memorial Hospital, Phoenix AZ, USA*

Coronary heart disease (CHD) is the leading cause of mortality in women in the United States, accounting for nearly 250,000 deaths each year. It is also a prominent cause of morbidity and disability among women, particularly in the older age group. Coronary revascularization in women is perceived to be associated with higher complication rates and lower success rates compared with men. We studied acute and long-term clinical outcomes following percutaneous coronary intervention (PTCA) in women with hemodynamically significant obstructive CHD. From 1/95 to 12/98, 1,028 women underwent PTCA at our center. Mean age at presentation was 66.5 ± 11.6 years (range 24–94 years). The majority presented with unstable angina (45%), while 26.4% presented with acute MI. Co-morbidities included: age ≥ 70, 44.1%; diabetes, 32.8%; prior MI, 25.3%; prior CABG, 16%; multivessel disease, 15.3%; EF < 40%, 17.3%. There was a history of smoking in 32.8% and CHF in 17.3%. Cardiogenic shock was present in 7.6%. On angiography, 53.2% of lesions were ostial or proximal, subtending large volumes of myocardium; one-third of all lesions represented LAD distribution. The lesion was in the native vessel in 96.6%. Stent (ST) was deployed in 33.5% of all PTCA procedures, either electively or for suboptimal result. Stented vessels were ≥3 mm in diameter. Post-ST high-pressure dilatations were performed (mean 16.1 atm). Adjunctive IABP support was used in 17.5%. Glycoprotein IIb/IIIa inhibitors were used in 12.8%. Patients received antiplatelet therapy following the procedure.

Results: Procedural success (≤20% residual; TIMI 3 flow) was obtained in 97.2% of women. Acute re-PTCA was required in 2.3%; 1.6% required CABG surgery before discharge. *There were only 2 in-hospital deaths in this series.* Vascular access site complications due to IABP use were seen in 5/180 patients (2.8%). Mean global LVEF at discharge was 43.9%*. Mean hospital stay was 2.46 days.

12-month Follow-Up [96.8% complete; Mean Follow-Up 6.74 months]

SAT	TLR-PTCA	CABG	Stroke	Death	EFS	Mean LVEF
7	87	39	18	46	782	49.0%;
(2.0%)	(8.5%)	(3.8%)	(1.8%)	(4.4%)	(76.1%)	*$p = 0.046$

SAT: subacute stent thrombosis; TLR: target lesion revascularization; EFS: event-free survival

Conclusions: (1) This large series demonstrates that percutaneous intervention is a safe and effective therapeutic option in women with hemodynamically significant CHD. (2) Procedural success was high and in-hospital adverse events were infrequent, despite unstable presentations and significant co-morbidities at baseline. (3) The incidence of SAT, access site complications and neurological events was low. (4) At 12-month follow-up, the rate of TLR was acceptable and major adverse cardiac event-free survival was high, with *significant* improvement in global LV systolic performance. (6) Our data suggests that an aggressive therapeutic strategy for prompt and effective salvage of jeopardized myocardium in women presenting with significant CHD can eliminate gender-related negative outcomes historically reported with coronary intervention in women.

PRIMARY AND SECONDARY PREVENTION IN CORONARY ARTERY DISEASE

2490 The association of socioeconomic factors with incidence, mortality, and one-year prognosis of first myocardial infarction

V. Salomaa, H. Miettinen, M. Niemelä, M. Ketonen, K. Pyörälä. *For the FINMONICA MI Register Study Group; Dept. of Epidemiol, National Public Health Institute, Helsinki, Finland*

Low socioeconomic status (SES) is usually associated with increased risk of coronary heart disease deaths. Reduction of socioeconomic health differentials has been one of the main goals of health policy in many countries, including Finland.

Methods: First ever myocardial infarction (MI) events (n = 8445) recorded by the FINMONICA MI register during 1983–1992 among men and women aged 35–64 years were included in the study. Data on SES were obtained by a record linkage of the MI register data with the files of Statistics Finland on the basis of social security number, unique to every citizen of Finland. Taxable income and education level were used as the indicators of SES.

Results: The age-standardized rate ratios and 95% confidence intervals of first MI events by taxable income among men were as follows:

Income	Incidence	Prehospital deaths	0–28 day deaths	0–365 day deaths
Low	1.67 (1.57–1.78)	3.39 (2.96–3.88)	3.18 (2.82–3.58)	3.18 (2.84–3.55)
Middle	1.84 (1.73–1.95)	2.33 (2.03–2.68)	2.30 (2.04–2.59)	2.34 (2.09–2.62)
High	1	1	1	1

The rate ratios are adjusted for age, study area, urban/rural residence, and study year. The findings in women were consistent with those in men.

Conclusions: The mortality from first MI events was more than three times higher in the lowest than in the highest income group. In part, the mortality difference was due to the difference in incidence, but mainly it was due to the considerable difference in prehospital sudden deaths.

2491 Prevalence of coronary heart disease within a population of 901,829 sampled in the UK, and level of secondary prevention of coronary heart disease among those identified

A.J.B. Brady, J.B. Pittard. *Glasgow Royal Infirmary, Glasgow; Staines and Thameside Medical Group, Staines, UK*

Purpose: Several small studies have been published recently which document the prevalence of coronary heart disease (CHD) in different regions within the United Kingdom (UK). The present survey was undertaken nationwide to define the extent of CHD in the community and assist family doctors to audit whether measures for secondary prevention for individuals with CHD were being addressed in their practice.

Methods: 548 doctors working in 137 medium to large family practices took part. 12 research nurses spent 18 months collecting the data. The average total number of patients in each practice was 7215, with an average of 4 physicians in each practice.

Results: From a total number of 901,829 individuals, the medical records of 24,431 patients were identified as having CHD. The prevalence therefore was 2.7%, i.e., each physician looked after about 50 patients with established CHD. 64.6% of patients were aged 60–79, and 17.1% were 80 or older. 59.5% were male. The table shows the distribution of disease and the level of secondary prevention:

Angina pectoris	21,275	87.1%
Previous MI	10,164	41.6
CABG/PTCA	3,848	15.7
Heart failure	1,306	5.3
Continued smoking	5,722	23.4
Hypertension (>160/90 mm Hg)	9890	40.5
Diabetes mellitus	2,644	10.8
Multiple risk factors (2 or more)	8395	34.4
Cholesterol ever recorded	14,205	58.1
Cholesterol > 5.0 mmol/l	10,807	(76.1% of recorded values)
No record ever of cholesterol	10,226	41.9

Conclusions: High proportions of patients in the UK with established CHD have inadequate secondary preventive measures. 86% have high cholesterol levels, or have never had it measured; 23% continue to smoke and 40% have hypertension. The majority of the patients are middle aged or elderly. It is clear that secondary prevention of CHD in the UK offers a great opportunity for improved management. This data will be used to generate a model for health promotion in CHD to be applied at the level of the family practice.

2492 Familial aggregation of body mass index: a population-based family study in eastern Finland

R. Fuentes, I-L. Notkola, S. Shemeikka, J. Tuomilehto, A. Nissinen. *Dept. of Public Health & General Practice, Univ. of Kuopio, Kuopio; Dept. of Epidemiology and Health Promotion, National Public Health Institute, Helsinki, Finland*

To investigate the familial aggregation of BMI a cross-sectional study of children at age of 15 and their biological parents was carried out in a rural community in eastern Finland.

Two hundred twenty four children were invited, 184 families agreed to participate (82%), from which 144 were included in the analysis. Comprehensive health and lifestyle questionnaires were completed by the participants before physical measurements.

Significant positive correlations of BMI were found between the mother and the offspring ($r = 0.31$, $p < 0.001$, $n = 140$), the father and the offspring ($r = 0.23$, $p = 0.017$, $n = 107$), the mother and the daughter ($r = 0.26$, $p = 0.044$, $n = 63$) and the mother and the son ($r = 0.36$, $p = 0.001$, $n = 77$). The adjustments for the parent's age, education and family history of acute myocardial infarction and the offspring's gender did not change these results. There was a higher proportion of the offspring in the highest quartile of BMI when the mother has obesity (OR = 3.1, 95% CI = 1.2–8.0, n = 140, mother obesity = BMI $\geq$ 27.3) and when one or both parents have obesity (OR = 2.8, 95% CI = 1.0–8.0 for one parent with obesity; OR = 4.6, 95% CI = 1.1–20.0 for both parents with obesity; n = 103; obesity = BMI $\geq$ 27.3 for mothers and $\geq$27.8 for fathers).

The study confirmed the aggregation of BMI in families. The stronger obesity association between the mother and the offspring may confirm the mother's key role in the primary prevention of obesity.

2493 Acute myocardial infarction is increasing in Spanish men

S. Sans, A. Puigdefàbregas, G. Paluzie, R. Martínez, I. Pérez, I. Balaguer Vintró. *Institute of Health Studies, Department of Health and Social Security, Barcelona, Spain*

Spain has the second lowest CHD mortality in Europe. Mediterranean diet and lifestyle are conventionally invoked as protective factors for this favourable pattern. However, this country has undergone many socio-economic changes over the last 20 years which could affect this pattern. The WHO-MONICA project was set up to monitor trends in CHD morbi-mortality and risk factors. The aim of this paper is to report on attack rate trends of acute myocardial infarction (AMI) from 1985 to 1996 for the ages 35 to 64 in Spain.

Methods and data are from the population-based register of the WHO-MONICA Project carried out in a metropolitan area of the Northeast of the country covering one million population. Sources of information were hospital discharge lists, death certificates, necropsy records and direct information from physicians, patients and relatives. More than 40 hospitals were monitored. All cases were validated through medical records, using the project diagnostic criteria and undergone external quality control. Rates were age-adjusted to the European standard population. Trends were calculated by linear regression.

Results: 11,443 cases were registered. Of these, 36% were classified as definite acute myocardial infarction. The average attack rate (MONICA-definition 2) of AMI was 107 per 100,000 (189 men, 28 women). Attack rates of AMI increased at a rate of 2.5% annually ($p < 0.06$) from 142 to 208 in men. No significant changes were observed in women. Rates increased more for recurrent (5%, $p < 0.008$) than for first events (2.1%, $p < 0.02$) and more for fatal (3.4%, $p < 0.02$) than for definite non-fatal events (2.2%, $p < 0.03$). 28-day case fatality did not significantly change over the period ($\beta = 0.008$, $p = 0.49$). Official country-wide hospital statistics also show a 29% increase of AMI admission rates for all ages between 1986 and 1995.

Conclusion: Overall AMI attack rates in middle aged men are increasing in Spain. Primary and secondary prevention programs are needed.

2494 Regional differences in cardiovascular disease mortality and major risk factors within Oslo: an ecological analysis

A.K. Jenum, D.S. Thelle, I. Stensvold[1]. *Dept. of Epidemiologic Research, University of Oslo, Oslo; [1]Department of Preventive Medicine, Ullevål University Hospital, Oslo, Norway*

Cardiovascular disease (CVD) mortality, ischaemic heart disease (IHD) mortality and all cause mortality vary considerably between different districts in Oslo. We examined the CVD risk factors and mortality according to socio-economic status (SES) in the 25 administrative districts of Oslo. This analysis is based on data from CVD surveys comprising 6897 men and 7323 women 40 years of age in the period 1985–88. The correlations between area-specific mortality rates for persons 45–74 years of age in 1991–95, area indicators of SES and CVD risk factors, were estimated. The proportion of the population being daily smokers, having low education, having high income, and the sex-specific mean cholesterol and systolic blood pressure levels of the areas, were used as independent variables in the regression analyses.

For both genders this ecological analysis demonstrates strong associations between mortality and major cardiovascular risk factors. The mortality rates as well as the cardiovascular risk factors are also highly related to the socio-economic indicators, with correlation coefficients (Pearson) of 0.74 for smoking and CVD mortality, and −0.78 for high income and ischaemic heart disease (IHD) mortality for both genders. Smoking explained 70% of the regional differences in all cause mortality for men and 46% for women, and for CVD mortality rates, 61% and 49% respectively. Corresponding figures for IHD mortality were 61% and 46%. Diastolic blood pressure and total cholesterol are closely related to the socio-economic indicators and to smoking in both genders.The relative strength of the cardiovascular risk factors on the all cause mortality, CVD mortality and IHD mortality in the multivariate analyses differ between males and females. This is particularly seen for total cholesterol which explains a larger proportion of the CVD mortality in women than men (42% v. 24%). Also physical inactivity shows strong correlation with mortality for both genders, with correlation coefficients of 0.69 for men and 0.64 for women with respect to CVD mortality.

Conclusion: Cardiovascular risk factors and life style habits on population level from the mid 1980s are strongly related to mortality, and explain a large proportion of the regional variations in mortality in Oslo in the 1990s. The mortality rates and risk factors are highly associated with area-based SES indicators. A gender difference in the preventive measures giving priority to men could affect risk factors on population levels and result in weaker explained variances of mortality for men than women.

2495 Air Force/Texas Coronary Atherosclerosis Prevention Study: relative benefit of primary prevention in subgroups with different absolute risk according to U.S. NCEP ATP-II and joint European guidelines

A.M. Gotto, Jr., E. Whitney, E.A. Stein, D.R. Shapiro, M. Clearfield, S. Weis, P.A. Beere, D.J. Watson, J.R. Downs, J.S. de Cani. *Wilford Hall Medical Center, San Antonio TX; University of North Texas Health Science Center, Fort Worth TX, USA*

Background: The Air Force/Texas Coronary Atherosclerosis Prevention Study (AFCAPS/TexCAPS) demonstrated that, for generally healthy persons with average LDL-C and below average HDL-C, treatment with lovastatin, 20–40 mg/day, reduced the risk of a first acute major coronary event by 37% vs. placebo, in addition to diet and lifestyle measures.

Design/Methods: This was a randomized double-blind placebo controlled study of 6605 men and women; mean duration was 5.2 years. Post-hoc analyses were performed within subgroups according to those who would (Rx+) and would not (Rx−) be recommended for drug treatment by U.S. (NCEP-ATP II) and Joint European (Euro) guidelines.

Results: Only 17% and 20% of the cohort would have met the U.S. and European guidelines, respectively. The interactions between treatment and the subgroup factor were not significant (p = 0.384, p = 0.684, respectively).

Risk Subgroup	Treatment	N	Cases	Rate[1]	Relative Risk	(95% CI)[2]	P[3]
U.S. Rx+	Lovastatin	530	27	1.00	0.53	(0.33, 0.84)	0.006
	Placebo	566	53	1.87			
U.S. Rx−	Lovastatin	2774	89	0.62	0.57	(0.51, 0.88)	0.003
	Placebo	2735	130	0.93			
Euro Rx+*	Lovastatin	658	43	1.30	0.66	(0.45, 0.97)	0.034
	Placebo	652	63	1.96			
Euro Rx−**	Lovastatin	2608	70	0.52	0.61	(0.45, 0.82)	0.001
	Placebo	2592	113	0.85			
Overall	**Lovastatin**	**3304**	**116**	**0.68**	**0.63**	**(0.50, 0.79)**	**<0.001**
	Placebo	**3301**	**183**	**1.09**			

Note: 95 persons without SBP at baseline could not be classified based on the Joint European Guidelines; *high or very high risk; **low to moderate risk; [1]% per year or 100 person-years at risk; [2]Cox model stratified by site and gender; [3]between treatment group log rank statistic stratified by site and gender

Conclusions: Clinical benefit was consistent between subgroups and overall cohort for both Guidelines, despite different levels of absolute risk. [In such cases, the effect within the overall cohort is the best estimate within subgroups.] This suggests that in addition to current recommendations for persons at high risk, significant benefits can also be achieved with lovastatin treatment for persons at lower absolute risk, in addition to lifestyle and diet interventions.

COST-EFFECTIVENESS OF INTERVENTIONS

2496 Cost-effectiveness of simvastatin in diabetic patients with coronary disease: results from 4S

B. Jonsson, J. Cook[1], T. Pedersen[2], D. Gomes[3]. *Stockholm School of Economics, Stockholm, Sweden; [1]Health Economics Statistics, Merck Research Labs, Blue Bell PA, USA; [2]Cardiology, Aker Hospital, Oslo, Norway[3]Outcomes Research, Merck & Co. Inc., Whitehouse Station NJ, USA*

Diabetes is a major source of morbidity, mortality and medical costs. Clinical results from the Scandinavian Simvastatin Survival Study (4S) demonstrated a 55% reduction in the risk of coronary death and nonfatal MIs in diabetic patients with coronary disease treated with simvastatin.

The purpose of this study is to investigate the cost-effectiveness of simvastatin in these patients, using prospectively collected outcomes data from 4S. Diabetic patients were identified using two different classifications schemes. First, according to Clinical History (202 Diabetic, 4242 Non-Diabetic) and second based on the new American Diabetes Association (ADA) Definition (483 Diabetic, 678 Impaired Fasting Glucose (IFG), 3237 Normal Fasting Glucose (NFG)).

There was a reduction in cardiovascular hospitalization due to simvastatin therapy in all subgroups. The difference was greatest for the diabetic group, regardless of the classification scheme used. Reductions in hospitalizations in the diabetic group resulted in substantial hospital cost savings that offset 67% to 76% of the drug cost using Swedish costs(depending on the classification used).

Cost effectiveness results for diabetic patients ranged from 1600 ECU per life year gained (based on clinical history) to 3200 ECU per life year gained (based on ADA criteria) using Swedish costs. In the other European countries evaluated, intervention with simvastatin maintains a favorable cost-effectiveness ratio independent of differences in local health care unit costs.

Conclusion: Regardless of diabetic classification scheme, treatment with simvastatin in all 4S subgroups resulted in cost per life year gained estimates that are well within the range generally considered to be extremely cost effective compared to other medical interventions. Based on the results of 4S, cholesterol lowering with simvastatin provides good value for money in both diabetic and non-diabetic patients with cardiovascular disease.

2497 Cost-effectiveness of stenting as strategy of coronary revascularization in diabetic patients with one-vessel disease

A. Iñiguez, F. Navarro, R. Ibargollin, C. Serrano. *Interventional Cardiology Unit, Cardiology Department, Fundación Jiménez Díaz, Madrid, Spain*

Despite some subgroups of diabetic (D.) patients (P.) have poor outcome after coronary angioplasty (C.A.), a subgroup of diabetic P. have only one vessel disease. In these P., C.A. may be an efficient and cost/effective strategy.

The aim of the study was to evaluate the effectiveness (E.) and cost/effectiveness (C/E) of a successful revascularization by C.A. in a consecutive series of D. vs non-D. P., with and without stent implantation. An analytic model was used to determine incremental C/E. Effectiveness was defined as the absence of death, acute myocardial infarction or need of revascularization at 6 months follow-up.

A total of 302 P. were included and evaluated. Mean age of P. was 65 ± 8 years. There were 202 P. with stent implantation (33 D. and 169 non-D.) and 100 with balloon without stenting (25 D. and 75 non-D.).

The results were as follows:

Group	Effectiveness	Cost ($)/100 p.	C/E
D-Stent	70%	1.279.078	18.273
D-Balloon	56%	1.355.249	24.201
Non-D-Stent	83%	1.152.281	13.883
Non-D-Balloon	76%	1.061.533	13.968

Stenting in D. P. with one vessel disease, implied a net saving of 5.928 $ at 6 months follow-up. Nevertheless, in these contex stenting does not added significant effect in terms of costs and C/E for non-D. P.

In conclusion, in the population included with one vessel disease, a successful coronary balloon angioplasty is a low efficient strategy of treatment for diabetic P., in these setting stenting appears to be the most Cost/Effective percutaneous therapy.

2498 The cost and effects of combining stenting with abciximab derived from the EPISTENT study

B.A. Van Hout, J.E.F. Van Rijkom[1], A.M. Lincoff[2]. *IMTA, Erasmus University Rotterdam, Rotterdam; [1]Pharmaco-epidemiology & Pharmacotherapy, Utrecht University, Utrecht, Netherlands; [2]Department of Cardiology, The Cleveland Clinic Foundation, Cleveland OH, USA*

Objective: To assess the balance between the costs and effects of the combination of abciximab with coronary stenting compared to stenting without abciximab and compared to balloon angioplasty with abciximab.

Method: Estimates of costs and effects are based on data from the EPISTENT study (n = 2399) carried out in the US and Canada. Effectiveness is calculated in two ways: MI-free survival and survival free of major cardiovascular events (MACE-free survival). Costs were calculated per patient by multiplying data about resource utilization and events with Dutch estimates of unit costs (based on detailed data from the Benestent II and the Capture study). Account was taken of the use of abciximab, the index revascularisation (with bail out stents), MI's (Q-wave and non Q-wave), and subsequent revascularisations (PTCA, stent and CABG). Costs and effects are assessed after one and six months.

Results: At month 6 the additional costs per additional MI free survivor are estimated at EUR 41,509 for adding stents to abciximab and at EUR 13,572 for adding abciximab to stents. The corresponding upper 95% limits are EUR 1,483,392 and EUR 27,179. When considering the costs per MACE-free survivor the additional costs per additional MACE-free survivor are respectively EUR 12,862 (upper 95% limit: EUR 29,636) and EUR 15,164 (upper 95% limit: EUR 48,468).

Costs and effects at one and six months

	PTCA + stents (N = 809)	PTCA + abciximab (N = 796)	Stent + abciximab (N = 794)
Month 1: costs	EUR 6,939	EUR 6,526	EUR 7,734
Month 1: MI/MACE free	88.88%/85.78%	93.22%/89.32%	94.33%/93.32%
Month 6: costs	EUR 7,721	EUR 7,605	EUR 8,537
Month 6: MI/MACE free	87.64%/78.37%	91.33%/76.51%	93.58%/83.75%

Conclusions: At 6 months, a combination of the use of abciximab and stenting leads to an increase in event free survival at higher costs. How one should prioritize depends on the value attached to the prevention of MI's or the prevention of revascularisations.

2499 Comparing direct and indirect 1-year costs for elective percutaneous transluminal coronary angioplasty, stenting and directional coronary atherectomy: evaluation with a cost-analytic model

A. Pfund, T. Kurscheid, G. Wendland, K. Lauterbach, H.W. Höpp. *Department of Cardiology and Institute for Health Economics, Medicine and Society at the University of Cologne, Germany*

Background: Coronary stenting and directional coronary atherectomy (DCA) has been shown to reduce the frequency of restenosis and the need for repeat revasularisations compared to conventional angioplasty (PTCA), however at higher primary interventional costs. To compare the additive costs of complications and reinterventions we develpoed a computerized analytic model, that deals with the direct medical costs as well as the indirect ones such as loss of productivity.

Methodes and results: The average interventional costs for the three procedures were obtained from a total of 300 elective 1-vessel-interventions in our clinic. The probabilities of early and late complications (death, bypass surgery, vascular complications and repeat interventions) in the first year after revascularisation were derived from a review of the literature since 1994 (STRESS, BENESTENT, BOAT, OARS). Average costs (± standard deviation) for one year were determined by using a Monte Carlo simulation of 10,000 intervenions for each procedure.

Calculating the direct medical costs, PTCA (4891 ± 4982 Euros) turned out to be less expensive than stenting (5253 ± 4516 Euros) and DCA (6100 ± 4076 Euros). The rate of restenosis for stent implantation theoretically would have to be less than 19% (DCA 1%), to reduce the costs to the PTCA level. If the indirect costs for a average collective of patients (average age 60 years, 50% employed) are considered as well, stenting (8625 ± 11407 Euros) is cheaper than PTCA (9074 ± 14990 Euros) and DCA (9220 ± 9929 Euros). Sensitivity analyses show that the sequence depends on the patient's age: For patients younger than 54.3 years, DCA is the cheapest treatment and for patients older than 63.9 years it is PTCA. For working patients under 65 years, stenting (60 years: 11998 ± 21009 Euros) and DCA (12338 ± 18057 Euros) are less expensive than PTCA (13256 ± 28420 Euros), as long as the restenosis rate of the angioplasty is above 30%.

Conclusions: Considering the direct 1-year medical costs, despite a higher rate of restenosis and an increased need for repeat revascularisations PTCA appears to be the cheapest interventional technique because of its low primary costs. If indirect costs caused by loss of productivity are taken into account, stenting and DCA are more cost effective, mostly because of the patient's reduced period of work inability.

2500 Cost-effectiveness of intravascular ultrasound guidance for stent implantation: results of the randomized Restenosis after Intravascular Ultrasound Stenting (RESIST) study

François Schiele, Nicolas Meneveau, Marie-France Seronde, Liu Ping-Ming, Sanjiv Gupta, Jean-Pierre Bassand. *University Hospital Saint-Jacques, Besançon, France*

Background: 155 pts were randomized to stent deployment with vs without Intravascular Ultrasound (IVUS) guidance. At 6 months, a non significant 6.6% difference in restenosis was observed (22.2% vs. 28.8%, p = 0.18) and at 18 months, a 12% difference in event free survival (EFS) (p = 0.059). Procedural costs and the cost/effectiveness ratio (CER) were calculated.

Methods: Procedural costs at stent implantation and total procedural costs including cost of repeat lesion revascularization procedures were calculated in Euros. CER per % of restenosis avoided and CER per % of EFS gained.

Results: Procedural costs at stent implantation were 17% higher in the group with IVUS, (2970 ± 680 vs 2530 ± 923 Euros, p = 0.001). This overcost was the result of the use of more balloons (1.68 vs 1.49 balloons per patient) plus the cost for IVUS catheters in the IVUS group. Event free survival at 18 months follow-up was 59/79 (75%) in the IVUS group, vs 48/76 (63%) in the control group and less lesion revascularization procedures were needed in the IVUS group (21/79 vs 31/76, p = 0.03). The total procedural cost in the IVUS group was 11% higher than in the control group (3223 ± 883 vs. 2896 ± 1253 Euros, p = 0.001). CER was 67 Euros per percent of restenosis avoided and 37 Euros per percent of EFS gained at stent implantation, and total CER was 49 vs 27 Euros for restenosis and EFS respectively

Cost	IVUS group	Control
At stent implantation	2970 ± 680	2530 ± 923
Total cost	3223 ± 883	2896 ± 1253

Conclusion: IVUS guidance in stent implantation led to a 17% over cost, that was reduced to 11% when including the costs for lesion revascularization procedures. The CER does not favour IVUS guidance.

2501 Assessment of cost and effectiveness in the treatment of congestive heart failure

K. Neeser, A. Brandt, A.J. Palmer. *IMIB, Riehen, Switzerland*

The launching of new potent drugs in the treatment of chronic diseases increase at the first glance the health care expenditure but optimise the efficiency by reducing the treatment of complications. To assess the costs-effectiveness of different treatment strategies in patients suffering on CHF a computer based model was developed to compare medical outcomes (number and severity of complications, duration of hospitalisation, number of visits, changing the NYHA-class) with cost consequences (basic and complication treatment). The model is mainly based on medical literature (AIRE, CIBIS, CONSENSUS, DIG, SAVE, SOLVD)

Method: A Markov disease model considering cohort specification (age, gender, NYHA-class), NYHA-dependent drug utilisation, complication rate (unstable angina, acute myocardial infarction, stroke, worsening of CHF, mortality) and complication-related direct costs (drugs, investigations, hospitalisations) was developed. To provide a realistic course of CHF the average age of CHF patients (66 years), the age-dependent mortality rate and the distribution of NYHA classes (I-IIa: 30%, IIb-III: 36%, III-IV: 34%) are taken into account for the simulation period of 5 years. The treatment in scenario A in mild and moderate CHF patients is digitalis + diuretics (DD) and in severe CHF patients DD + ACE-inhibitors (ACE-I). Cohort B is treated in mild and moderate CHF patients with DD + ACE-I and in severe CHF DD + ACE-I + a/b-blocker.

Results: The medication costs in scenario B are between 37 to 55%/year higher than in scenario A. On the other hand the total costs in scenario B are merely increased by 0.7 to 13%/year and the mortality rate is reduced by 26 to 39%.

Year	Drug cost A (SFr)	Drug cost B (SFr)	Total cost A (SFr)	Total cost B (SFr)	Mortality A (%)	Mortality B (%)
1	2738	3755	6752	6801	20.8	12.7
2	4666	6714	11493	12100	31.9	21.2
3	6306	9350	15518	16796	40.3	28.1
4	7765	11785	19088	21118	47.3	34.2
5	9077	14061	22294	25154	53.4	39.6

Conclusion: A more intensive treatment regime results in less cardiovascular events and mortality rate. In this example the additional expenditure per CHF patient is not completely compensated by prevented complication but causes nevertheless an optimised utilisation of the limited sources.

CORONARY HAEMODYNAMICS: THEORY AND CLINICAL APPLICATION

2502 Coronary microvascular dysfunction downstream from a severe stenosis effect on coronary reserve measurement following angioplasty

G. Sambuceti, M. Marzilli, S. Fedele, C. Marini, V. Positano, A. L'Abbate. *CNR Institute of Clinical Physiology, Pisa, Italy*

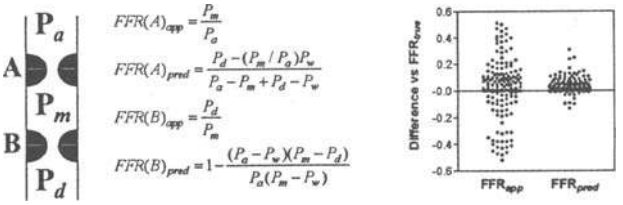
Impairment of coronary flow reserve (CFR) may persist following coronary angioplasty (PTCA). We tested the hypothesis that this phenomenon reflects a pre-existing microcirculatory disorder. To this purpose, coronary blood flow velocity and distal coronary pressure were monitored before and after PTCA in 15 patients with single vessel disease and normal left ventricular function. Blood flow velocity was normalized by cross sectional area at the Doppler catheter tip to obtain a blood flow index (CBFI). Distal coronary pressure was measured by a fiberoptic guidewire. Maximal vasodilation was induced by intracoronary adenosine (2 mg). In the whole group, minimal microvascular resistance (defined as the ratio between distal coronary pressure and adenosine-CBFI) was 2.35 ± 1.99 mmHg/ml/min and did not change following PTCA (2.68 ± 2.11, ns). Although average CFR increased following revascularization from 1.75 ± 0.6 to 3.28 ± 1.67 ($p < 0.01$), it remained abnormally low (<3) in 7 patients. These patients, compared with the remaining 8, showed similar trans-stenotic pressure gradient, under maximal vasodilation, both before (43 ± 21 vs 50 ± 13 mmHg, respectively, ns) and following (8 ± 8 vs 8 ± 7 mmHg, respectively, ns) PTCA. By contrast, they showed higher values of minimal microvascular resistance both before (3.71 ± 1.16 vs 1.17 ± 0.78 mmHg/ml/min, respectively, $p < 0.01$) and following (3.97 ± 1.63 vs 1.55 ± 1.87 mmHg/ml/min, respectively, $p < 0.02$) PTCA. To verify whether this phenomenon was related to a higher extravascular compression or to a reduced cross-sectional area of maximally dilated microvessels, pressure-flow relationships were constructed in each patient, using maximal CBFI values (Y axis) obtained at two different distal coronary pressures (before and after PTCA). The slope of the line connecting the two points was defined as "maximal microvascular conductance", its intercept with X axis as "opening pressure" an index of extravascular tissue pressure. With respect to the remaining, the 7 patients with low CFR following PTCA had similar values of opening pressure (9 ± 6 vs 15 ± 12 mmHg, respectively, ns), but lower values of maximal conductance (0.23 ± 0.45 vs 2.65 ± 2.5 ml/min/mmHg, respectively, $p < 0.05$). Thus, following successful revascularization, a persistently low CFR may be observed in a sizeable number of patients. This abnormality may be caused by pre-existing elevated microvascular resistance and not be the consequence of PTCA. This phenomenon seems related to a reduced microcirculatory cross sectional area rather than than by an elevated extravascular compression.

2503 Fractional flow reserve of serial coronary stenoses: theoretical model and animal validation

B. De Bruyne, N.H.J. Pijls[1], D. Hodeige[2], G.R. Heyndrickx. *Cardiovascular Center, Aalst; Department of Physiology; [2]University of Louvain, Brussels, Belgium; [1]Catharina Hospital, Eindhoven, Netherlands*

Background: Fractional flow reserve (FFR), an index of coronary conductance, equals the ratio of the hyperemic pressures distal and proximal to a stenosis. FFR has been well validated in case of isolated stenosis.

Objective: To determine, in case of sequential stenoses (A and B, fig 1), the FFR of each lesion separately, i.e. after removal of the other one.



Method and results: Apparently, the FFR (FFR_{app}) of stenoses A and B can be calculated by the mere ratio of the pressure immediately distal and immediately proximal to the respective lesions. However, this might underestimate the influence of coronary occlusive pressure (P_w) as well as the mutual influence of each lesion on the other one. Therefore, a theoretical model was developed to predict the FFR (FFR_{pred}) of each lesion separately. These equations (fig 1) were validated in 5 open chest dogs in which two stenoses in series of varying severities (n = 155) were created. FFR_{app} and FFR_{pred} were compared to the actual FFR (FFR_{true}) obtained after removal of the other stenosis. FFR_{true} correlated well with FFR_{pred} but not with FFR_{app}.

Conclusion: In case of sequential stenoses, it is possible to predict the FFR of each lesion separately, only when the influence of the second lesion and the influence of P_w are taken into account.

2504 Conflicting haemodynamic evaluation of intermediate coronary lesions by comparison of fractional flow reserve and blood flow velocity reserve

M. Meuwissen, M. Siebes, S.A.J. Chamuleau, C.E. Schotborgh, K.T. Koch, R.J. de Winter, M. Bax, J.J. Piek. *Cardiology Dept., Academic Medical Center, Amsterdam, Netherlands*

Background: Fractional flow reserve (FFR) and coronary flow velocity reserve (CFR) are used to evaluate hemodynamic severity of coronary lesions. However, there is limited information regarding the direct comparison between both diagnostic techniques in intermediate coronary lesions.

Methods: Quantitative coronary angiography was performed in 82 patients (111 coronary lesions) to determine lesion severity. Distal coronary pressure and blood flow velocity were assessed with sensor equipped guidewires during baseline and maximal hyperemic conditions (12–18 mcg i.c. adenosine) to determine FFR and CFR. CFR was also measured in an angiographic normal reference vessel (CFR-ref). Agreement between FFR and CFR was determined at cut off values of 0.75 and 2.0 respectively.

Results: Coronary lesion severity varied between 43–79% diameter stenosis (mean: 60 ± 11%). Concordant results between CFR and FFR were obtained in 84 lesions (76%); discordant results were obtained in 27 lesions (24%) in 23 patients (28%). FFR was > or equal to 0.75 and CFR < 2.0 was documented in 12 lesions (Group A); FFR was < 0.75 and CFR > or equal to 2.0 in 15 lesions (Group B). Both groups had a normal CFR-ref. Clinical, hemodynamic and angiographic characteristics (risk factors, age, heart rate, aortic pressure and geometric lesion severity) were similar in both groups. Differences are presented in the table below.

Group	FFR	CFR	CFR-ref
A (n = 12)	0.83 ± 0.05	1.63 ± 0.22	2.60 ± 0.72
B (n = 15)	0.67 ± 0.07*	2.57 ± 0.47*	3.48 ± 0.73**#

*P < 0.0001 and **P < 0.05 compared to group A; #P < 0.003 compared to CFR

Conclusion: Discordant results between fractional flow reserve and coronary flow velocity reserve were observed in 24% of the intermediate coronary lesions. The hemodynamic significance of a coronary lesion, assessed by FFR only, may be obscured by a reduced CFR in the presence of a normal reference CFR. On the other hand, a normal CFR indicating a non-significant lesion, may accompany an abnormal FFR. These findings emphasize that combined pressure and flow velocity data are mandatory for accurate characterization of coronary lesion severity in approximately one quarter of the patients.

2505 Coronary pressure measurement to assess the individual haemodynamic significance of multiple, sequential stenoses within one coronary artery

N.H.J. Pijls, B. De Bruyne[1], G.J.W. Bech, G.R. Heyndrickx[1], J.J.R.M. Bonnier. *Catharina Hospital, Eindhoven, Netherlands; [1]Cardiovascular Center Aalst, Belgium*

The presence of one stenosis in a coronary artery influences the hemodynamic behavior of another stenosis in the same artery, which confounds the calculation of both coronary and fractional flow reserve (FFR) of each lesion separately. Recently, it was shown in animals that the FFR of each individual lesion as it would be after treatment of the other lesion(s), could be predicted beforehand by the formulas:

$$FFR_{prox} = P_d - (P_m/P_a) \cdot P_w/P_a - P_m + P_d - Pw$$

$$FFR_{dist} = 1 - (P_a - P_w) \cdot (P_m - P_d)/P_a \cdot (P_m - P_w)$$

where FFR_{prox} and FFR_{dist} indicates the FFR of the proximal and distal stenosis, as it would be after elimination of the other stenosis; and where P_a, P_m, P_d, P_w indicate mean aortic pressure, coronary pressure between both stenoses, coronary pressure distal to both stenoses, and coronary wedge pressure, respectively, all measured during maximum hyperemia.

Methods: In the present study, these formulas were tested in 32 humans with at least 2 stenoses within one coronary artery. In 19 patients, the proximal stenosis was stented first, in 13 patients the distal first. Coronary pressures were measured by the 0.014″ Pressure Wire™ (used as primary guide wire in these procedures), before any intervention was done, after stenting of one lesion, and after stenting of both lesions.

Results: After stenting of one stenosis, the hyperemic gradient across the second stenosis increased significantly from 10 ± 7 to 19 ± 11 mmHg. On the other hand, the predicted FFR of a particular stenosis, calculated beforehand by the formula's, versus the true FFR of the same lesion as measured directly by the hyperemic distal to proximal pressure ratio after having eliminated the other stenosis, were very close together (r = 0.92; Δ% = 4 ± 4%).

In conclusion: When 2 or more stenoses are present within the same coronary artery, coronary pressure measurement accurately predicts the true hemodynamic significance and FFR of each individual stenosis as it will be after eliminating the other stenosis.

2506 Prevalence of microvascular dysfunction in patients with severe coronary artery disease

J. Ge, J. Qian, R. Bhate, D. Baumgart, D. Welge, O. Oldenburg, M. Haude, H. Chung, M. Raus, R. Erbel. *Dept. of Cardiology, University-GH Essen, Germany*

Background. Coronary flow velocity reserve (CFVR) estimation is the current concept for assessment of physiological significance of an epicardial coronary artery stenosis and a complementary technique during coronary intervention. Recently, relative coronary flow velocity reserve (rCFVR), which is the ratio of CFVR in the stenotic coronary artery to the CFVR in the normal reference coronary in the same patient is preferred to CFVR as it is independent of many factors affecting absolute CFVR such as resting blood velocity, heart rate, arterial pressure, left ventricular hypertrophy, previous myocardial infraction. The purpose of the study was to investigate the frequency of microvascular abnormality in the reference vessel in order to address the significance of rCFVR.

Methods and Results: Intracoronary Doppler flow measurement was performed in the target and reference coronary arteries in 107 patients (87 males, 59 ± 10 years) who had angiographically severe stenosis of a single coronary artery. The CFVR was measured in the reference vessel and before, after interventions in the target vessel. Patients were divided into two groups according to the CFVR < 3.0 (group A) or CFVR ≥ 3.0 (group B) in the reference vessel.

CFvR	Before	After	Reference vessel
Altogether	1.93 ± 0.68	2.64 ± 0.86*	3.01 ± 0.78*#
Group A (n = 48, 45%)	1.75 ± 0.61	2.37 ± 0.86*	2.31 ± 0.37*+
Group B (n = 59, 55%)	2.07 ± 0.71	2.87 ± 0.82*	3.58 ± 0.51*#

*p < 0.0001 (after intervention and reference vessel vs. before intervention); #p < 0.0001; +p = NS (#,+ = reference vessel vs, after intervention)

Conclusion: Microvascular dysfunction exists in nearly half of reference vessels in patients with severe coronary stenosis. The CFVR presents in a large variety in the reference vessel in individuals. Therefore, rCFVR is a much more reliable parameter than CFVR in individuals in clinical decision making and assessment of coronary intervention.

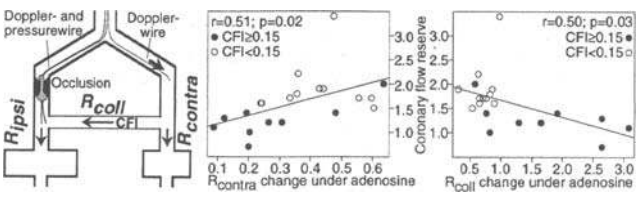
2507 Effect of collateral and collateral-adjacent vascular resistance alterations on the coronary flow reserve of a collateral-receiving artery

Michael Billinger, Martin Fleisch, Ali Garachemani, Franz Eberli, Bernhard Meier, Christian Seiler. *University Hospital, Cardiology, Berne, Switzerland*

Background: It has been hypothesized that vascular resistance changes during hyperemia in the collateral (R_{coll}) as well as the collateral-supplying (contralateral, R_{contra}) and -receiving (ipsilateral, R_{ipsi}) areas may influence the coronary flow reserve (CFR) of an ipsilateral region (CFR < 1: coronary steal).

Methods: This study in 20 pts (60 ± 10 years) undergoing percutaneous coronary revascularization measured adenosine-induced CFR during *vessel patency* distal to the stenosis using an intracoronary (i.c.) 0.014″ Doppler wire. Subsequently and during *vessel occlusion,* simultaneous distal ipsilateral flow velocity and pressure (P_{occl}) as well as contralateral velocity measurements via a third i.c. wire were obtained before and during adenosine infusion (140 mg/kg/″; figure). From those measurements and simultaneous mean aortic pressure (P_{ao}, mmHg), a collateral flow index (CFI) as well as the vascular resistance indices R_{coll}, R_{contra} and R_{ipsi} were computed. CFI = (P_{occl} − 5)/(P_{ao} − 5). The study population was subdivided into a group with CFI ≥ 0.15 and a group CFI < 0.15.

Results: CFI ranged from 0.0–0.58. The coronary stenosis to be dilated was similarly severe in the two groups: 84 ± 13% versus 77 ± 11% (NS). R_{ipsi} remained unchanged during adenosine, and CFR was not associated with R_{ipsi}: CFR = 1.6 ± 0.6; r = 0.04.



Conclusions: Aside from the influence of the stenosis severity on the downstream CFR, hypermia-induced alterations of vascular resistances of the collateral bed itself and also of the collateral-supplying vascular area codetermine CFR directly and inversely, respectively. These interrelations of vascular areas do not occur in pts with poorly developed collaterals (figure), and they are manifest in the absence of ipsilateral resistance changes. This is the first study in humans to demonstrate comprehensively the validity of a theoretical model explaining the occurrence of coronary steal via collaterals.

MYOCARDIAL INFARCTION: NEW DEVELOPMENT IN DIAGNOSIS AND TREATMENT

2508 Mechanical thrombectomy during percutaneous intervention for acute myocardial infarction: experience with the angiojet® rheolytic system

J.A. Silva, S.R. Ramee, J.R. Saucedo[1], A.S. Lanoue[2], K.J. Dandreo[2], Y. Zhang[2], K. Ho[2], R.E. Kuntz[2]. *Department of Cardiology, Ochsner Clinic, New Orleans LA; [1]Department of Cardiology, University of Arkansas, School of Medc, Little Rock; [2]Department of Cardiology, Beth Israel Deaconess, Harvard Med. Sc, Boston MA, USA*

Objective: To prospectively assess the efficacy of the POSSIS AngioJet® rheolytic system in acute transmural myocardial infarction (MI) in patients with evidence of angiographic thrombus presenting within 24 hours of symptom onset.

Methods: 115 patients (mean age 61 ± 12 years, 67% males) from 9 US centers were included. 36% had prior MI and 13% presented with cardiogenic shock. Culprit lesions were: LAD (26%), LCX (11%), RCA (39%), left main(1%) or a saphenous vein graft(23%). Mean ejection fraction was 43 ± 12%. Adjunctive percutaneous revascularization was performed in 97%: PTCA alone (33%), coronary stenting (62%), and atherectomy (2%).

Results: Procedural success (achievement of <50% final diameter stenosis with TIMI 2 or 3 flow) was observed in 92%. Clinical success (procedural success and freedom from in-hospital MACE) was achieved in84%. Minimum lumen diameter increased from 0.52 ± 0.56 mm (83% diameter stenosis) to 1.44 ± 0.66 mm (52% diameter stenosis) after rheolytic thrombectomy, to 2.30 ± 0.66 mm (23% diameter stenosis) after final treatment. Angiographic thrombus area decreased from 63 ± 73 mm^2 to 20 ± 35 mm^2 after rheolytic thrombectomy. Procedural complications included distal embolization in 12% evident by angiography, perforation in 3%, and sustained no reflow in 5%. At 30-day follow-up no additional patients died, but 4% had recurrent MI and 3% required PTCA.

Conclusions: Rheolytic thrombectomy effectively removes intracoronary thrombus before definitive plaque treatment in patients with acute MI, with an acceptable complication rate.

2509 In vitro streptokinase resistance test for rapid prediction of coronary artery patency by angiography after acute myocardial infarction

A. de Meester, K. Al Shwafi, B. Pirenne, P. Vranckx, J. Renkin, J. Col. *Jolimont Hospital, Haine-St-Paul and University of Louvain Medical School, Brussels, Belgium*

Early and sustained grade 2–3 flow according the Thrombolysis in Myocardial Infarction (TIMI) criteria, obtained after the 60-minutes (min) infusion of 1.5 MU streptokinase (SK) for acute myocardial infarction, was strongly related with reperfusion achievement and long-term prognosis (GISSI-2). SK thrombolytic efficacy is hampered by the presence of unsuspected antibodies or inhibitors in blood. In-vitro SK resistance screening (SK RES test), expressed as time > 50 sec for 100 U/ml SK to lyse a fresh autologous thrombus using a new bedside test (Thrombolytic Assessment System, TAS™) was prospectively assessed, before SK infusion, in 72 patients admitted for acute myocardial infarction within 12 hours after the onset of symptoms. We analysed the predictive value of SK RES test for reperfusion detected by angiography, assessing infarct-related coronary artery patency (TIMI 2–3) and left ventricular ejection fraction (LVEF) within the first 48 hours after thrombolysis.

Results: The incidence of potential RES was 19% (14/72 patients); in these patients, occluded or minimal perfusion (TIMI 0–1) occurred more frequently than in predicted responders. Odds ratio 4.5 (95% CI 1.5–13.6).

	SK RES test ≤ 50 sec	SK RES test > 50 sec	p value
Patients	n = 58	n = 14	
TIMI 2–3	84% (49/58)	36% (5/14)	0.0007
TIMI 3	81% (47/58)	21% (3/14)	0.0001
LVEF (%)	54 (45–60)	47 (37–53)	0.001

Median (25th–75th percentiles).

Conclusion. This pilot study provides the first evidence that a convenient bedside test assessing SK RES would efficiently screen patients for optimal angiographic and clinical response to SK.

2510 The acute coronary syndrome diagnosis and prognostic evaluation by troponin I is influenced by the test system affinity to different troponin complexes

M. Möckel, A.H.B. Wu[1], K. Berg, G. Heller Jr.[2], F.R. Klefisch, O. Danne, C. Müller[3], N.V. Ulrich[4], M. Riehle, U.A. Frei. *Nephrology/Intensive Care Medicine, Charité/Campus Virchow-Klinikum, Berlin, Germany; [1]Clinical Pathology and Laboratory Med., Hartford Hospital, Hartford CT, USA; [2]Medical Sociology and Social Medicine, Philipps-University of Marburg, Marburg; [3]Institute of Clinical Chemistry, Charité/Campus Virchow-Klinikum, Berlin; [4]Cardiology Dept., Charité/Campus Mitte, Berlin, Germany*

Cardiac troponins are established in acute coronary syndrome (ACS) diagnosis and risk assessment. Recently it was shown that cardiac troponins are released as T-I-C complex and than further degraded to T and I-C. It is not known whether the various affinity to the T-I-C and I-C complex of different troponin I test systems influence the diagnostic value of the test results in clinical practice.

Patients and Methods: We included 162 patients (61.28 SD11.05 years) with suspected acute myocardial infarction (AMI)in the study. In 109 patients AMI was confirmed during hospital stay by WHO criteria. Blood samples were taken at admission, after 1, 2, 4, 8, 12 and 24 h. Troponin I (TnI) was measured using the Opus®plus (TnI-O, cutoff 1.6 μg/L) and the Stratus® (TnI-S, cutoff 1.5 μg/L) analysers. TnI-O has high affinity to the binary (I-C) and TnI-S to the ternary (T-I-C) troponin complex. A 6 months follow up with respect to death and recurrent ACS was performed (combined primary endpoint).

Results: The sensitivity (SE), specificity (SP) and positive predictive value (PPV) for AMI diagnosis are listed below.

	0–2 hours	2–4 hours	4–8 hours
TnI-O/SE	75.2%	81.7%	89.0%
TNI-O/SP	92.5%	92.5%	90.6%
TNI-O/PPV	95.3%	95.7%	95.1%
TNI-S/SE	82.6%	90.8%	93.6%
TNI-S/SP	86.8%	88.7%	81.1%
TNI-S/PPV	92.8%	94.3%	91.1%

Logistic regression analysis with control for age, gender, diagnosis and mode of reperfusion therapy (PTCA or thrombolysis) shows prediction of the primary endpoint by TnI-S > 8 μg/L (optimal cutoff) at admission (Odds ratio 11.4, p = 0.0042). The use of the optimal cutoff for TnI-O resulted in an Odds ratio of 3.4 (p = 0.0552). Due to the small number of patients with unstable angina (n = 53), no significant prediction of outcome could be shown in those patients.

Conclusions: The affinity to the early released troponin T-I-C complex does not relevantly add on the AMI diagnostic properties of a TnI test system. Independent prognostic information could be obtained in patients with high TnI values at admission by the system with higher T-I-C affinity only. These patients have to be classified as having a longer delay between onset of symptoms and start of treatment. Therefore, in patients with acute coronary syndromes a troponin I test system with high affinity to the early released T-I-C complex provide a small but significant benefit in risk assessment.

2511 Plasma soluble P-selectin levels in acute myocardial infarction and its relationship with the success of thrombolytic therapy

M. Kayikcioglu, L. Can, M. Zoghi, H. Kultursay, S. Payzin, C. Turkoglu. *Cardiology Dept., Ege University Medical School, Izmir, Turkey*

P-selectin, an integrated membrane protein in platelets and endothelial cells, mediates adhesive interactions between platelet (plt), leukocyte and endothelium to form thrombi. The purpose of this study was to investigate plasma level of soluble(s) P-selectin in patients (pts) with acute myocardial infarction (AMI) and the effect of successful thrombolysis on P-selectin levels.

Methods: A total of 32 AMI pts (26 male,mean age:54 ± 12) within the first 6 hours of chest pain were enrolled prospectively. Criteria for exclusion were inflammatory or neoplastic disease or an infectious disease within the last six weeks. Levels of P-selectin were determined by enzyme-linked immunoabsorbent assay on plasma taken from systemic veins of pts with AMI, stable angina (SA, n = 18), and the healthy controls (n = 15). Samples were obtained before, three and 24 hours after initiation of reperfusion therapy. Peak creatin phosphokinase (CPK) levels, plt and white blood cell (WBC) counts were also determined. Tissue plasminogen activator was used as thrombolytic therapy. Seven pts showed recurrent angina or failure to reperfusion.

Results: The plasma sP-selectin levels were significantly higher in the AMI group than the other 2 groups (86.7 ± 8.7 ng/ml, p < 0.05). The plasma sP-selectin levels were similar in SA and control groups (29 ± 4 vs 25 ± 7 ng/ml, p = ns). In pts with AMI we observed a strong correlation between the sP-selectin levels and peak CPK levels (r = 0.72, p < 0.05) and a moderate correlation with the WBC count(r = 0.064, p < 0.05.) A significant increase in sP-selectin levels was observed at 3 hours after successful thrombolysis (p < 0.005) and was followed by a decrease near to the baseline level late after reperfusion. But, pts with failed reperfusion showed sustained high levels of sP-selectin at 24 hours of the thrombolytic therapy (p < 0.05).

Conclusion: Plasma sP-selectin level is elevated in pts with AMI and it increases further following reperfusion therapy. This increase in sP-selectin levels is probably induced by the activation of endothelial cells, WBC, or plts after myocardial ischemia and reperfusion during AMI. Therefore sP-selectin can be considered as a systemically detectable indicator of the local coronary plt-WBC-endothelium interaction leading to AMI. As the elevated sP-selectin levels are sustained in pts with failed reperfusion, the serial p-selectin level expression may be used as an indicator of successful thrombolysis in AMI.

2512 Basic fibroblast growth factor, a potent promoter of angiogenesis, is a useful predictor of the progression of ventricular remodelling in acute myocardial infarction patients

K.I. Kapetanios, E.V. Economou, C.I. Stefanadis, C.E. Pitsavos, D.M. Farmakis, K. Vassiliadou, M.G. Toutouza, P.K. Toutouzas. *Cardiology Dept., University of Athens, Athens, Greece*

It has been recently reported that bFGF, a strong angiogenic peptide, enhances myocardial collateral development in an animal model of experimental coronary occlusion. The aim of our study is to clarify the role of bFGF in the early and late phase of acute myocardial infarction (AMI) in patients.

Methods: 27 patients with first attack of AMI, and no previous history of any other disease, were examined for plasma levels of bFGF, measured by ELISA, and compared to corresponding levels of 20 Normal controls (NC) with mean values: 1.61 ± 0.25 pg/ml. All pts were divided in 2 sex and age-matched groups. Group A: pts with minor AMI, EF > 45% and no subsequent LV dysfunction. Group B: pts with large infarct size, EF < 45% and heart failure. Plasma samples were collected at the time of hospital admission (O hours) and 6 h, 12 h, 18 h, 24 h, 48 h, 3 days, 4 d, 7 d, 15 d and 30 d thereafter. The mean latency period between symptom-onset and admission was 2.0 ± 1.0 h. All pts received thrombolysis.

Results are expressed as mean values ± SEM in pg/ml as follows:

Pts	0 h	6 h	12 h	18 h	24 h	48 h	3 d	4 d	5 d	7 d	15 d	30 d
A (13)	3.23 ± 1.9 ◇	1.55 ± 0.3	2.52 ± 0.9 *	1.20 ± 0.2 *	1.20 ± 0.2 *	1.74 ± 0.5	1.26 ± 0.2 *	1.32 ± 0.2 *	2.12 ± 0.6	5.9 ± 2.7 ◇	5.61 ± 3.6 ◇	5.7 ± 2.6 ◇
B (14)	5.15 ± 0.7 ◇	2.44 ± 0.4	2.11 ± 0.3 *	2.45 ± 0.4 *	2.0 ± 0.34 *	2.34 ± 0.4 *	2.55 ± 0.4	2.51 ± 0.3	2.96 ± 0.4	13 ± 6.3 ◇	13.8 ± 6.3 ◇	13.9 ± 3.3 ◇

p < 0.05 compared to corresponding values of: a) NC (◇) b) the relevant first plasma sample (*) (Wilcoxon test).

Conclusions: Both groups developed an initial high bFGF level but only in group B this increase was significant compared to NC. This may imply that acute hypoxia, due to reduced vascular flow, could be the same stimulus for this rise in both groups. This early peak is followed by a gradual decrease in both groups, probably due to thrombolytic therapy, and a late rebound of bFGF values. This rebound is significant compared to NC only in group B, leading in increased collateral vessel formation probably as an attempt to alter the progression of heart failure. Therefore, bFGF could be used as an early predictive marker for the quality of ventricular remodeling following AMI.

2513 In-hospital and long-term outcome of right ventricular infarction in a defined community population: the Mayo Clinic coronary care unit experience

R.J. Gumina, R.S. Wright, J.G. Murphy, W.L. Miller, J.P. Grill, S.L. Kopecky. *Mayo Clinic, Rochester MN, USA*

Background: Right ventricular myocardial infarction (RV-MI) is a complication of non-anterior wall MI that is often fatal if unrecognized. The short-term and long-term outcome of RV-MI remains ill defined in the current era of aggressive reperfusion therapy although recent studies have suggested a benefit for primary PTCA with RV-MI.

Methods: We analyzed 910 consecutive patients admitted to the Mayo Clinic CCU from Rochester, MN with acute MI from January 1988 until March 1998. We have compared the in-hospital and long-term mortality of patients with clinically determined RV-MI (n = 42) to those without RV-MI (n = 868).

Results: The in-hospital mortality rate of RV-MI (28.6%) was increased compared to Non-anterior MI without RV-MI (7.2%) and anterior MI (11.4%), p < 0.001. Patients with RV-MI had increased utilization of primary reperfusion therapy: RV-MI 67% vs Non-Ant MI 42% vs Ant MI 50%, p = 0.002. The use of beta-blockers differed between groups: RV-MI 48% vs Non-Ant MI 65% vs Ant MI 69%, p = 0.02. Median time from symptom onset to reperfusion therapy did not differ among groups. The pre-discharge EF in RV-MI (53%) was not significantly different from Non-Ant MI (53%) but was different than Ant MI (45%), p = 0.001. The odds ratio (OR) of in-hospital mortality, even after multivariate adjustment, remained increased in RV-MI: 3.64 (1.62–7.82), compared to anterior MI (p = 0.002). The relative risk (RR) of long-term mortality, after multivariate adjustment, was not increased in the RV-MI group: RV-MI RR 1.30 (0.78–2.14), p = 0.31 compared to Non-Ant MI without RV-MI. The RR of long-term mortality was reduced in Non-Ant MI without RV-MI compared to Ant MI: 0.79 (0.62–1.00), p = 0.05.

Conclusions: While the in-hospital morbidity and mortality of RV-MI remains increased, despite aggressive use of primary reperfusion therapy, the long-term survival of RV-MI is comparable to Non-Ant MI. The increased in-hospital mortality is not explained by a lack of aggressive utilization of reperfusion therapy, but may in part be explained by decreased utilization of beta-blocker adjunct medical therapy.

ALTERNATIVE TREATMENT OPTIONS FOR STABLE ANGINA

2514 Aggressive lipid lowering versus coronary angioplasty in subgroups of the AVERT trial: post hoc analyses

D. Waters, B. Pitt[1], W.V. Brown[2], D. MacDougall[3], L.S. McCormick[3], D.M. Black[3]. *Division of Cardiology, Hartford Hospital, Hartford, CT; [1]University of Michigan Medical Center, Ann Arbor, MI; [2]Emory University School of Medicine, Atlanta, GA; [3]Research Dept., Parke-Davis, Ann Arbor MI, USA*

Background: PTCA has been shown to relieve symptoms better than medical therapy with a slightly higher event rate, but no clinical trial has included aggressive cholesterol lowering as part of medical therapy.

Methods: The Atorvastatin Versus Revascularization Treatments Trial (AVERT) randomized 341 patients referred for PTCA to atorvastatin 80 mg/day or to PTCA followed by usual care. Included were patients with 1 or 2 vessel disease, an LDL-cholesterol of 3.0 mmol/L or more, and an exercise level of 4 mins (treadmill) or 20 W/min (bicycle) without 2 mm or more of ST depression. Excluded were patients with CCS angina class > 2, left main of 3 vessel disease, ejection fraction < 40%, PTCA within 6 months, unstable angina or MI within 2 weeks, or previous bypass surgery. All patients were followed for 18 months, at which time mean LDL-cholesterol had decreased by 46% and 18%, to 2.0 and 3.1 mmol/L in the atorvastatin and PTCA groups respectively. The primary efficacy parameter was the composite incidence of cardiac death (n = 2), nonfatal MI (n = 9), CVA, CABG (n = 11), PTCA (n = 39), or hospitalization for worsening angina with objective documentation (n = 36).

Results: Overall, 22 atorvastatin and 37 PTCA patients experienced an endpoint event (13% vs 21%, p = 0.048). The event rate was higher with 2 vessel (31/148, 20.9%) than 1 vessel disease (28/193, 14.5%), but was lowered by atorvastatin compared to PTCA in both groups: 24.4% to 17.1% with 2 vessel and 18.2% to 10.6% with 1 vessel disease. Events were more common in symptomatic than in asymptomatic patients, 18.9% vs 8.9%, but were lowered by atorvastatin in both subgroups. ST depression was induced by exercise in 158 of the 341 patients (46%). The event rate was less with atorvastatin, 8.6% vs 19.3%, in patients with inducible ischemia.

Conclusions: Although retrospective subgroup analyses are of limited value, particularly in a small trial such as AVERT, the advantage of atorvastatin over angioplasty/usual care extended to 1 and 2 vessel disease, to asymptomatic and class 1–2 patients, and to those with inducible ischemia. Aggressive cholesterol lowering with atorvastatin can delay or eliminate the need for angioplasty in a broad spectrum of patients with stable coronary disease.

2515 ACE inhibition with ramipril improves left ventricular function at rest and post-exercise in patients with stable ischaemic heart disease and preserved left ventricular systolic function

R. Willenheimer, E. Rydberg, L. Oberg, S. Juul-Möller, L. Erhardt. *Dept. of Cardiology, Malmö, Sweden*

Angiotensin-converting-enzyme inhibition counteracts myocardial ischemia as well as myocardial and vascular remodeling. Experimentally it attenuates diastolic dysfunction caused by myocardial ischemia, and may have clinical significance in patients with stable ischemic heart disease and preserved left ventricular systolic function.We aimed to assess the effects of a 6-month ramipril intervention on left ventricular function at rest and post exercise in patients with stable ischemic heart disease and preserved left ventricular systolic function.

Methods: Patients (n = 98, age 65 ± 9 years, 37% women) with stable ischemic heart disease and preserved left ventricular systolic function were randomized to ramipril 5 mg/day (n = 32), ramipril 1.25 mg/day (n = 34), or placebo (n = 32). Resting and post maximum exercise echocardiography/Doppler examinations were performed at baseline and after 6 months.

Results: Changes over 6 months in resting transmitral E-wave deceleration time (Edt) and Edt adjusted for heart rate (Edt/RR) differed between the ramipril 5 mg, ramipril 1.25 mg, and placebo groups, indicating a favourable effect of ramipril: Edt 24 ± 82 (ramipril 5 mg), −1 ± 69 (ramipril 1.25 mg), and −29 ± 64 ms (placebo), respectively, P = 0.012; Edt/RR 30 ± 105, 2 ± 61, and-28 ± 69 ms, respectively, P = 0.015. Changes over 6 months in the difference between resting and post exercise Edt/RR also varied between groups, indicating a favourable effect of ramipril: −53 ± 137 (ramipril 5 mg), −28 ± 118 (ramipril 1.25 mg), and 35 ± 101 ms (placebo), respectively, P = 0.029. Resting atrioventricular plane displacement improved in the combined ramipril groups compared to the placebo group: 0.2 ± 0.8 mm vs −0.2 ± 1.3, P < 0.05.

Conclusions: Ramipril treatment during 6 months, in patients with stable ischemic heart disease and preserved left ventricular systolic function, improved resting left ventricular function and reduced the exercise induced diastolic filling abnormalities usually seen in these patients.

2516 Efficacy and safety of trimetazidine in patients with persistent stable angina pectoris under β-blocker therapy: TRIMPOL II multicentre study

H. Szwed[1], Z. Sadowski[1], R. Pachocki[2], K. Klepacka[2], W. Elikowski, A. Koronkiewicz, A. Mamcarz, W. Orszulak, E. Skibińska, K. Szymczak, J. Świątek, M. Winter, R. Złotoś-Adamczyk. *[1]National Institute of Cardiology; [2]Servier Polska, Warsaw, Poland*

The aim of the study was to assess the antianginal efficacy of trimetazidine, a metabolic agent which improves cardiac metabolism in ischemia, in patients with persistent angina pectoris despite metoprolol.

Methods: 227 patients with stable effort angina despite metoprolol (50 mg b.i.d.) were included in this multicenter double-blind randomized placebo controlled trial with a follow-up period of 12 weeks. All patients had proven coronary artery disease and stable angina (>3 months). Before inclusion all patients had two stable (<20% variability) positive treadmill exercise tests separated by one week. At inclusion patients were randomized to trimetazidine (20 mg t.i.d.) + metoprolol (50 mg b.i.d.) or placebo + metoprolol for a 12-week treatment period.

Exercise treadmill testing was again performed at four and twelve weeks. Main criteria of evaluation were improvement at 12 weeks in the following: exercise time to 1 mm ST segment depression, total walking time, work capacity, time to onset of angina.

Results: 227 patients (114 trimetazidine, 113 placebo, mean age 54.8 years), with no statistically significant inter-group differences in demographic characteristics, completed the 12-week treatment period. Results are shown in the table below:

	Trimetazidine + Metoprolol ($W_{12} - W_0$)	Placebo + Metoprolol ($W_{12} - (W_0)$	Inter-group differences
Increase time to 1 mm ST-segment depression (%)	28.5%*	12.6%*	p < 0.01
Increase total walking time (%)	16.6%*	7.6%*	p < 0.01
Increase work capacity (%)	15.6%*	4.8%	p < 0.01
Time to onset of angina	27.4%*	12.2%*	p < 0.01

*p < 0.01

In conclusion, after a 12-week treatment period, trimetazidine significantly improved all ergometric and electrocardiographic parameters compared to placebo in patients with stable angina pectoris treated with metoprolol.

2517 Temporary sympathectomy for refractory angina

C. Hammond, A. Leach[1], M.R. Chester[1]. *Cardiothoracic Centre, Liverpool; [1]The National Refractory Angina Centre, Liverpool, UK*

Purpose: Post-revascularisation angina which is refractory to conventional treatment is a growing clinical problem which has yet to be addressed adequately. Repeat coronary artery bypass surgery, palliative angioplasty and transmyocardial laser therapy are often attempted but are expensive and have an associated increase in mobidity and mortality. Permanent cardiac sympathetic denervation is an effective technique that is presently being re-evaluated following advances in the technique of thoracoscopic surgery, however there are difficulties associated with nerve regeneration, future treatments should the pain recur and concerns regarding patients with poor left ventricular function.

Methods: We report our first 54 consecutive patients who underwent temporary left stellate ganglion block (LSGB) for severe angina following failed revascularisation using 15 mls of 0.5% bupivacaine. All patients had typical angina and were taking maximally tolerated oral antianginal medication. Patients completed standardised HAD and Seattle Angina questionnaires. Stellate ganglion block was performed as per usual operator practice and temporary cardiac sympathetic denervation was confirmed using power spectral analysis of heart rate variability (HRV).

Results: There were no serious adverse complications. Only one patient was admitted overnight due to nausea and all other patients were treated as outpatients. Patients were initially evaluated one week after their procedure, and then followed until their pain recurred. Daily GTN usage was reduced from 6.6 ± 5.1 to 1.9 ± 3 ($p < 0.001$). Canadian Class Status was reduced from 3.4 ± 0.6 to 1.4 ± 1.6 ($p < 0.001$). The average length of time completely painfree in patients with changes in HRV suggestive of effective cardiac sympathetic denrvation was 5.6 ± 5.0 weeks compared to 0.3 ± 0.5 weeks in patients with no such alterations ($p < 0.001$). Quality of life was also significantly improved.

Conclusions: This pilot study suggests that temporary left stellate ganglion block is capable of ameliorating severe angina for much longer than the local anaesthetic effect of bupivacaine. It offers the prospects of this therapy being developed as an outpatient treatment for refractory angina. A double blind randomised placebo controlled study is underway funded by the British Heart Foundation.

2518 Comparison of prognostic surveys used in the Multicentre Study of Enhanced External Counterpulsation (MUST-EECP)

P.F. Cohn, R.R. Arora, T.M. Chou, P. Jain, W. Nesto, B. Fleishman, L. Crawford, I. McKiernan, W. Lawson. *SUNY Health Sciences Center, Stony Brook NY, USA*

Because of the need for non-invasive therapy in patients with chronic angina pectoris refractory to conventional therapy, a multicenter placebo-controlled trial of enhanced external counterpulsation (EECP) was begun in the United States in 1995 with enrollment concluded in May 1997. Immediate improvement in various ischemic parameters was noted in the actively treated group (AC) compared to the inactive or sham group (IC), but it was unclear whether long-term clinical benefits would be present as reported previously in observational non-randomized studies.

Methods: To assess long-term clinical benefit, two separate protocols were employed. In *Method 1*, mail and telephone surveys were instituted by nurse coordinators in 80 patients who were at least 3 months post-treatment.

In *Method 2*, 125 patients were enrolled in a quality of life evaluation using 1) SF-36, and 2) Quality of Life Index – Cardiac Version III (QLI). Post-treatment mail surveys were collected at 3, 6, 9 and 12 months by an independent consulting firm.

Results: In *Method 1*, 40 patients were in the AC and IC groups with a mean follow-up time of 12 months. Hospitalization rates for both groups were similar, but improvement in symptoms was more significant in the AC group (28/40 v s 15/40, $p < 0.01$).

In *Method 2*, the AC group had significantly greater improvement than the IC group in 1) SF-36: Bodily Pain ($p < 0.01$), and Health Transition ($p < 0.05$), and 2) QLI: Health and Functioning ($p < 0.05$) at 12 months.

Conclusion: In the MUST-EECP trial AC patients reported significant improvement compared to IC patients in health status regardless of the follow-up methodology.

2519 Draft guidelines for the management of refractory angina on behalf of the UK Refractory Angina Group

M. Chester. *The National Refractory Angina Centre, Liverpool, UK*

Refractory angina is a clinical diagnosis. It is based on the presence of symptoms of angina that are thought to be caused by coronary insufficiency and which are not controllable by a combination of anti anginal medication, angioplasty or coronary artery bypass surgery. The presence of demonstrable myocardial ischaemia is desirable but is not an absolute requirement for including a patient in the guideline process.

What follows is the "consensus" algorithm from the Refractory Angina Group in November and is now presented for peer review/consultation. This is a draft proposal and that individual practitioners will have to take account of local resource provision.

1. Diagnosis requires a cardiological and cardiothoracic surgical opinion that further revascularisation is unfeasible. Regular angiographic review is recommended to exclude "new" revascularisable disease.
2. Outpatient assessment to include: Review of pain history, drug history and physical exam.
3. Outpatient counselling to include explanation of management plan, lifestyle advice.
4. Rehabilitation. Involving exercise programme, lifestyle advice, relaxation training.
5. Psychotherapy. Based on established psychological assessment methods.
6. Transcutaneous electrical nerve stimulation. Based on Mannheimer protocol.
7. Temporary sympathectomy. Unilateral left stellate ganglion block, T3/4 paravertebral block in stages. Based on the Liverpool protocol.
8. Spinal cord stimulation.
9. Opioids.
10. Destructive sympathectomy.
11. Laser myocardial revascularisation. Only as part of a formal clinical trial.

Angina alone is not an indication for cardiac transplantation.

Recommendations: Closer links between cardiologists and pain specialists is essential. Clearly a great deal of research is required. Where RCTs are unfeasible there is an overwhelming case for comparative studies.

SIGNAL TRANSDUCTION IN ISCHAEMIC PRECONDITIONING

2520 Mechanical stretch mimics preconditioning and ameliorates the detrimental effect of angiotensin II in vivo

E.K. Iliodromitis, D.V. Vlahakos, E. Bofilis, A. Papalois, G.K. Karavolias, D.Th. Kremastinos. *2nd Dept of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

Volume overload protects against myocardial infarction and this protection is completely blocked by gadolinium (Gd^{3+}), a stretch receptor antagonist. Angiotensin II (AII) mimics preconditioning (PC) in vitro limiting the infarct size. The aim of this study was to investigate whether AII infusions and/or mechanical stretch from hypertensive response are PC analogues in vivo.

Methods: Anesthetized rabbits (n = 7–10/group) were used to study PC with the following standard protocol: 5 min of intervention (AII infusion or aortic constriction) – 10 min of reperfusion (rep) – 30 min of ischemia – 120 min of rep. Pressor (5 μg/ml) or non-pressor (1 μg/ml) doses of AII were either infused intravenously (IV) or directly into the left atrium (LA) and blood pressure was continuously monitored. The infarcted (I) and the risk areas (R) were delineated with the aid of Zn-Cd fluorescent particles and tetrazolium chloride staining. Infarct size is expressed as I/R ratio in % as mean ± 1 SEM.

Results:

	Intervention	Pressor response	Infarct size
Group A	AII 5 μg/ml IV	Hypertension	31.2 ± 4.8
Group B	AII 5 μg/ml LA	Hypertension	$52.2 \pm 6.9^{*}$
Group C	No intervention	Normotension	39.6 ± 6.1
Group D	AII 1 μg/ml IV	Normotension	42.1 ± 5.9
Group E	AII 1 μg/ml LA	Normotension	$48.9 \pm 3.5^{*}$
Group F	Aortic constriction	Hypertension	$17 \pm 3.7^{**}$
Group G	Aortic constriction + Gd^{3+}	Hypertension	48.8 ± 4.2

$^{*}p < 0.05$ vs *A*. $^{**}p < 0.001$ vs G.

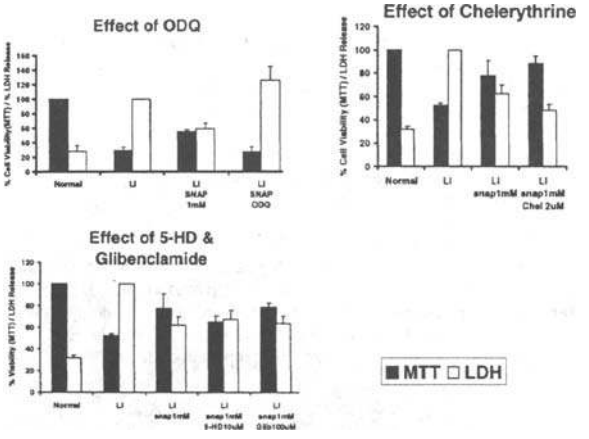
Conclusion: AII fails to mimic PC in vivo; direct LA administration of pressor or non-pressor doses of AII increases infarct size. By contrast, hypertensive response from IV pressor doses of AII ameliorates the direct AII toxicity on myocardium. Mechanical stretch by itself due to aortic constriction can mimic PC, an effect blunted by Gd^{3+}.

2521 Mechanism of early ischaemic preconditioning by nitric oxide is guanylate cyclase dependent but independent of protein kinase C or sarcolemmal/mitochondrial ATP-sensitive potassium channels

R.D. Rakhit, R.J. Edwards, M.S. Marber. *Department of Cardiology, KGT School of Medicine, The Rayne Institute, St. Thomas' Hospital, London, UK*

Nitric oxide (NO) can mimic early ischaemic preconditioning (PC) in cultured neonatal rat cardiocytes but the mechanism of this protection is unknown.

Methods: Pre-treatment for 90 minutes with the nitric oxide donor s-nitroso-N-acetyl-L-penicillamine (SNAP) followed by 30 minutes under normal culture conditions protected against subsequent 6 hours of lethal ischaemia (LI). We studied the effect of the specific guanylate cyclase inhibitor ODQ 10 μM, the PKC inhibitor chelerythrine 2 μM, together with glibenclamide 100 μM and 5-hydroxydecanoate (5-HD) 10 μM (blockers of sarcolemmal and mitochondrial ATP-dependent K^+ channels respectively) on SNAP-induced protection. Cell viability was quantified by LDH release and MTT bioreduction. Glibenclamide, 5-HD, ODQ and chelerythrine did not alter tolerance to ischaemia when given alone.



Results & conclusion: SNAP produced a significant increase in MTT conversion and a reduction in LDH release ($p < 0.01$) compared to SI alone. This protection was abolished by ODQ ($p < 0.01$) but unaffected by the presence of chelerythrine, glibenclamide or 5-HD. This suggests that early PC by NO is guanylate cyclase dependent but independent of PKC or mitochondrial/sarcolemmal ATP-dependent K^+ channels.

2522 The inhibition of p38α during index ischaemia may underlay ischaemic preconditioning

A.T. Saurin, C.A. Foley, J. Mockridge, R.J. Heads, M.S. Marber. *Dept. Cardiology, Rayne institute, Kings College, London, UK*

Activation of protein kinase C (PKC) and more recently mitogen-activated protein kinases (MAPKs) have been associated with the cardioprotective effect of ischaemic preconditioning. We examined the interplay between these two kinases in a characterised model of ischaemic preconditioning in cultured rat neonatal cardiocytes, were expression of active PKC-δ results in protection. Two members of the MAPK family, p38 and p42/44, were activated transiently during preconditioning with 90 min simulated ischaemia and 30 min re-oxygenation. Surprisingly, overexpression of active PKC-δ, rather than augmenting, completely abolished this activation. We therefore determined if a similar effect occurred during lethal simulated ischaemia. Lethal ischaemia activated only p38 MAPK (280 ± 45% activation, $p < 0.01$), which was attenuated by overexpression of active PKC-δ. Moreover preconditioning, which gives rise to a similar level of protection, caused a strikingly similar inhibition of ischaemia-induced p38 activation (111 ± 26% activation, $p < 0.01$). To determine if this reduced p38 phosphorylation was the cause, or an effect, of preconditioning, we used SB203580, a p38 inhibitor, in attempt to protect myocytes against lethal ischaemia alone. SB203580 significantly reduced ischaemic injury (CK release 38.0 ± 3.1%, LDH release 77.3 ± 4.0% and MTT bioreduction 127.1 ± 4.8% of control, $n = 20$, $p < 0.05$). Cells infected with adenoviruses encoding wild-type p38α or p38β, show differential activation of p38 ($p < 0.001$) during sustained simulated ischaemia, since p38α remains activated (148 ± 36% activation) whereas p38β is deactivated (36 ± 10% activation, $p < 0.01$). Prior preconditioning prevented this activation of p38α (84 ± 15% activation, $p < 0.05$). Hence inhibition of p38α during index ischaemia may represent a common mechanism for preconditioning-induced cardioprotection.

2523 Mechanisms of delayed cardioprotection in a human cardiocyte cell line

R. Carroll, D.M. Yellon. *The Hatter Institute, UCL Hospitals & Medical School, London, UK*

Evidence of delayed preconditioning or second window of protection (SWOP) in man is limited. We investigated the mechanisms of SWOP in an adult human cardiac myoblast cell line (Girardi cell) model, with particular reference to the role of the mitochondrial K_{ATP} channel. Girardi cells were grown to confluence and submitted to a variety of interventions: Group 1 were preconditioned (PC) by incubation in ischaemic buffer (KCl 16 mmol, lactate 20 mmol, pH 6.5) in an hypoxic chamber (argon 95%, carbon dioxide 5%) for one hour. Group 2 were preincubated with the P38 kinase inhibitor, SB203580, 30 minutes prior to PC. Group 3 were incubated with adenosine, a known trigger for PC, 100 uM for 20 mins. All groups were allowed to recover for 24 hours prior to being subjected to lethal simulated ischaemia (LSI), consisting of 3 hours incubation in ischaemic buffer with a pH of 6.3 in the hypoxic chamber. A further group of preconditioned cells were treated with the mitochondrial K_{ATP} channel blocker 5-hydroxydecanoate sodium 50 uM (5-HD), 30 mins prior to LSI. Lactate dehydrogenase enzyme release into medium was assayed as an index of cell injury and expressed as percent of total releasable LDH.

Group	Ischaemic injury index [mean (SEM)]
ischaemia	36.4 (1.1)
PC	12.1 (0.9)*
PC + SB203580	28.6 (2.8)
PC + 5-HD	31.9 (4.8)
Adenosine	11.9 (2.0)*
Adenosine + SB203580	25.3 (2.9)

*$p < 0.001$ vs ischaemia by one way ANOVA

Conclusion: In this human cardiac cell model, adenosine and PC provide delayed cardioprotection against LSI. These effects appear mediated via a P38 kinase signalling pathway and effected by the opening of the mitochondrial K_{ATP} channel.

2524 Myocardial protection during serial balloon angioplasty (PTCA): ischaemic preconditioning?

R.J. Edwards, S. Redwood, M. Webb-Peploe, E. Tomsett, R.D. Rakhit, M.S. Marber. *Department of Cardiology, Rayne Institute, St. Thomas's Hospital, London, UK*

Myocardial preconditioning is a powerful technique for reducing infarct size in animal models. Serial balloon inflation during PTCA is a potential human model but it is not clear if ischaemic tolerance on subsequent inflations is due to collateral recruitment or preconditioning. Patients with LAD disease underwent 2 balloon inflations of >3 min separated by >5 min reperfusion. Balloon occlusion pressure (Pocc) was measured with a 0.014" pressure wire positioned distal to the balloon. Collateral flow index was calculated on the basis of simultaneous measurements of mean aortic (Pa) and coronary sinus pressure (CSP): (Pocc-CSP)/(Pa-CSP). Myocardial ischaemia was assessed with degree of ST shift, from the surface ECG chest lead with greatest deviation. The patient on a scale from 0–10 graded pain severity.

		Collateral Flow Index		ST Deviation		Chest Pain	
Patient	Age	Occ 1	Occ 2	Occ 1	Occ 2	Occ 1	Occ 2
1	56 m	0.09	0.19	7.5	2.5	10	5
2	68 m	0.16	0.15	0.7	0	0	0
3	57 m	0.15	0.18	1.5	0.9	6	6
4	58 m	0	0	10.2	6.7	10	7
5	56 f	0	0	0.8	0.8	6	6
6	56 m	0.2	0.25	0.8	0	9	5
7	58 m	0.38	0.37	1.8	1.5	9	8
8	56 f	0.32	0.29	0.3	0.3	3	2
9	52 m	*0*	*0.02*	*9*	*7.2*	*5*	*4.5*
10	51 m	*0*	*0*	*6.7*	*3.3*	*3*	*1.5*
	Mean	*0.13*	*0.146*	*3.93*	*2.32**	*6.1*	*4.5**
	SD	± 0.1	± 0.1	± 3.9	± 2.7	± 3.4	± 2.6

(*$P < 0.01$ Occlusion 2 v Occlusion 1, paired t-test)

Conclusions: 1. We demonstrate that ischaemic parameters improve significantly during the second balloon occlusion, 2. This protection is achieved without significant collateral recruitment providing evidence for preconditioning in man.

2525 Attenuation of the maximum ST-segment depression, the value of CK-MB Isoenzyme and the ejection fraction in the first Q anterior wall myocardial infarction: a new method of confirming spontaneous ischaemic preconditioning?

Z. Mijailović, M. Krgović, Z. Ćosić, B. Djokić, V. Tadić, M. Prcović. *Clinic of Cardiology, MMA, Belgrade, Yugoslavia*

Background: In the induced models of ischaemic preconditioning which have a protective effect for the ischaemic myocardium (repeated stress tests, pacing tachycardia, PTCA) an attenuation of the maximum value of ST-segment depression (ASTD) was noted.

We studied ASTD as an indicator of the spontaneous adaptation to ischaemia during 3 successive ischaemic attacks (A1, A2, A3) in the first Q myocardial infarction (AMI), the total izoenzyme CK-MB value [$\sum$(CK-MB)] and the ejection fraction of the left ventricle (EF).

Methods: Eighty pts (61 m/19 f, mean 59 ± 4 yrs), at the onset of AMI, immediately upon entering the coronary unit were subjected to 24 h ECG Holter monitoring (ECGH) and the maximum ST-segment depression value was measured during A1, A2, A3, with periods of spontaneous reperfusion. All pts were divided into group A with a statistically significant ASTD and group B with no significant ASTD. During the 7 days following AMI, the Σ(CK-MB) value has been analyzed; the EF was measured by echocardiography. Fibrinolythics therapy was not applied to the pts and during ECGH they did not receive beta-blockers. Coronarography had not shown a significant difference between A and B in the severity of the coronary disease.

Results:

Group	n	Average values of max. STD (mm)			$\sum$(CK-MB) (iu/l)	EF (%)
		A1	A2	A3		
A	36	2.62 ± 0.2	1.73 ± 0.1*	1.46 ± 0.1*	64.18 ± 8.1**	48 ± 5**
B	44	2.86 ± 0.1	2.81 ± 0.2	2.94 ± 0.2	99.48 ± 6.2	27 ± 5

*p < 0.001 vs. A1; **p < 0.001 vs. group B

Conclusion: Pts in group A showed significantly lower average $\sum$(CK-MB) value and significantly higher average EF value, compared to group B ($p < 0.001$). This could confirm the importance of ASTD as a clinical indicator of the existence of spontaneous adaptation and ischaemic preconditioning in some pts with their first Q AMI.

THE HEART IN HYPERTENSION: NEW ASPECTS OF CARDIOVASCULAR STRUCTURE AND FUNCTION

2526 Macrophage chemoattractant protein-1 and macrophage inflammatory protein-1a serum levels in hypertensive patients with or without significant hyperlipidaemia

J. Parissis, D. Mentzikof, K. Venetsanou, M. Kalantzi, N. Ziras, M. Gikopoulos, K. Merkouris, S. Karas. *Amalia Fleming Hospital and St. Anargiri Hospital, Athens, Greece*

Objective: The activation of monocytes with infiltration into the vessel wall is an early event in atherogenesis. C-C chemokines may play a role in the recruitment and activation of monocytes/macrophages in this disorder. This study investigates the differences in serum activity of representative C-C chemokines, such as macrophage chemoattractant protein-1 (MCP-1) and macrophage inflammatory protein-1a (MIP-1a), between hypertensive patients with significant hyperlipidemia and hypertensive patients without this condition.

Methods: Serum levels of MCP-1 and MIP-1a were determined by Elisa assays in 38 patients (29 men and 9 women) with moderate hypertension and 15 age-matched healthy controls. Patients (n = 18) with total cholesterol (TC) ≥ 240 mg/dl and LDL-C ≥ 160 mg/dl were classified as group A, while patients (n = 20) with values less than the above, as group B. All patients did not receive any medications before blood sampling for laboratory measurements.

Results: Data (mean ± SD) are shown in the table:

Pts	Age (yrs)	SBP (mmHg)	DBP (mmHg)	TC* (mg/dl)	LDL-C* (mg/dl)	MCP-1** (pg/ml)	MIP-1a*** (pg/ml)
Group A (n = 18)	58.2±6.3	172±6.1	103±4.8	261.2±11.7	169.9±7.9	198.4±29.3	24.3±4.1
Group B (n = 20)	56.7±7.1	170±6.8	105±4.2	218±12.3	138.3±8.7	150.7±33.2	19.8±3.9
Controls (n = 15)	54.3±5.9	125±4.3	88±3.8	208.5±14.8	133.2±9.1	116.2±24.3	15.4±3.1

* p group A vs B < 0.01, ** p group A vs B < 0.01, p group A vs controls < 0.001, p group B vs controls < 0.05, *** p group A vs B < 0.05, p group A vs controls < 0.005, p group B vs controls < 0.05

In group A, MCP-1 and MIP-1a values were significantly correlated with LDL-C ($r = 0.49$, $p < 0.05$ and $r = 0.56$, $p < 0.01$, respectively). No correlation was found between smoking and C-C chemokine serum activity in study population.

Conclusions: MCP-1 and MIP-1a serum levels are elevated in hypertensive patients, especially in those with significant hyperlipidemia. This elevation may reflect the initiation and progression of inflammatory atherosclerotic process triggered by arterial hypertension and enhanced by its coexistence with hyperlipidemia.

2527 Effects of short-term with an ACE inhibitor or an angiotensin II antagonists on vascular content of ICAM-1 in spontaneously hypertensive rats

E. Porteri, A. Piccoli, D. Rizzoni, D. Guelfi, G. Pasini, M. Castellano, C. Perani, E. Agabiti Rosei. *Chair of Internal Medicine, Dept. of Medical and Surgical Sciences, University of Brescia, Italy*

Objective: It has been demonstrated that intercellular adhesion molecule-1 (ICAM-1) plays a role in leukocyte extravasation through the endothelium. Since ICAM-1 contributes to the trapping of monocytes on local vascular walls, it may participate in the process of atherogenesis. We have evaluated the effects of an ACE inhibitor, enalapril (ENA) and of an angiotensin II receptor blocker, candesartan cilexetil (CAND), administered either at hypotensive or at non-hypotensive dosage, on structural alterations of mesenteric small resistance arteries in SHR as well as on vascular content of ICAM-1.

Design and Methods: One hundred and three rats were included in the study: 16 SHR were treated with low-dose (ld, 1 mg/kg/day) ENA, 14 with low-dose (ld, 0.5 mg/kg/day) CAND, 16 with high-dose (hd, 25 mg/kg/day) ENA, 21 with high-dose (hd, 15 mg/kg/day) CAND, while 18 WKY and 18 SHR were kept untreated (unt). Treatment was from age 4 to 12 weeks. Systolic blood pressure (SBP) was measured non-invasively every week. Mesenteric small arteries were dissected and mounted on a micromyograph (Mulvany's technique), and the media:lumen ratio (M/L) was calculated. The small mesenteric arteries content of intercellular adhesion molecule-1 (ICAM-1) was evaluated by ELISA on tissue homogenate.

Results: The results are summarized in the Table. SBP was significantly reduced only by the high doses of ENA or CAND. M/L was significantly greater in unt SHR than in unt WKY. A significantly smaller M/L was observed in SHR treated with the high doses of ENA or CAND, in comparison with untreated SHR and with SHR treated with the low doses of the drugs. ICAM-1 vascular content was greater in unt SHR than in unt WKY, and was almost normalized by treatment with both low and high doses of ENA or CAND.

Table	SBP (mm Hg)	M/L (%)	ICAM (ng/g of tissue)
unt'WKY	155 ± 15***	9.2 ± 1.9***	135 ± 69***
unt SHR	246 ± 25	14.0 ± 2.4	366 ± 233
SHR ENA ld	218 ± 18	13.2 ± 2.1	193 ± 55*
SHR CAND ld	221 ± 27	13.7 ± 2.2	149 ± 80**
SHR ENA hd	157 ± 20***#	10.7 ± 1.7***	149 ± 43**
SHR CAND hd	175 ± 19***	11.8 ± 1.9**	133 ± 72**

(* = p < 0.05, ** = p < 0.01, *** = < 0.001 vs. SHR unt; # = p < 0.001 vs. CAND hd)

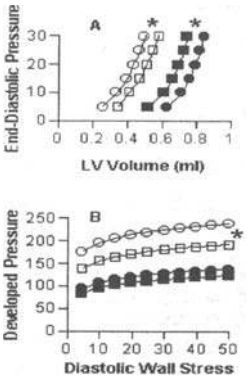
Conclusions: ENA and CAND at either low or high doses were able to normalize the vascular content of ICAM-1, while only the high, hypotensive dose was able to induce a reduction of vascular structural alterations. Our data suggest that ENA and CAND could be effective in preventing the adhesion of inflammatory cells, and, consequently, may exert an antiatherogenic action, even at non hypotensive doses.

2528 Effects of hypertension in heart failure following myocardial infarction

Franz R. Eberli, Bruno K. Podessor, Ronglih Liao, Soeun Ngoy, Carl S. Apstein, Mohit Jain. *Cardiology, University Hospital Berne, Switzerland; Boston University School of Medicine, Boston MA, USA*

Hypertension (HTN) induces concentric left ventricular hypertrophy (LVH) and thus increases LV contractile function and decreases wall stress. Large myocardial infarction (MI) results in overall LV dilation and decreased LV contractile function. We tested whether in heart failure post-MI HTN was able to induce additional compensatory LVH and increase contractile function.

Male, Dahl salt-sensitive (SS) and salt resistant (SR) rats underwent coronary ligation or sham operation. 4 weeks of high-salt diet induced HTN in SS rats (>160 mmHg systolic blood pressure) but no HTN (NHTN) in SR rats. LV pressure-volume relationship (PV) were established in isolated, red-cell perfused hearts. Four groups were studied: Sham + NHTN (□, n = 8), Sham + HTN (○, n = 8). MI + NHTN (▫, n = 12), and MI + HTN (●, n = 8). Infarct sizes were similar in MI + NHTN and MI + HTN groups (48 ± 4% vs 46 ± 3% of LV, ns). In non-infarcted hearts HTN resulted in concentric LVH (HW/BW = 4.4 ± 0.1 vs 5.5 ± 0.2 mg/g, Sham + NHTN vd Sham + HTN, $p < 0.05$) as indicated by a leftward shift in the PV curve. In post-MI heart failure HTN resulted in further eccentric LVH (HW/BW = 5.3 ± 0.2 vs 6.0 ± 0.2 mg/g, MI + NHTN vs MI + HTN, $p < 0.05$) as indicated by a rightward shift in the PV curve (Fig A). HTN elevated contractile function in Sham rats ($p < 0.05$), but did not increase systolic function in MI + HTN compared to MI + NHTN rats (Fig B).



Conclusion: Dilated hearts post-MI still possess the ability to hypertrophy secondary to HTN. However, HTN does not increase contractile function and results in further LV dilation post-MI.

2529 Is dietary salt intake a determinant of left ventricular diastolic function in young women with mild essential hypertension?

B. Say, M.M. Türkmen, B. Yaymacı, L. Saraç, E. Dağlar, Y. Başaran, F. Turan. *Koşuyolu Heart and Research Hospital, İstanbul, Turkey*

Previous studies have shown dietary salt intake as an independent determinant of left ventricular hypertrophy (LVH) in established essential hypertension; however, diastolic dysfunction might occur with or without LVH. This study was designed to examine the relation of dietary salt intake with the LV diastolic filling at the onset of hypertension in previously untreated young women with mild essential hypertension.

Methods: 42 young female patients (mean age 30.4 ± 2.7 yrs) with mild essential hypertension (group 1) and 36 age-matched female normotensive control subjects (group 2) underwent 24 hour blood pressure monitoring in parallel with 24 hr urinary sodium excretion and plasma renin activity. 2-D guided M-mode echocardiography with pulse-wave Doppler was performed to evaluate the structural and diastolic filling properties of left ventricle. Logistic regression analysis was performed to identify the independent determinants of left ventricular diastolic filling.

Results: In group 1 patients, the higher the urinary sodium excretion, the greater were the ratio of velocity time integrals A/E (VTI A/E) ($r = 0.57$, $p < 0.001$), maximal velocities (V max A/E) ($r = 0.48$, $p < 0.05$) and atrial filling fraction ($r = 0.54$, $p < 0.01$). On the contrary, group 2 patients showed an inverse correlation of sodium excretion with the diastolic filling parameters (all $p < 0.01$). Sodium excretion was related to plasma renin activity but in reverse in hypertensives ($r = -0.43$, $p < 0.05$). Logistic regression analysis identified sodium excretion (group 1: VTI A/E: $p < 0.0001$; group 2: VTI A/E: $p = 0.001$) and heart rate (group 1: VTI A/E: $p = 0.007$; group 2: VTI: A/E $p = 0.06$) as independent determinants of diastolic function in both groups. LV mass, enddiastolic volume index and endsystolic wall stress were not related to diastolic function parameters in either group.

Conclusion: Dietary salt intake assessed by sodium excretion over 24 hrs is a powerful determinant of LV diastolic dysfunction at the onset of hypertension, and even before the manifestation of LVH in young women.

2530 Exercise echocardiography is an optimal non-invasive stress test for the diagnosis of coronary artery disease in hypertensive subjects

T. Pasierski, H. Szwed, B. Malczewska, B. Firek, M. Kośmicki, M. Rewicki, I. Kowalik, Z. Sadowski. *National Institute of Cardiology, Warsaw, Poland*

The aim of the study was to compare efficacy and side effects profile of electrocardiographic exercise stress test (EST), exercise echocardiography (EE) and dobutamine echocardiography (DE) applied for the diagnosis of coronary artery disease (CAD) in hypertensive patients (pts) with angina.

Methods: Study group included 197 pts, age 53 ± 9 years, 65 women, with treated (stage I and II) arterial hypertension, without history of myocardial infarction. Maximal exercise was performed on treadmill with Bruce protocol. EKG was evaluated continuously and wall motion was assessed before and just after the end of exercise. DE was performed with continuous i.v. infusion up to 40 μg/kg/min. with atropine 0.25–1.0 mg added in 44% of pts. Positive EST result was defined as ≥1 mm ST depression. Positive EE and DE result was defined as a new or increased wall motion abnormality after stress, calculated as a wall motion score index (WMSI). Left ventricular hypertrophy (LVH) evaluated with M mode echocardiography and defined as LV mass index > 117 g/m^2 in men and >104 g/m^2 in women was present in 45% pts.. Significant CAD (stenosis > 50%) was present in 59% pts.

Results:

	EST		EE		DE	
LVH	+	−	+	−	+	−
Sensitivity (%)	80	75	87	77	80	68
Specificity (%)	66*	56#	100*	94#	100*	96#

EE/DE vs. EST * - $p < 0.01$, # – $p < 0.001$.

Sensitivity differences were not significant. Specificity and sensitivity of evaluated methods were not different according to the presence of LVH. Maximal double product was significantly higher at EE than at DE (23852 ± 6408 vs. 20607 ± 5400 mm Hg/min., $p < 0.0001$) WMSI was also higher at EE than at DE (1.17 ± 0.14 vs. 1.12 ± 0.09, $p < 0.001$), what facilitated image interpretation. Systolic blood pressure increased above 240 mm Hg or declined more than 5 mm Hg from resting values more common at DE than at EE (7% vs. 2%, $p < 0.05$). New arrhythmia was induced with both DE and EE (18% vs. 13%, p = ns). Side effects like anxiety (7%), headache (7%) and paresthesia (37%) were reported at DE but not at EE.

Conclusions: In hypertensive patients with the symptoms of angina both stress echo methods are highly accurate and significantly more specific than exercise electrocardiographic test, independently from the presence of LVH. Treadmill exercise is associated with lower frequency of significant blood pressure variation and is better tolerated than infusion of dobutamine. Exercise echocardiography should be regarded as a method of choice in the diagnosis of coronary artery disease in hypertensive patients

2531 Coronary calcium as a predictor of coronary events in hypertensive patients: three years follow-up

J. Shemesh, M. Motro. *On behalf of the INSIGHT, calcification study investigators; The Cardiac Rehabilitation Institute, Sheba Medical Center, Tel Hashomer, Israel*

Coronary calcium (CC), easily detected by dual slice spiral CT (CT) is a marker of coronary artery disease. This study was aimed to investigate the predictive value of CC for cardiovascular events in hypertensive patients.

Methods: Five hundred forty four hypertensive patients (53% male, mean age 65 ± 6 years) were selected as a side arm of the INSIGHT protocol (International Nifedipine Study Intervention as a goal for Hypertension Therapy). All underwent CT and were followed for a period of 3 years (mean 27.6, median 36.0 months).

Results: Eighty three patients developed one or more cardiovascular events: In 59 the first event was coronary (acute MI: 18; sudden death: 3; angina: new; 4 worsening; 7, unstable: 16; coronary angiography: 9; PTCA: 1; CABG: 1) and vascular in 24 (TIA: 7; CVA: 17). Among 148 patients who had no CC (Total calcium score = 0) 9 (9.4%) developed event – 5 coronary and 4 vascular, while of the 387 patients who had CC (total score > 0) 74 (19.2%) had events – 54 coronary and 20 vascular. Results from Cox regression analysis, where the first cardiovascular event was considered as the terminal event, and age, sex, BMI, smoking, diabetes mellitus, hypercholesterolemia, family history of CAD, LVH, proteinuria and presence of CC as covariates demonstrated that the following factors significantly increase the probability of developing an event:

		RR	95% CI	P value
Coronary event:	Presence of CC	3.7	1.5–9.4	0.005
	Male gender	3.3	1.7–6.5	<.001
Vascular event:	Proteinuria	5.8	2.4–14.4	<.001
	LVH	2.6	1.0–6.7	0.039
	Family history of CAD	3.0	1.0–9.4	0.050

Conclusions: The presence of CC on dual slice CT quadruples the risk of developing a coronary event within 3 years. This technique is helpful in stratifying hypertensive patients.

NEW TRENDS IN MITRAL VALVULAR SURGERY

2532 Determination of plasma brain natriuretic peptide concentrations may improve the timing of surgical intervention in patients with chronic mitral regurgitation

C.I.O. Brookes, M. Kemp, J. Hooper, P.J. Oldershaw, N.E. Moat. *Royal Brompton Hospital, London, UK*

The long-term prognosis in patients who have had mitral valve surgery for chronic MR is not good. These poor results often reflect irrevesible LV impairment which is sustained and not detected prior to surgical referral. BNP synthesis and secretion is increased in a number of conditions associated with LV dysfunction and could potentially be used as a marker of early LV disease in chronic MR.

We studied 22 patients with isolated non-rheumatic chronic MR and echocardiographic evidence of at least moderate MR and 8 normal volunteers. Eleven patients were symptomatic and 10 of these were on the waiting list for valvular surgery. Plasma BNP was measured, after extraction, by radioimmunoassay. All subjects had normal renal function.

Mean plasma BNP (±SD) in all patients was higher in patients than normals: 20.9 (16.9) vs 3.4 (0.9) pmol/l; p 0.007. Plasma BNP in patients in NYHA I was 12.6 (7.0), NYHA II/III 17.1 (6.0) and NYHA IV 42.6 (23.6) pmol/l; p = 0.002 I vs IV, p = 0.019 II vs IV and p = 0.189 I vs II. Only 2 patients had normal BNP concentrations (<5.2 pmol/l) and both were asymptomatic. Two asymptomatic patients had levels >20 pmol/l with normal LV end-systolic dimensions (ESD) and both have subsequently developed symptoms within 6 months of follow-up. Those patients with increased LVEDD and normal LVESD (n = 14) had similar concentrations to those with normal LVEDD and ESD (n = 8): 17.95 (11.2) vs 17.8 (8.0); p = 0.89. There was no correlation between BNP levels and LV dimensions, fractional shortening or left atrial size: r = 0.083, r = 0.002, r = 0.051.

Plasma BNP concentrations are elevated in patients with isolated chronic MR prior to the development of symptoms or echocardiographic evidence of LV impairment. These results suggest that serial measurements of plasma BNP may be useful as a means of assessing progressive LV dysfunction in patients with MR but longitudinal studies are required to determine whether surgical intervention on the basis of BNP levels alters the long-term prognosis in these patients.

2533 Double orifice repair: a new approach for the surgical correction of myxomatous mitral regurgitation with bileaflet prolapse (Barlow's disease)

F. Maisano, J. Schreuder, M. Oppizzi, A. Castiglioni, B. Fiorani, M. Dora, P.L. Stefano, G. La Canna[1], O. Alfieri. *Cardiochirurgia, San Raffaele Hospital, Milan; [1]Cardiologia, Spedali Civili, Brescia, Italy*

Myxomatous disease with prolapse of both mitral leaflets is a surgical challenge. Repair of mitral regurgitation (MR) due to elongated subvalvar apparatus, redundant leaflets and dilated mitral annulus (fig 1), requires complex surgical procedures associated with unpredictable results. Double orifice repair is a new method of reconstruction particularly suitable for the correction of MR in Barlow disease.

Methods: Since 1993, we observed 62 consecutive pts (mean age 51 yrs) with Barlow disease. Regurgitation was due to elongated chordae and prolapse of both leaflets in 42 pts; in 20 pts, chordal rupture was also associated. Forty-nine patients were in NYHA class I and II while 13 were class III or IV. Pre-op planimetric valve area was 6.9 ± 1.46 cm^2. All patients underwent double orifice mitral repair (creation of two orifices by suturing the free edges of the leaflets in the middle portion (fig 2).

Results: There were no perioperative deaths. Post-op TEE showed no MR in 39 pts, mild in 21, and moderate in 2 pts. No patient had postoperative SAM. Planimetric post-op valve area was 3.3 ± 0.59 cm^2, no gradient across the valve was ever detected. Follow-up was complete (92 pt-yrs). There were no late deaths. One patient was reoperated for recurrent MR due to endocarditis and underwent mitral valve replacement (freedom from reoperation 89 ± 11% at 4 years). At latest follow up all patients but one are in NYHA class I or II, and echocardiography demonstrates stability of the repair and regression of ventricular volumes.

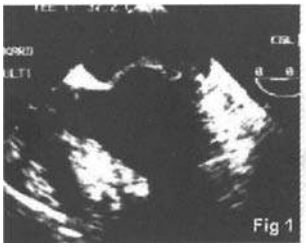


Fig 1

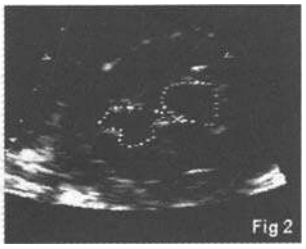

Fig 2

Conclusions: The double orifice repair technique is a simple and reproducible method for the surgical correction of myxomatous MR. The simplicity of the technique opens the perspective for percutaneous repair of mitral regurgitation.

2534 Simplified repair of mitral valve billowing and prolapse (Barlow): assessment of 84 consecutive patients

R. Fasol, B. Pfannmüller, R. Hacker. *Herz- und Gefaess-Klinik GmbH, Bad Neustadt/Saale, Germany*

Background: Mitral valve repair in patients with billowing and prolapse (Barlow) can be a demanding surgical procedure. We evaluated a simplified repair technique, addressing the essential physiologic components of repair.

Patients and Methods: 1,705 patients underwent mitral valve surgery in our hospital between 01.1994 and 06.1998. 84 patients (4.9%) had a mitral valve billowing and prolapse syndrome (Barlow). Of the 84 patients 60 were male (71.4%), the mean age was 53.5 ± 13.1 years (range 22 to 80). Mitral repair was performed in 65 patients (77.4%) using modified Carpentier techniques (=complete resection of the middle scallop of the posterior leaflet, a folding plasty with the remaining lateral scallops, combined with a triangular resection of the anterior leaflet) and an annuloplasty with a Carpentier-Ring. 19 patients had to undergo mitral valve replacement (22.6%), including 6 patients with non-successful initial intraoperative repair attempts and 1 patient who had emergency mitral replacement on the first postoperative day after valve repair due to SAM. Follow-up information was obtained by telephone interviews with cardiologists, family physicians and patients.

Results: There were 2 hospital deaths (2.3%) and one late death (1.2%). All 3 patients had a mitral valve replacement. In the group of 65 repair patients there was no hospital and no late death. Analyzing the percentages of successful mitral valve repair operations, our results increased from 65.2% in 1994 to 93.4% in 1996 and 100% in 1998 – due to our modified and simplified repair techniques. Echocardiography showed satisfactory mitral valve function in all patients. No residual regurgitation was found in 74 patients (88.1%), mild regurgitation in 7 (8.3%) and moderate regurgitation in 3 patients (3.6%). At the time of follow-up, 93.0% of all patients were in NYHA functional class I or II, all describing their quality of life as "normal". There were no late reoperations, no thromboembolic, bleeding or other complications.

Conclusion: Our data suggest that mitral valve repair in patients with prolapse and billowing (Barlow) is possible in evely patient.

2535 The natural history of mitral valve disease after aortic valve replacement

A. Sagie, A. Porter, M. Vaturi, Y. Shapira, O. Vitray, B.A. Vidne. *Dan Scheingarten Echocardiography Unit and Dept. of Cardiothoracic Surgery, Rabin Medical Center, Beilinson Campus, Petach Tikva, Israel*

The aim of this study is to describe the progression of mitral valve disease (MVD and the need for late mitral valve replacement (MVR) in pts after aortic valve replacement (AVR) without mitral valve surgery.

Patients & Methods: 52 pts (83 males, 69 females; mean age at follow up 66 ± 13 years, range 28–93) were followed after AVR for a mean of 9.0 ± 6.5 years. The etiology for AVR was rheumatic in 40.1% of pts. Pre- and postoperative data were derived from the clinical and/or angiographic transthoracic echocardiographic records.

Results: At the time of AVR, 68 pts (44.7%) had MVD; 21 (13.8%) mitral stenosis (MS) [16 (105%) mild, 4 (2.6%) moderate and 1 (0.65%) severe]; 47 (30.9%) mitral regurgitation (MR) [24 (15.8%) mild, 14 (9.2%) moderate and 9 (5.9%) severe]. 8/68 (5.26%) had combined mitral disease. At follow-up, 141 pts (92.7%) had MVD including 44 pts (28.9%) with MS [28 (18.4%) mild, 14 (9.3%) moderate and 2 (1.3%) severe] and 97 pts (63.8%) with MR [36 (23.7%) mild, 28 (18.4%) moderate and 33 (21.7%) severe]. 24 pts (15.8%) who had no evidence of MS preoperatively had so at follow up. In the group with baseline MS, 4/16 pts (19%) with mild disease progressed to moderate disease; the remaining 71.4% were unchanged. 53 pts (34.9%) who did not have MR preoperatively had so at follow up. In 17/47 pts with baseline MR (36.1%), disease progression was noted, while 57.4% showed no change. Despite the high rate of MVD at follow up, 80.8% of pts were in functional class I and II. Only 5 pts (3.3%) underwent MVR, none combined with AVR, after a mean of 20.25 years (range 4–26).

Conclusions: MVD is a common echocardiographic finding in patients late after AVR. Nevertheless, the majority of pts (81%) are clinically stable. Since mitral valve surgery was needed in only a few pts, we conclude that pts with mild and probably moderate MVD undergoing AVR, should not have concomitant mitral valve surgery.

2536 Curative treatment of atrial fibrillation in patients with simultaneous mitral valve replacement with intraoperative radio frequency ablation

M. Knaut, S.M. Tugtekin, S.G. Spitzer[1], G. Hindricks[2], H. Kottkamp[2], S. Schueler. *University Dresden, Cardiovascular Institute, Dresden; [1]Institute for Cardiovascular Research, Dresden; [2]Cardiovascular Institute, University, Leipzig, Germany*

Introduction: The original MAZE procedure has become the gold standard in the operative therapy in patients with chronic atrial fibrillation. For simplification of the operative procedure we analyzed the efficiency of a continuous right and left atrial ablation line application by using radio frequency ablation (rfa) for the treatment of atrial fibrillation in patients with mitral valve replacement (MVR).

Methods: In 10 patients (pts; 5 m and 5 f, age range 45–74 years, mean 62 ± 10 years) suffering from mitral valve disease atrial fibrillation was documented for 18 ± 14 months. A continuous ablation line was performed through a right atrial transseptal approach starting at the posterior mitral valve annulus and incorporating all pulmonary veins. Electric isolation of the right atrial isthmus was performed using a new manual electrode. All pts received an additional MVR.

Results: Perioperative survival is 100%. The duration of intraoperative rfa was between 17–33 min. (mean 24 ± 5 min). No perioperative complications occurred. Eight pts had a sinus rhythm at the time of hospital discharge, 3 of them a previous cardioversion. In 4 pts with high grade AV-block a dual chamber pacemaker was implanted.

Conclusions: Electric isolation by an ablation line between the mitral anulus and the pulmonary veins and electric isolation of the right atrial isthmus can terminate chronic atrial fibrillation by interruption of the reentry circle. This procedure may become a new standard in therapy for patients with mitral valve replacement and chronic atrial fibrillation.

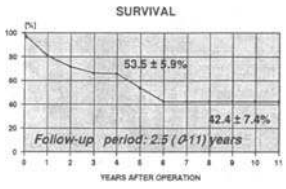
2537 Early and long-term results after surgery for ischaemic dilated cardiomyopathy associated with mitral regurgitation

N. Radovanovic, Lj. Petrovic, B. Mihajlovic, M. Kovac, S. Nicin, M. Mijatov, V. Scekic, Z. Jonjev, V. Torbica, M. Fabri. *University Clinic of Cardiovascular Surgery, Novi Sad, Yugoslavia*

Background: The pathogenetic mechanism of chronic mitral regurgitation is considered to be due to the combination of papillary muscle dysfunction, left ventricular and annular dilatation and myocardial dyskinesia. These processes lead to remodelling of the fibrous skeleton of the heart, which is an important part of remodelling of the left ventricle. We have reviewed our group of 163 operated patients with chronic ischemic dilated cardiomyopathy (IDCM), ejection fraction (EF) below 30%, and mitral regurgitation (MR).

Methods: There were 149 male (91%) and 14 female patients, aged 34–70, with the mean age of 56.1 years. The mean EF was 22.6 ± 4.9%, and the mean left ventricular diastolic internal diameter 7.0 cm. Among those, 70% (115/163) had signs of congestive heart failure before surgical therapy. All patients had undergone myocardial revascularisation and Reductive Annuloplasty of Double (mitral and tricuspid) Orifices (RADO). Our technique preserves normal shape and flexibility of the mitral and tricuspid valve, corrects remodelling of the fibrous skeleton on the base of the heart and changes the geometry of the left and right ventricle.

Results: Postoperative mortality-30 days was 4.9% (8/163). Closing date of the follow-up study was February 15, 1998. The figure shows 10-year survival.



Conclusion: We conclude that this severe group of patients with IDCM, IMR and EF below 30% can be operated with low operative risk. After RADO and optimal myocardial revascularisation, a significant improvement in all hemodynamic parameters was observed, as well as good long term results. We recommend RADO as a very important associated procedure during myocardial revascularization in patients with IDCM associated with MR.

RARE FORMS OF CARDIOMYOPATHY: A CLINICAL CHALLENGE

2538 Abnormal cardiac energetics measured in vivo by ^{31}P magnetic resonance spectroscopy in the MELAS syndrome

R. Lodi[1], B. Rajagopalan[1], A.M. Blamire[1], J.G. Crilley, P. Styles[1], D.M. Turnbull[2], P.F. Chinnery[2]. *[1] MRC-MRS Unit, John Radcliffe Hospital, Oxford; [2]Department of Neurology, University of Newcastle-upon-Tyne, Newcastle-upon-Tyne, UK*

The MELAS (Mitochondrial Encephalopathy, Lactic Acidosis and Stroke-like episodes) syndrome results in most cases from a maternally inherited A-to-G point mutation in the gene for $tRNA^{Leu\ (UUR)}$ at nucleotide 3243 (A3243G) in the mitochondrial genome (mtDNA). Genetic variability contributes to the marked phenotypic variability which is characteristic of mtDNA disorders. Cardiomyopathy is the predominant phenotype in some families.

Methods: Using ^{31}P MRS we measured phosphocreatine (PCr)/ATP in 8 subjects carrying the A3243G mtDNA mutation (3 clinically affected and 5 carriers from 4 families) and 18 normal subjects. Family A had a family history of a cardiomyopathy and families B to D did not. Patients lay prone in a 2T magnet. MRI was used to position the heart in the centre of the magnet. 1D slice-selective chemical shift imaging was used to obtain ^{31}P spectra from 1 cm slices parallel to the chest wall. Saturation slabs were used to remove signal from skeletal muscle. Position of cardiac spectra were identified from the images and areas of PCr, ATP and 2, 3 DPG peaks were calculated. PCr/ATP was corrected for blood contamination and saturation. Left ventricular dimensions were measured with echocardiography and EF and LV mass index (LVMI) calculated.

Results: PCr/ATP in the subjects was significantly reduced as compared to controls (1.9 ± 0.7 v 2.9 ± 0.3, $p < 0.01$). PCr/ATP was significantly lower in family A (1.3 ± 0.6) as compared to patients B to D (2.4 ± 0.2, $p = 0.025$). EF was normal in all 8 patients. There was no significant correlation between LVMI and PCr/ATP.

Conclusions: This study shows that there is a deficit of cardiac energy metabolism in the MELAS syndrome in the absence of LV hypertrophy or contractile abnormalities. This suggests that cardiac metabolic changes may precede the development of mechanical dysfunction. It is thought that abnormal mitochondria may produce free radicals which may further damage their function. Our findings provide a rationale for treatment aimed to prevent further deterioration in cardiac mitochondrial function in the MELAS syndrome, in particular in subjects with high levels of the A3243G mutation and a family history of cardiomyopathy.

2539 Clinical profile and long-term follow-up of 37 families with arrhythmogenic right ventricular cardiomyopathy

A. Nava, B. Bauce, C. Basso[1], C. Villanova, A. Rampazzo[2], M. Muriago, L. Daliento, G. Buja, D. Corrado, G.A. Danieli[2], G. Thiene[1]. *Departments of Cardiology; [1]Pathology; [2]Biology, University of Padua, Italy*

Arrhythmogenic right ventricular cardiomyopathy (ARVC) is a primary myocardial disease frequently familial in origin. Systematic investigation of family members might better define its clinical spectrum and natural history.

A total of 365 subjects in 37 families were studied. In 19 families the proband died suddenly at a young age and ARVC was diagnosed at autopsy. In the remaining 18 families the proband had ventricular arrhythmias and the diagnosis was confirmed by endomyocardial biopsy. Protocol of investigation included basal ECG, 24 hour ambulatory ECG, signal-averaged ECG, exercise stress test, and 2-D and Doppler echocardiography. Ventricular and coronary angiography as well as RV endomyocardial biopsy were performed in 47 patients (pts).

Of the 365 subjects, 151 (41%) were affected, 157 (43%) were unaffected, 17 (5%) were carriers and 40 (11%) were classified as uncertain. The mean age of affected pts at diagnosis was 31 ± 13 years (range 4–64). By echocardiography 59% had mild, 35% moderate and 6% severe form of ARVC. Of affected pts, 60 had ventricular arrhythmias. Of these, 49 were treated with antiarrhythmic drugs and 2 with implantable cardioverter defibrillators. Analysis of the pedigree showed that males are more frequently affected than females ($p = 0.02$). Of the 28 families who underwent linkage analysis, 6 (22%) mapped to chromosome 14q24.3, 4 (14%) to chromosome 2q32.1–32.3 and 4 (14%) to chromosome 1q42–q43. No linkage was found in 14 (50%) families. Exercise performance was restricted in all affected pts. During a mean follow-up was 8.5 ± 4.6 yrs (range 2–18), 1 pt died and 15 developed an overt form of ARVC.

In conclusion, ARVC is a progressive disease with clinical findings appearing predominantly during youth. Systematic evaluation of family members can lead to early identification of ARVC. Several genes seem to be involved as to suggest genetic heterogeneity. Early diagnosis, exercise restriction and drug treatment may turn ARVC into a favourable clinical outcome. Affected family members appear to have a good prognosis over the mean follow-up of 8.5 ± 4.6 yrs.

2540 Identification of arrhythmogenic right ventricular cardiomyopathy from the surface ECG: parameters for discrimination from idiopathic right ventricular tachycardia

T. Wichter, K. Wilke, W. Haverkamp, G. Breithardt, M. Borggrefe. *Dept. of Cardiology and Angiology; University of Münster, Germany*

Arrhythmogenic right ventricular cardiomyopathy (ARVC) is an important disease underlying ventricular tachyarrhythmias and sudden death in young pts with apparently normal hearts. The major differential diagnosis is idiopathic right ventricular outflow-tract tachycardia (RVO-VT). A clear separation of the diseases is clinically relevant, because ARVC has a less favourable prognosis and therefore requires detailed diagnostic evaluation and effective antiarrhythmic treatment.

To assess the diagnostic value of different ECG findings for electrocardiographic distinction between ARVC and RVO-VT, 12-lead ECG and signal-averaged ECG recordings from pts with ARVC (n = 151 pts), RVO-VT (n = 142 pts) and a normal control group (n = 417) were analyzed qualitatively and quantitatively, using a graphic tableau:

	ARVC	RVO-VT	Control
T-wave inversion > V2	54.3%*	33.0%	1.4%
max. QRS-duration (V_{1-3})	114 ± 19 ms*	104 ± 13 ms	98 ± 11 ms
max. QRS > 110 ms (V_{1-3})	51.7%*	21.0%	12.9%
Epsilon potential	22.5%*	2.8%	0%
Late potential (25 Hz)	41.4%*	11.7%	3.0%
QRS-dispersion	40 ± 13 ms*	34 ± 10 ms	33 ± 9 ms
QT-dispersion	54 ± 21 ms	47 ± 16 ms	40 ± 13 ms

* = $p < 0.001$ for ARVC vs. RVO-VT and control

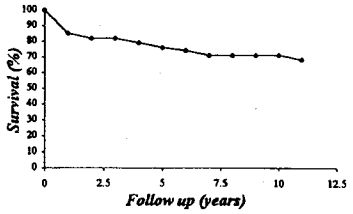
Conclusion: In pts with ARVC, all ECG parameters showed limited sensitivity. However, the presence of right precordial QRS prolongation, epsilon-potentials or late potentials were highly specific and may be helpful to distinguish ARVC from idiopathic RVO-VT

2541 Long-term follow-up of 34 adults with isolated ventricular non-compaction: poor prognosis due to fatal arrhythmias, congestive heart failure and systemic emboli

Jerry Rojas, Vreni Widmer, Christine Attenhofer Jost, Erwin Oechslin, Rolf Jenni. *Division of Echocardiography, University Hospital of Zurich, Switzerland*

Background: Isolated ventricular non-compaction (IVNC) of the left ventricular myocardium is an increasingly detected congenital heart disease due to arrest of compaction of the loose meshwork of myocardial fibers during intrauterine life. Echocardiographically, typically there are excessive trabeculations and intertrabecular spaces perfused from the cavity. The clinical features in adults are: congestive heart failure (CHF) due to diastolic, ventricular arrhythmias and systemic emboli.

Methods and results: We obtained a prospective long-term follow-up of 34 adults with IVNC diagnosed in our echocardiography laboratory from 1984 to 1998. The age at diagnosis was 43 ± 18 years. The left ventricular ejection fraction was 35 ± 11%. The average follow-up was 3.9 ± 3.3 years. Ventricular tachycardias occurred in 5 patients (pts; 15%), CHF in 16 pts (47%), systemic emboli in 11 pts (32%). 11 pts (32%) died 3.4 ± 2.9 years after diagnosis.



In 7 pts, the cause for death was known: sudden cardiac death (4 pts), emboli (pulmonary emboli + cerebrovascular accident: each in 1 pt) and CHF (1 pt). 4 pts (12%) underwent heart transplantation because of untreatable CHF within 1 year of diagnosis. The youngest pt was a 16 year old male with palpitations as the only symptom; the oldest pt a 73 year old female CHF.

Conclusions: The prognosis of adults with IVNC is poor with a high rate of death (32%) or heart transplantation (12%) on long-term follow-up. Ventricular arrhythmias, systemic emboli and CHF are common. Early heart transplantation and oral anticoagulation may improve outcome.

2542 Influence of frataxin on the cardiomyopathy of patients with Friedreich's ataxia

N. Bit-Avragim, A. Perrot, S. Cordini, A.E. Ellmer, L. Schöls[1], C. Epplen[1], F.R. Kreuz[2], Ch. Zühlke[3], S. Bubel[3], F. Laccone[4], R. Dietz, H.P. Vogel[5], K.J. Osterziel. *Franz-Volhard-Klinik, Berlin; [1]Neurol. Klinik & Institut f. Humangenetik, Bochum; [2]Institut f. Klinische Genetik, Dresden; [3]Institut f. Humangenetik, Lübeck; [4]Institut f. Humangenetik, Göttingen; [5]Neurol. Klinik, Berlin-Buch, Germany*

Concentric hypertrophic cardiomyopathy has been recognized as specific for the diagnosis of Friedreich's ataxia (FA) and is present in almost all patients with typical FA. FA is an autosomal recessive, progressive neurodegenerative disorder caused by unstable GAA repeat expansion in the first intron of frataxin gene (chromosome 9q13). Recently, it was reported that the size of this repeat may be associated with clinical severity of cardiomyopathy in FA patients.

Methods: In order to investigate the influence of the GAA repeats on cardiac hypertrophy in FA patients from the German population we analysed clinical data of 70 patients including ECG and echocardiography (49% men, mean age = 32 ± 11 years, onset = 15 ± 8 years). The size of repeats of both alleles was determined using PCR and agarose gel electrophoresis. DNA of 100 blood donors without FA was used as control group.

Results: According to the median of repeats all FA patients were divided into 2 groups (Gr. 1: patients with repeat value below than the median; Gr. 2: patients with repeat value above than the median). Interventricular septal thickness was significantly smaller in Gr. 1 of FA patients (10.8 ± 1.8 mm) compared to Gr. 2 (12.3 ± 2.4 mm; $P < 0.02$). Moreover, a positive correlation was demonstrated between the number of repeats on longer allele and ratio interventricular septal thickness/posterior wall thickness ($r = 0.96$; $P = 0.054$).

In conclusion, increased size of GAA repeats is associated with left ventricular wall hypertrophy in FA patients. These data suggest that the unstable GAA repeat expansion might influence cardiac hypertrophy in FA patients.

2543 Are sporadic cardiac myxomas a DNA repair-deficient disease?

J. Parissis[1,3], G. Sourvinos[1], D. Arvanitis[2], S. Karas[3], F. Sotsiou[4], D.A. Spandidos[1]. [1]*Medical School of Crete, Heraclion;* [2]*Medical School of Thessaly, Larissa;* [3]*Amalia Fleming Hospital, Athens;* [4]*Evangelismos Hospital, Athens, Greece*

Objective: A recently discovered feature of the neoplastic cells is the elevated mutational rate which is reflected in the instability of the microsatellite DNA (microsatelite instability, MIN). MIN is an early event in DNA repair-deficient diseases and its implication in the pathogenesis of sporadic cardiac myxomas has not been previously investigated. The aim of our study was to analyse the incidence of MIN in sporadic cardiac myxomas, as a possible pathogenetic mechanism of these rare neoplasms.

Methods: Eleven surgically excised sporadic cardiac myxomas were assessed for MIN using 30 highly polymorphic microsatelite markers (Research Genetics, Inc, USA) located on a wide range of chromosomal arms. DNA was extracted from myxoma tissue specimens as well as the respective normal tissue and subjected to polymerase chain reaction (PCR). PCR products were electrophoresed in a 10% polyacrylamide gel and silver stained. MIN was scored by comparing the electrophoretic pattern of the microsatellite markers amplified from the paired DNA preparations (pathological/normal tissue). The analysis in the MIN positive cases was repeated at least twice and the results were highly reproducible.

Results: Microsatellite analysis showed that 7 cardiac tumors (64%) exhibited MIN in at least one marker. Five specimens were classified as tumors with high MIN (unstable for $\geq$2 genetic loci), while the other 2 specimens as tumors with low MIN (unstable for <2 genetic loci). The highest incidence of MIN was found for the marker D17s855, which lies within BRCA1. Other markers with high incidence of MIN were D17s250 (proximal to BRCA1) and D17s579. MIN was more frequently detectable in chromosome 17 than the other studied chromosomes. No association was found between the presence of MIN and the age, the tumor location or the tumor size.

Conclusions: MIN is a highly detectable phenomenon in sporadic cardiac myxomas indicating the presence of a decreased fidelity in DNA replication and repair in myxoma tissue. This observation suggests that sporadic cardiac myxomas may be a DNA repair-deficient heart disease.

PULMONARY HYPERTENSION: NEW PHARMACOLOGIC APPROACHES

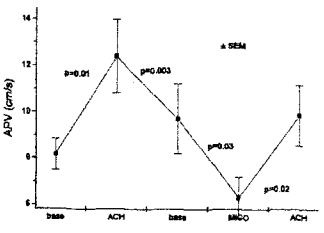
2554 Vasoconstriction in pulmonary hypertension by potassium channel blockade

E. Wellnhofer, A. von Stammer, R. Ewert[2], C. Opitz[1], E. Fleck, F.X. Kleber[1]. *Dept. of Int. Med./Cardiol., Campus Virchow, Charité, HU & DHZB;* [1]*Dept. of Int. Med., Unfallkrankenhaus Berlin;* [2]*Dept. of Cardiothoracic & Vasc. Surg. DHZB, Berlin, Germany*

Potassium channels are supposed to be involved in the regulation of the basal vascular tone in pulmonary hypertension (PH) based on experimental evidence. Objective: A clinical evaluation of the interaction of endothelium-dependent residual vasodilatatory reserve with potassium channel blockade in PH.

Methods: In 8 patients with severe pulmonary hypertension (mean pulmonary artery pressure 54 $\pm$ 9 mmHg; pulmonary vascular resistance 17 $\pm$ 7 mmHg l^{-1} min) local vasoreactivity was tested in a pulmonary branch artery by infusion of 10^{-5} M acetylcholine (ACH) at baseline and after blockade of K^+ channels (K^+blockade) using 10^{-5} M miconazol. Average peak blood flow-velocity (APV) was determined using a 0.014" Doppler guidewire. Local diameters were controlled by intravascular ultrasound.

Results: Significant changes of systemic hemodynamics could be avoided by local testing. Local diameter changes could be ruled out. A reduction of local flow velocity (8 cm/s to 4 cm/s, $p < 0.05$) was associated with K^+blockade. Absolute flow velocity increase following infusion of acetylcholine was not impaired by K^+blockade suggesting independent mechanisms.



Conclusions: Potassium channels are involved in maintaining the basal flow in patients with PH. Drugs with potassium channel blocking side-effects may be deleterious and potassium channel opening may be an important therapeutic target in the treatment of PH and may explain the positive experience with iloprost combining potassium channel opening and PGI2 stimulation. Functional testing by ACH may fail to diagnose the role of endothelial hyperpolarizing factor in PH.

2555 Efficacy and safety of UT-15, a prostacyclin analogue, for primary pulmonary hypertension

V. McLaughlin, R. Barst, S. Rich, L. Rubin, E. Hom, S. Gaine, S. Blackburn, J. Crow. *Rush Medical College, Chicago IL; United Therapeutics Corp., Research Triangle Park NC, USA*

Primary pulmonary hypertension (PPH) is a severe and potentially fatal disease. Chronic intravenous prostacyclin (PGI2) improves exercise tolerance, hemodynamics, and survival in PPH, but at the expense of infections and other complications due to the nature of the delivery system and instability of the drug. UT-15, a stable PGI2 analogue with a longer half life, may be given subcutaneously, obviating the need for a permanent central venous catheter. The primary objective of this study was to assess the safety of chronically administered continuous subcutaneous infusion of UT-15 in PPH. Twenty-six patients with PPH (NYHA Class III/IV) were enrolled in a multicenter, double-blind, placebo-controlled, 2:1 randomized, 8 week trial. UT-15 or placebo was initiated at 2.5 or 5.0 ng/kg/min and the dose was adjusted based on PPH symptoms or on adverse events attributable to the study drug. There were 5 men and 21 women with a mean age of 35 $\pm$ 20 years. Baseline hemodynamics (PVR 13.9 units and 15.2 units) and exercise capacity as measured by the six minute walk test (372 m and 384 m) were similar in the UT-15 (n = 17) and placebo (n = 9) groups. The mean infusion rate for the UT-15 group was 14.5 $\pm$ 2.6 ng/kg/min and for the placebo group was 38.9 $\pm$ 6.7 ng/kg/min. Two patients did not complete the study because of intolerable side effects. The most common side effects were: headache (76%), diarrhea (59%), nausea/vomiting (59%), flushing (47%), and jaw pain (35%). Of patients randomized to UT-15, 88% of the patients experienced pain and 94% erythema at the injection sites, which was adequately controlled with treatment. One patient (11%) randomized to placebo experienced pain and erythema at the injection sites. Walk distance improved by 28 $\pm$ 11 m (8%) in the UT-15 group while it declined by 6 $\pm$ 27 m (1%) in the placebo group. Pulmonary vascular resistance index declined by 5 $\pm$ 1 unit in the UT-15 group while it increased by. 3 $\pm$ 2 in the placebo group. UT-15 is a safe treatment of PPH and affects hemodynamics and exercise tolerance favorably.

2556 Effect of inhaled Iloprost® on pulmonary artery pressure: results of an acute haemodynamic study and one month follow-up

Friedrich M. Fruhwald, Christian Hesse, Martin Trinker, Werner Klein. *Karl-Franzens-University of Graz, Austria*

Background: Currently prostacyclin is the gold standard for treatment of pulmonary hypertension. Prostacyclin leads to marked improvement in haemodynamics and outcome in primary pulmonary hypertension. The major shortcomings of Epoprostenol® are tachyphylaxis and the need for a central venous line. Iloprost® is a stable analogue of Epoprostenol® with longer half-life but similar pharmacological properties. Both Epoprostenol® and Iloprost® can be aerosolised with similar effects on haemodynamics compared to intravenous application. The role of inhaled Iloprost® in long-term treatment of pulmonary hypertension, however, is still unclear.

Methods: We investigated 11 patients (2 male, 9 female; mean age 46 $\pm$ 19 years) with pulmonary hypertension. Four patients suffered from primary and seven patients from secondary pulmonary hypertension. Before haemodynamics were studied patients underwent transthoracic echocardiography with assessment of pulmonary artery pressure by Doppler. Haemodynamics were studied using a Swan-Ganz-catheter. After assessment of pulmonary pressure and pulmonary vascular resistance 20 μg of Iloprost® were inhaled and haemodynamics were reassessed. The daily dose of inhaled Iloprost® was 100 μg. Doppler echocardiography was used as a follow-up tool.

Results: All but one patient responded to inhaled Iloprost® with a fall of pulmonary pressure or resistance. There was a good correlation between Doppler-estimated pulmonary artery pressure and invasively measured pulmonary artery pressure ($r = 0.704$, $p < 0.05$). After inhalation of Iloprost® there was a significant fall in right ventricular systolic pressure from 82 $\pm$ 21 to 62 $\pm$ 20 mmHg ($p = 0.01$), pulmonary artery systolic pressure from 84 $\pm$ 23 to 70 $\pm$ 23 mmHg ($p = 0.02$) and in pulmonary vascular resistance from 718 $\pm$ 460 to 548 $\pm$ 353 dyn.sec.cm^{-5} ($p < 0.05$). Iloprost® had no effect on right atrial pressure and on pulmonary capillary wedge pressure. No side effects were observed. After one month there was no change in Doppler estimated pulmonary artery pressure compared to pretest levels (75 $\pm$ 20 vs 73 $\pm$ 20 mmHg, p: n.s.).

Conclusion: In patients with pulmonary hypertension inhaled Iloprost® leads to acute improvement of haemodynamic parameters. Furthermore, Iloprost® has the potential to keep pulmonary pressure stable, although no further improvement was seen after four weeks. The reason for this is unclear. Therefore, further investigations are needed to elucidate the role of Iloprost® in the treatment chronic pulmonary hypertension.

2557 Sustained effect of beraprost sodium in patients with primary and secondary pulmonary hypertension

C.D. Vizza, S. Sciomer, S. Morelli, P. Di Marzio, B. Pezza, C. La Valle, D. Padovani, A. Di Roma, C. Iacoboni, M. Servigniani, F. Fedele. *Dept. Cardiovasc and Respiratory Sciencee & I Toracic Surgery University of Rome, Italy "La Sapienza"*

Clinical and hemodynamic effects of long-term beraprost sodium treatment in patients with severe pulmonary hypertension were studied. Eight patients (1 male, 6 female; age 49 ± 8 years) with vascular lung disease (4 primary pulmonary hypertension, 3 chronic pulmonary tromboembolism, 1 Eisenmenger' syndrome), and severe hemodynamic impairment (RAP 6 ± 4 mmHg, PAPm 54 ± 7 mmHg, PCWP 5 ± 3 mmHg, CI 1.7 ± 0.4 L/min/m^2) received beraprost sodium (1–2 mcg/kg a day in 3 or 4 administrations) in adjunction to standard therapy (oral anticoagulants, digoxin, furosemide, enalapril, nifedipine). During the first 3 weeks the starting dose (20 mcg t.i.d.) was increased as tolerated, and in case of systemic hypotension (SBP < 100 mmHg) the dose of enalapril or nifedipine was reduced. Functional class (NYHA), effort tolerance (six minute walk test, 6MWT) and systolic pulmonary pressure by echo-Doppler study of tricuspid regurgitation (PAPs) were evaluated at baseline, at one and three months. During follow-up we had no drug-related major side-effects. One patient died for refractory congestive heart failure within 40 days.

Results:

	Baseline	1 month	3 month	p <
NYHA class	3.7 ± 0.4	3.1 ± 0.6	2.6 ± 0.5	^°°
6MWT, mt	200 ± 68	241 ± 80	299 ± 65	^°°
PAPs, mmHg	98 ± 21	88 ± 18	83±	^°°

^/^ = p < 0.01/<0.001 1 month vs baseline; °/°° = p < 0.01/<0.001 3 months vs Baseline

Conclusion: Beraprost causes a significant and sustained reduction in PAPs with a concomitant improvement in functional class and effort tolerance These promising data should be confirmed in a larger double-blind study in order to define the potential role of this oral-active PGI2 derivative as a therapeutic option in pulmonary hypertension.

2558 Endotoxin challenge markedly alterates regulation of the endogenous pulmonary endothelin system

T. Dschietzig, K. Alexiou, M. Bobzin, J. Koch, K. Stangl, F. Brunner[1]. *Charité Berlin, Medizinische Klinik I, Berlin, Germany[1] Karl-Franzens-Universität Graz, Institut für Pharmakologie, Graz, Austria*

Recently, the pulmonary endothelin (ET) system has been shown to play a major role in sepsis-induced adult respiratory distress syndrome (ARDS). However, only rare data exist on the regulation of endogenous pulmonary endothelins under basal and septic conditions. We investigated, therefore, in isolated, blood-free perfused rat lungs pulmonary vascular release of big ET-1 and ET-1 under baseline conditions and after endotoxin challenge using different pharmacological approaches. Control lungs (n = 7) released 14.6 ± 1.5 pg/ml big ET-1 and 0.49 ± 0.07 pg/ml ET-1 over 2 h. Endotoxin challenge (n = 7) significantly (p < 0.05) increased big ET-1 (1.5fold) and ET-1 (1.4fold). A-127722, an ETA receptor-selective antagonist (100 nM, n = 7), did not affect peptides under basal conditions, but significantly decreased big ET-1 (0.6fold) without affecting ET-1 after endotoxin. A-192621, an ETB receptor-selective antagonist (500 nM, n = 6), markedly elevated basal ET-1 (2.6fold). This effect disappeared after endotoxin challenge; big ET-1 was not changed by A-192621. Inhibition of nitric oxide (NO) synthesis by L-NOARG (100 μM, n = 6) did not influence basal release of ET peptides, but lessened endotoxin-stimulated big ET-1 (0.45fold) without changing ET-1. ODQ, an inhibitor of soluble guanylyl cyclase (sGC) (20 μM, n = 6), and meclofenamic acid, an inhibitor of cyclooxygenase (COX)(50 μM, n = 6–10) had no effect on basal or endotoxin-stimulated peptide release. We conclude that basal pulmonary release of big ET-1 and ET-1 is modified neither by NO, sGC, nor by COX. Furthermore, elevation of basal ET-1 by ETB receptor blockade indicates stoichiometric binding conditions prevailing in pulmonary vasculature. Abolition of this effect after endotoxin challenge points to an alteration of the functional status of ET receptors during sepsis. We suggest that the decrease in endotoxin-stimulated release of big ET-1 by ETA and ETB receptor blockade, and by inhibition of NO synthesis is either due to hightened activity of endothelin-converting enzyme or alteration of receptor affinity for big ET-1. The present findings demonstrate a complex alteration of ET receptor status and/or regulation of peptide synthesis by endotoxin, which has to be considered when using ET antagonists in septic ARDS.

2559 Endothelin-A receptor antagonism improves pulmonary and systemic haemodynamics in patients with severe pulmonary hypertension

S. Apostolopoulo, Z. Kyriakides[1], D.J. Webb[2], G. Karavolias[1], G. Kyrvassilis, D. Kremastinos[1], S. Rammos. *Paediatric Cardiology Division, Onassis Cardiac Surgery Center, Athens; [1]2nd Cardiology Division, Onassis Cardiac Surgery Center, Athens, Greece; [2]Univ of Edinburgh, UK, Western General Hospital*

Endothelin-1, a powerful vasoconstrictive peptide, has been implicated in the pathophysiology of pulmonary hypertension (PH) by various investigators. The purpose of this study was to evaluate the effect of a short-term administration of an endothelin A (ET_A) receptor antagonist in patients with severe chronic PH.

Methods: The study group consisted of 10 pts (NYHA II–IV) aged 28.2 ± 14.6 yrs with severe chronic PH and systolic pulmonary artery pressure (PAP) 112.2 ± 31.8 mmHg. One pt had primary PH, 2 pts primary PH in conjunction with an atrial septal defect, 4 pts secondary PH after correction of congenital heart defects, 2 pts secondary PH with uncorrected congenital heart disease, and 1 pt secondary PH due to ischaemic heart failure. After baseline haemodynamic measurements, all pts underwent continuous infusion of BQ-123, an ET_A receptor antagonist, for 60 min at 200 mmol/min in the right atrium with haemodynamic evaluation at 30 and 60 min of the infusion and 30 min after the end of the infusion. No adverse effects were noted.

Results: Significant improvement was noted on pulmonary vascular resistance (PVR), systemic cardiac index (Qs), pulmonary cardiac index (Qp) and effective cardiac index (Qeff), with no effect on mean PAP due to the improved cardiac index.

	Baseline	60 min BQ-123	Effect	p value
PvR (Woods units)	20.6 ± 11.7	17.1 ± 11.5	↓ 16.8%	<0.005
Qs (L/min/m^2)	2.9 ± 0.8	3.3 ± 1.0	↑ 15.3%	<0.05
Qp (L/min/m^2)	4.5 ± 5.6	5.9 ± 7.5	↑ 30.1%	<0.05
Qeff (L/min/m^2)	2.5 ± 0.8	2.9 ± 1.1	↑ 17.7%	<0.05
mean PAP (mmHg)	75.3 ± 23.0	73.5 ± 22.4	NS	NS

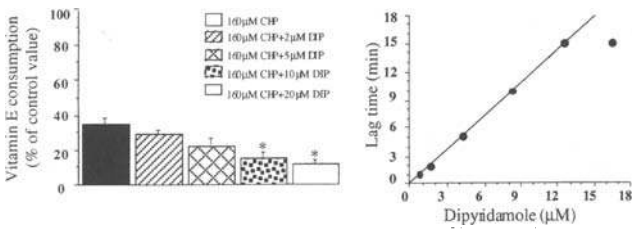
Conclusion: Short-term administration of ETA receptor antagonist significantly improves haemodynamics in pts with severe chronic PH. New avenues for further research on endothelin antagonists as treatment options in this prognostically poor patient population need to be pursued.

OXIDANT STRESS AND ANTIOXIDANT THERAPY

2560 Dipyridamole as an antioxidant agent ex vivo

C. Kusmic, C. Busceti, C. Petersen, E. Picano, R. Barsacchi[1]. *Institute of Clinical Physiology, CNR, Pisa; [1]Department of Physiology and Biochemistry, University of Pisa, Italy*

To test the antioxidant effect of therapeutic doses of dipyridamole on cellular membranes, red blood cells were chosen as an appropriate model to study oxidative stress induced by hydroperoxides because of their high content in heme-Fe^{2+}. The oxidative stress was induced by incubation with 160 μM cumene hydroperoxide (CHP) and expressed by three main factors: lipid peroxidation by means of kinetics of decrease in fluorescence emission of the probe incorporated in the cell membranes, vitamin E consumption and intracellular thiol content. The concentrations of dipyridamole tested (2–20 μM) did not exceed human pharmacological doses. After 7 minutes of incubation at 25°C with the oxidant and 20 μM dipyridamole thiol content was 50.1% ± 2.6 compared with 31.5% ± 2.4 (n = 10) in the absence of the drug. After 12 minutes vitamin E consumption was reduced to 11.7% ± 2.3 compared with 35.3% ± 3.4 (n = 11) in the absence of dipyridamole. Dipyridamole added five minutes after the oxidation reaction suppressed the fluorescence decay for a time proportional to the drug concentration.



In conclusion, at clinically realistic doses dipyridamole shows a definite, concentration-dependent anti-oxidant effect. It protects membranes from oxidation and spares the antioxidant power of red blood cells.

2561 Production of oxygen radicals during hypoxia and reoxygenation induces cellular damage and pH changes in cardiac myocytes: possible stimulation for post-ischaemic matrix remodelling

C.F. Peng, G.A.J. Riegger, A. Sigel. *Klinik fuer Innere Medizin II, Universitaet Regensburg, Regensburg, Germany*

Introduction: The common inducers of necrosis and programmed cell death (apoptosis) include oxygen free radicals, which are also implicated in the pathogenesis of myocardial ischemic reperfusion injury. In addition, ischemia-induced acidosis may contribute to activation of growth factors and, thus, to remodeling of the cardiac extracellular matrix. Therefore, the present study was designed to establish a reliable cell culture model of necrosis and apoptosis, to link production of oxygen radicals to biochemical parameters of cellular damage and to find protective mechanisms to maintain a physiological pH during ischemic reperfusion injury.

Methods: Neonatal rat myocytes were cultured in 2% oxygen for 24 hours to produce hypoxic conditions and then exposed to 20% oxygen for additional 12 hours to simulate reoxygenation.

Results: Hypoxia and reoxygenation stimulated the production of oxygen radicals, as indicated by decreased glutathione concentrations. Further, they decreased extracellular pH and increased lactate concentrations ($p < 0.05$). However, both pH as well as production of oxygen radicals depended on the beating rate of cardiac myocytes, since quiescent myocytes neither changed pH nor produced significant amounts of oxygen radicals during hypoxia. In addition, hypoxia lead to a 10-fold increase in LDH leakage ($p < 0.05$) and an almost complete loss in creatine kinase (CK) activity ($p < 0.05$). Furthermore, reoxygenation was followed by nucleosomal DNA fragmentation that was detectable by gel electrophoresis (DNA ladder) as well as significant induction of Fas receptor, cytochrome c and caspase 3, mediators of apoptotic cell death. In order to investigate whether acidosis is due to anaerobic glycolysis and lactate production we treated normoxic myocytes with hydrogen peroxide (H_2O_2). Dose-dependent studies documented the same acidosis with increasing doses of H_2O_2. In addition, anti-oxidants, such as carvedilol, BM 91.0228 or vitamin E maintaned a physiological pH during hypoxia and reoxygenation. Furthermore, they partially inhibited LDH and CK leakage and completely inhibited morphological features of apoptosis as well as DNA laddering. Finally, anti-oxidative treatment prevented the induction of Fas receptor, cytochrome c and caspase 3, following reoxygenation.

Conclusion: Taken together, these results suggest that hypoxia alone induces significant production of oxygen radicals, and, thus, may lead to necrosis and apoptosis. In addition, they document the acidic effect of oxygen radicals on extracellular pH, which can be prohibited by treatment with anti-oxidants.

2562 Protective effects of antioxidant enzymes during low-flow ischaemia and reperfusion in the aged rat heart

P. Assayag[1,2], S. Tanguy[1], J. de Leiris[1], M.C. Toufektsian[1], F. Boucher[1], B. Swynghedauw[3], S. Besse[1]. *[1]ESA CNRS 5077, Université Joseph Fourier, Grenoble; [2]Service de Cardiologie Hôpital Bichat; [3]INSERM U127, Paris, France*

Antioxidant enzymes (AOE) have protective effects in adult heart after no-flow ischemia. The aged heart is more vulnerable to low-flow ischemia, and has reduced AOE activities. We investigated the effects of AOE during both low-flow ischemia (LFI) and ischemia-reperfusion (I/R), in adult and in aged myocardium. In the LFI protocol, isolated hearts from 4 and 24 month old rats were subjected to an ischemic perfusion at 15% of their initial coronary flow without (4 I, n = 13; 24 I, n = 15) or with AOE (superoxide dismutase + catalase, 50 UI/ml) (4 I-E, n = 10; 24 I-E, n = 10). Active tension (AT) and coronary resistance (CR) were recorded at baseline, 30 and 60 min of perfusion. In the I/R protocol AT and coronary flow (CF) were recorded at baseline and after 30 min of reperfusion following 45 min of non-paced low-flow (15%) ischemia, without (4 I/R, n = 9; 24 I/R, n = 9) or with AOE (4 I/R-E, n = 7; 24 I/R-E, n = 8).

Results: Mean ± SEM in % of baseline value.

LFI	AT		CR	
	30 min	60 min	30 min	60 min
4 I	25 ± 4	17 ± 3	478 ± 80	655 ± 126
4 I-E	40 ± 5*	34 ± 5*	220 ± 33*	237 ± 37*
24 I	18 ± 2	18 ± 3	760 ± 112†	885 ± 108
24 I-E	28 ± 4*	18 ± 3	343 ± 128*	386 ± 100*

*$p < 0.05$ vs age-matched group, †$p < 0.05$ 24 mo vs 4 mo I and I/R group.

I/R	AT	CF
	30 min	30 min
4 I/R	77 ± 4	73 ± 6
4 I/R-E	73 ± 3	127 ± 18*
24 I/R	50 ± 7†	52 ± 9†
24 I/R-E	74 ± 5*	116 ± 13*

*$p < 0.05$ vs age-matched group, †$p < 0.05$ 24 mo vs 4 mo I and I/R group.

In conclusion: 1) AOE improve contractile and coronary dysfunction induced by prolonged low-flow ischemia in adult and aged hearts, but with a less sustained effect in the aged hearts 2) Reperfusion-induced contractile and coronary dysfunctions are greater in the senescent heart and 3) AOE significantly prevent these reperfusion-induced alterations in the aged heart, indicating a major role of oxidative stress during reperfusion in aged rats.

2563 Myocardial dysfunction is also induced by application of polymorphonuclear granulocytes at different times of ischaemia/reperfusion via release of reactive oxygen species

C. Seligmann, A. Bock, M. Schimmer, Y. Simsek, T. Leitsch, U. Rauch, C. Tschoepe, H.P. Schultheiss. *Department of Cardiology, University Hospital Benjamin Franklin, Berlin, Germany*

It is well known that polymorphonuclear granulocytes (PMN), applicated in early reperfusion, significantly contribute to ischemia-reperfusion injury. In addition to this well-known fact, we investigated in the present study whether PMN applicated at different times of ischemia/reperfusion are also able to induce a myocardial dysfunction.

Isolated, perfused and pressure-volume work performing guinea pig hearts were exposed to a 30 min low-flow ischemia (1 ml/min), reperfused (5 ml/min) and PMN (1.000/μl perfusion buffer) were applicated as 1 min bolus during the 15th min of ischemia or in the 1st or 5th min of reperfusion in the presence of thrombin (0.3 U/ml perfusion buffer), respectively. Intracoronary PMN-retention (RET in percent of PMN applied) and recovery of external heart work (REHW-postischemic external heart work in percent of preischemic external heart work) were quantified. In further experiments, superoxide-dismutase (SOD) was added (10 U/ml perfusion buffer) to examine whether a potential PMN-induced myocardial dysfunction is mediated by release of reactive oxygen species during ischemia. Ischemic and reperfused hearts without PMN application in the presence of thrombin (REHW) or non-ischemic hearts with PMN application in the presence of thrombin (RET) served as controls.

Application of PMN during ischemia, the 1st or the 5th min of reperfusion significantly reduced REHW (62.6 ± 5%, 63 ± 4% or 66.8 ± 4%, respectively) as compared with control (91.6 ± 2%). RET significantly increased (70 ± 3%, 35 ± 4 or 41 ± 7, respectively) as compared with control (10 ± 3%). Coapplication of SOD led to a significant increase of REHW (81 ± 4%, 81.8 ± 2 or 83 ± 3, respectively), RET was almost unchanged by these measures, however.

We conclude that PMN are able to induce a reactive oxygen species-mediated myocardial dysfunction at all times of the ischemia-reperfusion process.

2564 Carvedilol inhibits hypoxia- and reoxygenation-induced necrosis and apoptosis in cardiac myocytes: evidence for cardioprotection by antioxidants

A. Sigel, C.F. Peng, G.A.J. Riegger. *Klinik fuer Innere Medizin II, Universitaet Regensburg, Regensburg, Germany*

Introduction: Necrosis and programmed cell death (apoptosis) are recognized as causes of cardiac myocyte loss with ischemia- and reperfusion-induced injury. The present study was designed to establish a reliable cell culture model of necrosis and apoptosis in-vitro, to link morphological findings to biochemical parameters of cellular damage and to compare the effects of carvedilol, a hybrid drug involving beta-1, beta-2 and alpha blocking as well as anti-oxidative properties, with its anti-oxidative metabolite BM 91.0228 and the non-selective adrenergic beta-blocker propranolol.

Methods: Neonatal rat myocytes were cultured in 2% oxygen for 24 hours to produce hypoxic conditions and then exposed to 20% oxygen for additional 12 hours to simulate reoxygenation. Drug treatment started 2 hours prior to hypoxia either with carvedilol (3 μM), BM 91.0228, propranolol or vehicle for the entire duration of hypoxia and reoxygenation.

Results: Hypoxia and reoxygenation significantly decreased intracellular glutathione concentrations, indicating stimulated production of oxygen radicals. In addition, in vehicle and propranolol treated cells hypoxia lead to a 10-fold increase in LDH leakage ($p < 0.05$) and an almost complete loss in creatine kinase (CK) activity ($p < 0.05$). This pattern of severe necrosis further increased after additional 12 hours of reoxygenation. Furthermore, in vehicle and propranolol treated cells reoxygenation was followed by nucleosomal DNA fragmentation that was detectable by gel electrophoresis (DNA ladder) as well as significant induction of Fas receptor, cytochrome c and caspase 3, mediators of apoptotic cell death. By contrast, carvedilol and BM 91.0228 partially inhibited LDH and CK leakage and completely inhibited morphological features of apoptosis as well as DNA laddering. Finally, both drugs prevented the induction of Fas receptor, cytochrome c and caspase 3, following reoxygenation.

Conclusion: Taken together, these results suggest that reoxygenation augments hypoxia-induced necrosis and apoptosis in cardiac myocytes. In addition, they indicate that the induction of Fas receptor, cytochrome c and caspase 3 may set the stage for this process. They further document that the anti-oxidative properties of carvedilol and BM 91.0228 prevent both necrosis and apoptosis. These effects could not be seen with non-selective beta-blockade alone, and, thus may indicate the cardioprotection of anti-oxidative therapy.

2565 Superoxide anion but not nitric oxide is released from neutrophils in the response to stimuli released from myocardium during coronary angioplasty

R. Parucki, M. Słomczyński, J. Rzezniczak, A. Szczepanik, R. Kalawski, H. Wysocki, D. Angerer, J. Mańczak, T. Siminiak. *J. Strus Hospital and University Medical Sciences, Poznan, Poland*

Background. Activated neutrophils (PMN) are known to be a rich source of free oxygen radicals, including the superoxide anion (O_2^-), in the ischaemic and reperfused myocardium. Free oxygen radicals contribute to the development of myocardial reperfusion injury. Activated PMN have also been shown to release, in certain pathophysiological conditions, vasodilator nitric oxide (NO). PMN activation has been evidenced to occur as a result of myocardial ischaemia and/or endothelial injury during coronary angioplasty (PTCA). This may be related to PMN direct contact with the endothelium or a response to PMN-oriented stimuli.

Aim. To verify whether PTCA procedure results in the release of mediators capable of stimulation of O_2^- and NO production by PMN.

Methods. 18 patients (aged 38–65; mean 47 years) scheduled for PTCA of proximal stenoses in LAD were enrolled. Coronary sinus and arterial plasma samples were taken before balloon inflation (I), immediately after the first deflation (II) and 5 min. after the last deflation (III). Plasma samples were incubated with PMN obtained from healthy donors and O_2^- and NO production were measured by spectrophotometric assays.

Results.

	Superoxide anion nmol/5 × 10^6 PMN/10 min		Nitric oxide nmol/10^7 PMN/30 min	
Plasma from:	cor. sinus	artery	cor. sinus	artery
I	16.1 ± 2.1	15.8 ± 2.2	17.1 ± 4.2	22.4 ± 7.2
II	27.8 ± 2.8*#	16.1 ± 2.6	19.1 ± 5.1	20.8 ± 5.1
III	19.1 ± 1.9	16.9 ± 2.1	21.8 ± 5.9	21.5 ± 4.9

Mean values ± SEM, *$p < 0.05$ vs artery #$p < 0.05$ vs. I and III;

Conclusion: Mediators stimulating neutrophil O_2^- but not NO production are released to the coronary sinus after balloon deflation during PTCA.

GUIDANCE FOR PERCUTANEOUS INTERVENTIONS (PART II)

2575 30 months follow up of an IVUS-guided balloon angioplasty

A.W. Frey, G.W. Stone[1], F.G. StGoar[2], T.H. Linnemeier[3], H. Mudra[4], J.M. Hodgson[5]. *Kardiologie Abteilung, Herz-Zentrum, Bad Krozingen, Germany; [1]Cardiovascular Research Foundation, Washington DC; [2]Cardiovascular Institute, El Camino Hospital, Mountain View; [3]St. Vincents Hospital, Indianapolis MA, USA; [4]Kardiologie Abteilung, Städt. Krankenhaus Neuperlach, Munich, Germany[5]Cardiology Dept, MetroHealth Hospital, Cleveland, USA*

The CLOUT Study showed that quantification of arterial remodeling by means of IVUS allows oversizing of balloons resulting in improved angiographic outcome. The longterm outcome of this strategy was obtained at a clinical follow up (median time 2.5 years, range 25–75%: 1.8–3.3 years) in 97 of 100 pts from CLOUT without CABG.

Results:

Patients: Diabetes 21%, 41% prior MI, 61% multivessel disease. Mean reference vessel diameter:2.68 ± 0.48, mean balloon diameter: 3.38 ± 0.43, balloon/artery ratio: 1.30 ± 0.16. QCA analysis showed reduction of%diameter stenosis from 73 ± 16 to 19 ± 14. Final minimal area by IVUS was 4.3 ± 1.2 mm. At 30 month follow up 6.3% pts died (2.1% cardiac, 4.1% had MI and 27.5% had TLR, including 5.2% CABG and 22.3% re-PTCA). Thus cardiac death MI or TLR occurred in 28 (28.9%) pts. Non-TLR also was required in 19.6% pts. Independent multivariate predictors of TLR were diabetes ($p = 0.04$) reference segment plaque area ($p = 0.04$) and vessel size (EEM) ($p = 0.02$).

Conclusions: Despite improved procedural results with IVUS guided balloon sizing in the relative small vessels in CLOUT late adverse events still occurred frequently from recurrent disease at the target site and progressive disease elsewhere. Future strategies must therefore focus on even more aggressive approaches to reduce restenosis and stabilize atherosclerotic plaque.

2576 Hyperemic coronary flow after optimized intravascular ultrasound-guided balloon angioplasty and stent implantation

R.A.M. van Liebergen, J.J. Piek, K.T. Koch, R.J.G. Peters, R.J. de Winter, K.I. Lie. *Cardiology Dept., B2, Academic Medical Center, Amsterdam, Netherlands*

Recent studies indicate the safe coronary luminal enlargement and "stent-like" long-term outcomes using upsized balloons guided by intravascular ultrasound (IVUS).The present study evaluates the acute physiological gain of adjunctive IVUS-guided balloon angioplasty and stent implantation.

Methods: After angiograpically guided balloon angioplasty in 20 patients with 1-vessel disease and normal left ventricular function, IVUS was performed to determine the size of the adjunctive balloon using the mean of the maximal luminal diameter and the maximal diameter of the external elastic membrane measured in the adjacent proximal and distal reference segments. Serial adenosine-induced hyperemic blood flow velocity measurements were performed, using a 0.014" Doppler guide wire, to determine the physiological lumen obstruction after standard balloon angioplasty, followed by IVUS-guided balloon angioplasty and stent implantation.

Results: Upsized balloon angioplasty (increase balloon size: 0.98 ± 0.26 mm; balloon:artery ratio 1.35 ± 0.21) resulted in an additional increase of arterial dimensions: minimal lumen diameter (MLD) 2.18 ± 0.38 mm to 2.73 ± 0.51 mm;%diameter stenosis (%DS) 34 ± 13% to 19 ± 22%; IVUS assessed minimal lumen area (MLA) 7.53 ± 1.55 mm^2 to 10.24 ± 2.22 mm^2 (all $P < 0.0001$). Major dissections (* type C) did not occur. Hyperemic blood flow velocity increased from 49.8 ± 20.1 cm/s to 59.1 ± 22.9 cm/s ($P < 0.05$) after IVUS-guided balloon angioplasty. Adjunctive stent implantation resulted in a further increase of MLD to 3.84 ± 0.51 mm,%DS to −9 ± 21% and MLA to 13.39 ± 1.80 mm^2 (all $P < 0.0001$), while hyperemic blood flow velocity remained unchanged (61.2 ± 24.7 cm/s, $P = 0.7$).

Conclusions: Upsized IVUS-guided balloon angioplasty increases arterial coronary dimensions and the distal hyperemic blood flow velocity. Adjunctive stent implantation does not yield a further gain in the hyperemic blood flow velocity, indicating the absence of a functional residual lumen obstruction after IVUS-guided balloon angioplasty. These findings may explain a stent-like clinical outcome reported after IVUS-guided balloon angioplasty.

2577 Predictors of coronary flow reserve before and after balloon angioplasty

M. Albertal, G. Van Langhenove, P. Serrano, S.G. Carlier, M.A. Costa, R.T. van Domburg, C. Di Mario, E. Verna, C. Hanet, P.W. Serruys. *On behalf of the Debate I investigators, Thoraxcenter and Cardialysis, Rotterdam, Netherlands; Centro Cuore Columbus, Milan; Ospedale di Circolo, Varese, Italy; Clinique St. Luc, Brussels, Belgium*

A coronary flow reserve (CFR) cut-off value of 2.5 after balloon angioplasty (BA) has been shown to be a predictor of 6-month clinical outcome. The influence of coronary risk factors (RF) and vessel geometry in predicting a cut-off value of coronary flow reserve of 2.5 before and after balloon agioplasty have not been studied in a prospective fashion.

Methods: 225 consecutive patients undergoing BA were evaluated as part of Debate I study. Intracoronary Doppler (ID) measurements of the target vessel were performed before and after BA. We investigated the predictive power of RF and quantitative angiographic measurements (QCA) on the binary distribution of the cutoff value of CFR before and after BA.

Results: By multivariate logistic regression, diameter stenosis before BA{(DS), odd ratio (OR): 1.20; confidence interval (CI): 1.06–1.35} was found as independent predictors of a CFR < 2.5 before BA. Post-BA, increasing age (OR: 1.06; CI: 1.02–1.10) and female gender (OR:2.99; CI:1.18–7.58) appeared to be independent predictors of a CFR after BA. No other angiographic (cross-sectional area, minimun luminal diameter, acute gain, lesion length, collateral supply, Ambrose lesion type classification and coronary segment) or patient demographics (diabetes mellitus, family history, hypertension, hypercholesterolemia) were independent predictors of a low CFR before or after BA.

Conclusion: 1) preintervention, the only determinant of CFR in significant lesions was the DS. 2) After BA, age and female gender appeared to have an influence attenuating the CFR. 3) CFR before BA or QCA mesurements post-BA did not predict CFR post-BA. 4) Aiming for an adequate CFR post-BA in the female and elderly groups lower values may be required. This should be taken into consideration while assessing the results of interventional procedures with intracoronary Doppler.

2578 Six-month quantitative angiographic and intracoronary ultrasound (ICUS) outcome obtained by ICUS-guided "stent-like" balloon angioplasty: a comparison with stent implantation

Y. Ozaki, T. Yasukawa, H. Tukamoto, H. Hattori, M. Maekawa, M. Kakihana, H. Shinjo, K. Takagi, Y. Oki, T. Kobayashi. *Aichi Medical University, Nagakute, Japan*

We hypothesized that stent-like balloon angioplasty (BA) guided by intracoronary ultrasound (ICUS) may convey a favourable long-term outcome.

Methods: To test this hypothesis, we prospectively performed ICUS guided BA and 6-month angiographic and ICUS follow-up (fup) in 77 patients. Balloon sizing was performed using ICUS guidance where maximum balloon size was related to maximal vessel area at the lesion site. A "stent-like" result was defined as a minimal luminal area (MLA) > 70% of reference lumen area (Ref-LA) by ICUS, <30% residual diameter stenosis by QCA, and no dissection. When stent-like results were not achieved by BA alone, a stent was implanted to fulfill this criteria. Thirty eight patients (49%) underwent BA alone and 39 (51%) required stent implantation as well. Quantitative angiographic (QCA) and ICUS examinations were performed in all patients. Angiographic restenosis was defined as ≥50% diameter stenosis by QCA.

	ICUS-guided BA Stent	p-value	
QCA:			
Ref. Diam. pre (mm)	2.92 ± 0.54	2.88 ± 0.44	ns
MLD pre (mm)	1.12 ± 0.35	1.03 ± 0.30	ns
MLD post (mm)	2.14 ± 0.44	2.63 ± 0.42	<0.01
MLD fup (mm)	1.73 ± 0.55	1.57 ± 0.49	ns
ICUS:			
MLA post (mm2)	5.89 ± 1.99	8.21 ± 2.28	<0.01
MLA fup (mm2)	5.02 ± 1.98	4.68 ± 2.77	ns
Restenosis rate	23%	22%	ns

Conclusions: Although it was only possible to achieve a stent-like result using ICUS guided BA in 49% of cases, this stent-like result does convey a favourable 6-month angiographic and ICUS outcome similar to stent implantation.

2579 Intravascular ultrasound guided stenting does not further reduce in-stent restenosis

J. Ge, R. Bhate, D. Baumgart, D. Welge, O. Oldenburg, M. Haude, S. Sack, R. Erbel. *Dept. of Cardiology, University-GH Essen, Germany*

Background: Intravascular ultrasound (IVUS) is claimed to be superior to quantitative coronary angiography (QCA) in stent implantation but, long-term results of IVUS guided vs. QCA with adjunct high pressure balloon deployment on intracoronary stenting are lacking. The purpose of the study was to compare the long-term effects of these modes of stent implantation on stent restenosis rate.

Methods and Results: From March 1994 to December 1997, 1122 patients had undergone intracoronary stenting, of which, 486 patients received IVUS guided (group A) and 636 patients received QCA guided high pressure balloon stent deployment (group B). In group A, 291 single stents (60%) and 195 (40%) multiple stents were deployed. In group B, 410 (64%) single stents and 226 (36%) multiple stents were deployed. IVUS guided stent deployment was defined as cross-sectional area in the stent > 80% of the average cross-sectional area of the proximal and distal reference segments. High pressure implantation was done with 16 ± 2 atmosphere to get residual stenosis of < 10%. The results were evaluated at a mean period of 8 ± 2 months. A total of 235 cases were found with in-stent restenosis (21%). Group A had 105 cases (39 cases with single in-stent restenosis and 66 cases with multiple stents). Group B had 130 cases (53 cases with single in-stent restenosis and 77 with multiple stents).

Stent restenosis	Single stent	Multiple stents	p
Group A (n = 105)	13.4%	33.8%	<0.001
Group B (n = 130)	12.9	34.1%	<0.001

Conclusion: IVUS guided stent deployment leads to a non significant reduction in angiographic restenosis rate compared to QCA with high pressure balloon deployment on long term evaluation. IVUS may be more cost-effective for plaque specific debulking prior to stenting.

2580 Coronary flow reserve immediately after stenting is not able to tell the late outcome

J. Qian, J. Ge, D. Baumgart, S. Sack, G. Görge, M. Haude, R. Erbel. *Dept. of Cardiology. University-GH Essen, Germany*

Studies have shown that coronary flow velocity reserve (CFVR) after intervention may predict the long-term outcome. The purpose of this study is to evaluate the value of CFVR immediately after successful stenting in the prediction of late restenosis.

Methods and Results: Intracoronary Doppler were performed using a 0.014 inch FloWire® (Cardiometrics) in 68 patients (male 57, age 59.1 ± 10.3 years) who underwent intracoronary stent implantation. Intracoronary bolus injection of adenosine (12 μg for right coronary artery and 18 μg for left coronary arteries) was used to induce maximal coronary vasodilation. Baseline average peak velocity (bAPV), hyperemic average peak velocity (hAPV) and CFVR were measured pre-, immediately post- successful stenting and at 6-month follow-up. Patients were divided into two groups according to the CFVR after stenting (Group I, CFVR ≥ 2.5, n = 37 and Group II, CFVR < 2.5, n = 31). In-stent restenosis at 6-month were compared between the two groups. A significant improvement of CFVR was observed immediately after stenting (2.63 vs. 1.89, p < 0.001). A significant higher bAPV after stenting was found in Group II compared with Group I. A total of 19 (27.9%) of 68 patients occurred in-stent restenosis at follow-up (12 in Group I, 7 in Group II). No significant difference concerning restenosis rate was found between the two groups.

	Group I n = 37	Group II n = 31	p
bAPV (cm/s)	15.4 ± 5.6	24.9 ± 12.4	<0.001
hAPV (cm/s)	48.7 ± 18.4	44.8 ± 19.5	NS
CFVR	3.26 ± 0.57	1.88 ± 0.38	<0.001
Restenosis rate (%)	32.4	22.6	NS

Conclusion: Improvement of CFVR could be obtained after successful stenting. However, CFVR immediately after stenting is not able to predict the late outcome.

MODULATION OF ENDOTHELIAL FUNCTION

2581 Nitric oxide induces a cGMP-independent intracellular calcium rise in endothelial cells

R. Berkels, R. Rösen[1], P. Khorgami[1], W. Klaus[1]. *Institut für Pharmakologie, Cologne[1] Institut für Pharmakologie, Cologne, Germany*

Nitric oxide has got various functions in biological systems. It serves as a neurotransmitter in the brain, and in higher doses as an antibacterial compound produced by macrophages. Moreover, endothelial cells release NO which regulates vascular tone and inhibits platelet aggregation and leukocyte adhesion to the vessel wall. NO diffuses from the endothelium to vascular smooth muscle cells, activating a guanylate cyclase, causing vasorelaxation. Elevated cGMP levels decrease intracellular calcium via cGMP dependent kinases.

The aim of this study was to investigate whether exogenous nitric oxide affects intracellular calcium levels in endothelial cells.

Therefore, using FURA-2 loaded porcine aortic endothelial mono-layers the influence of the synthetic NO donors S-nitroso-N-acetyl-D,L-penicillamine (SNAP) (half life of approximately 4 hours) and N-methyl-N(6-N-methylammoniohexyl)aminodiazen-1-ium-1,2-diolate (NOC-9) (half life of approximately 3 min) on intracellular calcium levels was measured. Both NO donors induced a calcium increase in endothelial cells which could be confirmed with an aqueous NO gas solution. The following investigations were performed with NOC-9. The calcium increase seems not to be due to a cGMP-dependent process since the specific inhibition of the NO-stimulated guanylate cyclase with ODQ did not diminish the NO-induced rise in calcium concentration and a treatment with the cGMP analogue 8-bromo-cGMP did not significantly increase intracellular calcium. The elevation of the intracellular calcium level is probably due to a calcium influx since the removal of extracellular calcium as well as an inhibition of receptor operated calcium influx with SKF-96365 significantly reduces the NO induced calcium increase. Thus, besides the well known negative feedback inhibition of NO on the endothelial NO-synthase these cells seem to express other targets for NO independent of the cGMP signal cascade.

2582 Elevated levels of uric acid potentiate endothelial dysfunction associated with hypercholesterolaemia

M.B. Britten, M. Elsner, D.H. Walter, A.M. Zeiher, V. Schächinger. *Clinic of Internal Medicine IV, Dept. of Cardiology, J.W. Goethe University of Frankfurt/Main, Germany*

In hypercholesterolemia, activation of the xanthinoxidase causes generation of vascular oxygen radicals, which results in reduction of NO-mediated vasodilation. On the other hand, xanthinoxidase also generates uric acid. Therefore, we assessed, whether elevated levels of uric acid in hypercholesterolemia are associated with impaired epicardial, endothelium-dependent vasodilation. In 28 normocholesterolemic and 23 hypercholesterolemic patients with an angiographically normal or minimally diseased (<30% focal stenosis) LAD or LCX, we tested the endothelium-dependent vasoreactivity by i.c. infusion of acetylcholine (Ach, 10^{-6} M).

Results: Hypercholesterolemic patients with a serum level of uric acid $\geq$ 6 mg/dl had a significantly greater vasoconstriction (31 $\pm$ 14%, n = 9) compared to patients with a serum level of uric acid < 6 mg/dl (9 $\pm$ 15%, n = 14; p = 0.002). There was a significant inverse relation between Ach-induced endothelial vasoreactivity and serum levels of uric acid in patients with hypercholesterolemia ($r = -0.72$; $p < 0.001$), whereas no significant correlation could be found in normocholesterolemic patients ($r = 0.27$; p = n.s.). There was no association between serum concentrations of cholesterol and uric acid ($r = 0.1$; p = n.s.).

Conclusions: Elevated concentrations of uric acid in patients with hypercholesterolemia are associated with an exaggerated paradoxical epicardial vasoconstriction to acetylcholine. Prospective studies are warranted to determine whether lowering of uric acid concentrations is associated with an improvement of endothelium-dependent vasodilation.

2583 Does endothelium-derived nitric oxide contribute to the coronary response to magnesium, the so-called natural, physiological calcium blocker?

H. Teragawa, M. Kato, Y. Fukuda, H. Hirao, T. Yamada, Y. Muraoka, T. Yamagata, H. Matsuura, G. Kajiyama. *First dept. of Internal Medicine, Hiroshima University, Hiroshima, Japan*

Magnesium (Mg) is considered a natural, physiological calcium blocker. Recently, it has been reported that some kinds of calcium blockers have exert an endothelium-derived nitric oxide (NO)-induced vasorelaxing effect. It is still unknown whether endothelium-derived NO is involved in the vasoresponse of human coronary arteries to Mg. We performed the present study to examine whether the coronary response to Mg changed after intracoronary infusion of NG-monomethyl-L-arginine (L-NMMA), an NO synthesis inhibitor.

Methods: Seventeen patients with normal coronary arteries were enrolled for this study. Magnesium sulfate (MgSO4) (0.2 mmol/min over 2 min) was infused into the left coronary ostium before and after intracoronary infusion of L-NMMA (200 μmol/5 min). Coronary blood flow (CBF) and coronary vessel resistance (CVR) were calculated by quantitative angiography and Doppler flow velocity measurements.

Results: Intracoronary infusion of MgSO4 caused dilatation of the epicardial coronary arteries (percent change from baseline, mean $\pm$ SEM, 6.3 $\pm$ 0.6%, $p <$ 0.0001 vs baseline), increase in CBF (31.1 $\pm$ 6.8%, $p < 0.0001$), and decrease in CVR (−22.2 $\pm$ 3.8%, $p < 0.0001$). After infusion of L-NMMA, the response of these parameters to MgSO4 did not change (coronary diameter: 4.9 $\pm$ 0.7%; CBF: 25.3 $\pm$ 6.7%; CVR: −19.4 $\pm$ 4.7%, all $p < 0.0001$ vs baseline).

Conclusions: These findings suggest that endothelium-derived NO may not contribute to the coronary dilatation induced by Mg.

2584 Long-term estradiol treatment improves vasoactive intestinal polypeptide-mediated vasodilatation in atherosclerotic coronary Watanabe-rabbit arteries

T. Dalsgaard, A. Mortensen[1], J.J. Larsen[1], B. Ottesen. *Dpt. of Obstetrics and Gynecology 537, Hvidovre University Hospital, Hvidovre; [1]The Danish Food Agency, Copenhagen, Denmark*

The aim of this study was to investigate the influence of long-term treatment with 17-beta-Estradiol (E2) on the response to the two vasodilatatory peptides Vasoactive Intestinal Polypeptide (VIP) and Pituitary Adenylate Cyclase Activating Polypeptide (PACAP) in atherosclerotic coronary and cerebral arteries. Twenty five female ovariectomised Watanabe Heritable Hyperlipidemic rabbits were randomised to treatment for 16 weeks with either Placebo (n = 12) or E2 4 mg/day (n = 13). The chow used was semisynthetic in order to avoid the influence of phytoestrogens. Ring-segments of the posterior cerebral artery (PCA), the right proximal coronary artery (PROX) and the distal left coronary artery (LAD) were microdissected and mounted for isometric tension recordings in a myograph. The vessels were precontracted with Krebs buffer containing 30 mM Potassium. The dose-response relationship for VIP (10^{-10} to 10^{-6} M) and PACAP (10^{-10} to 10^{-6} M) were evaluated. E2 treatment significantly improved the maximal VIP-mediated dilatation (Emax, in percent of the precontraction) in PROX (45.8 $\pm$ 9.6% vs. 24.1 $\pm$ 3.7%, $p < 0.05$). There was no difference in Emax for the VIP-response in LAD (42.6 $\pm$ 3.6% vs. 33.8 $\pm$ 6.0%, p = 0.21) or CNS (60.2 $\pm$ 7.3% vs. 62.1 $\pm$ 4.8%, p = 0.82) between the two groups. There was no difference in Emax for the PACAP-mediated dilatation in neither PROX (47.9 $\pm$ 6.2% vs. 40.9 $\pm$ 4.0%, p = 0.35), LAD (32.1 $\pm$ 4.5% vs. 25.4 $\pm$ 3.3%, p = 0.24) or CNS (41.2 $\pm$ 6.9% vs. 37.8 $\pm$ 3.8%, p = 0.66) from the two groups. EC50 and pI2 for VIP and PACAP was not different between the two groups in any of the vessels. These results suggest that long-term treatment with E2 in atherosclerotic arteries improves the VIP-mediated, but not the PACAP-mediated dilatation in the proximal coronary arteries, where the atherosclerosis is most pronounced.

2585 Selective attenuation of relaxations mediated by the endothelium-derived hyperpolarizing factor in porcine coronary arteries following in vivo treatment with a balloon perfusion catheter

J. Bauersachs, M. Kirchengast[1], G. Ertl, W. Völker, J. Strotmann. *II. Med. Klinik, Universitätsklinikum Mannheim; [1]Knoll AG, Ludwigshafen, Germany*

Endothelium-derived hyperpolarizing factor (EDHF) and nitric oxide (NO) play a crucial role for vascular homeostasis. Endothelial dysfunction is a well-known phenomenon following coronary angioplasty (PTCA). Besides PTCA, balloon catheters are increasingly used with low pressure inflation for short-term occlusion of coronary arteries e.g. for brachytherapy or angioscopy. Whether these interventions induce long-term endothelial damage is unclear.

Methods and Results: We investigated vascular reactivity *ex vivo* in porcine coronary arteries 12 weeks following *in vivo* treatment with a novel balloon perfusion catheter. The catheter was advanced to the left descending coronary artery (LAD) and the balloon was inflated to completely occlude the LAD (30 min, 1.2 bar). Distal coronary flow was maintained using a roller pump system. After 12 weeks angiography failed to reveal any signs of stenosis. In isolated coronary rings preconstricted with U46619, sodium nitroprusside-induced relaxation was identical in all vessels investigated. Endothelium-dependent bradykinin-induced relaxation was not significantly altered in rings from the balloon-treated part of the LAD. However, following NO synthase inhibition using N^G-nitro-L-arginine, bradykinin-induced maximum relaxation was markedly attenuated in these rings (21 $\pm$ 7%), as compared to control rings (67 $\pm$ 6%, n = 12, $p < 0.001$). This relaxation was mediated by EDHF since it was completely abolished following preconstriction with KCl.

Conclusion: Even in the absence of any angiographic signs of stenosis, short-term treatment with a balloon catheter at low inflation pressure induces long-term functional disturbances of the coronary endothelium. Although the clinical relevance of these findings is uncertain, EDHF-mediated relaxation may be a particularly sensitive marker of subtle endothelial damage.

2586 Coronary vasomotor response to nifedipine is modulated by functional and morphological coronary alterations

M. Weis, S. Pehlivanli, S.M. Wildhirt[1], C. Schulze[1], U. Wilbert-Lampen, P. Überfuhr[1], W. von Scheidt. *Medical Unit I, University Hospital Grosshadern, Munich; [1]Cardiac Surgery Dept., University Hospital Grosshadern, Munich, Germany*

Despite the known coronary vasodilator potential of nifedipine the impact of endothelial dysfunction and/or intimal hyperplasia on nifedipine (N)-induced coronary vasodilation is unknown. It was the aim of this study to investigate N-induced epicardial and microvascular response in cases of normal endothelial function, endothelial dysfunction, normal coronary morphology and intimal hyperplasia.

Methods: The investigation was performed in 70 patients 5 ± 5 months after HTx. Coronary microvascular function (Doppler FloWire) was determined with i.c. acetylcholine (ACh; 150 μg/5 min; i.c.), adenosine (ADO;800 μg/5 min; i.c.) and N (0.2 mg/30 s). Proximal and distal epicardial diameter changes to ACh, ADO and N were investigated using QCA. IVUS was used to detect significant intimal hyperplasia (mean maximal intimal thickening > 0.6 mm). In a subgroup (n = 38) coronary sinus and aortic endothelin (ET) levels were determined.

Results: Epicardial dilation to N was more pronounced in distal compared to proximal segments (18 ± 15% versus 10 ± 11% diameter increase) and was inversly correlated to epicardial diameter change in response to ACh (r = −0.24; p = 0.04). In cases of intimal hyperplasia distal vasodilation was increased compared to normal segments (24 ± 8% versus 16 ± 6% diameter increase; p = 0.03). Coronary flow response to N was comparable to ADO- and ACh-mediated flow increase (2.1 ± 0.6 compared to 2.6 ± 1 and 2.5 ± 0.9, respectively). A trend was observed between high ET plasma levels in the coronary sinus and an improved microvasodilation to N (p = 0.04).

Conclusion: N is a potent epicardial and microvascular vasodilator, comparable to ADO. Epicardial dilation to N is augmented in cases of epicardial endothelial dysfunction and/or intimal thickening. The association between microvascular response to N and ET levels in the coronary sinus suggests that the mechanism of N-induced microvascular vasodilation is at least in part modulated by ET.

VASCULAR REMODELLING: BASIC MECHANISMS

2587 Apoptosis is significantly higher in arteries with enlargement versus constrictive remodelling after ballon angioplasty

E. Durand, F. Addad[1], F. Vilde, C. Brasselet, F. Vinchon, M. Desnos, C. Guérot, A. Lafont. *Cardiology Dept, Boucicaut Hospital, Paris; [1]INSERM U411, Paris, France*

Background: Apoptosis has been previously described after balloon angioplasty but data regarding arterial remodeling and restenosis are missing and contradictory, respectively. This study was therefore designed to evaluate the relationship among apoptosis, arterial remodeling, and restenosis after balloon angioplasty in the atherosclerotic rabbit model.

Methods and Results: Atherosclerosis was induced in femoral arteries of 16 New Zealand white rabbits by air-desiccation and high cholesterol diet. One month later, angioplasty was performed. Apoptosis, arterial remodeling, and residual stenosis were evaluated by TUNEL and histomorphometry respectively. Apoptosis was significantly more important in arteries with enlargement remodeling than in those with constrictive remodeling (34 ± 7% vs 8 ± 7%, p = 0.03; 34 ± 4% vs 4 ± 2%, p = 0.01 respectively at day 14 and 21). Residual stenosis inversely correlated with apoptosis (r = −0.57, p = 0.02).

Conclusions: These findings suggest that apoptosis may play a role in arterial remodeling and restenosis after balloon angioplasty. Strategies aiming at enhancing apoptosis might participate to promote enlargement remodeling, and to prevent restenosis after balloon angioplasty.

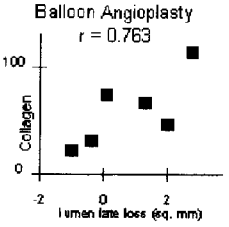
2588 Increased collagen synthesis and content in stented versus balloon treated arteries

C.W. Li, W.J. Cantor, R. Robinson, J.N. Wylie, A.W. Barolet, W. Tsui, C. Mar, B.H. Strauss. *Medicine, Division of Cardiology, St. Michael's Hospital, Toronto, Canada*

Although balloon angioplasty (BA) upregulates arterial wall collagen synthesis and collagen content, it is unclear which layers of the vessel wall are involved. Furthermore, the collagen response after arterial stenting has not been studied. We studied collagen synthesis and content in the various layers of the vessel wall after stenting and BA. In a double-injury model in normocholesterolemic rabbits, adjacent iliac arteries underwent BA (3.0 mm) or stent placement (Nir, 3.0 × 16 mm). Animals were sacrificed at 1 (n = 8) and 10 weeks (n = 16). The intima was separated from the medial-adventitial layer. These were incubated ex-vivo in ^{14}C-proline containing medium for 6 hrs. Collagen content (μg OHprol) and synthesis (cpm/segment) (mean ± SEM) were determined by assays for ^{14}C-OHproline and total hydroxyproline, respectively. Late lumen loss was calculated from intravascular ultrasound (IVUS) measurements done immediately after BA injury or stenting and at 10 weeks. We found stenting significantly increases collagen synthesis (2–3 fold) and total content (2 fold) at 1 and 10 weeks compared to balloon angioplasty. This effect is present in both the intima and media-adventitial layers (see Table). At 10 weeks lumen area by IVUS decreases from 3.4 ± 0.38 mm^2 to 2.7 ± 0.64 mm^2 and from 5.2 ± 0.18 to 4.6 ± 0.29 mm^2 respectively in BA and stented arteries. Late lumen loss was found to correlate best with intima collagen content in BA arteries (n = 6) (see figure) but not in stented arteries.

	Intima 1 wk	Med/adv 1 wk	Intima 10 wk	Med/adv 10 wk
Collagen synthesis				
BA	714 ± 391	797 ± 247*	154 ± 43*	376 ± 90*
Stent	1240 ± 331	2485 ± 699	450 ± 130	805 ± 115
Collagen content				
BA	27 ± 6	164 ± 25*	48 ± 7*	181 ± 21*
Stent	34 ± 4	252 ± 26	103 ± 9	385 ± 47

*p < 0.05 Stent versus BA.



Collagen response and mechanism of late lumen loss after injury might be different in stenting versus balloon angioplasty.

2589 Urokinase plasminogen activator in injured adventitia augments fibroblast differentiation to myofibroblasts, early proliferation and neoadventitia growth

Y.E.V. Parfyonova, O.S. Plekhanova[1], R.S.H. Bibilashvily[2], V.V. Stepanova, N.I. Kalinina[3], A. Bobik[4], V.A. Tkachuk. *Molecular Endocrinology Lab., Cardiology Research Center, Moscow; [1]Dept. of Atherosclerosis, Cardiology Research Center, Moscow; [2]Gene Engeniering Lab., Cardiology Research Center, Moscow; [3]Exp.Atherosclerosis, Cardiology Research Center, Moscow, Russian Federation; [4]Baker Medical Research Institute, Alfred Hospital, Melbourne, Australia*

The activation of adventitial fibroblasts, their differentiation, proliferation, migration and involvement in neointima formation are important contributors to the failure of revascularization procedures such as coronary angioplasty and aortocoronary saphenos vein grafts. The mechanisms regulating the differentiation of the adventitial fibroblasts to myofibroblasts and their proliferation are not to be fully elucidated. Growth factors together with a variety of proteolytic enzymes are thought to be involved in the early proliferation and migration of fibroblasts after adventitial injury. This study was designed to investigate in vivo how elevations in urokinase plasminogen activator (uPA) and its proteolytic activity affect fibroblasts differentiation, proliferation and adventitia remodeling following following surgical injury of the rat carotid adventitia.

Methods: The left common carotid artery of the rats was subjected to surgical injury followed by perivascular application of uPA (ruPA) or a proteolytically inactive ruPA, in which glutamine has been substituted for histidine in position 204 (ruPA H/Q). The effects of these forms of ruPA on fibroblasts differentiation (the expression of alpha-actin), proliferation (the expression of proliferating cell nuclear antigen (PCNA)) and adventitia remodeling (the quantitative morphometry) were assessed 96 hours after injury.

Results: The frequency of alpha actin positive cells in adventitia increased in injured artery comparing to uninjured vessel (p < 0.05). Recombinant uPA increased the frequency of PCNA positive cells (p < 0.05) but ruPA H/Q was ineffective. At this time r-uPA also increased the size of the neoadventitia by 50% and ruPA H/Q did not induce such changes. Recombinant uPA also increased the frequency of PCNA positive cells in injured adventitia whereas ruPA H/Q did not affect such parameters.

In conclusion, the elevation in uPA following injury of the rat carotid artery adventitia augments fibroblast differentiation to myofibroblasts, their early proliferation and increase in the size of the neoadventitia. These effects are highly dependent on its proteolytic properties.

2590 Constrictive arterial remodelling after balloon angioplasty is not related with the absence of macrophages and endothelial cells

M. Ruitenberg, G. Pasterkamp, D.P.V. de Kleijn, B.J.G.L. de Smet, A.H. Schoneveld, C. Borst. *Experimental Cardiology Dept., Utrecht University Medical Center, Utrecht, Netherlands*

Constrictive arterial remodeling is a major determinant of restenotic luminal narrowing following balloon angioplasty. Reports on the relation of local constrictive remodeling with inflammatory processes and the presence of endothelium are controversial.

Methods: Atherosclerosis was induced in the iliac arteries of 16 Yucatan micropigs by a combinaton of denudation and atherogenic diet. Balloon angioplasty was performed in 38 arteries, with serial intravascular ultrasound before and after intervention and at 1 (n = 6 vessels), 2 (n = 8), 4 (n = 5), 7 (n = 5), 14 (n = 8) or 42 (n = 6) days follow up. Remodeling was expressed as% change of vessel area on ultrasound at follow up compared with post angioplasty values. All segments were stained on the presence of macrophages (acid phosphatase) and endothelial cells (lectines). The area of staining for macrophages was measured in the intima and media using analySIS and expressed as% of the total vessel wall area. The staining for endothelial cells was expressed as percentage of the luminal circumference.

Results: Vessel area decreased over time among groups, indicating a time related remodeling response: from +39% at day 1, +13% at day 2, −1% at day 4, −2% at days 7 and 14 towards −11% at day 42 (+ = enlargement, − = shrinkage). Endothelial cell coverage increased slowly over time (day 1 49 ± 20% to 66 ± 25% at day 42). Macrophage content was highest at day 7 and 14 (3.4 ± 2.3 and 3.6 ± 2.0%, respectively) and lowest at day 1 (1.3 ± 1.5%). Regression analysis for the pooled data revealed no relation between the extent of remodeling and endothelial coverage nor macrophage content ($r = 0.08$ for macrophages and $r = -0.31$ for endothelial coverage, for both, $p > 0.1$). Also for the separate time points no relation between the extent of remodeling and macrophage content nor endothelial coverage could be demonstrated.

Conclusion: The mode of post angioplasty remodeling is not related with macrophage content nor with endothelial coverage.

2591 Matrix metalloprotease-2 and -9 activity is associated with luminal narrowing following balloon dilation in rabbits

D.P.V. De Kleijn, J.M.J. Rebel, E. Velema, C. Borst, M.J. Post[1]. *Lab. of Experimental Cardiology, Utrecht University Hospital (G02 523), Utrecht, Netherlands; [1]Angiogenesis Center, Harvard Medical School, Boston MA, USA*

Luminal narrowing after balloon angioplasty, is the result of intimal hyperplasia and constrictive remodeling. The local arterial size decrease is probably a result of degradation and resynthesis of extracellular matrix surrounding the arterial cells. A major component of the extracellular matrix in arteries is collagen which is degraded by a family of matrix metalloproteinases (MMPs). The aim of the present study is to investigate the association between MMP activity and luminal narrowing after balloon dilition.

Methods: In 32 rabbits, we performed balloon dilation in the iliac artery. Animals were terminated at 2 days, 1, 2 or 4 weeks follow up. Quantitative angiography was performed at dilation and termination. Histomorphologic analysis and zymography was performed on the dilated and non-dilated (control) contralateral arteries.

Results: Two days after balloon dilation, MMP-9 activity increased 1.6 ± 0.2 times in the dilated arteries compared to the control arteries, and increased 1 week after intervention to 2.9 ± 0.4 times. At 2 and 4 weeks, MMP-9 activity returned to control levels. MMP-2 activity increased, only at two weeks, to 1.6 ± 0.2 times in the dilated artery compared to the control artery. Two weeks after balloon dilation, lumen diameter had decreased 0.58 ± 0.07 mm (0.46 ± 0.07 mm due to constrictive remodeling, 0.11 ± 0.04 mm by intimal hyperplasia). At 4 weeks, late lumen loss was 0.75 ± 0.05 mm and neointima thickness 0.16 ± 0.04 mm(21% of loss).

Conclusions: In response to balloon injury, the increase in MMP-9 activity preceeds the increase in MMP-2 activity. MMP-2 and -9 activity increases before and during the shrinkage of the ballooned segment which supports the hypothesis that MMPs play a role in constrictive arterial remodeling following balloon angioplasty

MINOR MYOCARDIAL INJURY: DOES IT MATTER?

2593 Angiographic findings in patients with refractory unstable angina according to the troponin T status

C. Heeschen, C.W. Hamm, M. Brandt[1], M.L. Simoons[1]. *Cardiology Dept, University Hospital Hamburg, Hamburg, Germany; [1]Thoraxcenter, Erasmus University, Rotterdam, Netherlands*

The CAPTURE trial enrolling patients (pts) with unstable angina documented treatment benefit for abciximab which was particular evident in patients with elevated troponin T (TnT). As mechanism of TnT release remains unclear so far we related the angiographic data to the TnT status. In 853 patients angiograms at baseline and 24 hrs after allocated treatment were centrally assessed with respect to TIMI flow, lesion severity, and visibility of thrombus.

Results: TnT > 0.01 μg/L was found in 58% and > 0.1 μg/L in 31% of the pts. Thrombus was visible in 14.6% of pts with TnT > 0.1 μg/L versus 4.2% for TnT negative pts ($P = 0.004$). In 95.5% of patients with visible thrombus TnT release > 0.01 μg/L was detectable. Complex lesions (type > B2/C; 37.8 vs. 25%; $P < 0.001$) and TIMI flow < 2 (15.7 vs. 5.2%; $P < 0.001$) were more frequent in TnT positive pts. Abciximab was effective with respect to reduction of visible thrombus and increase of TIMI flow in TnT positive pts only. TnT status, but not angiographic findings, served as an independent predictor for both outcome and efficacy of treatment with abciximab.

Conclusions: Complex lesion characteristics and thrombus formation at baseline were significantly connected to the TnT release. However, TnT status was the more powerful predictor of increased cardiac risk. Accordingly, TnT can be considered as a more sensitive marker for the underlying pathology leading to the refractoriness of treatment in patients with unstable angina.

2594 Higher microinfarction rate by stenting and rotational atherectomy than by balloon angioplasty

J. Herrmann, S. Sack, C. von Birgelen, L. Volbracht[1], M. Haude, A. Schmermund, D. Welge, D. Baumgart, R. Erbel. *University Clinic Essen, Department of Cardiology; [1]Department of Laboratory Medicine, Essen, Germany*

Background: Significant elevations of creatine kinase (CK), CK-MB, and troponin T (TnT) after successful coronary interventions have been recognized as markers of peri-interventional myocardial necrosis.

Methods: In order to answer the question if the interventional techniques have a different influence on the incidence of these myonecrotic events, 639 consecutive patients were subdived in those with balloon angioplasty (PTCA), stenting (STENT), and rotational atherectomy (ROTA). Blood samples were taken before the intervention as well as 6, 12, and 24 hours after the procedure. Enzyme activity assays were used for CK/CK-MB level quantification, rapid bedside test (Cardiac T™, Boehringer Mannheim) for the detection of a TnT release. Normal range values at baseline were obligatory for study inclusion.

Results:

	PTCA (n = 168)	Stent (n = 429)	ROTA (n = 42)
CK 1.5–3	4 (2.4%)*	38 (8.9%)*	2 (4.8%)
CK > 3	1 (0.8%)*	14 (3.3%)**	6 (14.3%)*/**
pos. TnT	7 (4.1%)*	92 (21.4%)*	16 (38.1%)*

(*/**$p < 0.001$, CK > 3: $p = 0.05$ for PTCA vs. Stent; CK 1.5–3: $p < 0.05$ for PTCA vs. ROTA, n.s. for STENT vs. ROTA)

Conclusion: Peri-interventional myocardial necrosis occurs more frequently after stenting and rotational atherectomy than after balloon angioplasty. Extensive squeezing of atherosclerotic plaques, ablation of particles, and distal microembolization are possible mechanisms, that can explain the higher incidence of myonecrotic events seen with stenting and rotational atherectomy than with balloon angioplasty.

2595 Influence of coronary stenting on the frequency of minor myocardial damage ("infarctlet") after percutaneous transluminal coronary angioplasty

B. Mark, R. Zahn, K. Dönges, B. Fraiture, B. Frilling, F. Fischer, D. Nagel[1], D. Seiler[1], J. Senges. *Herzzentrum Ludwigshafen; [1]Institut für Klinische Chemie, Klinikum Ludwigshafen, Germany*

An elevation of cardiac enzymes after percutaneous transluminal coronary angioplasty (PTCA), indicating a minor myocardial damage ("infarctlet") is supposed to be of important prognostic value. Since most of the published data were recorded before the "era of stenting" little is known about the influence of coronary stenting on the frequency of these infarctlets.

Methods: Since October 1997, 560 patients (pts.) who underwent PTCA for stable or unstable angina were included in a prospective registry. An acute myocardial infarction in the past 48 hours was an exclusion criterion. Total-CK, CK-MB and troponin T were measured before intervention, 1 to 2 hours and 8 to 24 hours after intervention. Clinical and procedural data were documented.

Results: 271 pts. (48%) underwent the procedure for stable angina and 289 pts. (52%) had an unstable angina. An implantation of at least one coronary stent occurred in 270 pts. (48%). These pts. showed a significant higher rate of elevated cardiac enzymes:

Elevated enzyme	Stent implantation	Without Stent	p-value
Total-ck	16%	6%	<0.001
CK-MB	45%	30%	0.011
Troponin T	25%	11%	<0.001

Pts. with coronary stenting were not different in the demographic and clinical characteristics compared to pts. without stentimplantation. However, there was a 10-fold higher rate of documented reasons for enzymatic abnormalities in stented pts. such as side branch occlusion or major dissection (23% vs. 2%, p < 0.001)

Conclusion: Coronary stenting is associated with an increase in the frequency of elevated cardiac enzymes (total-CK 2.7-fold, troponin T 1.5-fold). The ongoing follow-up (6 and 12 months) has to reveal the prognostic relevance of the observed enzymatic abnormalities.

2596 Incidence of myocardial enzyme release following multivessel stenting in the ARTS trial

E. Sousa, R. Carere, N. Buller, V. Legrand, G. Schuler, P. Roose, C. Macaya, F. Fernandez-Aviles, F. Unger, P.W. Serruys. *On behalf of the the ARTS study group. Cardialysis, Rotterdam, Netherlands*

Background: Rise in CK and CKMB following transcatheter treatment has been extensively scrutinized and the incidence of enzyme release following single lesion treatment ranges between 3 and 17%. The actual incidence of enzyme release following multivessel treatment has not been documented in larger trials.

Method: In the ARTS study, comparing conventional CABG to multivessel stenting, 600 patients (pts) were randomized to percutaneous treatment and received 2.9 ± 1.2 stents per patient, implanted at a maximum pressure of 13 ± 3 atm, resulting in a total length of 47.4 ± 21.6 mm of stented vessel. CK and CKMB were sampled at 6, 12 and 18 hours post-procedure. CK and/or CKMB were not available in 3% of the patients. Patient and lesion related parameters (n = 1027), pre-, peri and post procedural were itemized and analyzed in a multivariate logistic model.

Results: Overall enzyme release was observed in 30% of the patients.

Above normal	6 hours	12 hours	18 hours	Max value
CKMB 1–2x	16%	21%	23%	20%
CKMB 3–5x	4%	6%	6%	4%
CKMB > 5x	4%	7%	6%	6%

Among the 78 univariated significant variables related to the enzyme release 9 parameters were retained in the multivariate model: 1. CKMB pre-procedure (p = 8.E-07), 2. stenosis RCA pre-crux (p = 0.0004), 3. any side branch occlusion of LAD (p = 0.003), 4. side branch occlusion of proximal LAD (p = 0.01), 5. irregular contour LAD (p = 0.015), 6. urgent admission to hospital post-randomization) (p = 0.017), 7. total stent length (p = 0.032), 8. maximal post-stent dilatation pressure (p = 0.038), 9. EF% at screening (p = 0.048).

Conclusion: The observed incidence of enzyme release in this population appears to be higher than in pts with single lesion treatment and is related either to acute ischemic events occurring shortly before the procedure or related to lesional and procedural characteristics. The prevention (use of IIB/IIIA antagonist receptors) and the long-term significance of this enzyme release (MACE) remains to be elucidated.

2597 Cardioprotective effect of β-blocker therapy in reducing CK-MB release after coronary intervention

S.K. Sharma, A. Kini, S. Kini, G. Dangas, E. Brown, T. Bertea, J.D. Marmur. *Division of Cardiology, Box 1030, Mount Sinai Hospital, New York NY, USA*

It has been shown that patients on β-blocker therapy sustaining myocardial infarction (MI) have lower infarct size compared to those not on β-blockers most likely mediated by blunting the heightened adrenergic tone and decreasing myocardial oxygen demand. CK-MB enzyme elevation has been shown to occur in 10–33% of cases after successful coronary intervention. To evaluate whether β-blockers exert similar protective benefit after coronary intervention, we analyzed the incidence of post procedure CK-MB elevation in 1675 consecutive patients undergoing coronary interventions; of these 643 (38.4%) patients were taking β-blockers prior to their intervention and 1032 (61.6%) were not on β-blockers. Incidence of CK-MB release was 13.2% in patients on β-blockers as compared to 22.1% in the patients who were not on β-blocker therapy (p < 0.001). Among the various factors analyzed in a multiple linear regression model, no β-blocker use (p < 0.001), diffuse/multiple lesions (p < 0.01), peripheral vascular and aortic disease (p < 0.01), stent use (p < 0.02) and CCS angina class III-IV (p < 0.02) independently correlated with CK-MB elevation. During mid-term follow-up at 15 ± 3 months, there have been 5 deaths in the β-blocker group (0.78%) and 17 deaths in the no β-blocker group (1.74%); p = 0.045.

Conclusion: These non-randomized data suggest that prior β-blocker therapy has a beneficial effect in limiting the CK-MB release during coronary interventions. This intriguing observation needs to be verified in a prospective manner or by pooled data analysis of several previous interventional trials reporting CK-MB release in relation to β-blocker use.

2598 Importance of chest pain early after percutaneous coronary intervention: incidence and relation to ECG changes, cardiac enzymes and follow-up events

M. Schüepp[1], E. Ullmer[2], M. Weinbacher[2], M. Pfisterer[1], A. Scholer[3], R. Ritz[2], P. Rickenbacher[1]. *Divisions of [1]Cardiology; [2]Intensive Care Medicine; [3]Clinical Chemistry, University Hospital, Basel, Switzerland*

Currently, the clinical relevance of chest pain (CP) and elevated cardiac enzymes after percutaneous coronary interventions (PCI) is controversial. Therefore, we studied the incidence of CP early after PCI and its correlation with ECG changes, cardiac enzymes, clinical and procedural variables and follow-up events.

Methods. The study population consisted of 199 consecutive patients (pts) (men 84%, mean age 60.1 ± 9.4 years) after primary successful PCI (21% PTCA, 79% stent). During the first 16 hours following PCI, the occurrence of CP was noted, ECG's were recorded at 0 and 16 hours and serial measurements of CPK, CK-MB, CK-MB mass (MB-M), myoglobin (myo) and troponin I (tro I) at 0, 4, 8 and 16 hours were performed. 76 pts (38%) with elevated enzyme levels at time 0 were excluded. A clinical follow-up was obtained at 6 months.

Results. 40 pts (32.8%) experienced CP, new ECG changes were detected in 3 (2.5%). Enzyme levels in pts with/without CP are shown below:

CP	CPK		CK-MB		MB-M		myo		tro I	
	+	−	+	−	+	−	+	−	+	−
0	70	78	17	17	2.0	2.0	26	25	0.2	0.2
4	87	78	16	16	5.1	2.6*	54	30*	0.5	0.1
8	121	81*	20	17*	10.6	4.3*	51	27*	1.3	0.6
16	163	82*	24	18*	17.8	5.4*	40	27*	2.4	0.4*

(*p < 0.05)

Significantly more pts with CP had MB-M and tro I levels higher than twice the upper normal limit 16 hours after PCI: 43.6 vs 11.1% (<.0001) and 45.0 vs 17.5% (<.003) respectively. CP and tro I showed no correlation with clinical and procedural variables. MB-M was associated with balloon size (<.03), stent diameter (<.02) and hypertension (<.05). We found no correlation of CP or enzymes with ECG changes. Elevated tro I (<.002) and MB-M (<.04) but not CP could be identified as risk factors for recurrent CP during follow-up.

Conclusion: CP early after PCI correlated with elevated cardiac enzymes but not with ECG changes indicating periinterventional myocardial necrosis. Elevated cardiac enzyme levels early after PCI are associated with recurrent CP during follow-up.

PAEDIATRIC CATHETER INTERVENTION

2618 Transcatheter closure of membranous ventricular septal defects with a new nitinol prosthesis in an animal model

C. Rickers[1], J. Weil[1], X. Gu, Y. Han, M. Urness, J. Berry, K. Amplatz.
[1]University Hospital Eppendorf, Hamburg, Germany; University of Minnesota, Minneapolis MN, USA

The purpose of the study was to evaluate a new device for closure of perimembranous VSD in a natural swine model.

Materials and Methods: Transcatheter closure of membranous VSD was attempted in 11 Yucatan minipigs with natural membranous VSDs. The device is constructed from 0.004 inch Nitinol wires with two retention buttons and a connecting waist filled with polyester fibers. Two different designs where used in this study: concentric retention buttons (n = 3) and eccentric design with a 2 mm small flange toward the aorta (n = 8). A 6 or 7 F introducing sheath was used to deliver the device.

Results: Successful implantation of the device was achieved in all animals. Complete closure rate was 54.5% (6/11) immediately after placement and 100% at one week. The aneurysm of membranous septum increased significantly in size in two of the three animals using the concentric device, but none of the cases using the eccentric device. Trace to moderate aortic regurgitation was presented in 2 of the 3 animals using the concentric device, and in 1 of 8 animals using the eccentric device. Three animals had a trace to moderate tricuspid regurgitation. Pathologic examination showed the devices to be covered by smooth, glistening neoendothelium at three months.

Conclusions: Effective occlusion of membranous ventricular septal defect is feasible and save with this new nitinol prosthesis. The eccentric device has advantages in a follow-up period of three months.

2619 Stent implantation in coarctation of the aorta: indermediate-term follow-up and technical considerations

B.(V).D. Thanopoulos[1], G.S. Tsaousis[1], M. Dukic[2], G.S. Papadopoulos[1], S. Simeunovic[2]. *[1]Departments of Pediatric Cardiology, "Aghia Sophia" Children's Hospital, Athens, Greece; [2]University Children's Hospital, Belgrade, Yugoslavia*

The purpose of this study was to present initial and intermediate-term results of stent implantation (SI) in children with coarctation of the aorta (CoA). A small number of previous studies, most of them preliminary, have reported use of stems for CoA with encouraging results.

Methods: Thirteen patients (pts), aged 5 months to 15 years (mean = 11 ± 4 years) with CoA underwent SI. Eight pts had significant re-CoA; 5 pts following previous surgical repair and 3 after balloon dilation. Three and two pts had local and long-segment CoA, respectively. SI was performed under antegrade angiographic guidance (transeptal placement of a Berman 6F to 8F diagnostic catheter into the left ventricle or the aorta).

Results: Immediate after SI the mean peak systolic gradient (MPSG) fell from 47 ± 28 mmHg to 4 ± 5 mmHg ($p < 0.05$). Proximal stent migration without adverse effects occurred in one pt during an attempt for further dilation. No any other complication was observed. At follow-up catheterization (9 pts, 1 to 5 years after SI) no significant change ($p > 0.05$) was noted in the MPSG (6 ± 5 mmHg) and the mean CoA diameter (14 ± 1 mm). At the latest follow-up (26 ± 18 months) the arm to leg blood pressure gradient is 11 ± 7 mmHg. Neither complications nor stent fracture was encountered.

Conclusions: SI may be a useful alternative to balloon dilation or surgery in selected children with CoA. AAG may improve the safety and the efficacy of the procedure.

2620 Interventional occlusion of big atrial septal defects larger than 20 mm diameter with the Amplatzer septal occluder

F. Berger, P. Ewert, M. Gittermann, P.E. Lange. *Dept of Congenital Heart Diseases, Deutsches Herzzentrum Berlin, Berlin, Germany*

Since the last 10 years (Y) various devices have been used for interventional occlusion of atrial septal defects (ASD). Most of these were limited for the use in defects up to 20 mm diameter. 1997 the Amplatzer Septal Occluder (ASO) was introduced and its use was extended for defects up to 34 mm diameter. We report about our clinical experience in the use of the ASO in big ASD larger than 20 mm diameter.

Method: Stretched diameter of the device was measured by inflating the sizing balloon within the defect up to originate a waist in the balloon. An ASO 1–2 mm larger than the waist of the balloon was choosen and implanted through 9–11 French sheathes. In opposite to the implantation into smaller defects pullback of the device onto the atrial septum was only performed when the connecting stent of the ASO was developed to achieve the maximal centering characteristics and have the maximal diameter of the retention skirt of the left atrial disc to find support on the edges of the defect. Thereafter the right atrial disc was deployed and actively configured by advancing the sheath and the delivery cable against the atrial septum. After placement the fixation of the device and the mechanical stability was proven by an extensive "Minnesota wiggle". The ASO was released only when TEE showed no or just a trivial residual colour flow through the connecting stent, otherwise repositioning was performed.

Results: Out of 225 patients (P) after successful occlusion of interatrial defects 30 P (3.9–77.7 y old) had defects larger than 20 mm diameter (median 22 mm diameter (20–32), 25/75% quartiles = 20/26 mm) Occlusion could be performed without any complications or embolization. Mean shunt size was Qp:Qs 2.3:1 (1.5–3.7:1), mean flouroscopy time 12.4 min (4.1–24.1). In 90% of the P complete closure after intervention could be shown by TEE with colour flow doppler 4 weeks after implantation, hospital stay was 3 days. 3 P showed insignificant residual shunt. Except the 1 P with persistent atrial fibrillation only 2 P showed transient atrial tachyarrhythmias within the first 3 months after implantation controllable by β-blocker treatment.

Conclusion: Transcatheter closure of large ASD with the ASO is feasible safe and effective. Embolization or complication risk seem not to be higher if one adheres to the different sizing- and implantation-procedure for large defects.

2621 One single centre and six-year experience with percutaneous occlusion of atrial septal defect: results with four different occluders

F. Godart, C. Rey, M.A. Cajot[1], C. Francart, G. Vaksmann, G.M. Brevière. *Departments of Paediatric Cardiology; [1]Anaesthesiology, University of Lille, France*

Percutaneous closure of atrial septal defect (ASD) is available for many years. The aim of this study is to present and compare our 112 consecutive patients who underwent transcatheter occlusion of ASD.

From April 1992 to November 1998, 116 percutaneous closures were attempted in 112 patients. Occluders included Sideris device (1992–97, n = 71, group 1), ASDOS device (1996–97, n = 9, group 2), Amplatzer device (1997–98, n = 29, group 3) and Cardioseal device (1998, n = 3, group 4).

	n	SD	Fluor. time	Success		Residual Sht	
				n	%	n	%
Sideris	71	19.3 ± 4.7	23.8 ± 13.7	54	76	16	30
ASDOS	9	20.2 ± 2.8	48.5 ± 18.3	6	67	3	50
Amplatzer	29	20.3 ± 4.4	7.2 ± 8	27	93	0	0
Cardioseal	3	9.7 ± 6.0	24 ± 14.7	2	67	-	

SD = stretched diameter (mm); Fluoro. = fluoroscopy (min); Success = success of implantation; Sht = shunt at latest follow-up.

In group 1, implantation succeeded in 54 pts. During follow-up (up to 6 years), 38 pts had no residual shunt; but one of them had to be operated due to cardiac perforation. Sixteen pts had residual shunt (shunt ≤ 3 mm, n = 10), and 2 of them had to be operated for significant shunting. Silent fracture of one leg occurred in 2 pts and 2 other pts had to be recatheterised to retrieve embolised counter-occluder. In group 2, implantation succeeded in 6 pts and 3 of them had no residual shunt at follow-up (up to 21 months). In group 3, implantation succeeded in 27 pts. Another one had to be operated at day 1 because of embolization of the occluder to pulmonary artery. During follow-up (1 year), no pt had residual shunt. In group 4, implantation succeeded in 2 pts.

Conclusion: Our recent experience indicates that Amplatzer device is an efficient occluder for percutaneous closure of ASD. This devices produces higher occlusion rates of ASDs with shorter fluoroscopy time.

2622 Pre-seeding of atrial septal defect closure devices (STARFlex) with autologous cells improves short-term ingrowth

C. Jux, H. Bertram, P. Wohlsein[1], M. Bruegmann[1], P. Wuebboldt, K. Hoeper, T. Paul, G. Hausdorf. *Department of Paediatric Cardiology, Hannover Medical School, Hannover; [1]Institute of Pathology, Hannover Veterinarian School, Hannover, Germany*

Background: Interventional closure of suitable atrial septal defects (ASD) has become an attractive alternative in comparison to the surgical standard therapy. Rapid, complete and firm ingrowth of the closure device into the surrounding myocardial tissue is a major determinant in assessing the interventional procedure's quality since it reduces potential complications such as residual defects, thrombo-/embolism, friction lesions and arm fractures. The purpose of this study was to evaluate the influence on ingrowth of an ASD-occluder pre-seeded with autologous cells in an experimental animal model.

Methods: An ASD was created in anaesthetised sheep (35–40 kg, n = 6/group) by transseptal puncture under fluoroscopy and subsequent standardised balloon dilatation with increasing balloon diameters. Fibroblasts were isolated from a small skin biopsy and expanded in culture using routine techniques. After allowing for healing of the defect edges (2 weeks) the ASD's were closed using either autologous pre-seeded or conventional (acellular) devices. STARFlex®-devices, a self-centering modification of the CardioSEAL®-device, were employed percutaneously in all animals through the same 10F sheath. After a follow-up period of 10 days to 3 months animals were sacrificed and the device within the heart examined macroscopically and histologically.

Results: ASD-occluders pre-seeded with autologous cells showed a significantly improved ingrowth after only 10 days compared to both, our own control group after 3 months and data published previously in the literature. In particular, pre-seeded devices showed a several times thicker layer of connective tissue consisting of a network of fibroblasts, fibrocytes, capillaries and small vessels and newly synthesised collagen fibres on both atrial sides of the device. Compared to the thin layer of ingrown tissue in the periphery of conventional occluders the fibrous tissue on pre-seeded devices embedded not only the dacron fabric, but also completely covered the spring arms of the device underneath a layer of endothelium which was in continuity with the atrial endocardium.

Conclusion: In an experimental sheep model pre-seeding of septal occluders with autologous cells results in an improved short-term ingrowth. A thicker layer of connective tissue attaches the implant more rapidly, completely and firmly to the adjacent atrium.

2623 Advances in stent treatment for stenotic ductus arteriosus in newborns and infants with hypoplastic left heart syndrome

I. Michel-Behnke, K.J. Hagel, J. Bauer, H. Akintürk[1], D. Schranz. *Pediatric Cardiology Dept., Childrens Hospital JLU Giessen, Giessen; [1]Cardiovascular Surgery Dept., JLU Giessen, Giessen, Germany*

Maintaining Ductus arteriosus (DA) patency in infants with hypoplastic left heart syndrome (HLHS) by Palmaz stents for bridging to heart transplantation (HTX) has been demonstrated. The objective of our study was to assess the feasibility of DA stenting in pts with HLHS with facilitated implantation techniques and advanced stent technology.

Methods: 30 stents were implanted in the DA of 26 pts with HLHS. 4 pts received 2 stents placed in series. Palmaz stents (n = 9) were delivered from the pulmonary artery (PA) route mostly using long sheath guidance (7–8F). Implantation of JO-stents (n = 21) was performed without long sheath protection..

Results: All patients survived the catheterization procedure. The final stent diameter varied from 5 to 10 mm. Five pts had stent placement to reach an outpatient status awaiting HTX, the others had progressive DA stenosis with hemodynamic and metabolic deterioration including cardiopulmonary resuscitation in 4 pts. DA patency was achieved for up to 52 days. Switching to more flexible stents allowed using 4 or 5F introducer sheaths, long sheath guidance could be avoided further decreasing morbidity.11 pts underwent HTX, and 3 palliative surgery according the Norwood I procedure, 1 patient reached Hemifontan by combined DA-stenting and PA-banding, 1 had corrective surgery, 2 are still waiting for a heart donor at home. 7 pts died in right heart failure awaiting further surgery.

Conclusion: Progress in stent technology facilitates implantation procedure. Effective widening in ductal stenosis offers rescue therapy in ductus dependent heart defects. Pts with HLHS can reach an outpatient status awaiting HTX. Combination with PA-banding offers the possibility of late palliative surgery as well as transplantation.

NEWER ASPECTS ON BETA-BLOCKADE IN CONGESTIVE HEART FAILURE

2628 Selective β-1 blockade improves left ventricular energy status, systolic and diastolic function in the rats with postinfarct heart failure

E. Omerovic, E. Bollano, M. Basetti, V. Kujacic, A. Hjalmarson, B. Soussi, F. Waagstein. *Wallenberg Lab., Sahlgrenska Univ. Hosp., Göteborg, Sweden*

Background: The results from recent clinical studies support the concept of beta-blockade therapy in congestive heart failure (CHF). However, the mechanisms for the beneficial effects of beta-blockade in CHF are incompletely understood. The aim of this study was to evaluate the effects of selective beta1-blockade on left ventricular (LV) energy status and function in rats during early postinfarct remodeling phase.

Methods: Male Sprague-Dawley rats body weight (BW) 200–250 were used. Myocardial infarction (MI) was induced by ligation of the left coronary artery. Two different groups of rats were studied: rats with MI treated with metoprolol (5 mg/kg/h; n = 8) during 4 weeks and rats with MI placebo treated (n = 6). All rats were investigated with 31P MRS and transthoracic echocardiography (ECHO) 3 days (3 d) and 3 weeks (3 w) after induction of MI. Infarct size was estimated by ECHO and only rats with large MI were selected. Volume-selective 31P MRS was performed on 20 cm bore, 2,35T Bruker Biospec BMT 24/30 magnet using cardiac gated ISIS (Image Selected in Vivo Spectroscopy) method.

Results: The results are summarized in the table. Treatment with metoprolol increased LV PCr/ATP ratio indicating improved myocardial energy reserve. At the same there was improvement in parameters reflecting LV systolic and diastolic function in the rats treated with metoprolol compared to the placebo group.

	PCr/ATP	EF%	DT ms	HR beats/min
Metoprolol	1.2 ± 0.09 *	3.4 ± 1.8 *	17 ± 3 *	−168 *
Placebo	0.04 ± 0.056	−9.66 ± 1.8	3 ± 3	−73

The values represent the means ± SEM of the difference before and after the treatment, * = $p < 0.05$ v.placebo. PCr/ATP = phosphocreatine/adenosine-3-phosphate ratio, EF = ejection fraction, DT = deceleration time of mitral E-wave, HR = heart rate

Conclusion: Metoprolol improves myocardial energy status in the rats during early postinfarct remodeling period. The beneficial effect on cardiac bioenergetics may be an important mechanism for the improvement in LV systolic and diastolic function after selective beta-1 blockade.

2629 Influence of long-term metoprolol treatment on the myocardial adrenergic nervous activity in patients with congestive heart failure as measured by MIBG uptake

Paul A.R. de Milliano, André C. de Groot, Berthe L.F. van Eck-Smit, Pieter A. van Zwieten, Jan J. Tijssen, Kong I. Lie. *Ziekenhuis Hilversum, Hilversum; Academic Medical Center, Amsterdam, Netherlands*

Background. Intensified myocardial adrenergic nervous stimulation resulting in down-regulation of the β-receptors has been demonstrated in patients with congestive heart failure (CHF). Myocardial ^{123}I-MIBG (analog of norepinephrine (NE)) uptake is reduced in cardiomyopathy resulting from both a reduced re-uptake 1 and increased release of NE from adrenergic nerve endings. We hypothesized that metoprolol has a favorable effect on MIBG uptake reflecting improvement of myocardial adrenergic nervous system integrity at the presynaptic level.

Methods. 59 consecutive patients (pts) with stable CHF class II or III and an EF < 35% entered the titration phase after measurement of baseline parameters. Starting dose was 25 mg metoprolol, maximal dose 150 mg. Pts who tolerated at least 50 mg were randomized to receive either placebo (n = 11) or one of 3 doses of metoprolol: 50 (n = 5), 100 (n = 11) or 150 (n = 27) mg depending on their maximal tolerated dose. ^{123}I-MIBG uptake was measured using SPECT imaging 4 hours after injection.

Results. Mean age of the randomized pts was 65 ± 10, 54% were in class II. Mean dose of metoprolol in the randomized pts was 126 ± 35 mg.

	Placebo			Metoprolol		
	baseline	6 months	Δ (%)	baseline	6 months	Δ (%)
MIBG	90 ± 44	82 ± 26	−8	87 ± 46	103 ± 56	+22*
NE	3.7 ± 1.7	4.2 ± 3.0	31	3.5 ± 2.1	3.8 ± 2.3	107
EF	27 ± 6	28 ± 9	9	26 ± 9	32 ± 9*	36
EDD	70 ± 4	71 ± 6	1	74 ± 10	67 ± 10*	−9.5

Results are expressed as mean ± SD. * = $p < 0.05$; MIBG = myocardial uptake (counts/voxel), NE = plasma NE (nmol/l). EF = ejection fraction (%), EDD = end diastolic diameter (mm).

Conclusion. Myocardial MIBG uptake increased significantly during treatment with metoprolol in CHF pts indicating a presynaptic effect of metoprolol in patients with congestive heart failure.

2630 Effect of metoprolol on QT, QT dispersion and left ventricular function in patients with heart failure

C.A. Schneider, A. Stäblein, F. Waagstein[1], M. Böhm. *For the German, Swedish, Finnish heart failure research group; Klinik III für Innere Medizin, Universität zu Köln, Cologne, Germany; [1]Wallenberg laboratory for cardiovascular research, Department of Cardiology, Sahlgrenska University Hospital, Gothenborg, Sweden*

The exact effects of metoprolol (meto) on cardiac de- and repolarisation in patients with depressed left ventricular function are unclear. QT, corrected QT (QTc), QT dispersion (disp.) and QTc dispersion were therefore assessed in a 12-lead rest ECG of 103 patients with moderately depressed left ventricular function before and 6 months after oral metoprolol (50 mg t.i.d, n = 50) or placebo (n = 53) therapy in a prospective, randomized, double blind study. Left ventricular ejection fraction (LVEF) was assessed by radionuclide angiography at baseline and 6 months later.

Results:

	Placebo		Meto	
	Baseline	6 months	Baseline	6 months
LVEF [%]	27 ± 7	28 ± 10	27 ± 7	35 ± 10*
Heart rate [/min]	83 ± 16	79 ± 14	77 ± 14	66 ± 15*
QT [ms]	416 ± 43	419 ± 43	424 ± 41	436 ± 47
QTc [$ms^{1/2}$] Bazett	482 ± 49	476 ± 48	475 ± 43	454 ± 47*#
QTc [$ms^{1/3}$] Fridericia	419 ± 77	407 ± 68	404 ± 63	361 ± 66*§
QT disp. [ms]	64 ± 25	63 ± 23	65 ± 21	67 ± 27
QTc disp. [ms]	78 ± 30	73 ± 31	73 ± 25	71 ± 31

*$p < 0.001$ vs. metoprolol baseline, #$p < 0.02$ vs. placebo 6 months, §$p < 0.001$ vs. placebo 6 months.

Conclusion: QTc decreased and LVEF increased significantly in patients treated with meto. Thus, the decrease in QTc duration may reflect stabilization of the action potential which may contribute to the antifibrillatory effect of metoprolol and to the improved prognosis in these patients.

2631 Different intrinsic activity of bucindolol, carvedilol and metoprolol in human left ventricular myocardium

C. Maack, M. Flesch, M. Südkamp[1], M. Böhm. *Klinik III für Innere Medizin; [1]Klinik für Herz- und Thoraxchirurgie der Universität zu Köln, Cologne, Germany*

Objective: In clinical trials, beneficial effects of the β-adrenoceptor (AR) antagonists bucindolol (BUC), carvedilol (CARV) and metoprolol (METO) on left ventricular (LV) function in patients with chronic heart failure (CHF) have been observed. Nevertheless, the effects of these agents on the β-adrenergic system, i.e. receptor regulation, appear to be different. As these differences could be explained by different receptor interaction, this study investigates intrinsic activity as well as G-protein interaction of BUC, CARV and METO in human myocardium.

Methods: Radioligand binding studies using [^{125}I]-ICYP were performed in human LV myocardial preparations. Functional experiments were performed in intact LV myocardium from patients with CHF.

Results: BUC and CARV bind non-selectively to β_1- and β_2-ARs. BUC reveals agonist-like binding properties on β_1- and β_2-ARs, CARV predominantly on β_1-ARs, as the binding curves are shifted to the right by GppNHp. In contrast, METO is 35-fold β_1-selective, and the binding is not affected by GppNHp. At concentrations producing the same amount of β-AR occupation, METO antagonized isoprenaline-enhanced force of contraction (FOC) to a much higher degree than CARV and BUC ($p < 0.01$). In muscles that were prestimulated with forskolin, a diterpene that facilitates coupling of G-proteins with adenylate cyclase, BUC increased FOC in 38% of the experiments and decreased it in 62%. CARV decreased FOC by 27 ± 8%, METO by 89 ± 2% ($p < 0.001$ vs. CARV and BUC).

Conclusion: In human myocardium, METO possesses greater inverse agonist activity than CARV and BUC. BUC even exerts intrinsic sympathomimetic activity. This might lead to different negative inotropic effects upon initiation of β-blocker treatment in patients with CHF. Agonist-like binding of CARV and BUC, but not METO may have implications on the degree of phosphorylation of cardiac β-ARs and might be responsible for the different regulation of ventricular β-ARs in patients with CHF that were treated with these agents.

2632 Combination therapy with metoprolol and felodipine reduce benefit in resting and exercise haemodynamics as compaired with metoprolol alone in patients with severe chronic heart failure

Frank Edelmann, Markus Knapp, Gregor Simonis, Christof Weinbrenner, Martin U. Braun, Carsten Schwencke, F. Joachim Meyer, Rita Wipplinger, Ruth H. Strasser. *University of Heidelberg, Dept. of Cardiology, Heidelberg, Germany*

In addition to the standard therapy with diuretics, digitalis and ACE inhibitors, beta-adrenergic blockers have become a widely accepted strategy in the treatment of chronic heart failure (CHF). The role of calcium antagonists in CHF are controversial. Especially the hemodynamic effect of a combination of β-blocker therapy with long acting calcium antagonists has not been established yet.

To evaluate the hemodynamic changes induced by a combined therapy with β-blockers and calcium antagonists added to the standard therapy, patients with CHF (ejection fraction < 40%) were treated in a prospective, randomized, double-blind, placebo controled study with either metoprolol alone (titrated up to 100 mg/d, n = 13, MP) or combined metoprolol with felodipine (titrated up to 10 mg/d, n = 13, MF). At baseline and after 6 months, hemodynamic parameters were determined by right heart catheterization at rest and during exercise.

The heart rate at rest decreased significantly ($p < 0.05$) in both groups (MF: −10.3%; MP: −15.5%). Under maximal exercise, however, only metoprolol alone led to a significant reduction in heart rate (MF: −7.6% n.s.; MP: −19.2%, $p < 0.001$). Mean pulmonary arterial pressures were significantly decreased at rest and during maximal exercise only in the MP group (−30.4% and −23.4%), but not in the MF group, where only minor changes occurred. Furthermore the stroke volume index increased significantly at rest (MF: +13.5% n.s.; MP: +29.7%, $p < 0.05$) and during maximal exercise (MF: +17.7% n.s.; MP: +40.2%, $p < 0.01$) in the metoprolol group, but not under combination therapy.

In conclusion: Only β-blocker therapy as add on to the standard therapy lead to an improvement in resting and exercise hemodynamics in patients with severe CHF. In contrast, the combined therapy even mitigated the hemodynamic improvement seen on the β-blocker therapy alone suggesting the superior role of β-blockers in CHF.

2633 Effects of long-term β-blockade on the pattern of left ventricular diastolic filling in patients with dilated cardiomyopathy

N.P. Nikitin, A.L. Alyavi, V.Y.U. Goloskokova. *Department of Internal Medicine, The 1st Tashkent Medical Institute, Tashkent, Uzbekistan*

Recent clinical trials confirmed beneficial effects of beta-blockade in patients with dilated cardiomyopathy (DC). However, therapeutic benefits of beta-blocker therapy in patients with different patterns of left ventricular (LV) diastolic filling are less clear. This study was designed to evaluate clinical and cardiac effects of long-term therapy with metoprolol in patients with DC and restrictive LV filling, with the focus on the transmitral flow pattern.

Methods: 48 patients (aged 44 ± 9 years) were enrolled into the study. Patients were included if they were in sinus rhythm and had the restrictive pattern of LV diastolic filling at baseline. Twenty-four patients were randomised to standard therapy (ACE inhibitors, diuretics and digoxin), and 24 patients to metoprolol in addition to the standard therapy. Metoprolol was started at a dose of 10 mg daily and was progressively titrated up to the maximal doses of 100–150 mg daily. Patients underwent an assessment of functional status (NYHA classification and the 6-minute walk test). M-mode, B-mode echocardiography, and cardiac Doppler studies were performed to assess indices of LV systolic function and diastolic filling.

Results: patients were followed for 18 months. Mortality was not an end point in this study. The improvement in NYHA functional class and exercise capacity was significantly greater in the metoprolol group compared to the standard therapy group. Both therapies produced comparative effects on echocardiographic indices of LV systolic function. However, their effects on Doppler indices of LV diastolic filling were significantly different. After 18 months, the restrictive pattern of LV filling converted into a nonrestrictive pattern in 68% of patients on metoprolol compared to 28% patients on the standard therapy ($p < 0.05$).

In conclusion, long-term beta-blockade showed a strong potential in reversing the restrictive pattern of LV filling into a nonrestrictive pattern in patients with DC.

NEUROHORMONAL INHIBITION IN HEART FAILURE: EXPERIMENTAL AND CLINICAL ASPECTS

2643 Cardio- and nephroprotective effects of endothelin antagonists in uraemic cardiomyopathy of rats

B.R. Brehm, F. Gaschler, S. Brehm, M. Klaussner, B. Wiesinger, K. Amann[1], G. Friedemann[2], H. Heinle[2], T. Risler, S.C. Wolf. *Medical Clinik III, [2]Institute of Physiology, University of Tübingen; [1]Institute of Pathology, Heidelberg, Germany*

Increased endothelin-1 (ET-1) levels were found in patients with chronic renal failure These correlate with the severity of renal failure. Patients with elevated ET-1 concentrations have an increased cardiovascular mortality.

Methods: Male rats were subtotally nephrectomized and treated with an endothelin$_A$-receptor antagonist (30 mg/kg/d, LU302146) or an endothelin$_{AB}$-receptor antagonist (30 mg/kg/d, LU302872) for 12 weeks. One group was left untreated (SNX) and one was sham operated (sham). Determined were ET-1 serum-, ET-1 urin-concenetration, protein-excretion, heat weight and pulmonary β-adrenergic receptor density (β-AR), left ventricular contractility (LC) and relaxation (LR). The basal radical formation in aortas were measured

Results: ET-1 concentrations in the serum were increased with ET_A-(8.21 ± 0.96 fmol/ml) and ET_{AB}-antagonists (7.22 ± 0.7) compared to SNX (3.42 ± 0.61). ET-1 excretion was augmented in all groups. Myokardial hypertrophy was decreased by ET_A and ET_{AB} antagonists. Basal radical production decreased with both ET_A- or ET_{AB}-antagonists by 40%. The pulmonary β-AR increased from 733 ± 53 fmol/mg protein (sham) to 886.07 ± 41 in SNX but was not influenced by ET_A or ET_{AB}-antagonists. α-subunit of the stimulatory G-protein was increased in SNX by 53% and was not changed by ET antagonists. LC and LR were decreased in SNX by 40%. this was prevented by ET_{AB} antagonist treatment. Protein-excretion of SNX (174.4 ± 32 mg/d) was increased in comparison to the ET_A-group (72.9 ± 26.6) and the ETAB-group (116.0 ± 36.1, vs sham: 13.5 ± 3 mg/d).

Conclusion: Treatment with ET_A and ET_{AB} antagonists improve left ventricular function and inhibit ventricular hypertrophy as well as radical formation in rat aorta. These data show that in uremic cardiomyopathy ET-antagonists have cardio- and nephroprotective effects.

2644 Treatment with the endothelin-A receptor antagonist LU 135252 improves renal dysfunction in rats with chronic heart failure following myocardial infarction

J. Bauersachs[1], D. Fraccarollo[1], J. Widder[1], P. Rohmeiss[2], G. Ertl[1], C. Braun[2]. *[1]II., [2]V. Medizinische Klinik, Universitätsklinikum Mannheim, Germany*

Renal dysfunction is a common phenomenon in rats with chronic heart failure following myocardial infarction.

Methods: We investigated the effect of treatment with an endothelin (ET) antagonist on renal function in rats with experimental heart failure (HF) 12 weeks following myocardial infarction and compared with sham-operated animals (SHAM). Rats were treated by gavage starting on the 7th postoperative day either with placebo (HF-P, SHAM-P) or with the selective ET_A-receptor antagonist LU 135252 (30 mg/kg/d; HF-L, SHAM-L). Only animals with extensive myocardial infarction (≥46% of left ventricle) were included in the study. Infarct size was matched between HF-P and HF-L. Endogenous creatinine clearance, urinary excretion of endothelin and fractional sodium excretion were determined 12 weeks following myocardial infarction.

Results: Endogenous creatinine clearance was significantly lower in HF-P compared to SHAM-P (HF-P: 0.64 ± 0.05 vs. SHAM-P: 0.81 ± 0.04 ml/min/100 g bw; p = 0.01). Treatment with LU 135252 significantly improved renal function in chronic HF (HF-L: 0.98 ± 0.21 vs. SHAM-L: 0.83 ± 0.10). Urinary endothelin excretion was significantly lower in HF-P compared to SHAM-P (HF-P: 180 ± 60 vs. SHAM-P: 303 ± 19 pg/24 h; p = 0.01). In the treatment group, no difference could be observed between HF and SHAM, although the ET_A-receptor antagonist markedly increased urinary endothelin excretion (HF-L: 536 ± 111 vs. SHAM-L: 462 ± 86). Fractional sodium excretion was similar in the four groups.

Conclusion: Our data demonstrate a restoration of impaired renal function in chronic ischemic heart failure by treatment with the selective ETA-receptor antagonist LU 135252. These results offer a promising therapeutical option for the treatment of renal insufficiency in patients with chronic heart failure.

2645 Effect of long-term therapy with trimetazidine in cardiomyopathic Syrian hamster BIO 14:6; effect on the defective cardiac Na,K-ATPase

F. Paganelli[1], N. D'hahan[3], K. Robert[1], S. Pierre[2], J.M. Maixent[2]. *[1]Department of Cardiology, North Hospital, Marseille; [2]Biochemical Laboratory, School of Pharmacy Marseille; [3]Biology Laboratory, Ecole Centrale Paris, Châtenay-Malabry, France*

Effects of chronic therapy with the anti-ischemic agent, trimetazidine (T), on the progression of left ventricular failure on survival was assessed in the BIO 14:6 cardiomyopathic hamster (CMH). Abnormal calcium homeostasis and spasms of the microcirculation producing transcient focal ischemia, have been postulated to be at the origin of the cell death in the CMH. Active transport of Na^+ and K^+ across the cardiac cell membrane essential for excitability and contractility, was reported to be altered in CMH early.

Methods: T was administered in the drinking water at the dose of 18 mg/kg body wt/day from 30 to 350 days of age (n = 26). Aged-matched golden syrian hamsters served as healthy control (C). The cytosolic Ca^{++} concentration in cardiac myocytes was measured using the Ca-sensitive fluorescent dye Fura 2. The expression of the catalytic α-subunit isoform of Na,K-ATPase has been investigated in microsomal membranes by immunoblotting employing polyclonal anti rat fusion protein and enzymological assays.

Results: CMHs suffered reduced longevity and heart hypertrophy. At 220 days CMHs displayed a calcium overload. When compared to controls, there was a significant decrease ($p < 0.05$) in α1 subunit isoform of Na,K-ATPase. The membrane Na,K-ATPase activity was also significantly lower in CMH than Na,K-ATPase activity may be due to a decreased density of the expression of α1 polypeptides. T increased the median survival time of CMH by 57% and cardiac hypertrophy disappeared. The mean cytosolic Ca^{++} concentration in CMH myocytes (543 ± 28 nM) was reduced by 54% by T. The Na,K-ATPase activity and membrane protein expression were significantly improved by T ($p < 0.05$). In conclusion, a long term T treatment that improves the survival of CMH, would reduce cytosolic Na+ and Ca^{++} overloads in this animal model of human cardiomyopathy.

2646 The bradykinin receptor antagonist icatibant attenuates the effects on blood pressure of acute ACE inhibition in normal man

I. Squire, K. Okane[1], N. Anderson[1], J.L. Reid[1]. *Department of Medicine & Therapeutics, University of Leicester, Leicester; [1]Medicine & Therapeutics Dept., University of Glasgow, Glasgow, UK*

The pharmacological effect of ACE inhibitors (ACEI) may be partly mediated via bradykinin (BK) accumulation.We investigated the effect of the specific BK2 receptor antagonist icatibant on the blood pressure and neuro-hormonal response to acute ACE inhibition in normal man.

Methods: We performed a four phase, double-blind, double-dummy, placebo controlled study in 12 male volunteers (22.9 ± 1.9 years) on a normal Na diet. Icatibant (10 mg iv) was coadministered over the first 15 minutes of a 2-hour infusion of the ACEI perindoprilat (1.5 mg i.v.). In each phase, volunteers received one of: perindoprilat (P)+ placebo (PI); icatibant (I) + placebo; perindoprilat + icatibant; placebo + placebo. Blood pressure, heart rate and neuro-hormonal (plasma ACE activity, active renin concentration (ARC) and Ang I and Ang II concentrations) were measured at intervals to 12 hours after the start of infusions. We prospectively decided to analyse the data from the first 3 hours from the start of drug infusion plus the full 12 hour observation period. Haemodynamic and laboratory data were compared between groups following baseline and placebo correction. A mixed model ANOVA was fitted to all data using BMDP. The maximum change in MAP and HR on each study day was calculated for each volunteer.

Results: Over the first 3 hours P reduced MAP (mean max reduction 8.1 mmHg, $p < 0.0005$ cf placebo). I alone raised MAP (mean max increase 6.1 mmHg, p = 0.001 cf placebo). The fall in MAP with P was attenuated by coadministration of I (mean max reduction 6.5 mmHg, p = 0.001 cf P alone). Over the same period, P was associated with an increase (mean max increase 2.8 bpm, $p < 0.0005$ cf placebo) and I with a reduction (6.5 bpm, $p < 0.0005$ cf placebo) in HR. Coadministration of I did not alter the HR response to P alone (p = 0.059). Similar patterns were observed for the full 12 hour period. Comparison of the area under the MAP/Time curve for each treatment arm supported the findings of the statistical model. P inhibited (95.4 ± 3.7%) ACE activity, increased ARC and lowered the [Ang II/Ang I + Ang II] ratio (Each $p < 0.0005$ cf placebo). Co- administration of I had no effect on neurohormonal responses to P.

Conclusions: BK2 antagonism attenuates the BP lowering effect of acute ACE inhibition in normal man. BK may be involved in the control of resting BP in man.

2647 Dose of angiotensin converting enzyme inhibitors in patients with heart failure: understanding the gap between clinical trials and clinical practice

D.E. Manyari, R. Gutierrez[1], I. Belenkie[2], R.T. Tsuyuki[1], D.P. Humen[1], K. Teo[1], P.W. Armstrong[1]. *Cardiology Dept., University of Alberta, Edmonton AB; [1]Cardiology Dept., University of Alberta, Edmonton AB; [2]Cardiology Dept., University of Calgary, Calgary AB, Canada*

Background: High dose (clinical trial dose = CTD) angiotensin converting enzyme inhibitors (ACEI) are more efficacious than low dose in treating patients (Pts) with heart failure (CHF). However, the proportion of Pts with CHF who may be able to tolerate the CTD is unknown.

Methods: We undertook a prospective study of consecutive Pts with CHF seen at the CHF Clinics of 2 Canadian University Hospitals. The only inclusion criteria was that they were followed at one of the specialized clinics (by cardiologists with special interest and expertise in CHF) for at least 3 months. A careful history of their therapy with ACEI was obtained directly and confirmed by chart review. Suboptimal dose ACEI was defined as <7.5 mg bid for enalapril, <25 mg tid for captopril, or <15 mg od for lisinopril.

Results: We studied 200 consecutive Pts (138 males), mean (± SD) age of 69 ± 12 years and mean ejection fraction of 31 ± 12%. There were 28, 87, 71 & 14 Pts in NYHA functional class I, II, III & IV, respectively. Only 68 Pts (34%) were taking ACEI at CTD. In the remaining 132 Pts (66%), the reasons for the use of suboptimal dose or no ACEI were: symptomatic low blood pressure, renal dysfunction, and h/o ACEI-induced skin rash, cough or hyperkalemia, as noted in the Table. In only 22 of these 132 Pts (11% of the total) were we successful in increasing the dose of ACEI to the CTD levels, usually by decreasing the dose of diuretics. The majority of Pts who tolerated up titration of ACEI were in functional class I & II. At the end of the study, only 45% of Pts (34 + 11%) were able to tolerate the CTD.

Table

	Low BP	RD	Cough	Other	Total
Sub-Op Dose	51	15	2	19	87 (44%)
No ACEI	14	13	9	9	45 (22%)
Total	65 (32%)	28 (14%)	11(6%)	28 (14%)	132

ACEI = angiotensin converting enzyme inhibitor; BP = blood pressure; RD = renal dysfunction; Sub-Op = suboptimal. Percentage (%) is relative to the total study population.

Conclusion: Despite efforts to maximize the the dose of ACEI in a patient population with CHF followed at specialized CHF clinics, less than one half of Pts were able to tolerate the recommended CTD. The gap between clinical trials and clinical practice is more complex than just physician's failure to comply with practice guidelines.

2648 Renal, cardiac and endocrine effects of long-term vasopeptidase inhibition in chronic heart failure

D.R. McClean, H. Ikram, I.G. Crozier, M. Hume, M. Reynolds, A.M. Richards, M.G. Nicholls. *Cardiology Department, Christchurch, New Zealand*

Combined inhibition of neutral endopeptidase(NEP) and angiotensin converting enzyme(ACE) is postulated to be advantageous in treatment of chronic heart failure(CHF). The purpose of this substudy was to evaluate the mechanisms of potential benefit in CHF(cardiac, renal, neurohumoral)in a subgroup of patients from the first study of chronic vasopeptidase inhibition with omapatrilat in CHF.

Methods: The study was a randomised, double blind, single-centre study in 41 patients with NYHA Class II-IV, LVEF < 40%. Patients were randomised to 2.5, 5, 10, 20 or 40 mg once daily. Clinical status assessment, echocardiography, and digital applanation tonometry were performed at baseline and after 3 months of chronic therapy. Data for all doses combined and also dose-dependent changes [2.5 mg, 5–10 mg, 20–40 mg] are shown.

Results: There was an improvement in patient clinical assessment of heart failure status at 3 months** [20–40 mg (improved moderately) vs. 2.5 mg (no change)**].

Table 1

	HR bpm	EF %	SBP mmHg	Uvol ml/24 hr	Una mmol/24 hr	ANP pmol/l	BNP pmol/l	EPI pmol/l
Baseline	71	24	131	1797	112	66.0	47.8	148
3 months	67*	28**	116**	2148**	135**	65.3	39.3**	101**
Change	from	Baseline	2.5 mg		5–10 mg		20–40 mg	
EF	%		−3.4		6.73**		7.41**	
Wallstress	g/cm^2		29.4		−33.5		−66.4*	
SBP	mmHg		−3.6		−16.8		−25**	
Una	mmol/24 hr		12.1		14.1		47.2	
ANP	pmol/l		−13.6		−4.0		12.5	

SBP = systolic blood pressure; Uvol = urinary volume; Una = urinary sodium; EPI = epinephrine; p < 0.05*, p < 0.01*.

Conclusion: Three month omapatrilat treatment in patients with CHF resulted in improved clinical status. There was a dose-dependent improvement in LVEF secondary to afterload reduction. The increased urine sodium and volume excretion at 3 months suggests a natriuretic and diuretic effect which may have a delayed onset. The increase in ANP at higher doses, despite the paradoxical fall in BNP and hemodynamic improvement, is consistent with NEP inhibition.

MEDICAL THERAPY IN ACUTE CORONARY SYNDROMES

2662 Heparin anticoagulation treatment during hyperfibrinogenaemia in acute coronary attacks

I.S. Posada, I. Larrañaga, S. Hevia, M.I. Soto, A. Testa, J.C. Sanmartín, A. Veganzones, M.F. Urgellés, G.I. Cubero, V. Barriales. *Central Hospital of Asturias, 33006 Oviedo, Spain*

Background: in patients with acute myocardial infarction (AMI) fibrinogen levels (F) after thrombolytic therapy correlate with heparin consumption and ischaemic events (Ies). A controlled trial was designed to ascertain whether: 1. hypercoagulation and thrombin generation was a common fact in the first month after AMI. 2. it would be possible to decrease thrombin activity and Ies with long-term heparin treatment.

Methods: patients with AMI treated with streptokinase were allocated at random to receive either heparin (H) i.v. for one week, followed by nadroparin (LMWH) for 14 days (Prolong H Group; n = 80) or 5.700 u/day of nadroparin 2 days (Control Group; n = 68). Assays of Trombin-Antithrombin Complex (TAC) and prothrombin fragments 1 + 2 (FRAGM) were performed on days 3 and 30 to assess thrombin activity (Thr Ac).

Results: the table shows Thr Ac for both groups:

	CTAT			FRAGM		
	Control G	Prolong G	P	Control G	Prolong G	P
Day 3	7.3 ± 6	5.9 ± 5	0.5	2.2 ± 1	1.2 ± 0.7	0.03
Day 30	5.8 ± 5	4.0 ± 2	0.05	1.9 ± 1	1.5 ± 0.7	0.07

In the acute phase Thr Ac was similar in patients with Ies and those without complications. On day 30, the mean values of Thr Ac were within the normal range in patients with a favorable course (CTAT = 4.5 ± 2; FRAGM 1.7 ± 1) but remained elevated in cases with Ies (CTAT = 7.0 ± 4; FRAGM 3.14 ± 2; p 0.03)

Conclusions: 1. Patients with AMI have high Thr Ac 72 h after STK treatment, when F levels begin to rise. 2. Thr Ac is higher in the control Group 3. There is a trend for F levels and Thr Ac to normalize one month later, but patients with major Ies show persistently elevated values of F, CTAT and FRAGM.

2663 High-dose hirulog enhances speed and stability of reperfusion compared to heparin in conjunction with thrombolytic therapy: continuous ST-segment recovery in the HERO-I study

M.W. Krucoff, C.L. Green, J.K. French[1], A. Maas[2], K.M. Trollinger, I. Straznicky[1], J. Andrews[1], H.D. White[1]. *Cardiology Dept, Duke University Medical Center, Durham NC, USA; [1]Cardiology Dept, Green Lane Hospital, Auckland, New Zealand; [2]Cardiology Dept, VA Medical Center, Durham NC, USA*

Adjunctive therapy may influence the speed and/or the stability of reperfusion following thrombolytic therapy for acute MI. Continuous digital 12-lead ST-segment recovery analysis provides quantitative measures of reperfusion. All pts with MI by ST elevation, <6 hr. of chest pain, given streptokinase and randomized to heparin, low-dose and high-dose Hirulog in the HERO-I study who underwent ST-monitoring were analyzed. From 210 pts, 180 studies were analyzable for: absolute PEAK ST levels (uV); >50% recovery at 90 minutes suggesting reperfusion (ST-90); time to >50% recovery lasting >4 hr. (STABLE ST (min.)); recurrent ischemia before STABLE ST (RE-ST); and LATE ST re-elevation after STABLE ST. Data were analyzed blinded to therapy. For results, given as median or percentage, see table.

Table

Variable	Heparin	Low dose	High dose	*p-value
No. patients	60	61	59	
Peak	528	498	400	0.070
ST-90	51%	63%	76%	0.006
Stable ST	128	118	118	0.116
Re-ST	63%	47%	36%	0.006
Late ST	24%	17%	9%	0.028

*p-value compares heparin vs. high dose Hirulog

Conclusions: Hirulog, especially high dose Hirulog, significantly enhances the speed and stability of reperfusion in combination with streptokinase in acute MI.

2664 The combined use of pravastatin and thrombolysis in acute myocardial infarction: effect on the patency of infarct-related artery

L. Can, M. Kayikcioglu, H. Kultursay, C. Gurgun, A. Altintig, C. Turkoglu.
Cardiology Dept., Ege University Medical School, Izmir, Turkey

The effect of cholesterol lowering drugs in acute myocardial infarction (AMI) is not well established. In this study pravastatin was administrated to pts with AMI, in combination with thrombolytic therapy. Effects on arterial stenosis and restenosis after PTCA were evaluated by coronary angiography. One hundred fifty consecutive pts with first MI were prospectively enrolled in the study and randomized into two groups. Group-I(n = 72), received pravastatin (40 mg/day) within the first hour of thrombolytic therapy irrespective of serum lipid levels. Group-II (n = 78) was given only thrombolytic therapy without any cholesterol lowering agent. All pts were within the first 6 hours of chest pain. In both groups tissue plasminogen activator and streptokinase administration rates were similar. Basal characteristics of the groups were also similar. Lipid levels were determined immediately after admission and after 1 and 6 months. Infarct related arterial (IRA) stenosis rates were compared between the two groups by quantitative coronary angiography one month after the infaction. A total of 71 pts (34 pts (47%) in pravastatin-group and 37 pts (48%) in control group) underwent invasive intervention. After the 6-month follow-up, pts were reevaluated with clinically and angiographically for restenosis. Groups were compared for restenosis rates of the infarct related arteries with respect to the serum lipid levels.

Results: see table.

Comparison of the groups

	Pravachol-group	Control-group	p
Clinical Reperfusion	56 (78%)	56 (73%)	ns
LDL (mg/dl) admission	145 ± 30	149 ± 40	ns
LDL (mg/dl) 6th month	98 ± 17	144 ± 27	0.00
IRA lesion% 1st month	86 ± 10	90 ± 66	ns
6th month	45 ± 22	67 ± 25	0.000
Restenosis rates	11(33%)	15(41%)	ns

Combined use of cholesterol lowering drug and thrombolytic therapy in AMI did not affect short-term arterial patency on the first month angiography; however, at 6-month control, arterial patency and restenosis rates were better for patients receiving pravastatin. Reduction in restenosis rates may be due to regulation of endothelial or platelet functions as well as lowering of blood cholesterol levels by pravastatin.

2665 Incomplete Infarction Trial of European Research Collaborators Evaluating Prognosis Post-Thrombolysis (INTERCEPT): a randomized comparison of diltiazem once daily and placebo following thrombolysis-treated myocardial infarction

W. Boden, K. Fox, R. Scheldewaert. *On behalf of the INTERCEPT Investigators; Veterans Affairs Medical Center, Syracuse NY, USA; Royal Brompton Hospital, London, UK; Synthélabo, Paris, France*

Diltiazem has been demonstrated to reduce cardfiac events following non-Q-wave infarction. We hypothesized that this agent would likewise reduce events following thrombolysis-treated myocardial infarction, both settings being associated with "incomplete infarction" occurrence.

We performed a double blind, multicenter, parallel group, sequential analyzed study in 874 patients treated with thrombolysis for acute myocardial infarction comparing the effects of treatment with diltiazem 300 mg once daily (D) and placebo (P) on subsequent cardiac event recurrences. Patients were randomized within 36–96 hours of pain onset and treated for up to 6 months All patients recieved ASA.

Main inclusion criteria were: age up to 75 years, prolonged chest pain with ECG signs of ischemia and enzyme proven myocardial necrosis, thrombolysis-treatment and ASA prior to 12 hours after pain onset and absence of congestive heart failure. Baseline patients characteristics were comparable.

For the primary endpoint, consisting of the cumulative first event rate of cardiac death (CD), non-fatal reinfarction (NFR) and medically refractory ischemia (RI), 97 events (22.6%) and 131 events (29.5%) occurred in, respectively D and P treated patients (HR 0.78; 95%CI 0.60–1.02; p = 0.07), a 23% relative reduction. Significant reductions favoring D were observed in non-fatal events and in the need for myocardial revascularisation (MR) for ischemia recurrences. NFR + RI decreased by 26% (HR 0.76; 95% CI 0.58–1.00; p = 0.05), NFR + MR decreased by 37% (HR 0.67; 95% CI 0.46–0.96; p = 0.03) and MR was reduced by 42% (HR 0.61; CI 0.39–0.96; p = 0.03). No major safety issues were encountered.

We conclude that diltiazem once daily can be safely administered as secondary prevention following thrombolysis-treated myocardial infarction and exerts important favorable effects in decreasing non-fatal events and myocardial revascularisation procedures.

2666 Are there differences in the treatment of acute myocardial infarction in West and East Germany after unification? The Myocardial Infarction Registry (MIR)

F. Fischer[1], R. Zahn[1], K.K. Haase[1], R. Schiele[1], S. Wagner[1], S. Schneider[1], R. Grube[2], H.J. Gutschmidt[3], B. Baumgärtel[4], J. Senges[1]. *[1]Heart Centre Ludwigshafen; [2]Freiberg; [3]Kiel; [4]Freital, Germany*

After unification in 1989 differences in the treatment of acute myocardial infarction in West and East Germany may persist. We compared the therapy of acute myocardial infarction in West and East Germany.

Methods: The Myocardial Infarction Registry (MIR) is a prospective, multicenter registry of patients with acute myocardial infarction in West and East Germany from 01.04.1997 to 31.03.1998. 14608 patients were treated at 211 hospitals.

Results:

	West G.	East G.	p-value
Patients (n)	8990	5618	
Age (median, years)	68	69	NS
Female sex (%)	34.1	36.7	NS
Prehospital delay (median, min)	180	210	<0.001
Contraindication for thromholysis (%)	6.1	6.3	NS
Thrombolysis and/or PTCA (%)	51.3	37.7	<0.001
Thrombolysis (%)	40.8	28.9	<0.001
PTCA (%)	8.5	7.0	<0.001
Aspirin (%)	92.9	86.3	<0.001
β-blocker (%) 1	56.4	50.1	<0.001
ACE-inhibitor (%)	53.6	51.6	<0.001

G. = Germany

Conclusion: Even nearly 10 years after unification, significantly more patients in West Germany were treated with reperfusion therapy and adjunctive therapy, including aspirin, β-blockers and ACE inhibitors.

2667 An optimised therapy strategy in patients with ami is associated with a reduction in hospital mortality: results of the Myocardial Infarction Registry (MIR) in Germany 1998

S. Wagner[1], R. Schiele[2], S. Schneider[2], F. Fischer[2], H.J. Gutschmidt[3], J. Senges[2]. *For the MIR study group; [1]Dep. of Cardiology, Klinikum Bruchsal; [2]Herzzentrum Ludwigshafen; [3]Städtisches Krankenhaus Kiel, Germany*

Daily practice of the treatment of patients with AMI in community hospitals may differ from recommendations of randomised trials. We sought to determine the use of reperfusion therapy and adjunctive drugs improving prognosis of AMI and their influence on hospital outcome.

Methods: The Myocardial Infarction Registry (MIR) is a multicenter and prospective observational registry with 217 participating hospitals in Germany. The primary aim of the study is to optimise therapy strategies in the treatment of AMI. All patients with q-wave AMI, admitted within 96 hours after the onset of pain were included from 12/96–5/98. Base line characteristics and the use of the combined therapies improving prognosis (reperfusion therapy, aspirin, betablocker and ACE-inhibitor) were registered. The treating physicians were obliged to document why a therapy was not given. A multiple logistic regression analysis was applied to calculate the influence of therapy on intrahospital mortality.

Results: In total 14598 patients with AMI were registered. Mean age was 67 years, 65% were male. 46% received a reperfusion therapy. Aspirin was given to 90%, betablocker to 54% and ACE-inhibitors to 53% of the patients.

Influence of reperfusion and adjunctive therapy on hospital mortality

	odds ratio	95% CI
Reperfusion therapy	0.7	0.6–0.8
Aspirin	0.6	0.4–0.7
Betablocker	0.6	0.5–0.7
ACE-inhibitor	0.5	0.4–0.6

Conclusions: In patients with AMI the combined treatment of reperfusion therapy, aspirin, betablocker and ACE-inhibitor is associated with a reduction in intrahospital mortality. Participation in a quality registry and the obligation to document why a therapy is not given may result in an increased use of reperfusion and adjunctive therapy.

ULTRASONIC EVALUATION OF CORONARY FLOW RESERVE

2668 Coronary flow reserve is supranormal in endurance athletes: a transthoracic echocardiographic study

D.J. Hildick-Smith, P.J. Johnson[1], C.R. Wisbey, E.M. Winter[1], L.M. Shapiro. *Cardiac Unit, Papworth Hospital, Cambridge; [1]Sports Physiology Dept, De Montfort University, Bedford, UK*

Background: Coronary flow reserve measurements offer a valuable assessment of microvascular coronary circulation. Invasive means of assessing coronary flow reserve do not allow investigation of states of health. Transthoracic echocardiography has recently been shown capable of assessment of coronary flow reserve. We therefore aimed to compare and contrast coronary flow reserve in endurance athletes and healthy sedentary controls.

Methods and Results: 29 male endurance athletes (age 27.3 ± 6.6 yrs, BMI 22.1 ± 1.9 kg/m^2) and 23 male controls (age 27.2 ± 6.1 yrs, BMI 23.9 ± 2.6 kg/m^2) with no coronary risk factors underwent transthoracic echocardiographic assessment of distal left anterior descending coronary artery diameter and flow both at rest and during intravenous adenosine infusion (140 mg/kg/min). Distal LAD diameter and flow were adequately assessed in 19 controls (83%) and 26 athletes (90%). Distal LAD diameter in athletes (2.04 ± 0.25 mm) was not significantly greater than that of sedentary controls (1.97 ± 0.27 mm; p = ns). Percent increase in LAD diameter following 400 microgrammes sublingual nitrate, however, was greater among athletes (14.1 ± 7.2%) than controls (8.8 ± 5.7%; p < 0.01). Left ventricular mass index in athletes (130 ± 19 g/m^2) exceeded that of controls (98 ± 14 g/m^2; p < 0.01). Resting flow among athletes (10.6 ± 3.1 ml/min, 8.2 ± 2.2 ml/min/100 g LVmass) was less than that of controls (14.3 ± 3.6 ml/min, 4.4 ± 1.2 ml/min/100 g LVmass); both p < 0.01). Hyperemic flow among athletes (61.9 ± 17.8 ml/min) exceeded that of controls (51.1 ± 14.6 ml/min; p = 0.02), but not when corrected for LV mass (25.9 ± 5.6 vs 28.5 ± 7.4 ml/min/100 g LVmass; p = ns) Coronary flow reserve was therefore substantially greater amongst athletes (5.9 ± 1.0) than controls (3.7 ± 0.7; p < 0.01)

Conclusions: Coronary flow reserve in endurance athletes is supranormal and endothelium-independent vasodilatation is enhanced. Hypertrophy of the myocardium per se does not necessarily impair coronary flow reserve. Adenosine transthoracic echocardiography is a promising technique for the investigation of coronary flow reserve.

2669 Increased chronotropic sensitivity and reduced coronary flow reserve are associated with inotropic incompetence during β-adrenergic stimulation in patients with mild hypertension

M. Kozàkovà, C. Palombo, G. Bigalli, C. Morizzo, A. Magagna[1], L. Ghiadoni[1], S. Taddei[1], A. Salvetti[1], A. L'Abbate. *Cardiology Dept., Institute of Clinical Physiology, Pisa; [1]Department of Internal Medicine, Pisa, Italy*

Whether or not coronary function is impaired in pts with mild arterial hypertension (HBP) is still debated. Aim of this study was to assess coronary flow reserve (CFR) and the response of coronary flow to beta-adrenergically mediated increase in chronotropic and inotropic myocardial activity in pts with mild HBP.

Methods: in 10 normotensive subjets (N) and 10 age- and gender-matched pts with mild HBP, all without coronary artery disease, coronary flow velocity (CFV) in LAD was monitored by TEE-Doppler at baseline and during stepwise Dobutamine infusion (DOB: steps of 15, 30 and 60 μg/kg/3 min) under continuous BP and ECG monitoring. LV fractional shortening (FS) and septal systolic thickening (SST) were assessed simultaneously by transthoracic echo. CFR was estimated just before DOB by Adenosine infusion (ADO: 700 μg/kg/5 min).

Results: in pts vs controls, MBP was 104 ± 15 and 97 ± 13 mmHg, HR 84 ± 14 vs 81 ± 15 bpm and LV mass index 144 ± 56 vs 110 ± 15 g/sqm (p = n.s. for all). Basal FS and SST were also comparable. CFR was significantly lower in pts (2.5 ± 0.4 vs 3.7 ± 1.1, p < 0.01), due to higher baseline CFV (32 ± 11 vs 22 ± 5 cm/sec, p < 0.05) and comparable maximal CFV (78 ± 18 vs 79 ± 18 cm/sec). The higher basal CFV was related to higher rate-pressure product (RPP: 12321 ± 2166 vs 10845 ± 2884 mmHg*bpm, p < 0.05).

During DOB, chest pain, ST-shift or LV asynergy never occurred, and the ratio of maximal achieved to basal CFV was 1.9 ± 0.4 in pts and 1.7 ± 0.4 in N (n.s.). In both groups, significant direct relations between stepwise increase in CFV and the corresponding increments in HR, FS and SST were found (r value between 0.513 and 0.714); however, compared to N, pts had steeper increase (p < 0.05) in HR (14 ± 15 vs 6 ± 12 bpm) and CFV (15 ± 12 vs 8 ± 9 cm/sec), but lower increase in SST (7 ± 10% vs 16 ± 14%, p < 0.05).

Conclusion: in pts with mild HBP, increased resting CFV and chronotropic sensitivity to adrenergic stimulation may lead to encroach CFR even during submaximal stress, possibly resulting in an inadequate inotropic response despite the absence of significant structural abnormalities.

2670 Visualization of proximal left coronary artery blood flow and identification of proximal left coronary artery stenosis using transthoracic Doppler echocardiography

N. Yashima, M. Nasu, A. Tashiro, S. Kuriki, M. Ito, H. Yamaguchi, N. Sato, H. Mukaida, H. Niinuma, K. Hiramori. *Second Department of Internal Medicine, Iwate Medical University, Morioka, Japan*

This study evaluated the ability of transthoracic Doppler echocardiography to visualize proximal left coronary artery flow and assess coronary artery stenosis.

Subjects and method; We studied 78 healthy volunteers (22 males, 56 females, mean age 58.9 years) and 48 patients who were suspected of coronary artery disease without previous anterior myocardial infarction (40 males, 8 females, mean age 64.5 years). Transthoracic Doppler echocardiography was performed on all subjects using Sequoia (Acuson, Mountainview) with 2.5 ~ 7.0 MHz transducers and coronary angiography was then performed on all patients. Subjects were divided into the following 3 groups: 78 volunteers, Group I; 17 patients with stenosis (>50% stenosis in diameter) at proximal left coronary artery (PLCA) from main trunk to segment 7 according to AHA classification, Group II; 31 patients without PLCA stenosis, Group III.

Results; PLCA flow could be visualized during diastole by color Doppler in 84.6% of volunteers (66/78) and in 83.3% of patients (40/48). Aliasing signals were found in only 2 of 78 volunteers in the 39 cm/s Nyquist limit. In contrast, 18/40 patients (11 Group II, 7 Group III) showed aliasing signal under the same condition. The highest diastolic mean velocity (HDMV) measured by pulsed Doppler without angle correction at several points within PLCA was higher in Group II than in Group III (p < 0.001). On the other hand, the lowest diastolic mean velocity (LDMV) within PLCA was similar between Group II and Group III (p = N.S.). The flow velocity ratio (HDMV/LDMV) 2.0 within PLCA could distinguish between Group II and Group III with a sensitivity of 73.3% and specificity of 80%.

Conclusion; The present findings indicate that the combined use of color Doppler and pulsed Doppler echocardiography provides an effective means of visualizing proximal left coronary artery blood flow and thus provides a non-invasive method of identifying proximal left coronary stenosis.

2671 Non-invasive and direct diagnosis of restenotic lesion after coronary intervention on transthoracic Doppler echocardiography

A. Tashiro, M. Nasu, H. Niinuma, N. Yashima, S. Kuriki, H. Yamaguchi, M. Ito, H. Mukaida, N. Sato, K. Hiramori. *Internal Medicine Dept., Iwate Medical University, Morioka, Japan*

According to recent development of ultrasound instrument with high-sensitive Doppler, epicardial coronary artery flow has been visualized by transthoracic Doppler echocardiography (TTDE). The aim of this study was to estimate the accuracy of non-invasive and direct diagnosis of restenotic lesion after coronary intervention to proximal left anterior descending artery (LAD) by TTDE using new instrument.

Methods: TTDE studies were performed with a Acuson Sequoia C256 system. In consecutive 44 patients who were previously done coronary intervention to LAD lesion, TTDE and coronary arteriography (CAG) were examined, simultaneously. Coronary flow mapping in LAD by TTDE was performed by the color Doppler-guided pulsed Doppler. Diastolic mean velocity ratio (DMVR = HDMV/LDMV) in LAD was calculated from highest diastolic mean velocity (HDMV) and lowest diastolic mean velocity (LDMV). The correlation between DMVR from TTDE and percentage of diameter stenosis (%DS) from CAG was investigated.

Results: In 40 of 44 patients (91%), DMVR could be measured by TTDE. There was significant quadratic correlation; $y = 1.3 - 0.2x + 0.01x^2$, between DMVR (y) from TTDE and%DS (x) from CAG (r = 0.90, p < 0.0001). If DMVR was 2.0 or more which was regarded as an abnormally high value, restenotic lesion with 50 or more%DS was diagnosed with 91% sensitivity, 96% specificity, and 93% accuracy.

Conclusion: The ratio of lowest velocity to highest velocity in LAD by TTDE was a very useful parameter to evaluate the restenotic lesion in LAD after coronary intervention, non-invasively, directly, and accurately.

2672 Evaluation of left internal mammary artery flow reserve with dobutamine echocardiography: comparison to flow reserve by adenosine Doppler echocardiography and to the LAD territory ischaemic responce

G. Athanassopoulos, E. Petropoulou, C. Hasikides, G. Karatasakis, D.V. Cokkinos. *Cardiology Dept, Onassis Cardiac Surgery Center, Athens, Greece*

Transthoracic adenosine Doppler echocardiography (ADEN) may be used for the evaluation of left internal artery mammary grafted to left anterior descending artery (LIMA/LAD) flow reserve (CFR).

Aim of the study was to assess the respective CFR (CFRdob) during dobutamine stress echocardiography (DOB) and to interrogate its relationship with CFR by ADEN (CFRaden).

Moreover the estimated CFR was evaluated in comparison to the detection of ischemic response by DOB in the LAD territory.

Patients/Methods: Twenty consecutive pts with CABG and LIMA/LAD underwent DOB followed post 20 min by ADEN. CFR was estimated at the phase of 30 μg/kg/min of DOB (CFRdob) and post ADEN at140 μg/kg/min for 6 min (CFRaden). The peak velocities (Vpeak: cm/sec) and the respective time-velocity integrals (TVI: cm) of proximal LIMA were evaluated in systole (S) and diastole (D) at rest (R) and during both DOB and ADEN. Four/20 pts had an ischemic response by DOB in the LAD territory.

Results: Doppler flow profile of LIMA had similar S characteristics during DOB and ADEN. However CFR was greater by ADEN: (table)

	SVpeak	DVpeak	SVTI	DVTI	CFR
DOB	87 ± 31	40 ± 8	15 ± 7	10 ± 4	1.21 ± 0.5
ADEN	81 ± 22	48 ± 12	16 ± 6	13 ± 3	1.63 ± 0.5

p = 0.04.

The degree of underesimation of CFR by DOBwas related with CFR(aden): r = 0.51, p = 0.05. However in 3/20 pts CFR(dob) was greater than CFR(aden).

The 4/20 pts with ischemia detected in the LAD territory by DOB had decreased CFR compared to pts with normal DOB response in similar% both by ADEN (1.25 ± 0.1 vrs 1.61 ± 0.5: 29%) and DOB (0.95 ± 0.3 vrs1.24 ± 0.6: 30%).

In conclusion, CFR of the LIMA/LAD may be estimated during DOB but it usually underestimates respective CFR estimated by ADEN. Despite the greater values of CFR during its evaluation by ADEN, detection of ischemia by DOB in the LAD territory is related with a similar decrease of CFR by both means.

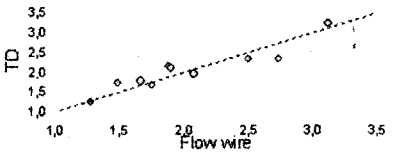
2673 Transthoracic Doppler evaluation of mammary artery grafts-flow reserve after minimal invasive bypass surgery: validation by intravascular Doppler flow wire measurements

G.P. Meyer, B. Laudenberg, H. Drexler, D. Hausmann. *Dept. of Cardiology and Angiology, Hannover Medical School., Hannover, Germany*

Background: Transthoracic doppler (= TD) of the left internal mammary artery (LIMA) during adenosine infusion is used to evaluate flow reserve after minimal invasive direct coronary artery bypass (MIDCAB)-surgery. The aim of the study was to validate the noninvasive doppler measurements by invasive flow wire (= FW) measurements.

Methods: 10 patients undergoing MIDCAB-surgery of the left anterior descending coronary artery (LAD) were examined 5–8 days after surgery. Parasternal TD-measurements were performed using a 10 MHZ linear array probe on a HDI 3000 (ATL, Bothell) at rest and during adenosine infusion (140 μg/kg/min) for assessment of flow reserve. FW- measurements of the LIMA were simultaneously performed using a 0.014-inch Doppler guide wire. Graft patency was proved by angiography in all patients but one, who showed a 71% stenosis of the graft.

Results: There is a high agreement between TD-data and intramammary FW-measurements of LIMA-flow reserve. Fig. compares adenosine induced increase in average peak velocity (= flow reserve) in TD and FW. Correlation coefficient r = 0.93; Regression equation: TD = 0.29 + 0.85 × FW ± 0.20;



Conclusions: Noninvasive doppler measurements of the LIMA flow reserve represent a reliable tool in the functional assessment of LIMA-grafts after MIDCAB surgery.

PROGNOSTIC VALUE OF STRESS ECHOCARDIOGRAPHY

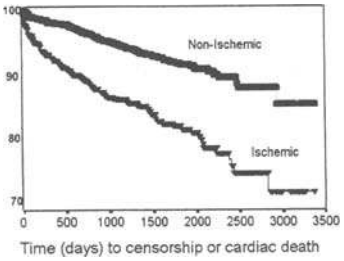
2674 Ischaemia at dobutamine echo is an independent predictor of cardiac death

T. Marwick, A. Pasquet, C. Case, S. Sawada. *University of Queensland, Brisbane QLD, Australia; Cleveland Clinic and Indiana University, Cleveland OH, USA*

Dobutamine echo (DbE) has been shown to predict subsequent cardiac events, but insufficient pts have been studied to examine cardiac death rather than soft, composite endpoints. Moreover, prediction of events has been based on abnormal DbE, including scar segts which identify all risk rather than treatable risk. We sought whether ischemia at DbE could be used to predict cardiac death.

Methods: Standard DbE protocols were performed in 3156 pts (age 63 ± 12 y, 1801 men) with known or suspected CAD at two large US echo labs. Studies were interpreted using a 16-segment model by expert observers, and pts were classified as having normal findings, ischemia or scar. Survival curves were generated from follow-up over 9 years (mean 3.8 ± 1.9). A Cox proportional hazards model was developed to analyze the effect of ischemia, independent of other determinants of outcome. Significant CAD was identified in 746 of 1073 pts (70%) undergoing coronary angiography.

Results: Ischemia was identified in 2429 (77%). Cardiac death occurred in 259 patients and 41 (1.3%) were lost to follow-up. Ischemia was an independent predictor of cardiac death (RR 2.7, p < 0.001), even in models including angiographic disease extent (ischemia RR 1.8, p = 0.005; 3 vessel disease RR 2.1, p = 0.006; 1 and 2 vessel p = ns).



Conclusion: Ischemia at DbE is an independent predictor of cardiac death, even when angiographic anatomy is known.

2675 Prognostic significance of stress echo in women with high pretest probability of coronary artery disease

J.I. Davar, E. Roberts, J.G. Coghlan, T.R. Evans, D.P. Lipkin. *Department of Cardiology, Royal Free Hospital, London, UK*

Prevalence of significant CAD in women with typical angina is lower than in males. Non-Invasive imaging techniques are frequently used in this cohort of patients for further risk stratification. Prognostic significance of Stress Echo (SE) in women with high pre-test probability of CAD is not evaluated.

Aim of the study was to assess prognostic significance of SE in women with high – ≥80% – pre-test probability of CAD.

Methods: From the database of the Cardiology Department of the RFH 133 women (mean age 63 ± 9 y) with pre-test probability of CAD ≥ 80% who underwent SE (treadmill or dobutamine SE) between 1995 and 1998 were selected. The Bruce protocol was used during Treadmill SE. Dobutamine-atropine SE was performed according the conventional protocol. Events looked for were cardiac deaths, myocardial infarctions, unstable angina, revascularisation. Cox proportional hazard model was used to evaluate ability of clinical variables to predict an event.

Results: There were 93 negative SE (NSE) in this high risk population. Mean F/U was 20.1 ± 8.5 months. There were 9 events: 8 (2 cardiac deaths, I admission with unstable angina, 5 revascularisations) in positive stress echo (PSE) group and 1 in NSE group (angioplasty after worsening of angina at 20 months). Only two variables were identified as univariate predictors of cardiac events: positive SE (p = 0.0003) and age (p = 0.0188). With Cox step-wise analysis positive SE was found to be the only independent predictor of future cardiac events: Odds Ratio = 19.1. The event-free survival rate to 20 months post stress was 98% for patients with a negative SE and 79.6% for patients with a positive SE (p = 0.0001).

Conclusion: 1. Negative Stress Echocardiography predicts low risk of future cardiac events in women with high (≥80%) pre-test probability of CAD. 2. Positive Stress Echo in women with high pre-test probability of CAD identifies pts. likely to experience a cardiac event.

2676 Long-term prognostic significance of dobutamine stress echocardiography in patients with medically stabilized unstable angina

S. Díez-Aja, M. Sitges, C. Pare, M. Azqueta, X. Bosch, F. Miranda, M. Velamazan, J. Magriña, G. Sanz. *Cardiovascular Institute, Hospital Clínic, Barcelona, Spain*

We have previously reported the safety and usefulness for risk stratification of dobutamine-atropine stress echocardiography (DSE) in patients with medically stabilized unstable angina (UA) in a short follow-up period of three months. The aim of the present study was to assess if the prognostic value of DSE is maintained through time. One hundred twenty-two patients (pts) were studied (mean age 64 ± 12 years, 29 women). DSE was performed on third day after hospital admission in eligible pts. Endpoints were recurrent unstable angina, myocardial infarction (MI) or cardiac death. Patients undergoing coronary revascularization before hospital discharge were excluded.

Results: Mean follow-up was 24 ± 7 months (0.5, 34). Nine of the 21 pts (43%) with a positive DSE presented cardiac events during follow-up: 2 patient died, 1 had MI and 6 had recurrent class III-IV angina requiring hospital readmission. Among 81 pts with negative DSE, 1 (1%) died, 1 (1%) had MI and 12 pts (15%) had recurrent angina. Event-free survival of pts with a negative DSE for ischemia was 82% compared to 55% for those with a positive DSE (Log Rank 9.37; p = 0.002). Survival without MI was 94% in pts with a negative DSE compared to 84% for those with a positive DSE (Log Rank 6.60; p = 0.01). Predictors of cardiac events during follow-up were history of previous MI, ECG abnormalities on admission, left ventricular (LV) ejection fraction and a positive result of DSE for ischemia. Multivariate analysis selected LV dysfunction and a positive DSE as independent predictors of cardiac events.

Conclusions: DSE performed early in medically treated patients with UA allows their early discharge from hospital and shows a good prognostic capability at a long term follow-up.

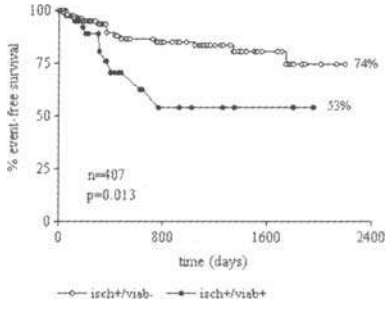
2677 Prognostic significance of biphasic response to dobutamine stress echo following uncomplicated myocardial infarction

R. Bigi, A. Desideri[1], R. Rambaldi, A. Galati[2], C. Coletta[2], J.J. Bax[3]. *Cardiology Dept, E. Morelli Hospital, Sondalo; [1]Cardiology Dept, S. Giacomo Hospital, Castelfranco Veneto; [2]Cardiology Dept, S. Spirito Hospital, Rome, Italy; [3]Cardiology Dept, University Medical Center, Leiden, Netherlands*

Aim: to evaluate the prognostic significance of biphasic (BR, low-dose improvement with high-dose deterioration) as compared to monophasic (MR, deterioration without improvement) response to dobutamine stress echo (DSE) in pts. with uncomplicated myocardial infarction (MI).

Methods: 407 pts. undergoing DSE within 10 days of MI were followed-up to 23 (range 1–78) months for reinfarction, death and unstable angina. Revascularized pts. were censored. Both low-dose (up to 10 mcg/kg/min) and high-dose response (up to 40 mcg/kg/min with additional atropine) were assessed.

Results: 194 pts. had positive DSE (46 with BR and 148 with MR). Sixty events occurred (20 MI, 11 death and 29 unstable angina). BR was associated to lower (p < 0.05) % event-free survival and shorter (p < 0.01) event-free time than MR. The event rate in BR and, respectively, in MR was: 4.3% vs. 3.3% for reinfarction, 4.3 vs. 1.35% for death and 13% vs. 6.7% for unstable angina.



Conclusions: the biphasic response is associated with increased risk of cardiac events in patients with positive DSE following uncomplicated MI.

2678 Prognostic value of pharmacological stress echocardiography in patients with left bundle-branch block

F. Lattanzi, L. Cortigiani, P. Landi, M.L. de Alcantara, W. Mathias, N. Gandolfo, A. Galati, A.R. Lucarini, E. Picano. *Institute of Clinical Physiology, Pisa, Italy*

Patients with left bundle branch block (LBBB) have an increased risk for cardiac death, especially when underlying coronary artery disease is present.

To evaluate the prognostic value of stress echocardiography in this setting, we interrogated the EPIC-EDIC multicenter stress echo trial data bank and selected 175 patients with LBBB (111 males, mean age 65+9 years; 55 with previous myocardial infarction) submitted to high dose dipyridamole (74 patients) or dobutamine (101 patients) stress echocardiography. All enrolling centers had been quality-controlled for stress echo reading. Peripheral reading directly entered the data bank. Stress echocardiography was positive for myocardial ischemia in 62 patients. During a follow-up period of 21+18 months, 47 cardiac events occurred (10 deaths, 9 acute myocardial infarctions, and 28 revascularization procedures). Cardiac events were significantly more frequent in the patients with positive when compared to the patients with negative test (30/62 vs 17/113, respectively; 48% vs 15%; p < 0.01). The three-year infarction-free survival was significantly lower for patients with positive when compared with those with negative stress echocardiography (68% vs 92%, respectively; p < 0.02).

In conclusion, pharmacological stress echocardiography is effective in prognostic stratification of patients with resting LBBB.

2679 Prognostic contribution of left ventricular inotropic reserve evaluated by dobutamine stress echocardiography in left bundle-branch block

G. Athanassopoulos, E. Petropoulou, M. Marinou, P. Cokkinos, G. Karatasakis, D.V. Cokkinos. *Cardiology Dept, Onassis Cardiac Surgery Center, Athens, Greece*

Aim of the study was to assess the contribution of left ventricular (LV) inotropic reserve estimated by dobutamine stress echocardiography (DOB) in order to evaluate prognosis in patients with LBBB.

Patients and Methods: 66 patients with LBBB underwent DOB. LV endsystolic (ES) and enddiastolic (ED) volumes (vol) were estimated at rest (R) and peak dobutamine (D). The ejection fraction at R and D and their difference dEF were calculated.

The 66 pts were followed up for 27 ± 21 months. None had an ischemic event; 4 pts died due to progressive severe heart failure and 13 more had an episode of acute or progressive decompensation (CHF events: group F). The other 49 pts had an uneventfull follow up (group N).

Results: Incidence of underlying coronary artery disease was similar between F/N (5/17 vrs 16/49). F and N groups had also at R similar: LVEDvol/diameter, EF, QRS duration, wall thickness/LVED diameter ratio (RelWth). However group N had greater increase of EF post Dob both in absolute values and% changes:

	LVEDdiam	LVEDvolR	%dEF	dEF	EFR	QRS	RelWth
F	6.6 ± 1	188 ± 47	−12 ± 18	−6 ± 8	42 ± 9	149 ± 12	0.26 ± 0.3
N	6.4 ± 1	207 ± 131	29 ± 34	11 ± 12	43 ± 18	143 ± 23	0.27 ± 0.05
			p = 0.03	p = 0.02			

The relative risk (RR) for CHF event when dEF > 0 was 6 (95% CI 1.4–24). In contrast ischemia detection by DOB had a RR of only 1.6 (95% CI 0.8–3).

Using logistic regression analysis for prediction of CHF event, both EFR and LVEDvolR had much lower contribution than the presence of a dEF > 0 (respective odds ratio: 0.6 and 1 vs 4.45)

Using the Kaplan Meier analysis, when the criterion of dEF>0 was considered, then a better outcome for CHF event was found for those pts who increased EF post Dob (long rank = 4.5, p = 0.032)

Conclusion: LV inotropic reserve evaluation by DOB in LBBB pts provides significant prognostic information for heart failure decompensation. This information is independent from LV resting function, degree of dilatation and detection of underlying ischemia by DOB.

PTCA IN ACUTE CORONARY SYNDROMES

P2698 Cost-effectiveness of direct coronary stenting

B. Chevalier, B. Glatt, P. Guyon, T. Royer. *Centre Cardiologique du Nord, Saint-Denis, France*

Direct stent implantation (DSI), without any prior dilatation tecnique, is progressively used, in selected lesions, with a good feasibility in previous reports. In order to assess its cost-effectiveness, we analyzed two groups of 50 consecutive isolated single lesion PTCA performed during 1st and 2nd quarter of 1998 using DSI or conventional stenting technique. Baseline patient-related and lesion related data were similar in both groups except age and calcification grade, higher in case of predilatation. Count of disposable PTCA items, PTCA duration and angiographic frame numbers recorded on the DICOM CD were assessed:

	DSI+	DSI−	p
N of guiding catheters	1.2 ± 0.6	1.22 ± 0.5	NS
N of wires	1.04 ± 0.2	1.18 ± 0.5	NS
N of balloons	1.27 ± 0.4	1.31 ± 0.7	NS
N of stents	1.04 ± 0.2	1.22 ± 0.6	<0.05
PTCA duration (min)	30 ± 9	42 ± 12	<0.001
N of frames	871 ± 400	1194 ± 410	<0.001

Thus, despite its use in less calcified lesion, DSI is not associated with a major reduction of disposable items consumption, except for stent/lesion ratio. Radiation exposure and cathlab occupancy are dramatically reduced in case of DSI.

P2699 Is primary coronary stenting a feasible and safe strategy?

D. Carrié, M. Hamon, J.P. Monassier, K. Khalife, B. Citron, L. Sarfaty, S. Mourali, J. Fourcade, J. Puel. *Department of Cardiology, Purpan Hospital, Toulouse, France*

Primary stenting – i.e., stenting of lesions with no prior balloon dilatation is a new technique which offers a less expensive and faster alternative to the currently accepted technique.

From April until August 1998, an open registry (5 centers) evaluated the safety and performance of the Tenax coated coronary stent (Biotronik) in a "real world" population of patients with coronary artery disease.

266 consecutive implantations were collected in 241 patients (pts). In this group, direct stenting was performed in 48 pts (64.5 ± 12.7 years – 18.8% females) and 50 procedures. The clinical indication for intervention was stable angina (12.5%), unstable angina (40%), acute myocardial infarction (MI) (10.4%), recent MI (35.4%), and silent ischemia (2.1%). Target lesion was LAD in 40%, L Cx in 12% and RCA in 44%, saphenous vein graft in 2% and left main in 2%. 56% of pts had complex characteristic lesions (B2-C). Two stent lengths were used (15 mm in 82% of the cases, 20 mm in 18%). The stent was used as a system, premounted in a balloon delivery system. The three balloon diameters used were 3 mm (48%); 3.5 mm (44%) and 4 mm (8%). High pressure balloons were used for stent deployment with a mean inflation pressure of 12.5 bars. 48% of the pts underwent individual inflation deployment, while 52% required one secondary dilatation. All 50 procedures were successful. No stents were lost during the procedure and no stenosis was found after stenting.

Clinical follow-up was obtained in 44/48 pts at 5.8 months. No deaths, MI or CABG occurred during this period. Target lesion revascularization was required in 2.3% (1/44 pts) and 2.27% (5/220 pts) in the other group of stenting with prior balloon dilatation

Conclusions: Primary stenting using the Tenax stent is a new and very encouraging technique. The clinical and angiographic outcomes of our preliminary experience suggest it is a promising design that needs further evaluation in larger randomized clinical trials.

P2700 Direct coronary stenting without balloon predilatation in selected lesions: short and mid-term results

Y. Guérin, X. Favereau, T. Corcos, D. Pentousis, M. Toussaint, H. Hodroge, G. Dutheil, F. Funck. *Centre Médico-Chirurgical Parly 2, Le Chesnay, France*

In order to simplify the procedure and to limit vessel injury, we prospectively studied the safety and efficiency of direct stent implantation without balloon predilatation in selected coronary lesions, using the balloon expandable ACS Multi-Link™ stent (15 to 28 mm length). Bifurcations with a significant side-branch and calcified lesions were excluded.

Methods: From November '95 to September '98, 395 patients (83% male) with 453 lesions were treated by this technique. Mean age was 63.8 ± 11.9 years. Clinical indications for stenting were unstable angina in 226 pts (57%), acute or recent MI in 98 (25%), symptomatic restenosis in 43 (11%) and silent ischemia in 28 (7%). Lesions were eccentric in 47%, angulated in 15%, ostial in 7%, with a mean length of 12.2 ± 6.5 mm (7–25) and a mean reference vessel diameter of 3.2 ± 0.7 mm. Procedure was mainly performed with 6F guiding catheters (96%).

Results: Primary stent crossing through the stenosis was successful in 440 lesions (97.1%); in the last 13 lesions, stenting was successfully performed after balloon predilatation. Complete stent deployment (mean inflation pressure = 14.3 ± 2.7 atm) was attained in 423/440 (96.8%); in the 17 others lesions, high pressure adjunctive PTCA with short balloon was required to achieve optimal stent expansion. Five threatening dissections occurred distally to the stent and were treated by a secondary stent. No major in-hospital complications were noted. Two symptomatic sub-acute coronary occlusions (0.5%) occurred during the first month. At 6 months follow-up, target lesion revascularization (TLR) concerning the 278 first patients was 5.9% (19/321 lésions).

Conclusion: Direct coronary stent implantation without balloon predilatation seems safe and efficient in selected lesions. The excellent initial and mid-term results must be validated by randomized studies.

P2701 Single-centre experience of direct stent implantation in 1,000 patients

B. Chevalier, B. Glatt, P. Guyon, T. Royer. *Centre Cardiologique du Nord, Saint-Denis, France*

De novo coronary stenting has been validated in some coronary lesions by several randomized studies. In this setting, we used, from 10/95 to 12/98, direct stent implantation (DSI) without prior dilatation technique in 1000 pts excluding age > 70, onset of (related to the target artery) angina or MI > 3 months, TIMI 0 occlusion. Clinical indication were almost exclusively acute syndromes: unstable angina 52%, recent MI 26%, acute MI 13% and stable angina in 9%. Lesions were simple in 61% and complex in 39%. Clinical success was 98.2%, MACE rate was 1.4% and stent thrombosis was 0.5%. Additional balloon inflation was used in 23% and additional stenting in 4%. Technical success (defined as a successful deployment of the stent on the target lesion) was correlated with DSI/total stenting ratio in our practice and depends on the stent/delivery device system:

	Technical success	DSI ratio
Multilink™	94%	16%
RXMultilink™	86%	5%
NIRPrimo™	96%	25%
Multilink Duet™	97%	36%

All direct stenting failures were successfully treated with conventional technique. Stent loss rate was 0.3%. There were 3 cases of partial failure to deploy the stent with residual stenosis from 31% to 39%.

Thus, DSI is feasible in selected coronary lesions and its use is dependent on delivery device quality.

P2702 A randomized comparison of direct coronary stenting without angioplasty predilation and conventional stent implantation for acute coronary syndromes

R. Sabatier, M. Hamon, E. Lecluse, E. Saloux, B. Valette, G. Grollier, J.-C. Potier. *Cardiology Dept, CHU de Caen, Caen, France*

Background: Direct coronary stenting without balloon predilation has been shown to be an alternative strategy for treatment of highly selected coronary lesions in which stent implantation is planned. However no randomized study has been performed to assess the immediate and long term results of this new strategy of direct coronary stenting by comparison to conventional stent implantation after balloon predilation.

Methods: In the SWAP (Stenting Without Angioplasty Predilation) study, 120 patients with acute coronary syndromes eligible for coronary dilation were randomized to direct coronary stenting without balloon predilation (Group A) or to stent implantation after conventional balloon predilation (Group B). Highly calcified lesions, lesions in a tortuous vessel and persistent total occlusions after angioplasty guide wire placement were excluded. Only tubular premounted Nir® stents were used with high pressure stent deployement.

Results: Baseline clinical and angiographic characteristics of the study patients were similar in the two groups. No difference was observed in procedural success rates and the occurrence of no-reflow was indentical in both groups. Acute gain measured by quantitative coronary angiography was similar in the 2 groups. Duration of the procedure and radiation exposure time were shorter in group A ($p < 0.001$). The cost of the procedure was reduced in group A ($p < 0.01$). In-hospital and one month outcome (including death, acute myocardial infarction, target lesion redilation and bypass surgery) were not different between the two groups.

Conclusion: The present randomized study demonstrates the safety of direct coronary stenting without angioplasty predilation in selected acute coronary syndromes-related lesions. This new strategy of stent implantation reduces the cost of the procedure. One month clinical outcome is excellent and long-term follow-up is ongoing.

P2703 Comparison of three coronary stenting techniques in acute myocardial infarction angioplasty

B. Chevalier, P. Guyon, T. Royer, B. Glatt. *Cardiologie Interventionnelle, Centre Cardiologique du Nord, Saint-Denis, France*

In order to define the best way to treat patients with acute myocardial infarction (AMI) using coronary stenting, we retrospectively studied in the last 15 months, all consecutive pts treated, in a single center, with angioplasty and coronary stenting in an occluded vessel (TIMI 0 or I) which was related to AMI (= 65% of all AMI PTCA). Pts were selected within 24 hours after the onset of symptoms. Rescue angioplasty after lytics failure and cardiogenic shocks were excluded from the study. Three groups were analyzed: A – AMI pts (N = 161) treated with direct angioplasty and conventional stenting after balloon dilatation, B – AMI pts (N = 64) treated with direct angioplasty using direct stent implantation without any prior dilatation technique (in this group, initial TIMI flow 0 or I became at least II after crossing of the wire through the occlusion), C – AMI pts (N = 23) receiving prehopsital (in intensive mobile care unit) infusion of abciximab 20 minutes before the angioplasty and treated with conventional stenting (using predilatation). Final flow was independently assessed in the three groups using TIMI classification and TIMI frame count measured with the distal landmark method. The rate of final TIMI III flow was identical in A and C groups (87%) and signficantly higher in B group (97%) compared to group A ($p < 0.05$). Mortality rate was lower in group B (0% versus 8% in group A, $p < 0.05$).

Thus, direct stent implantation without prior balloon inflation is associated with a higher rate of TIMI III flow and lower mortality than conventional stenting technique. If this benefit is a translation of a bias selection of pts with flow improvement after wire crossing or a real benefit due to thrombus and/or atheroma entrapment by direct stent deployment may be discussed. Additional benefit of abciximab infusion to direct stenting needs further studies.

P2704 Improvement of global and regional left ventricular function by rapid thrombectomy catheter angiojet after acute myocardial infarction

T. Suzuki, M. Nakamura, K. Matsuda, H. Hara, T. Takagi, K. Mitsuo, T. Yamaguchi. *3rd Department of Internal Medicine, Toho University Ohashi Hospital, Tokyo, Japan*

Backgrounds: Late reperfusion has been reported to be useful for the prevention of left ventricular remodeling post acute myocardial infarction (AMI). However, adequate reperfusion of the infarct bed may be difficult to obtain in late reperfusion, because of a large amount of intracoronary thrombus. Thrombectomy catheter, AngioJet (POSSIS Medical, Inc. MN), may be useful for adequate restoration of infarct artery and myocardial salvage.

Methods: The goal of our study is to evaluate the effect of thrombus removal on LV myocardial salvage in late reperfused AMI patients. A total of 48 AMI patients presenting TIMI 0 flow and undergoing late reperfusion (elapsed time more than 12 hours) were enrolled in this study. Subjects were divided into 2 groups according to the reperfusion strategy. Group P consists of 25 patients underwent primary angioplasty, and group A consists of 23 patients underwent AngioJet followed by adjunctive angioplasty. Left ventriculogram was performed on admission and at 3 months follow up and ejection fraction (EF) and regional wall motion (RWM) by means of centerline method were calculated.

Results: There was no difference in elapsed time (group P: 14 ± 17 hours, group A: 19 ± 19 hours) and LV remodeling. Improvement of EF was significantly greater in group A more than that in group P (see table).

Serial changes in LV function

	Pre LVEF	Pre RWM	Change LVEF	Change RWM	Change EDVI	Change ESVI
Group A	46.1±12.9	−2.7±0.7	10.9±6.6	0.86±0.52	12.8±20.1	−6.7±11.6
Group P	55.1±13.1	−1.8±0.8	3.4±9.7	0.54±0.61	0.0±32.7	−1.0±17.8
P-value	0.06	NS	<0.02	0.10	NS	NS

Conclusions: These preliminary data may suggest that thrombus removal by AngioJet is an effective strategy for the recovery of left ventricular function in late reperfused AMI patients.

P2705 Coronary angioplasty with liberal use of stents in patients with unstable angina: clinical and electrocardiographic predictors of in-hospital outcome

A. Dellavalle, S. De Servi[1], S. Repetto[2], S. Chierchia[3], A. Repetto[4], A. Vado, G. Steffenino. *On behalf of the R.OS.A.I. Study Group; Division of Cardiology, Ospedale S Croce, Cuneo; [1]Ospedale di Legnano; [2]Ospedale di Circolo, Varese; [3]Ospedale San Raffaele, Milan; [4]Policlinico S. Matteo, Pavia, Italy*

The clinical and electrocardiographic (ECG) presentation is a strong prognostic factor in patients (pts) with unstable angina (UA); its importance, however, is debated in patients treated with PTCA and liberal use of stents.

Methods: from 04/97 to 04/98 patients submitted to coronary arteriography due to UA in the participating centers were included in a prospective registry to monitor both the use of revascularization procedures and the acute outcome.

Results: of 987 pts included in the registry 571 (58%) were treated with PTCA: age was 62 ± 12 y, 123 were female, LVEF was 0.55 ± 0.1, 328 (57%) had multivessel disease. UA type IIIB or IIIC was present in 281/571 pts (49%). Refractory UA, prolonged (>10 min) chest pain, and both were present in 133, 217 and 85 pts, respectively. Stenting was performed in 486/571 pts (85%), and it was elective in 335; abciximab was used in 42 pts, and ticlopidine and/or aspirin in all. In-hospital major adverse cardiac events (MACE) (death, AMI, urgent CABG/re-PTCA) occurred in 29/571 pts (5.1%). Among clinical and ECG variables those shown in the table were significantly associated with a worse outcome. Pain-related ST-segment depression ≥ 1 mm, and ST-segment elevation/T-wave pseudo-normalization (present in 42% and 41.5% of pts, respectively) were not predictive of outcome after PTCA, although ST elevation was significantly associated with refractory + prolonged UA ($p = 0.001$) and UA classes IIIB or IIIC ($p = 0.0001$).

	Yes	MACE%	No	MACE%	χ^2	p
Prolonged UA	217	8.3	354	3.7	3.82	0.041
Prol. + refr. UA	85	11.7	486	3.9	9.26	0.006
IIIB or IIIC UA	279	7.2	292	3.1	4.94	0.02
Recent AMI	108	9.2	463	4.1	4.82	0.031
LVEF < 0.4	38	13.2	533	4.5	5.51	0.036

In *multivariate analysis* only prolonged + refractory UA ($p = 0.0056$) and LVEF < 0.4 ($p = 0.042$) were associated with MACE after PTCA.

In conclusion: prolonged + refractory UA and a low LVEF remain predictors of MACE before discharge in pts with PTCA and liberal use of stents.

P2706 Stenting of a total coronary occlusion in the course of an acute ischaemic syndrome carries a high rate of chronic restenosis

M. Sansa, A. Campi, A.S. Bongo, A. Pappalardo, G. Giacomarra, P. Bergamo, C. Cernigliaro. *Divisione II Cardiologia, Ospedale Maggiore della Carita, Novara, Italy*

In a population of 235 consecutive patients (182 M – 53 F) with acute ischemic syndromes, treated with stenting in the acute phase, we were able to repeat angiography in 221 pts (94%); patients who were not re-studied at 6 months refused the procedure; there were no deaths or re-hospitalization in these patients.

Two groups were analysed according to the anatomy at the initial presentation before the procedure:

– Group A: acute total occlusion of the culprit vessel before stenting (28 pts)
– Group B: patent culprit vessel before stenting (193 pts)

Fifteen patients were re-studied early (within 30 days) because of symptoms. The remaining population had control angiography at 6 months. Results were analysed using Fisher Exact Test.

Results: In the 15 patients studied at 30 days stent thrombosis or severely impaired flow within the stent was found in 3 out of 28 patients in Group A and in 12 out of 193 patients in Group B. In the remaining 206 patients re-studied at 6 months no stent thrombosis was found. Re-stenosis rate within the stent was however found in 9/25 (Group A) and in 33/181 (Group B):

	Thrombosis at 30 days	Restenosis at 6 months
Group A	3/28 (10.7%)	9/25 (36%)
Group B	12/193 (6.1%)	33/181 (18.2%)

Study Limitations: no GP IIb/IIIa antagonist were employed in this study.

Conclusions: 1. A high stent thrombosis rate was found at 30 days in both groups, with no statistically significant difference ($p = 0.29$ NS).

2. A higher chronic re-stenosis rate was evident in the group who presented initially with an occluded culprit vessel (36%; $p = 0.041$) while, in the group with initially patent vessel, the restenosis rate was comparable to that reported for elective procedures (18.2%).

P2707 Efficacy of heparin coated stent in the early setting of acute myocardial infarction

E.K. Shin, M.S. Sohn, J.W. Son, D.K. Jin, T.H. Ahn, K.K. Koh, I.S. Choi. *Division of Cardiology, Gachon Medical College, Heart Center, Inchon, South Korea*

Primary stenting for acute myocardial infarction(AMI) is being increased with improved late outcome compared to PTCA. However potent antiplatelets, anticoagulants and antithrombotic agent have been used, due to the risk of stent thrombosis. Heparin coated (HC) stent has been tested to decrease platelet deposition and thrombotic events compared to uncoated (UC) stent

The purpose of this study was to evaluate the effects of HC stent on the major cardiovasclular complications and safety in the early setting of AMI. Included patients arrived at the Cardiac Cath. lab. no later than 6 hrs from the onset of chest pain. Ninety nine patients were implanted with 108 HC stents (Corline Heparin Surface, Jomed. Sweden). 23 patients (23%) showed a large thrombus burden angiographically before stenting. No patients received postprocedural heparin or GpIIb/IIIa receptor antagonist (Abciximab) even in patients with a large thrombus burden. All patients were given aspirin indefinitely and ticlopidine for 4 weeks. Patency of infarct related artery was tested by CAG at 2 wks and 6 months, respectively.

The angiographic and procedural success rate were 100% and 98%, respectively.

	30 days	6 months
Major Adverse Cardiac Events		
Death (%)	2 (2/99)	4.8 (4/84)
Recurrent MI (%)	0	0
TLR (%)	0	6.0 (5/84)
Angiographic		
Reocclusion (%)	0 (0/82)	1.8 (1/55)
Restenosis (%)		12.7 (7/55)

Conclusion: HC stenting in AMI eliminated the need of postprocedural anticoagulation without significant increase in MACE and reocclusion, and with the acceptable restenosis rate. In addition, HC stent was safe and feasible even in the large thrombus burden.

P2708 Percutaneous transluminal ultrasound thrombolysis in native coronaries in the setting of acute coronary syndromes

D. Brosh, I. Herz[1], S. Laniado, H.I. Miller, U. Rosenschein. *Cardiology Dept., Tel Aviv Med Centre, Tel Aviv; [1]Catheterization Laboratory, Beilinson Medical Center, Petach Tikva, Israel*

Percutaneous coronary ultrasound thrombolysis (CUT) in AMI induced effective reperfusion and myocardial salvage. The purpose of the Acolysis Registry was to investigate ultrasound thrombolysis in multiple clinical settings of intra-coronary thrombosis.

Methods: Patients (pts) with acute coronary syndromes and angiographically suggested thrombus were treated by CUT.

Results: Pts (n = 126) were mostly male (80%) and aged 55 ± 12 years. The vessels were occluded (TIMI grade 0–1) in 84%. The clot median age was 3 days (range 0–60 days). The pts presented with unstable angina (42%), myocardial infarction (29%), and post infarction angina (29%). CUT (41 kHz, 18 w) was attempted in the RCA (52%); LAD (38%); and LCX (10%). Successful recanalization (TIMI2–3) was achieved in 89% of the pts with residual stenosis of 69 ± 20%. Final angiogram revealed successful recanalization in 98% of pts (TIMI flow 3 in 94%) and residual stenosis of 6 ± 10%. Device-related adverse events were recorded in 1 pt with non-Q wave MI and 4 pts with angiographically-evident embolization. There were no deaths, emergent coronary artery bypass graft surgery, Q wave MI. Adjunct PTCA and/or stent was used in 97%. Reopro and thrombolytic agents were used in 16% and 2% (respectively) of the cases.

In conclusion: coronary ultrasound thrombolysis is a very safe and effective device solution for the treatment of high-risk, thrombus-rich lesions in the native coronary arteries.

P2709 30-day mortality after early invasive approach in unstable coronary artery disease

E. Diderholm, B. Lagerqvist, L. Wallentin. *Dept of Cardiology, University Hospital Uppsala, Sweden*

Background: There is an ongoing debate whether patients with unstable coronary artery disease (UCAD) should be treated conservatively or with an early revascularisation. The TIMI III B and the VANQWISH studies did not show any reduction of death/MI by an invasive strategy. In the latter there was an unexpectedly high mortality rate (11.6%) in patients treated with CABG. We report the 30 days mortality in the invasive group in the FRISC II trial and relate the mortality to patient characteristics.

Method: In the FRISC II-trial 2456 patients with UCAD were randomised to a direct invasive strategy (n = 1223) with coronary angiograms and, if appropriate, early revascularisation within the first 7 days or to a noninvasive approach. Patients with previous CABG were excluded. All patients were treated with s.c. lmwh (dalteparin) b.i.d. until revascularisation.

Results: 1223 patients were randomised to invasive strategy. Angiography was performed in 98.1%, CABG in 35.2%, PTCA in 42.7%. Median time from admission to PTCA and CABG was 3 and 7 days respectively. 15 patients (1.2%) died within 30 days from randomisation/revascularisation – 9 after CABG, 1 after PTCA and 5 after angiography before revascularisation. The 30 days mortality after CABG was 2.1%, PTCA 0.2%.

Pt characteristics	Alive 30 days	Dead 30 days	
n	1208	15	
Age (mean ± SD)	64.7 ± 9.3	73.2 ± 5.7	p < 0.001
Female sex	28.3%	60%	p < 0.02
Diabetes	12.2%	53.3%	p < 0.001
Previous MI	22.4%	53.3%	p < 0.01
ST-depression at entry	45.1%	71.4%	p < 0.05
3 VD or main stem stenos	29.8%	79.6%	p < 0.001

Conclusion: In UCAD early revascularisation can be performed with a low mortality. However, the risk is increased at high age, female sex, diabetes, previous MI, ST-depression at entry and advanced coronary artery disease.

P2710 Comparison of outcome of recurrent and first acute myocardial infarction patients in Israel in 1992–1996

A. Shotan, S. Gottlieb, U. Goldbourt, V. Boyko, H. Reicher-Reiss, M. Arad, L. Mandelzweig, H. Hod, S. Behar. *Heart Institute, Sheba Medical Center, Tel Hashomer, Israel*

Patients (pts) with recurrent myocardial infarction (MI) are at increased risk for complications and death. However, the impact of therapeutic interventions on their outcome has not been assessed.

Methods: We compared 1093 recurrent MI pts (26%) with 3202 first MI pts (74%) included in the National Israeli Thrombolytic Survey conducted during 1–2/92, 1–2/94 and 1–5/96 in the 25 coronary care units operating in Israel.

Results: 7-day, 30-day and 1-year mortality was 10, 16, and 26% in pts with recurrent MI vs. 6, 9 and 14% among first MI pts, respectively. The relative risks of mortality ± 95% confidence interval, adjusted for age, gender, hypertension, diabetes, prior angina, anterior MI, Killip class, thrombolysis, or revascularization-(PTCA/CABG), were as follows:

	7-day	30-day	1-year
Thrombolysis treated pts			
Recurrent MI	1.69 (1.09–2.65)	1.51 (1.03–2.23)	1.18 (0.90–1.55)
First MI	0.94 (0.68–1.30)	0.84 (0.64–1.18)	0.79 (0.64–0.97)
Early CABG or PTCA treated pts			
Recurrent MI	0.36 (0.16–0.73)	0.45 (0.23–0.77)	0.66 (0.46–0.96)
First MI	0.37 (0.19–0.64)	0.55 (0.36–0.83)	0.66 (0.48–0.90)

Conclusions: This study suggests that thrombolytic therapy is not beneficial in pts with recurrent MI and that they should probably undergo early revascularization. The data of this study need confirmation in prospective, randomized trials.

P2711 Improved survival rate for stented lesions after a strategy of provisional stenting for acute coronary syndromes and myocardial infarction

A.W. Frey. *Kardiologie Abteilung, Herz-Zentrum, Bad Krozingen, Germany*

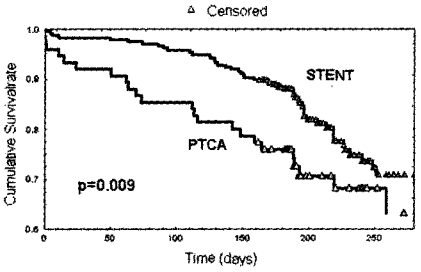
Treatment of myocardial infarction and acute coronary syndromes by means of immediate coronary angioplasty is still a matter of debate. We investigated retrospectively the clinical outcome of patients treated with coronary angioplasty within 24 hours after onset of symptoms. Stents were deployed if an optimal PTCA result could not be achieved (visual estimation of residual stenosis < 20%). We investigated 2 groups: pts receiving a Stent 237/312 (77%) or not (POBA) 75/312 (23%). 243 pts with 312 lesions were included in this cohort. Follow up was completed for 6 month, mean follow up time 208 days (213 and 193 days respectively).

Patients: Age 61 ± 11 years, 77% male, 50% former MI, Angioplasty was successful (residual stenosis < 50%, no MACE) in 71% of the PTCA group and 99% of the Stent group. When pts were admitted to the cathlab 29% (POBA) and 32% (STENT) had an occluded vessel. Procedure was successful in 80% (POBA) and 99% (STENT). 1 Death and 1 CABG occurred in the POBA group, 1 MI in the STENT group. Major cardiac events during follow up are listed below:

% (n)	Death	MI	CABG	Re-PTCA
POBA	8% (4)	2% (1)	13% (6)*	27% (13)
Stent	4% (7)	2% (5)	4% (7)	22% (42)

* p = 0.015, MI = Myocardial Infarction

The lesion specific MACE survival rate is shown in the figure.



Conclusion: In a strategy of provisional stenting in patients with acute MI or coronary syndromes, stenting improves significantly late outcome, despite a sufficient angiographic result after acute PTCA.

RESTENOSIS

P2712 Predictors of recurrent restenosis after rotational atherectomy of diffuse in-stent restenosis at 6-month angiographic follow-up: a serial intravascular ultrasound study

P.W. Radke, J. vom Dahl, R. Hoffmann, P.K. Haager, F. Kastrau, U. Janssens, H.G. Klues, P. Hanrath. *Medical Clinic I, RWTH University Hospital Aachen, Germany*

Treatment of long and diffuse in-stent restenosis (ISR) remains challenging. Rotational atherectomy (RA) with adjunct PTCA is an alternative therapeutic approach in this clinical setting based on the concept of "tissue debulking". This study was intended to determine clinical, procedural, angiographic and intravascular ultrasound (IVUS) predictors of recurrent ISR at 6-month angiographic follow-up.

Methods: RA with adjunct low-pressure PTCA was performed in 40 patients with diffuse ISR (lesion length: 22 ± 20 mm). Serial IVUS measurements were performed before intervention, post RA and after adjunct PTCA. Follow-up angiography was available for all patients 6 ± 1 month after RA.

Results: Procedural success was achieved in all patients. Recurrent restenosis (>50% diameter stenosis [DS] by quantitative angiography) was observed in 18/40 patients (45%). Predictors of recurrent restenosis are given in the table. Target lesion revascularisation rate (TLR) at 6 month was 38% (15/40 patients).

	Restenosis	No Restenosis	p-value
Baseline DS (%)	83 ± 22	72 ± 17	<0.01
Stent Length (mm)	40.5 ± 21.3	21.5 ± 14.1	<0.001
Lesion Length (mm)	35.1 ± 20.2	15.2 ± 14.1	<0.001
Neointimal Recoil (%)	23.2 ± 13.6	8.9 ± 8.3	<0.001

Conclusions: RA with adjunct PTCA is an effective treatment strategy for diffuse ISR and results in a recurrent restenosis rate of 45% at 6-month angiographic follow-up. Diameter stenosis before intervention, total stent length, total lesion length and amount of acute neointimal recoil after RA were identified as predictors of recurrent restenosis.

P2713 A higher average shear stress is paradoxically predictive of restenosis and/or mace after balloon angioplasty in human coronary arteries

G. Van Langenhove, S. Carlier[1], M. Albertal, E. Boersma, P.W. Serruys. *Interventional Cardiology Dept, Thoraxcentre, Rotterdam; [1]Experimental Echo Lab – Ee2302, Erasmus University, Rotterdam, Netherlands*

Background: Vascular wall shear stress (WSS) is the frictional force exerted by the flowing blood at the vessel wall of the artery. In animal models, a higher WSS after balloon angioplasty (BA) has been associated with reduced intimal hyperplasia. Up to now, direct measurements of WSS and its impact on the outcome of balloon angioplasty – major adverse cardiac events (MACE) and/or restenosis (R) – have not been investigated in human coronary arteries.

Methods: For the patients (p) included in the DEBATE I trial where the predictive value of intracoronary Doppler flow velocity measurements for clinical outcome has been investigated, we have computed WSS following the Hagen-Poiseuille formula: WSS = 4 mu Q/pi r^3, with mu being blood viscosity (0.003 Ns/m^2), Q blood flow (m^3/s), r radius (m) of the coronary vessel, measured by quantitative angiography. After BA, Doppler data where available in 202 p distally to the lesion, in 56 p in the treated lesion and in 183 p proximally. We compared WSS between patients with and without MACE and/or R.

Results are summarized in the table. A multivariate logistic regression analysis demonstrated that with the measurements available at the site of angioplasty (minimal lumen diameter (MLD) and in-lesion average peak velocity), WSS in the lesion was the only predictor of MACE or restenosis (r = 0.22, p = 0.02). MLD, diameter stenosis and coronary flow reserve were excluded as statistically significant independent predictors of the clinical outcome.

Results

Mean (sd) [N m^{-}]	MACE or R (n = 72)	No events (n = 130)	p (Wilcoxon)
WSS prox	1.29 (0.62)	1.07 (0.54)	0.013
WSS in-lesion	4.51 (2.41)	2.97 (1.57)	0.016
WSS distal	0.76 (0.46)	0.84 (0.40)	0.028

Conclusion: The results of our study show that acute high shear stress in a treated lesion after balloon angioplasty might not be as beneficiary as previously assumed. Possibly, a higher shear stress at the post-PTCA site, presenting arterial wall injury, might enhance mural thrombus formation, with increased restenosis induction.

P2714 Repeated percutaneous interventional procedures for coronary in-stent restenosis: a quantitative angiographic study

N. von Welser, A. Kastrati, J. Dirschinger, J. Mehilli, T. Schilling, J. Pache, H. Schühlen, A. Schömig. *Deutsches Herzzentrum; 1. Med. Klinik rechts der Isar, TU München, Munich, Germany*

Several studies suggest that repeated percutaneous balloon angioplasties at the same coronary lesion are associated with a progressively increased risk of restenosis and that short time intervals between successive procedures are predictive of subsequent restenosis. We assessed the probability of angiographic restenosis when repeated percutaneous transluminal coronary interventions (repeated stent or repeat PTCA) were performed for lesions with restenosis after previous coronary stent placement.

Methods: Follow-up angiography was routinely advised after all procedures. Restenosis was defined as recurrence of ≥50% diameter stenosis determined by quantitative coronary angiography. Subject of the study were 1824 consecutive patients with successful coronary stent placement in 2307 lesions.

Results:

	Primary Intervention (2307 lesions)	First Reintervention (389 lesions)	Second Reintervention (78 lesions)
Incidence of restenosis, %	30	39	49
Target lesion revascularization rate, %	17	20	26

In multivariate analysis diabetes, small vessel size, long and complex lesions were predictive of recurrent restenosis. In addition, the number of previous interventions and a shorter time interval up to the reintervention were also predictive of restenosis.

Conclusions: Repeated interventions at the coronary lesion previously treated with stent placement are associated with a progressive increase in the restenosis rate. Factors known as predictors for the first occurrence of restenosis continue to play this role also for recurrences. The number of reinterventions is an independent risk factor for restenosis. Other forms of therapy should be sought for patients with recurrent restenosis.

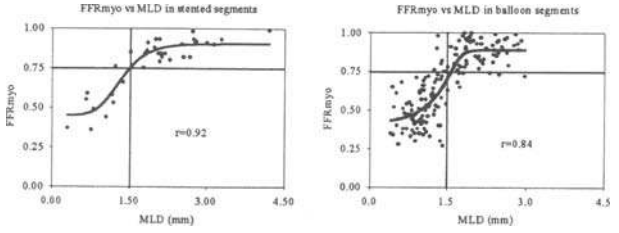
P2715 Quantitative coronary angiography and myocardial fractional flow reserve for evaluation of in-stent restenosis

S. Verheye, B. De Bruyne, P. Nellens, G.R. Heyndrickx, W. Wijns.
Cardiovascular Center, OLV-Hospital, Aalst, Belgium

Background: Due to the angiographic limitations of assessing the severity of instent restenosis (R), we evaluated myocardial fractional flow reserve (FFRmyo), derived from the transstenotic pressure gradient. We hypothesized that the benefit of stenting (S) is not only due to the larger minimal luminal diameter (MLD, mm) but also the circular anatomy.

Methods: Quantitative angiographic analysis (QCA) and FFRmyo were measured in 38 stents (36 pts, mean age 59 y; 27 male) at 253 ± 139 days after S (fig. left) and compared to 110 'de novo' stenotic segments, treated by balloon angioplasty (fig right).

Results: The mean angiographic diameter stenosis (DS, %) was 33 ± 21. The R rate (DS ≥ 47, cut-off value for lesion significance according to Gould) was 32%. The mean MLD at follow up was 2 ± 0.85 with a reference vessel diameter of 2.88 ± 0.55. The measured mean FFRmyo at follow-up was 0.78 ± 0.17. As illustrated, there is a better relationship between FFRmyo and MLD in stented arteries than in balloon arteries.



Conclusions: (1) QCA correlates significantly with FFRmyo in chronically stented arteries and (2) the relation between QCA and FFRmyo is tighter in stented versus balloon segments. Thus, at seemingly identical MLD, the better FFRmyo after S may be due to a better luminal symmetry, resulting in a larger cross sectional area.

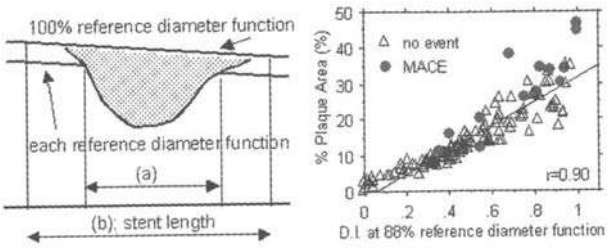
P2716 A novel quantitative parameter for evaluating diffuse in-stent narrowing at follow-up angiography

Y. Ishii, A.W.M. van Weert[1], H. Koops[1], J. Ter Horst[1], E. Hekking[1], K. de Marie[1], J.H.C. Reiber. *Department of Radiology, Leiden University Medical Center, Leiden; [1]Heart Core B.V., Leiden, Netherlands*

It is important to know whether in-stent restenosis is of a diffuse or focal nature, since diffuse stenosis may more easily lead to myocardial ischemia physiologically. The plaque volume in the stent is also important because plaque-rich stenosis may need subsequent therapy to reduce the incidence of restenosis after re-intervention. The purpose of this study, therefore, is to establish a new parameter for the objective description of the degree of diffuse or focal disease within the stent and to evaluate its relation with clinical events.

Methods: A total of 105 patients (134 lesions) with Wiktor-GX® Stents were evaluated at follow-up angiography. According to the QCA-CMS® definition, lesion length is derived from the 100% reference diameter function. By moving the reference diameter function downwards in the diameter function, the lesion length at each percentage of the diameter function can be calculated. Dividing this length (a) by the stent length (b) provides a Diffuse Index (D.I. = a/b), a value between 0 and 1, indicating little or diffuse plaque throughout the entire stent, respectively. The percentage plaque area (%PA) was calculated by dividing the plaque area by the sum of the plaque and luminal area within the stent. Major Adverse Cardiac Event (MACE) was defined as death, myocardial infarction, or Target Lesion Revascularization (TLR).

Results: There was a good correlation between the D.I. at 88% reference diameter function and the%PA (r = 0.90). The combination of D.I.> 0.75 and %PA > 25% resulted in a high incidence of subsequent MACE (9/20).



Diffuse Index.

Conclusions: The combination of percentage plaque area (%PA) and the new parameter Diffuse Index (D.I.) is valuable in the clinical decision making process of TLR.

P2717 Comparison of different strategies to detect restenoses after intracoronary stenting

F. Post, H.-J. Rupprecht, P. Stähr, J. Meyer. *II. Medical Clinic, University of Mainz, Germany*

After intracoronary stenting the restenosis rate is reported to be in the range of 20%–30%. Still the optimal strategy for detection of patients with relevant restenoses is still a matter of debate. Thus, we compared 4 different strategies for the indication for controll angiography in 200 consecutive patients (pat.) with single-vessel-disease.

Method: All pat. presented with single-vessel-disease which was treated with at least 1 intracoronary stent. All pat. reported of angina pectoris (AP) and all pat. had angiographic controll between 4 and 12 months after stenting. Before angiographic controll pat. were asked for recurrent AP and a stress-ECG was performed. Restenosis was defined as diameter stenosis of at least 50% within the stented segment. We compared the sensitivity and specifity of 4 different noninvasive strategies to detect restenosis: 1. all pat. with recurrent AP (AP) have controll angiography 2. all pat. with recurrent AP and abnormal S-ECG (AP and S-ECG) have controll angiography 3. all pat. with recurrent AP and/or abnormal S-ECG (AP and/or S-ECG) have controll angiography 4. all pat. with abnormal S-ECG (S-ECG) have controll angiography.

Results: Restenosis rate was 28%. The table shows specifity and sensitivity.

Strategy	Sensitivity	Specificity
AP	73%	77%
AP and S-ECG	48%	68%
AP and/or S-ECG	38%	89%
S-ECG	84%	56%

Conclusion: The sensitivity and specificity were high for recurrent AP. Sensitivity by selecting pat. with recurrent AP and abnormal S-ECG. Nevertheless 16% of patients with restenosis will not be detected with noninvasive strategies.

P2718 In-stent restenosis: predictors of target lesions revascularization after repeat intervention

I. Bossi, C. Klersy[1], A.J. Black[2], R. Cortina, M. Bernies, C. Jordan, J.C. Laborde, B. Cassagneau, J. Fajadet, J. Marco. *Clinique Pasteur, Toulouse, France; [1]I.R.C.C.S. Policlinico S. Matteo, Pavia, Italy; [2]Geelong Hospital, Geelong VIC, Australia*

Background: In-stent restenosis (ISR) can be safely treated by repeat percutaneous procedure (rePTCA). Reported subsequent target lesion revascularization (TLR) have varied from 20% to 80% and seem related to the type of restenotic lesion.

Methods: 262 rePTCA for ISR performed in 239 pts between May 1995 and January 1998 were retrospectively analyzed to identify any possible predictors of subsequent TLR. RePTCA was performed using balloon only (89%) or non-elective additional stenting (11%). Unstable angina was reported in 53.8%, stable angina in 42.7% and recent MI in 3.3%. Mean ISR-lesion length measured by Quantitative Coronary Arteriography was 16.7 ± 8.6 mm. Lesion characteristics were defined as FOCAL (≤10 mm), DIFFUSE (>10 mm within the body of the stent), PROLIFERATIVE (>10 mm beyond the stent margins) or total occlusion, and were present in 37%, 30%, 29% and 4% respectively. Reference Diameter was 3.08 ± 0.36 mm and post-rePTCA MLD was 3.07 ± 0.35 mm.

Results: The long-term clinical follow up (394 ± 232 days) was obtained in 229 pts (96%) and showed 1.7% total mortality and 19.1% TLR. The 6-month event free survival rate was 0.83 ± 0.02 (95% CI 0.78–0.87). The multivariate predictors of TLR after rePTCA are shown in Table:

Variables	Hazard ratio	95% CI	P Value
Time to ISR < 90 days	4.46	2.08–10.47	<0.0001
ISR pattern	1.59	0.93–2.71	0.088
Reference Diameter	0.34	0.13–0.91	0.030

Conclusion: Smaller post-rePTCA MLD and early intimal proliferation are independent predictors of TLR.

P2719 Six-month clinical and angiographic results of rotational atherectomy for in-stent restenosis

M.E. Fuentes, E. García, R. López-Palop, E. Pérez-David, J. Soriano, J. Botas, J. Elízaga, M. Abeytua, F. Sarnago, J.L. Delcán. *"Gregorio Marañón" Hospital, Madrid, Spain*

Background: Long-term results of balloon angioplasty for the treatment of intrastent restenosis (IR) have been disappointing with a rate of recurrence approaching 80%. The few reported studies on rotational atherectomy (RA) have not explored long-term angiographic restenosis.

Objectives: To study efficacy and safety of RA for the treatment of IR.

Methods: We analyzed the acute clinical and angiographic results of 114 consecutive cases and clinical and angiographic six-month follow-up. 128 stents (30% P-Schatz, 23% Wiktor, 7% Wallstent, 11% AVE, 9% Multilink, 20% others) with IR (60% diffuse) were treated with RA.

Results: Lesions were located in LAD (48%), RCA (37%), LCX (14%) and SVG (1%). Procedural success (<50% residual stenosis without major complications) was 97%. There were three cases of non-Q wave myocardial infarction (MI). No death, emergency surgery or Q-wave MI were observed. 195 burrs were used; mean burr/artery ratio was 0.79 ± 0.16. Balloon PTCA at a mean deployment pressure of 8.8 ± 3.18 atm was performed in 108 cases. IR was reduced from a mean of 67.05 ± 13.9% to 24.8 ± 11.1%. IVUS was performed in 22 cases, showing an acute gain of 1.51 ± 1.0 to 4.8 ± 0.98 mm^2 after the procedure. 96 patients (p) completed 6-month follow-up. None died during follow up. One p suffered MI and 2 p were referred for elective surgery. Clinical restenosis occurred in 14 (19%). In 73 p (70%) angiographic evaluation was performed showing restenosis in 28 (39%). A burr size < 2.15 mm was the only predictive factor of recurrence of restenosis (p < 0.005).

Conclusions: RA for the treatment of IR can be performed with a high rate of procedural success. RA can be considered the most effective device to treat IR.

P2720 Treatment of diffuse in-stent restenosis: short and long-term results of excimer laser angioplasty versus rotational coronary atherectomy

R. Mehran, G. Dangas, G.S. Mintz, M.A. Peterson, J.M. Ahmed, A.D. Pichard, L.F. Satler, K.M. Kent, M.B. Leon. *Washington Hospital Center, Washington DC, USA*

Background: Debulking with either excimer laser angioplasty (ELCA) or rotational atherectomy (RA) each appear to improve late recurrence in diffuse in-stent restenosis (ISR) lesions compared to balloon angioplasty alone, but there have been no comparative studies of these debulking strategies.

Methods and Results: We compared 250 diffuse ISR lesions in 182 patients treated with ELCA (n = 124) or RA (n = 126). Baseline patient characteristics, total occlusions (8%), stent use (27%), and angiographic success (100%) were similar in the two groups. Quantitative coronary angiography was performed and patients were followed-up clinically (table).

	ELCA	RA	p
SVG lesions (%)	43.4	5.6	<0.001
Lesion length (mm)	16 ± 2	18 ± 2	NS
Ref. Diam (mm)	2.98 ± 0.57	2.85 ± 0.41	0.02
Final Diam. Stenosis (%)	18.1 ± 5	18.7 ± 4	NS
In-hosp. Non-Q-MI (%)	9.8	7.9	NS
In-hosp. MACE* (%)	3.4	0	0.06
One-year TLR** (%)	31.4	21.6	0.05

*MACE = death/MI/urgent intervention; **TLR = target lesion revascularization

Conclusions: (1) Similar procedural results are achieved with both ELCA and RA; (2) There is a trend towards reduced in-hospital MACE with RA, possibly due to fewer SVG lesions; (3) Despite smaller vessel size, RA use was associated with lower TLR, suggesting that higher ablation efficiency may impact late clinical outcomes. A prospective, randomized clinical trial should compare these two athero-ablative strategies as an adjunct to balloon angioplasty for the treatment of diffuse in-stent restenosis is indicated.

P2721 In-stent restenosis patterns predict subsequent target lesion revascularization after treatment with balloon angioplasty

I. Bossi, C. Klersy[1], A.J. Black[2], R. Cortina, C. Jordan, J.P. Laurent, B. Cassagneau, J.C. Laborde, J. Fajadet, J. Marco. *Clinique Pasteur, Toulouse, France; [1]I.R.C.C.S. Policlinico S. Matteo, Pavia, Italy; [2]Geelong Hospital, Geelong VIC, Australia*

Background: In-stent restenosis (ISR) can be safely treated by repeat percutaneous procedure (rePTCA). Reported subsequent target lesion revascularization (TLR) have varied from 20% to 80% and seem related to the type of restenotic lesion.

Methods: Different angiographic patterns of ISR and their role in predicting the need of subsequent TLR at 6 months and at 12 months follow-up were retrospectively analyzed in 262 ISR lesions treated with rePTCA (balloon only 89%; non-elective additional stents 11%) for ISR performed in 239 pts between May 1995 and January 1998.

Results: Patterns of ISR were: 37% FOCAL (length ≤ 10 mm), 30% DIFFUSE (length > 10 mm within the body of the stent), 29% PROLIFERATIVE (PROLIF) (length > 10 mm beyond the margins of the stent) and total occlusion (TO) 4%.

At long-term follow-up (381 ± 230 days) the likelihood of TLR for proliferative and diffuse patterns versus focal ISR, was 2.69 (95% CI = 1.18–6.10; p = 0.02) and 1.94 (95% CI = 0.82–4.59; p = 0.12) respectively. The TLR rate at 6 and at 12 months for different patterns is as follows:

TLR	FOCAL	DIFFUSE	PROLIF	TO	P value
6 months	6/64 (9.4%)	12/62 (19.4%)	14/62 (22.5%)	2/9 (22%)	0.05*
12 months	7/46 (15.2%)	14/44 (31.8%)	18/48 (37.5%)	2/8 (25%)	<0.05*

P value for linear trend Focal < Diffuse < Proliferative < Total.

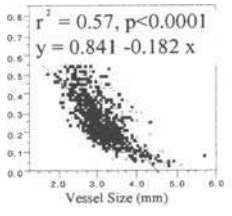
Conclusion: After the treatment of ISR with balloon or additional stenting, increasing severity of restenosis pattern correlates with increasing TLR.

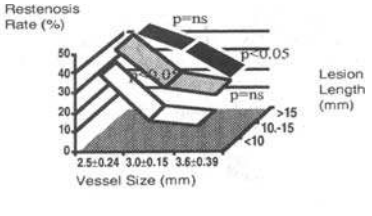
P2722 The interaction of lesion length and vessel size on incidence of angiographic restenosis rate after stenting

T. Nishida, L. Finci, M. Ferraro, M. Adamian, J. DeGregorio, R. Albiero, L. Di Francesco, C. Di Mario, A. Colombo. *Centro Cuore Columbus, Milan, Italy*

Aim of this study is to investigate the risk factor of angiographical restenosis after percutaneous coronary stenting.

Method: We analyzed the restenosis rate after coronary stenting in 1670 consecutive patients treated using high balloon pressure with IVUS guide. The logisitic regression (LR) on 42 variables found the lesion length (LL) and vessel size (VS) the most important predictors of restenosis. The left figure show high linear correlation Fit of LR probability of VS for restenosis. On the right is the interaction of LL and VS on restenosis analyzed at level of three typical vessel sizes.





Conclusions: Restenosis rate after coronary stenting ranged 13%–45% and was influenced by LL and VS. A decrease in reference vessel size bellow 3.0 mm and an increase in lesion length significantly increased the restenosis rate. An increase above 3.0 mm in vessel size lowered the restenosis rate only in lesion with the length of >15 mm. These finding may help to guide stent implantation.

P2723 A study of autopsy vessels after stenting

P. Gonschior, C. Vogel-Wiens, S. Milz[1], H.B. Hangler[2], H.A. Lehr[3]. *Deutsches Herzzentrum und I. Med. Klinik, Klinikum rechts der Isar, Technische Universität München, Munich; [1]Dept. of Anatomy, LMU München, Munich; [3]Dept. of Pathology, University of Mainz, Germany; [2]Surgical Dept., University Innsbruck, Austria*

Alterations of the vessel wall immediately after implantation of stents are analyzed in experimental studies but human vessel data immediately after stenting are rare. We analyzed vessels of 18 patients who died after coronary interventions. The formaline fixed arteries were cut serially and evaluated semiquantitative. The average age of the patients was 58 years and all showed multiple vessel disease, 50% with severe impairment of cardiac ejection fraction. 90% had unstable angina before the intervention. The reasons for fatal events were as follows: 10 patients died due to sudden cardiac events, 7 had relevant concommitant diseases and two patient were transplanted. All patients had balloon angioplasty before stent implantation was performed.

All explanted vascular segments had significant plaque burden leading to lumen reduction even if the angiographic lumen was not impaired and showed variation of plaque burden, calcification, tissue hyperplasia and foam cell clusters. The interventional treated vessel segments showed longitudinal and circumferential dissections. Three vessels had dissections not covered with stents leading to total lumen occlusion. Additional thrombotic occlusions were seen in five vessels, all segments had thrombotic appositions. Immediately after angioplasty the treated vessel segments revealed massive infiltration with neutrophile granulocytes close to the dissection. Later than two days the leukocytes were mainly located at the stent struts (30–50% of all present struts). At sites of neutrophile infiltration, the fraction of synthetic myocytes with abundant endoplasmatic reticulum, reduction of contractile filaments was increased, and an increased proliferation ratio (3.5% vs. 0.3%) was found in areas without dissection

Immediately after interventional treatment an intense cellular infiltration was found triggered by mechanical trauma. This intensive infiltration of neutrophils was followed by myocyte proliferation.

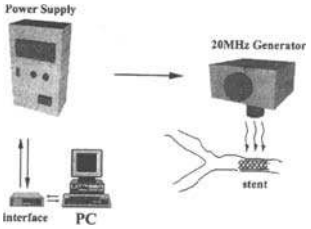
P2724 A new method for external heat delivery in arterial stents in vivo: a promising tool to stimulate cell apoptosis and prevent restenosis?

C. Stefanadis, L. Diamantopoulos, E. Tsiamis, C. Vlachopoulos, K. Toutouzas, N. Giatrakos, D. Tsekoura, P. Toutouzas. *Hippokration Hospital, Athens Medical School, Athens, Greece*

Background: Cell apoptosis is an important mechanism involved in the process of restenosis after coronary interventions. It has been suggested that heating of tissues may induce cell apoptosis.

Methods and Results: To induce heating of arteries in vivo we have developed a new method that uses electromagnetic energy to heat metals from a distance. Electromagnetic energy of a high-power 20 MHz generator is driven to a specially designed inductor to create an alternating magnetic field. Voltage and current drain are fully controlled by a personal computer (PC). As the magnetizing force on the metallic target (i.e. stent) periodically changes, additional energy is drained from the generator (to compensate for the lagging of the magnetizing flux) and appears on the metallic target as heat. This type of energy heats only metals leaving other materials or tissues unaffected. Thus, stents within the body can be heated from the outside and subsequently transmit heat to their surrounding tissues.

By regulating the generator's output power we achieved in in-vitro and in-vivo studies (femoral arteries, 5 pigs) effective heating of metallic stents of different compositions up to 100°C from a distance of 15 cm. Moreover, the nitinol stents were expanded remotely in a controlled fashion.



Conclusions: This new method that uses electromagnetic energy to heat metallic stents from a distance may be used for thermotherapy of coronary arteries after coronary stenting with the aim to reduce restenosis or for remote re-expansion of nitinol stents.

P2725 Fucoidan inhibits vascular smooth muscle cell proliferation and migration and is suitable for coating of stents

R. Köster[1], K. Gutensohn[2], J. Dürig[3], T. Bruhn[3], J. Kähler[1], W. Terres[1], C.W. Hamm[1], P. Kühnl[2], T. Meinertz[1]. *[1]Departments of Cardiology; [2]Transfusion Medicine; [3]Hematology; University Hospital Eppendorf, Hamburg, Germany*

Proliferation of vascular smooth muscle cells (SMC), a major pathomechanism of restenosis after PTCA, is stimulated by growth factors released from activated platelets. Fucoidan is a polysaccharide with subfractions of different molecular weight: FF7/1 (150 kD), FF7/2 (100 kD) and FF7/3 (50 kD). We investigated the effects of these fractions on SMC proliferation, platelet activation and aggregation.

Proliferation of cultured human vascular SMC incubated with different fucoidan fractions was analysed by growth assays. Platelet rich plasma of healthy volunteers was incubated with FF7/1, FF7/2 and FF7/3 at concentrations of 1.10 and 50 μg/ml. Platelet activation dependent expression of p-selectin and glycoprotein 53 was quantified by flow cytometry with antibodies CD62p and CD63. Platelet aggregation (PA) was measured by turbidimetry.

Proliferation of SMC was inhibited dose-dependently by FF7/1 and FF7/3 (FF 7/1: 39 ± 4%, FF7/3: 51 ± 3% vs control, $p < 0.05$). Platelets were activated by FF7/1 (+9.5 ± 2.3% and +7.0 ± 2.5% CD62p and CD 63 signals vs control, $p < 0.05$) whereas FF7/3 did not activate platelets significantly. PA was dependent on the fucoidan concentration and on the molecular weight. PA was stimulated by the high molecular weight fraction FF7/1, whereas the low molecular weight fraction FF7/3 did not induce a significant change of PA compared to control (FF7/1 vs FF7/3: 26.7 ± 14.2% vs 7.8 ± 3.5% increase in light transmission, $p < 0.02$).

Conclusions: Fucoidans inhibit proliferation of human SMC. The low molecular weight fraction, which does not activate platelets, may be useful for the prevention of restenosis and for coating of stents.

P2726 Separate and combined effects of continuous intravenous administration and local delivery of β-cyclodextrin sulfate (CDT) on intimal hyperplasia after angioplasty in swine

N. Meneveau, B. Klugherz, B. Chaquour, V. Anand, J.E. Tomaszewski, M. Joullié, E. Macarak, P.E. Weisz, R.L. Wilensky. *Hospital of the University of Pennsylvania, Philadelphia PA, USA*

Beta-cyclodextrin-sulfate (CDT) binds basic fibroblast growth factors, is anticoagulative, and reduces intimal hyperplasia after continuous IV infusion or perivascular placement in rats. We assessed the separate and combined effects of continuous IV administration and local delivery of CDT on neointimal formation in the porcine coronary arteries following balloon injury, using a 2 × 2 factorial design.

Pigs were randomized into 4 groups: 1) control, 2) continuous IV of 100 mg CDT/kd/d, 3) intramural delivery of 1250 mg CDT, 4) continuous IV of 100 mg CDT/kg/d and intramural delivery of 1250 mg CDT. Intramural delivery was performed using a Cordis Crescendo Catheter. Vessels were harvested at 14 days and evaluated for the maximal intimal thickness (MIT) and intimal area (IA) which was normalized to the injury index (II). Damage related to the local delivery was assessed by the II and combined histological criteria including adventitial rupture, retromedial hematoma, aneurysm and dissection.

	Control (n = 22)	Local (n = 22)	IV (n = 22)	IV + Local (n = 22)
MIT (mm)	0.45 ± 0.1	0.38 ± 0.1†	0.29 ± 0.6*	0.27 ± 0.1*
II	0.21 ± 0.1	0.25 ± 0.2	0.26 ± 0.1	0.22 ± 0.1
IA/II (mm^2)	2.82 ± 0.6	3.03 ± 4†	1.67 ± 0.7*	1.95 ± 0.8*
Damage (%)	6 (27%)	5 (23%)	7 (32%)	7 (32%)

Mean ± SD: *$p < 0.005$ vs control: †$p < 0.05$ vs IV and IV + local.

Conclusion: Intravenous administration of CDT had substantial effect on intimal hyperplasia while intramural delivery had no effect. No additional arterial injury is observed after delivery with a medication with anti-coagulation properties.

P2727 Local delivery of paclitaxel before stent implantation in a porcine restenosis model

M. Oberhoff, S. Cetin, R. Al Ghobainy, C. Herdeg, B. Horch, S. Schröder, A. Baumbach, K.R. Karsch. *Department of Cardiology. University of Tübingen, Germany*

Paclitaxel is a new microtubule stabilizing drug with potent antitumor activity. It influences the cytoskeleton equlibrium by increasing the assembly of stable microtubules and thereby interacts with many cellular functions. The aim of this study was to evaluate the potential of paclitaxel to prevent restenosis in vivo after intracoronary stent implantation.

Methods: After local intracoronary delivery of 10 ml paclitaxel (10 μmol/l) with the double balloon perfusion catheter tantalum stents were placed in the application area of the left anterior descending artery in 10 pigs (balloon vessel ratio 1.1–1.3). Fourteen pigs served as control with stent implantation only. Vessels were excised 4 weeks following intervention. All pigs received 5,000 units of heparin at the beginning of the procedure and were treated with 100 mg aspirin daily starting three days before. Histopathology was performed on all vessels. Morphometric parameters of restenosis and vascular remodeling namely neointimal area (NA), percent area stenosis (PAS) and vessel area (EEL) were measured.

Results: No significant difference was observed in both groups in regard to NA (2.36 $\pm$ 1.03 mm^2 vs 4.09 $\pm$ 2.06 mm^2), PAS (46.9 $\pm$ 17.0% vs 66 $\pm$ 20.7%) and EEL (4.95 $\pm$ 0.95 mm^2 vs 6.24 $\pm$ 2.12 mm^2).

Conclusion: Local paclitaxel delivery had no beneficial effect on restenosis after stent-implantation. The lack of efficacy is most probably due to the strong and continous proliferative action of the metal stent.

P2728 Catheter-based delivery of ribozymes targeting PCNA mRNA after stenting reduces neointimal hyperplasia in a porcine model

M. Sebastian, H. Honda, J. Robbins[1], J. Hausleiter, R. Makkar, N. Eigler, F. Litvack. *Cardiovascular Intervention Center, Cedars-Sinai Medical Center, Los Angeles CA; [1]Immusol Incorporated, San Diego CA, USA*

Background: In-stent stenosis caused by neointimal hyperplasia may potentially be inhibited by cytostatic therapy based on molecular biology techniques.

Methods: We synthesized chimeric DNA:RNA hammerhead ribozymes (Rz) directed against mRNA coding for the key cell cycle regulatory protein PCNA (proliferating cell nuclear antigen). The ribozymes combined with a lipid vehicle were delivered intramurally using a microporous catheter (Crescendo®, Cordis, Miami, FL.) after placement of a nitinol stent in nonlipemic porcine coronary arteries. Control arteries were stented without ribozyme. Angiographic follow-up and histomorphometry were performed at the 30-day timepoint.

Results: Angiographic minimal lumen diameter (MLD) at follow-up was improved in Rz-treated vessels compared to controls, and final percentage diameter stenosis was reduced (see Table). Histomorphometric data will also be presented.

QCA results

	N	Ref. Vessel (mm)	MLD (mm)	Diam. Stenosis (%)
Control	9	3.0 $\pm$ 0.4	1.2 $\pm$ 0.4	60 $\pm$ 12
Rz	8	2.8 $\pm$ 0.3	1.7 $\pm$ 0.5*	40 $\pm$ 17*

*P < 0.05 vs. control

Conclusion: Anti-PCNA ribozymes delivered locally after coronary stenting reduce in-stent stenosis in the porcine model. Plans for clinical evaluation are underway.

P2729 Statin therapy substantially reduces restenosis after coronary stent implantation in patients with the PI^{A2} glycoprotein IIb/IIIa receptor polymorphism

D.H. Walter, V. Schächinger, M. Elsner, S. Mach, S. Dimmeler, W. Auch-Schwelk, A.M. Zeiher. *Internal Medicine IV, Div. of Cardiology, University of Frankfurt, Germany*

Background: The platelet GPIIb/IIIa PI^{A2} polymorphism has been associated with the occurrence of acute coronary syndroms and higher risk of coronary stent thrombosis. Platelets also play a central role in restenosis development by inducing neointimal proliferation after coronary interventions. Besides lipid lowering effects, statins exhibit antiproliferative, antiinflammatory and antithrombotic properties, thereby potentially interfering with the major processes of in-stent restenosis.

Methods: Therefore, we investigated the effect of statin therapy on clinical and angiographic outcome in the presence or absence of the PI^{A2} allele in 506 patients following successful coronary stent implantation.

Results: (6 month follow-up)

Stent-Restenosis ≥50%	No Statin N = 250	Statin N = 256	p-value
PI A1/A1-Genotype	68/197 (34.5%)	55/200 (27.5%)	0.1
PI A1/A2-Genotype	25/53 (47.2%)	15/56 (26.8%)	0.02

The occurrence of major adverse coronary events (myocardial infarction, death, need for target vessel revascularisation) during 6 month follow up was substantially reduced among patients with the PI^{A2} allele receiving statin therapy (49.1% vs. 28.6%, p = 0.02).

Conclusion: Statin therapy dramatically abrogates stent restenosis and improves clinical outcome in patients bearing the PI^{A2} allele, suggesting that statins preferentially reduce neointimal proliferation after stent implantation in those patients.

IMAGING IN ONE EMERGENCY DEPARTMENT

P2730 Is myocardial perfusion by echocardiography useful in the management of patients with chest pain in the emergency department?

A. Moraes, F. Morcerf, M. Carrinho, E.T. Mesquita, R. Bassan, H. Dohmann. *Hospital Pró-Cardíaco & ECOR, Rio de Janeiro, Brazil*

Background: We previously showed that myocardial perfusion is accurately assessed by myocardial contrast echocardiography (MCE) with PESDA in pts with stable coronary artery disease (CAD). However its utility for pts undergoing a rapid evaluation for possible ischemia in a Chest Pain Center (CPC) has not yet been evaluated. Accordingly, we assessed the ability of MCE to identify the perfusion patterns in these pts.

Methods: 49 pts (35 male, 59 $\pm$ 14 years, 28–90) were admitted to a CPC to investigate possible ischemia due to CAD. First ECG and initial CK-MB were non-diagnostic. According to the chest pain characteristics 3 groups were formed: A- typical angina: 11 pts; B- suggestive of angina: 21 pts; and C-non-suggestive of angina: 17 pts. MCE with triggered (1:1) 2nd harmonic imaging, was visually assessed (2 independent investigators), at rest and after IV injection of adenosine (ADN), using PESDA (sonicated solution of 1 ml 20% albumin, 12 ml 5% dextrose and 8 ml decafluorobutane gas), continuously infused at 1–2 ml/min. A marked and homogeneous contrast enhancement after ADN was defined as normal perfusion, and absence or heterogeneous enhancement in the walls was considered a perfusion defect. Coronary angiography (ANG) was obtained in 26 pts (in 11/11, 12/20 and 3/16 pts from groups A, B, and C respectively) within 48 hours from MCE. For each patient 3 LV territories (related to right coronary, circumflex and left anterior descending arteries) were considered.

Results: 78 territories were analyzed in pts with ANG with 33 related to coronary artery with obstruction ≥ 75% (all but one with abnormal perfusion); and 45 territories supplied by normal or no flow limiting (<75%) coronary artery (43 with normal perfusion). The sensitivity was 97%, the specificity was 95.5% and the global accuracy was 96.2%.

Conclusion: MCE with ADN is an accurate method to study myocardial perfusion in pts admitted to a CPC to elucidate the etiology of a chest pain.

P2731 Role of two-dimensional echocardiogram to improve diagnostic accuracy of acute coronary insufficiency in patients with chest pain and no ST-segment elevation

M. Scofano, R. Bassan, E.T. Mesquita, C.H. Sanmartin, A. Volschan, M. Fabrício, H.F. Dohmann, J.F. Soares. *On behalf of Chest Pain Project investigators; Pró-Cardíaco Hospital/PROCEP, Rio de Janeiro; Department of Statistics, Federal University of Minas Gerais, Brazil*

Patients who present to the emergency room with chest pain and no ST segment elevation in the ECG constitute a clinical decision problem as many may have acute coronary insufficiency (AMI/UA). Serial determinations of plasma markers of myocardial injury are usually necessary, thus prolonging hospital stay.

Methods: We have developed an algorithm to evaluate these patients using chest pain type, serial ECG and plasma CKMB measurements, and 2-D Echo on admission. From a series of 1003 consecutive patients with chest pain 354 had neither ST segment elevation nor left bundle branch block (LBBB) in the first ECG, had performed Echo on admission and could have a final diagnosis made after appropriate work-up. Chest pain was prospectively classified either as typical/suggestive of angina (positive) or non-suggestive/not angina (negative). First ECG was designated as positive (ST depression/T inversion) or negative (normal/non-specific). Echo was designated as positive (segmental/global dysfunction in non-Q wave areas) or negative (normal contraction). Final diagnosis were AMI/UA (n = 215) or non-AMI/UA (n = 139).

Results: Positive predictive value of Echo was slightly better than first ECG and chest pain (90% vs 87% vs 80%, respectively) but negative predictive value was worse (49% vs 51% vs 80%). Adding Echo to chest pain and ECG improved the predictive value of any series of results of these tests except when both negatives.

Conclusion: In patients with chest pain and no ST elevation or LBBB, Echo is mostly informative when positive. A negative Echo does not rule out AMI/UA in any setting. Echo does not help for diagnosis when chest pain and ECG are both negative.

P2732 Acute tissue harmonic echocardiography is superior to biochemical variables in early risk stratification of patients presenting with non-ST-segment elevation acute coronary syndrome

R. Senior, J. Swinburn, P. Stubbs, P. Soman, N. Stephens, D. Gaze, A. Lahiri. *Northwick Park Hospital, Harrow, UK*

Recent studies have shown that the early measurement of the biochemical markers Troponin T (TnT) and Troponin I (TnI) as well as the inflammatory markers CRP, Interleukin-6 (IL-6) and Tissue necrosis factor alpha (TNF) appear useful as predictors of an adverse cardiac outcome in patients admitted with non ST segment elevation acute coronary syndromes (ACS). The purpose of the study was to examine the role of systolic wall thickening (SWT) abnormalities assessed by acute tissue harmonic echocardiography (TH Echo) in risk stratifying this patient group.

Methods: Patients admitted within 6 hours of chest pain with ACS were studied. Venous samples were taken on admission and batch assayed for CRP, IL-6, TNF, TnT and TnI which were scored as positive if they exceeded their upper reference range. Patients underwent TH Echo at presentation and the SWT was scored as normal or abnormal. The other variables were scored as positive if they exceeded their upper reference range.

Results: 80 patients were studied a mean of 175 mins from chest pain and were followed up for a median period of 227 days during which there were 28 cardiac events (4 deaths, 4 AMI and 20 revascularisation). Univariate analysis using clinical data, biochemical variables, ECG changes and TH Echo data showed that significant predictors of cardiac event were: abnormal SWT (p = 0.003), previous AMI (p = 0.02) and an abnormal ECG at presentation (p = 0.03). In the stepwise multivariate Cox's regression model only abnormal SWT achieved significance (p = 0.006; relative risk 3.9; 95% CI 1.5–10.3).

Conclusion: Abnormal SWT assessed by acute TH Echo was superior to the other variables measured in the early risk stratification of chest pain.

P2733 Comparison between two-dimensional echocardiography and myocardial perfusion imaging in the emergency department in patients with possible myocardial ischaemia

S. Paventi, E. Di Luzio[1], M.A. Parafati[2], U. Bevilacqua. *Coronary Care Unit II Internal Medicine Institute; [1]Nuclear Medicine Laboratory Radiology Institute; [2]Public Health Institute, University "La Sapienza", Rome, Italy*

Background. Accurate identification of patients (pts) at high risk for acute coronary syndromes among those seen in the emergency department (ED) with possible myocardial ischemia (MI) and nonischemic electrocardiograms (ECG) is problematic. Both 2-dimensional echocardiography (ECHO) and myocardial perfusion imaging with technetium-99m-sestamibi (T99mS) can identify pts at low and high risk; however, comparative studies are lacking.

Methods and Results. Pts initially considered at low or moderate risk for myocardial ischemia on the basis of the presenting history, physical examination, and ECG underwent both ECHO and T99mS within 4 hours of ED presentation. Positive ECHO was defined as at presence of segmental wall motion abnormalities or moderate to severe global systolic dysfunction; positive perfusion imaging was defined as a perfusion defect in association with abnormal wall motion, thickening, or both. End points included MI, percutaneous transluminal coronary angioplasty, and positive stress perfusion imaging. Both imaging procedures were performed in the ED on 205 pts. Ten pts had MI, and an additional 5 pts underwent percutaneous transluminal coronary angioplasty. ECHO and T99mS were positive in all 15. Overall agreement between the 2 tecniques was high (concordance 89%, with a κ coefficient 0.76) in the 37 who had MI or underwent coronary angiography. For all pts, concordance was 89%, with a κ coefficient of 0.68.

Conclusions. Agreement between ECHO and T99mS is high when used in pts in the ED with possible MI. Both techniques identified pts at high risk who required admission and those who could be safely discharged directly from ED.

NEW MARKERS IN ACUTE MYOCARDIAL INFARCTION

P2734 Ultrafast diagnosis of acute myocardial infarction by analysis of myoglobin kinetics

G. Belotti, M. Biffi[1], E.F. Viganò[1], G. Tommasini. *Cardiology Department; [1]Clinical Chemistry Department, Ospedale Treviglio Caravaggio, Treviglio, Italy*

Background. Early biochemical diagnosis of AMI is usually based upon detection of serum myoglobin beyond the normal range. We hypothesized that by analyzing myoglobin kinetics rather than looking at absolute values an even earlier diagnosis could be made.

Methods. We studied consecutive patients admitted to emergency ward within 4 hours from the onset of chest pain. Serial blood samples were obtained on admission, at 30 and 60 min; myoglobin percent (δ%) increase between admission and 30 min (0–30′) and between admission and 60 min (0–60′) were calculated. Serum myoglobin concentration was determined by the Beckman Kit on an Access Analyzer. The final diagnosis of AMI was based on serial sampling of specific biochemical markers of myocardial necrosis, ECG and 2D-echocardiogram.

Results. We enrolled 105 patients (pts, 65 male, mean age 61 yr., range 34–83); 46 (44%) had 'definite' AMI; the remaining were found to have no evidence of infarction. The efficacy of the proposed method, the interplay between sensitivity and specificity at different thresholds (T) of myoglobin δ% were assessed by the receiver operator curves (ROC).

	T	Sensitivity	Specificity	W	p
δ% 0–30′	11/21	97/90	73/93	0.956	<.0001
δ% 0–60′	11/21	100/100	79/84	0.973	<.0001

Conclusion. In this study population, the analysis of myoglobin kinetics yielded excellent diagnostic performance. An increase of myoglobin at 30 min exceeding the above thresholds (11/21%) allows very early identification of nearly all patients with acute myocardial infarction.

P2735 The role of out-of-hospital ECG recording in patients with an acute coronary syndrome

H.R. Arntz, C. Strunz, L. Schnitzer, S. Schmidt, J. Breckwoldt, H.P. Schultheiss. *Klinikum Benjamin Franklin, Free University Berlin, Germany*

Symptoms and ECG are the cornerstones of differential diagnosis and therapy of pts with an acute coronary syndrome (ACS). The aim of this prospective study was to determine how an out-of-hospital 12-channel ECG (O-ECG) together with the first in-hospital ECG (H-ECG) adds to the diagnosis and acceleration of therapeutic decisions in ACS patients.

Results: 227 consecutive pts with nitro-refractory angina pectoris (age 68 ± 14 years, 60% males, median duration of symptoms 56 min) were investigated. 20% (n = 45) of the pts showed major differences in the comparison of O-ECG's and H-ECG's (registered with a median time difference of 39 min).

73 (32%) pts had signs of an acute myocardial infarction (MI) (ST elevation in ≥2 leads) which was not present in the O-ECG of 4 pts. Of 43 pts (19%) with a subacute MI (Q waves and ST elevation or negative T waves) in the H-ECG, 12 had signs of an acute MI in the O-ECG, 3 signs of an old MI, and 28 pts had an identical O-ECG and H-ECG. Of 44 pts (19%) with signs of an old MI in the H-ECG (Q waves or QS complexes without ST elevation), 5 pts had signs of an acute MI in the O-ECG, 1 a subacute MI, 3 ST depressions and in 35 pts both ECG's were identical. In the remaining 67 pts (30%), 31 had only a ST depression in the H-ECG, a negative T wave (n = 6) bundle branch block (n = 12) or were normal (n = 18). In the O-ECG's of these 67 pts, 5 had the signs of an acute MI. Of the 69 pts with an acute MI in O-ECG, 54 (78%) received immediate prehospital thrombolysis by the emergency physician, and 13 (18%) were referred to acute PTCA/Stenting.

Conclusion: An ECG recorded at the scene in pts with an ACS not only allows immediate causal therapy (i.e. early prehospital thrombolysis) but is also a key and time-saving tool for evaluation of the patient and decision-making after hospital admission.

P2736 Non-invasive prediction at 60 minutes of failed reperfusion

John K. French, Krishnan Ramanathan, Jacqueline Andrews, James T. Stewart, Roger Johnson, Mayanna Lund, Barbara Williams, Ralph M.L. Whitlock, Arthur C. Maas, Mitchell W. Krucoff, Harvey D. White. *Department of Cardiology, Green Lane Hospital, Auckland, New Zealand*

The early restoration of TIMI-3 flow following thrombolytic therapy for acute myocardial infarction (AMI) results in improved survival. To attempt to non-invasively predict lack of reperfusion (TIMI 0–2 flow) at 90 min, continuous ST segment monitoring, 60 min ECG's, and blood levels of myoglobin, CKMB (mass) and troponins T and I were obtained, in 60 patients undergoing angiography 90 minutes following streptokinase (1.5×10^6 MU over 30–60 min) for AMI. Using ratios of protein levels at 60 min to baseline (prior to streptokinase), we determined an index which predicted failure to achieve TIMI-3 flow at 90 minutes. At 90 min, the 29 patients (48%) with TIMI 3 flow had higher levels of myoglobin, CKMB (mass), troponins T and I at 60 and 90 min compared to patients with TIMI 0–2 flow. A ratio of ≤5 of any of these 4 proteins at 60 min detected TIMI flow 0–2 with 90% to 97% sensitivity, 37% to 53% specificity, 61% to 81% positive and 66% to 92% negative predictive accuracy. ST segment resolution ≤ 70% on 60 min ECGs was 75% sensitive and had 61% negative PA in determining TIMI flow 0–2 at 90 min. Steady state 50% ST recovery (sustained >4 hours) by 60 min was 96% sensitive and had 88% negative predictive accuracy. Multivariate predictors of failure to achieve TIMI 3 flow were: a troponin T ratio £5 at 60 min, and steady state 50% ST segment recovery (both $p < 0.02$).

Conclusion: Failure of TIMI-3 reperfusion can be predicted by troponin T levels and ST segment resolution by 60 min, facilitating triage of patients who may benefit from further reperfusion therapies.

P2737 Evaluation of myocardial reperfusion with serial assessment of electrocardiographic ST-segment after primary percutaneous transluminal coronary angioplasty

J. Watanabe, S. Nakamura, S. Hamada, T. Sugiura, T. Fujimoto[1], M. Baden[1], T. Iwasaka. *Second Department of Internal Medicine, Kansai Medical University, Moriguchi City, Osaka; [1]Division of Cardiology, Takarazuka Hospital, Takarazuka, Japan*

Impaired myocardial reperfusion after primary coronary angioplasty(PTCA) implicates ongoing structural and/or functional problem of distal microcirculation and poor functional outcome. To evaluate the relation between ST change and impaired myocardial reperfusion immediately after angiographically successful (TIMI 3 grade flow) primary PTCA, we studied 51 pts with first acute Q wave myocardial infarction(MI)(ant:27, inf:24, mean age:64) with angiographically successful PTCA. Methods. The lead showing the greatest ST elevation in the 12-lead ECG was investigated before and immediately after PTCA and the resolution of ST elevation (dST = before-after PTCA) was calculated. A successful myocardial reperfusion was determined by quantitative tetrofosmin perfusion scintigraphy and defined as change(before-after PTCA)of 4 and more in the total defect score(DS)[the sum of defect score in each 13 segments: from 3(complete defect) to 0 (normal perfusion)]. Results. Twenty-four pts had impaired myocardial reperfusion (<4 change in DS: G1) and 27 pts had successful myocardial reperfusion (4 and more in DS: G2). The two groups did not differ significantly in age, site of MI, time from admission to PTCA, elapsed time and collateral grade. There was no significant difference in the degree of ST elevation before PTCA between G1 (1.9 ± 1.9 mm) and G2 (2.2 ± 1.4 mm). Pts in G2 showed a reduction in ST elevation after PTCA, but pts in G1 showed no significant change in ST elevation (dST = 1.7 ± 0.3 mm vs. −0.2 ± 1.5 mm: $p = 0.02$). Of 14 pts with ST re-elevation (dST>0) immediately after PTCA, 10 pts(71%) were in G1 and 4 pts in G2. Among 37 pts with no ST re-elevation (dST is 0 and less), 14 pts(38%) were in G1 and 23 pts in G2. The sensitivity and specificity of ST re-elevation in predicting impaired myocardial reperfusion were 42% and 85%, respectively. Conclusions. ST re-elevation is a specific ECG manifestation of impaired myocardial reperfusion after angiographically successful primary PTCA.

P27387 Serial change in fatty acid metabolism during acute phase of anterior myocardial infarction assessed by 123I BMIPP imaging

H. Matsuo, T. Matsubara, T. Segawa, T. Yamaki, K. Sano, K. Watanabe, Y. Matsuno, A. Murata, S. Tanaka, S. Watanabe. *The Department of Cardiology, Gifu Prefectural Hospital, Gifu City, Japan*

Iodine-123-labeled-15-iodophenyl-3-methyl-pentadecanoic acid (BMIPP) has been proposed as a potential myocardial fatty acid(FA) probe. However, little is known about serial changes in FA utilization in myocardium that has been exposed to acute ischemia in patients with myocardial infarction(MI). We examined 28 consecutive patients with acute anteroseptal MI whose infarct related artery was successfully recanalized. Fourteen patients were spontaneously recanalized(SR), and the rest of 14 patients had occluded LAD which was successfully revascularized by primary PTCA(PTCA). Serial BMIPP studies were obtained within 72 hours(BMIPP1), 5–8 days(BMIPP2), and about 30 days after onset(BMIPP3). Tc-99m tetrofosmin imaging to determine area at risk(AAR) and infarct size(IS) was performed on admission and about 30 days after onset. Defect severity in BMIPP and TF was quantitatively assessed using polar map display as the severity index.

Results: Serial change in FA utilization in relation to AAR are shown in the table. BMIPP defect within 72 hours after onset(BMIPP1) were significantly smaller than AAR and larger than IS in both the SR and PTCA groups, and the severity improved during the very early phase of acute MI[AAR (mean 140SD67) > BMIPP1 (mean114 SD63) > BMIPP2 (mean97SD63) > BMIPP3 (mean89 SD62) > IS (mean67SD55)]. In addition, greater improvement during the superacute phase(BMIPP1 to BMIPP2) was observed in patients with SR which resulted in less myocardial damage compared with that of patients with totally occluded vessel subsequently undergone PTCA.

The severity of abnormal FA utilization

	BM1/AAR	BM2/AAR	BM3/AAR	IS/AAR
PCTA	86.1 ± 7.5	74.7 ± 12.5	69.6 ± 14.5	59.1 ± 21.1
SR	68.8 ± 19.3	50.7 ± 22.7	43.6 ± 30.8	43.6 ± 30.8
	P < 0.01	P < 0.01	P < 0.01	P < 0.01

Conclusion: FA utilization assessed by BMIPP showed dynamic changes during the acute phase of MI, and the degree of this improvement depend on the severity of ischemia.

P2739 Soluble vascular cell adhesion molecule as a marker of vessel patency after thrombolysis

R.T. Murphy, N. Mulvihill, B. Foley, P. Crean, M.J. Walsh. *Dept. of Cardiology, St. James's Hospital, Dublin 8, Ireland*

Soluble Vascular Cell Adhesion Molecule as a marker of vessel patency after thrombolysis.

Introduction: Soluble Cell Adhesion Molecules (sCAMs) have been shown to be elevated in Acute Myocardial Infarction (AMI).They have also been implicated in reperfusion injury and may be involved in leucocyte binding and extravasation to the reperfused myocardium.We set out to characterise the pattern of sCAM expression in the first 24 hours following AMI treated with thrombolysis and to assess its relationship with vessel patency.

Methods: Patients presenting with AMI, eligible for

thrombolysis, had serum drawn prior to thrombolysis and 60 minutes, 4, 12, and 24 hours post thrombolysis. A group of age and sex matched controls were used for comparison; they had serum drawn at 0 and 24 hours. All patients underwent coronary angiography within 5 days of presentation. Soluble Vascular Cell Adhesion Molecule-1 (sVCAM-1), soluble Intercellular Adhesion Molecule-1 (sICAM-1) and sE-Selectin were measured using an ELISA technique (R+D).

Results: 27 patients have entered the study to date (male/female = 23/4, mean age 59 ± 8 years). The levels of sVCAM-1, but not sICAM-1 or sE-Selectin, increased significantly in the first 24 hours post thrombolysis (474 to 676 ng/ml, $p < 0.001$). sVCAM-1 levels in patients with patent infarct related vessels and TIMI 3 flow rose significantly (434 to 676 ng/nl, $p < 0.002$). Conversely, sVCAM-1 levels in those patients with an occluded vessel or TIMI 1 flow, did not increase significantly (614 to 718 ng/nl,$p = 0.42$).

Conclusion: sVCAM-1 levels rise after successful thrombolysis in AMI and may be a marker of vessel patency.

P2740 The role of cytokines (IL-6, IL-8) and their soluble receptors (sIL-6R) in acute myocardial infarction

C. Panagoulis[2], L. Kavallierou[1], Ac. Zacharoulis[1], G. Lianidis[2], Ap. Zacharoulis[2], C. Politis[1]. [1]*3rd Regional Blood Transfusion Center;* [2]*Cardiology Department General Hospital of Athens, Greece, "G. Gennimatas"*

Interleukin 6 (IL6) plays a primary role in the synthesis of human acute phase proteins. Interleukin 8 (IL8) has a regulatory role in ischemic myocardium Moreover, it is well known that during AMI several acute phase responses take place. The objective of this study was to investigate the value of the cytokines as early diagnostic markers.

Methods: The serum levels of IL6, IL8 and sIL6R were examined in 30 patients with AMI, after admission (0 h) and at 24, 48 and 72 h later. The results from the patients group (24 male, 6 female, mean age 67.3 years) were compared with the respective ones of 100 blood donors (control group, 70 male, 30 female, mean age 36.5 years). Cytokines were measured by an Elisa assay.

Results are shown in tables 1 and 2.

Table 1. Patients with AMI

Cytokines	0 h	24 h	48 h	72 h	p
IL 6 pg/ml	18.3 ± 5.7	25.0 ± 8.2	35.6 ± 11.2	54.8 ± 16.5	<0.001
IL 8 ≫	16.7 ± 5.6	22.7 ± 6.0	41.7 ± 11.2	22.2 ± 8.1	<0.001
sIL6R ≫	7.5 ± 5.5	5.1 ± 3.5	3.1 ± 2.3	2.2 ± 2.5	<0.001

Table 2

Groups	No	IL6	IL8	sIL6R
Patients	30	18.3 ± 5.7	16.7 ± 5.6	7.5 ± 5.5
Blood donors	100	8.8 ± 3.6	7.3 ± 4.8	4.1 ± 2.6
p		<0.001	<0.001	<0.001

In conclusion, the serum levels of cytokines in patients with AMI were increased at all sampling points from admission to discharge, compared with levels in control subjects. The serum IL6 level reached its peak approximately 72 h (54.8), while IL8 level 48 h (41.7) after admission. The complex of IL6 and SIL6R acts agonistically. There was a significant positive linear correlation ($r = 0.8$) between levels of IL6 and IL8. IL6 may be the main mediator of acute phase response in patients with AMI.

P2741 Plasma cyclic-GMP: a marker of infarct-related artery patency?

G.K. Karavolias, E.K. Iliodromitis, M. Markianos, G.N. Theodorakis, Z.S. Kyriakides, T. Apostolou, D.Th. Kremastinos. *2nd Dept. of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

Plasma cyclic-GMP (cGMP) increases during the first hours of acute myocardial infarction (AMI), declining 24 h later. The aim of this study was to correlate plasma cGMP levels with angiographic data in AMI patients (pts).

Methods: 23 AMI pts admitted within 3 h of the onset of symptoms, were included in this study. Circulating plasma cGMP levels were measured 3, 6, 12 and 24 h after the onset of pain. Immediately after the last blood sample was taken, all pts underwent coronary angiography and were grouped according to the infarct-related coronary artery (IRA), the number of diseased vessels (NDV) and the patency (PAT) of the IRA. IRA was considered patent if there was a type 2 or 3 TIMI flow.

Results:

	(in pmol/ml)	3 h	6 h	12 h	24 h
NDV	1 (N = 10)	21.4 ± 3.1	13.2 ± 2.1	11.1 ± 2.0	12.6 ± 2.8
	2 (N = 10)	21.7 ± 3.5	11.4 ± 1.9	12.9 ± 2.2	10.5 ± 0.9
	3 (N = 3)	26.2 ± 6.9	14.8 ± 5.8	10.6 ± 6.0	4.7 ± 1.6
IRA	LAD (N = 14)	21.5 ± 2.4	11.6 ± 2.1	12.9 ± 2.2	10.4 ± 2.1
	LCX (N = 4)	27.2 ± 8.2	15.3 ± 2.0	9.9 ± 1.3	8.3 ± 2.6
	RCA (N = 5)	20.2 ± 4.1	13.3 ± 3.4	10.3 ± 3.8	13.3 ± 3.5
PAT	YES (N = 15)	19.4 ± 2.1√	11.0 ± 1.8	10.5 ± 1.8	7.0 ± 0.9*√
	NO (N = 8)	27.3 ± 4.3#	15.7 ± 1.9	14.3 ± 2.0	17.4 ± 2.2*#

NDV: P = NS between 1, 2 or 3 vessels. IRA: P = NS between coronary arteries (LAD, LCX, RCA). IRA PAT: (YES vs NO); 24 h, $P < 0.001$* PAT YES: (3 h vs 24 h) $P < 0.001$√, PAT NO: (3 h vs 24 h) P:NS#

Conclusions: In AMI pts, cGMP plasma levels are not related to the NDV and the IRA, but to the PAT; cGMP plasma levels are higher in pts with non patent IRA. In the case of non patent IRA, cGMP levels do not decline from baseline readings, as observed with the patent group.

P2742 Significance of reciprocal anterior ST-segment depression in inferior acute myocardial infarction: a clue for multivessel disease

M. Zoghi, H. Kültürsay, İ. Türkoğlu, A. Sağcan, O. Yavuzgil, C. Gürgün, L. Can, M. Akın, S. Payzin, C. Türkoğlu. *Ege University, Department of Cardiology, Izmir, Turkey*

Although reciprocal ST-segment depression in patients (pts) with acute inferior myocardial infarction (AMI) is a common ECG finding, its significance is not yet established. In this prospective study we investigated the relationship of relative ST-segment elevation (STE) and reciprocal ST-segment depression (STD) with the extent of coronary artery disease.

Methods: Eighty-seven patients (pts) with inferior AMI, receiving thrombolytic therapy and undergoing coronary angiography within one month after AMI were enrolled in this study. The electrocardiographic maximum STE (STEmax) in leads II–III and maximums STD (STDmax) in precordial leads were measured. Pts were divided into 3 groups according the STDmax and STEmax. In Group I. there were 29 pts (mean age: 55 ± 4, male: 62%) who had STDmax > STEmax, Group II. Consisted of 20 pts (mean age: 57 ± 5, male: 64%) with STDmax < STEmax. In Group III. 38 pts (mean age: 54 ± 6, male: 70%) had no reciprocal ST-segment depression in ECG's. Vessel lumen narrowing >50% in angiography was accepted as significant.

Results: Demographic and clinical variables were similar in all groups. Significant left anterior descending artery lesion was present in the majority of Group I. patients. A Dominant right coronary artery was the most frequently involved infarct vessel with severe reciprocal changes during inferior myocardial infarction.

Group (n = 87)	SVD % (n = 48)	MVD % (n = 39)	P	IRA %		P
				RCA	Cx	
I (n = 29)	35	65	0.04	82	18	<0.001
II (n = 20)	70	30	0.02	70	30	0.02
III (n = 38)	63	37	0.04	58	42	0.2

(SVD: Single vessel disease, MVD: Multi vessel disease, IRA: Infarct related artery, RCA: Right coronary artery, Cx: Circumflex artery)

Conclusion: 1) The presence of reciprocal anterior STD in greater magnitude than STE during inferior myocardial infarction increases the likelihood of multi-vessel disease, namely left anterior descending artery involvement. This simple ECG finding may be used to differentiate high risk patients for a more aggressive approach.

2) A dominant RCA is more frequently involved with inferior myocardial infarction in the presence of severe reciprocal anterior ST depression.

P2743 PTX3, a prototypic long pentraxin, is a sensitive marker of acute myocardial infarction in humans

G. Peri, R. Latini, M. Introna, P. Ghezzi, D. Corradi[1], J.D. Sipe[2], A. Mantovani, G. Olivetti[1]. *Cardiovascular Research, Istituto Mario Negri, Milan; [1]Pathology Dept., University Medical School of Parma, Parma, Italy; [2]Biochemistry, Boston University, Boston MA, USA*

Inflammation is an important component of ischemic heart disease,as reflected by raised serum levels of the "short" pentraxin C reactive protein (CRP).PTX3 is a prototypic long pentraxin whose expression is induced by cytokines. To test the hypothesis that PTX3 increases in acute myocardial infarction (AMI)in humans we studied the amount of PTX3 in the blood in 37 patients admitted to Coronary Care Unit (CCU)3.2 ± 3.2 hours after onset of AMI symptoms. Patients with history of inflammatory disorders were excluded. The majority of the patients received within the first 24 hours thrombolytics and oral aspirin. Plasma concentrations of PTX3 and CRP were measured up to hospital discharge by sandwich ELISA. To confirm that increased plasma concentration of PTX3 is the result of myocardial damage fragments of human hearts collected from 8 patients who died in heart failure within 48 hours after AMI, or from causes different from cardiovascular diseases (n = 4) and from one normal donor were used either frozen or fixed in formalin. In each case several sections were stained with MNB4 and MNB6 rat monoclonal anti PTX3 antibodies. PTX3 plasma concentrations were higher than the mean + 2SD of age- and sex-matched controls (2.01 ng/ml) in 27 out of 36 AMI patients. PTX3 peaked in plasma a median of 7.5 h(3 to 48 h)after CCU admission and mean peak concentration was 6.94 ± 11.26 ng/ml. At hospital discharge (12 ± 4 days), plasma concentrations of PTX3 were lower than the normal cutoff value in all but 3 patients. In contrast, CRP peaked in plasma a median of 24 h (3 to 72 h) after CCU admission, much later than PTX3 ($p < 0.001$). Plasma concentrations of PTX3 were unrelated to age, AMI site or extension and Killip class at entry. Patients aged more than 64 years and females had significantly higher PTX3 concentrations at 24 h ($p < 0.05$). CRP at 24 h was higher in patients with Killip 2–3 and in those not receiving aspirin maintenance therapy ($p < 0.05$). Immunohistochemically, PTX3 was detected in cardiomyocytes and endothelial cells from normal hearts, while fibroblast staining was very weak or absent. In infarcted myocardium PTX3 did not stain the damaged cells with empty cytoplasm whereas myocyte labeling was still present in the border zone. In conclusion, PTX3 is present in cardiomyocytes and endothelial cells of normal human myocardium and is absent in necrotic cardiomyocytes. Plasma concentration of PTX3 increases after the onset of symptoms of AMI much earlier than pentraxin CRP. Thus PTX3 appears to be released by the damaged myocytes and may be used as a sensitive initial marker for AMI.

P2744 Early cardiac marker testing predicts myocardial infarction by 90 minutes

S.M. Ng, P. Krishnaswamy[1], R. Morrisey[1], A. Maisel[1]. *University of California, San Diego, School of Medicine, La Jolla CA; [1]Cardiology Dept, Veteran's Healthcare System, San Diego, San Diego CA, USA*

Background: Early and accurate evaluation of patients with chest pain is critically important for their appropriate triage and management.

Aim: We asked whether frequent serial testing of a panel of cardiac markers that utilized myoglobin, troponin I, and CK-MB (Triage®, Biosite Diag.) could accurately diagnose patients within 90 minutes of arriving in the emergency room.

Methods: In patients presenting to the emergency room with chest pain, quantitative cardiac markers were drawn at the point-of-care at 0, 30, 60, and 90 minutes. Cardiac markers were also drawn at 3 and 6 hours to substantiate final diagnosis of myocardial infarction. Troponin I was positive for myocardial infarction if >1.0 ng/ml. CK-MB was positive if >8.9 ng/ml. Myoglobin was considered positive if increasing >25% over 90 minutes and final value was >150 ng/ml.

Results: Of 918 patients presenting with chest pain, 45 had the final diagnosis of myocardial infarction. Of this group, troponin I was elevated in 84% by 90 minutes. With the addition of elevated CK-MB and increasing or elevated myoglobin, all 45 MI's were accurately diagnosed by 90 minutes (sensitivity 100%). In patients presenting less than 6 hours after symptom onset, myoglobin alone (absence of increased troponin I or CK-MB) detected 4 MI's by 90 minutes. The specificity of troponin I was 100%, while that of myoglobin in all patients without renal failure was 98.4%. Myoglobin specificity in patients presenting <6 hours after symptom onset was 96.5%.

Conclusion: Patients presenting with chest pain can be accurately diagnosed by 90 minutes when serial testing of a combination of cardiac markers are utilized.

P2745 Fatty acid-binding protein, a new marker useful in the early triage of chest pain patients presenting with equivocal ECGs

B. Haastrup[1], S. Gill[1], S. Risom[2], M. Hørder[2], T. Haghfelt[1], J. Glatz[3]. *[1]Department of Cardiology; [2]Department of Genetics and Biochemistry, Odense University Hospital, Odense, Denmark; Cardiovascular Research Institute, Maastricht, Netherlands*

More than 80% of all patients suspected of AMI and more than 40% of patients with later confirmed AMI present with equivocal ECG-findings. Thus, other diagnostic tools for early triage are needed.

Purpose: To evaluate a new marker, fatty acid-binding protein (FABP), which has been proposed as a very early and cardiospecific marker.

Methods: One hundred thirty consecutive patients admitted to the CCU for suspected AMI < 6 h from onset of symptoms with equivocal ECG-findings were enrolled. A blood sample was drawn on admission and – in 66% of the cases – repeated after 1–2 hours. Analysis was made for FABP, myoglobin, CK-MB mass, and troponin I. Sensitivity, specificity, and predictive values for AMI-diagnosis < 6 h from onset were calculated at prespecified cut-off values.

Results:

	FABP (10 μg/l)	Myoglobin (90 μg/l)	CK-MB (6.5 μg/l)	Tn I (2 μg/l)
Sensitivity	89 (68–98)	78 (56–92)	44 (24–66)	33 (16–56)
Specificity	87 (80–91)	90 (84–94)	97 (93–99)	98 (94–100)
PVpos	52 (33–70)	56 (35–76)	73 (38–93)	75 (35–97)
PVneg	98 (95–100)	96 (95–100)	92 (86–96)	90 (85–95)

AMI-prevalence 13.8%. 95% CI in brackets.

ROC-curve analysis revealed no sign. differences in the performance of FABP compared to myoglobin ($p = 0.52$) or CK-MB mass ($p = 0.22$), while both FABP and myoglobin performed sign. better than Tn I ($p = 0.03$ and 0.01, resp.).

Conclusion: FABP as well as myoglobin possess high sensitivities and very high negative predictive values. The two markers seem equally useful in the early triage of AMI-suspicious patients with equivocal ECG-findings, in particular in the early rule-out of AMI.

P2746 Increased endothelin-1 cardiac production in the acute phase of myocardial infarction

I. Cecioni, F. Rocchi, G. Baldereschi, N. Marchionni, M. Boddi, P.A. Modesti, G.G. Neri Serneri. *Clinica Medica Generale e Cardiologia, University of Florence, Florence, Italy*

Increased plasma concentration of endothelin-1 (ET-1) in the acute phase of myocardial infarction was reported. Experimental studies showed that chronic ET-1 receptor antagonist administration may improve ventricular remodelling and survival in myocardial infarction.

In the present study cardiac production of ET-1 was investigated in 9 patients with anterior acute myocardial infarction (AMI), with preserved hemodynamic status, who did not undergo thrombolysis. Serial blood samples for ET-1 assay were withdrawn during cardiac catheterization from peripheral vein (V), artery (A) and coronary sinus (CS) on the first day of AMI and repeated on the 2nd, 3rd, 7th, and 14th day. Blood samples from V, A and CS were also withdrawn from 11 patients with atypical chest pain who underwent coronary angiography and served as reference control values. ET-1 plasma concentration was measured by radioimmunoassay using a specific polyclonal rabbit antibody after chromatographic extraction.

In control subjects ET-1 A-CS gradient was 0.04 ± 0.05 pg/ml. During the first 3 days following AMI plasma concentration of ET-1 was significantly increased both in arterial and peripheral venous blood ($p < 0.05$), without any significant increase in the peripheral A-V gradient. Conversely, cardiac production of ET-1 was increased, as indicated by the elevated A-CS gradient (0.81 ± 0.34 pg/ml, on the first day, $p < 0.01$ vs controls), which remained high up to the 3rd day. Thereafter, A-CS gradient decreased and on the 7th and 14th day was similar to controls.

In conclusion, cardiac ET-1 production sharply increases during the first week following myocardial infarction.

P2747 Cardiac adrenergic system in acute myocardial infarction

A. Boncompagni, M. Boddi, M. Coppo, R. Becherini, E. Pedemonte, N. Marchionni, G.G. Neri Serneri. *Clinica Medica e Cardiologia, Careggi, Florence, Italy*

An activation of the systemic adrenergic system is known to occurr in patients with acute myocardial infarction (AMI), but no information is available on the role of the cardiac adrenergic system. This study was aimed to investigate cardiac adrenergic system in AMI.

In 27 patients (all males, aged 56 ± 7 yrs) with anterior AMI norepinephrine (NA) concentration was assayed in aortic, coronary sinus and peripheral venous blood at the 5th and at 20th day from AMI. Left ventricular end-systolic volume (LVESV), end-diastolic volume (LVEDV) and ejection fraction (EF) were measured by echocardiography on the 5th and 20th day and 6 months after AMI. Twelve patients who performed coronary angiography for atypical chest pain formed the control group.

AMI patients had peripheral venous NA concentration in the range of controls (171 ± 67 pg/ml) throughout the study. Conversely, at the 5th day all patients had a positive transcardiac NA gradient, significantly different from controls ($p < 0.01$). At the 20th day NA transcardiac gradient remained positive only in 10/27 patients. After 6 months the 10 patients with persistent activation of cardiac adrenergic system showed higher LVESV and LVEDV and lower EF than the 17 patients without cardiac adrenergic activation ($p < 0.05$).

A persistent cardiac adrenergic activation may be indicative of the development of left ventricular dysfunction in patients with AMI.

P2748 Evaluation of a rapid bedside test for streptokinase resistance applied in acute myocardial infarction

K. Al Shwafi, A. de Meester, B. Pirenne, P. Vranckx, J. Col. *Université Catholique de Louvain, Brussels, Belgium*

Streptokinase (SK) remains a widely used thrombolytic agent in the treatment of acute myocardial infarction (AMI). Its lytic activity is variably hampered in the presence of specific neutralizing antibodies formed due to previous SK administration or streptococcal infaction, thus inducing streptokinase resistance (SKR). A rapid bedside test, introduced with the thrombolytic assessment system (TAS™), based on autologous clot lysis onset time (LOT) as a quantitative measurement of the lytic response to 100 U/ml SK in vitro for detection of SKR (resistant when LOT > 50 sec). To evaluate this test, 93 AMI patients were screened before the initiation of a standard dose of SK, ST segment elevation and lytic activity intensity were monitored during and up to 3 hours from the start of SK, and coronary angiography was done within 48 hours.

Results:

Clinical assessment % patients	LOT ≤ 50 sec (responder)	LOT > 50 sec (resistant)	P value
Efficient lytic activity	79%	38%	0.002
≥50% ST resolution on			
– continuous monitoring	80%	48%	0.012
– 3 hrs 12-lead ECG	88%	26%	<0.0001
TIMI grade 3 flow	81%	21%	<0.0001

Conclusion: 1) Clinical outcome was significantly less favorable in those with prolonged LOT in response to the in vitro SK challenge. 2) This bedside test can be a useful tool for rapid identification of streptokinase resistance and therefore could contribute to prompt selection of an alternative therapy before SK initiation.

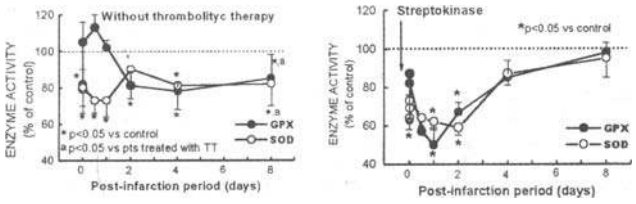
THROMBOLYTIC THERAPY

P2749 Effects of thrombolytic therapy on erythrocyte antioxidant activity in post-infarction period

D.V. Simic, T. Simic[1], J. Mimic-Oka[1], D. Milanovic, Z. Reljic[1], M. Pljesa, B. Ivanovic, D. Kalimanovska-Ostric, D. Matic, A. Arandjelovic. *Institute of Cardiovascular Disease; [1]Institute of Biochemistry School of Medicine, Belgrade, Yugoslavia*

The deleterious effects of free radicals in acute myocardial ischemia/reperfusion are rather well known. However, the potential later effects of thrombolytic therapy (TT) on endogenous antioxidative status in post-infarction period are less well investigated.

Methods: We followed the time course of erythrocyte antioxidant activity in 25 patients (pts) with first acute myocardial infarction (MI). 12 pts were administered i.v. Streptokinase and 13 pts were treated without thrombolysis. Control group consisted of 24 healthy subjects. Glutathione peroxidase (GPX) and superoxide dismutase (SOD) were determined immediately after admittance to the hospital and subsequent TT, during first post-infarction day (1/2, 6, 12, 24 hrs) and 2, 4, and 8 days after MI.



Results: In pts without TT, time course of erythrocyte antioxidant level revealed an unbalanced GPX and SOD activities during first two days after MI. By the end of the study enzyme activities remained significantly lower than control levels in these pts. On the other hand, patients treated with TT demonstrated a pronounced rise in the activities of both GPX and SOD immediately after treatment, followed by concerted decrease until third post-infarction day. During further post-infarction period in pts treated with Streptokinase, erythrocyte antioxidant activity gradually recovered and finally reached control levels (day 8).

Conclusions: It can be concluded, that thrombolysis in pts with acute MI has later beneficial effects on their antioxidant status, which may contribute to the better overall prognosis in these pts.

P2750 Monocyte chaemotactic protein-1 rises after thrombolysis for acute myocardial infarction

R.T. Murphy, N. Mulvihill, J.B. Foley, P. Crean, M. Walsh. *Dept. of Cardiology, St. James's Hospital, Dublin 8, Ireland*

Introduction: Reperfusion injury after thrombolysis may be mediated by leucocyte infiltration and an inflammatory cascade. Animal models of reperfusion have demonstrated that neutrophil and monocyte chaemotaxis is largely mediated by Monocyte Chaemotactic Protein-1 (MCP-1). We set out to characterise the changes in MCP-1 levels in patients with Acute Myocardial Infarction (AMI) treated with thrombolysis.

Methods: Patients presenting with AMI, eligible for thrombolysis,had serum drawn at presentation, and at 60 minutes, 4, 12, and 24 hours post thrombolysis. Serum was centrifuged and stored at -70°C. MCP-1 levels were measured using an ELISA technique (R+D).

Results: 25 patients have entered the study to date (male/female = 21/4, mean age 56+/7). The average time from onset of pain to lysis was 210 ± 83 minutes. Levels of MCP-1 were significantly elevated at all time points post lysis compared to levels pretreatment.

Time (hours)	0	1	4	12	24
MCP-1 (pg/ml)	194	338	362	367	332
	–	$p < 0.01$	$p < 0.04$	$p < 0.02$	$p < 0.04$

P value = compared with MCP-1 at 0 hours.

There was a correlation of MCP-1 levels at 24 hours with peak creatine kinase levels ($r = 0.521$, $p = 0.05$).

Conclusion: Levels of MCP-1 increase post thrombolysis in AMI, reflecting leucocyte chaemotaxis during reperfusion and providing a potential mechanism for reperfusion injury.

P2751 The effect of tissue plasminogen activator on cerebral artery vasoreactivity

M.J. Cipolla. *Vascular Surgery, Oregon Health Sciences University, Portland, Oregon, USA*

The risks associated with thrombolytic therapy, whether for treatment of acute myocardial or cerebral infarction, include intracerebral hemorrhage and edema. One possible mechanism of damage from thrombolysis is a direct effect of tissue plasminogen activator (tPA) on the cerebral vessels themselves. This study investigated the direct effect of tPA on cerebral artery function, including myogenic responses and vasoreactivity.

Methods: Posterior cerebral arteries, isolated from male SD rats, were mounted in a special arteriograph system that allowed control of transmural pressure (TMP) and measurement of lumen diameter. Arteries were perfused with either physiologic saline solution (PSS, n = 6) or PSS + 100 μg/mL tPA (tPA, n = 6). After a 1 hour equilibration at TMP = 25 mmHg, TMP was increased stepwise to 200 mmHg and back to 75 mmHg and diameter recorded. Reactivity to serotonin (5HT, 0.01–10 μM) and vasodilation to acetylcholine (ACh, 10 μM) were also compared.

Results: The amount of pressure-dependent tone that arteries developed was significantly less in the presence of tPA:%tone = 21 ± 3% in tPA vs. 31 ± 3% in PSS ($p < 0.05$). tPA arteries also could not withstand pressure as well and underwent forced dilatation (loss of tone) at significantly lower TMP: 142 ± 10 vs. 179 ± 4 mmHg ($p < 0.01$). In addition, tPA arteries recovered less tone than PSS arteries following forced dilatation when TMP was returned to 75 mmHg: 17 ± 2% vs. 28 ± 3% ($p < 0.01$). Reactivity to 5HT was diminished in tPA vs. PSS arteries (EC50 = 88 ± 11 nM vs. 58 ± 4 nM; $p < 0.05$), as was the response to ACh which dilated arteries 10 ± 2% in tPA vs. 20 ± 4% in PSS ($p < 0.05$).

Conclusion: tPA perfusion has significant effects on cerebral artery reactivity and myogenic responses. Since the control of arterial diameter, both pressure- and agonist-induced, is crucial for cerebrovascular resistance and autoregulation of cerebral blood flow, any disturbance of these mechanisms may have damaging effects during or after tPA perfusion.

P2752 Accelerated streptokinase (0.75 MU in 10 minutes) and enoxaparin in the prehospital management of acute myocardial infarction

G. Tatu-Chitoiu, M. Oprisan, O. Cismara, T. Sfiriac, A. Marinescu, R. Marinescu, R. Turcu. *Department of Cardiology, Emergency Hospital, Department of Ambulance, Bucharest, Romania*

Background: 1. We previously reported the safety and superiority of the inhospital administration of accelerated Streptokinase (1.5 MU infused in 20 min. or 0.75 M.U. over 10 min.) in the management of acute myocardial infarction (AMI) as compared to the standard regimen (SSK-1.5 M.U. in 60 min.). 2. Enoxaparin (ENOX) is a low molecular weight heparin which also have a fibrinolytic activity.

Objective: The safety and efficacy of the prehospital bolus of 0.75 MU SK in 10 min. in association with i.v. 40 mg. ENOX and 250 mg. of aspirin has been evaluated.

Methods: In 52 patients (pts.), age 58 ± 9, with well defined AMI, a combination of 0.75 M.U. of SK infused in 10 min. and followed by i.v. 40 mg. Enoxaparin plus 250 mg. Aspirin was administrated at the patient's home. After admision every patient received i.v. 40 mg. ENOX twice a day for the next 48 hours and aspirin 250 mg. daily. Three bedside criteria were used as revealing the coronary reperfusion (CR): 1. The rapid resolution of the chest pain. 2. The rapid decreasing of the ST segment elevation by more than 50% from the initial value. 3. The rapid increasing of the enzymes revealing necrosis. We evaluated the rates of CR, 21 day mortality, symptomatic hypotension, and of the haemorrhagic events.

Results: The CR was performed in 42 pts. (80.7%). No major haemorhagical events or other significant complications of the SK administration were registered. Three pts. without signs of CR died (5.7%). Symptomatic hypotension appeared in 17 pts. (32.7%) This side effect proved to be transient and well controlled with routine therapy in all pts.

Conclusion: The combination accelerated 0.75 M.U. SK-ENOX-aspirin is a safe and very efficient regimen in the prehospital management of AMI.

P2753 Rapid detection of streptokinase resistance

N. Mulvihill, J. McRedmond[1], M. Kane[1], M. Walsh, D.J. Fitzgerald[1]. *Department of Cardiology, St. James Hospital, Dublin; [1]Department of Clinical Pharmacology, Royal College of Surgeons in Ireland, Dublin, Ireland*

The development of neutralising antibodies to streptokinase (SK) preclude its repeated use. Neutralising antibodies have been detected up to four years after initial treatment with SK. The effect of these antibodies, resistance to the fibrinolytic action of SK, is measured using the SK neutralising activity assay (SNA). The aim of this study was to assess SK resistance using a new rapid latex bead agglutination assay and to correlate this with the SNA measurement of SK resistance.

Methods: Patients presenting with acute myocardial infarction had serum samples taken prior to thrombolysis and then one and six months after discharge. Resistance to SK was measured using the SNA (in vitro clot lysis test). We also measured SK resistance using the latex bead assay: if significant neutralising antibodies are present in patients serum then agglutination occurs with in 5 minutes. Resistance to SK is scored 0–6 depending on the degree of agglutination.

Results: 14 patients have been studied to date (10 M/4 F, mean age 62 ± 10 yrs). Data is expressed as mean ± SEM. SNA increased significantly after treatment with SK (120 ± 17 U/ml before SK, 2230 ± 952 U/ml at 1 month, $p < 0.01$ and 1075 ± 208 U/ml at 6 months, $p < 0.05$). Similarly the latex agglutination score increased after SK (0/6 pre SK, 5/6 at 1 month, $p < 0.01$ and 4/6 at 6 months, $p < 0.03$). There was a strong correlation between SNA and the latex score ($r = 0.67$, $p < 0.01$ at 1 month and $r = 0.61$, $p < 0.03$ at 6 months).

Conclusion: Estimation of SK resistance using the latex bead assay correlates well with SNA. The latex agglutination assay has the potential to rapidly patients who will not respond to SK before administration of this thrombolytic agent.

P2754 Gender and geographic variations in thrombolytic treatment for acute myocardial infarction

M. Garcia, S. Sans, M. Martin. *For the COEUROWOMEN Investigators, Biostatistics and Epidemiology Section, School of Medicine, Autonomous University; Institute of Health Studies, Barcelona, Spain*

Case fatality of acute myocardial infarction (AMI) in women is higher than in men in some countries but not in others. Explanations for gender differences in case fatality are controversial. Furthermore, gender biases in diagnosis and treatment of AMI have been described. Aim of this paper is to study gender and cross-cultural differences in thrombolytic treatment for hospitalized cases of definite AMI for the ages 35 to 64,when thrombolytic treatment was still not widely adopted.

Methods: All (n = 3,412) hospitalized definite AMI events occurred in 1989–90 in five European regions of Finland, U.K. France and Spain taken from population based registres following the WHO-MONICA protocol were examined, 22% were AMI in women. Multiple logistic models were used to identify factors associated with treatment with fibrinolytics.

Results: Compared to men, women were on average significantly older, less often smokers, arrived later at hospital, had more atipycal pain, were less likely to be admitted to a coronary care unit (82% vs 89%) and of having had a previous AMI, more likely to have had an anterior MI, had less often an ST elevation, more often hypertensive, and less likely to receive thrombolytics (35 versus 40%). On multiple logistic analysis after adjusting for risk factors, care and clinical variables, women still received less thrombolytics (OR = 0.83, 95%CI = 0.66–1.02). There were no significant interactions of gender with other variables. All centres were less likely than U.K. centers to give thrombolytics. The clinical characteristics of patients on arrival at hospital, mainly the ST-segment elevation (OR = 3.9) and presence of typical chest pain (OR = 2.4) as well as being admitted to a coronary care unit (OR = 9.4) were the strongest determinants of the use of thrombolytic treatment.

Conclusions: Women tended to receive less thrombolytic treatment than men for definite hospitalized AMI in Europe, independent of geographical and clinical characteristics.

P2755 The use of reperfusion therapy in acute myocardial infarction

D. De Bacquer, G. De Backer, Z. Doyen[1], N. Popelier, P. de Smet[1], M. Kornitzer[1]. *Department of Public Health, University of Ghent, Ghent; [1]Department of Public Health, Free University of Brussels, Brussels, Belgium*

The use of reperfusion therapy in acute myocardial infarction (AMI) was investigated in a stratified random sample of all patients aged 35–84 years, hospitalised in Belgium in 1995. A 2-step sampling method as applied: from all acute hospitals of the country a random sample was selected, stratified by region and by hospital size. In each selected hospital a random sample of patients with a discharge diagnosis for AMI was selected, stratified by age and by gender. The refusal rate was less than 5%. Results are based on a total of 965 patients from 44 hospitals. Thrombolysis was equally used in large or small hospitals in both regions. In premature cases in men (<55 years) thrombolysis was used in 61% as compared to 50% in those aged ≥ 55 years; thrombolysis was used in 59 and 39% of women aged respectively <65 and ≥65 years. Patients with a definite AMI entering within 12 hours of onset of symptoms and with ST-elevation (49% of total) received thrombolysis in 75% with the only difference by prematurity: 82% in premature cases and 67% in the older groups. "Door to needle times" were respectively <20 minutes and <60 minutes in 26 and 82% of premature men, 21 and 82% in men aged ≥ 55 years, 19 and 76% in premature women and 32 and 82% in women aged ≥ 65 years.

In-hospital PTCA was used in 189 patients but in only 40 (4%) on the day of admission.

These results observed in a representative sample of the patients entering with an AMI, show a widely use of reperfusion therapy. More attention should go to the elderly, particularly in women.

P2756 Increased risk of cardiac rupture in women who received thrombolytic therapy in acute myocardial infarction

A. Solodky, I. Herz, A. Assali, T. Ben Gal, Y. Birnbaum, V. Boyko[1], S. Behar[1]. *[1]Neufeld Cardiac Research Institute, Sheba Medical Center, Tel Hashomer; Rabin Medical Center (Campus Beilinson), Petah Tikvah, Israel*

Background: Thrombolytic therapy (TLX) in AMI is associated with more complications in women than in men.

Methods: We reviewed the charts of all patients (pts) who received TLX for AMI hospitalized in all CCU's operating in Israel (n = 26) during a national survey lasting 5 months during 1996. We focused on cardiac rupture (free wal rupture and ventricular septal defect).

Results: Out of 2,377 AMI pts, 1,162 (49%) received TLX therapy. Characteristics and outcome of these pts according to gender were as follows:

	Total (%)	Female (%)	Male (%)
Number	1162	263 (23)	899 (77)
Age	60.6 ± 12	68.0 ± 11.4	58.5 ± 11.7*
Hypertension	405 (35)	145 (55)	260 (29)*
Diabetes Mellitus	271 (23)	84 (32)	187 (21)*
Prior AMI	186 (16)	39 (15)	147 (16)
Killip > 1	187 (16)	66 (26)	121 (14)*
CK	1884 ± 1662	1644 ± 1510	1955 ± 1698**
Cardiac rupture	32 (2.7)	16 (6.1)	16 (1.8)*
Hemorrhagic complic.	54 (4.6)	16 (6.1)	38 (4.2)
24 hr mortality	35 (3)	13 (4.9)	22 (2.4)***
7-day mortality	64 (5.5)	28 (10.6)	36 (4.0)*
30-day mortality	89 (7.7)	39 (14.8)	50 (5.6)*

*$p < 0.001$; **$p = 0.004$; ***$p = 0.04$

In a step-wise logistic regression analysis the most important independent predictors of cardiac rupture are age (OR 1.77; CI 1.24–2.60), female gender (OR 1.94; CI 0.88–4.30) and Killip > 1 on admission (OR 3.08; CI 1.43–6.62).

Conclusion: Alternative types of reperfusion should be considered for the management of AMI in women with increased admission risk.

P2757 Two accelerated streptokinase regimens are equivalent and more efficient than the standard 1.5 MU in 60 minutes regimen in patients with acute myocardial infarction

G. Tatu-Chitoiu, C. Teodorescu, P. Capraru, A. Tatu-Chitoiu, M. Dan, M. Guran, V. Chioncel, A. Bumbu, M. Dorobantu. *Department of Cardiology, Emergency Hospital, Bucharest, Romania*

Background: Since 1995 our cardiologists have the liberty to choose among three Streptokinase regimens for the management of patients (pts.) with acute myocardial infarction (AMI): Two accelerated (ASK) regimens (ASK1: 1.5 MU infused in 20 min. and ASK2: 0.75 MU in 10 min. followed after 60 min. by a new bolus of 0.75 MU in 10 min. if the signs of coronary reperfusion (CR) do not appear) and the standard (SSK) 1.5 MU over 60 min. one.

Objective: The results obtained within the last 4 years with the two ASK regimens as compared with the SSK one are presented.

Patients and Methods: Between January 1st, 1995 and December 31st, 1998, 618 pts. admitted within the first 6 hours after the onset of AMI received SK. In 312 pts. cardiologists chose the ASK regimens (ASK1-165 pts., ASK2-147 pts.) In 306 pts. the SSK regimen was administrated. All pts. received heparin and aspirin. Three bedside criteria of CR were used: 1. The rapid resolution of the chest pain. 2. The rapid decreasing (within 3 hours) of the ST segment elevation by more than 50% from the initial value. 3. The rapid increasing of the enzymes revealing necrosis. We evaluated the safety, the ratio of CR and the 30-day mortality.

Results: The rations of CR were similar in the two ASK subgroups: ASK1: 79.3%; ASK2-80.2% and significantly higher that the one of 61.7% registered in the SSK group ($p < 0.001$). The 30 day mortality was 6.7% in the ASK group and 11.11% in the SSK group ($p = 0.07$). No major haemorhagical complications were registered. Symptomatic hypotension was more frequent in the ASK group (34.9%) than in SSK group (22%). This side effect proved to be transitory and well controlled in all pts. using a rapid infusion of natrium chloride solution.

Conclusions. 1. The two ASK regimens are equivalent. 2. The ASK regimens are safe and followed by a higher rate of CR as compared to the SSK regimen. 3. The short-term mortality seems to be lower in pts. treated with ASK regimens.

P2758 Platelet reactivity and streptokinase resistance following antecedent streptokinase therapy for myocardial infarction

D.A. Gorog, N. Ahmed, G.J. Davies. *Cardiology Department, Hammersmith Hospital, ICSM, London, UK*

Aims: First time thrombolysis with streptokinase (SK) in MI is established but efficacy of subsequent SK is unknown. We aimed to assess the efficacy of second administration of SK.

Methods: Platelet reactivity to shear stress, spontaneous and SK-induced thrombolysis, and SK-antibody titres were measured *in vitro* in 28 patients who had received SK for MI and compared to 15 controls. Non-anticoagulated venous blood was tested using an overall *in vitro* technique to assess thrombotic and thrombolytic activities. Blood is drawn in pulses through a capillary tube where haemodynamic forces induce platelet aggregation culminating in occlusion. Dislodgement/disintegration of the stabilised thrombus under pressure reflects thrombolysis. The time for (1) occlusive thrombus formation under high shear stress (platelet reactivity), and for (2) dislodgement of the thrombus (thrombolysis) is measured. This was repeated adding 12.5, 25 and 50 U/ml SK in *vitro*.

Results: SK-antibody titres were inversely related to time from MI. Platelet reactivity was greatly enhanced in patients ($p < 0.0001$). Spontaneous thrombolysis in patients was poor and in 17 failed to occur. In contrast, thrombolysis occurred in all but one control. In patients platelet reactivity was strongly related to thrombolytic activity ($r = -0.516$; $p = 0.0029$). The dose-response relationship of *in vitro* SK to thrombolytic effect was poor in patients compared to the steep dose-response curve of controls. SK *in vitro* was at least 4 times more effective in controls than in patients.

Conclusion: Chances of achieving patency with second administration of SK are poor. SK-antibody titre is not a reliable index of resistance and second time treatment with higher doses of SK cannot be tailored to the patient.

P2759 Clinical presentation of reocclusion of the infarct-related artery after successful thrombolytic therapy: impact of collateral filling

M.A. Brouwer[1], G. Veen[2], C.J. Werter[2], A. Meyer[2], J. Karreman[2], F.W.A. Verheugt[1]. [2]*Free University Hospital Amsterdam;* [1]*Heartcenter, University Hospital Nijmegen, Netherlands*

Background: Reocclusion of the infant related artery (IRA) after successful thrombolytic therapy (TT) is associated with unfavorable outcome on both short- and long-term. This study describes the impact of collateral circulation on clinical presentation of patients with a reoccluded IRA.

Methods: Patients studied received TT for suspected acute myocardial infarction, had an angiographically confirmed open IRA < 48 hrs after TT, and underwent follow-up angiography at three months (APRICOT-trial). Cardiac events were scored between both angiographies.

Results: Reocclusion was observed in 29% of patients (71/248), with information on collateral development available in 66: 37 had collaterals of good quality compared to 29 who showed poor (n = 22) or no (n = 7) collateral circulation.

	Reocclusion (n = 66)		p-value
	Good Collaterals n = 37	Poor/no Collaterals n = 29	
Asymptomatic	15 (40%)	11 (38%)	0.83
Angina	18 (49%)	4 (14%)	<0.001
Angioplasty	1 (3%)	3 (10%)	<0.001
Reinfarction	3 (8%)	11 (38%)	<0.001

Conclusion: Reocclusion of the IRA was clinically silent in about 40% of patients, irrespective of the quality of collateral circulation. In case of symptomatic reocclusion patients with good collaterals more often presented with angina, whereas reinfarction was more frequent when collateral filling was inadequate.

P2760 One versus 4.5-year prognosis in patients with first acute myocardial infarction: the impact of thrombolysis

I. Shapira, A. Pines[1], E.Z. Fisman[2], U. Goldbourt[2], Y. Villa[3], Y. Drory[2]. *Cardiology Dept., Tel Aviv Sourasky Medical Center, Tel Aviv;* [1]*Medicine "T" Dept., Tel Aviv Sourasky Medical Center, Tel Aviv;* [2]*Cardiac Rehabilitation Institute, Sheba Medical Center, Tel Hashomer;* [3]*Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Purpose: To define possible predictors for early (30 days^{-1} year) and late (1–4.5 years) mortality in patients <65 years old with first acute myocardial infarction (FAMI). Design: Prospective longitudinal study. Setting: Eight major centrally located Israeli hospitals provided data during one year.

Methods: The cohort included 1214 patients, 83% men, 37% hypertensives, 23% diabetics and 14% with previous anginal syndrome.

Results: Multivariate analysis showed that Killip class and thrombolysis were the only significant predictors for 1 year survival (odd ratio [OR] = 2.89; 95% confidence interval [CI] = 0.94 to 4.03, p = 0.03 and OR = 2.4; CI = 1.08 to 5.64, p = 0.03, respectively). Thrombolysis no longer affected the 4.5 year survival, while Killip class (OR = 1.57; CI = 1.03 to 2.39, p = 0.03), female gender (OR = 2.28; CI = 1.30 to 3.99, p = 0.004), diabetes mellitus (OR = 1.87; CI = 1.08 to 2.32, p = 0.02) and peripheral vascular disease (OR = 2.49; CI = 1.03 to 6.02, p = 0.04) entered the multivariate model. Hypertension and past history of ischemic heart disease had a significance of 0.09 and 0.05, respectively.

Conclusions: Thrombolysis appears to be an independent predictor for early but not for late survival in young patients with FAMI. Female gender and diabetes mellitus are important predictors for late mortality in this population.

P2761 Geographic variation among hospitals participating in a world-wide thrombolytic trial: an Intime-II substudy

R.P. Giugliano, J. Llevadot, E.M. Antman, C.H. McCabe, A. Foxley[1], A. Skene[1], R. Wilcox[2], P. Chew[3], K-L. Neuhaus[4], E. Braunwald. *Cardiovascular Division, Brigham and Women's Hospital, Boston MA;* [3]*Bristol-Myers Squibb, Princeton NJ, USA;* [1]*Nottingham CTDC;* [2]*University Hospital, Nottingham, UK;* [4]*Stadtische Kliniken Kassel, Kassel, Germany*

Background: Large international megatrials in acute myocardial infarction (MI) typically involve a heterogeneous mix of hospitals and countries. The magnitude and importance of this heterogeneity has not been well studied.

Methods: We surveyed all 855 hospitals participating in InTIME-II (nPA vs tPA for AMI) regarding location, size, teaching status, and practice patterns. Hospitals were divided into 4 geographic categories: Western Europe (WE), Eastern Europe (EE), Latin America (LA), North America (NA).

Results: Hospital characteristics (100% response) varied widely by region (see table). 30-day outcomes (death, re-MI, stroke) by region and hospital characteristics will be available after unblinding in March 1999 and will be presented.

Hospital characteristics by geographic region

	WE	EE	LA	NA	chi-sq p
No. hospitals, n	503	91	54	207	–
City/Referral hospital, %	65	97	96	57	<0.0001
No. hospital beds < 300 beds, %	24	13	54	57	<0.0001
300–699 beds, %	50	35	33	37	
>700 beds, %	26	51	13	6	
No. ICU beds < 10 ICU beds, %	26	11	17	21	<0.0001
10–29 ICU beds, %	58	42	48	49	
>30 ICU beds, %	16	47	35	30	
Teaching hospital, %	61	87	78	51	<0.0001
Lytic decision by cardiologist, %	62	92	87	42	<0.0001
Cardiologist manages inpatient, %	67	91	94	82	<0.0001
On-site PTCA available, %	38	60	76	42	<0.0001
%AMI treated w/ primary PTCA	8	13	21	15	<0.0001
On-site CABG available, %	17	53	83	37	<0.0001

(Data represent column percentages)

Conclusions: Hospitals participating in this worldwide AMI megatrial from EE and LA tended to be large, city, teaching, cardiology-dominant, tertiary centers; while hospitals in WE and NA included many smaller, local, non-teaching, general hospitals. These differences may be important considerations when comparing clinical outcomes among geographic regions in international MI megatrials.

P2762 Prediction of early reperfusion after streptokinase in acute myocardial infarction by a new test for functionally neutralising streptokinase antibodies

S. Gill, S.R. Kristensen[1], B. Haastrup, T. Haghfelt. *Dept. of Cardiology, Odense University Hospital, Odense;* [1]*Dept. of Clinical Chemistry, Odense University Hospital, Odense C, Denmark*

Object: Approximately 25% of patients with acute myocardial infarction (AMI) do not obtain reperfusion after treatment with streptokinase (SK). We investigated, whether the occurrence of functionally neutralising SK antibodies as assessed by a new bedside test was related to the time to reperfusion.

Methods: Thirty-one patients with significant ST-elevation in the ECG, admitted to the CCU with a symptom delay of max. 6 hours, and treated with 1.5 MIU SK were included. Continuous vectorcardiography (VCG) was performed and the time to a 50% decrease in ST-VM from maximum was defined as reperfusion time. Citrated plasma was collected on admission and the level of functionally neutralizing SK antibodies was estimated by "TAS Streptokinase Test Panel", Nyco Med, measuring the lysis time of clotted fibrin in the sample (prolonged lysis time indicates presence of antibodies).

Results: Median age was 61.5 years. 74.2% were male. 20 (64.5%) had successful reperfusion within 90 minutes, assessed by VCG. The correlation between time to reperfusion and the estimated amount of functionally neutralizing SK antibodies was rS = 0.34 (Spearman's test, p = 0.07). The diagnostic performance (sensitivity, specificity, predictive value of positive (pV(+)) and negative (pV(−)) test) predicting unsuccessful reperfusion within 90 minutes from start of SK is listed in the table below.

	Sensitivity	Specificity	pV(+)	pV(−)	Diagn. accuracy
>120 sec.	90.9%	30.0%	41.7%	85.7%	51.6%
>150 sec.	81.8%	55.0%	50.0%	84.6%	64.5%

Conclusion: A weak correlation between time to reperfusion after SK and the amount of functionally neutralizing SK antibodies was found. However, we conclude that the TAS Streptokinase Test Panel cannot be recommended for clinical use for decision making prior to choice of thrombolytic agent, since the pV(+) for prediction of unsuccessful reperfusion after SK assessed by VCG is low.

P2763 Effect of thrombolysis on plaque morphology in patients with acute myocardial infarction

M. Gyongyosi, P. Yang, A. Hassan, D. Glogar. *Division of Cardiology, 2nd Department of Internal Medicine, University Medical School of Vienna, Austria*

Thrombolytic therapy has been confirmed to improve the survival rate in patients (pts) with acute myocardial infarction (AMI). The aim of this study was to examine the differences in plaque morphology (determined by intrvascular ultrasound /IVUS/) between pts with or without thrombolysis in AMI.

Method Clinical (age, gender, coronary risk factors), qualitative (soft/hard plaque, plaque eccentricity, presence of thrombus, rupture, calcification, adaptive/constrictive remodeling) and quantitative (minimal lumen, external elastic membrane /EEM/ and plaque cross-sectional area /CSA/ and plaque burden of the infarct-related lesion, proximal and distal reference segments) IVUS, and angiographic (minimal lumen diameter /MLD/, reference diameter /RD/ and %diameter stenosis /%DS/) data of 27 pts with thrombolysis (85% men, 57 ± 3 y, Group A) were analysed and compared with that of 23 pts without thrombolysis (70% men, 61 ± 6 y, Group B) 6 ± 3 days after AMI.

Results There were no differences in clinical data between the two groups. Intracoronary thrombi and soft plaque were found significantly more frequently in Group B, however, despite thrombolysis, 56% of pts in Group A also exhibited thrombi in IVUS (Table 1; $^*p < 0.05$).

Table 1

	Eccentric	Soft	Rupture	Thrombus	Calcification	Adaptives remodeling	Constrictives remodeling
Group A	59%	48%	37%	56%	37%	37%	22%
Group B	48%	**70%***	52%	**70%***	26%	22%	22%

Minimal lumen CSA of the target lesion, proximal and distal reference segments were significant greater after thrombolysis (Table 2; $^*p < 0.05$).

Table 2

	Infarct-related lesion				Proximal ref.	Distal ref.
	lumen CSA [mm²]	EEM CSA [mm²]	plaque CSA [mm²]	plaque burden [%]	lumen CSA [mm²]	lumen CSA [mm²]
Group A	**4.47 ± 2.71***	15.44 ± 3.57	9.87 ± 4.28	69.8 ± 15.8	**9.77 ± 3.78***	**7.81 ± 3.69***
Group B	3.84 ± 1.81	13.88 ± 4.43	10.03 ± 4.31	70.7 ± 13.2	8.91 ± 3.93	6.61 ± 2.7

Quantitative coronary angiography did not show any differences between the two groups (MLD 1.81 ± 0.66 vs 1.71 ± 0.58 mm, RD 2.86 ± 0.93 vs 2.81 ± 0.53 mm, %DS 67.5 ± 18.3 vs 57.0 ± 16.2% in Group A vs B).

Conclusions Despite thrombolysis, 56% of pts exhibited intracoronary thrombi after AMI. Quantitative IVUS, but not quantitative angiography exhibited a significantly better lumen dimensions after thrombolysis in AMI.

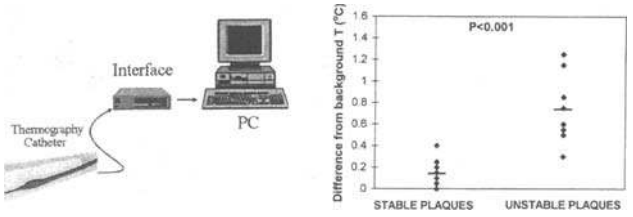
MECHANISMS OF PLAQUE INSTABILITY

P2764 Unstable plaques have increased temperature compared with stable plaques

C. Vlachopoulos, C. Stefanadis, L. Diamantopoulos, E. Tsiamis, I. Kallikazaros, C. Stratos, D. Markou, A. Michaelides, P. Toutouzas. *Hippokration Hospital, Athens Medical School, Athens, Greece*

We have shown in vivo that temperature (T) heterogeneity is increased in acute ischemic syndromes (*Ann Intern Med 1998; 129: 1079–80*). To compare the thermal status of unstable and stable plaques, we measured the T of the coronary arteries in 8 patients with unstable angina who were catheterized for coronary intervention on an emergency basis and were found to have except for the culprit lesion an additional lesion (with similar % stenosis) to another vessel. Seven RCAs, 6 LADs and 3 LCxs were studied. The culprit lesion was identified with ECG, angiographic and IVUS criteria. T was measured with a catheter-based technique that was designed and developed in our laboratory (left figure). The 3F thermography catheter incorporates a thermistor at its distal end (accuracy: 0.05 °C, time constant: 300 msec; spatial resolution 0.5 mm).

Results: Difference of plaque T from healthy wall T (background T) was larger in the unstable plaques (right figure).



Conclusions: Unstable plaques have increased temperature compared with stable plaques. This new insight into the pathophysiology of unstable ischemic syndromes may prove useful in predicting plaque rupture and thrombosis.

P2765 Infection burden in acute coronary syndrome: predominant role of Chlamydia pneumoniae

S. Blankenberg, H.-J. Rupprecht[1], C. Bickel[1], J. Lotz[2], W. Schlumberger[3], K. Steinhagen[3], G. Rippin[4], J. Meyer[1]. *II. Medical Clinic, [1]II. Medical Clinic, [2]Clinic for Clinical Chemistry, [3]Euroimmun, Gross-Grönau[4] Institute for Medical Statistics, University Clinic, Mainz, Germany*

Introduction: There is growing evidence that previous and recurrent infection play a role in the development of acute coronary syndrom. We evaluated the prevalence of anti Chlamydia pneumoniae IgG (Cp_IgG, previous infection), anti Chlamydia pneumoniae IgA (Cp_IgA, recurrent activity) and anti Respiratory Syncytial Virus IgG (RSV_IgG) as respiratory tract infection markers as well as anti Cytomegalovirus IgG (CMV_IgG) and anti Cytomegalovirus IgA (CMV_IgA) in stable (SAP), unstable anigna (UAP), acute myocardial infarction (AMI), and a control group (CG).

Methods: In 950 patients (pts) with angiographically documented coronary artery disease (CAD) – at least one stenosis > 50% – and in a CG antibody levels of Cp_IgG [Ratio; cut off: 1.5], Cp_IgA [Ratio; cut off: 1.5], CMV_IgG [Relative Units (RU); cut off: 20], CMV_IgA [Ratio; cut off: 1] and RSV_IgG [RU; cut off: 100] were determined on admission to hospital. Pts were divided by clinical event into the groups: SAP, UAP (classified by Braunwald classification) and AMI.

Results: 566/950 (59.6%) of the pts had SAP, 207/950 (21.8%) UAP, 177/950 (18.6%) AMI. The power of the CG was n = 158.

Infection and acute coronary syndrome

Mean	CG	SAP	UAP	AMI	p
Cp_IgA [Ratio]	1.68	1.96	1.92	2.05	0.026
Cp_IgG [Ratio]	1.54	1.72	1.73	1.58	0.054
CMv_IgA [ratio]	0.49	0.5	0.52	0.55	n.s.
CMv_IgG [RU]	107.4	119.6	121.2	121.9	n.s.
RSv_IgG [RU]	92.1	93.2	88.1	84.8	n.s.

data presented are mean Ratio/Relative Units of antibody titers

Conclusion: CAD and acute coronary syndrom is not associated with a burden of several here tested infectious agents. Only recurrent infection of Cp demonstrated by elevated antibody levels of Cp_IgA is related to the prevalence of CAD, especially acute coronary syndrom. This strengthens the hypothesis of a pathognomonic role of infection with Cp in the development of CAD.

P2766 Helicobacter pylori infection influence the extent of coronary artery disease: results of a cross-sectional study

S. Blankenberg, H.-J. Rupprecht[1], C. Bickel[1], W. Schlumberger[2], G. Rippin[3], J. Meyer[1]. *II. Medical Clinic, University Clinic, Mainz; [1]II. Medical Clinic, University Clinic, Mainz; [2]Euroimmun, Gross-Grönau[3] Institute for Medical Statistics, University Clinic, Mainz, Germany*

Background: The causative role of Helicobacter pylori (Hp) infection in pathogenesis of coronary artery disease (CAD) is discussed controversially. No association was found between previous Hp infection and prevalence of myocardial infarction whereas elevated hp antibody titers could be demonstrated in patients (pts) with angiographically proven CAD. We aimed to examine the influence of severity of Hp infection on the extent of coronary atherosclerosis.

Methods: In 1035 patients (pts) with suspected CAD we performed angiography. Antibody titers of Hp_IgG were measured by ELISA technique. Severity of infection was determined by anti Hp_IgG Relative Units [RU]. We developed a coronary atherosclerosis score by determing for each angiogram the number of affected vessel area (stenosis > 50% in a vessel area) (vessel score), the number of stenosis > 50% (0 = 0; 1 = 1; 2–4 = 2; >4 = 3) (stenosis score) and the number of atherosclerotic altered segments (0 = 0; 1 = 1; 2–7 = 2; 8–15 = 3) (segment score).

Results: 244/1035 (23.5%) of the pts had one vessel disease, 249 (24.1%) two vessel disease, 397 (38.4%) three vessel disease, and 145 (14%) no CAD.

Hp infection and extent of CAD

Mean anti Hp_IgG	0	1	2	3	p
Vessel score	86.5	99.4	112.4	111.7	0.01
Stenosis score	88	99.6	114.2	109.6	0.003
Segment score	85.6	93.6	111.9	108.6	0.007

Data shown are mean values of anti Hp_IgG [Relative Units] depending on the different atherosclerosis scores

Conclusion: In pts with angiographically documented CAD there is a significantly higher prevalence of Hp-infection. Furthermore we could demonstrate that the extent of angiographically documented atherosclerotic lesions defined by three different scores is significantly associated with the severity of previous Hp-infection.

P2767 Inflammation and coronary restenosis postangioplasty, hunting for genetic links

M. Irurita, R.Y.L. Zee, A. Fernandez-Ortiz[1], C. Macaya[1], E. Pintor[1], A. Fernandez Cruz[1], K. Lindpaintner, M. Irurita[2]. *Brigham And Women's Hospital, Harvard Medical School, Boston MA, USA; [1]Hospital Universitario San Carlos, Madrid; [2]Las Palmas, Spain*

Restenosis is the major complication of percutaneous transluminal coronary angioplasty (PTCA), occurring in about 20–50% of all initially successful procedures. The involvement of inflammatory-mediator cascades in the pathophysiology of restenosis post-PTCA is receiving increasing attention. The genes for E-selectin (E-sel), tumor necrosis factor-alpha (TNF-α) and -beta (TNF-β) have been recently implicated. We had the opportunity to investigate this question in a large, prospective cohort characterized by two quantitative coronary angiographic studies in all subjects.

Methods and Results: Common allelic polymorphisms for these genes were characterized in a cohort of 779 patients of whom 342 patients ("cases") had developed restenosis (as defined by >50% loss of lumen compared to immediate post-procedure results) a follow-up angiography at 6 months post-PTCA. Allele frequencies for the E-sel E1 and E2 alleles (allele E1/E2, absence/presence of PstI restriction site) were 0.11 and 0.89 in cases, and 0.09 and 0.91 in controls. Allele frequencies for TNF-α N1 and N2 alleles (allele N1/N2, absence/presence of NcoI restriction site) were 0.15 and 0.85 in cases, and 0.14 and 0.86 in controls. Allele frequencies for TNF-β N3 and N4 alleles (allele N3/N4, absence/presence of NcoI restriction site) were 0.70 and 0.30 in cases, and 0.74 and 0.26 in controls, respectively. All observed genotype frequencies were in Hardy-Weinberg equilibrium. There was no evidence for an association between genotype and restenosis or degree of lumen loss (adjusted for covariates).

In conclusions: Our data, collected in the largest study of its kind so far, indicate that the common polymorphisms tested of E-selectin, tumor necrosis factors-alpha, and -beta are not associated with incidence of restenosis following PTCA and are therefore not useful markers for risk assessment.

P2768 Alterations in leukocyte adhesion molecule expression and function in the acute coronary syndromes

Graham S. Hillis, Antoinette Mangione, Ierachmiel Daskal, William C. Dalsey. *Albert Einstein Medical Center, Philadelphia PA, USA*

The adhesion of leukocytes to vascular endothelium is an important factor in the pathophysiology of the acute coronary syndromes (ACS). One of the principal mediators of this process is the $\alpha_M\beta 2$ leukocyte integrin, composed of CD11b and CD18 chains. The aim of the current study was to identify whether CD18/CD11b expression by neutrophils (PMN) and monocytes (Mø), and PMN CD18 *function*, is altered in patients with an ACS.

Methods: Subjects included 22 patients with an ACS, 12 patients with angiographically proven coronary artery disease (CAD) but stable symptoms and 12 healthy controls (HCs). All patients were, taking maintenance aspirin and all controls took 325 mg daily for >72 h prior to blood sampling. Cell surface CD18 and CD11b expression on PMNs and Mø was determined by flow cytometry. PMN CD18 function was measured by passing whole blood through scrubbed nylon columns and calculating percentage adhesion. In this assay 98% of adhesion is mediated by CD18. Adhesion results are expressed as percentage (±SEM). Groups were compared using the Mann-Whitney U test.

Results: There were no significant differences in PMN CD11b or CD18 expression between the three groups. PMN adhesion is, however, lower in patients with an ACS (9.5 ± 2.1) compared to HCs and patients with stable CAD (9.5 ± 2.7 and 15.3 ± 2.1 respectively, $p < 0.05$). Mø from patients with an ACS express higher levels of CD11b and CD18 than those from either HCs or patients with stable CAD ($p < 0.05$ for both chains and groups).

Conclusion: The expression of CD18/CD11b on peripheral PMNs is unaltered in stable CAD or the ACS (though other work suggests that extensive myocardial necrosis results in activation). PMN adhesion is reduced in the ACS, in keeping with reported changes in sepsis. In contrast, CD18/CD11b expression on Mø is increased. The explanation for these complex changes remains to be fully elucidated but may shed light on the pathophysiology of the ACS.

P2769 Overexpression of tissue factor in unstable angina and myocardial infarction

P. Sibilia[2], M. Ballet-Méchain[1], P. Chapon[1], G. Trémeau[1], H. Milon[1], G. Cozon[2]. *[1]Department of cardiology, Croix-Rousse Hospital, Claude Bernard University Lyon I; [2]Immunology laboratory, Croix-Rousse Hospital, Claude Bernard University Lyon I, France*

Many studies suggest a role for inflammation and thrombosis in the physiopathology of coronary disease. Increased expression of activation markers (Mac-1, tissue factor (TF)) have been detected on leukocyte membrane during inflammatory response. TF, initiator of clotting cascade, plays a central role in the evolution of a stable coronary disease to an acute ischaemic syndrome. The aim of this study was to detect TF on circulating leucocytes and soluble TF in plasma from patients with coronary disease according to their clinical status.

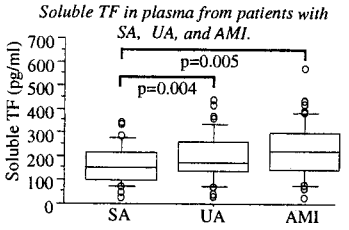
Methods: 147 consecutive patients addressed for coronary angiography were included and classified, according to Braunwald criteria, in stable angina (SA, n = 40), unstable angina (UA, n = 51), and acute myocardial infarction (AMI, n = 56). Circulating blood leucocytes were stained for TF molecules with fluoresceine-conjugated monoclonal antibodies, and were analysed in flow cytometry. Soluble TF was measured in plasma using Elisa assay.

Results: only results concerning monocytes were significant.

Number of patients with high and normal monocyte TF expression according to clinical status.

	SA		UA		AMI	
	n	%	n	%	n	%
High	2	5	12	24*	12	21**
Normal	38	95	39	76	44	79
Total	40	100	51	100	56	100

*$p = 0.018$ SA vs UA; **$p = 0.037$ SA vs AMI; High is ≥ mean + 2 SD in SA group



Soluble TF in plasma from patients with SA, UA, and AMI.

Conclusion: Increase of TF in plasma and on monocyte surface in patients with UA or AMI suggests a role of circulating monocytes in acute ischaemic syndromes. However, absence of correlation between monocyte membrane and plasma TF (data not shown) indicates the possible role of other cells (as endothelial cells) for TF production.

P2770 Chlamydia pneumoniae antibodies and their relationship with restenosis in coronary heart disease patients

H. Oflaz, E. Yılmaz, Y. Nişancı, P. Çekmeceli, A. Ağaçfidan, F. Mercanoğlu, G. Yılmaz, S. Umman, M. Meriç, K. Büyüköztürk. *Department of Cardiology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey*

The aim of this study was to investigate the presence and clinical importance of Chlamydia Pneumoniae (CP) antibodies in coronary heart disease (CHD) patients who had undergone percutaneous transluminal coronary angioplasty (PTCA) and coronary stenting (CS). The study population consisted of 32 CHD patients (7 women, 25 men, 55.7 ± 10.1 years) who had PTCA (13 pts, 40.6%) and CS (19 pts, 59.4%) and 25 healthy subjects (5 women, 20 men, 51.6 ± 8.3 years) as the control group. Sera just obtained before PTCA and CS and 3 and 6 months later were stored at −20°C until being tested. Spesific IgG and IgM antibodies against CP were detected by microimmunofluorescence method. Sera with a dilution of 1/128 with which the elementer bodies of CP gave fluorescence were accepted CP IgG positive. CP IgM antibodies were negative in all of the three sera of all the patients. CP IgG antibodies were detected in 3 of 25 (12%) healthy subjects and 17 of 32 (53%) CHD patients ($p = 0.013$). Control coronary angiographic investigation applied six month later revealed restenosis in 16 of the 32 patients (50%). Restenosis was detected in 12 of the 17 patients who had CP IgG antibodies (70.6%) were as in 4 of the 15 patients (26.6%) who were negative CP IgG antibodies ($p = 0.013$). In our study it was found out that CP IgG antibody positivity was higher in CHD patients than the healthy control group. This supports recent findings describing the CP infection in the pathogenesis of atherosclerosis. Prospective and cohort studies are needed to explain the role of CP IgG antibodies in the pathogenesis of coronary atherosclerosis and restenosis.

P2771 An inflammatory, but not an anti-inflammatory, cytokine profile is present in patients with unstable angina and correlates with prognosis

X. Bosch, F. Miranda, X. Filella[1], S. Díez-Aja, J.L. Marín[1], G. Sanz. *Cardiovascular Institute; [1]Biochemistry Laboratory, Hospital Clinic, Barcelona, Spain*

Background: Inflammation plays a major role in the pathophysiology of acute coronary syndromes. In unstable angina (UA), IL-6 plasma levels are known to be elevated, and the degree of elevation seems to correlate with prognosis. Recently, an anti-inflammatory cytokine profile (high IL-10 to tumor necrosis factor-alfa (TNF-α) ratio) has been observed to be associated with prognosis in infectious disease, and also in patients (pts) with UA.

Objectives and methods: To assess if an anti-inflammatory cytokine profile is present in pts with UA, we prospectively studied 104 consecutive pts with Braunwald Class IIIB UA. Blood samples were drawn at admission and before therapy was initiated. Mean age of pts was of 65 years, and 29% were female.

Results: Sixty-five per cent of pts had plasma IL-10 levels below the detection level of ≥5 pg/mL. During a 3 month follow-up 18 pts died, had a myocardial infarction or were readmitted for a new episode of unstable angina. Compared with pts with good clinical evolution, pts with cardiac events had similar levels of TNF-α (30 ± 30 vs 29 ± 29, p = NS), and lower levels of IL-10 (3.4 ± 6 vs 19 ± 40, $p < 0.001$). Also, the frequency of pts with IL-10 levels ≥ 5 pg/mL was less in the group with cardiac events (16.7% vs 36.4%, p = 0.07). Furthermore, TNF-α to IL-10 ratio was of 6.4 ± 6.3 vs 2.5 ± 4.5, $p < 0.05$, and the IL-1β to IL-10 ratio was of 6.3 ± 9 vs 1.8 ± 4, $p < 0.05$, in pts with and without events.

Conclusion: An anti-inflammatory cytokine profile has not been observed in pts with UA. On the contrary, low levels of IL-10 and high TNF-α and IL-1β to IL-10 ratios seem to be associated with a poor prognosis in pts with UA.

P2772 Different inflammatory response after stent implantation in unstable versus stable angina

D. Spaziani, B. Morelli, M. D'Urbano, F. Passoni, C. Grassi, L. Lazzati, F. Cafiero, S. De Servi. *Unita' Operativa di Cardiologia ed Ematologia, Ospedale Civile di Legnano, Legnano, Italy*

Plasma levels of cytokines and inflammatory mediators are frequently increased in acute ischemic syndromes, yet their time course after successful PTCA is unknown. The purpose of this study was to compare changes of interleukin (IL)-6, an index of inflammation, and von Willebrand factor (vWF), an index of endothelial activation, after successful PTCA with stent implantation in pts with unstable and stable angina.

Methods: Thirty-one pts (23 men, 8 women, mean age 69 years, range 49–88) had unstable angina, defined as angina at rest, Braunwald Class IIB–IIIB or IIC–IIIC (UA group); 21 pts (19 men, 2 women, mean age 58 years, range 50–76) had stable angina, defined as exercise-induced chest pain with positive exercise stress test (SA group). All pts underwent successful PTCA of 1 vessel, followed by stent implantation. Plasma levels of interleukin-6 (IL-6) and vWF antigen were measured by ELISA prior to PTCA, 24 hours after PTCA and 30 days (d) thereafter.

Results:

(mean + SD):

	pre-PTCA		24 h post-PTCA		30-d post-PTCA	
	UA	SA	UA	SA	UA	SA
IL-6 (pg/ml)	7.1 ± 7.4*	2.9 ± 3.6	7.5 ± 6.5	5.0 ± 6.6	2.9 ± 3.1§	3.2 ± 3.5°
vWF (%)	120 ± 38	104 ± 40	127 ± 28	107 ± 23	107 ± 20§	108 ± 15

*p = 0.02 pre-PTCA UA vs pre PTCA SA; §p < 0.005 30-d UA vs pre-PTCA UA; °p = 0.005 30-d SA vs pre-PTCA SA.

In conclusion, although plasma baseline levels of IL-6 are higher in UA pts than in SA pts, they equalize 30 days after a successful PTCA followed by stent implantation. A similar trend is observed for vWF changes. IL-6 levels increase early after PTCA in SA pts, but not in UA pts: it is likely that in the latter group, the inflammatory reaction induced by the procedure is counterbalanced by the remotion of the cause of the raised baseline levels (unstable plaque).

INFLAMMATION IN ACUTE CORONARY SYNDROMES

P2773 Soluble intercellular adhesion molecule-1 levels are of diagnostic, but not prognostic, value in patients with chest pain

Graham S. Hillis[1], Carol Terregino[2], Pam Taggart[1], Anthony Killian[2], Ning Zhao[1], William C. Dalsey[1], Antoinette Mangione[1]. *[1]Albert Einstein Medical Center, Philadelphia PA; [2]Cooper Hospital/University Medical Center, Camden NJ, USA*

C-reactive protein (CRP) is a non-specific marker of inflammation, which is often raised in patients with unstable angina and appears to be associated with an adverse outcome. Soluble intercellular adhesion molecule-1 (sICAM-1) is, however, a sensitive and specific marker, released from activated endothelium. We hypothesised that plasma sICAM-1 levels would be of diagnostic and prognostic value in patients presenting to the emergency department (ED) with chest pain.

Methods: A convenience sample of 123 patients were studied prospectively. Eligible patients had >15 min of chest pain within the prior 24 h, thought clincally to represent myocardial ischaemia and requiring hospital admission. Subjects with a history of conditions which affect sICAM-1 levels were ineligible and 4 patients who had such conditions diagnosed during admission were excluded. All eligible patients who gave consent were included in data analysis (n = 119). Cardiac troponin I, creatine kinase-MB_{mass}, CRP and sICAM-1 were assayed on arrival to the ED. On the basis of previous data, positive levels were prospectively defined as >2 ng/ml, >5 ng/ml, >1 mg/dl and >260 ng/ml respectively. Study end-points were a discharge diagnosis of an acute coronary syndrome (ACS) and/or an adverse event (AE) in hospital (death, acute myocardial infarction or coronary revascularisation), determined by investigators blinded to study blood results. The relationship between these end-points and a diagnosis of an ACS and/or suffering an AE was assessed by logistic regression.

Results: Fifty-two (of 119; 44%) patients had an ACS and 30 (25%) experienced an AE. When all markers were entered into the regression equation the only independent predictors of a patient having an ACS were cTnI and sICAM ($p < 0.01$ and 0.05 respectively). Only cTnI, however, was an independent predictor of a patient experiencing an AE in hospital ($p < 0.001$).

Conclusion: Elevated sICAM levels assist in the early detection of patients with cardiac chest pain but are not independent predictors of AEs in hospital.

P2774 Development of auto-antibodies in acute coronary syndromes: prognostic implications of cardiac injury and humoral immunity

G. Dangas, M.A. Peterson, J.M. Ahmed, M.M. Konstadoulakis, A.M. Cohen, J.N. Nanas, A. Sadaniantz, C.I. Stefanadis, J.H. Chesebro, P.K. Toutouzas. *Cardiology Research Foundation, Washington DC; Mount Sinai School of Medicine, New York NY; Massachusetts General Hospital, Boston MA; Brown University, Providence RI, USA; National University of Athens, Greece*

Background. During myocardial injury, intracellular proteins are released into the circulation and may trigger the development of auto-antibodies (AAb) as has been described after surgery. The clinical significance of these AAb is unknown. We hypothesized that ischemic injury may be in part related to AAb, which may have prognositc implications.

Methods. We investigated the presence of IgG AAb against actin, myosin, and troponin after an acute ischemic clinical event, and their correlation with CPK and Troponin-I (TnI) in 33 consecutive patients hospitalized for acute coronary syndromes (ACS) without a history of myocardial infarction, and 25 in controls who had no evidence of coronary disease. Measurements were done in-hospital, at 1 and 3 months, and patients were followed clinically for 2 years. The non-parametric Wilcoxon z-test was used for comparisons.

Results. In-hospital, the group with ACS was 39% antiactin+, 44% antimyosin+, and 27% troponin+. In contrast, the respective AAb+ of the controls were 13%, 18%, 9% ($p < 0.04$, ACS vs. control). At 1 month, 50% were actin+, 44% myosin+, and 33% troponin+, and no further change was observed at 3-month follow-up. At 1 and 3 month follow-up, persistence of either antiactin or antimyosin AAb correlated with elevated in-hospital TnI ($z < 0.03$) and CPK ($z < 0.01$). Conversely, elevated TnI at 1 or 3 months correlated with positive AAb in-hospital: antimyosin ($z = 0.03$), antitroponin ($z = 0.02$) and antiactin ($z = 0.08$). AAb+ at 1 or 3 months correlated with reinfarction at 2 year follow-up (100% vs. 25% for AAb−, p = 0.01).

Conclusions. (1) Ischemic myocardial injury is associated with presence of AAb. (2) Patients with elevated TnI and CPK develop AAb at follow-up. (3) Persistence of AAb correlates with elevated TnI at 3 month follow-up, which may signify sub-clinical cardiac injury, and with reinfarction at 2 year follow-up.

P2775 Acute phase proteins in the prognostic classification of unstable angina pectoris

H. Koukkunen, K. Penttilä[1], I. Penttilä[1], K. Pyörälä. *Department of Medicine, Kuopio University Hospital, Kuopio; [1]Department of Clinical Chemistry, Kuopio University Hospital, Kuopio, Finland*

Inflammatory process has been found to play an important role in the pathogenesis of coronary heart disease (CHD) and in the prognosis of CHD patients. We examined the prognostic value of acute phase proteins C-reactive protein (CRP), interleukin-6 (IL-6), tumor necrosis factor alpha (TNF-alpha) and fibrinogen in patients with unstable angina pectoris (UAP).

Methods: This study is based on a series of 263 patients with the diagnosis of UAP admitted to the Kuopio University Hospital (159 men and 104 women, median age 68 years). Blood samples for the measurement of CRP, IL-6, TNF-alpha and fibrinogen were drawn at admission. Maximum troponin T (TnT) levels were used in data analyses. Median follow-up time with regard to CHD mortality was 17 months.

Results: Age-standardized incidence rates for CHD death in tertiles 1–2 and tertile 3 for CRP were 2.2% and 13.0%, for IL-6 2.3% and 13.7%, for TNF-alpha 3.2% and 11.2%, and for fibrinogen 3.1% and 10.7%, respectively. Cox hazard ratios and 95% CIs (tertile 3 vs tertiles 1–2), adjusted for age, were: 2.51 (1.41–4.45) for CRP, 2.38 (1.31–4.34) for IL-6, 1.88 (1.09–3.24) for TNF-alpha, and 1.99 (1.16–3.41) for fibrinogen. Hazard ratios remained essentially unchanged after further adjustment for the duration of chest pain during hospitalisation and TnT levels.

In conclusion, elevated levels of acute phase proteins, in particular CRP and IL-6, are strong predictors of CHD death in patients with UAP, independently of the duration of chest pain and TnT levels in the acute phase.

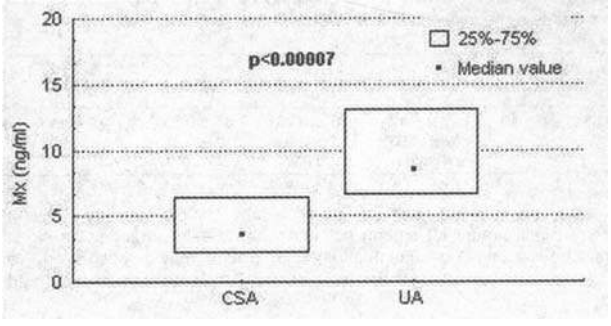
P2776 Evidence of antiviral and/or antiself activity of the immune system in severe unstable angina

F. Clementi, D. Milazzo, L.M. Biasucci, M. Narducci, R. Manta, A. Maseri. *Institute of Cardiology UCSC Rome, Rome, Italy*

Background: A growing body of evidence suggests an involvement of systemic activation of inflammatory response in the pathogenesis of acute coronary syndromes. However the mechanism which leads to the activation of this inflammatory response is still unclear. We therefore studied the activation of the Interferon-1 (IFN-1) system (which consists of IFN alfa and IFN beta), typically involved in viral and autoimmune diseases, as a possible mechanism.

Materials and methods: As a marker of IFN-1 pathway activation we measured Mx-protein serum levels, obtained through peripheral venous sample, in 22 patients (pts) with Unstable Angina (UA) admitted to our Coronary Care Unit, in 29 pts with Chronic Stable Angina (CSA). Mx is an intracellular protein principally produced by leukocytes, directly and exclusively induced by IFN-1 system. We used the Magic Lite Mx Immunoassay, developed by Chiron Diagnostic. Inclusion criteria for UA was angina (Braunwald class IIIb), no more than five days before blood samples collection. Exclusion criteria were recent viral infection (fever or influenza-like symptoms within 30 days), autoimmune diseases or neoplasia.

Results (median and quartiles): Mx-protein serum levels were significantly higher in UA pts vs. CSA pts, being respectively 14.4 (5.6–13.7) ng/ml, 4.4 (2.04–6.4) ng/ml ($p < 0.00007$).



Mx blood concentration; CSA vs. UA

Conclusion: Our data show a significant activation of INF-1 pathway in UA pts vs CSA pts. However this activation is much smaller then that elicited by a systemic viral infection or by a systemic autoimmune disorder (in which MX protein reaches level of ≥100 ng/ml). Our finding suggest that a mild or localized activation of the immune system versus viral or self antigens might be a component of the inflammatory activity commonly detectable in UA.

P2777 Neopterin, C-reactive protein, cardiac troponin I and coronary events in patients with unstable angina

X. Garcia-Moll, F. Coccolo, F. Boa, J. Nisbet, J.C. Kaski. *Cardiological Sciences Dept, St George's Hospital Medical School, London, UK*

Background: Prognosis in patients with unstable angina (UA) is worse in the presence of raised cardiac troponin I (cTnI) and C-reactive protein (CRP) concentrations. Complex coronary stenoses (CCS) are a marker of risk in patients with rapidly stabilized UA. This study investigated whether cTnI is related to CCS and inflammation markers in patients with rapidly stabilized UA.

Methods: We studied 88 consecutive UA patients (57 men) who stabilized within 24 hours of admission, and with normal CK levels during the first 48 hours of coronary care admission. In 55 patients who underwent coronary angiography all coronary stenoses ≥30% were assessed and classified as 'complex' or 'smooth'. Serum cTnI, CRP and neopterin concentrations were measured within 24 hours of admission.

Results: Patients with high cTnI serum concentration (≥0.4 μg/L) were significantly older ($p = 0.002$), had a higher prevalence of diabetes mellitus ($p = 0.019$) and hyperlipidaemia ($p = 0.034$), and had higher CRP ($p = 0.020$) and neopterin levels ($p = 0.032$). Angiographic disease severity was similar in patients with normal cTnI compared to those with high cTnI, but patients with high cTnI had a significantly larger number of CCS ($p < 0.0001$). We observed a correlation between cTnI and neopterin ($p = 0.014$) and also with CRP ($p = 0.096$). cTnI ($p = 0.002$) and neopterin ($p = 0.45$) but not CRP ($p = 0.98$) were independently associated to the number of CCS in a multiple regression analysis.

Conclusions: cTnI is associated with the number of CCS and inflammation markers in patients with rapidly stabilized UA, which may explain the long term prognostic value of cTnI in these patients.

P2778 Is there a difference in the role of inflammation between patients with recent onset angina and patients with progressive angina?

Ernesto R. Ferreirós, Carlos P. Boissonnet, Rodolfo Pizarro, Mariano Falconi, Arturo Cagide, Oscar Bazzino. *Department of Cardiology, Hospital Italiano de Buenos Aires, Argentina*

The pathophysiological mechanisms in the different types of clinical presentations of unstable angina are controversial. Our objective was to explore the role of the markers of inflammatory activity in patients with recent onset angina (ROA) and with progressive angina (PA).

Methods: 210 consecutive patients with unstable angina and no prior myocardial infarction nor total CK elevation post admission were included. Measurements of C-reactive protein (CRP) level at admission, at 48 hours and at discharge were performed, as well as a continuous Holter ECG recording during the initial 24 hours. In 101 (48.1%) patients, the episode of unstable angina was the first manifestation of coronary heart disease (ROA). The remaining 109 patients (51.9%) had prior history of chronic stable angina (PA).

Results: Mean age was 66.1 ± 11.1 years, 62.9% were male; 63.3% received prior treatment with aspirin, and 43.8% had ST segment depression on admission ECG. Overall levels of C-reactive protein* at admission, 48 hours and at discharge were 0.5 (0.3–1.0), 0.7 (0.3–1.6) and 0.8 (0.3–2.4) mg/dl and those of fibrinogen† were 333.9 ± 89.6, 353.5 ± 94.4 and 372.4 ± 109.7 mg/dl respectively. Univariate analysis of baseline characteristics showed:

	ROA	PA	p
CRP at admission* (mg/dl)	0.6 (0.3–1.1)	0.3 (0.15–0.8)	<0.05
CRP 48 hours* (mg/dl)	0.7 (0.3–2.2)	0.8 (0.3–1.5)	ns
CRP at discharge* (mg/dl)	0.8 (0.4–3.1)	0.8 (0.3–2.0)	ns
Fibrinogen at admission† (mg/dl)	324.9 ± 89.4	342.2 ± 89.5	ns
Prior treatment with aspirin	37 (36.6%)	96 (88.0%)	<0.001
Age (years)†	65.3 ± 12.3	66.8 ± 10.2	ns
Silent Ischemia	20 (19.8%)	34 (31.2%)	0.08 (ns)
Heart Failure	7 (6.9%)	16 (14.7%)	0.11 (ns)

(*median and 25–75% interquartile ranges, †mean ± SD).

When logistic regression analysis was performed adjusted to aspirin intake before admission, the difference in CRP levels at admission between patients with ROA and PA was no longer observed.

Conclusion: These results suggest that the role of inflammation is similar in the different subgroups of patients with unstable angina. Previous treatment with aspirin seems to delay the crescendo pattern of evolution of the acute phase reactants during the clinical period of instability.

P2779 Interleukin-6 response during acute myocardial infarction: overall reduction of postinfarct inflammation by early reperfusion?

W.K. Lagrand[1], F. Nijland[1], C.E. Hack[1,2], O. Kamp[1], C.A. Visser[1]. [1]Free University Hospital; [2]CLB, Sanquin Blood Supply Foundation, Amsterdam, Netherlands

Background: Animal studies convincingly have demonstrated that reperfusion of ischemic myocardium induces local inflammatory reactions in infarcted myocardial tissue. To what extent this occurs in humans is not fully clear.

Methods: We investigated the course of Interleukin-6 (IL-6) in relation to early successful reperfusion after acute myocardial infarction (AMI) in 44 patients with a first AMI. The course was examined by assessing peak levels of IL -6 during AMI, as well as its total release, as was calculated from time-integral analysis adjusted for elimination. This method was chosen as it was shown in individual patients that peak levels of IL-6 rather poorly reflected the total amount of IL-6 produced. Twenty-nine patients fullfilled clinical and biochemical criteria of early reperfusion (+).

Results:

	n	Total	Peak IL-6		
			≤12 hours	>12 hours	P
Peak IL-6 (ln, ng L^{-1})					
Reperfusion (+)	29	$1.9 \pm 1.0^{*}$	$1.6 \pm 1.1^{\#}$	$2.3 \pm 0.7^{\dagger}$	0.05
Reperfusion (−)	15	$2.7 \pm 0.8^{*}$	$2.8 \pm 0.7^{\#}$	$2.6 \pm 0.8^{\dagger}$	NS
IL-6 release (ln, ng L^{-1}·hrs)					
Reperfusion (+)	29	$8.3 \pm 1.3^{**}$	$7.9 \pm 1.5^{\#\#}$	$8.7 \pm 0.8^{\dagger\dagger}$	0.05
Reperfusion (−)	15	$9.2 \pm 0.9^{**}$	$9.2 \pm 0.5^{\#\#}$	$9.3 \pm 1.1^{\dagger\dagger}$	NS

$^{*}P = 0.02$, $^{\#}P = 0.02$, $^{\dagger}P$ = NS, $^{**}P$ = NS, $^{\#\#}P = 0.04$, $^{\dagger}P$ = NS

Peak IL-6 levels occurred significantly earlier after onset of chestpain in patients with reperfusion than in those without (17.5 ± 10.5 (n = 29), versus 26.8 ± 15.0 hours (n = 14), respectively, P = 0.04). IL-6 release, and to less extent peak levels, were best (positively) correlated with infarct size in patients without reperfusion.

Conclusions: Both peak and release levels of IL-6 after AMI are significantly lower in patients with early successful reperfusion. We conclude that the extent of the overall inflammatory reactions after AMI are limited by early successful reperfusion.

VIABILITY AND VENTRICULAR FUNCTION AFTER ACUTE CORONARY SYNDROMES

P2780 Electromechanical 3D endocardial mapping: follow-up study after successful myocardial revascularization

K.-C. Koch, C. Stellbrink, A. Sasse, J. vom Dahl. *Department of Cardiology, University Hospital Aachen, Aachen, Germany*

Nonfluoroscopic three-dimensional endocardial mapping using the NOGA™ system has been suggested as a new method for electromechanical assessment of the left ventricle. We performed NOGA mapping before and after successful myocardial revascularization in patients with prior myocardial infarction.

Methods: Nine patients (pts, 7 male, 59 ± 9 years) with prior (>2 weeks) myocardial infarction and corresponding wall motion abnormalities undergoing single- or multi-vessel PTCA were studied before and 6 month after revascularization. All patients underwent metabolic imaging with F-18 FDG PET prior to PTCA. For electromechanical assessment the left ventricle was divided into 12 regions and the regional unipolar electrogram amplitude (UA) and regional linear shortening (LS) were measured and calculated by the NOGA system.

Results: All patients had a sufficient PTCA result at 6-month follow-up. As assessed by PET, 29 of 108 ventricular regions were hypoperfused but displayed preserved metabolism (mismatch). In mismatch regions LS increased from 5.6 ± 3.4% to 10.4 ± 4.5%, in the remaining regions from 7.1 ± 4.7% to 10.3 ± 3.5%. The UA in mismatch regions was 9.9 ± 4.1 mV prior to PTCA and 10.5 ± 3.5 mV at follow up (correlation r = 0.23). In the remaining 79 regions the UA was 10.6 ± 4.8 mV at baseline and 10.7 ± 3.6 mV at follow up (r = 0.71, $p < 0.001$). The UA increased in regions with a difference in LS (ΔLS) between baseline and follow up >2% (9.8 ± 4.8 mV to 10.8 ± 3.9 mV) whereas it decreased in regions with a ΔLS < 2% (11.7 ± 3.6 mV to 10.4 ± 2.6 mV).

Conclusion: Serial endocardial electromechanical mapping can detect improvement in regional left ventricular function after successful myocardial revascularization. Hypoperfused but viable regions benefit more from revascularization. Improvement of regional mechanical function is associated with an increase of the unipolar electrogram amplitude in these regions.

P2781 Myocardial infarct size and the risk of left ventricular remodelling: clinico-orphopathological study

E. Vataman. *Chisinau, Moldavia*

Background: Multiple studies suggest that the QRS scoring system (QRSs)using observation of Q-and R-wave duration, R/Q and R/S amplitude ratios in the standard 12-lead electrocardiogram (ECG) and precordial ECG mapping is useful in estimating left ventricular (LV) function after myocardial infarction (MI).

Methods: The correlation of QRSs with quantitative autopsy was examined in 1269 cases of intrahospitally deceased patients (pts) with acute MI (age 67.9 ± 0.55 yrs). The 1st group included 1108 (87.3%) pts without anatomic signs of left ventricle aneurysm (LVA). The 2nd group included 161 (12.7%) pts with LVA (gr. 2a – 56 pts with acute LVA, gr. 2b – 105 pts with chronic LVA). Anterior location of MI was 58.9% in gr. 2a and 39.6% in gr.2b. The QRS score of the MI size at the moment of decease did not differ significantly, but its evolution from the debut of MI has been +3.18 ± 0.89% ($p < 0.001$) in whole, respectively +2.60 ± 1.47% in gr.1, +5.24 ± 1.9 in gr. 2a, +2.01 ± 1.27 in gr.2b. ST segment depression (Sum ST/nST)dominated in gr. 2a, demonstrating a larger injury of potentially viable periinfarct region. The morphological parameters signified the predominant presence of cardiac spheric remodelling signs in pts with chronic LVA. This was accompanied by differences in volume (gr. 1 – 400+11.0 mm^3, gr. 2a – 411 ± 15.8 mm^3, gr. 2b – 433 ± 16.0 mm^3) and heart mass (resp. 537 ± 10.8 g, 531 ± 19.5 g, 570 ± 21.7 g).

Conclusion: It is concluded that the QRSs will be clinicaly usefull in the early identification of LV postinfarct aneurysm and cardiac remodelling.

P2782 Left ventricular function in patients with and without persistent myocardial viability after acute myocardial infarction

A.S. Knudsen, A.Z. Darwish, A. Nørgaard, O. Gøtzsche, K. Thygesen. *Department of Cardiology and Medicine, Aarhus County Hospital, Aarhus University Hospital, Aarhus, Denmark*

Acute myocardial infarction (MI) may elicit left ventricular remodelling and subsequent left ventricular dysfunction. The aim of the present study was to evaluate the influence of persistent myocardial viability on left ventricular function and dimension after MI.

Twenty-seven patients with a first acute MI were included and went through low-dose dobutamine echocardiography (LDDE) (0, 5 and 10 mcg/kg/minute) on day 6, 30 and 90 after the MI. Echocardiographic assessment of wall motion index (WMI), left ventricular enddiastolic volume index (EDDi), endsystolic volume index (ESDi) and ejection fraction (EF) was made. Patients with positive response in more than 2 myocardial segments at LDDE on day 90 were regarded as possessing persistent viability.

Of the 27 patients, 9 patients had persisting viability on day 90, 18 had not. No significant difference between patients with or without persistent viability was found with reference to infarct location, Q-waves or frequency of thrombolytic treatment. Patients without persistent viability had significantly more myocardial segments affected by the infarction ($p = 0.01$). No significant differences in EDDi, ESDi or EF appeared between the groups, but a trend of increase in EDIi ($p = 0.07$) as well as ESDi ($p = 0.08$) among patients without viability was seen. Patients without persistent myocardial viability had significantly higher WMI at all examinations and a significant increase in WMI from day 6 to day 90. The viable patients remained with stable WMI.

		WMI			
Day		6	30	90	
Non-viable	n = 18	1.29 ± 0.17	1.35 ± 0.26	1.38 ± 0.28	p = 0.04 day 6–90
Viable	n = 9	1.16 ± 0.05	1.13 ± 0.09	1.10 ± 0.11	ns
		p = 0.005	p = 0.006	p = 0.002	

In conclusion, a deterioration of left ventricular contraction occurs during the first 3 months after MI among patients with no echocardiographic signs of persisting viability. Subsequent left ventricle dilation may be suspected. No signs of reduced function or dilation were seen among patients with preserved viability.

P2783 Myocardial viability without biphasic response during dobutamine stress echo predicts a favourable left ventricular remodelling after myocardial infarction

C. Coletta, A. Sestili, R. Ricci, A. Galati, R. Rambaldi[1], R. Bigi[1], N. Aspromonte, E. De Marchis, M. Lenoli, V. Ceci. *[1]Cardiology Division, S. Spirito Hospital, Rome; Cardiology Division, E. Morelli Hospital, Sondalo, Italy*

Recent data suggest a favourable influence of myocardial viability (MV) on left ventricular remodeling (LVR) process after acute myocardial infarction (MI) and primary angioplasty. The aim of this study was to evaluate the LVR phenomenon after a first, uncomplicated MI in relation to the presence of MV, inducible ischemia and biphasic response during dobutamine stress echo (DSE).

Methods: 145 consecutive patients (pts) referred for DSE were considered (age: 57, M = 127). All were free from recurrent MI or coronary surgery procedures in the first 6 months after their MI. DSE (5 to 40 μg/kg/m′ + atropine when needed; 3′ steps) was performed 8 ± 4 days after MI. A >1 wall motion score (WMS) decrease at low doses of dobutamine (5–20 mg) identified MV. Ischemia was present in case of >1 WMS increase at high doses of dobutamine. The presence of both MV and ischemia was defined as biphasic response. Indexed end-diastolic and end-systolic volumes (EDV, ESV, ml/m2) from the baseline DSE and from a 2D echo performed 6 months after MI were separately calculated in blinded conditions (modified Simpson's rule). Changes of LV volumes (Δ) were calculated and compared for absolute (ΔEDV, ΔESV) and relative values (Δ% EDV, Δ% ESV). MI site, thrombolysis, CK peak, rest ejection fraction and WMS were also considered.

Results: Pts were divided according to DSE results (Gr 1: no MV, no ischemia; Gr 2: no MV, ischemia+; Gr 3: MV+, no ischemia; Gr 4: MV+, ischemia+). All basic clinical variables were comparable in the four groups.

	ΔVTD	Δ%VTD	ΔVTS	Δ%VTS
Gr 1 (50 pts)	2.7 ± 10.5	5.4 ± 18.2	1.2 ± 8.1	6.8 ± 25.8
Gr 2 (30 pts)	6.9 ± 17.1	13.0 ± 24.9	1.7 ± 10.3	5.5 ± 29.5

§ = p < 0.005 Gr 3 vs Gr 1 and Gr 2; * = p < 0.0001 Gr 4 vs Gr 3

Conclusions: Post-infarction pts with MV during DSE present a different LVR depending on residual dobutamine-inducible ischemia: 1) In pts without inducible ischemia, LV dilatation does not occur; 2) In patients with biphasic response LV dilatation is present and comparable to pts without MV.

P2784 History of hypertension improves left ventricular function early after acute myocardial infarction: analysis by Doppler echocardiography

M. Galderisi, A. Petrocelli, A. Izzo, A. Alfieri, O. de Divitiis. *Division of Emergency Medicine, Federico II University, Naples, Italy*

We assessed the influence of history of arterial hypertension on left ventricular (LV) systolic and diastolic functions and their reciprocal interactions early after acute myocardial infarction (AMI).

Methods: Standard Doppler-echo was performed in pre-discharge period to 86 patients with AMI, divided in 2 groups: 52 normotensives (N) and 34 hypertensives (H, based on previous evidence of diastolic blood pressure > 90 mmHg and/or of antihypertensive therapy). Twenty healthy subjects were the control group. Patients were excluded for previous AMI, clinical signs of heart failure or cardiogenic shock, valvular heart disease, atrial fibrillation, post-AMI angina. M-mode LV mass was indexed for height. Two-dimensional LV volumes and ejection fraction (EF) were determined. Doppler-derived stroke volume (SV) was calculated. Transmitral diastolic peak velocity E/A ratio, atrial filling fraction (AFF) and E wave deceleration time (DT) were measured.

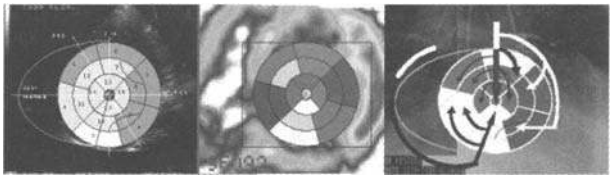
Results: H had comparable age and heart rate but higher blood pressure and LV mass index than the other 2 groups (all $p < 0.001$). H had also larger end-diastolic volume, reduced end-systolic volume, greater EF and SV (all $p < 0.01$) in comparison with N. E/A ratio was higher (1.3 ± 0.2 and 1.4 ± 0.3 respectively) and DT shorter in both H and N than in controls (all $p < 0.001$) but AFF was greater and DT longer (158 ± 15 msec vs. 149 ± 12 msec) in H vs. N (both $p < 0.01$). Significant relations of SV with both AFF ($r = 0.40$, $p < 0.01$) and DT ($r = 0.53$, $p < 0.001$) were found in H but not in N ($r = 0.19$ and $r = 0.15$, both NS).

In conclusion, diastolic pseudonormalization is detectable in both groups early after AMI, but prolonged DT and increased AFF characterize H, as imprint of previous diastolic dysfunction due to both increased afterload and LV mass. Based on the relations found between SV and both AFF and DT, the improvement of LV systolic observed in H is supported, throughout a greater atrial contribution to LV filling, by greater utilization of Starling mechanism.

P2785 Differentiation between hibernating myocardium and dysfunctionating left ventricular segments caused by remodelling, using polar map integration of imaging techniques

Z. Koszegi, E. Balogh, A. Kertesz, L. Balkay[1], L. Galuska[2], I. Hegedüs, T. Fulop, L. Voith, I. Edes. *Dept. of Heart and Lung Disease, University Medical School of Debrecen, Debrecen; [1]PET Centre, University Medical School of Debrecen, Debrecen; [2]Nuclear Medicine Dept, University Medical School of Debrecen, Debrecen, Hungary*

The aim of this study was to integrate the wall motion, the perfusion and the metabolic results. Data from echocardiography, coronary angiography and SPECT/PET in 16 left ventricular segments were compared in a polar map display. 10 patients with previous myocardial infarction were selected (mean age: 50.1 ± 12.2 years, EF: 34.1 ± 12.7%). The segments showing wall motion abnormality with less than 50% ^{18}FDG activity were regarded as infarcted (scarred) regions. The cases with more than 50% relative ^{18}FDG activity in the dysfunctioning regions, and with more than 70% diameter stenosis in the supplying epicardiac coronary arteries, were defined as hibernating myocardium. Dysfunction caused by remodelling was considered if coronary angiography did not reveal significant coronary artery stenosis in the supplying epicardial artery. The incidence of perfusion- metabolic mismatches in the segments was examined by comparing the Tc-99m-MIBI SPECT with the ^{18}FDG-PET results. The data revealed 48 (46.6%) dysfunctioning segments with low metabolic activity (infarction-I). In 29 (28.2%) segments with significant coronary stenosis on the supplying coronary artery, the metabolic activity was maintained (hibernation-H). In 26 (25.2%) segments, the hypo- or akinesia was associated with (nearly) normal epicardial coronary branch (remodelling-R).



Wall motion, FDG and coronary polar map.

A significant correlation ($r = 0.77$, $p = 0.01$) was found between the incidencies of R and I segments. No correlation was noted for the incidences of the H and I segments ($r = 0.11$, $p = 0.76$). The presence of perfusion-metabolic mismatch was detected only in 45% of the H regions (13/29). The results show that remodelling is more frequent after large myocardial infarction, and mismatch pattern can be demonstrated only in a part of hibernating myocardium.

P2786 Echocardiographic assessment of left ventricular remodelling following closed-chest infarction in the rabbit: a physiologically relevent model

R.D. Rakhit, R.J. Edwards, M.J. Wright, Z. Yousef, M.S. Marber. *Department of Cardiology, The Rayne Institute, St. Thomas's Hospital, Lambeth Palace Road, London, UK SE1 7EH*

Introduction: Ventricular dynamics following myocardial infarction (MI) is critically dependent on the presence of an intact pericardium However, current small animal models of infarction involve breach of the pericardium. We have developed a novel closed-chest model of MI in the rabbit and characterised the changes in left ventricular function and geometry using transthoracic echocardiography (TTE).

Methods: 8 adult New Zealand White rabbits underwent coronary angiography followed by MI by placement of a thrombogenic coil in the proximal circumflex artery. 6 age and weight-matched rabbits underwent sham procedures. TTE was performed using a 5 mHz transducer. M-mode-derived measurements of end-systolic diameter (ESD), end-diastolic diameter (EDD) left atrial diameter (LA) and % fractional shortening (FS) were performed at day 0 and days 1, 3, 7, 14, 28 and 84. Mitral doppler signals were also compared pre- and post-MI.

Results: statistically significant ($p < 0.01$) changes in ESD and FS were seen from day 7 post-MI (table). A non-significnt early increase in EDD was observed at day 7 which became significant ($p < 0.05$) by day 84. Non-significant increases in LA were also observed. A striking change in mitral filling pattern was also seen in some infarcted rabbits indicating restrictive physiology.

		Day 1	Day	Day 7	Day 14	Day 28	Day 100
ESD	MI	0.64 ± 0.08	0.65 ± 0.06	0.77 ± 0.05	0.81 ± 0.04	0.88 ± 0.06	1.34 ± 0.14
(cm)	Sham	0.60 ± 0.04	0.63 ± 0.02	0.62 ± 0.01	0.65 ± 0.02	0.67 ± 0.004	0.75 ± 0.04
EDD	MI	1.11 ± 0.05	1.38 ± 0.15	1.43 ± 0.11	1.57 ± 0.06	1.49 ± 0.08	2.10 ± 0.09
(cm)	Sham	1.14 ± 0.03	1.39 ± 0.06	1.40 ± 0.05	1.39 ± 0.04	1.50 ± 0.03	1.66 ± 0.02
FS	MI	53.9 ± 1.8	54.3 ± 2.2	50.9 ± 3.2	44.9 ± 2.4	44.9 ± 2.0	36.94 ± 4.40
(%)	Sham	56.9 ± 1.5	54.8 ± 0.7	55.5 ± 1.0	56.8 ± 2.2	58.3 ± 0.8	54.5 ± 2.22

Conclusions: We have characterised the echocardiographic changes in a clinically relevant small animal model of left ventricular remodelling following myocardial infarction. Dilatation was associated with a significant early increase in left ventricular ESD and late increase in EDD similar to the situation in humans. This model, we believe, will provide a powerful tool in the investigation of experimental heart failure.

P2787 Relationship between Q-wave regression and viability in the anterior myocardial infarction

G. Mobilia, P. Zanco[1], V. Costa, M. Binotto, F. Di Pede[2], G. Ferlin[1], R. Buchberger, E. Piccolo[2]. *Montebelluna (TV); [1]Castelfranco Veneto; [2]Mestre-Venezia, Italy*

The meaning of Q-wave regression after an acute myocardial infarction (AMI) has not yet been completely established. Particularly the relationship between Q-wave regression and viability was never reported.

Methods: We studied 26 pts with first Q-wave anterior AMI, retrospectively selected. A standard 12-lead ecg was registered on the hospital admission, before the hospital discharge and at follow-up; nitrogen-13-ammonia (NH3) and fluorine-18-fluorodeoxyglucose (FDG) positron emission tomography (PET) was also performed within one month of the onset of symptoms. An ecg-score (following the millimetre of regression of Q-wave and/or increase of R-wave in corresponding leads from V1 to V4, from discharge to follow-up) was attributed at every pt. PET viability was defined as an FDG uptake $\geq$ 50% of the maximum, whereas a perfusion-metabolic mismatch was considered present when the NH3 uptake was significantly lower than FDG uptake.

Results: The mean follow-up was 22 ± 13 months. In the 11 pts without viability (group 1) the attributed mean ecg-score was of 2.62 ± 3.88 mm. In the 15 pts with viability (group 2) the mean ecg-score was of 14.63 ± 10.44 mm ($p = 0.001$ vs group 1). In the 7 pts with viability and without mismatch (group 2a) the ecg-score increased of 22.4 ± 8.5 mm ($p < 0.0001$ vs group 1) while in the 8 pts with viability and with mismatch (group 2b) the ecg-score increased of 8.16 ± 6.96 mm ($p = 0.003$ vs group 2a and 0.05 vs group 1).

Conclusions: Our study shows that, in the anterior AMI, the regression of the ecg signs of necrosis is related with the presence of viability in the infarcted area. Moreover, in presence of a metabolic-perfusion mismatch, the regression is lower.

P2788 Prediction of cardiac events with cardiopulmonary exercise testing soon after myocardial infarction

G. Mazzotta, E. Casati, M. Falcidieno, R. Lionetto[1]. *Cardiology Dept., E.O. Ospedali Galliera, Genova; [1]Clinical Epidemiology and Trials, IST, Genoa, Italy*

Aim of this investigation was to assess the prediction of cardiac death, re-infarction or heart failure (IV NYHA), in the subsequent clinical course after an uncomplicated myocardial infarction. We explored the predictive power of clinical variables and variables derived from exercise testing, performed one month after infarction. We studied 164 consecutive patients (131 males), their mean age was 60 ± 10 years. Exercise testing with breath by breath gas exchange evaluation was performed with an erect bicycle, with 25 W initial workload and 25 W increases every 3'. In 54 patients unable to cycle, treadmill exercise testing was performed with the Bruce protocol. Patients were followed up for 11.5 ± 10 months. Their data were also compared with our population of 74 healthy volunteers (46 males, mean age 43 ± 12), who also underwent cardiopulmonary exercise testing.

Results: In the healthy volunteers, peak VO_2 was 30 ± 9 ml/kg/min, the 95th inferior percentile being at 18 ml/kg/min. Anaerobic threshold (measured with the V-slope method, operator-controlled) was at a VO_2 of 16 ± 7 ml/kg/min, the 95th inferior percentile being at 10.5 ml/kg/min. In the patients, peak VO_2 was 19 ± 5 ml/kg/min ($p < 0.001$ vs normal volunteers), anaerobic threshold was at 11 ± 3 ml/kg/min ($p < 0.001$ vs normal volunteers). Twenty-three patients had cardiac events (death, reinfarction or heart failure). At univariate analysis, age ($p = 0.01$), peak VO_2 ($p < 0.0001$) and VO_2 at the anaerobic threshold ($p < 0.001$) were associated with cardiac events. At logistic regression analysis, the sole variable significantly and independently associated with cardiac events (and also with cardiac death alone) was VO_2 at peak exercise. The best cut-off limit to subdivide patients at different risk of events was 12 ml/kg/min: 18 patients with less than 12 ml/kg /min VO_2 at peak exercise had 36% and 68% risk of a cardiac event at 1 and 2 year follow up, compared with 3% and 10% risk in the remaining patients ($p = 0.0001$).

Conclusions: Soon after myocardial infarction, peak VO_2 is an extremely powerful predictor of subsequent cardiac death, reinfarction or heart failure during medical therapy, and adds significant information to clinics and exercise test data. The best cut-off value of peak oxigen consumption for the prediction of the individual risk of cardiac events is 12 ml/kg/min.

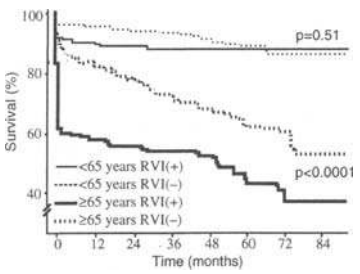
P2789 The interactive effect of age and right ventricular involvement on the increase in mortality in patients with inferior myocardial infarction is restricted to the early phase

H. Bueno, R. López-Palop, E. Pérez-David, M. Martínez-Sellés, J. García-García, J.L. López-Sendón, J.L. Delcán. *Hospital General Universitario "Gregorio Marañon", Madrid, Spain*

Right ventricular involvement (RVI) increases mortality in patients with inferior myocardial infarction (IMI), particularly in those of advanced age. The duration of the interaction between age and RVI on the increase in mortality in patients with IMI is unknown.

Methods. The short- and long-term mortality of 798 consecutive patients admitted to our CCU with an IMI of less 48 hours of evolution was studied. We performed an stratified analysis according to the patients' age (≥65 years old versus <65 years) and to the presence of RVI (defined by echocardiographic and/or electrocardiographic criteria). A complete follow-up was obtained in 98% of patients.

Results. In the whole group, the mean age was 64 years, 78% were men and 54% received reperfusion therapy. The median follow-up time was 45 months. Survival curves by each stratum are shown in the graph.



Conclusions: In IMI, RVI is associated with a lower long-term survival only in elderly patients. However, this difference in survival is a consequence of the increase in mortality produced in the early phase.

P2790 Perioperative prognostic value of dipyridamole echocardiography in vascular surgery: a large-scale multicenter study on 509 patients

R. Sicari, A. Ripoli, E. Picano, A. Djordjevic-Dikic, R. Di Giovanbattista, G. Minardi, S. Matskeplishvili, S. Ambatiello, G. Pulignano, M. Accarino.
Institute of Clinical Physiology, Pisa, Italy

Background: Patients undergoing major vascular surgery are at relatively high risk of cardiac events, and pharmacological stress echocardiography is increasingly used for perioperative risk stratification.

The aim of the study was to evaluate the value of dipyridamole echocardiography test (up to 0.84 mg/kg over 10') in predicting cardiac events in a large scale, multicenter, prospective, observational study design.

Method and Results: 509 patients (mean age 66 ± 10 years) were studied prior to vascular surgery by dipyridamole stress echocardiography in 11 different centers. All patients underwent preoperative clinical risk assessment according to the American Heart Association guidelines. No major complications occurred during dipyridamole stress echocardiography. Technically adequate images were obtained in all patients; however, in four patients only the low dipyridamole dose (0.56 mg/kg over 4 min) was given for limiting side effects. Eighty-eight (17.3%) had a positive test. Perioperative events occurred in 31 patients (6.1%): 6 deaths, 11 myocardial infarctions and 14 unstable angina. Sensitivity and specificity of dipyridamole stress echocardiography for predicting spontaneous cardiac events were 81% and 87%, respectively, with a positive predictive value of 28% and negative predictive value of 99%. By multivariate analysis the difference between wall motion score index at rest and peak stress, test positivity and ST segment depression during dipyridamole infusion were independent predictors of any perioperative cardiac event.

Conclusion: Dipyridamole stress echocardiography is safe and well tolerated in patients undergoing major vascular surgery, and provides an effective preoperative screening test for the risk stratification of these patients, mainly due to the extremely high negative predictive value, which is a potent predictor of complication-free procedure.

P2791 Can doppler myocardial imaging segmental velocities predict regional contractile recovery 3 months post successfully treated Q-wave acute infarction?

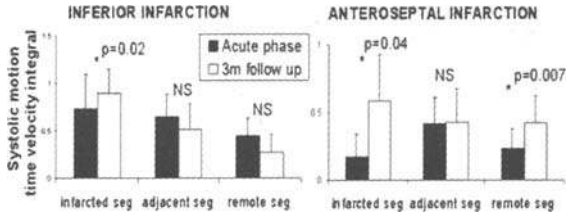
T. Kukulski, B. Shams[1], E. Swahn[1], B. Wranne, G.R. Sutherland[1].
Department of Clinical Physiology, University Hospital, Linköping[1] Department of Cardiology, Linköping Heart Centre, Linköping, Sweden

The LV recovery after acute myocardial infarction (AMI) is related to successful reperfusion. Both global and regional indices can be useful for LV function monitoring. Since Doppler Myocardial Imaging (DMI) measures segmental velocities it can provide valuable information on regional changes of reperfused myocardium.

Aim: The aim of this study was to assess feasibility of Doppler Myocardial Imaging technique in monitoring the regional recovery in patients post AMI.

Methods: 20 pts (aged 49–81 y, 10F) with AMI were evaluated by Colour DMI within 24 h since onset of the symptoms and 3 months post AMI. Only patients with first Q wave AMI and without ischemic events during the follow up period were enrolled to this study. Successful reperfusion was confirmed in 14 pts (gr.III). The infarcted, adjacent and remote segments were established on the base of 2 D grey scale image in 10 pts with anteroseptal (Gr. I) and 7 pts (Gr. II) with inferior AMI. A 70–80 fps colour DMI data set was acquired and peak systolic velocity (Vel), time velocity integral (Integr) were computed.

Results: In all patients the 3 months follow up study showed an increase in segmental Vel and Integr for infarcted segments in both Gr I and II(see Figure). LV FS increased from 24.9 ± 3.4 to 30.8 ± 6.7% (p = ns). Negative correlation was found between CKMB level and Integr measured in acute phase of AMI (R = −0.52, p = 0.01). In Gr.III an increase in both Vel (2.2 ± 1.5 vs 3.4 ± 2.1, p < 0.05) and Integr (0.32 ± 0.31 vs 0.71 ± 0.3, p < 0.001) was also noted.



Conclusions: Despite nonsignificant global function improvement significant increase in peak systolic velocity and velocity integral was observed in infarct/reperfused segments. Thus DMI can identify segmental functional recovery after successful reperfusion.

P2792 Does the presence of significant mitral regurgitation protect against left ventricular thrombus formation after acute myocardial infarction?

F. Macor, L. Ascione, F. Antonini-Canterin, F. Chiarella, P. Giannuzzi, D. Lucci, A.P. Maggioni, R. Piazza, I. Stoian, G.L. Nicolosi. *On behalf of the GISSI-3 Echo Substudy Investigators; C. Studi ANMCO, Florence, Italy*

Rationale: A role of mitral regurgitation in protecting against left ventricular thrombosis (LVT) after acute myocardial infarction has been previously suggested, but this hypothesis is still controversial.

Methods: From the GISSI-3 echo sub-study population, 757 patients with their first myocardial infarction were studied by echocardiography performed (1) from 24 to 48 hours, (2) at discharge, (3) after 6 weeks and (4) after 6 months. The diagnosis of LVT was based on the dectection of an echo-dense mass with defined margins visible throughout the cardiac cycle in at least two orthogonal views.

Results: In 64 patients (8%) left ventricular thrombosis was detected in one or more examinations. Compared to the remaining 693 patients, subjects with left ventricular thrombosis were significantly older (64.6 ± 13.0 vs 59.8 ± 11.7 years, p < 0.005), had larger infarction (extent of wall motion asynergy: 40.9 ± 11.5 vs 24.9 ± 14.0%, p < 0.001), more depressed left ventricular ejection fraction at admission (43.3 ± 6.9 vs 48.1 ± 6.8%, p < 0.001) and greater left ventricular volumes at admission (87 ± 22 vs 78 ± 18 ml/m^2, p < 0.001; 50 ± 17 vs 41 ± 14, p < 0.001; for end-diastolic and end-systolic respectively). The use of thrombolysis and aspirin did not differ between the 2 groups (respectively 71% vs 74% and 81% vs 86%, p NS). The prevalence of moderate to severe mitral regurgitation at Color Doppler at admission was higher in patients who had left ventricular thrombosis at any time (10.2% vs 4.2%, p < 0.05). A stepwise multiple logistic regression analysis established that the only independent variable related to the presence of left ventricular thrombosis was the extent of wall motion asynergy (p < 0.0001).

Conclusions: Moderate to severe mitral regurgitation in patients after myocardial infarction does not seem to protect against left ventricular thrombus formation; on the contrary its prevalence is higher in these patients. The only independent determinant of left ventricular thrombosis is the extent of the akinetic-diskinetic area detected at the echo performed between 24 and 48 hours from symptoms onset.

P2793 Left atrial remodelling after acute myocardial infarction: an analysis of the GISSI-3 echo substudy

F. Macor, F. Antonini-Canterin, L. Ascione, P. Giannuzzi, A.P. Maggioni, D. Lucci, R. Piazza, I. Stoian, P. Temporelli, G.L. Nicolosi. *On behalf of the GISSI-3 Echo Substudy Investigators; C. Studi ANMCO, Florence, Italy*

Background: While several studies have tried to assess the remodeling process of the left ventricle after acute myocardial infarction (AMI), no significant information is available of the related changes of the left atrium.

Methods: 757 patients from the GISSI-3 Echo substudy with their first AMI aged from 22 to 88 years (mean 60 ± 12 years) were considered. Echocardiograms were performed at 24–48 hours after AMI (T1), before discharge (T2), after 6 weeks (T3) and after 6 months (T4). Left atrial remodeling was defined as early (T1–T2) and late (T2–T4). Maximal left atrial area (A) was obtained from the apical 4 chamber view at end-systole.

Results: Early left atrial remodeling (T1–T2) was characterized by an increase of A from 17.2 ± 3.7 to 17.6 ± 3.8 cm^2 (repeated measures analysis of variance, time effect: F = 8.8, p < 0.005; inter-observer difference: 0.08 ± 1.53 cm^2). In the univariate analysis the increase of A was positively related to the increase in left ventricular sphericity (r = 0.09, r = 0.08 for diastolic and systolic respectively, p < 0.05). In a stepwise multiple linear regression the only variable independently related to this change was left ventricular ejection fraction at T1 (variables at T1 considered in the model were: age, max cpk plasma level, extent of a-diskinetic area, left ventricular volumes, ejection fraction and sphericity indexes, peak E and A wave and E wave deceleration time at Doppler mitral inflow). Similarly, late left atrial remodeling (T2–T4) was characterized by an increase of A up to 17.9 ± 3.5 cm^2 (F = 5.9, p < 0.005). The variable independently related to the late changes was E wave deceleration time at Doppler mitral inflow. When variables at T2 were considered, late remodeling was independently related to E wave peak velocity at Doppler mitral inflow. Patients with moderate to severe mitral regurgitation at Color Doppler at T1 had higher A (18.5 ± 3.5 vs 17.1 ± 3.7 cm^2, between subjects effect: F = 8.6, p < 0.005) but the increase over time did not differ from that in patients with mild or absent mitral regurgitation (interaction F = 0.1, p NS).

Conclusions: Both early and late left atrial remodeling occur after AMI. The main factors related to the remodeling were left ventricular ejection fraction (early remodeling) and left ventricular filling characteristics (late remodeling). Although patients with significant mitral regurgitation had greater left atrial dimensions, the pattern of left atrial remodeling in these patients was not significantly different from the overall population.

HOW TO FIGHT WITH THE THROMBUS DURING INTERVENTION

P2794 The Rescue PT catheter: a simple and effective alternative for the removal of intracoronary thrombus

V. van Ommen[1], E. Heymen[2], R. Michels[2], H. Bonnier[2], J. van Asseldonk[2], J. Vainer[1], J. Koolen[2]. [1]*Department of Cardiology, University Hospital Maastricht;* [2]*the Netherlands, Catharina Hospital Eindhoven, Netherlands*

Thrombus is by far the most frequent cause of acute coronary syndromes. Removal of the thrombus by thrombolytic agents carries the risk of severe bleeding, primary PTCA the risk of distal embolisation.

The aim of this study was the evaluation of the safety and efficacy of thrombus aspiration using the Rescue PT catheter, a 4.5 F polyurethane semi monorail catheter with an oblique end. It can be advanced over a 0.014 inch guide wire. Vacuum is applied by a small suction device.

Methods: Angiographic and clinical aspects were evaluated in 50 pts (51 vessels; 46 coronary arteries and 5 bypass grafts) with angiographic suspicion of a considerable amount of fresh intravascular thrombus (<10 hours). 44 Pts were treated in the acute phase of a myocardial infarction, 29 pts after failed thrombolysis. In 7 pts thrombosuction was performed because of distal embolisation, in 4 alredy present before and in 3 after initial thrombosuction.

Results: Thrombus could be removed in 46/51 vessels and TIMI 3 flow was present in 9 vessels before, 42 after thrombosuction and 47 after additional therapy. In 42 vessels additional therapy (PTCA, stent, thrombolysis) was applied. Angiographic signs of distal embolisation possibly caused by thrombosuction occurred in 3 vessels. Distal embolisation was successfully treated by thrombosuction in 5/7 Pts. 2 Pts died in-hospital because of cardiogenic shock that was already present before the procedure.

Conclusion: The Rescue PT catheter proved to be an effective and safe alternative for the removal of fresh thrombus from coronary arteries and bypass grafts. It is also particularly useful if distal embolisation is present.

P2795 Cost-effectiveness of rheolytic thrombectomy for thrombus-containing coronary lesions: final results from the VEGAS 2 trial

D.J. Cohen, R. Cosgrove, R. Berezin, J.J. Popma[1], R.E. Kuntz, S.E. Ramee[2]. *Cardiology Division, Beth Israel Deaconess Medical Center, Boston MA;* [1]*Cardiology Division, Brigham and Women's Hospital, Boston MA;* [2]*Cardiology Dept, Oschner Clinic, New Orleans, USA*

Despite advances in mechanical and pharmacological therapy, thrombus-containing lesions are at high risk for adverse events and remain a challenging subset for percutaneous coronary revascularization. Rheolytic thrombectomy with the Angiojet device can safely remove intracoronary thrombus, but the overall cost-effectiveness of this technique is unknown.

Methods: We determined in-hospital and 1-year follow-up costs for 347 patients with thrombus-containing lesions who were randomized to treatment with intracoronary urokinase (UK; 6 to 30 hour infusion, n = 169) or immediate thrombectomy with the Angiojet device (AJ; n = 178). Catheterization laboratory costs were based on measured resource utilization and 1998 unit costs, while all other costs were estimated from hospital charges and cost-center specific cost-to-charge ratios.

Results: Compared with UK, AJ reduced the incidence of periprocedural MI (12.2% vs. 30.3%, $p < 0.001$) and major vascular complications (4.5% vs. 17.7%, $p < 0.001$) and shortened length of stay by nearly one day (4.2 vs. 4.9 days, $p = 0.02$). As a result, AJ reduced procedural costs, ancillary costs, and physician fees (see Table) and produced net cost savings of more than $5000 per patient ($16,803 vs. $22,723, $p < 0.001$). Regression analysis demonstrated that the in-hospital cost savings with AJ were explained by reduced ischemic complications (15%), reduced vascular complications (19%), and avoidance of multiple procedures (66%). These cost savings were maintained at one year follow-up ($21,657 vs. $27,372, $p < 0.001$).

In-hospital and 1-year costs

	Angiojet	Urokinase	P-value
Initial procedure	$8064 ± 2730	$9733 ± 4108	<0.001
Repeat procedures	$392 ± 1413	$847 ± 1927	<0.001
Hospital stay	$6732 ± 5926	$8637 ± 5843	<0.001
MD fees	$1615 ± 490	$3506 ± 1138	<0.001
Initial hospitalization	$16803 ± 7397	$22723 ± 8998	<0.001
Subsequent hospitalizations	$4853 ± 11,085	$4649 ± 10852	NS
1-year total	$21657 ± 14966	$27372 ± 14022	<0.001

Conclusions: Compared with standard treatment with intracoronary UK, rheolytic thrombectomy both improves clinical outcomes and reduces overall medical care costs for patients with thrombotic coronary lesions.

P2796 Influence of lesion morphology on markers of blood coagulation and ischaemia before and after PTCA

M. Ries, H.-J. Rupprecht, G. Hafner[1], S. Walte, C. Espinola-Klein, J. Meyer. *II. Medical Clinic;* [1]*Clinic of Clinical Chemistry, University Clinic, Mainz, Germany*

The aim of the study was to evaluate the influence of lesion morphology on markers of blood coagulation and ischemia before and after PTCA.

Methods: 187 patients with angina pectoris were pre-PTCA divided in three groups on the basis of the ischemia related artery according to angiographic lesion morphology. The classification follows the criteria by Ambrose. Group I: stenosis >50% with smooth or slightly irregular morphology. Group II: asymmetric stenosis >50% with irregular contours/ulcerations. Group III: stenosis with an intracoronary thrombus. Fibrinogen, thrombin antithrombin III complex (TAT) and troponin-I (Tn-I) levels were determined pre- and 4, 8 and 24 hours post-PTCA. The highest values post-PTCA are given in the table. The groups were compared using Wilcoxon's test.

Results:

	Group I n (%)	Group II n (%)	Group III n (%)	p
fibrinogen > 350 mg/l pre-PTCA	16 (20%)	20 (36%)	4 (27%)	n.s.
fibrinogen > 350 mg/l post-PTCA	22 (30%)	14 (36%)	*6 (75%)*	0.039
T A T > 4.1 μg/l pre-PTCA	48 (54%)	35 (49%)	11 (55%)	n.s.
T A T > 4.1 μg/l post-PTCA	18 (22%)	13 (24%)	*7 (54%)*	0.047
Tn-I ≥ 0.4 μg/l pre-PTCA	9 (19%)	8 (26%)	*5 (63%)*	0.043
Tn-I ≥ 0.4 μg/l post-PTCA	13 (28%)	10 (32%)	*6 (75%)*	0.037

Conclusion: Patients with thrombotic lesions show significant higher levels of fibrinogen and TAT post-PTCA in comparison to patients with non-thrombotic lesions (group I + II). Tn-I levels were pre- and post-PTCA significantly higher in group III than in group I + II.

P2797 Improved outcome of diabetics submitted to coronary angioplasty with concomitant use of abciximab? A practical insight

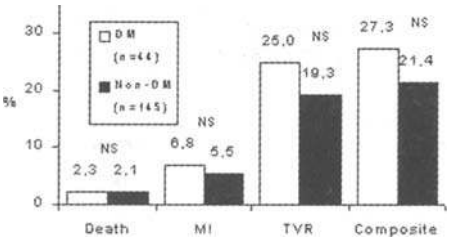
R. Teles, J. Ferreira, M. Almeida, M. Ribeiro, C. Aguiar, F. Machado, J. Batista, J. Palos, A. Silva, R. Seabra-Gomes. *Cardiology Dept., Santa Cruz Hospital, Lisbon, Portugal*

Background: Diabetics have a particularly important cardiac event rate after coronary angioplasty (PTCA). It is unknown if recently introduced IIb/IIIa receptor antagonists can modify this ominous prognosis.

Aim: To analyse safety and efficacy of abciximab in the outcome of diabetics (DM) submitted to PTCA compared with non-DM patients (pts).

Methods: We evaluated 189 pts (mean age 59 ± 10 years, 14% female) submitted to PTCA with abciximab from June 1996 to March 1998. DM was present in 44 pts (23%). Baseline demographic and clinical characteristics were similar in DM and non-DM pts. Clinical presentation for PTCA was an acute coronary syndrome in 45% of pts in DM versus 32% in non-DM pts (NS). Stent implantation was 89% in DM versus 83% in non-DM pts (NS). Unplanned ("rescue") use of abciximab was 41% in DM versus 37% in non-DM pts (NS).

Results: The rate of hemorrhagic complications requiring blood transfusion therapy was 6.8% in DM versus 0.7% in non-DM pts ($p = 0.06$). Thrombocytopenia (<50' 10^9/L) occurred in 2.3% of DM versus 2.8% of non-DM pts. Follow-up at 6-months was (figure):



Conclusions: In this study, the occurrence of major acute coronary events at 6-months follow-up did not differ significantly between diabetic and non-diabetic patients undergoing PTCA with abciximab.

P2798 In-hospital predictors of major complications following intracoronary stenting with ticlopidine-aspirin in patients with unstable angina: a rational basis for the selected use of glycoprotein IIb/IIIa inhibitors

M. Angioï[1], C. Bauters[2], C. Gangloff[1], E. Van Belle[2], A.C. Vançon[1], J.M. Lablanche[2], N. Danchin[1], M.E. Bertrand[2]. *Service de Cardiologie; [1]CHU de Nancy; [2]Lille, 54500 Vandoeuvre, France*

Prior studies have shown a significant reduction of major complications using abciximab during intracoronary stent placement, especially in acute coronary syndromes. Nonetheless, particularly because of its cost, the use of this treatment in a prophylactic way remains limited. The aim of our study was to assess in-hospital predictors of major complications in patients with unstable angina, in order to determine in which subset this treatment would be the more beneficial. We studied 287 consecutive pts (220 men, mean age 64 years) with rest unstable angina (Braunwald class II and III) who underwent intracoronary stent placement followed by ticlopidine-aspirin therapy, whitout planned use of abciximab in our 2 centers in 1995–96. Indication for stent placement was bail-out in 17 pts (6%), sub-optimal results in 189 pts (66%) and elective in 81 pts (28%). Successful stent placement was achieved in 96%. Our end-point for major in-hospital complications was the cumulative rate of death, Q-wave MI, large non Q-wave MI (CK > 5 × ULN) and emergency CABG. A major complication occurred in 16 pts (5.6%). Univariate predictors were Braunawald class III (9.3 vs 3.3%, $p < 0.03$), 3-VD (10.3 vs 3.3%, $p < 0.009$), female gender (10.4 vs 3.8%, $p < 0.03$), bail-out procedure (35 vs 3.7%, $p < 0.00001$) and age (mean age in case of a major complication 70 ± 8 vs 64 ± 11, $p < 0.02$). On multivariate analysis, Braunwald class III ($p < 0.05$), female gender ($p < 0.01$) and 3-VD ($p < 0.03$) were predictors of major complications.

Thus in the setting of rest unstable angina ceratin subsets of patients were at high risk of developing a major complication following intracoronary stent placement with ticlopidine-aspirin. In these selected cases, prophylactic use GP IIb/IIIa inhibitors might be advisable.

P2799 The use of clopidogrel instead of ticlopidine after intra-coronary stent insertion: initial results in stents of ≤3 mm diameter

A.L. Calver, L.J. Blows, K.D. Dawkins, H.H. Gray, J.M. Morgan, I.A. Simpson. *Wessex Cardiothoracic Centre, Southampton University Hospital, UK*

Patients with small stents (≤3 mm diameter) are at increased risk of stent occlusion. Ticlopidine is now used routinely in addition to aspirin to prevent stent thrombosis but is unlicensed in the UK and causes neutropaenia in 2.4% of patients. Clopidogrel, which is chemically related to ticlopidine, has recently become available. It has no increased risk of neutropaenia and is cheaper than ticlopidine. In all patients treated in our institution with stents ≤ 3 mm we compared outcome in those treated with aspirin and ticlopidine (Dec–Jul 97/98, Group T) and those treated with aspirin and clopidogrel (Aug–Dec 98, Group C). In Group T there were 190 patients (253 lesions, 274 stents, age 59.1 ± 10.7 yrs, 72% male, 31% unstable angina). 64% had 1 stent, 36% had >1 stent. In Group C there were 118 patients (157 lesions, 173 stents, age 60.6 ± 9.4 yrs, 75% male, 20% unstable angina). 68% had 1 stent, 32% had >1 stent. All patients had heparin during stent insertion and similar stents were used in both groups. Vessels treated (Group T vs C): LAD 47% vs 51%; Cx 25% vs 22%; RCA 22% vs 20%; D1 2.4% vs 1.2%; 1x 1.2% vs 2.4%; L main 0% vs 1.9%; vein graft 2.4% vs 1.9%. Lesion characteristics: A 37% vs 41%, B1 33% vs 34%, B2 16% vs 16%, C 14% vs 9%. Indication for stent: elective 65% vs 60%, sub-optimal result 30% vs 38%, bail-out 2.5% vs 1.2%, restenosis 1.8% vs 0.8%. Length of hospital stay was 1.8 vs 1.6 days. In Group T complications at 30 days were: cardiac death 1, stent occlusion 3 (1.6%), non-Q wave MI 2, urgent revascularisation 4 (Major adverse cardiac & cerebral events (MACCE) 5.2%) In Group C complications at 30 days were cardiac death 1, non-cardiac death 1, stent occlusion 0, non-Q wave MI 2, urgent revascularisation 0 (MACCE 3.4%). Follow-up was available in 100% of patients in Group T and 98% of patients in Group C and was 203 ± 79 and 61 ± 25 days respectively. Although the follow-up period is short in Group C at present, early indications are that clopidogrel can be used safely instead of ticlopidine in patients with stents ≤ 3 mm in diameter.

P2800 Geographic variability in outcomes within an international trial of glycoprotein IIb/IIIa inhibition in patients with acute coronary syndromes: results from PURSUIT

Martijn Akkerhuis, Jaap W. Deckers, Eric Boersma, Robert A. Harrington, Janina Stepinska, Robert M. Califf, Eric J. Topol, Maarten L. Simoons. *For the PURSUIT Investigators; Thoraxcenter, University Hospital Rotterdam, Netherlands; Duke University, Durham NC; Cleveland Clinic Foundation, Cleveland OH, USA*

Aims The aim of the present study was to analyze the factors that might contribute to the geographic variations in patient outcome and treatment effect as observed in the PURSUIT trial.

Methods In PURSUIT, 9461 patients with acute coronary syndromes were randomized to the platelet inhibitor eptifibatide or placebo for 72 h in 27 countries in 4 geographic regions including Western (WE, n = 3697) and Eastern Europe (EE, n = 1541) as well as North (NA, n = 3827) and Latin America (LA, n = 396). Endpoint was the 30-day composite of death or MI. In the initial univariate analysis, the treatment effect appeared greater in NA than in WE, while no effect was apparent in LA and EE. However, the confidence intervals for these effects were wide and overlapping. In order to more precisely study the differences, a subdivision in an early and late outcome and treatment effect was made, analyzed as the rate of death or MI at 72 h censored for percutaneous coronary intervention (PCI) and the rate between 3 and 30 days. Additional analyses were performed with different definitions of MI using higher thresholds of CK-MB elevation. Multivariable analysis was used to evaluate the relation between region and outcome and to determine the adjusted eptifibatide treatment effect.

Results Major differences in baseline demographics were apparent among the 4 regions; in particular, more patients from EE had characteristics associated with impaired outcome. Also, interventional treatment varied considerably with more patients from NA undergoing PCI. Despite differences in the 72-h event rate, eptifibatide consistently reduced the composite of death or MI among all 4 geographic regions and for all definitions of infarction. Absolute reductions ranged from 0.7–1.5% in WE, 0.6–1.2% in NA, −0.1–1.5% in EE, and 3.5–5.6% in LA. After correction for baseline characteristics, the benefit of eptifibatide was similar in all regions. In patients undergoing PCI during study drug infusion in WE (n = 266) and NA (n = 931), there was a dual treatment benefit with eptifibatide. During medical therapy preceding the intervention, an absolute reduction in MI was observed ranging from 2.0–4.8% in WE and 0.9–3.0% in NA, while the reduction in procedure- related events ranged from 2.1–2.9% in WE and 2.7–4.3% in NA for different MI definitions. No rebound occurred. After multivariable adjustment neither benefit nor rebound was apparent after 3 days in all regions, except in LA. In general, the differences in outcome and treatment effect among regions were greatest when the protocol definition of MI (CK-MB > 1) was applied. When stricter definitions were used, differences became smaller and disappeared with the assessment by the investigator.

Conclusion The analysis suggests that the apparent differences in patient outcome and treatment effect can largely be explained by differences in demographics and adjunctive treatment strategies as well as by the methodology of MI definition and the adjudication process.

P2801 Long-term oral glycoprotein IIb/IIIa inhibition with xemilofiban in patients undergoing percutaneous coronary intervention: results from EXCITE

P.W. Serruys[1], H. Darius[2], C. Moris[3], W. O'Neill[4], M. Knudtson[5], R. Anders[6], J.H. Kleiman[6], K. Barker[6], G.-A. van Es[7], J.O. Symons[7]. *[1]Thoraxcenter, Univ. Hosp. Rotterdam, Netherlands; [2]Klinik der Johannes Gutenberg Univ., Mainz, Germany; [3]Hospital Central de Asturias, Oviedo, Spain; [4]William Beaumont Hosp., Royal Oak MI, USA; [5]Foothills Hosp., AB, Canada; [6]G.D. Searle & Co., Skokie IL, USA; [7]Cardialysis, Rotterdam, Netherlands*

Background: Intravenous GP IIb/IIIa antagonists have demonstrated efficacy in preventing the thrombotic endpoints of death, MI and urgent revascularisation when administered immediately prior to and for up to 48 hours after PTCR. This trial was set up to investigate whether oral administration has the same acute effect as intravenous GP IIb/IIIa antagonists and whether long-term administration further improves long-term outcome.

Methods: The EXCITE study was an international, multicenter, randomised, placebo-controlled trial of 7232 patients (pts) to test the efficacy of the oral GP IIb/IIIa antagonist xemilofiban (xemi) administered prior to and chronically for up to 6 months after PTCR with and without stent (S) placement. All pts were treated with ASA and heparin; all S pts received xemi continuously, or ticlopidine for 2–4 weeks followed by xemi placebo. Two doses of xemi were tested. The primary endpoint was time to the first occurrence of the composite of death, MI, or urgent revascularisation, and time to death or MI over the 6-month study period. Additional analysis explored the effect of xemi on the same endpoints in pts treated with balloon angioplasty alone, or with additional stent deployment.

Results: Approximately 71% of pts received S at the discretion of the operator. At the end of the 6-month follow-up, 13.6% of pts treated with placebo, and 14.1% and 12.6% of pts treated with 10 mg and 20 mg of oral xemi TID respectively, experienced endpoint events (NS). At 30 days following PTCR, pts treated with PTCR without S had lower event rates than those receiving stents. By 180 days, this trend had reversed and endpoint events had occurred more frequently in pts without S than in those in whom S had been deployed.

Conclusions: Chronic treatment with xemi was not superior to 2–4 weeks therapy with ticlopidine in pts receiving S, or chronic ASA therapy for those receiving balloon angioplasty alone. These findings should provoke further research into the role of chronic platelet GP IIb/IIIa receptor blockade in preventing ongoing thrombotic cardiac events.

P2802 Platelet activation and platelet-monocyte interaction during coronary intervention: is there a genetic influence?

H. El Gendi, A.G. Violaris, T.F. Ismail, V.K. Gulati[1], M. Sumiya[1], G. Bashir, D.J. Sheridan. *Division of NHLI, St Mary's Hospital, Academic Cardiology Unit, London; [1]St Mary's Hospital, Department of Medicine, London, UK*

Background: Coronary intervention may be complicated by acute thrombotic occlusion and late restenosis as a result of events initiated by endothelial trauma and propagated by platelet activation. The aim of our study was to assess the degree and duration of local and systemic platelet activation during coronary intervention; to correlate this with the degree of endothelial damage and the presence of PlA2 polymorphism (a known risk factor for coronary disease) and further to examine the level of platelet-monocyte adhesion (PMA) and monocyte activation which platelet activation may trigger.

Methods: Coronary sinus (CS) and peripheral blood samples were collected at baseline, post-1st balloon inflation and post-angioplasty in 21 patients undergoing successful left system coronary angioplasty. Platelet activation was determined by flow cytometric detection of PAC-1 expression (a marker of platelet activation). Endothelial damage was assessed by measuring solube thrombomodulin (sTM) levels by ELISA. PlA genotype was assessed by PCR of the polymorphic region followed by restriction enzyme digestion and electrophoresis of the PCR product to reveal the allele-specific restriction fragment length polymorphism. PMA was assessed by double staining with CD14 (a monocyte specific marker) and GP1b (a platelet specific marker). Monocyte activation was assessed by quantifying the degree of L-selectin mean channel fluorescence(MCF)down- regulation.

Results: All patients demonstrated significant platelet activation in the CS immediately after the 1st inflation, (20.63 vs 8.13 at baseline, $P < 0.001$), but not in the periphery(14.35 versus 7.7 at baseline P = NS). Platelet activation did not correlate with the degree of endothelial damage as assessed by sTM levels ($P = 0.8$), however, there was a trend towards increased platelet activation in patients polymorphic to PlA2 ($P = 0.08$). There was a significant albeit transient increase in local PMA after the 1st inflation (51.4 ± 4.9 vs 37.7 ± 2.4 at baseline $P = 0.019$) leading to a significant increase in systemic monocyte activation at 24 hours (46.9 ± 6 vs 66.4 ± 5.1 at baseline, $P = 0.02$).

Conclusion: Coronary intervention results in local platelet activation and PMA which in turn may lead to prolonged systemic monocyte activation. Platelet activation does not correlate with the degree of endothelial damage but may correlate with the presence of PlA2 polymorphism. Our results provide new insight into the mechanisms involved in restenosis and therefore possible therapeutic approaches to the thrombotic complications which may follow coronary intervention.

P2803 Successful percutaneous intervention in patients with total coronary occlusions results in increased local platelet activation compared to those with stenoses

H. El Gendi, A.G. Violaris, T.F. Ismail, R.A. Foale, D.J. Sheridan. *Division of NHLI, St Mary's Hospital, Academic Cardiology Unit, London, UK*

Background: Successfully dilated coronary occlusions have a higher restenosis rate compared to non-occlusive stenoses. Peri-interventional platelet activation correlates with restenosis, but has not been assessed in the context of occlusive versus non-occlusive stenoses.

Aim: to compare the degree and duration of platelet activation in patients with occlusions against those with stenoses during percutaneous transluminal coronary angioplasty.

Method: Platelet activation was prospectively examined in 30 patients undergoing successful left coronary system intervention. Nineteen patients (15 males, mean age 63) had non-occlusive stenoses ($66 \pm 5\%$ (mean $\pm$ SD) stenosis), and 11 patients (4 males, mean age 62) had total occlusions. Coronary sinus blood samples were collected at baseline, post-first balloon inflation and post-angioplasty. Platelet activation was assessed by flow cytometric quantification of percentage platelet PAC-1 expression. PAC-1 is a neoepitope found only on the conformationally active form of the GPIIb/IIIa receptor following platelet activation. Platelets were stained with fluorochrome-conjugated monoclonal antibodies directed against CD42a (a constitutively expressed general platelet marker) and PAC-1 (an activation-dependent marker). Platelets were electronically gated on the basis of staining for CD42a and forward scatter characteristics and the percentage expressing PAC-1 measured.

Results: All patients demonstrated significant platelet activation in the coronary sinus immediately after the first balloon inflation, as measured by the percentage of platelets positive for PAC-1. In the stenosis group, platelet activation increased from $6.3 \pm 1.1\%$ at baseline to $14.3 \pm 2.8\%$ after the first inflation ($P < 0.02$), but returned to baseline ($7.0 \pm 1.8\%$, P = NS) post-angioplasty. By contrast, in the occlusion group, platelet activation increased from $7.9 \pm 1.4\%$ at baseline, to $23.7 \pm 5.0\%$ ($P = 0.007$) after the first inflation and remained high at the end of the procedure ($23.5 \pm 5.4\%$, $P < 0.04$ vs baseline).

Conclusion: Our data shows that patients with successfully dilated total occlusions have more prolonged platelet activation after intervention than those with stenoses. This observation supports the hypothesis that prolonged platelet activation may play a major role in the development of reocclusion and restenosis after successful dilatation of total occlusions. Patients with total occlusions may therefore benefit from a more aggressive anti-platelet regime.

P2804 Reduced procedural risk for coronary catheter interventions in carriers of the coagulation factor-VII Gln353 gene

K. Stangl, P.M. Mrozikiewicz[1], I. Cascorbi[1], M. Laule, I. Roots[1], G. Baumann. *Med. Klinik, Kardiologie, Campus Mitte, Charité, Humboldt Universität, Berlin, Berlin[1] Klinische Pharmakologie, Charite, Humboldt Universität, Berlin, Germany*

Background: Increased coagulation factor VII (FVII) activity represents an independent risk factor for acute thrombotic events in the course of coronary artery disease (CAD). The mutation Arg353Gln of FVII is known to decrease FVII activity. Presence of Gln353 was suggested as protective against CAD and myocardial infarction. It is unclear whether Gln353 mutation reduces susceptibility to develop complications after coronary catheter interventions.

Methods and Results: 666 consecutive CAD patients who underwent coronary catheter interventions (280 coronary angioplasty [PTCA], 104 coronary atherectomy [DCA], and 282 stenting) were observed for a 30-day composite endpoint, including need for target-vessel revascularisation, myocardial infarction, and death. The Arg353Gln polymorphism of FVII was determined by PCR/RFLP assay. The frequencies of homozygotes for Arg353, heterozygotes, and homozygotes for Gln353 in the whole group were 76.4%, 22.2%, and 1.4%, respectively. Composite endpoint appeared in 43 cases (30 target vessel revascularisation, 12 myocardial infarction, and 1 death). These complications occurred with 2.5% in carriers of at least one Gln353 allele (4 out of 157 cases), and with 7.7% in homozygotes for Arg353 (39 out of 409; odds ratio, 0.32; 95% confidence interval, 0.08–0.90; $P = 0.013$). A trend of allele dependent reduction of risk was also observed if we separated complications according to device.

Conclusions: The Gln353 allele of FVII confers significant protection against complications after angioplasty.

P2805 Minimal heparinization in PTCA: is heparin really warranted?

E. Kaluski, R. Krakover, G. Cotter, A. Hendler, I. Zyssman, O. Milovanov, A. Blatt, M. Leitman, E. Zimmerman, V. Nahman, E. Goldstein, Z. Vered. *Assaf Harofeh Cardiology Institute, Zerifin, Israel*

Objective: To assess the safety of mini-dose (2,500 units intravenous bolus) unfractionated heparin in PTCA.

Methods: 100 out of 113 (88.4%) consecutive patients undergoing PTCA were prospectively enrolled to the study. All enrolled patients received mini dose unfractionated heparin (MDUH), prior to guiding catheter insertion, with no subsequent heparin administration. Two physicians assessed the patient and lesion characteristics as well as PTCA results. Femoral sheaths were removed within 2 hours after PTCA. Patients were followed up by telephone monthly after their discharge.

Results: Angiographic and clinical success were achieved in 94% and 91% respectively. There was one in-hospital death. Emergency coronary bypass surgery and stroke did not occur. One patient experienced acute closure 6 hours after PTCA. 56 patients (56%) received stents (36 of these without previous balloon dilatation). There were 5 cases (5%) of side -branch compromise: two of these resulting in mild CPK rise. 4 patients had reduced TIMI flow after PTCA. One case of mild non-occlusive in-stent thrombosis was detected. No bleeding or vascular complications were detected. Mean follow up of 62 ± 35 days) revealed no additional deaths, one myocardial infarction, and 6% repeat target vessel revascularization (TVR).

Conclusion: MDUH appears to be safe in non-emergency PTCA, and has the potential of reducing bleeding complications, hospital stay and cost, and set the stage for ambulatory trans-femoral PTCA. Larger double-blind heparin dose optimization studies, with long term stringent follow up protocol, need to confirm this impression.

P2806 Bleeding and vascular complications after percutaneous coronary interventions and abciximab

A. Cote, M. Bell, B. Nasseri, P. Berger, D. Holmes. *Cardiovascular Diseases Dept, Mayo Clinic, Rochester MN, USA*

Hemorrhagic and vascular complications contribute significantly to the morbidity of percutaneous coronary intervention (PCI) and are risk factors for long-term mortality. The safety of adjunctive abciximab has not been documented outside the setting of clinical trials which have involved highly selected pts.

Methods: We prospectively recorded the incidence of bleeding and peripheral vascular complications in 2623 consecutive pts undergoing PCI (841 with and 1782 without abciximab). Heparin was used according to the EPILOG guidelines.

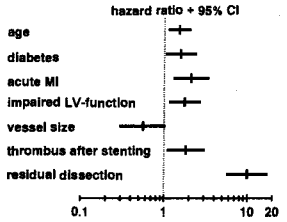
Results: Major bleeding (decrease in Hb > 5 g/dL, decrease in hematocrit > 15% or intracerebral hemorrhage) occurred in 2.1% of pts who received abciximab and 0.7% of pts who did not ($p = 0.002$). Minor bleeding (decrease in Hb > 3 g/dL, decrease in hematocrit > 10%) occurred in 14% of pts who received abciximab and 6% of those who did not ($p < 0.001$). Pseudoaneurysms or AV fistulae occurred in <1% of pts. Among 254 pts treated within 12 hrs of an acute MI, major bleeding occurred in 5.7% of 140 pts who received adjunctive abciximab versus 2.6% in the 114 pts who did not; minor bleeding occurred in 18.6% and 17.5%, respectively.

Conclusions: Adjunctive abciximab was associated with a significantly higher frequency of bleeding in pts undergoing PCI particularly in the setting of acute MI. Although the incidence of major bleeds was relatively low, minor bleeding occurred more frequently than reported from randomized trials. Further strategies to reduce these complications are required.

P2807 Risk for early major adverse cardiac events after coronary stent placement in the era of ticlopidine

Helmut Schühlen, Adnan Kastrati, Jürgen Pache, Martin Hadamitzky, Julinda Mehilli, Josef Dirschinger, Albert Schömig. *1. Medizinische Klinik rechts der Isar; Deutsches Herzzentrum, Technische Universität, Munich, Germany*

Previous risk analyses for MACE during the first 30 days have stressed the importance of ticlopidine therapy and of an optimal angiographic result. Data focussing on patients with ticlopidine therapy are not available. Therefore we analyzed all 3676 patients with ticlopidine therapy after successful stenting within a 4-year period (without cardiogenic shock). Risk analysis by Cox proportional hazard models included 23 clinical, angiographic and procedural factors.



The overall MACE rate was 3.4% (death, 1.1%; myocardial infarction, 1.0%; TLR, 2.1%); 50.0% of all events occurred during the first 3 days, 77.8% during the first 2 weeks. The significant and independent risk factors identified are illustrated in the graph.

Conclusions: This retrospective analysis illustrates the risk associated with older age, diabetes, acute myocardial infarction, impaired LV function, smaller vessel size and an intracoronary thrombus at the end of a procedure. The most prominent factor however, an uncovered residual dissection, underscores the need for an optimal angiographic result.

P2808 C825T polymorphism in the gene encoding for the β3 subunit of heterotrimeric G proteins is not associated with an increased risk of thrombosis and restenosis following coronary stent placement

N. von Beckerath, W. Koch, A. Kastrati, M. Seyfarth, C. Feßel, A. Schömig. *Deutsches Herzzentrum; 1. Med. Klinik, TU München, Munich, Germany*

C825T polymorphism in the gene encoding for the β3 subunit of heterotrimeric G proteins (*GBN3*) is strongly associated with a splice variant of Gβ3 lacking 41 amino acids. *In vitro* presence of the splice variant Gβ3-s results in increased G_i signaling. C825T polymorphism has been associated with essential hypertension, coronary artery disease and myocardial infarction. Its role in the processes of vessel thrombosis and restenosis after percutaneous coronary interventions has yet not been studied.

Methods: C825T genotype of 562 consecutive patients who underwent coronary stent placement was determined. In 468 patients (83%) a 6-month follow-up angiography was performed.

Results: CC genotype was present in 46%, CT in 45% and TT in 9% of the patients. No significant differences regarding clinical, angiographic and procedural characteristics were found between carriers of T allele (CT + TT) and homozygous carriers of C allele (CC). Four patients with and three patients without T allele suffered from subacute stent thrombosis ($p = 0.86$). Restenosis (≥50% diameter stenosis in QCA) was found in 33% of CC, 28% of CT and 33% of TT patients ($p = 0.56$). Carriers of the T allele (CT + TT) had a restenosis rate of 29% *verca* 33% in patients homozygous for C allele ($p = 0.40$). Late lumen loss was 1.04 ± 0.77 mm in CT and TT patients and 1.12 ± 0.81 mm in CC patients ($p = 0.27$). No significant difference was found in target vessel revascularization rates between patients with (17.5%) and patients without (19.7%) T allele ($p = 0.50$).

In conclusion, these results do not support a relevant role for C825T *GBN3* polymorphism in the mechanisms leading to thrombosis and restenosis after coronary stent placement.

P2809 Polymorphisms in the fibrinogen and the glycoprotein IIIa genes and recurrent restenosis after second PTCA

H. Völzke[1], S. Hertwig[2], R. Rettig[2], W. Motz[3]. [1]*Medical Department B;* [2]*Department of Physiology, Ernst Moritz Arndt University Greifswald;* [3]*Centre of Cardiology Karlsburg, Germany*

Recurrent restenosis limits the benefits of PTCA in about 30% of cases. We have recently investigated the association of the β-fibrinogen G/A-455 (Fib455 G/A) and the glycoprotein IIIa PI A1/P1 A2 (GP IIIa PIA1/PIA2) gene polymorphisms with the risk of restenosis after coronary angioplasty (PTCA). This study was designed to investigate whether the these polymorphisms are associated with recurrent restenosis after a second PTCA.

Methods: One hundred and fifty-four out of 511 consecutive PTCA patients were re-dilated on a restenotic lesion and investigated prospectively. One hundred and forty-three patients (92.9%) underwent follow-up angiography. Recurrent restenosis was defined as >50% progression of the residual stenosis after the second PTCA. Patients were genotyped using PCR and PCR/RFLP techniques. The frequencies of recurrent restenosis were compared among patients with different Fib and GP IIIa genotypes.

Results: The overall frequency of recurrent restenosis was 31%. Baseline clinical data (sex, age, history for diabetes and hypertension, current blood pressure, current smoking, serum lipid levels) did not differ among patients with and without recurrent restenosis. Patients with different Fib455 and GP IIIa genotypes showed similar frequencies of recurrent restenosis (35% in Fib455GG genotyped patients vs. 27% in C allele carriers; n.s. and 30% in GP IIIa PIA1/A1 genotyped patients vs. 35% in PIA2 allele carriers; n.s.).

In conclusion: These results show that the Fib 455 G/A and the GP IIIA PIA1/PIA2 polymorphisms are not associated with the risk for recurrent restenosis after a second PTCA.

P2810 Loading dose of ticlopidine: a simplified approach to intracoronary stent management

F. Paganelli[1], M.C. Alessi[2], R. Gelisse[1], A. Saadjian[1], V. Tarasmasco, I. Juhan-Vague[2], S. Lévy[1]. [2]*Department of Haematology and Haemostasis;* [1]*Department of Cardiology, University of Marseille, School of Medicine, Marseille, France*

Backgroun: Ticlopidine (T), in addition to aspirin reduced both stent thrombosis and ischemic complications post percutaneous transluminal coronary angioplasty (PTCA). Action of T is slow and take at least three days to have a full inhibitory effect on platelet aggregation. It has been demonstrated that a loading dose of T (1500 mg a day) exerts the same effect in 24 hours. We hypothesized that a loading dose of T given the day before PTCA, might reduce the hospital stay without more ischemic complication (non-Q-wave myocardial infarction, NQWMI).

Methods: We reviewed outcomes in 376 consecutive patients (pts) treated with ticlopidine prior to stenting. We assessed the occurrence of NQWMI (an elevation in creatine kinase > 220 IU/L with >4% MB fraction) between the group with loading dose and standart dose.

Result: 212 pts received T (500 mg/day) 3 days before and 164 pts received a loading dose (1500 mg) the day before PTCA. There were no major in-laboratory ischemic complication (death, Q wave MI, emergency bypass surgery) within the study population. Characterics of pts were as follow.

	Loading dose	Standart dose
Number of patients	164	212
Mean age (year)	68.3	57.6
Unstable angina (%)	40.8*	23.7
Previous bypass (%)	2	2
B2 or C lesion (%)	63.4*	43.5
Diabetes (%)	31.2	20.2
Average n° of treated vessels	1.7	1.1
Mean left ventricular ejection fraction (%)	37.2*	53.4
Non-Q-wave myocardial infarction (%)	20.1	21.6
Days in hospital (mean ± SD)	5.3 ± 3.8*	9.7 ± 4.2

*$p < 0.05$

Conclusion: Despite high risk criteria for PTCA*, giving a loading dose of T the day before PTCA may reduce the hospital stay without more ischemic complication.

LATE RESULTS OF CORONARY INTERVENTION

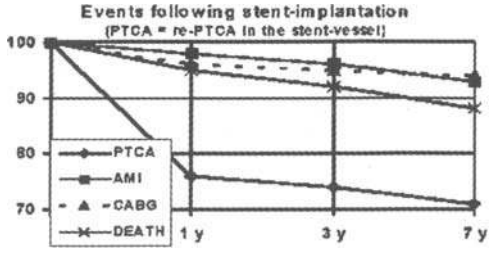
P2811 8 years clinical follow-up after intracoronary stent implantation

M. Conze, G. Strupp, G. Schreiner, B. Plappert, T. Bonzel. *Medizinische Klinik I, Klinikum Fulda, Fulda, Germany*

The clinical outcome of the first consecutive 100 patients (mean age 59 y [27–79], 84% male) with intracoronary stent implantation (Palmaz-Schatz) in our hospital since 1990 was studied.

Clinical follow-up was obtained over a mean observation period of 5.8 years (4–8 y). Angiographic controls were performed after 3, 6 or 12 months, clinical controls in 1995 and in 1998.

Indications for stenting were unsuccessful PTCA in 88% (39% total vessel occlusion, 49% recoil > 50%) and restenosis in 12%. Stent implantation was performed in 8.8% of all PTCA procedures in this period. Mean EF was 61% (24–89%). Anti-coagulation consisted of ASS, heparin and coumadine. The percentage of patients with 1, 2 or 3-vessel disease was 42%, 39% and 19%. After 1 y angiographic controls revealed a 26% cumulative rate of restenosis (stenosis > 50%), 94% of these underwent successful re-PTCA. Up to february 1998 the total number of deaths was 12% (including 4 non-cardiac deaths), of myocardial infarctions was 7%, CABG 6%, 16% PTCA in different vessels, re-PTCA in stented vessels 29%.



Events following stent implantation.

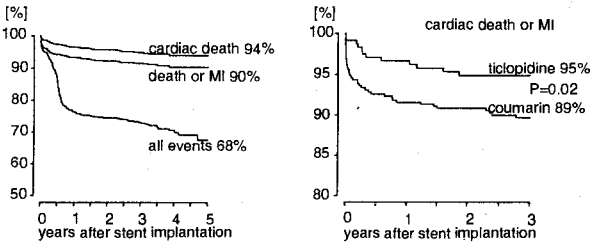
Within 8 years after stent implantation, mortality, incidence of myocardial infarction or CABG in unselected patients are low. There is a low rate of re-PTCA after 1 y and in the observation period beyond 1 y. Serious adverse long-term effects of coronary stent implantation were not observed.

P2812 Five-year clinical outcome after coronary stent placement

H. Walter, A. Kastrati, M. Röhl, T. Ludwig, A. Wehinger, F.-J. Neumann, A. Schömig. *Deutsches Herzzentrum; 1. Med. Klinik rechts der Isar, TU München, Munich, Germany*

There is still little information about the clinical long-term follow-up after coronary stent placement and whether the initial benefit of antiplatelet therapy is maintained over time. The present study investigates the long-term course (more than three years) of 632 patients (pts) who had successful coronary stent implantation from May 1992 to May 1995. The postinterventional therapy was conventional anticoagulation with coumarin in 62% of the pts and combined antiplatelet therapy (CAT) with aspirin und ticlopidine in 38%. Long-term follow-up was completed in 97% of the pts. Repeat angiography 6 months after stent placement was carried out in 82% of the patients and restenosis rate (≥50% diameter stenosis) was 26.5%. Clinical endpoints were cardiac death, myocardial infarction (MI), repeat angioplasty or coronary artery bypass surgery.

The Kaplan-Meier curves (left) show the event-free survival over 5 years of follow-up. The figure on the right shows the comparison between the two therapy groups after three years.



With a five-year cumulative cardiac death rate of 6%, coronary stenting is associated with a good clinical long-term outcome. The proven initial benefit of pts with CAT is maintained at long-term.

P2813 Ten-year follow-up after intracoronary stenting

F. Post[1], H.J. Rupprecht[1], B. Nowak[1], R. Erbel[2], W.-A. Werth[1], J. Meyer[1]. [1]*II. Medical Clinic, University of Mainz;* [2]*Department of Cardiology University of Essen, Germany*

The use of intracoronary stents has rapidly increased within the last decade. Nevertheless, very little is known so far about the long-term outcome of intracoronary stenting. Thus, we examined 58 patients at a mean of ten years after intraoronary stenting.

Method: In 58 patients, who received a Palmaz-Schatz stent at a mean of ten years before follow-up, data was obtained from hospital charts, a contact with the personal doctor and a contact with the patient. The patients were asked to complete a structured interview at our center; if this was not possible the interview was sent to the patient to be completed. Data then was analyzed for the following endpoints: death of any cause (Death), myocardial infarction (MI), Re-PTCA of any vessel (Re-PTCAP), CABG and any of the events mentioned above (Any event).

Results: The table shows the results: 14 patients died within follow up period of 10 years, 7 patients of cardiac death, 3 patients of non-cardiac death and in 3 patients the cause was not known.

	First year	After first year	Overall
Death	2 (3.4%)	12 (20.7%)	14 (24.1%)
MI	2 (3.4%)	4 (6.8%)	6 (10.3%)
Re-PTCA	14 (24.1%)	14 (24.1%)	28 (48.3%)
CABG	6 (10.3%)	8 (13.8%)	14 (24.1%)
Any event	21 (36.2%)	18 (31.0%)	39 (67.2%)

Conclusion: Ten years following Palmaz-Schatz stent implantation we did observe favourable results, especially after the first year. Since nowadays acute complications are less than 10 years ago this data are very promising.

P2814 Long-term results with the Wiktor coil stent: angiographic data from a consecutive series of 300 lesions

J. Wöhrle, T. Becke, J. Maier, M. Kochs, M. Höher. *Dept. of Cardiology, University of Ulm, Ulm, Germany*

Coil stents have been suspected to be associated with an increased rate of delivery failures, of recoil, and of restenosis due to plaque protrusion. In this study we analyzed the clinical and the angiographical outcome of a consecutive, 'real-world' series of Wiktor™ stent implantations.

A total of 374 stents were implanted in 300 lesions (248 de-novo and 52 restenotic; 128 LAD, 32 CX, 122 RCA, 18 CABG) from 283 patients. The clinical status included 9% acute and 26% recent myocardial infarctions, 31% unstable and 34% stable angina. There were 57% AHA type B2/C stenoses, including 48 total occlusions. Stent indications were an unsatisfying PTCA result in 82%, vessel closure in 5%, and primary stenting in 13%.

Success rates of stent delivery increased from 91.3% (initial 51 lesions) to 98.4%. Post-procedure ticlopidine and ASS was given for 2–3 months. Angiographic follow-up was performed in 81% after 175 ± 47 days. MLD [mm] was 0.48 ± 0.43 pre PTCA, 2.32 ± 0.59 after stenting, and 1.61 ± 0.97 at follow-up, resulting in a late loss index of 0.36 ± 0.55. The balloon-to-artery ratio was 1.24 ± 0.23 with a reference diameter (RD) of 2.66 ± 0.73 mm pre PTCA and a 16.2 ± 8.6% residual stenosis after stenting.

The occurrence of restenoses significantly correlated ($p < 0.05$) with the use of high pressure dilation, the number of stents per lesion, a smaller RD, and a lower MLD post stenting. No impact had lesion type and location, dissection type and the balloon-to-artery ratio.

	RD ≥ 3.0 mm	RD < 3.0 mm	MLD ≥ 2.5 mm	MLD < 2.5 mm
Restenosis	19.6%	41.9%	25.0%	41.8%
Reinterventeion	14.3%	34.4%	15.3%	35.9%

(RD = reference diameter pre PTCA, MLD = minimal lumen post stenting)

We conclude that coil stent delivery failure is much less frequent than suspected. The restenosis rate in an unselected patient group is comparable to more recent multi-cellular stents and remains below 20% in larger vessels.

P2815 Four years follow-up of the start trial, a randomized stenting versus PTCA study

M. Masotti, A. Serra, F. Fernández-Avilés[1], J. Alonso[1], F. Gimeno[1], T. Colman[2], J. Zueco[2], J.L. Delcán[3], E. García[3], J. Calabuig[4], A. Betriu. *Cardiovascular Institute, Hospital Clínic, Barcelona; [1]Hospital Clínico, Valladolid; [2]Hospital Marqués de Valdecillas, Santander; [3]Hospital Gregorio Marañon, Madrid; [4]Clínica Universitaria, Pamplona, Spain*

Background: Randomized trials have conclusively shown that, compared with angioplaty (PTCA), stent implantation reduces restenosis rate in "de novo" coronary artery lesions. Although this seems to translate into early clinical benefit, the impact of stenting on clinical events has not been assessed in the long run.

Objective: The present investigation was conducted with the aim of ascertaining whether the long term clinical outcome of patients (pts) treated with stents was better than those of pts undergoing PTCA.

Methods: Clinical data of START (Stent vs Angioplasty Restenosis Trial), a spanish multicenter randomized study, were analyzed at a mean of 52.4 ± 17 months after randomization in 436 (96%) of 452 pts enrolled. The following end-points were considered: cardiac death, target lesion revascularization (TLR), and non fatal myocardial infarction (MI).

Results:

	Death	TLR	MI	Total
Stent (225)	6 (2.7%)	27 (12%)	5 (2.2%)	38 (17%)
PTCA (211)	5 (2.4%)	52 (24.6%)	6 (2.8%)	63 (30%)
p	ns	<0.00	ns	<0.01

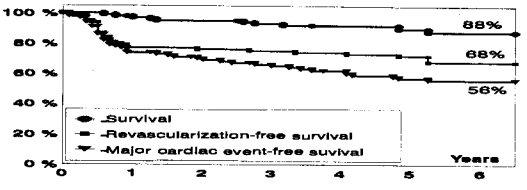
Conclusions: The early clinical benefit of stenting is sustained in the long run, as manifested by a significant reduction in the necessity of further revascularization procedures beyond the ensuing 4 years.

P2816 Five-year follow-up after coronary stenting: survival, event-free survival and freedom from new revascularization

J.J. Alonso, J.M. Durán, F. Gimeno, B. Ramos, J.C. Muñoz, L. de la Fuente, E. García-Morán, A. Ortiz, A. Serrador, F. Fernández-Avilés. *Hospital Universitario, Valladolid, Spain*

To assess the clinical efficacy of coronary stenting (CS) 5 or more years after implantation we followed 130 consecutive pts (mean age: 61 ± 9 years, 88% males) who underwent successful CS in 138 lesions from January 1991 to January 1993. Angiographic follow-up (FU) was performed in 95% of pts at 6.9 ± 4 months Clinical FU was completed for 97% of pts. Mean time to clinical FU was 5.0 ± 1.2 years (range: 5–6.5 years). Left ventricular ejection fraction was 0.62 ± 0.12 and 48% of pts had multivessel disease. Indication for PTCA was unstable angina in 66% of pts and CS was elective in 56%.

At six months 24% of pts (CI 95%: 17–32%) had angiographic restenosis (>50% QCA-criterion). During FU, 14 pts (11%, CI 95%: 6–18%) died (7 cardiac deaths) and 7 pts (5%) required admission for AMI or unstable angina. Stent failure demanded a new revascularization in 19% of pts (CI 95%: 13–27%). However over the last 4 years of FU, only 1 pts (0.8%) needed new revascularization due to Stent failure. At the end of FU 91% of surviving pts remained asymptomatic whereas freedom from angina or major cardiac events was 61%.



Thus: 1) survival, angina-free survival, and event-free survival 5 o more years after CS are acceptable; 2) After 1 year post-CS, events and revascularization related with the stented vessel are exceptional.

P2817 Immediate and long-term clinical and angiographic results of coronary stenting in stable and unstable angina patients

D. Trabattoni, S. Galli, A. Loaldi, P. Montorsi, F. Fabbiocchi, L. Grancini, S. Cozzi, P. Ravagnani, A.L. Bartorelli. *Institute of Cardiology, University of Milan, "Monzino" Foundation, IRCCS, Milan, Italy*

Higher rates of major adverse events and restenosis after PTCA have been reported in unstable angina compared to stable angina patients. Aim of our study was to compare clinical and angiographic outcomes following coronary stent implantation in 736 stable (S) and 360 unstable (U) angina pts between May '92 and February '98. The analysis of major coronary risk factors showed a relative increase in male gender (86.5% vs 79.7%, p = 0.004), higher cholesterol levels (52.9% vs 45.5%, p = 0.02) and a previous history of Q-wave MI (41.4% vs 31.9%, p = 0.002) in S compared to U pts. No differences were observed in coronary disease extension (1-VD: 53.8% S vs 51.9% U, ns; 2-VD: 31.8% vs 35.5% U, ns; 3-VD: 14.4% S vs 12.5% U, ns), stented vessel (LAD: 49% S vs 53.4% U, ns; RCA: 30% S vs 28.7% U, ns; LCx: 17.8% S vs 12.8% U, p = 0.02; Graft: 2.9% S vs 5% U, ns) and lesion type (A: 5.7% S vs 7.8% U, ns; B1: 41.7% S vs 32% U, p = 0.05; B2: 40.6% S vs 49% U, ns; C: 12.4% S vs 11.4% U, ns). Coronary lesions were longer in S pts: 16.7 ± 8.6 mm vs 13.8 ± 7.8 mm in U (p = 0.01). Bailout stenting in U pts was twice that observed in S (20.2% vs 11.8%, p = 0.001) due to a more frequent occurrence of flow limiting dissections and abrupt closure. Similar were the number of stent/pt (S: 1.14 ± 0.41, U: 1.15 ± 0.55, ns), maximal inflation pressure (S: 15.3 ± 2.33 atm, U: 14.6 ± 2.96 atm, ns) and final balloon diameter (S: 3.53 ± 0.56 mm, U: 3.54 ± 0.5 mm, ns) in both groups. High procedural and clinical success were achieved in U pts (95.8% and 96.4%), similar to that obtained in stable angina (96.6% and 97.9%, ns). Amongst in-hospital complications, no differences were observed in stent thrombosis (0.5% S vs. 0.9% U, ns) and need for urgent CABG (0.5% S vs 1.4% U, ns) while a greater incidence of death (0.1% S vs 1.6% U, p = 0.006), Q and non-Q wave MI (1.7% S vs 4.7% U, p = 0.009) and major bleeding (0.9% S vs 4.1% U, p = 0.0007) occurred in U pts. Cumulative data of 6-mos F/U, so far available in 70% of S and 72.9% of U pts, showed a three-fold higher incidence of recurrent angina in U pts (4.4% S vs. 10.6% U, p = 0.001) but no difference in the rate of Q-wave MI (0.5% S vs. 0.9% U, ns), death (0% S vs 0.8% U, ns), Re-PTCA (14.5% S vs. 16.2% U, ns) and CABG (2.5% S vs 2.9% U, ns). Angiographic restenosis was 25.8% in S and 35.8% in U pts (p = 0.002).

Conclusions: 1. Stenting was associated with high and comparable acute success in S and U pts; 2. Although MACE were observed more frequently in unstable angina, their incidence was significantly lower than that previously reported for PTCA; 3. Six-month F/U showed higher recurrence of angina and angiographic restenosis in unstable pts.

P2818 Long-term angiographic patency of recanalized chronic coronary total occlusions associated with sub-intimal dilatation

E. Tsuchikane, T. Kobayashi, N. Awata, O. Katoh[1]. *Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka; [1]Kyoto Katsura Hospital, Kyoto, Japan*

Successful recanalization of chronic coronary total occlusions (CTO) by PTCA sometimes involves sub-intimal dilatation (SID) which produces pseudo lumen. However, long-term patency of recanalized CTO associated with SID is unknown. This study aimed to examine the long-term angiographic outcomes of recanalized CTO with SID. Five hundred and seven CTO (TIMI flow grade = 0, occlusive duration ≥ 3 months) were successfully recanalized by PTCA. Long-term follow-up angiography was obtained in 427 lesions (84.2%) 215 ± 142 days after the initial PTCA. One hundred and twenty-eight lesions were recanalized with SID (SI group) and 299 lesions without SID (I group). There were significant differences in lesion morphology and procedural results between the two groups (Table). Stents were implanted in 36% of SI group and in 26% of I group. Initial restenosis rate, times of revascularization (TLR) and final patency rate are shown in the table.

	SI group (n = 128)	I group (n = 299)	P value
Reference diameter ≥ 2.5 mm	46.1%	56.9%	0.04
Occlusion length ≥ 20 mm	47.7%	29.1%	0.002
Post MLD ≥ 2.0 mm	17.9%	39.1%	<0.0001
Initial restenosis rate	80.5%	47.8%	<0.0001
Times of TLR	1.5 ± 1.5	0.9 ± 1.1	<0.0001
Final patency rate	89.1%	95.7%	0.03

In SI group, primary stenting provided the patency rate of 100% ($p < 0.01$ vs 84.8% of non-stenting sub-group), and it was the only predictor of final patency detected by multiple regression analysis.

Conclusion: Recanalized CTO with SID has a disadvantage in lesion morphology and procedural results which requires frequent TLR. However, a favorable long-term patency can be expected, especially by primary stenting, even if CTO is recanalized with SID.

TRANSMYOCARDIAL REVASCULARIZATION

P2819 Transmyocardial revascularization and percutaneous myocardial revascularization improve exercise tolerance: results from the cardiogenesis ATLANTIC and PACIFIC trials

N. Ali. *Section of Cardiology 111B, VA Medical Center, Houston TX, USA*

Background: Transmyocardial Laser Revascularization (TMR) and Percutaneous Myocardial Laser Revascularization (PMR) are being investigated for the treatment of patients with intractable angina that is refractory to conventional therapies. The ATLANTIC TMR and PACIFIC PMR prospective randomized trials evaluate whether TMR and PMR can improve functional capacity in patients with CCSAS Class III or IV angina.

Methods: In the ATLANTIC Trial, 182 patients with Class III or IV angina untreatable by conventional therapies were randomized at 16 centers in the US to continuing medical therapy or to continuing medical therapy plus surgical TMR with the CardioGenesis TMR System. In the PACIFIC Trial, 235 patients were randomized at 13 sites (12 in the US, 1 in the UK) to continuing medical therapy or to continuing medical therapy plus PMR with the CardioGenesis PMR System. All patients in both studies showed objective evidence of reversible ischemia by dipyridamole thallium scans and had an LV Ejection Fraction of >30%. Improvement in exercise time under standardized testing was a primary endpoint in both studies.

Results: In the ATLANTIC Trial, treated patients showed an average improvement in exercise tolerance of 31% at 3 months, and a continued improvement of 35% over baseline at 6 months. In the PACIFIC Trial, treated patients showed an average improvement of 28% at 3 months. Furthermore, analysis of data from the ATLANTIC Trial showed that ST segment depression indicative of ischemia occurred at higher work loads at both 3 and 6 month following TMR. This provides objective evidence of improvement in ischemia and functional capacity.

Conclusions: Results indicate that myocardial laser revascularization, whether performed surgically or percutaneously, results in clinically significant improvement in functional capacity in Class III and Class IV patients. 12-month ATLANTIC and 6-month PACIFIC randomized data will be presented.

P2820 Six month follow-up of a prospective randomized trial of percutaneous transmyocardial revascularization vs medical therapy in patients with refractory angina

P. Whitlow, S.J. DeMaio, E.C. Perin, W.W. O'Neill, J.M. Lasala, J. Schneider, W.D. Knopf, A. Ezratty, F.A. Shawl, E. Powers. *Cardiology-F25, The Cleveland Clinic Foundation, Cleveland OH, USA*

Background: Percutaneous Transmyocardial Revascularization (PTMR) has been reported to improve angina in medically refractory patients ineligible for CABG and PTCA. A prospective randomized trial of Eclipse Holmium Laser PTMR vs Medical Therapy in inoperable, Class III–IV patients completed enrollment 10/98.

Methods: 335 patients were randomized 12/97–10/98: 169 to PTMR, and 166 to Maximal Medical Therapy (MM).

Results: Baseline characteristics were similar: Mean age 63 ± 11, 74% male, history of hypertension 75%, MI 67%, PTCA 68%, and CABG 82%, mean EF 47% ± 10, mean angina class 3.4 ± 0.5. 19 ± 7 channels were made in the ischemic myocardium of treated patients. Total procedure time averaged 86 minutes; total laser time averaged 23 minutes. There was one peri-procedural death, 5 other cases of cardiac tamponade (3.0%), and 4 peri-procedural non-Q MIs (2.4%). At 3-months, mean improvement in angina class for PTMR was twice that of the control group (1.6 vs 0.8 classes, class 1.8 vs 2.6, $p < 0.0001$). Exercise tolerance improved 18% (80 secs) in the PTMR group while decreasing 15% (84 secs) in MM ($p < 0.001$) in the 72 patients with complete 6 month data. At 6 months, total deaths are 5 (3.0%) in PTMR and 6 (3.6%) in MM (p = ns).

Conclusions: Initial results of this randomized study suggest that PTMR provides significantly greater angina relief and functional improvement than does medical therapy in patients with Class III-IV refractory angina. Complete 6-month follow-up data will be presented.

P2821 Percutaneous myocardial revascularization: results from the roll-in phase of the PACIFIC trial

S.N. Oesterle. *Massachusetts General Hospital, Boston MA, USA*

Percutaneous Myocardial laser Revascularization (PMR™) is being investigated for the treatment of patients with severe angina and judged unsuitable for conventional revascularization therapies (CABG or PTCA). Preliminary results from the U.S. and Europe demonstrated the safety of the procedure and suggest improvement in angina class and exercise tolerance following PMR. We present results including 12-month follow-up data from the roll-in (training) phase of the CardioGenesis PMR™ System (PACIFIC) Trial.

Methods: Patients received PMR treatment in the roll-in phase of the PACIFIC trial beginning in July 1997. To be eligible for PMR, patients were required to have: i) stable Class III or Class IV angina refractory to medical therapy; ii) ejection fraction of ≥ 30%, iii) demonstrated ischemia by stress nuclear imaging, and iv) judged to be ineligible for CABG or PTCA. The average patient age at 60, and the incidence of hypertension (69%), hyperlipidemia (79%) and diabetes (44%) were consistent with other TMR trials. The majority of patients had a history of CABG (26%), PTCA (8%) or both therapies (58%).

Results: PMR treatment was successfully completed in 72 patients. The procedural safety profile was encouraging with no procedural or device related deaths and no surgical intervention required. Primary endpoints of angina class (CCSAS) and exercise tolerance time (Modified Bruce Protocol) both demonstrated improvement. Fifty-nine percent of the baseline Class IV patients experienced a drop of 2 or more angina classes at 3 and 6 months post treatment. Exercise tolerance improved in both baseline Class III and IV patients, with Class III patients showing an average increase of 29% and Class IV patients experiencing an average increase of 51% in exercise time at 6 months. Anecdotal 12-month exercise data for these patients also appears promising. PMR patients experienced quality of life improvements as measured by the Seattle Angina Questionnaire. Adverse events were minimal and included one instance of myocardial perforation, treated with pericardiocentesis and one instance of complete heart block (pre-existing RBBB) requiring placement of a permanent pacemaker. There were 3 non-device, non-procedure related deaths in this severely ill roll-in cohort.

Conclusion: PMR may offer interventional cardiologists a new option for treatment of intractable angina secondary to diffuse coronary artery disease. PMR has an excellent safety record and appears to results in angina relief and increased exercise capacity. Further one-year follow-up data will be presented.

P2822 Percutaneous myocardial revascularization (PMR): initial results from the PACIFIC trial

N. Ali. *Section of Cardiology 111B, VA Medical Center, Houston TX, USA*

Background: Percutaneous Myocardial Revascularization is catheter-based approach to create ~6 mm deep laser channels in the myocardium from the endocardial surface. The PACIFIC Trial used the CardioGenesis Axcis System to test the hypothesis that PMR can palliate symptoms and improve exercise tolerance for patients with Class III or IV angina.

Methods: 235 patients with refractory Class III or IV angina untreatable by angioplasty or bypass surgery were randomized at 13 sites to medical therapy or to PMR plus medical therapy with the CardioGenesis Axcis PMR System. All patients had objective evidence of reversible ischemia by dipyridamole thallium, a wall thickness of greater than 8 mm in the targeted region and an LV Ejection Fraction of >30%. Typically 10–18 channels were created in each targeted ischemic region. The primary endpoints of the study were change in angina class and exercise tolerance.

Results: All treatments were completed safely and successfully. There were no procedural deaths, no incidents of procedural VF, and a single incident of procedural VT requiring cardioversion. There were no incidents of myocardial perforation requiring surgical intervention. At 3 and 6 months, the majority of treated patients showed improvement in both angina class and exercise tolerance. Treated patients showed an average 1.3-class drop in angina at 3 months. 47% of treated patients experienced a drop of two or more angina classes, and 28% of treated patients had Class I or no angina at three months, while the angina class of patients in the control arm remained virtually unchanged. On average, exercise tolerance decreased slightly in the control group (−2%) while improving more than 1 minute (28%) in the treatment group at 3 months. Interim analysis suggests continued improvement in the PMR group at 6 months.

Conclusions: Results indicate that PMR with the CardioGenesis system is a relatively safe procedure, is associated with negligible morbidity, and improves the symptoms and exercise capacity of patients suffering from severe angina. Complete six-month randomized study follow-up data will be presented.

P2823 Percutaneous direct myocardial revascularization guided by Biosense™ left ventricular mapping in patients with refractory coronary ischaemic syndromes

R. Kornowski, J.W. Moses[1], D.S. Baim[2], M.K. Hong, A. Stine, R.E. Kuntz[2], M.B. Leon. *Washington Hospital Center, Washington DC; [1]Lenox Hill Hospital, New York NY; [2]Beth Israel-Deaconess Hospital, Boston MA, USA*

Background: Laser myocardial revascularization has been explored as an alternative treatment strategy for patients with chronic refractory myocardial ischemic syndromes who are not candidates for conventional modes of coronary revascularization.

Methods and Results: We used the Biosense™ 3D magnetic guidance system for direct myocardial revascularization (DMR) in 76 pts with refractory ischemic coronary syndromes (52 men, age 62 ± 11 years, EF = 48 ± 11%) to perform percutaneous DMR using Ho:YAG laser @2 J × 1 pulse per laser channel. Successful laser channels created in pre-specified target zones were achieved in 75/76 pts. Overall major cardiac adverse events were 2.6%; including no death or emergent surgery; 1 post-procedure pericardiocentesis for pericardial effusion, and 1 minor embolic stroke. Treatment zones were: anterior (30), apex (1), lateral (32), inferior (24), and postero-lateral (24). The average number of laser channels was 26 ± 9 (range 11–51). No significant changes in LV function were noted by echo one day and one month post-procedure. One month exercise duration after DMR increased from 388 ± 177 secs (baseline) to 455 ± 170 secs ($p = 0.001$) in the first 56 pts and angina (CCS) improved from 3.2 ± 0.4 to 1.9 ± 0.7 @3 months ($p < 0.001$), with 58% of pts experiencing sustained symptomatic improvement. The improvement in exercise duration @1 month was highly correlated with the number of treatment zones ($p = 0.007$).

Conclusions: Percutaneous DMR guided by Biosense™ LV mapping 1) is feasible and safe; 2) early efficacy endpoints reveal improved angina and prolonged exercise duration at 1 and 3-m follow-up. A blinded randomized clinical trial is underway to establish definitive therapeutic value.

P2824 Acute and long-term results after catheter-based percutaneous myocardial laser revascularization in patients with end-stage coronary artery disease

B. Lauer, U. Junghans, F. Stahl, R. Kluge[1], G. Schuler. *Dept of Cardiology, Heart Center; [1]Dept of Nuclear Medicine, University of Leipzig, Germany*

Background: Catheter-based percutaneous myocardial revascularization (PMR) is a safe and feasible treatment for patients with refractory angina pectoris due to coronary artery disease which are not candidates for angioplasty or bypass grafting. The study evaluates the acute and long-term results after PMR in patients with end-stage coronary artery disease.

Methods: 60 Patients (P) (64.1 ± 9.0 years) were treated with PMR. Regions with stress induced ischemia were located by thallium scintigraphy in the anterior wall in 32 P, in the lateral wall in 21 P and in the inferior wall in 36 P (25 P had stress-induced ischemia in more than one region).

Results: PMR was successfully performed in all P. 11.4 ± 4.0 (6–21) laser channels were created per region treated. Creatine kinase levels rose from 80 ± 37 U/l before PMR to 149 ± 67 U/l after PMR. Adverse procedural effects included arterial bleeding in 1 P, transient renal failure in 1 P and small pericardial effusions (<5 mm) in 8 P detected echocardiographically not requiring drainage. Clinical symptoms, exercise time on standard bicycle ergometry and thallium uptake in the PMR-treated regions during thallium scintigraphy (compared to the non-treated septum) are given in the table:

	Baseline (n = 60)	3 months (n = 43)	6 months (n = 38)	12 months (n = 24)
CCS-class	3.3 ± 0.5	1.7 ± 1.0*	1.4 ± 0.7*	1.4 ± 0.9*
Exercise time (sec)	346 ± 141	447 ± 183*	460 ± 162*	442 ± 168*
Thallium uptake (%)	76 ± 15	74 ± 14	76 ± 14	74 ± 12

*: $p < 0.01$ vs. baseline

Conclusion: PMR results in significant and persisting improvement of anginal symptoms and increased exercise capacity, but thallium scintigraphy did not show improved myocardial perfusion after PMR.

P2825 Percutaneous direct myocardial revascularization: safety and feasibility of high-density myocardial laser therapy and 1-month follow-up

A. Keck, T. Twisselmann, R. Küchler, M. Schlüter, M. Özalp, R. Kitzing, Karl H. Kuck. *St. Georg Hospital, Hamburg, Germany*

The Biosense DMR™ technology combines a novel 3-dimensional (3D) navigation and mapping system with a catheter capable of delivering laser energy. After 3D reconstruction of the left ventricular endocardial contour, the tip of the laser catheter is visualized in real-time to allow positioning in the ischemic target region. A single laser pulse of 2 J is delivered to the myocardium when endocardial contact of the catheter is stable for 3 consecutive beats. 27 pts with severe coronary artery disease were included in this study. All pts were "no option" pts with regard to PTCA or CABG suffering of angina CCS III and IV (LV EF 58 ± 11%). **32 ± 7** laser channels (inter-channel distance approx. 8 mm) were delivered per pt. Periprocedural complications: Pericardial effusion in 2 pts, non-sustained VT in 4 pts. Follow-up (34 ± 3 days) was obtained from 21 pts (17 m, 4 f; 59 ± 11 years). Treadmill exercise time increased from 351 to 402 sec ($p < 0.05$), angina decreased from CCS 3.3 pre- to CCS 2.0 post DMR ($p < 0.05$). SPECT showed improvement in 11 pts, no difference in 6 pts and worsening in 4 pts.

Conclusion: High-density delivery of myocardial laser channels is a safe and feasible method when a computer guided navigation system is used. One month after DMR there is a significant increase in treadmill exercise time and a decrease in angina.

P2826 Efficacy and safety of percutaneous transluminal myocardial revascularization with the holmiun laser fiberoptic system

E. García[1], M. Viecca[2], M. Galli[2], A. Bertone[4], M. Abeytua[1], R. Moreno[1], J.L. Delcán[1]. [1]*Hospital Gregorio Marañón, Madrid, Spain;* [2]*Ospedale L. Sacco, Milan;* [3]*Ospedale S Anna, Como;* [4]*Ospedale Policlínico, Bari, Italy*

Purpose: To examine the safety and efficacy of performing Percutaneous Transluminal Myocardial Revascularization (PTMR) using the Eclipse laser system, the inmediate and midterm results of 53 patients who underwent the procedure at 4 different centers were analysed.

Methods: PTMR was performed in patients (p) with severe coronary artery disease unsuitable for surgical or percutaneous revascularization. Pre-procedure echocardiography was performed to assess myocardial wall thikness. The technique was performed via the femoral artery through a 9 French introducer. After the procedure, the patients underwent exercise test, when possible.

Results: Mean age was 64 ± 8 (71% male). Diabetes mellitus was present in 25 p (47%), hypertension in 27 (51%) and hipercholesterolemia in 34 (64%). All p were in class III or IV angina, 52 (98%) had multivessel disease, 28 (52%) had prior surgical and 23 (43%) previous percutaneous revascularization (PTCA). Mean left ventricular ejection fraction was 45 ± 9. In 4 p a combined PTMR and PTCA was performed. Procedural and fluoroscopy time was 52 ± 16 and 24 ± 12 minutes respectively. A total of 81 myocardial regions were treated (39 anterior, 29 latero-posterior and 17 inferior) producing an average of 14 ± 5 channels per procedure. There was no mortality or periprocedural myocardial infarction. Two patients had pericardial effusion (1 cardiac tamponade). At midterm follow up (6 ± 3 months) angina class improved in 44 (88%), there was no change in 5 (9%) and worsened in 1. Exercise test showed improved exercise tolerance in the 32 patients in whom it was performed. In 3 patients a repeated PTMR procedure was performed because or persistence of symptoms. No p has died or had suffered myocardial infarction at follow-up.

In conclusion: Percutaneous Transluminal Myocardial Revascularization is a safe and efficacious technique for reducing symptoms and improving exercise tolerance in patients unsuitable for conventional percutaneous or surgical revascularization.

P2827 Left ventricular electromechanical mapping for detection of myocardial viability in patients with impaired left ventricular function

H.E. Botker, J.F. Lassen, F. Hermansen[1], P. Sogaard, Y. Kim, A.K. Pedersen, L. Thuesen. *Department of Cardiology, Skejby University Hospital, Aarhus;* [1]*PET-Centre, Aarhus University Hospital, Aarhus, Denmark*

Aim: NOGA is a 3-dimensional left ventricular (LV) mapping sys-tem that uses low-intensity magnetic field energy to determine the localisation of sensor-tipped electrode catheters within the heart. We evaluated the ability of the system to distin-guish between irreversibly and reversibly dysfunctional myocar-dium in patients with impaired LV-function.

Methods: Unipolar voltage potentials and local endocardial shortening were measured in 13 patients (mean ± SD age 59 ± 12 years) with ischaemic cardiomyopathy (EF 32 ± 10%). Dysfunctional regions, identified by 2-D echocardiography, were characterised as irreversible when positron emission tomo-graphy (PET) revealed matched reduction of perfusion (13-N ammonia) and metabolism (18-FDG) and reversible when perfusion was reduced and metabolism preserved. For comparison with echocardiography and PET LV-mapping data were entered in a 9-segmental polar map.

Results: Out of 117 segments, 115 were assessable (table).

Segment characteristic	Unipolar voltage (mV)	Local Shortening (%)
Normal (n = 36)	11.5 ± 3.7	7.7 ± 3.3
Reversible (n = 30)	7.3 ± 3.1*	4.2 ± 2.5*
Irreversible (n = 49)	4.9 ± 2.2* **	2.9 ± 2.9*

*p < 0.01 vs. normal, **P < 0.01 vs. reversible. Mean ± SD.

Conclusion: LV electromechanical mapping detects electrical as well as mechanical impairment in irreversibly dysfunctional myocardium and impaired mechanical but preserved electrical activity in reversibly dysfunctional myocardium. LV mapping may enable detection of on-line myocardial viability in the catheterisation laboratory.

P2828 Radiofrequency percutaneous myocardial revascularization: a unique system for simultaneous radiofrequency percutaneous myocardial revascularization and gene therapy

R.R. Heuser. *Phoenix Heart Center, Phoenix AZ, USA*

Background: Percutaneous myocardial revascularization (PMR) and transmyocardial revascularization (TMR) use laser energy to form channels in the myocardium and stimulate angiogenesis in swine models. Combining TMR and gene therapy has been shown to yields greater angiogenesis than TMR alone. Recent studies indicate that radiofrequency energy–which is less expensive to administer than laser energy–is an effective means of stimulating angiogenesis.

Methods: A 0.014 cm radiofrequency guidewire was passed through 6 French and 3 French catheters for percutaneous insertion in 3 swine under general anesthesia. A total of 30 channels (1 cm apart) were formed using radiofrequency energy in each animal. Automated ventriculography confirmed the presence of channels, and the animals were sacrificed.

Results: No animal suffered cardiac tamponade using this technique, and radiofrequency energy was easily applied through the 6 French system. The catheter was flexible, yielding access to all areas of the myocardium in the left ventricle. Successful injection through this hollow wire system indicates that gene therapy material could be delivered through it. At sacrifice, multiple sites of ecchymosis were confirmed on the endocardial and epicardial surfaces, but there was no evidence of inappropriate perforation.

Conclusions: Percutaneously applied radiofrequency energy delivered through a hollow guidewire successfully generates nontransmural channels in swine and is less expensive and easier to administer than laser energy. Further study is needed to confirm the system's ability to stimulate angiogenesis and its utility in delivering gene therapy.

P2829 Parameters influencing the clinical outcome after percutaneous myocardial laser revascularization

U. Junghans, F. Stahl, M. Schoenauer, B. Lauer, G. Schuler. *Dept. of Cardiology, Heart Center, University of Leipzig, Germany*

Background: In the majority of patients with refractory angina pectoris due to end-stage coronary artery disease (CAD) percutaneous myocardial laser revascularization (PMR) leads to improvement of clinical symptoms and exercise capacity. The extent of improvement shows great variations. Clinical factors influencing the outcome after PMR have not yet been determined.

Methods: 45 patients (P) (mean age 64.1 ± 8.7 years; 38 men, 7 women) were treated with PMR. Clinical parameters (Canadian Cardiovascular Society [CCS] angina scale, use of additional nitroglycerin [semiquantitatively in 6 grades]) and results of non-invasive tests (bicycle exercise test, echocardiography) were analysed before and 3 months after PMR. Left ventricular function (LVF) was normal (ejection fraction [EF] > 60%) in 25 P. LVF was moderately reduced (EF 40–60%) in 14 P and severly reduced (EF < 40%) in 6 P.

Results:

Change in	EF > 60%	EF 40–60%	EF < 40%
CCS-class	−1.7 ± 0.9**	−1.7 ± 1.1**	−1.0 ± 0.9
Use of nitrates (grades)	−2.2 ± 1.8**	−2.1 ± 1.7**	−1.4 ± 1.7
Exercise capacity (s)	+73 ± 218	+193 ± 234*	−30 ± 222

*p < 0.005 vs baseline, **p < 0.001 vs baseline

The extent of CAD (1-, 2- or 3-vessel disease) and the number of laser channels created per region had no influence on clinical success.

Conclusion: Improvement of clinical symptoms after PMR was more pronounced in P with normal or only moderately reduced LVF compared to P with severely reduced LVF. Exercise capacity improved only in P with normal or moderately reduced LVF whereas it did not change in P with severely reduced LVF. Extent of CAD and number of laser channels seem to have no influence on clinical outcome after PMR.

P2830 Systolic function of lased myocardium improves after transcatheter laser therapy

M. Weisbach, T. Twisselmann, K. Hertting, E. Bahlmann, A. Keck, R. Küchler, K.H. Kuck. *Dept. of Cardiology, St. Georg Hospital, Hamburg, Germany*

Direct transcatheter application of laser energy to the endocard of the left ventricle with a non-fluoroscopic guided device (Laser-Star™, NOGA™) is a novel method for the treatment of end-stage coronary artery disease. It can improve angina stability and exercise capacity. Improvement of myocardial perfusion has been shown with SPECT. It is not known whether myocardial function can improve after treatment.

26 consecutive patients, age 61.7 (± 7.8) years, 84.6% male, with no options for interventional or surgical treatment received direct myocardial revascularisation (DMR). Based on a nine-segment-approach 46 myocardial segments were lased. An average of 29.4 (± 6.9) Single 2J-laser-pulses were delivered to scintigraphic proven ischemic myocardium, when the catheter position was stable for 3 consecutive beats. Echocardiography after an adapted nine-segment model was performed at baseline and 30 days after treatment. Contractility was classified in normal, hypokinetic, akinetic and dyskinetic for each segment.

A total of 225 segments could be examined, 52 lased (L), 173 non-lased (NL). In the L-group there was an improvement in contractilty in 11/52 (21%) segments after 30 days compared with 9/173 (5.2%) in the NL-group ($p = 0.011$). Most segments in both groups (L = 36 (69%), NL = 154 (89%)) showed no change in contractility within 30 days and deterioration of contractility occurred in 5/52 (10%) (L) vs. 9/173 (5.2%) (NL) segments (n.s.).

Conclusions. Treatment with transcatheter applied laser energy significantly improves systolic function of lased myocardial segments in comparison to non-lased areas in the same patients. The underlying mechanism discussed is angioneogensis in the lased areas. Further insights in the improvement of perfusion and the return of viability could be gained by stress echocardiography

SURGICAL TREATMENT OF ATRIAL FIBRILLATION

P2831 Maze procedure combined with mitral valve replacement or repair – late results

R. Bachowski, S. Woo, T. Mandecki[1], A. Blach, M. Skowerski[1], M.J. Matuszewski, W. Domaradzki. *2 Cardiac Surgery Dept., Silesian Heart Center, Katowice; [1]2 Dept. of Cardiology, Silesian Heart Center, Katowice, Poland*

Chronic atrial fibrillation associated with mitral valve disease is an important cause of morbidity due to embolic events and haemodynamic compromise.

40 patients (all women, mean age 54.7 years) with acquired mitral valve disease and chronic atrial fibrillation were randomized to two groups: group A had mitral valve replacement in 18 pts (90%) or repair in 2 pts (10%) combined with maze procedure. Group B had mitral valve replacement (19 pts – 95%) or repair (1 pt – 5%) only. The cause of mitral valve disease was rheumatic in 80% of patients. 24 pts (60%) had mitral stenosis, 8 pts (20%) had mitral regurgitation, 8 pts (20%) had mixed lesion. 2 pts had history of peripheral emboli in upper or lower extremities. 1 pt had previous embolic stroke. There were no peri- or postoperative deaths. Early postoperatively, in group A, sinus conversion was obtained in 80% of pts. 3 patients (15%) had AF and one patient had a temporary complete A-V block. In group B only 4 pts (20%0 were in sinus rhythm. Significant reduction in the left atrial size was documented by echocardiography in group A only (59 mm preoperatively vs. 47 mm postoperatively). However, in 12-month follow-up only 25% of pts in group A versus 15% of pts in group B still stayed in the sinus rhythm. The others had atrial fibrillation.

In our experience, encouraging early results of maze procedure combined with MVR are not confirmed in late follow-up. Despite significant reduction in left atrial size most patients go back to atrial fibrillation

P2832 Development of a safe and effective surgical treatment strategy for the curative treatment of atrial fibrillation using minimally invasive techniques

H. Kottkamp, F.W. Mohr, R. Autschbach, J. Onnasch, G. Schuler, G. Hindricks. *University Leipzig, Heart Center, Leipzig, Germany*

The Maze-operation is an effective but extensive and highly invasive procedure that requires long surgical bypass times with a considerable risk of complications. In an attempt to develop an effective but less aggressive therapeutic strategy, intraoperative radiofrequency (RF) ablation was performed in 11 pts. with chronic permanent AF during mitral valve surgery. Linear lesions (LL) in the left atrium were induced from the posterolateral mitral annulus to the left inferior pulmonary vein and continued via the upper left pulmonary and the upper right pulmonary vein to the lower right pulmonary vein. In 7 pts. access to the left atrium was achieved using a right atrial transseptal approach while in two pts. each the procedure was performed using a left atrial approach or a minimally invasive approach omitting thoracotomy. Induction of LL was achieved using a set of specially designed RF electrode probes (4–10 mm tip, temperature controlled; Sulzer Osypka Inc.). In 8 pts. RF energy was applied endocardially, while in 3 pts. endocardial and epicardial RF applications to the left atrium were performed. The efficiency of lesions induction was controlled by direct vision or using videoscopic techniques. All RF applications resulted in well delineated and contiguous atrial necrosis. Postoperatively, all pts. were in sinus rhythm. On days 2–5 following surgery 5/11 pts. developed a relapse of AF or atypical atrial flutter necessitating electrical cardioversion that was effective in all. Three of 7 pts. with a right atrial approach and 0/4 pts. with a left atrial approach or minimally invasive techniques required DDD-pacemaker implantation for sinus node dysfunction or AV-block. During follow-up (1–6 months) all but 1 pt. were in sinus rhythm or DDD-pacing.

Conclusions: The induction of contiguous left atrial lesion lines using intraoperative RF application seems to be safe and effective. The early experience with minimally invasive surgery shows that the technique is feasible and may develop to become an attractive therapeutic strategy to cure AF.

P2833 Long term follow-up of patients with mitral valve replacement and intraoperative radiofrequency ablation for curative treatment of atrial fibrillation

S.G. Spitzer, M. Knaut[1], G. Hindricks[2], H. Kottkamp[2], S.M. Tugtekin[1], S. Schüler[1]. *Electrophysiology Dept., Institute of Cardiovascular Research, Dresden; [1]Cardiovascular Institute, University Dresden, Dresden; [2]Elektrophysiologie, Herzzentrum Leipzig, Leipzig, Germany*

Background: The original MAZE procedure has become the standard in the operative therapy in patients with chronic atrial fibrillation (AF). The efficiency of a continuous right and left atrial ablation line application using radiofrequency ablation for simplification of the operative procedure was analyzed in patients with mitral valve replacement.

Methods: In 10 patients (5 male and 5 female, age 45–74 years, mean 62 ± 10 years) suffering from mitral valve disease AF was documented for 18 ± 14 months, the left atrial diameter was between 47 and 68 mm (55 ± 6 mm). A continuous ablation line was performed through a right atrial transseptal approach starting at the posterior mitral valve annulus and incorporating all pulmonary veins. Electric isolation of the right atrial isthmus was performed using a new manual electrode.

Follow-up visits for rhythm stability are scheduled for 6, 12 and 24 months after the operation.

Results: There was no death in this series. No patient showed perioperative complications. Eight patients had sinus rhythm at the time of hospital discharge, three of them had a previous cardioversion. In 4 patients with high grade AV-block a dual chamber pacemaker was implanted. The first long term follow-up was carried out 206 ± 35 days after the operation. Seven patients still had sinus rhythm, one of them after an additional cardioversion. Three of the patients with sinus rhythm recieve a low dose Sotalol therapy, 3 low dose beta-blocker therapy. One patient with sinus rhythm does not recieve any antiarrhythmic drugs at all. Two patients were found with atrial fibrillation. One patient has moved with unknown address.

Conclusions: Electric isolation by an ablation line between the mitral annulus and the pulmonary veins and electric isolation of the right atrial isthmus can terminate chronic atrial fibrillation by interruption of the reentry circle and maintain sinus rhythm over a period of six months.

VALVE PROSTHESES

P2834 Haemodynamic performance of medtronic freestyle aortic root replacement as compared to homografts: a prospective randomised trial

G. Melina, E.J. Birks, F. Bizzarri, L. Grieve, A. Khaghani, M.H. Yacoub. *Department of Cardiothoracic Surgery, Royal Brompton & Harefield Hospital, Harefield, Middlesex, UK*

Homografts offer many advantages, particularly when inserted as a root. The Medtronic Freestyle is an unstented valve which can be inserted as a root, but its haemodynamic performance and ventricular response have not previously been well evaluated.

In order to assess the haemodynamic response and ventricular changes, we have conducted a prospective randomised trial comparing Homograft with Freestyle aortic root replacement.

Methods: Since August 1997, 54 patients have undergone aortic root replacement, 22 with Homograft and 32 with Medtronic Freestyle valves, 38 were male and 16 were female. Fifteen patients had concomittent CABG and 6 had had previous cardiac surgery. We have performed a preoperative transthoracic echocardiographic evaluation in all patients and again at 6 weeks, 6 months and 1 year postoperatively. Echocardiography has been performed up to 1 year postoperatively in 29 patients (9 Homograft and 20 Freestyle). Left ventricular diameters (LVD), posterior wall and interventricular septum thickness, left ventricular mass (LVM), fractional shortening, ejection fraction (EF) and peak and mean gradients across the valve were measured.

Results: No statistically significant differences were found between Homograft and Freestyle groups over time, postoperatively. After 1 year, preoperative LVM decreased from 342.8 ± 26.5 g to 263.5 ± 31.5 g in the Freestyle group, with a significant improvement after 6 months (235.8 ± 27.3 g, $p < 0.05$ vs preop). Left ventricular EF improved from 58 ± 4.3% to 63.9 ± 5.4% in the Freestyle group and both systolic and diastolic LVD reduced (42.3 ± 3 mm vs 40.1 ± 3.7 mm and 57.5 ± 2.8 mm vs 50.8 ± 3.4 mm, respectively). Mean preoperative aortic peak gradient was 47.7 ± 7.5 mmHg in the Homograft patients and 74.7 ± 6.4 mmHg in the Freestyle group which significantly improved to 9.6 ± 3.4 mmHg ($p < 0.05$) and 10.6 ± 5.1 mmHg ($p < 0.05$), respectively, after 1 year.

Conclusions: Our data show that haemodynamic performance of the Freestyle valve is comparable to that of the Homograft for periods up to 1 year with considerable regression of LV mass in patients who received Freestyle valves. This is an ongoing study.

P2835 Improvement of endothelial cell adhesion on biological prosthesis by preseeding with autologous fibroblasts

H. Gulbins, D. Schmidt, A. Uhlig, R. Hilge, B. Meiser, B. Reichart. *Department of Cardiac Surgery, University Hospital Grosshadern, Munich, Germany*

Introduction: Endothelialization of biological prostheses, such as homografts or porcine aortic valves, may improve long-term durability by avoiding immune responses of the recipient. Purpose of our studies was to improve human endothelial cell seeding on such biological surfaces by preseeding of autologous fibroblasts.

Methods: In a first experiment pieces (4 cm^2) of cryopreserved aortic roots were seeded with endothelial cells (EC) for 24 hours. Groups 1–4 were preseeded with autologous fibroblasts using different times (8 or 16 h, 1 or 2 h stopping medium). The probes were then examined histologically and with the scanning electron microscope (SEM). In the second experiment complete human (n = 4) and porcine (n = 4) aortic roots were endothelialized (24 h) using a specially developed apparatus; 2 of each group were preseeded with fibroblasts (16 h). After a resting phase of 5 days they were perfused for one hour at a mean pressure of 70 mmHg. Specimen were taken after each culture step and after perfusion for examination (histologically and SEM).

Results: Fibroblasts formed a confluent cell layer after a seeding time of 16 hours. EC's could be seeded on these firboblasts and built a confluent cell layer. The same results were obtained by seeding on human aortic roots. Although porcine roots were pretreated with glycerol, obviously not all native cells were destroyed. This resulted in small defects of the cell layer. Fibroblast preseeded human aortic roots showed a nearby complete EC layer after perfusion; no interruptions of the fibroblast layer were seen. Aortic roots seeded only with EC's lost about 30% of their initial cell layer.

Conclusion: Preseeding with autologous fibroblasts improves endothelial cell adhesion of biological surfaces. For seeding on porcine valves a better preservation technique is necessary, that provides complete decellularization and therefore improves human cell seeding.

P2836 Cardiovascular tissue engineering: scaffold precoating with human autologous extracellular matrix for improved cell attachment

Q. Ye, G. Zund, A. Schoeberlein, P. Benedikt, A.C. Schmid, P. Vogt, Marko Turina. *Clinic for Cardiovascular Surgery, University Hospital Zurich, Switzerland*

Cell attachment to a scaffold is a precondition for the development of bioengineered valves and vascular substitutes. This is generally facilitated by the use of precoating factors, but they are heterologous and might be immunogenic. We used human autologous extracellular matrix (ECM) to precoat polyglycolyc acid (PGA) scaffolds, and compared the cell attachment with conventional precoating methods.

Methods: Tissue from the ascending aorta of a heart donor was cultured to obtain human myofibroblasts. Autologous ECM was extracted from the same aortic tissue. PGA scaffolds, measuring 1.0 × 1.0 × 0.3 cm, were precoated with autologous ECM, human serum, or poly-L-lysine; control group was pre-treated with phosphate buffered saline (PBS). Myofibroblasts (10^6 cells, passage 4) were seeded onto each scaffold and were allowed to attach for one hour. The number of cells attached to the meshes was determined using MTT-assay. Scanning electron microscopy was performed to document the extent of cell attachment.

Results: Compared to the control group, precoating with human serum, poly-L-lysine and ECM increased number of attached cells by 24%, 53% and 48%, respectively. Differences between precoating groups were significant ($p < 0.01$), except for ECM versus poly-L-lysine. Scanning electron microscopy also demonstrated the high degree of cell attachment to the PGA fibres on scaffolds precoated with ECM and poly-L-lysine.

Conclusion: Precoating polymeric scaffold with autologous human extracellular matrix is a very effective method of improving cell attachment in cardiovascular tissue engineering without the potential risk of immunologic reactions.

P2837 World wide performance of the Freestyle® stentless aortic bioprosthesis during a follow-up of five years

Leo H.B. Baur, Jean Dumesnil, Xu Y. Jin, Arie Pieter Kappetein, Mark Hazekamp, Ernst E. van der Wall, Albert V.G. Bruschke, Hans A. Huysmans. *For the Freestyle® World Wide Study Group; Cardiology Dept., Leiden University Medical Center, Leiden, Netherlands*

Introduction: Stentless aortic xenografts do not require lifelong anticoagulation. However, the effectiveness of the valve during long term follow-up has not been proven. Therefore the hemodynamic performance of a new type stentless bioprosthesis, Freestyle®, implanted in the aortic position was evaluated in a prospective, nonrandomized multicenter clinical trial.

Methods: In 1100 pts a Freestyle® aortic xenograft 19–27 mm was implanted in 21 centers throughout the world. Implantation was performed using three different techniques (Subcoronary (SC), Root-Inclusion (RI), Full Root (FR)). Performance of the bioprosthesis was evaluated with 2D-echocardiography and Doppler-ultrasound 4 weeks. 3–6 months, and every year during a follow-up of 5 years after implantation.

Results: Mean aortic valve pressure gradients for the different techniques (SC, RI, FR) were 11.6 ± 6.7, 9.9 ± 7.5, 6.4 ± 4.4 mmHg respectively at 4 weeks after surgery and decreased to 7.7 ± 5.4, 7.7 ± 7.9, 5.5 ± 4.0 mmHg respectively after 3–6 months. The gradients remained at this low level throughout the follow-up of 5 years ($p < 0.0001$). Cardiac index for the different techniques was stable at 2.9 ± 0.9 (SC), 3.1 ± 0.9 (RI) and 2.5 ± 0.8 (FR) L/min/m^2 throughout the study period (n.s). Calculated effective orifice area (eoa) was 1.6 ± 0.6 (SC), 1.9 ± 0.7 (RI) and 1.9 ± 0.6 (FR) cm^2 after 4 weeks and remained so throughout follow-up (n.s). In 34% (SC), 19% (RI) and 13% (FR) of the patients valvular insufficiency grade 1 was observed and in 1% (SC), 1% (RI), 4% (FR) insufficiency grade 2. None of the pts had insufficiency grade 3 or 4.

Conclusion: Medium term hemodynamics of Freestyle® showed stable low gradients and excellent performance during a follow-up period of five years. Mechanics are superior to those reported from stented bioprostheses and mechanical valves.

P2838 Echocardiographic follow-up after mitral valve replacement with a cyopreserved homograft

P. Berdah, B. Iung, E. Garbarz, P. Lionet[1], J. Kamblock[1], R. Michaud, B. Farah, B. Cormier, G. Papouin[1], A. Vahanian. *Tenon Hospital, Cardiology, Paris; [1]Mamao Hospital, Cardiology, Papeete, French Polynesia, France*

Cryopreserved homograft (CH) has been recently proposed as a new substitute for mitral valve replacement (MVR). However, one of the concerns is related to the structural evolution of the homograft. We report the results of transthoracic echocardiograhic (TTE) follow-up (FU) after MVR with a CH.

Between 1993 and 1998, 44 patients (pts) underwent MVR using a CH. Post-operative complications were 3 deaths and 1 repeat MVR. Of the 40 remaining pts, 25 had ≥1 year FU and FU TTE was available in 23 of them (92%).

The 23 patients who had FU TTE had a mean age of 39 ± 14 years [11–66], 12 pts (52%) were in NYHA class III/IV, and 19 (83%) in sinus rhythm. The indications for MVR were acute endocarditis in 8 pts and rheumatic disease in 15. Total CH was implanted in 9 pts and partial CH in 14. Associated procedures were aortic homograft in 1, tricuspid homograft in 1, tricuspid annuloplasty in 2, and aortic repair in 2. Post-operative valve area (VA) was 2.2 ± 0.4 cm^2 and 9 pts had grade 1/4 regurgitation.

Mean FU was 37 months [13–54]. No pt died and 2 underwent reoperation: 1 after 5 years because of endocarditis on CH and the other at 4 years for deterioration of aortic repair. All patients were in NYHA class I or II at last FU. FU TTE showed VA of 2.0 ± 0.3 cm^2 [1.4–2.6], with 2 pts having <1.5 cm^2. Mean gradient was 4.8 ± 2.6 mmHg. The degree of regurgitation was 1/4 in 8, while no pt had regurgitation > 2/4. Mean left ventricle end-diastolic diameter was 49 ± 4 mm and shortening fraction 36 ± 7%.

In conclusion: Mid-term TTE FU after MVR by a CH shows continuing good valve function in most pts. However, longer FU is necessary to detect deterioration.

P2839 Regression of left ventricular mass in patients with a small aortic root after the Ross operation as compared to patients who received a small-size mechanical aortic rosthesis

F. Pieters, L. Hatle, Z. Al-Halees, M. Shahid, M. Al-Amri. *Department of Cardiovascular Diseases, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia*

In pts with small size aortic valve mechanical prostheses significant gradients are often found with Doppler echocardiography, which is not the case after the Ross operation. We compared regression of left ventricular mass (LVM) post valve replacement as an expression of the effect of these gradients on the LV.

Methods: We reviewed our population with size 19 and 21 mechanical prostheses (CM19 and CM21 group) and Ross pts with comparable preoperative aortic annulus (LVOT) dimension. Compared groups were matched for age, body surface area (BSA), pre-operative indexed LV size and mass, severity of aortic stenosis and regurgitation and of mitral regurgitation. Pts with > grade 2 post-operative aortic regurgitation during follow up (FU) were excluded. Gradients and left ventricular ejection time corrected for heart rate (LVETc) were measured in the mechanical prosthesis groups. LVM was compared preoperatively and during FU and was indexed (LVMi) since part of the population had increasing BSA during FU.

Results: No significant differences were noted between the groups in blood pressure and BSA pre-operatively and during FU. Gradients and LVETc were significantly higher in the CM19 than in the CM21 group. Regression of LVMi occurred in all groups and was most significant in the Ross pts and the CM21 group but not significant in the CM19 group during prolonged FU:

LVM index	Pre-op	6 mth p value	2 yr p value	4 yr p value
Ross (LVOT21) n = 23	128 ± 29	79 ± 14 <0.000001	80 ± 17 <0.000001	75± 19 <0.00001
CM 21 n = 34	137 ± 35	91 ± 23 <0.00001	90 ± 27 <0.000001	90 ± 26 <0.00001
Ross (LVOT 19) n = 14	112 ± 31	74 ± 16 <0.002	74 ± 13 <0.002	71 ± 8 <0.001
CM 19 n = 16	121 ± 36	94 ± 28 <0.05	99 ± 27 ns (0.1)	104 ± 27 ns (0.2)

Conclusion: Small mechanical prostheses frequently show high gradients and a small AVA especially when size 19 is used. Regression of LVMi in pts with a small aortic root is significantly more pronounced after the Ross operation as compared to pts who underwent valve replacement with a size 19, but not as compared to pts with a size 21 mechanical prosthesis. Lowest values of LVMi were seen in Ross pts.

P2840 Different characteristics of interstitial cells from human heart valves, pericardium and skin

P.M. Taylor, S.P. Allen, M.H. Yacoub. *Cardiothoracic Surgery, Imperial College at Harefield Hospital, Middlesex, UK*

Heart valves consist of a matrix of collagen and elastic fibres containing interstitial cells (ICs) – fibroblasts (fibs), myofibroblasts and smooth muscle cells (SMCs) – covered by endothelial cells. Fibs can differentiate into myofibroblasts which are characterised by the presence of stress fibres containing the a-actin isoform present in SMCs. The aim of this study was to determine whether valve ICs were uniquely different from pericardium (peri) and skin ICs by determining their phenotype and investigating their intracellular Ca^{2+} ($[Ca^{2+}]_i$) response to vasoactive agents.

ICs cultured from human heart valves (n = 13), peri (n = 3) and skin (n = 4)were grown on glass coverslips and stained by immunofluorescence. $[Ca^{2+}]_i$ changes were evaluated by loading the cells with fura 2-AM, a calcium ratiometric dye and analysed using the IonVision system. ICs from skin expressed virtually no SM a-actin or SM myosin. 57 ± 9% (mean ± sem) of cells from valves and 24 ± 10% of cells from peri expressed SM a-actin and occasionally some cells (<4%) expressed SM myosin. ICs from peri and skin always expressed a fibroblast surface antigen, whereas expression was variable on valve ICs (80 ± 7%). Transient increases in $[Ca^{2+}]_i$ were induced when angiotensin II (Ang II), endothelin-1 (ET-1), 5-HT and U46619, the TXA2 mimetic, were added at 10^{-7} M (see table). The response of valve and peri ICs to Ang II and 5-HT were similar, however, pericardial cells were exquisitely sensitive to ET-1 and virtually unresponsive to U46619. Skin fibs were least responsive to all agents.

Table. Average increase in $[Ca^{2+}]$ ± sem (nM)

	ET-1	Ang II	5-HT	U46619
Valve	259 ± 36	397 ± 159	249 ± 47	192 ± 23
Peri	630 ± 218	391 ± 64	218 ± 53	41 ± 5
Skin	111 ± 34	138 ± 15	85 ± 46	163 ± 20

In conclusion, ICs from heart valves consist of a mixed population, the majority of which express SM a-actin and may be classified as myofibroblasts. Fewer cells from peri and no cells from skin expressed SM a-actin, suggesting that most of these cells were fibs. The heterogeneous $[Ca^{2+}]_i$ responses indicated that a number of receptor signalling pathways existed in all cell types. Evaluation of the nature of these events may help to elucidate the role of myofibroblasts in valve function.

P2841 105 Ross procedures: mid-term echocardiographic follow-up

C. Savoye, A. Prat, J.L. Auffray, E. Hubert, L. Goullard, G. Deklunder. *EFCV, CHRU Lille, France*

Pulmonary homograft function, pulmonary autograft in aortic position dimensions and function were assessed in a prospective echocardiographic study in mid term follow up.

Between March 92 and July 98, 105 patients (25 F and 80 M) underwent the Ross procedure; mean age at implant was 28.4 ± 10 years. Transvalvular gradients (G) and autograft size at three levels (annulus, sinuses and proximal ascending aorta) were measured in the postoperative period, at 6 months and annually.

Results: Perioperative mortality was 4.7%. One hundred patients had a mean 28.6 months echocardiographic follow up (range: 0.5 to 6.6 years), during which four non-cardiac deaths occurred. In these series, two patients underwent late reoperation (1 endocarditis, 1 proximal suture line dehiscence).

	Postoperative	Late	p
Peak G Ao (mmHg)	4.8 ± 2.9	5.1 ± 3	ns
PeakG Pulm (mmHg)	7.6 ± 5.8	12.5 ± 8	<0.0001
Annulus (mm)	24.7 ± 3	24.9 ± 3.4	ns
Sinuses (mm)	34.1 ± 4	36 ± 4.5	<0.0001
Prox. Aorta (mm)	29.1 ± 3.4	31 ± 4.5	<0.0001

There was no moderate nor severe regurgitation in the postoperative period. Two moderate pulmonary (2%) and 4 moderate aortic (4%) regurgitation developped during follow up.

Conclusion: The mid term follow up of Ross procedures shows 1) stability of autograft gradients and slight increase in peak pulmonary gradients (without moderate nor severe obstruction), 2) no severe regurgitation and 3) slight increase in autograft dimensions at sinuses and proximal aorta.

PHARMACOLOGY AND DRUG THERAPY

P2842 Reduction of myocardial infarct size with sCR1sLex, an alternatively glycosylated form of human soluble complement receptor type 1 (sCR1), possessing Sialyl Lewis X

K. Zacharowski, G. Hafner[1], H.C. Marsh[2], C. Thiemermann. *William Harvey Research Institute, London, UK; [1]Clinical Chemistry, University of Mainz, Mainz, Germany; [2]AVANT Immunotharapeutics, Needham, USA*

Introduction: There is evidence that the activation of the complement system and the expression of adhesion molecules in response to myocardial ischaemia may initiate a number of pathophysiologic responses that contribute to the progression of myocardial ischaemia and reperfusion injury. Certain animal disease models which have been shown to be complement dependent using the soluble human complement receptor type 1 (sCR1) and have also been shown to be selectin-dependent using the sLex tetrasaccharide. There is preclinical evidence that inhibition of the complement system or inhibition of PMN's leads to a reduction in tissue injury.

Objective: This study investigated the effects of soluble complement receptor type 1 (sCR1) or sCR1sLex, agents which function as a complement inhibitor or as a combined complement inhibitor and selectin adhesion molecule antagonist, respectively, on the infarct size and cardiac troponin T (cTnT) release caused by regional myocardial ischaemia and reperfusion in the rat.

Methods: Seventy-three, male Wistar rats (210–310 g) were anaesthetised, tracheotomised and ventilated. The jugular vein and carotid artery were cannulated to administer drugs and to measure mean arterial blood pressure, respectively. The chest was opened by a left-side thoracotomy and an atraumatic needle was placed around the left anterior descending coronary artery (LAD). After a stabilisation period of 30 min, the rats were subjected to 30 min occlusion of the LAD followed by 2 h of reperfusion. Haemodynamic parameters were continuously recorded and at the end of the experiments infarct size (with p-nitro-blue tetrazolium) and cTnT release were determined.

Results: The mean values for the AR ranged from 51 ± 3% to 54 ± 3% and, hence, were similar in all animal groups studied ($p > 0.05$). Infusion of sCR1 (1, 5 or 15 mg/kg, n = 5, 6 or 5) or sCR1sLex (1, 5 or 15 mg/kg, n = 5, 13 or 13) 5 min prior to LAD-reperfusion caused a reduction in infarct size from 61+2% (PBS-control, n = 10) to 46 ± 8%, 21 ± 10% and 31 ± 7% or 45 ± 7%, 35 ± 6% and 35 ± 4%, respectively. Infusion of sCR1 (15 mg/kg, n = 5) or sCR1sLex (15 mg/kg, n = 5) also reduces the myocardial TnT release from 80 ± 20 ng/ml (control) to 13 ± 7 or 4 ± 1 ng/ml, respectively.

Conclusions: Thus, sCR1 or sCRsLex significantly reduce infarct size and cardiac TnT release caused by 30 min of regional myocardial ischaemia and 2 h of reperfusion in the rat. The mechanims of the cardioprotective effects of sCR1 or sCR1sLex are not entirely clear, but may be due complement inhibition and/or prevention of the adhesion and activation of neutrophils.

P2843 Multiple cardiovascular disease risk factor reduction: a one-year weight loss intervention trial with orlistat

C. Lucas, J. Hauptman, M. Boldrin, J. Dallas, K.R. Segal. *Roche Laboratories, F Hoffmann-La Roche, Nutley, USA*

The presence of multiple cardiovascular disease (CVD) risk factors within the same individual increases the overall risk of morbidity and mortality and such clustering of CVD/metabolic risk factors (high blood pressure, hypercholesterolemia, hyperinsulinemia) is far more prevalent in obese persons. The aim of the present analysis was to assess the impact of a one-year weight loss intervention on multiple CVD risk factors. The intervention consisted of a hypocaloric diet (500–800 kcal/day deficit) plus either orlistat 120 mg tid (n = 1508), a non-systemically acting gastrointestinal lipase inhibitor which reduces dietary fat absorption, or placebo (n = 1075). Data were derived by pooling 5 randomized, double-blind, placebo-controlled trials conducted in Europe and the US. Presence or absence of the following CVD risk factors were applied to categorize subjects based on these criteria: LDL-cholesterol: >3.362 mmol/L; diastolic blood pressure > 90 or systolic > 140 mmHg; fasting serum insulin > 90 pmol/L. At randomization, 70% of subjects in both groups had one or more of these risk factors. After 1 year, orlistat-treated patients had lost significantly more weight than placebo recipients (9.0 ± 0.2% vs 5.6 ± 0.3% of initial body weight, $p < 0.001$). A total of 27.2% of orlistat patients with 1 or more risk factor at baseline had no risk factors present at 1 year, (vs 13.9% of placebo-treated patients, $p < 0.01$). The number of risk factors present was reduced in 30.5% of orlistat patients vs 23.4% of placebo patients, and were increased in 27.4% of placebo patients vs 19.1% of orlistat patients. Thus, the greater weight loss in patients treated with orlistat plus hypocaloric diet compared with diet alone was associated with greater improvements in CVD risk status. Orlistat may be of benefit for the treatment of obese subjects at high risk of CVD.

P2844 BK_{Ca} channels mediate testosterone-induced coronary artery relaxation in vitro

G.A. Figtree, C.M. Webb, P. Collins. *Imperial College School of Medicine at the National Heart & Lung Institute, London, UK*

Testosterone (T) relaxes coronary arteries (CA) in vitro, an effect which appears to be mediated by potassium (K^+) channels. The lack of inhibition of testosterone-induced relaxation by glibenclamide suggests that the ATP-sensitive K^+ channel is not involved. We therefore investigated the possible role of calcium-sensitive K^+ (BK_{Ca}) channels in the mediation of T-induced CA relaxation in vitro. Epicardial CA rings from male and female rabbits were suspended in organ baths for measurement of changes in isometric tension. A concentration response curve to K^+ (10–80 mM) was performed, then repeated after a 20 min incubation in T (10 μM). Control curves in rings incubated in the specific BKCa channel inhibitor iberiotoxin (IbTx; 100 nM) were then constructed and repeated after co-incubation for 20 min with T. T-induced relaxation was then performed in the presence of IbTx. Response was measured as % contraction compared with control at the same concentration of K^+. Incubation in IbTx significantly reversed the attenuation of contraction by T to K^+ (table).

$[K^+]$	10 mM	20 mM	40 mM	80 mM
Control	8.1 ± 3.8	48.6 ± 7.2	91.3 ± 4.6	100 ± 0
T	3.0 ± 1.1	25.0 ± 3.3*	50.1 ± 6.8**	74.3 ± 9.2
IbTx	18.0 ± 10.4	67.1 ± 7.6	98.1 ± 1.9	100 ± 0
IbTx + T	22.9 ± 21.9	68.8 ± 14.3*	90.6 ± 12.8*	92.5 ± 13.0

(Values are mean % contraction ± SEM. *P < 0.05, **P < 0.01)

IbTx, in concentrations previously found to close BK_{Ca} channels, reversed the CA relaxing effects of T suggesting that the opening of BK_{Ca} channels is likely to contribute to T-induced relaxation in CA's.

P2845 $Endothelin_A$ receptor antagonism increases myocardial ischaemia during coronary angioplasty

Z.S. Kyriakides, T.M. Kolettis, L. Mihalis, A. Antoniadis, A. Tasouli, D.Th. Kremastinos, D.J. Webb[1]. *Onassis Cardiac Surgery Center, Athens, Greece; [1]University of Edinburgh, UK, Western General Hospital*

There exist conflicting results regarding the cardioprotective effects of endothelin (ET) receptor antagonists on myocardial infarct limitation in animals. In the present study we examined the effects of BQ-123 (15 patients), an ET_A receptor antagonist, on myocardial ischemia during angioplasty.

Methods: Thirty patients with stable angina were studied while undergoing angioplasty for a single artery lesion. According to the protocol, all patients underwent a minimum of 3 balloon inflations (BI) all of 120 s in duration. Between the 2nd and 3rd BI, an intracoronary (IC) infusion of either BQ-123 (15 patients) in saline or normal saline (15 controls) was infused at the rate of 3 ml/min (BQ-123 300 nmol/min) for 20 min. IC and surface ST-segment elevation in mV and pain score were measured at the end of the 3 BIs.

Results:

	(Mean ± SD)	1st BI	2nd BI	3rd BI
BQ-123	IC ST	1.22 ± 0.48	0.91 ± 0.56*	1.13 ± 0.62
	Surface ST	0.17 ± 0.18	0.14 ± 0.18	0.17 ± 0.21
	Pain score	51 ± 17	35 ± 13*	37 ± 15*
Controls	IC ST	1.26 ± 0.55	1.02 ± 0.55	0.77 ± 0.56*†
	Surface ST	0.20 ± 0.15	0.12 ± 0.09*	0.10 ± 0.07*†
	Pain score	54 ± 17	38 ± 15*	28 ± 10*†

*p < 0.05 vs 1st BI; †p < 0.05 vs BQ-123 group. Blood pressure and heart rate were similar during the 3 BIs in the 2 groups.

Conclusion: These findings indicate that ETA receptor antagonism increases myocardial ischemia during angioplasty.

P2846 Effects of phosphodiesterase-5 inhibition on myocardial ischaemia in patients with chronic stable angina in therapy with β-blockers

G.M.C. Rosano, F. Leonardo, P. Pagnotta, F. Pelliccia, B. Sposato, R. Patrizi, E. Cerquetani, G. Marazzi, S.L. Chierchia. *Istituto H San Raffaele, Roma-Milano, Milan, Italy*

Phosphodiesterase 5 inhibition (PD5I) has been suggested to be potentially hazardous and to increase the risk of cardiac events in pts with coronary artery disease (CAD). To verify whether PD5I with Sildenafil (S) affects exercise-induced myocardial ischemia in pts on beta-blockers we studied 14 pts with known CAD and positive exercise test (ET) in a randomized, double-blinded, placebo-controlled study.

Methods: All pts underwent off-therapy a baseline ET and were then started on Atenolol (A, 100 mg o.d.). After a run-in phase of 2 weeks, pts underwent a second ET and were randomized to receive either S (50 mg) or Placebo (P) given in a random order in 2 different days, 2 days apart. ET was repeated 2 hours after the administration of S or P.

Results: All pts had >1 mm ST↓ while off-therapy. Eight pts had a negative exercise test response after A, which was unaltered by the adjunct of either S or P. In the remainders, A significantly prolonged time to 1 mm ST↓ and exercise time. S and P did not reverse the beneficial effect of A upon exercise-induced myocardial ischemia.

	Baseline	A	A + S	A + P
1 mm ST↓				
HR (bpm)	123 ± 21	115 ± 12	116 ± 10	114 ± 16
SBP (mm Hg)	178 ± 24	182 ± 22	178 ± 24	184 ± 28
Time (sec)	412 ± 45	584 ± 42	592 ± 35	579 ± 52
Not Attained		8/14 (57%)	8/14 (57%)	8/14 (57%)
Peak Exercise				
HR (bpm)	131 ± 24	130 ± 18	132 ± 16	128 ± 22
SBP (mm Hg)	186 ± 26	184 ± 32	182 ± 28	186 ± 26
Time (sec)	523 ± 54	754 ± 42	762 ± 53	748 ± 39

In conclusion, phosphodiesterase 5 inhibition with S can be safely administered in pts with chronic stable angina whose symptoms and exercise test response are well controlled by beta-blocker therapy.

P2847 Calcium activated potassium channels regulate NO-mediated vasodilation through modulation of vascular superoxide anion production

L. Bang, S. Boesgaard, J.E. Nielsen-Kudsk, N.G. Vejlstrup, J. Aldershvile. *Medical Department B2141, Rigshospitalet, Copenhagen, Denmark*

Recent in vitro data suggest, that endothelial large conductance calcium activated K^+ channels (BKCa) modulate the vascular response to nitric oxide (NO), but the in vivo implications of this interaction is not clear. This study investigates 1) the effect of BKCa modulation on nitroglycerin-derived NO-mediated vasorelaxation in isolated rat coronary arteries, the isolated perfused rat heart and consious unrestained rats and 2) characteristics of BKCa-mediated effects on NO-induced vasorelaxation. Administration of iberiotoxin (IbTX (10^{-7} M), a specific inhibitor of BKCa) reduced Emax of the nitroglycerin (NTG) concentration-relaxation curve in isolated coronary arteries from 89 ± 2% to 33 ± 2% ($p < 0.05$). Infusion of IbTX (0.1 mg/kg) reduced the in vivo hypotensive effect of NTG by 55% (before IbTX: 32 ± 3 mmHg, vs after IbTX: 15 ± 3 mmHg, $p < 0.05$). Additionally, the NTG-induced increase in coronary flow in the isolated perfused heart was reduced by 77 ± 6%, $p < 0.05$ after IbTX (10^{-7} M) infusion. Incubation with indomethacin, an inhibitor of prostaglandin synthesis, the endothelin receptor antagonist BQ-123 or an inhibitor of NO synthase did not affect the response to IbTX on isolated vessels, suggesting that the effect of IbTX is independent of a potential depolarization-induced vasoconstrictor release. In contrast, the inhibitory effect of IbTX on coronary blood flow changes was significantly ($p < 0.05$) counteracted by in vivo intravenous pretreatment with the superoxide scavenging agent PEG-SOD (30.000 units/kg). The results suggest, that blockade of endothelial BKCa in rats significantly reduce NO-induced effects in conscious animals, isolated coronary arteries and the isolated perfused heart. This effect probably occurs through BKCa-induced changes in the vascular membrane potential regulating superoxide anion production.

P2848 Major cardiovascular events following infusional 5-fluorouracil and cisplatin antineoplastic therapy

F. Macor, N. Meneguzzo, F. Antonini-Canterin, E. Viel, D. Pavan, L. Barzan, G. Franchin, U. Tirelli, G.L. Nicolosi. *Cardiology Dpt A.R.C. and C.R.O. Pordenone, Aviano, Italy*

Background: Antineoplastic therapy with infusional 5-Fluorouracil (5-FU) is known to have several potential life-threatening cardiovascular side effects. The aim of this prospective study is to verify the possible predictive power of some ECG-related variables in this setting.

Methods: Sixty-three consecutive patients (men 53, women 10) aged 60 ± 9 years, affected by head and neck squamous cell carcinoma, received totally 216 courses of chemotherapy with 5-FU (1000 mg/m²/day continuous infusion for 5 days) and Cisplatin (100 mg/m² i.v. at day 1). Clinical examination and 12-lead ECG were performed at baseline and at day 1–3–5 of each course of chemotherapy.

Results: Antineoplastic therapy caused a decrease of heart rate (from 72 ± 13 to 65 ± 10 bpm, $p < 0.001$) and an increase of both QT and QT_c intervals (from 382 ± 37 to 409 ± 41 ms, $p < 0.001$ and from 412 ± 21 to 424 ± 32, $p < 0.001$). During a mean follow-up of 289 days (range 7–980 days) 8 major cardiovascular events (3 in-hospital) were recorded: 3 acute ischemic heart events (1 myocardial infarction and 2 unstable angina episodes), 2 fatal strokes, 2 sudden deaths (1 in-hospital cardiac sudden death) and 1 acute heart failure. In the patient who died suddenly in the hospital, an ECG taken 2 hours before the event showed a maximum QT interval of 530 ms (QT_c = 560 ms) and a maximum QT interval dispersion of 40 ms.

Conclusion: Sudden death, acute ischemic heart events, fatal stroke and acute heart failure have been observed following chemotherapy with 5 day infusional 5-FU and Cisplatin with an overall prevalence of 12.7%. The role played by the QT interval increase and QT dispersion in relation to these events should be further explored.

P2849 Nitrate tolerance and cross-tolerance in human internal mammary artery and saphenous vein following low-dose nitroglycerine infusion

P.R. Sage, I.S. de la Lande, I. Stafford, J. Stubberfield[1], J.D. Horowitz. *Cardiology Unit, The Queen Elizabeth Hospital, Adelaide; [1]Cardiothoracic Surgical Unit, The Royal Adelaide Hospital, Adelaide, Australia*

The mechanism of nitrate tolerance in man remains uncertain. Hypotheses include impaired metabolism of nitroglycerine (NTG) to nitric oxide, inactivation of nitric oxide, and desensitization of guanylate cyclase. The present study investigated these hypotheses utilizing segments of internal mammary artery (IMA) and saphenous vein (SV) from patients undergoing coronary artery bypass grafting for stable angina.

Methods: Patients were randomized to either 24 hours intravenous NTG at 10 micrograms/minute (Tolerant group) or 24 hours nitrate-free (Control group) prior to harvest of the IMA and SV. Segments of the vessels were preconstricted with noradrenaline to 70–80% of maximum and then relaxed with one of the nitric oxide donors; NTG, sodium nitroprusside (SNP) or the endothelium-dependent nitric oxide generator A23187.

Results: See table.

Vascular responses

	IMA Control Log EC50 (M)	IMA Tolerant Log EC50 (M)	IMA Control Emax (%)	IMA Tolerant Emax (%)
NTG	−7.73 (0.14)	−7.02 (0.08)*	97 (2)	85 (2)*
SNP	−7.04 (0.12)	−6.98 (0.15)	98 (1)	95 (1)
A23187	−7.53 (0.15)	−7.40 (0.13)	79 (4)	67 (3)#
	SV Control Log EC50 (M)	**SV Tolerant Log EC50 (M)**	**SV Control Emax (%)**	**SV Tolerant Emax (%)**
NTG	−7.03 (0.14)	−6.52 (0.13)*	97 (1)	84 (5)*
SNP	−6.84 (0.16)	−6.87 (0.22)	98 (1)	96 (3)
A23187	−7.63 (0.09)	−7.36 (0.10)	39 (5)	37 (4)

*$P < 0.01$, # $P < 0.05$ Control vs Tolerant via unpaired T-test. n = 6–10 in each group. Data are expressed as mean with standard error in brackets.

Conclusions: Low-dose intravenous NTG causes significant nitrate tolerance within 24 hours in human IMA and SV, with minimal cross-tolerance to A23187 and no cross-tolerance to SNP. These data are consistent with impaired metabolism of NTG to nitric oxide as the primary mechanism of nitrate tolerance in man.

P2850 Direct cardio-depressive effect of Cyclosporine A in human and rabbit myocardium: measurements of contractile parameters, SR calcium-content, and myofilament responsiveness

P.M.L. Janssen, O. Zeitz, B. Keweloh, U. Siegel, L.S. Maier, B. Pieske, J. Prestle, S.E. Lehnart, G. Hasenfuss. *Cardiology Dept, University Clinic Göttingen, Göttingen, Germany*

The immunosuppresive drug Cyclosporine A (CsA) is a key substance in pharmacological therapy following solid organ transplantation. CsA therapy is associated with severe side effects such as hypertony and renal complications, and cardiotoxicity. However, the mechanism underlying the direct cardio-depressive effects of CsA are largely unknown. In multicellular cardiac muscle preparations from rabbit hearts and from end-stage failing and non-failing human hearts we investigated the direct effects of CsA on contractile performance, sarcoplasmic reticulum (SR) Ca^{2+}-load, and on the actin-myosin matrix. In rabbit muscle preparations (n = 8) we observed a concentration dependent decrease in developed force to 50.2 ± 7.7% of control at 100 nmol/L with an EC50% of 1.9 ± 0.4 nmol/L. In muscle preparations (n = 6) from failing human hearts the maximal effect amounted to 55.6 ± 6.4% of control while EC50% was reached at 1.0 ± 0.3 nmol/L. These values are at and below the therapeutically applied plasma levels. Rapid cooling contractures revealed a decreased SR calcium load to 74.0 ± 7.4% in rabbit preparations (n = 8) and to 84.4 ± 6.5% in preparations from failing human hearts (n = 4). No direct effects were observed on the actin-myosin matrix: myofilament calcium sensitivity, cooperativity,and maximal force development of permeabilized preparations from the rabbit (n = 7) remained unchanged in the presence of CsA. Additionally, results obtained in muscle preparation from non-failing human hearts (n = 4) were similar to those obtained in rabbit muscles and preparations from failing human hearts. We conclude that CsA causes a direct, dose-dependent cardio-depressive effect at clinically relevant concentrations, most likely due to altered handling of Ca^{2+} by the SR.

P2851 Continuous treatment with pentaerythritol tetranitrate prevents the increase of LDL-oxidation in established atherosclerosis

A. Hacker, E. Noack, G. Kojda. *Institut für Pharmakologie, Heinrich-Heine-Universität, Düsseldorf, Germany*

Recent investigations in rabbits have shown that continuous treatment with the nitric oxide (NO) donor pentaerythritol tetranitrate (PETN, 6 mg/kg/day) for 16 weeks does not induce typical nitrate tolerance, sightly decreases aortic superoxide production and prevents the development of impaired endothelium-dependent vasorelaxation (EDR) induced by a high cholesterol diet. We sought to determine if continuous treatment with PETN can prevent oxidation of low density lipoprotein in established atherosclerosis. Three groups of 10 New Zealand White rabbits were fed a chow containing 0.75% cholesterol for 16 weeks. One group (CHOL16) served as control and two groups were fed for another 16 weeks a cholesterol-chow without (CHOL32) or with 6 mg PETN/kg/day (PETN32). LDL was islolated from blood taken after 16 weeks and after 32 weeks in CHOL32 and PETN32. Oxidation of 150 μg LDL protein by 1.7 μM CuSO4 was continuously monitored at 234 nm and the time to onset of oxidation (lag-time) which directly corresponds to the LDL-oxidation resistance was measured. After 16 weeks of cholesterol feeding the lag time was 214 ± 9 min. A similar lag time was measured in PETN32 after 32 weeks (220 ± 21 min). In striking contrast, the lag-time after 32 weeks in CHOL32 was significantly reduced to 168 ± 24 min (P = 0.035). These results suggest that the decrease of LDL oxidation resistance induced by cholesterol feeding in established atherosclerosis can be prevented by continuous treatment with the NO-donor PETN. This effect of PETN was accompanied by a protective action on EDR. Isolated aortic rings of CHOL16 showed a typical impairment of EDR with a maximal relaxation at 1 μM acetylcholine of 22.2 ± 8.5%. In CHOL32-rings EDR was completely impaired, while EDR in PETN32 (23.3 ± 9.1%) was similar to that of CHOL16. We suggest that long-term continuous treatment with PETN might have favourable antioxidative effects in established atherosclerosis.

P2852 40 mg aspirin are not sufficient to inhibit platelet function under conditions of limited compliance

A.-A. Weber, S. Liesener, T. Hohlfeld, K. Schrör. *Institut für Pharmakologie, Heinrich-Heine-Universität, Düsseldorf, Germany*

Aspirin is the standard agent for prevention of atherothrombotic vessel occlusions. Because of the permanent platelet inhibition, daily administration of low-dose (30–50 mg) aspirin will cumulate in a sufficient (>90%) inhibition of platelet thromboxane A2 (TXA2) synthesis. However, elderly patients adhere to aspirin treatment only on 40–70% of days (Carney et al., Health Psychol 1995;14:88). Thus, an effective treatment concept, designed to prevent atherothrombotic events, should be able to compensate for "missed" aspirin doses. In order to simulate patient "non-compliance", we have conducted a study in healthy volunteers, comparing 40 mg with 100 mg aspirin administered every second day.

Methods: 20 healthy male volunteers aged 21 to 37 were enrolled in the study. The effects of aspirin (40 mg vs. 100 mg) on collagen (0.3–5 μg/ml)-induced TXA2 formation (radioimmunoassay) and platelet aggregation (turbidimetry) in citrated plasma were studied in a randomized, double-blind cross-over design (14 days treatment, 14 days wash out).

Results: Collagen-induced TXA2 formation was significantly ($p < 0.001$) inhibited by both aspirin dose regimes. However, in contrast to the 100 mg dose, which sufficiently (>90%) blocked platelet thromboxane formation, only a partial (60–70%) inhibition was seen with 40 mg aspirin ($p < 0.01$ 40 mg vs. 100 mg). This was paralleled by a significantly ($p < 0.001$) reduced inhibition of collagen-induced platelet aggregation by 40 mg aspirin as compared to the 100 mg dose.

Conclusion: Under conditions of limited patients' compliance, a reduction of aspirin doses below 100 mg/d might result in an impairment of its antithrombotic efficacy.

P2853 Stereoselective effects of (R)- and (S)-carvedilol

K. Stoschitzky, P. Lercher, R. Maier, A. Sakotnik, P. Stoschitzky, P. Liebmann[1], W. Klein. *Department of Medicine/Division of Cardiology; [1]Institute of General and Experimental Pathology, Karl Franzens University, Graz, Austria*

Carvedilol is currently used as a racemic mixture, (R,S)-carvedilol, consisting of equal amounts of (R)-carvedilol, an alpha-blocker, and (S)-carvedilol, an alpha- and beta-blocker, which have never been clinically tested in their optically pure forms. We performed a randomized, double-blind, placebo-controlled, cross-over study in 12 healthy male volunteers. At intervals of 7 days, subjects received single oral doses of 25 mg (R,S)-carvedilol, 12.5 mg (R)-carvedilol, 12.5 mg (S)-carvedilol and placebo, respectively, at 8 a.m. as well as at 8 p.m. Exercise was performed at 12 a.m., and heart rate and blood pressure were measured before exercise, during the last minute of exercise, and after 15 min of recovery. Urine was collected between 10 p.m. and 6 a.m., and 6-sulfatoxy-melatonin (aMT6s, the main metabolite of melatonin which is almost completely eliminated in urine) was determined by RIA.

Compared to placebo, heart rate at exercise was reduced by (R,S)-carvedilol (−11%, $p < 0.001$) and (S)-carvedilol (−14%, $p < 0.001$) whereas (R)-carvedilol had no effect. Resting heart rate after 15 min of recovery was increased by (R)-carvedilol (+10%, $p < 0.01$) with no effect of (R,S)- and (S)-carvedilol at this time. None of the substances had any effect on diastolic blood pressure as well as on nocturnal excretion of aMT6s in urine.

Our results indicate that only (S)-carvedilol causes beta-blockade whereas (R)-carvedilol obviously increases sympathetic tone at rest. In contrast to other beta-blockers, none of the enantiomers of carvedilol appears to reduce nocturnal melatonin release. This unexpected result deserves further investigation

P2854 The Ca^{2+}-sensitizer EMD 57033 and CGP 48506 influence crossbridge interaction in human myocardium in a different mode of action

K. Brixius, S. Reicke, H. Reuter, D. Keller-Bartels, R.H.G. Schwinger. *University of Cologne, Germany*

Ca^{2+}-sensitizers may be beneficial in the treatment of heart failure as drugs without additional increase in intracellular free Ca^{2+} or energy cost.

Methods: The present study investigated the mode of action of the novel Ca^{2+}-sensitizers CGP 48506 (CGP) and EMD 57033 (EMD) on isometric force of contraction, the intracellular Ca^{2+}-transient (fura-2 method) and myosin-ATPase activity (ATPase) in left ventricular papillary muscle strips (PAP) and skinned fibers of PAP from human hearts (dilated cardiomyopathy, NYHA IV, heart transplants, n = 15).

Results: CGP (1–100 μM) and EMD (0.5–30 μM) increased force of contraction without changing the intracellular Ca^{2+}-transient. Both Ca^{2+}-sensitizers increased the sensitivity of the Ca^{2+}-induced force-generation (EC_{50} Ca^{2+} control: 1.52 μM, +CGP: 0.67 μM, +EMD: 0.96 μM). Only CGP, but not EMD, increased the Ca^{2+}-sensitivity of the ATPase (EC_{50} Ca^{2+} control: 1.08 μM, +CGP: 0.62 μM, +EMD: 0.99 μM). CGP did not change maximal Ca^{2+}-activated tension or ATPase, whereas EMD increased the maximal Ca^{2+}-activated force-gemeration but not maximal ATPase.

In conclusion, the Ca^{2+}-Sensitizers CGP 48506 and EMD 57033 enhance force via a different mode of action; only EMD 57033 increases maximal tension.

P2855 Effect of different oestrogen-progestin replacement therapy schemes upon exercise-induced myocardial ischaemia in female menopausal patients with coronary artery disease

G.M.C. Rosano, F. Leonardo, P. Pagnotta, F. Pelliccia, G. Panina, E. Cerquetani, B. Sposato, S.L. Chierchia. *Istituto H. San Raffaele, Roma-MilanoMilan, Italy*

Although in hormone replacement schemes progestins are required to reduce the likelihood of uterine malignancies, little is known on their possible detrimental effect upon the cardiovascular system. The aim of this study was to evaluate the effects of estrogen replacement alone and 2 different estrogen-progestin replacement therapy schemes upon exercise induced myocardial ischemia

Methods: After a baseline exercise test, 14 female menopausal pts with CAD received conjugated equine estrogens (CEE) 0.625 mg alone for 30 days. Then, they underwent a second exercise test and were randomized to receive in a cross-over design medroxyprogesterone acetate (MPA) either in continuous combined therapy (2.5 mg/daily) for 28 days or in cyclical therapy (10 mg od from day 16 to day 28).

Results: CEE increased time to 1 mm ST↓ compared to baseline (352 ± 185 vs 265 ± 133 s, $p < 0.01$). After CEE alone, 2 pts with a previously positive exercise test showed a negative exercise test. In these 2 pts, the test remained negative during continuous combined MPA therapy while become positive during cyclical MPA. CEE + continuous combined MPA increased both time to 1 mm ST↓ and exercise time compared to baseline (386 ± 165 vs 265 ± 133 s, $p < 0.01$, and 545 ± 198 vs 465 ± 186 s, $p < 0.05$, respectively). No difference was found between baseline and CEE + cyclical MPA in time to 1 mm ST↓ (268 ± 164 vs 265 ± 133 s, NS) and exercise time (455 ± 223 vs 465 ± 186 s, NS). One patient developed unstable angina during cyclical MPA.

In conclusion, continuous combined therapy with CEE + MPA improves exercise-induced myocardial ischemia in female pts with CAD, while the beneficial effect of CEE is abolished by cyclical therapy with MPA.

P2856 The addition of vitronectin receptor antagonism to a platelet glycoprotein IIb/IIIa inhibitor confers an additional antiproliferative effect

T.J.A. Chico, S. Bunting[1], D.C. Cumberland, D.C. Crossman. *Cardiovascular Medicine, University of Sheffield, UK; [1]Genentech Inc., San Francisco CA, USA*

Abciximab, but not Tirofiban or Eptifibatide, has reduced restenosis in a large trial. Abciximab differs from these other highly specific IIb/IIIa inhibitors in having equal affinity for the vitronectin receptor (VNR). We investigated whether a small molecule G3580, inhibitory for both IIb/IIIa and VNR would inhibit smooth muscle cell proliferation *in-vitro,* compared to Lamifiban, a specific IIb/IIIa inhibitor.

Methods: Porcine aortic vascular smooth muscle cells were plated in DMEM with 20% porcine serum onto fibronectin, laminin, collagen type IV, vitronectin or uncoated plastic. 24 hours after plating, they were treated with 100 μM of G3580 100 μM Lamifiban or control, (doses shown not to detach adherent cells). Cell proliferation was assessed at 48 and 96 hours.

Results: G3580 but not Lamifiban significantly reduced proliferation on both uncoated plastic (Light Units (SEM) at 96 hrs; Control 22.5 (1.5) Lamifiban 19 (7.5) G3580 4.5 (0.5), $p < 0.05$) and vitronectin; (at 96 hrs; Control 26.5 (0.5) Lamifiban 27.5 (1.5) G3580 8.5 (0.5), $p < 0.05$). Neither compound affected proliferation of PVSMC on fibronectin, laminin, or collagen IV.

An anti-proliferative effect mediated via VNR antagonism may explain the anti-restenotic effect of Abciximab.

P2857 Thyroxine administration prevents the deleterious effect of dobutamine on postischaemic function

D.D. Cokkinos, C. Pantos, E. Batali, I. Mourouzis, E. Kastelanos, P. Asimacopoulos, H. Karageorgiou, D. Varonos, Dennis V. Cokkinos. *1st Cardiology Department, Onassis Cardiac Surgery Center, and Department of Pharmacology University of Athens, Athens, Greece*

Aim: The aim of the study was to investigate the inotropic effect of dobutamine (DOB) administration on postischaemic dysfunction, in the setting of global ischaemia and reperfusion, in normal (NORM) and hyperthyroid (THYR) hearts.

Methods: Cardiac hypertrophy was induced in rats by thyroxine administration, twice a day, for 14 days, subcutaneously. Isolated rat hearts were perfused in a Langendorff preparation. Normal hearts after an initial stabilization period were subjected to 20 min of global, zero flow ischaemia followed by 45 min reperfusion without DOB (GpA, n = 6) and with DOB (GpB, n = 8), (10 μg/kg/min). We have shown that this DOB dosage to exerts a positive inotropic myocardial response in hearts without ischaemia. THYR hearts were subjected to the same protocol without DOB (GpC, n = 10) and with DOB (GpD, n = 12). Postischaemic recoveries of left ventricular developed pressure (LVDP) were expressed as % of the initial value (LVDP%). Left ventricular end-diastolic pressure (LVEDP) was measured in mmHg at 45 min of reperfusion.

Results: In NORM hearts, LVDP% was higher in GpA compared with GpB, 45.4 (SEM 4.2) vs 19.1 (2.7), $p < 0.05$ and LVEDP was lower in GpA than in GpB, 65.5 (8.6) vs 96.7 (6.4), $p < 0.05$. In THYR LVDP% was lower in GpC compared with GpD, 59.4 (4.6)c vs 72.1 (2.9), $p < 0.05$ while LVEDP was not different between the two groups 36.5 (5.7) vs 50 (5.0) p = n.s

Conclusion: In NORM hearts thyroxine administration does not alter postischaemic dysfunction. However it prevents postischemic dysfunction caused by dobutamine. This effect may be due to calcium handling interrelationships affected by both hyperthyroidism and dobutamine.

P2858 Potentiation of halofantrine-induced QTC prolongation by mefloquine

S.J. Coker, I.D. Lightbown, D.A. Hughes, J.P. Lambert, G. Edwards. *Department of Pharmacology and Therapeutics, The University of Liverpool, UK*

The antimalarial drug halofantrine can cause QT prolongation and torsade de pointes, and its effects may be greater in patients who have previously received mefloquine. To investigate possible interactions between these drugs, their effects have been determined in pentobarbitone-anaesthetized, female NZW rabbits prepared for measurement of arterial BP, limb lead ECG and epicardial and endocardial monophasic action potentials (MAP).

Mefloquine up to 10 mg kg^{-1} did not alter ECG intervals, heart rate (HR) or BP, but at 30 mg kg^{-1} caused profound reductions in BP. Halofantrine decreased HR and increased QTc. Prolongation of QTc by halofantrine was greater in rabbits which had received mefloquine 3 mg kg^{-1}. Halofantrine also caused Mobitz type I AV block and delays in repolarisation were seen on the MAPs. None of the rabbits had torsade de pointes.

Table 1. The effects of increasing doses of vehicle, halofantrine (HF), mefloquine (MQ), or halofantrine after 3 mg kg^{-1} mefloquine (HF + MQ).

	n	Dose		
		3 mg kg^{-1}	10 mg kg^{-1}	30 mg kg^{-1}
QTC interval (ms)				
Vehicle	6	305 ± 10	311 ± 14	311 ± 11
MQ	6	307 ± 19	317 ± 17	
HF	6	361 ± 26	410 ± 19*	410 ± 18**
HF + MQ	6	439 ± 18*†	452 ± 14*	461 ± 14**†
Halofantrine concentration (μM)				
HF	6	0.7 ± 0.1	3.2 ± 0.3	13.5 ± 1.7
HF + MQ	6	1.8 ± 0.3†	6.9 ± 1.7†	24.7 ± 4.3†

Values are mean ± s.e. mean. *$P < 0.05$, **$P < 0.01$ compared with vehicle, †$P < 0.05$ compared with HF, Kruskal-Wallis test.

Blood concentrations of halofantrine were approximately twice as high in the group that had received mefloquine. This indicates that mefloquine alters the distribution of halofantrine, thus providing an explanation for the ability of mefloquine to enhance halofantrine-induced QTc prolongation.

P2859 Different action of β-blockers on daytime and nighttime heart rate variability

B. Brembilla-Perrot, P. Houriez, O. Claudon, J.P. Preiss, D. Beurrier. *Cardiology, CHU of brabois, 54500 Vandoeuvre, France*

Beta-blockers (BB) have proven to be of beneficial effect in some heart diseases (HD) and arrhythmias, because of their correlations with autonomic nervous system. The present prospective study was undertaken to investigate the effects of BB on heart rate variability (HRV) according to the HD and the time.

Methods: we studied 60 patients (pts), aged 39 to 76 years (mean 56 ± 15). 40 of them survived a myocardial infarction, 12 to 24 months previously (group I-gr). 20 pts had did not have HD (gr II). 24 hour monitoring was performed at baseline and after 8 to 10 days of atenolol (100 mg/day, n = 35) or metoprolol (100 to 150 mg/day, n = 25) (BB). Measures of HRV in the time and frequency domains were calculated for the the entire 24 hours (h) and from 09:00 to 21:00 h (daytime) and 23:00 to 6:00 h (nighttime).

Results: the 24 h HRV analysis shows an improvement over control values in indices of parasympathetic tone, but the results were significant only for high-frequency power (HF) in groups I ($p < 0.01$) and II ($p < 0.05$). A decrease of the coefficient of variance (CV) was noted in gr II ($p < 0.05$). The analysis during the day and the night revealed a predominant action of BB during the night with HF increase from 64.5 ± 45 to 161 ± 111 ms^2 in gr I ($p < 0.001$) and from 99 ± 89 to 268 ± 348 ms^2 in gr II ($p < 0.02$). In gr II, daily HF power did not change after BB. The decrease of CV in gr II disappeared in the daily and nightly analysis.

Conclusion: beta-blockers enhance HRV indexes reflecting parasympathetic activity, mainly during the night in patients with and without ischemic heart disease. This effect could explain the beneficial effect of BB on general survival in patients with and without myocardial infarction.

P2860 Chronic transdermal 17β-oestradiol therapy lowers blood pressure in newly diagnosed hypertensive postmenopausal women

G.M.C. Rosano, B. Sposato, F. Leonardo, F. Pelliccia, G. Panina, E. Cerquetani, G. Germanò, S.L. Chierchia. *Istituto H. San Raffaele, Roma-Milano, Milan, Italy*

Hypertension has been considered as a contraindication for estrogen replacement therapy based on the assumption that the effect of the hormones used in menopause were similar to those of estrogens contained in oral contraceptive pills.

Methods: In a double blinded placebo controlled trial, the effect of chronic therapy with estradiol-17β (E2) on 24-hr ambulatory blood pressure monitoring (ABPM) was evaluated in 12 postmenopausal women (age: 54 ± 2.4 yrs) with newly diagnosed mild hypertension (SBP < 180, DBP < 100 mm Hg). All had menopausal symptoms and none was on hormone replacement therapy or antihypertensive drugs.

Results: After a 2-week run-in period, pts were randomized to receive E2 transdermal patches (50 mcg/day) or matched placebo for 4 weeks, after which they were crossed to complementar treatment after a 2 week washout period. ABPM was performed at baseline, and at the end of each treatment period. E2 treatment significantly lowered 24 hour mean blood pressure as well as mean daytime and nightime blood pressure:

	Baseline	E2	Placebo
24 h SBP	162 ± 11	142 ± 9*§	166 ± 12
24 h DBP	94 ± 6	86 ± 6**§§	94 ± 7
Day SBP	173 ± 10	156 ± 10**§§	172 ± 12
Day DBP	96 ± 6	88 ± 7**§§	94 ± 7
Night SBP	138 ± 14	122 ± 12*§	135 ± 16
Night DBP	88 ± 9	76 ± 8*§	86 ± 10

*p < 0.05, **p < 0.01 E2 vs baseline; §p < 0.05, §§p < 0.01 E2 vs placebo

In conclusion, chronic estrogen replacement therapy lowers blood pressure in untreated newly diagnosed hypertensive menopausal women. This therapeutic option should be considered when early menopausal women with recent onset hypertension are evaluated.

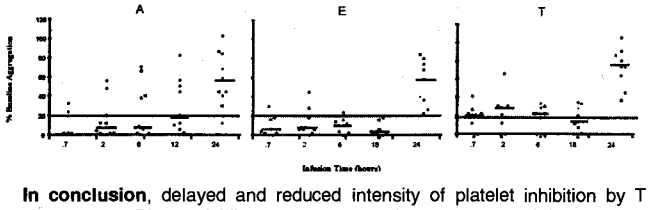
P2861 A randomized comparison of the time course, magnitude and consistency of platelet inhibition by abciximab, tirofiban or eptifibatide

D. Kereiakes[1], T. Broderick, E. Roth[2], D. Whang[2], T. Shimshak[2], J.P. Runyon[2], J. Schneider[2], P. Lacock[3], M. Mueller[1], C. Abbottsmith[2]. *[1]The Lindner Research Center, Cincinnati OH; [2]Ohio Heart Health Center, Cincinnati OH; [3]The Health Alliance Clinical Laboratories, Cincinnati OH, USA*

Platelet GP IIb/IIIa blockade reduces ischemic outcomes following percutaneous coronary intervention (PCI). No randomized comparative trials of GP IIb/IIIa blocking agents have been done.

Methods: We compared platelet function by standard light transmission aggregometry (LTA) with 20 μM ADP and rapid bedside assay (RPFA) during and following administration of either abciximab (A; 0.25 mg/kg bolus pushed, 0.125 mcg/kg/min to maximum 10 mcg/min over 12 hours), tirofiban (T; 0.4 mcg/kg/min bolus for 30 minutes, 0.1 mcg/kg/min infused over average 19.4 hours), or Eptifibatide (E; 180 mcg/kg bolus pushed, 2.0 mcg/kg/min infused over average 19.8 hours) on a randomized basis during PCI in 30 patients with unstable angina. No differences between therapies were observed for clinical outcomes or bleeding events.

Results: LTA for individuals and (–) medians are shown over time.



In conclusion, delayed and reduced intensity of platelet inhibition by T was observed. Platelet inhibition was similar during infusion of A or E. The more robust clinical outcomes reported from trials of A during PCI can not be explained by intensity of platelet inhibition during infusion alone. Randomized comparative clinical trials of these agents should be performed.

P2862 Increased superoxide concentration as a possible basis for platelet hyperaggregability and nitric oxide resistance in patients with ischaemic heart disease

A.S. Holmes, Y.Y. Chirkov, J.D. Horowitz. *Cardiology Dept, The Queen Elizabeth Hospital, Woodville, Australia*

We have previously observed that platelets from patients with stable angina pectoris (SAP) exhibit increased aggregation in response to ADP and are hyporesponsive to the anti-aggregatory effects of sodium nitroprusside (SNP) and other nitric oxide (NO) donors, irrespective of prior nitrate therapy. We now investigated the possibility that the observed phenomenon of NO resistance in platelets is associated with increased concentrations of superoxide radical (O_2^-), which is known to inactivate NO.

Methods: In blood samples from normal subjects (n = 18) and patients with SAP (n = 22) or acute coronary syndromes (ACS, n = 16) we studied inhibitory effects of SNP (10 μM) on ADP (1 μM)-induced platelet aggregation (impedance aggregometry) in conjunction with an O_2^- assay (lucigenin-enhanced chemiluminescence). Specificity of the O_2^- detection was verified with superoxide dismutase in combination with catalase (SOD/Cat).

Results: Platelets from patients of both groups were more aggregable (p < 0.01) and less responsive to anti-aggregating effect of SNP (p < 0.01) than platelets from normal subjects. O_2^- contents (chemiluminescence signal, mV; mean ± s.e.m.) are summarised in the Table. Platelet responsiveness to SNP was inversely correlated with both basal (r = –0.83) and post-aggregation (r = –0.99) O_2^- content. Among patients with SAP, higher O_2^- levels were recorded in those with 3-vessel stenosis (p < 0.05) than in those with 2- or 1-vessel stenosis. SOD/Cat normalised responses to ADP (p < 0.01) and SNP (p < 0.01) in patients, with no effect in normals.

Table. Chemiluminescence signal

O_2^- content	Normals	SAP	ACS
Before aggregation	62 ± 8	125 ± 20*	280 ± 60** #
After aggregation	200 ± 50	660 ± 80**	830 ± 180**

(*p < 0.05 and **p < 0.01 vs Normals; #p < 0.05 for ACS vs SAP)

Conclusion: Increased O_2^- concentration in blood of patients with both SAP and ACS contributes towards platelet hyperaggregability and hypo-responsiveness to anti-aggregatory effects of NO donors.

P2863 Effects of Na^+/Ca^{2+} exchange inhibitor, KB-R7943, on reoxygenation-induced injury in guinea pig papillary muscles

M. Mukai, H. Terada, S. Sugiyama, H. Satoh, H. Hayashi[1]. *Third Department of Internal Medicine, Hamamatsu Univ. School of Medicine, Hamamatsu; [1]Photon Medical Research Center, Hamamatsu Univ. School of Medicine, Hamamatsu, Japan*

The precise mechanism of Ca^{2+} overload on reoxygenation remains poorly defined. A possible candidate is a Ca^{2+} influx via the reverse-mode of Na^+/Ca^{2+} exchange (NCX). In order to study the pathophysiological role of Ca^{2+} influx via NCX for reoxygenation injury, we studied the effects of a novel agent that is reported to selectively block Ca^{2+} influx by NCX, KB-R7943 (2-[2-[4-(4-nitrobenzyloxy)phenyl]ethyl]isothiourea methanesulfonate).

Methods: Papillary muscles were obtained from the right ventricles of guinea pig heart. We investigated the effects of KB-R7943 (1) on contracture induced by a low-sodium (21.9 mM) perfusion to examine whether KB-R7943 inhibits Ca^{2+} influx via NCX, (2) on the action potentials and contractile parameters, and (3) on the incidence of reoxygenation-induced arrhythmias and the recovery of developed tension after reoxygenation.

Results: KB-R7943 dose-dependently suppressed the contracture tension during a low-sodium perfusion (23 ± 8% at 10 μM vs. 56 ± 11% steady-state developed tension in control group, n = 6, p < 0.05). KB-R7943 did not change action potential and contractile parameters. KB-R7943 significantly decreased the incidence of arrhythmias (4 of 9 muscles vs. 9 of 9 control muscles, p < 0.05), and shortened the duration of arrhythmias (16 ± 11 sec vs. 72 ± 14 sec in control muscles, p < 0.05) during the reoxygenation period after 60 min substrate-free hypoxia. KB-R7943 significantly enhanced the recovery of developed tension at 30 min after reoxygenation (83 ± 4% vs.69 ± 3% in control muscles, n = 9) (p < 0.05).

Conclusion: It is likely that KB-R7943 selectively inhibits the reverse-mode of NCX, attenuates reoxygenation-induced arrhythmic activity, and prevents contractile dysfunction in guinea pig papillary muscles. These results suggest that Ca^{2+} influx via the reverse-mode of NCX may play a key role in the mechanism of Ca^{2+} overload on reoxygenation.

P2864 Determinants of platelet responsiveness to nitric oxide donors in the presence and absence of ischaemic heart disease

Y.Y. Chirkov, A.S. Holmes, R.D. Wuttke, S.R. Willoughby, S. Stewart, P.R. Sage, J.D. Horowitz. *Cardiology Dept, The Queen Elizabeth Hospital, Woodville, Australia*

Our recent investigations have demonstrated that platelets from patients with stable angina pectoris (SAP) are hyporesponsive to the anti-aggregatory effects of the nitric oxide (NO) donors nitroglycerine (NTG) and sodium nitroprusside (SNP). Furthermore, this phenomenon was associated with increased superoxide (O_2^-) concentrations. We have now examined determinants of inter-individual variability in platelet responsiveness to NO in patients with SAP, acute coronary syndromes (ACS) and in normal subjects.

Methods: Inhibitory effects of NTG (100 μM) and SNP (10 μM) on ADP (1 μM)-induced platelet aggregation (impedance aggregometry in whole blood) in SAP (n = 53), ACS (n = 120) and normals (n = 52) were compared using uni- and multi-variate analysis. Coronary risk factors, extent of fixed coronary artery disease (CAD) and current medication were examined as possible correlates of response.

Results: In patients with SAP and ACS, platelet aggregability was greater (ANOVA: $p < 0.01$) than in normals. Platelet responsiveness to anti-aggregatory effects of NTG and SNP was similarly impaired in SAP and ACS ($p < 0.01$ vs. normals in both cases). Furthermore, in patients with SAP, NO responsiveness decreased with increasing extent of CAD. Neither individual, nor combined coronary risk factors were correlated with NO responses. While prophylactic nitrates, aspirin, ACE inhibitors, statins or calcium antagonists did not affect platelet responses to NO donors, responses were significantly increased with concomitant perhexiline therapy ($p < 0.05$ for SAP and $p < 0.01$ for ACS), and reduced in the presence of beta-adrenoceptor antagonists ($p < 0.05$ for ACS).

Conclusion: Despite the association of platelet NO resistance with increased O_2^- concentrations, extent of NO resistance is not correlated with coronary risk factors. However pharmacotherapy may modulate platelet responsiveness to NO donors.

P2865 Nitrate tolerance: non-invasive assessment using brachial artery and mitral Doppler ultrasonography

K. Muff Munk, J.E. Nielsen-Kudsk, K.E. Sorensen. *Dept. of Cardiology, Skejby Sygehus, Aarhus University Hospital, Aarhus N, Denmark*

The efficacy of long-term nitrate therapy is limited by the development of tolerance. This phenomenon is often studied by invasive hemodynamic measurements. We describe a simple clinical method for detection of arterial and venous nitroglycerin (NTG) tolerance. Tolerance was induced by continuous transdermal NTG administration. Eleven healthy volunteers were randomised in a double-blind cross-over study to NTG-patch (10 mg/24 hours) and placebo-patch for 7 days separated by a wash-out period of 6 days. In both periods, the acute response to NTG spray 0.4 mg was determined at 0 h, 6 h, day 3 and day 7. Brachial artery diameter was measured by high-resolution ultrasonography and mitral flow E velocity (early peak filling) by Doppler echocardiography.

In the placebo period, NTG spray significantly increased brachial artery diameter (0 h, 6 h, day 3, day 7 in mm: 4.3 to 4.9; 4.2 to 4.9; 4.3 to 4.9 and 4.3 to 4.9). In the NTG-patch period, the brachial artery before NTG spray was significantly dilated at 6 h, but at day 3 and day 7 the diameter again significantly declined due to development of arterial NTG tolerance. Also, NTG spray did not significantly further dilate the artery at day 3 and day 7 (0 h, 6 h, day 3, day 7 in mm: 4.2 to 4.8; 5.0 to 5.1; 4.7 to 4.9 and 4.5 to 4.9). In the placebo period, NTG spray at all time points significantly reduced the mitral E velocity due to its venodilating effect (0 h, 6 h, day 3, day 7 in m/s: 0.86 to 0.71; 0.82 to 0.68; 0.81 to 0.75 and 0.86 to 0.74). In the NTG-patch period, the response to NTG spray on E velocity was completely blunted at 6 h, day 3 and day 7 (0 h, 6 h, day 3, day 7 in m/s: 0.85 to 0.76; 0.78 to 0.77; 0.86 to 0.83; 0.88 to 0.87).

Thus, using a simple non-invasive technique we have demonstrated the development of arterial and venous NTG tolerance. This method is useful for investigating the mechanisms underlying nitrate tolerance and for evaluation of pharmacological interventions directed against tolerance.

COST-EFFECTIVENESS DECISION MAKING AND SOCIETY

P2866 Reduction of hospital costs for patients with acute non-Q-wave myocardial infarction or unstable angina treated with enoxaparin compared to standard heparin

G. Bozovich, E. Gurfinkel[1], D. Barreiro, F. Kuster[2], F. López, R. Mautner[1]. *Favaloro Foundation, Buenos Aires, Argentina; [2]Casa de Galicia, Montevideo, Uruguay*

Recently, enoxaparin has been approved for the treatment of unstable angina (UA) and non-Q-wave myocardial infarction (NQWMI) in Europe, the US, and other Western countries. Higher cost of daily treatment compared to unfractionated heparin (UFH) has been considered a limitation to the widespread use of this compound.

Methods: We analysed in-hospital costs for 256 patients included in the ESSENCE trial in South America. Patients were randomly assigned to either SQ enoxaparin or IV UFH for a minimum of 48 h and a maximum of 8 days. Data were collected from the initial hospitalisation and any re-hospitalisation at 30 days follow-up. Items analysed included daily hospital fees, enoxaparin and UFH costs, angiography and revascularization procedures, and professional fees.

Results: Mean duration of treatment was 82 h ± 48 h and 71 ± 46 h for UFH and enoxaparin, respectively (p = NS). Individual treatment cost was higher with enoxaparin ($ 93.75 ± 56.67 Vs 216.70 ± 141.24; p = 0.177). However, less urgent and total revascularization procedures were needed in the enoxaparin limb (12.6% Vs 20.2%), thus resulting in savings equivalent to $ 29.000/100 patients treated.

In conclusion: Higher costs of equivalent doses of enoxaparin compared to UFH are compensated by less revascularization procedures required by recurrent ischemia and infarction, resulting in reduced final costs.

P2867 A cost-effectiveness analysis of cardioverter-defibrillator implanted under local anaesthesia versus general anaesthesia

C. Kastanioti, E. Kyrozi, T. Maounis, V. Vassilikos, A. Manolis, D. Cokkinos. *1st Cardiology Department, Onassis Cardiac Surgery Centre, Athens, Greece*

Purpose: Implantable cardioverter-defibrillators (ICDs) with transvenous leads and downsized generators allow the use of simplified operative techniques. However, the efficacy and cost of these methods such as the implantation of ICDs under local anaesthesia remain to be evaluated.

Method: In 47 consecutive patients (pts) (mean age of 62 ± 12.5 years, mean ejection fraction of 34.3 ± 10.2%, coronary artery disease in 34 pts, cardiomyopathy in 13 pts and a history of ventricular tachyarrhythmias in all pts) an ICD was implanted. In 21 patients, implantation was performed under general anaesthesia, while in the remaining 26 under local anaesthesia with lidocaine with intravenous midazolam and propofol during defibrillation threshold (DFT) testing. A cost analysis was performed to determine if cost savings were associated with local vs. general anaesthesia.

Results:

	General anaesthesia	Local anaesthesia	Significance
Mean hospital stay (days)	7.05 ± 2.78	3.38 ± 1.3	p = 0.0120
Mean cost of implantation	1799 ± 645 Euro	1250.8 ± 528 Euro	p = 0.0000
Mean cost of hospital stay	1658.4 ± 653 Euro	804.2 ± 298 Euro	p = 0.0000
Mean time of implantation (min)	227 ± 50	173 ± 29	p = 0.0000

There was no operative or post-operative mortality and no major complications occurred except for one lead fracture and one case of acute pulmonary oedema, both in pts under GA.

Conclusions: This study demonstrates a reduction in the hospital charges and health care resource utilization, without any increase in the complication rate, operative and postoperative mortality, associated with ICD implantation when local rather than general anaesthetic technique is used.

P2868 Reduction in length of stay for acute myocardial infarction: lessons learned over 10 years in a defined geographic population

F.A. Sgura, R.S. Wright, J.P. Grill, G.S. Reeder, S.L. Kopecky. *Mayo Clinic, Rochester MN, USA*

Background: Hospital length of stay (LOS) for patients with acute MI has declined over the past two decades. The variability in the decline in LOS cannot be fully explained by new treatment strategies.

Methods: We identified a series of 849 patients admitted for acute MI to the Mayo Clinic Coronary Care Unit. We analyzed the impact of adjunct and reperfusion treatment on hospital LOS in acute MI, and the effect of time period on LOS. Three time periods were arbitrarily chosen: Period I (1988–1990); Period II (1991–1993); Period III (1994–1997).

Results: LOS significantly declined from 1988 until 1997 (10 to 5 days), $p < 0.01$. Adjunct and reperfusion therapy were associated with reductions in LOS by univariate analysis:

Use of	Change in LOS	p-value
Beta blocker	−2 days	<0.01
Aspirin	−2 days	<0.01
Lytic Agent	−1 day	<0.01
Primary PTCA	−1 day	<0.01

Weekday of admission and MI location did not affect LOS. Multivariate analysis suggested that the influence of time period was stronger than the influence of adjunct and reperfusion therapies, and was independent of other factors. The adjusted hazard ratios (HR) for reduced LOS was significant: HR Period II:Period I was 1.28 (95% CI 1.06–1.56) and HR Period III:Period I was 2.02 (95% CI 1.68–2.43). Overall mortality was 9.9%, and did not vary significantly from Period I to III ($p = 0.67$).

Conclusion: Our data demonstrate that clinical and non-clinical factors reduce LOS in acute MI. LOS was significantly reduced in patients who received adjunct and reperfusion therapy, but temporal period appeared to reduce LOS independent of the influence of treatment strategies. These data underscore the impact that non-clinical variables play on LOS in acute MI.

P2869 Impact of spironolactone on health-related quality of life in severe heart failure in the Randomized Aldactone Evaluation Study (RALES)

J. Johnson, B. Pitt[1], J. Tooley[2], A. Perez[2], K. Akhras[2]. *University of Alberta, Edmonton AB, Canada; [1]University of Michigan, Ann Arbor MI; [2]G.D. Searle, Skokie IL, USA*

Background: The Randomized ALdactone Evaluation Study (RALES) demonstrated that adding spironolactone, an aldosterone antagonist, to the current standard of care for heart failure significantly reduced all-cause mortality and cardiac mortality as compared to placebo. RALES involved more than 1600 patients with severe heart failure in 15 countries for an average of 24 months. While mortality was the primary outcome, the impact of spironolactone on self-reported health-related quality of life (HRQOL) was also assessed for a subsample of patients.

Methods: Subjects were randomized to receive either spironolactone 25 mg daily or placebo. HRQOL was assessed in a subsample of 88 subjects in 2 participating countries using the Medical Outcomes Trust Short-Form 36-item survey (SF-36). Assessments were made at baseline, 1, 2, 3, and 6 months after initiation of therapy. Change from baseline was assessed for the 8 dimensions of the SF-36, as well as the Physical (PCS) and Mental Composite Summary (MCS) scores of the SF-36.

Results: Sixty subjects (32 – spiro, 28 – placebo) had complete data for 6 months of follow-up. No significant differences were observed between active treatment and placebo in SF-36 scores at baseline. Statistically significant and clinically meaningful changes from baseline for all 8 SF-36 dimension scores in the spironolactone arm, compared to only 6 dimensions in the placebo arm, were observed at 3 and 6 months. At 3 months, the spironolactone group had significantly greater improvements in *Mental Health* (spiro = 19.9 ± 21.2 versus placebo 3.1 ± 20.9; $p = 0.004$) and *MCS* (spiro = 13.2 ± 11.8 versus placebo = 5.3 ± 11.6; $p = 0.016$) scores compared to the placebo group. The positive impact of spironolactone treatment on change from baseline *Mental Health* subscale scores continued to be statistically significant at 6 months (spiro = 17.5 ± 22.9 versus placebo = 4.5 ± 25.7; $p = 0.044$).

Conclusion: The addition of the aldosterone receptor blocking agent spironolactone to conventional heart failure therapy (ACE inhibitor, diuretic, ± digoxin) appears to positively impact self-reported HRQOL in subjects with severe heart failure. In particular, in this small sample of severe heart failure patients, the addition of spironolactone therapy appeared to have a strong, positive impact on mental health status, with no detrimental effect on physical health or functioning.

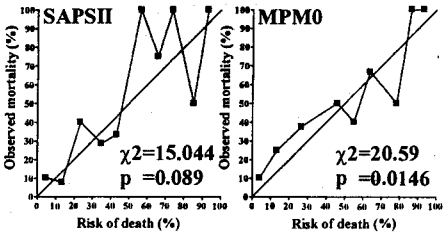
P2870 Outcome predicition by three different scoring systems (APACHE III, SAPSII, MPM_0) in 227 patients with acute cardiovascular disorders

U. Janssens, C. Graf, J. Graf, J. vom Dahl, P. Hanrath. *Medical Clinic I, University hospital of Aachen, Aachen, Germany*

Aim of this prospective study was to compare three different scoring systems (APACHE III [APIII], SAPS II and $MPMII_0$) in terms of outcome prediction (hospital mortality) in patients with acute cardiovascular disorders admitted to a medical intensive care unit (ICU) and to assess the correspondence between the observed and the expected (O/E) mortalities for SAPS II and $MPMII_0$ (calibration).

Methods: APIII, SAPS II and $MPMII_0$ were determined for all consecutive patients (pts) 24 hours after admission. Hospital mortality was recorded. Discrimination power for mortality prediction was assessed by the Receiver Operating Characteristic (ROC). Calibration of the models for SAPS II and $MPMII_0$ was assessed by goodness of fit's (GOF) statistics and calibrations curves.

Results: Between 11/97 and 2/98 227 pts (164 male [72.2%], 63 ± 12 years) were admitted to our ICU (17 CPR, 29 heart failures, 76 infarction, 17 cardiogenic shock, 21 cardiomyopathies, 31 unstable angina, 2 mvocarditis, 3 aortic dissections, 31 rhythm disturbances). Hospital mortality was 16.7% (38/227 pts). Area under ROC curve (AUC) for AP III was 0.82 ± 0.04, for SAPS II 0.77 ± 0.05 and for $MPMII_0$ 0.76 ± 0.05.



Calibration curve for SAPS II and MPMII0. χ^2 = value of the GOF test; $p < 0.05$ significant difference between O/E mortality.

O/E mortality correlated well in SAPS ($r = 0.83$) and MPM II_0 ($r = 0.94$). O/E mortality ratio was 1.47 for SAPS II and 1.52 for MPM_0.

In conclusion: Discrimination power for mortality was reliable in all 3 scoring systems. SAPS II and $MPMII_0$ both underestimated mortality. Therefore, customization of both models should be performed for our population.

CARDIOVASCULAR NURSING – MISCELLANEOUS

P2871 Functional and psychosocial determinants of rehospitalisation in elderly cardiovascular patients

P. Moons[1], E. Steeman[1], S. Bollen[1], K. Milisen[1], B. Wouters[1], S. Indenkleef[1], S. De Geest[1], I. Abraham[1,2]. [1]*Centre for Health Services and Nursing Research, Catholic University Leuven, Belgium;* [2]*Epsilon Group LLC, Charlottesville VA, USA*

Rehospitalisation is a prevalent problem in elderly cardiovascular patients and is associated with increased health care costs. Prevention of rehospitalisation is crucial in the care to the elderly. To identify patients at risk for rehospitalisation, this study examined the functional and psychosocial determinants of readmission in acute care hospitals in elderly cardiovascular patients.

Methods: This descriptive, longitudinal study included 128 hospitalised, frail elderly with cardiovascular disease (46% m.; 54% f.), with a mean age of 78 (SD = 8.2) years, in which a co-ordinated, multidisciplinary discharge planning and an intensive follow-up during 24 weeks was performed. Cardiovascular diseases comprised 15.7% hypertension, 9.4% ischemic heart disease, 2.4% disease of lung circulation, 39.4% other heart diseases, 52.0% cerebrovascular disease, 10.2% peripheral vascular and lymphatic disorders. Functional, depressive and cognitive status of patients were assessed using the ADL- and IADL-scale, Geriatric Depression Scale and Mini-Mental State Examination, respectively. Caregiver burden was evaluated by the Caregiver Burden Inventory. All patients and caregivers were monitored at 5 time-points during the study. Kaplan-Meier survival curves, log rank and the crude relative risk (RR) for each variable were computed.

Results: The cumulative probability for rehospitalisation 6, 12 and 24 weeks after discharge was 16%, 27% and 43%, respectively. Patients were predisposed for rehospitalisation if impaired cognition (log rank = 10.58; $p < 0.002$; RR = 3.45), increased caregiver burden (log rank = 3.89; $p < 0.05$; RR = 2.25), or dependence (through varying degrees) for clothing (log rank = 4.96; $p < 0.03$; RR = 2.75), for using the telephone (log rank = 8.13; $p < 0.005$; RR = 2.67) and for taking own medicines (log rank = 6.44; $p < 0.02$; RR = 8.38) was present.

Conclusion: Though multivariate analysis was not feasible due to limited sample size, this study indicated that rehospitalisation in frail elderly with cardiovascular morbidity is associated with cognitive decline, caregiver burden and selected functional parameters. These results allow health care workers to identify high-risk patients and to initiate appropriate interventions.

P2872 Morbidity and mortality in myocardial infarction complicated by nosocomial infection in a university coronary care unit in Brazil

M.A.S. Teixeira, E.M.N. Kalmar, L. Grandini, T.M.V. Strabelli, D.E. Uip, B. Caramelli. *Heart Institute (InCor), University of Sao Paulo Medical School, Sao Paulo, Brazil*

Background: The high incidence of invasive procedures in myocardial infarction (MI) could increase the risk for nosocomial infections on patients. Data about infection as a complication of MI is lacking.

Methods: We retrospectively analyzed prospectively collected data on 754 MI patients hospitalized in a 16-bed coronary care unit from January 1996 to December 1997. Demographic characteristics, infections and in-hospital case fatality rates were studied.

Results: Forty-two patients (5.5%) developed a nosocomial infection. The respiratory tract was involved in 21 episodes (41.4%) and the urinary tract in 13 (25.4%). A blood stream infection was detected in 13 (25.4%), cellulitis in 3 (5.8%), and peritonitis in one (1.9%). The table shows demographic data and in-hospital case-fatality rates in patients who developed or not a nosocomial infection. Female patients who died were significantly older than male (74.9 ± 9.0 and 66.9 ± 10.5 years respectively, $p < 0.001$). In-hospital case fatality rate was significantly greater in male patients who had infectious complications ($p < 0.001$).

Demographic data and in-hospital case-fatality rates

	Male (547)		Female (207)	
	Mean age (yrs)	Deaths	Mean age (yrs)	Deaths
Infected (42)	69.7 (46–83)	12 (41.4%)	68.1 (52–89)	4 (30.7%)
Non-infected (712)	60.9 (27.88)	48 (9.3%)	66.6 (30–91)	33 (17%)

Conclusions: On this population, nosocomial infection complicating an acute myocardial infarction had a great impact on mortality, mainly in male patients.

P2873 A prospective study of the complications on patients that underwent a continuous venous-venous haemofiltration in a cardiac intensive care unit

Mª Antonia Martinez Momblan, Mª Jesus Gómez Palomar, Carmen Gómez Palomar, Valeriana López Bargondia, Elisa Ocaña Torregrasa. *Hospital Santa Cruz y San Pablo, Barcelona, Spain*

A continuous hemofiltration is a very usefull technique in the I.C.U. The aim of this study is to analyze the actual situation and complications of the continuous venous-venous hemofiltration (CVVHD) in the cardiac ICU.

Material and Method: From November 1991 to July 1997 we had 67 patients in the I.C.U that underwent a CVVHD, but only 47 were studied. We analyzed descriptional and observational parameters in a prospective study from the medical records: hemodynamic, status, temperature, blood parameters, ultrafiltration and reposition levels, liquid balance, filter's duration, and symptomatology and other problems presented.

Results: Hypothermia was present in 41/47 (87.2%) of the patients, and 26 of them (53.3%) presented discomfort. The urea and creatinine clearance was insuficient in 18/47 of the patients (38.29%). Neurological problems appeared in 15/47 (31.9%). The duration of the filters is 13–18 hours. There are statystical differences between hypothermia and discomfort ($p = 0.03$), hypothermia and loading volume ($p = 0.02$), a major duration of the filter (48 h.) and lower creatinine clearance ($p = 0.045$).

The most important complications we found were hypothermia and acidosis due to the biological and the discomfortable situations.

Conclusions: The nurse's knowledge and a correct prophylaxis could avoid these complications. This brings us to the need to protocol this technique.

P2874 Can a coronary care-trained nurse expedite emergency department management of acute cardiac syndromes?

A.M. Kucia, K.T.N. Taylor, J.D. Horowitz. *Coronary Care Unit, The Queen Elizabeth Hospital, Adelaide, Australia*

A variety of options are currently under consideration for "fast tracking" patients (pts) who present to the Emergency Department (ED) with chest pain, possibly of cardiac origin, to definitive cardiac treatment (DCT). One possible strategy is the placement of coronary care-trained nurses (CCTN) as supernumerary personnel in ED's, but there is little data currently available to evaluate the potential efficacy of this approach.

We performed a pilot study in which an experienced senior CCTN was randomly assigned to work in a hospital ED for 16 hours per week; comparable hours over the same period without a CCTN in attendance were utilized for control data. The major endpoint assessed was time to DCT for pts with acute myocardial infarction (AMI).

During the assessment period, 893 pts were assessed as possible acute coronary syndromes (ACS). Mean assessment rates were 0.4 pts/hour with the CCTN (CCTN+) and 0.6 pts/hour with the CCTN absent (CCTN–). Times (mean ± standard deviation in minutes) to DCT for pts with ACS were:

Group (n)	CCTN+ (205)	CCTN– (688)
ALL ACS (91)	102 ± 85 (30)	117 ± 87 (61)
AMI (44)	80 ± 97 (15)	112 ± 102 (29)
AMI with thrombolytic/primary PTCA (19)	33 ± 27 (8)	54 ± 43 (11)

These pilot data therefore suggest that DCT may be expedited by assignment of senior coronary care-trained nurses to ED's. Larger controlled trials are necessary to evaluate whether those non-significant trends arise from Type II error and to determine therapeutic impact and cost:benefit implications of this strategy.

P2875 To sting or not to sting? A study into the warming of local anaesthetic prior to insertion

S. Noonan, A.M. Hill, A. Short, M.B. Buchalter. *Cardiology,Cardiac Catheter Room, University Hospital of Wales, Cardiff, UK*

Introduction: Cardiac catheterisation requires subcutaneous infiltration of local anaesthetic (lignocaine), around the right femoral arterial area. This aspect of the procedure is consistently described as the most unpleasant aspect of the procedure. The most frequent complaint noted was the stinging or a burning pain associated with subcutaneous infiltration.

Aim: To assess whether warmed lignocaine reduces local pain associated with coronary angiography.

Methods: A descriptive study of 42 patients undergoing routine cardiac catheterisation. The study was carried out over a two week period on alternate days. The patients were asked to report their pain to an observer and the responses noted on a Likert scale measuring 0–3. The lignocaine was warmed on the day and was not removed from the warmer until the doctor was ready.

Results: The average pain score (SD) in the warm group was 0.18 (0.64) v 0.84 (0.97) in the non warm group ($p < 0.0001$, t test). For discomfort of insertion 16/21 in the warm group had a pain score of 0 v 5/21 in the non warm group ($p < 0.006$ chi square) and for removal of femoral arterial sheaths 20/21 had a pain score of 0 v 12/21 in the non warm group ($p < 0.03$ chi square).

Conclusion: The simple procedure of warming lignocaine to 37°C reduces the pain of this invasive procedure. The study recommends this technique should be adopted.

PSYCHOLOGICAL ASPECTS OF CARDIOVASCULAR NURSING

P2876 Psychosocial variables in relation to prognosis in patients with stable angina pectoris: the APSIS study

Ewa Billing[1], Sven V. Eriksson[1], Paul Hjemdahl[2], Nina Rehnqvist[1]. *Karolinska institutet; [1]Dept of Intern Med, Danderyd Hospital, Danderyd; [2]Dept of Clin Pharmacol. Karolinska Hospital, Stockholm, Sweden*

Psychosocial variables were studied in 767 out of 809 patients (236 women) with stable angina pectoris, who participated in the Angina Prognosis Study in Stockholm, (APSIS). The patients were <70 years at inclusion, and were treated with either metoprolol or verapamil during a median follow-up of 3.4 years. Overall outcome did not differ between treatments. Psychosocial relationships are presently analyzed.

Method: The patients were interviewed about previous life events, sleep disturbances, psychosomatic symptoms, type-A behaviour, job strain and overall life satisfaction at inclusion. Questions about how the patients usually felt and health related problems are reported.

Results: 36 patients suffered a cardiovascular death (CVD) of which 10 were sudden deaths (SD). Thirty patients suffered a non-fatal MI and 96 were submitted to revascularization due to incapacitating angina pectoris. CVD was related to problems with sex life ($p < 0.001$) and these patients also performed least daily physical activity of all patients ($p < 0.05$). SD was related to several physical symptoms ($p < 0.01$); The patients pushed themselves harder in competition ($p < 0.01$) and they felt most burned out ($p < 0.01$). Sexual problems were also more common ($p < 0.001$). Patients suffering a non-fatal MI described feelings of loneliness ($p < 0.05$) and being missunderstod ($p < 0.05$). Patients who underwent revascularization mostly had problems related to physical symptoms ($p < 0.01$) and feelings of not getting any better ($p < 0.05$).

Conclusion: Listening to patients with stable angina pectoris is of importance since the patients own reporting of psychosocial variables may carry prognostic information.

P2877 Pacemaker users quality of life from a nursing perspective

D. Malm, J-E. Karlsson, B. Fridlund. *Department of Cardiology, County Hospital Ryhov, Jönköping; Dept. of Primary Health Care, Göteborg Univ., Gothenburg, Sweden*

Pacemaker users' quality of life (QoL) has been investigated in a number of studies in connection with which pacemaker system has been implanted, but not from a nursing perspective. QoL is difficult to define, but through the use of Orem's nursing perspective it was possible to focus on the entire individual. The purpose of the study was to describe pacemaker users' evaluations of their QoL in general, but also with respect to gender, age, civil status and occupation.

Method and Results: In total 182 patients (ages 26–93), 51% of whom were men, with pacemaker were randomly selected for interviews about their QoL in this cross-sectional study. The instrument used was Quality of Life Questionnaire. Data were grouped into an index in accordance with Orem's self-care theory, and it was shown by means of statistical analysis that the total QoL was good. A poorer QoL was found in regard to mental-physical health, the possibility of influencing one's own situation, and life style. Men, those who were co-habiting, and those <64 years of age assessed their QoL as higher.

Conclusion: By using Orem's self-care theory, information, choice of pacemaker system, support and education can be carried out in such a way that nursing care affects the entire QoL of the pacemaker users. It is of great importance to educate personnel who work in this area and to inform, advice and support the relatives, with the pacemaker users' self-care as the goal.

P2878 Patients with implantable cardioverter-defibrillator and their conceptions of the life situation: a phenomenographic analysis

B. Fridlund, E.-C. Lindgren. *Centre for Health Promotion Research, Halmstad University, Halmstad, and Department of Primary Health Care, Göteborg University, Gothenburg, Sweden*

The implantable cardioverter-defibrillator (ICD) is today widely used for the treatment of sudden cardiac near death episodes as a result of malignant ventricular arrhythmia. After examining the literature, only four descriptive studies, all carried out in the USA, with a qualitative analysis based on the ICD-patients' own perspective of their life situation have been found. The aim of this study was to describe how patients living with an ICD-device in south-western Sweden conceive their life situation.

Methods: As the focus was on the patients' conceptions from a holistic perspective, phenomenographic analysis was employed on a strategic sample of 15 ICD-patients.

Results: Six categories emerged: feeling safety, feeling gratitude, feeling of being, having a network, feeling a belief in the future, and gaining awareness.

In conclusion, even if the findings cannot be generalised due to the descriptive research design, they can illuminate the beneficial as well as intrusive effects of such a device. They emphasise the need for different support groups for patients and families as well as further education for personnel in hospital and primary health care.

P2879 A qualitative enquiry into the impact of heart attack on women: implications for nursing policy and practice

D. Shaw. *Faculty Of Health Studies, Buckinghamshire Chilterns University C, Chalfont St. Giles, Middx., UK*

Purpose: There is a dearth of literature on the experience of women following heart attack, and therefore little evidence upon which to base practice. This study aimed to contribute to this meagre research base, thus providing guidance for practice and identifying issues for more focussed investigation. It addressed the following research question: What is the psychological experience of women in the period surrounding heart attack?

Methods: This was an exploratory study in which thirty women and men, recruited from two centres, were interviewed at two time points (three weeks and three months) following their heart attack. Interviews were semi-structured and audio-tape recorded. Audio-tapes were transcribed and then subjected to content analysis, both by hand using two blind raters, and by the computer programme NUD.IST.

Results: Womens heart attacks occurred in a different context in respect of family and other social roles and relationships. They demonstrated different personal characteristics to the men. Women frequently ignored, misattributed or otherwise excused symptoms, even when they were very serious, and this very often resulted in excessive delay in help seeking behaviour. They reported not having seen themselves as being at risk, and had beliefs about causation which may have differed with those of health professionals.

The emotional response was different in women, who often had to return to ongoing social stressors. Women often resumed their household chores too early whereas men felt pressured to return to work. Neither group was well informed about their illness or rehabilitation issues such as advisable health related behaviour. Practical issues also contributed womens more difficult rehabilitation, including the presence of co-morbidities and dependence on others for transport to rehabilitation classes.

Conclusions: Women underestimated personal risk and were slow to recognise symptoms. A larger study focussing specifically on womens illness representations is likely to be fruitful and of benefit to rehabilitation practice. Neither men nor women received adequate information and advice about activity levels, and this was often very much to their detriment. Advice needs to be given to all patients and tailored to their individual lifestyle. Alternatives need to be considered for those patients who are unable to travel to rehabilitation classes.

CARDIOVASCULAR NURSING AND HEART FAILURE

P2880 Conceptions of the life situation among female patients with congestive heart failure

J. Martensson, J.-E. Karlsson[1], B. Fridlund[2]. *Jönköping[1]Department of Cardiology, County hospital Ryhov, Jönköping[2]Department of Primary Health Care, Göteborgs University, Gothenburg, Sweden*

Congestive heart failure (CHF) is a significant health problem for women, particularly elderly women. Results from several studies suggest a better long-term prognosis for CHF women. However, the small number of women and lack of comparisons with men in these studies make any consistent interpretation of the results impossible. The aim of this study was to describe, from a nurse's perspective, how female patients with CHF conceive their life situation.

Method and Results: A qualitative method was used with a phenomenographic approach, as this approach examines aspects of the surroundings as they are conceived. Five categories emerged in the results: feeling content, feeling a sense of support, feeling a sense of limitation, feeling anxiety and feeling powerless. A sense of limitation regarding working capacity and being able to support those in their surroundings causes patients with CHF to experience anxiety due to feeling insecure about themselves and in relation to their surround-ings. This may cause a feeling of worthlessness in women with CHF both concerning their own capacity and the fact that they feel they are a burden to those around them.

Conclusion: Through nursing intervention, these patients must receive help to break this vicious circle of feeling limited and powerless. This can be done by encouraging them to verbalize their feelings and set realistic goals and expectations, and by increasing their knowledge and that of their families concerning CHF and its symptoms, with a focus on self-care and existing possibilities. These measures will make it easier for women with CHF to maintain a hopeful perspective and a sense of control, competence, and self-esteem. A comparative study of men using the same research design and variables have been published.

P2881 Patients with congestive heart failure and their conception of the sleep situation: a first preliminary analysis

Anders Broström, Anna Strömberg, Ulf Dahlström, Bengt Fridlund[1,2]. *Department of Cardiology, University Hospital, Linköping; [1]Centre for Health Promotion Research, Halmstad University, Halmstad; [2]Department of Primary Health Care, Göteborg University, Gothenburg, Sweden*

Background: Polysomnografic studies have shown that patients with congestive heart failure (CHF) and Cheynes-Stokes respiration often have shorter total sleep time and a disturbed sleep structure with frequent arousals and sleep stage changes.

Aim: To describe, from a nurse's perspective, how patients with CHF conceive their sleep situation with focus on influencing factors and the handling of these factors.

Method: A qualitative design using a phenomenographic approach was employed. Conceptions were collected through semi-structured interviews with 20 CHF patients. The informants were selected strategically based on gender, age, civil status, education, NYHA-classification etiology and duration of heart failure. There were 13 men (38–83 years) and 7 women (45–85 years).

Results: In the preliminary analysis three categories emerged. The first category, the sleep situation, described how the patients conceived the sleep situation in accordance to reality and desire. The second category, consequences of the sleep situation, described how the patients were physically, emotionally and socio-culturally influenced by the sleep situation. The third category, coping with the sleep situation, described the patients intellectual and behavioural coping mechanisms.

Conclusion: The CHF patients described a desire for a peaceful and continuous sleep, but experienced a frequently interrupted sleep that gave both emotional and physical effects. The awakenings were often connected with dyspnea and anxiety that resulted in difficulties regaining the sleep. The following daytime sleepiness gave a feeling of further limitation in working capacity and led to that the patients participated less in social activities. The final analysis will give a deeper understanding of CHF patients conceptions of their sleep situation. This knowledge can help the nurses to support the patient in a better way to cope with this situation.

P2882 Can patients benefit from a clinical heart failure trial which proves to be negative? The patients' perspective

R. Yuval, K. Uziel, N. Gordon, S. Aviram, B. Karkabi, A. Merdler, M.Y. Flugelman, D.A. Halon, B.S. Lewis. *Cardiology Dept, Lady Davis Carmel Medical Center, Haifa, Israel*

Background: Clinical trials, the gold standard for the evaluation of new therapeutic strategies, may prove that a drug is beneficial, harmful or ineffective. The perspective of the pts participating in a trial of a drug which proves to be ineffective has not been studied.

Patients and Methods: Study group consisted of 42 consecutive pts participating in 3 heart failure trials shown to be ineffective (neutral effect) with regard to primary trial end-point (MACH-1 trial of mibefradil, REACH-1 trial of bosentan and CASCO trial of calcium sensitizer). 20 pts received active drug and 22 placebo. At end of the follow-up period, an anonymous self-completed questionnaire was administered and analyzed.

Results: Although all studies showed a neutral effect on primary study endpoint, 59% pts (68% placebo group, 48% active group, NS) reported moderate or marked subjective improvement after participating in the trial. The major reason for improvement was attributed by the patient to increased confidence (33/42 pts) and better clinical follow-up (8/42 pts). Degree of improvement was not related to whether they received placebo or active drug, although pts receiving active drug tended to report less improvement (see Table).

Subjective Patient Improvement

	Little or none	Moderate	Marked
Total	17 (41%)	16 (39%)	8 (20%)
Placebo	7 (32%)	9 (41%)	6 (27%)
Active drug	10 (52%)*	7 (37%)*	2 (11%)*

Degree of improvement reported by patient (*p = NS, active vs placebo)

Conclusions: In 3 clinical heart failure trials with drug which proved to be ineffective: 1. Half to two-thirds of pts participating in the trial reported subjective clinical benefit. 2. Clinical benefit was not related to whether on active drug or placebo, in keeping with known neutral result of the trial. 3. The higher than expected "placebo effect" should be taken into account in planning future clinical trials.

P2883 Patient-initiated calls to a heart failure nurse?

C. Cleuren[1], T. Jaarsma[2], C. Lucas[1]. *[1]University Hospital Maastricht, Maastricht; [2]Maastricht University Maastricht, Netherlands*

Specialised Heart Failure (HF) outpatient clinics and HF nurses are rather new developments in the Netherlands. In addition to patient education, one of the components of the specialised HF care is the telephone access to a HF nurse. Insight in the reason of patient initiated calls and the related nursing interventions can be helpful to further improve care, guide education of patients and of the nurses. The **objective** of this study was to describe the number and underlying reasons for a telephone call of patients to the HF nurse and to describe the nursing interventions needed.

Method: Data from the registration of the outpatient clinic HF nurse were analysed. Patients had a mean age of 73, 56% was male.

Results: During 1998, 223 patients visited the clinic, resulting in 960 clinic visits. In addition 64 patients received a nurse initiated telephone call to check on weight or medication. Of the 223 patients from the clinic, 78 patients called to the HF nurse, resulting in 274 telephone calls. The number of calls ranged from 1 to 14. Most important reasons for calling were weight change (30%) medication (15%) change in HF clinic visits (11%) and dyspnea (9%). Noticeable was the amount of calls with questions in regard to preparation for clinical tests (e.g. colonscopy) (7%). Most important interventions of the HF nurse were information, education and medication change (after consultation with the cardiologist).

Conclusion: Telephone access to a HF is a useful component of specialised HF nurse care.

INTERVENTIONAL CARDIOLOGY IN CARDIOVASCULAR NURSING

P2884 Local anaesthetic infiltration by registered nurses prior to femoral arterial sheath removal

H. Morrison, C. Taylor, A. Kimber, R.A. Miller, G.C. Stevens, S. Houston, J.R. Steicke, H. Ganendren, P.E. Aylward. *Coronary Care Dept., Ashford Community Hospital, Adelaide, Australia*

Vasovagal episodes occur during arterial sheath removal and compression of the femoral artery. The resultant hypotension can lead to potentially life threatening complications such as coronary occlusion. Vasovagal episodes appear to occur more frequently when sheath removal is some hours after the procedure, when the local anaesthetic has worn off, as is the case following percutaneous coronary interventions.

We hypothesized that the incidence of vasovagal episodes may be reduced with infiltration of local anaesthetic prior to sheath removal.

At our institution, Registered Nurses (RN) routinely remove arterial sheaths, often out of hours, when limited medical cover is available. We therefore trained RNs to administer lignocaine (1%) up to 5 mls around the sheath prior to its removal.

All patients had a femoral approach using a size 7 french catheter. The sheaths were left in situ varying from 2 hours to 14 hours (overnight). In 100 patients lignocaine was infiltrated in each quadrant approximately 1–2 cms from sheath, 3 to 5 minutes prior to sheath removal.

A vagovagal reaction was classified as symptomatic bradycardia, hypotension and light headedness which required treatment with atropine or atropine with haemaccel.

Results: The preliminary results from the 200 patients are presented below:

	Lignocaine	Control
Patients	100	100
Vasovagal Reaction	1	6 (p = 0.059)

There was no apparent difference in other complications between the two groups, in particular, no excess bleeding.

In our study, local anaesthetic infiltration by trained registered nurses reduced the incidence of vasovagal reactions. We recommend consideration of local anaesthetic administration to the sheath site prior to removal of femoral arterial sheaths for percutaneous interventions. This can be safely performed by trained Registered Nurses.

P2885 How soon can patients safely mobilise following a diagnostic cardiac catheter?

A.R. Houghton, D.L. Cottingham[1], A.H. Gershlick[1]. *Nottingham; [1]Department of Cardiology, Glenfield Hospital, Leicester, UK*

Patients undergoing a diagnostic cardiac catheter are usually mobilised four hours after the procedure. A desire to increase the number of patients undergoing day case procedures in order to reduce waiting lists has led to interest in the use of devices to seal femoral artery punctures – however, these devices are costly. If patients can safely mobilise shortly after haemostasis has been achieved by manual compression, this could lead to more rapid discharge without the need for such devices.

In our tertiary referral centre approximately 2300 cardiac catheters are undertaken per annum. This audit is part of a larger audit of haemostasis techniques following cardiac catheterisation which is currently in progress. The records of 50 consecutive patients undergoing manual compression following sheath removal after day case cardiac catheterisation were studied. Details of the time to mobilisation, the time to discharge and any complications were obtained.

All of the 50 patients studied underwent day case left heart catheterisation using 6 French femoral artery sheaths. Manual compression was performed after sheath removal in all cases. Of the 50 patients, 37 (74%) were mobilised after 30 minutes following manual compression and 48 (96%) were mobilised within 60 minutes. The remaining two patients were not mobilised until 95 and 100 minutes because of sedation they had received during the procedure. Two patients experienced minor oozing from the puncture site after mobilisation, both of whom responded to further manual compression. All 50 patients studied were discharged home within 150 minutes.

Rapid mobilisation of patients following manual compression after sheath removal is associated with a low rate of bleeding complications and may obviate the need for femoral puncture closure devices following routine day case diagnostic cardiac catheterisation.

P2886 Safe early ambulation and short femoral compression times after diagnostic left heart catheterisation using 4-F catheters

J.M. Ahmed[1], M.Y. Salame[2], M.W. Baig[1], G.E. Pain[1], D.C. Cumberland[2]. *[1]Doncaster Royal Infirmary; [2]Northern General Hospital Sheffield, UK*

Background: Early mobilisation following left heart catheterisation (LHC) results in an increased incidence of groin haematoma. 7F femoral arterial sheaths for diagnostic LHC usually requires approximately 10 minutes of femoral compression and patients are advised to stay in bed for 4 hours after sheath removal. 4-F femoral arterial sheaths cause a smaller arterial puncture and may therfore result in shorter compression and immobilisation times following sheath removal. We therefore assessed compression times at sheath removal and the incidence of haematoma with only 2 hours of bed rest.

Methods: We prospectively studied 70 patients (67 Males) undergoing diagnostic LHC using the 4-F (Quick Care 4F Infiniti TM, Cordis) sheaths and catheters. Post procedure, the groin was manually compressed for 2 mins and if oozing noted, the groin was compressed for further 1 min intervals until no oozing was observed. Patients sat up 1 hr post compression and mobilised 1 hour later.

Results: Mean groin compression time and (SD) required to stop oozing from the femoral arterial site was 3.17 (0.68) minutes. No groin haematoma was observed 4 hours after the procedure and prior to discharge.

Conclusion: 4-French diagnostic LHC resulted in a shorter femoral compression time than is traditionally required. Also, patients are able to safely mobilize after only 2 hours of bed rest.

P2887 Real life experience with arterial sealing devices: is manual pressure obsolete?

C. Cafri, A.E. Denktas, O. Rosales, G. Schroth, K. Fujise, H.V. Anderson, R.W. Smalling. *Cardiovascular Medicine Dept, Hermann Hospital/UT Medical School, Houston TX, USA*

Background: Multiple randomized trials have reported that the use of arterial sealing devices after diagnostic catheterization or coronary interventions is associated with lower complication rates and earlier ambulation compared with manual pressure. We prospectively evaluated whether these advantages exist in the clinical setting of unselected patients and multiple operators.

Method: One hundred and ninety two patients having interventional or diagnostic catheterization by twenty-five different physicians were prospectively analyzed. Clinical characteristics, complication rates and ambulation delay in patients with sealing devices or manual pressure were compared.

Results: In the manual pressure (n = 40), Angioseal (n = 86) and Perclose (n = 65) groups, coronary interventions were performed in 86%, 75% and 78% of cases respectively. Sheath sizes were 6F in 15%, 14% and 31% of cases respectively and 8F in 60%, 80% and 55%; GpIIbIIIa inhibitors were used in 31%, 26% and 31%. The success rate for local hemostasis with manual pressure was 90.5%, with Angioseal 86% and with Perclose 78%. (p = ns) Complications were seen in 15%, 26% and 26% respectively (p = ns): Hematoma in 7.5%, 17% and 12% (p = ns) and major bleeding in 2.5%, 3.5% and 1.5% (p = ns). Ambulation times are presented in the table below.

Ambulation Time	Manual Pressure	Angioseal	Perclose
0–2 hours	0%	5%	8%
2–6 hours	0%	27%	26%
6–12 hours	20%	26%	20%
>12 hours	70%	31%	23%

Global $p < 0.001$.

Conclusions: In a real life setting of unselected patients and multiple operators, sealing devices did not demonstrate clear advantage over manual pressure on successful hemostasis and complication rates. Early ambulation occurred in patients treated with the sealing devices. However, the majority of them began ambulating after six hours. The impact of closure devices, closure device learning curves and sub-optimal compliance with early ambulation protocols requires further investigation.

P2888 Is early ambulation 4 hours after coronary angiography with 7-F catheters safe?

R.G. Xuereb, M. Xuereb, A. Fenech. *Department of Cardiology, St. Luke's Hospital, G'Mangia, Malta*

Early ambulation after coronary angiography has been advocated with small diameter catheters. This however results in poorer image quality and entails greater operator experience.

Aim: To evaluate whether shorter bed rest (4 hours (hrs)) after coronary angiography using 7 F sheaths and catheters increases femoral complication rate when compared to conventional 8 hr bed rest. In particular, whether it increases the risk of bleeding after ambulation of the patient (pt) – late rebleeding.

Methods: 345 consecutive pts undergoing coronary angiography using 7 F sheaths and catheters were randomized to 4 hr (172 pts) and 8 hr (173 pts) bed rest after the procedure. Pts were examined on an out-pt basis within 4 days of the procedure by physicians blind to the randomized allocation. Both groups had comparable pt characteristics.

Results:

	4 hrs	8 hrs	Significance
No complications	115 (67%)	127 (73%)	NS
Small haematoma (<5 cm)	31 (18%)	24 (14%)	NS
Medium haematoma (5–10 cm)	22 (13%)	16 (9%)	NS
Big haematoma (>10 cm)	1 (0.6%)	4 (2%)	NS
Early rebleeding (during bed rest time)	4 (2%)	4 (2%)	NS
Late rebleeding (after ambulation)	2 (1.2%)	0	NS
Pseudo-aneurysm	1 (0.6%)	0	NS

In the 4 hr group 3 pts with rebleeding and the pt with a pseudo-aneurysm had a haematoma. Late rebleeding occurred immediately on ambulation in both pts. Recompression and a further 4 hr bed rest was resorted to without further complications. In the 8 hr group 2 pts with early rebleeding had a haematoma.

Conclusion: 4 hr bed rest after coronary angiography using 7 F sheaths and catheters is safe and does not confer an added risk of femoral complications. Late rebleeding is rare, occurs immediately on ambulation and is easily managed.

P2889 Is a tourniquet necessary for reaching haemostasis after PTCA via the radial artery?

Gees van Rossum-Helmhout, Thijs Hendriks, Bob Springorum, Ferdinand Kiemeney. *The Catherisation lab and general cardiology wards. Catheterisation lab, Onze LieveVrouwe Gasthuis Hospital, Amsterdam, Netherlands*

The aim of this trial is to determine if hemostasis can be safely achieved using only a pressure bandage for 6–8 hours following a PTCA or angiography via the radial artery using a 6 french introducer. In the past we noticed that application of pressure bandage with a tourniquet was painful and uncomfortable for the patient. The tourniquet also causes venous congestion.

Method: We studied the safety of obtaining hemostasis using only a pressure bandage without tourniquet. We studied 100 patients after PTCA or angiography via the radial artery using a 6 french, 23-cm introducer. The introducer was removed immediately after the procedure and a tight pressure bandage was applied. The endpoints were incidence of major and minor bleeding complications.

Results: 4 Out of 100 patients had minor bleeding which required no further action. 12 patients had bleeding immediately after the application of pressure bandage, one patient received re-application of pressure bandage with success and the 11 other patients required application of tourniquet to achieve hemostasis.

Conclusion: Hemostasis can effectively be obtained with a pressure bandage only. If bleedings occurs, it is usually immediately following application of the pressure bandage, any consequences are minor. We are presently researching a smaller pressure bandage to achieve better compression and to reduce the number of bleedings. The results will be available during my presentation.

P2890 Blood flow volume increase in cranial and abdominal arteries during eecp

R. Setiadji. *Preventif, Harapan Kita, Jakarta Barat, Indonesia*

We report result of the study of enhanced external counterpulsation (EECP), a non-invasive therapy for patients with coronary artery disease and chronic angina pectoris. The investigation was conducted to test hypothese increase of blood flow volume to cranial and abdominal region during EECP. The study was an experimental, pre-test post-test design. We enrolled 25 patients, of whom 15 have carotid-atherosclerotic (A) plaque and 10 non-atherosclerotic (NA) subjects. Eighty nine percent were males We used ultrasound to measure blood flow volume. Observed vessels were Abdominal Aorta, Communes Carotid Artery, Internal Carotid Artery, Vertebral Artery. Baseline characteristics were obtained before EECP. Second mesurements were performed forty five minutes during EECP. Comparison of baseline and during EECP measurements represents effect of EECP on the observed variables. Data were analyzed using student t test for paired samples. Results in non atherosclerotic subjects:

Flow	Before EECP mm^3	During EECP mm^3	p
Abdominal aorta	3670 ± 854.3	5410 ± 730.9	3.3×10^{-5}
Communes carotid artery	702.5 ± 144.1	798.9 ± 174.3	0.001
Internal carotid artery	441 ± 88.2	512 ± 124.1	0.020
Vertebral artery	133.6 ± 36.3	148.7 ± 42.0	0.0078

In atrherosclerotic subjects, abdominal aorta did not always apllicable to be measured, because of abdominal wall thickness. The result were:

Flow	Before EECP mm^3	During EECP mm^3	p
Communes carotid artery	570.1 ± 109.7	737.4 ± 130.4	3.7×10^{-5}
Internal carotid artery	321.5 ± 79.5	415.6 ± 159.2	0.0046
Vertebral artery	158.3 ± 67.2	196.3 ± 65.3	0.0041

In conclusion, during EECP blood flow volume was increased in all observed arteries both in Non Atherosclerotic and Atherosclerotic subjects during EECP.

P2891 Once-daily treatments with usual doses of the loop diuretic torasemide do not reduce serum zinc concentration

A.J. Reyes, W.P. Leary[1], R.D. Espinas. *Institute of Cardiovascular Theory, Montevideo, Uruguay; [1]Department of Pharmacology, University College, Cork, Ireland*

Hypozincaemia may cause hypogeusia, and thus increase salt intake, and it may also retard healing. Thiazides are usually regarded as the only diuretics that raise zinciuresis. However, we recently found that serum zinc (Zn) concentration, measured in blood drawn 3, 12 and 24 h after dosing, was lower on the seventh than on the first day of once-daily treatment with furosemide 40 mg in healthy adults. The aim of the present study was to evaluate the response of zincaemia to the loop diuretic torasemide (T).

Methods: Sixteen healthy subjects in a metabolic unit took once-daily oral doses of placebo, T 2.5 mg, T 5 mg, and T 10 mg, at 08.00 hours, over 4 separate single-treatment periods of 7 days each. A crossover, individually randomized and double-blind design was folowed. The renal instantaneous fractional excretion (FE) of Zn was evaluated by the standard procedure.

Results: None of the T treatments changed mean 24-h zinciuresis on day 1 nor on day 7. Mean zincaemia was not changed by T (mean ± SD):

Day	Once-daily treatment	Instantaneous FE of Zn (%) Hours after dosing		Serum Zn (μmol/litre) Hours after dosing		
		1.5	24	1.5	6	24
1	Placebo	0.46 ± 0.20	0.30 ± 0.09	15 ± 2	12 ± 2	15 ± 2
	T 2.5 mg	0.54 ± 0.32	0.31 ± 0.13	15 ± 2	13 ± 2	14 ± 2
	T 5 mg	0.54 ± 0.25	0.28 ± 0.13	16 ± 2	13 ± 2	15 ± 2
	T 10 mg	0.73 ± 0.38‡	0.25 ± 0.07‡	15 ± 2	12 ± 2	15 ± 2
7	Placebo	0.50 ± 0.30	0.35 ± 0.12	14 ± 2	12 ± 2	15 ± 2
	T 2.5 mg	0.54 ± 0.21	0.31 ± 0.12	14 ± 3	13 ± 2	16 ± 2
	T 5 mg	0.52 ± 0.25	0.35 ± 0.23	14 ± 2	12 ± 2	15 ± 2
	T 10 mg	0.59 ± 0.20	0.31 ± 0.11	15 ± 2	13 ± 2	15 ± 1

‡$p < 0.05$ compared with placebo.

In conclusion, T 2.5 and T 5 mg did not affect the renal tubular handling of Zn. T 10 mg tended to decrease Zn reabsorption from the preurine early after dosing on day 1, but a late-after-dosing rebound in this phenomenon avoided a net 24-h urinary Zn loss.

VARIOUS ASPECTS OF VALVULAR HEART DISEASE

P2892 Impairment of diastolic function in asymptomatic patients with severe aortic regurgitation and poor exercise tolerance

Dragos Vinereanu, Adrian A. Ionescu, Alan G. Fraser. *University Hospital of Wales, Cardiff, UK*

Asymptomatic patients with severe aortic regurgitation (AR) may have subclinical LV dysfunction, shown by a fall in EF on exercise by >5% with an absolute value of <50%, but simpler echo parameters would be helpful.

Methods: We assessed global and regional diastolic function as a possible marker of subclinical LV dysfunction, applicable at rest, in 21 asymptomatic patients (NYHA class ≤ 2a) with severe AR (jet area/LVOT area > 44%). EF was measured at baseline and peak exercise (Weber protocol). Global diastolic function was assessed by PW Doppler of the transmitral flow; peak early (E) and atrial velocities (A) were measured, and E/A ratio was calculated. Regional diastolic function was assessed using tissue Doppler echocardiography (TDE) of the mitral annular motion for the long-axis, and of the LV posterior wall for the short-axis. From the spectral traces we measured peak velocities during early filling (E_{DMI}) and atrial contraction (A_{DMI}). E_{DMI}/A_{DMI} ratio was calculated.

Results: In 11 patients, EF increased or did not change on exercise (from 55 ± 5% to 58 ± 4%, $p < 0.05$); in 10 patients it decreased by >5% (from 54 ± 4% to 42 ± 5%, $p < 0.001$), all these patients also having an EF on exercise <50%. At rest, there were no significant differences between the groups in EF, LV diameter indices, or end-systolic wall stress. 70% of the patients with poor exercise response had global diastolic dysfunction, with an E/A ratio < 1, in comparison with 36% of the patients with good exercise responses ($0.05 < p < 0.10$). All 21 patients had normal short-axis diastolic function, but 80% of the patients with poor exercise responses had long-axis diastolic dysfunction (E_{DMI}/A_{DMI} ratio < 1) in comparison with only 9% of the patients with good exercise responses ($p < 0.01$). Sensitivity and specificity to predict a poor exercise response of global E/A ratio < 1 were 70% and 64%, compared with 80% and 91% for an E_{DMI}/A_{DMI} ratio < 1 for long-axis function.

Conclusion: Diastolic function is impaired in asymptomatic patients with severe AR and poor exercise response. Long-axis diastolic dysfunction measured by TDE may provide a simple and reliable parameter of subclinical LV dysfunction in this group of patients.

P2893 Relationship between the rest parameters of the mitral valve and exercise capacity

M. Eren, E. Arykan, O. Bolca, B. Dagdeviren, T. Tezel. *Istanbul, Turkey*

Purpose: Interventional therapy to the mitral valve aim to provide the patient with a better exercise capacity. It is therefore crucial to detect the exercise capacity before deciding on the time of intervention. In this study, we aimed to demonstrate whether the rest parameters of the mitral valve relate to the restricted exercise capacity.

Methods: 46 patients (30 female) were enrolled to study. Patients with moderate/severe mitral insufficiency, moderate/severe aortic stenosis or insufficiency, lung disease, systolic or diastolic left ventricle dysfunction, chronic illness, and those who are unable to exercise were excluded. As for the mitral parameters; mitral valve resistance (MVr), planimetric valve area (MVApl), mitral valve area calculated with the continuity equation (MVAce), pressure half time of early diastolic filling (PHT), and transmitral mean pressure gradient (MPG) were obtained. The parameters were calculated as follows: MVr = MPG × DFP × 1.333/SV, MVAce = SV/VTIm, SV = Dao2 × 0.785 × VTIao. Abbreviations in the above formulas are Dao = aortic annulus diameter on the parasternal long-axis view, VTIao = time-velocity integral at the level of aortic annulus on the apical 5 chamber view, VTIm = time-velocity integral of PW Doppler tracing taken just distal to the mitral valve leaflets, DFP = diastolic filling period. All patients went thorough on exercise test due to the Bruce protocol. The MET value achieved was calculated as: ob-METs = 1.11 + 0.016(exercise time), predicted MET as: pre-METs = 16.6 − 0.16(age), and exercise capacity was derived as: (ob-METs/pre-METs) × 100. The relation between parameters of the mitral valve and exercise capacity was evaluated with the linear regression analysis.

Results: In our series of patients we found mean MVr 57.4 ± 33 dyn sec cm^{-5}, MVApl 1.41 ± 0.39 cm^2, MVAce 1.48 ± 0.40 cm^2, PHT 168 ± 54 msec, MPG 8.55 ± 5.14 mmHg, ob-METs 7.9 ± 2.2 METs, exercise capacity 82 ± 26%, rate of maximal heart rate achievement was 99 ± 13%. There' s statistically insignificant, low degree correlation between MVr, MVApl, MVAce, PHT, MPG and exercise capacity (correlation coefficients −0.39, 0.27, 0.33, −0.33, and −0.39 respectively).

Conclusion: In patients with mitral stenosis, the rest parameters showed no statistically significant relation with the exercise capacity, and this findings indicates that the decision on the time of intervention cannot be made depending on these parameters.

P2894 The role of cardiac rhythm on early and late outcome of percutaneous mitral balloon valvulotomy in rheumatic mitral stenosis

R. Enar, S. Rafizade, A. Arat-Ozkan, S. Pehlivanoglu, N. Yazicioglu. *Institute of Cardiology, Istanbul University, Istanbul, Turkey*

Previous studies have suggested that, being on sinus rhytm prior to percutaneous mitral balloon valvulotomy (MBV) is one of the determinants of favourable early and late outcome of MBV procedure. In this study we investigated the effect of baseline cardiac rhythm on the early (1st year) and late (5 years) restenosis rates of the patients (pts) with rheumatic mitral stenosis who underwent MBV. Restenosis is defined as 50% reduction of the increase in mitral valve area (MVA) obtained by MBV and/or MVA < 1.5 cm^2. The study group consisted of 224 pts with MVA < 1.5 cm^2 and echo score < 9. There were 184 pts in group A with sinus rhythm and 40 pts in group B with chronic atrial fibrillation. All pts underwent pre- and post MBV echocardiographic and hemodynamic evaluation at cardiac catheterization. Follow-up echocardiographic studies were done up to 5 years. In group A pts were younger (34.4 ± 9.1 vs 42.9 ± 10.5 years, $p < 0.001$) and there were more women (91.3% vs 65%, $p < 0.001$). Pre-MBV left atrial size, pulmonary artery pressure and diastolic mitral gradient were similar in both groups. In group A left atrial size was smaller and MVA was larger compared to group B (4.6 ± 0.5 vs 5.2 ± 0.7 cm and 1.08 ± 0.25 vs 0.99 ± 0.23 cm^2 consecutively) ($p < 0.001$ and $p = 0.03$ respectively). Post-MBV MVA was not different between the groups (2.19 ± 1.79 vs 1.85 ± 0.19 cm^2). At 1st and 5th year follow-up MVA was 1.87 ± 0.24 (184 pts) and 1.69 ± 0.25 cm^2 (134 pts) in group A, and 1.78 ± 0.67 (38 pts) and 1.61 ± 0.23 cm^2 (34 pts) in group B ($p = 0.03$ and $p > 0.05$ respectively). In group A 1st and 5th year restenosis rates were 1.1% (184 pts) and 26.9% and 0% and 23.5% in group B, and the differences were not significant. Cumulative restenosis rates at 5 year follow-up were 26.9% in group A and 23.5% in group B, and the difference was not significant. In conclusion, the early and late outcome of MBV in pts with severe mitral stenosis is not different with chronic atrial fibrillation compared to sinus rhytm prior to the procedure despite the unfavourable baseline characteristics of atrial fibrillation pts.

P2895 Percutaneous balloon mitral commissurotomy as a treatment for mitral valve restenosis after open or closed surgical commissurotomy, report of 35 cases

I. Nazeri, M. Madjid[1]. *Khatam al Anibia Hospital, Tehran; [1]Tehran, Iran*

Percutaneous mitral commissurotomy (PMC) using Inoue balloon has been shown to be a promising method of treatment for both primary mitral valve (MV) stenosis and MV restenosis after surgical commissurotomy (SC).

Methods and results: between Jan. 1992 and Jan. 1999, 425 patients (pts) underwent PMC in two medical centers. There were 63 (14.8%) males and 362 (85.2%) females with mean age of 30 years (20 to 60 yrs). 35 (8.75%) pts had underwent previous open (20%) or closed (80%) surgical commissurotomy 5 to 17 years before (mean 8 yrs). All these pts were symptomatic with III-IV NYHA class. 25 pts had atrial fibillation. Their echocardiographic MV stenosis score was between 7 to 14. 20% had mildly calcified mitral valves. 3 pts had organized clot in their left auricle.

Technical success (MV area > 1.5 cm^2) was achieved in all the 35 pts. PMC resulted in decrease of the mean MV peak gradient from 25 mmHg to 5 mmHg. The mean MV area increased from 1 cm^2 to 1.8 cm^2. Mean pulmonary artery pressure decreased from 50 mmHg to 30 mmHg. Mitral regurgitation (grade 1+ to 2+) developed in 4 (11%) pts and one pt required MV replacement after 6 months. All procedures were completed successfully without death, cardiac tamponade, stroke or emergency surgery.

Conclusion: PMC with Inoue balloon is an effective and safe technique for treatment of MV restenosis after open or closed surgical commissurotomy.

P2896 Non-invasive prediction of coronary artery disease in patients with valvular aortic stenosis by use of electron-beam computed tomography

Osamu Ito, Shouji Yamakami[1], Mituhiro Okamoto[1], Shinji Nagare[1], Hideki Saturai[1]. *Bisai City Hospital, Bisai; [1]Owari Prefectural Hospital, Ichinomiya, Japan*

Background: Preoperative coronary angiography is usually recommended for patients with aortic valve stenosis requiring valve surgery. The coronary artery calcium deposit detected with electron beam computed tomography (EBT) is a marker for coronary artery disease (CAD), but no data are available in patients with aortic valve stenosis. The aim of this study was to assess the capability of noninvasive measurement of coronary calcium deposit using EBT as a tool in the diagnosis of CAD in the patients with severe aortic valve stenosis.

Methods: Thirty-five patients (22 males and 13 females, mean age 64.5 ± 8.4 years) with aortic valve stenosis (maximal instantaneous ventriculo-aortic gradient greater than 50 mmHg) were included. Seven patients had significant CAD (>50% luminal stenosis in coronary arteries) (CAD-group) and 28 patients had no significant CAD (non CAD group) on coronary angiogram. Agatston total coronary artery calcium deposit scores (TCS) were calculated by use of EBT. TCS were compared between CAD-group and non CAD group.

Results:

	CAD group	Non CAD group	
Age (years)	66.0 ± 7.3	64.1 ± 8.7	n.s.
Sex (male/female)	6/1	16/12	n.s.
TCS	1428 ± 1240	102 ± 279	p < 0.001

TCS values > 500 had a sensitivity of 86%, a specificity of 96% and an accuracy of 94% for predicting CAD.

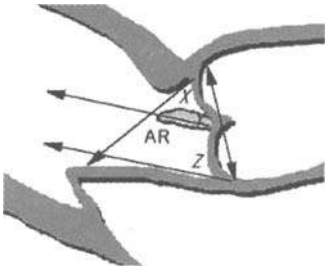
Conclusion: TCS using EBT can be useful for the noninvasive prediction of CAD in patients with aortic valve stenosis.

P2897 Structural features of the left ventricular outflow tract in physiological aortic valve regurgitation

H. Matsuoka, S. Yamachika[1], M. Hayano[1], K. Yano[1]. *Internal Medicine, NTT Nagasaki Hospital, Nagasaki; [1]Third Department of Internal Medicine, Nagasaki University, Nagasaki, Japan*

Since the advent of the color Doppler echocardiography, a small degree of aortic regurgitation(AR) has been detected with relative frequency in clinically normal elder heart. This study aimed at clearing the mechanism and quantitative definition of this physiological regurgitation.

Methods: 299 Japanese patients were selected from consecutive 906 patients underwent echocardiography from Jan. 1, 1996 to Dec. 31, 1998 at NTT Nagasaki hospital.In all the patients,the M,B mode echocardiogram was normal.AR was detected and AR jet area,length and width were measured by color Doppler echocardiography.The dimension of aortic annulus and the angles of anterior(X) and posterior portion of left ventricular outflow tract(Z) to aortic annulus and angle of AR jet(Y) to aortic annulus were measured in long axis diastolic view (figure).



Results: The incidence of AR was 24.4%. AR jet angle was 83 ± 17° (range 129 to 51),area was 34 ± 25 mm^2 (range 106 to 6),length was 13 ± 7 mm (range 36 to 4) and width was 3.5 ± 1.3 mm (range 6.2 to 0.7). AR-positive group was significantly elder than AR negative group(68 ± 13 vs. 59 ± 16 years p < 0.0001). Body mass index (BMI) and the angle of X were significantly smaller in AR-positive group than in AR-negative group(21.9 ± 2.8 vs. 22.8 ± 3.4 P = 0.03. 80 ± 13 vs.85 ± 11 P = 0.008). There was no significant difference in the angle of Z between two groups (76 ± 10 vs.76 ± 11).In AR-positive group, except for obesity (BMI was more than 26.4), angle of X was significantly directly correlated with thickness of interventricular septum, (r = 0.26 p = 0.03) and inversely correlated with diameter of aortic annulus(r = −0.27 p < 0.03).

Conclusion: Slight obstruction of anterior portion of left ventricular outflow tract was associated with physiological aortic valve regurgitation.

P2898 The relationship between spontaneous echocontrast and microembolic signals established with transcranial Doppler ultrasonography

C. Gürgün, M. Zoghi, F. Özerkan, C. Ceyhan, E. Ercan, C.S. Çınar, C. Türkoğlu. *Ege University Faculty of Medicine, Cardiology Department, İzmir, Turkey*

The purpose of this study was to search microembolic signals established with transcranial doppler ultrasonography (TCD) in patients with mitral stenosis (MS) and spontaneous echocontrast (SEC).

Methods: Fourty seven patients with MS were included into the study (30 women, 17 men, mean age: 41 ± 12). Exclusion criterions were thromboembolic events, multiple valve disease, and previous cardiac operation. All patients underwent transthoracic and then transesophageal echocardiography. Transcranial doppler records were recorded for 30 minutes from bilateral middle cerebral arteries as transtemporally with depth of 40–50 mm (Multy-doppler X4 TCD, with 2 MHz probe). During recording, signals shorter than 300 msec and higher than 9 dB were evaluated as the embolic signals. The patients were divided into two groups according to having SEC. There was no significant difference in the medical treatment of both groups. Findings were shown on the table. P < 0.05 was accepted as statistically significant

	SEC(+) n: 29	SEC(−) n: 18	P
MVA (cm^2)	1.28 ± 0.26	1.49 ± 0.4	0.03
MG (mmHg)	11.6 ± 5.5	12 ± 5	0.8
MR ≥ 2 degree (%)	17	55	0.01
AF (%)	65	27	0.02
Having Embolic signal (%)	63	27	0.03
Mean Embolic Signal (Count)	7 ± 4	3 ± 2	0.04
Mean Embolic Signal (dB)	17 ± 6	11 ± 4	0.04

MVA: Mitral valve area, MG: Mitral gradient, MR: Mitral Regurgitation, AF: Atrial fibrillation.

Conclusion: increased microembolic signals were detected with TCD in patients with mitral stenosis who were SEC positive. This finding supports the relationship between SEC and thromboembolic events.

P2899 Does mitral regurgitation prevent left atrial spontaneous echo contrast and thrombus formation and effect LA and LAA function in patients combined with mitral stenosis?

C. Kirma, C. Kaymaz, N. Özdemir, F. Turan, M. Özkan. *Cardiology Dept, Kosuyolu Heart & Research Hosp., Istanbul, Turkey*

It is well documented that in pts with rheumatic mitral valve disease, severe mitral regurgitation(MR) prevents spontaneous echo contrast(SEC) and thrombus(THR) formation in left atrium (LA) and left atrial appendage(LAA). However in pts with moderate to severe mitral stenosis(MS) the effect of concomitant mild to severe MR on incidence of LA-LAA SEC-THR and LA-LAA functions is not evaluated. This study aimed to investigate the effect of mild, moderate and severe MR on LA-LAA functions and SEC-THR formation in pts with MS. 256 pts (167 F, 98 M, mean age: 37 ± 15, 95 pts with no, 84 pts with mild, 45 pts with moderate, 32 pts with severe MR, 117 pts with sinus rhythm-SR, 139 pts with atrial fibrillation-AF) with MS (mitral valve area < 1.5 cm^2) who underwent TEE evaluation were taken into study. Midportion of LA flow velocity (both evaluated with horizontal and vertical planes, at the regions of free of MR jet) and flow velocities and ejection fraction of LAA were determined. Degree of MR was graded as (A)with no or mild,(B)moderate, (C)severe. Data were compared with regard to cardiac rhythm among the three groups.

In pts with SR, LA diameter and LA-LAA flow velocities of Group B (5.2 ± 0.6 cm, 0.33 ± 0.11, 0.35 ± 0.14 m/sec) and C (5.4 ± 0.2 cm, 0.35 ± 0.12, 0.37 ± 0.13 m/sec) were greater than Group A (4.5 ± 0.5 cm, 0.19 ± 0.12, 0.20 ± 0.13 m/sec) (p < 0.05). Incidence of LA-LAA SEC-THR of Group A (45.7%, 10.8%) were also greater than Group B (0%, 0%) and C (0%, 0%) (p < 0.05). In pts with AF diameter of LA in Group A (5.5 ± 1.6 cm) was lower than the other two groups (5.5 ± 1, 6.3 ± 1.3, 6.1 ± 0.8 cm Group B,C respectively, p < 0.05) and flow velocity of LA-LAA in Group C (0.18 ± 0.2, 0.19 ± 0.1 m/sec) was greater than the other two groups (0.05 ± 0.08, 0.07 ± 0.01; 0.06 ± 0.1, 0.08 ± 0.09 m/sec, respectively Group A,B) (p < 0.05). Incidence of LA-LAA SEC-THR in Group C (13%, 5.8%) was lower than the other two groups (86%, 49%; 75%, 28%, Group A, B respectively) (p < 0.01). Age,sex, peak and mean mitral gradient, mitral valve area were not different in both SR and AF in all groups(p > 0.05).

In conclusion, pts with moderate to severe MR protects against for LA-LAA SEC and THR formation as well as LA-LAA dysfunction in SR in pts with MS. However in pts with AF, mild to moderate MR does not protects against LA-LAA SEC and THR formation and does not preserve LA-LAA function, which all may be related to embolic events.

P2900 Surgical repair for severe mitral regurgation deteriorates the left atrium and left atrial appendage function

C. Kirma, C. Kaymaz, N. Özdemir, F. Turan, M. Özkan. *Cardiology Dept, Kosuyolu Heart & Research Hosp., Istanbul, Turkey*

Protective effect of significant mitral regurgitation (MR) for left atrium (LA) against spontaneous echo contrast (SEC) and thrombus (THR) formation is well evaluated. However, the effect of surgical repair of mitral valve for MR on LA and left atrial appendage (LAA) functions has not been study. Ninetyfour patients with severe MR (49 F, 35 M, mean age: 38 ± 14, 44 pts in sinus rhythm-SR, 50 pts in atrial fibrillation-AF) were included in the study. Each patient was evaluated with multiplane TEE preoperatively and within the first week after surgery. Mid portion of LA flow velocity (both with horizontal and vertical planes, at the regions free of MR jet) and flow velocites and ejection fraction of LAA were determined. Pre- and postopetative data were compared with regard to cardiac rhythm (SR and AF) and patients with unaltered rhythm postoperatively were included in the study. Patients with postoperative moderate to severe MR or pts with obstructive THR of the mitral valve were excluded from the study.

Left atrial diameter was found to be greater in patients with AF (5.3 ± 1.1 cm) than in pts with SR (4.7 ± 0.6 cm) postoperatively ($p < 0.001$). Mitral valve area, maximal and mean mitral gradient did not differ significantly between the two groups in postoperative state. Although none of the patients in SR had SEC (%0;0/44) or THR (%0;0/44) preoperatively, 4 patients (%9) showed evidence of SEC while none of the patients showed evidence of THR postoperatively ($p > 0.05$). Among patients with AF,%2 had SEC and%2 had THR preoperatively while%58 (29/50) had SEC and%26 (13/50) had THR postoperatively ($p < 0.001$).

In patients with SR, LA flow velocities (0.44 ± 0.12 vs 0.30 ± 0.12 m/sec) decreased and LAA functions (0.48 ± 0.15 vs 0.38 ± 0.13 m/sec, 48% ± 14 vs 36% ± 15) deteriorated significantly after the operation (preop vs postop, $p < 0.05$). In patients with AF postoprative LA flow velocities (0.37 ± 0.14 vs 0.20 ± 0.12 m/sec) were also decreased, and LAA functions (0.36 ± 0.13 vs 0.20 ± 0.12 m/sec, 34% ± 13 vs 22% ± 11) deteriorated significantly as compared to the preoperative state (preop vs postop, $p < 0.05$).

We conclude that in patients with MR in SR the surgical repair of MR deteriorates LA-LAA functions mildly in patients with AF surgical repair of severe MR deteriorates LA-LAA functions markedly and LA-LAA SEC and THR may develop consequently.

P2901 Prevalence of bicuspid aortic valve in children: a population study

M. Boschello, E. De Dominicis, C. Basso[1], C. Perrone, A. Cera, R. De Nardis, A. Mecenero, D. Bicego, G. Thiene[1]. *Cardiology Dept, Hospital, Arzignano; [1]University, Pathology Dept, Padua, Italy*

Bicuspid aortic valve (BAV) is estimated to be one of the most frequent form of congenital heart disease. Acquired stenosis due to calcification is a common complication and causes of death in young patients are infective endocarditis and dissecting aneurysm of the ascending aorta. Clinical and necroscopic observation suggest that BAV affect 1% to 2% of the general population. Data are not available in healthy people. The prevalence of BAV is assesed in a sample of 817 school-going children from a rural area of Veneto Region. 400 male and 417 female, 10 years old, all asymptomatic, were screnned by means of physical examination, 12 leads ECG and two-dimensional echocardiograf (2D echo). Four (3 M and 1 F) out of 817 (0.5%) were found to have a BAV, 1 of whom with mild incompetence. Among non-BAV: 3 (0.3%) had a dysplastic valve with a small left coronary cusp, 1 a rheumatic valve disease, 9 (1%) showed mild aortic incompetence. Aortic root size was increased in all BAV, particularly at sinus of Valsalva level (BAV mean 25.7 mm, 2 mmSD vs non-BAV mean 22.2 mm, 2.4 mm SD; $p = 0.02$). In conclusion, a low prevalence of BAV (0.5%) was found in school children population. BAV was strictly associated with aortic root enlargement. In these patients a 2D echo follow-up is mandatory.

VALVULAR HEART DISEASE – VARIOUS TOPICS

P2902 Effects of left atrial compliance on the pulmonary artery pressure in patients with pure mitral stenosis and sinus rhythm

J. Ha, N. Chung, Y. Jang, W.C. Kang, D.H. Choi, S.J. Rim, W.H. Shim, S.Y. Cho, S.S. Kim. *Cardiology Division, Yonsei Cardiovascular Center, Seoul, South Korea*

Background: Large left atrial(LA) V wave can be observed in pts with pure mitral stenosis(MS) because of decreased LA compliance. Few data are available regarding the relation between the magnitude of LA V wave and the peak pulmonary artery pressure(PAP) in MS. We hypothesized that PAP may be higher in pts with decreased LA compliance and large V wave.

Methods: We analyzed the right heart and transseptal catheterization data in 112 pts (16 male, 96 female, aged 39.1 years) of pure MS with sinus rhythm. Peak systolic, diastolic and mean pulmonary artery pressures were measured from the right heart catheterization. The magnitude of LA a, x and V wave was measured from transseptal catheterization. Two-dimensional and Doppler echocardiography were also performed to measure the left atrial size, mitral valve area (MVA), mean mitral gradient(MG) and valvular regurgitation. Multiple regression analysis was performed to identify the most important factor in the determination of PAP.

Results: Large V wave, defined if peak V wave height exceeded mean LA pressure by 10 mmHg or more, was observed in 44(39%) of 112 pts. Increased peak PAP (>50 mmHg) was observed in 35(31%) pts. Univariate analysis showed that factors associated with increased PAP were smaller MVA, higher MG, higher mean LA pressure and higher LA V wave; among them, LA V wave and ($p = 0.000$) and MG ($p = 0.001$) were significant independent factors for PAP in multivariate analysis.

Conclusion: In pts with pure MS with sinus rhythm, the magnitude of LA V wave is strongly associated with PAP and this finding may suggest that LA compliance is the most important factor determining PAP in pure MS.

P2903 Transoesophageal echo with three-dimensional reconstruction reveals organic tricuspid valve disease in patients with severe valve regurgitation and apparently normal cusp morphology

M.Y. Henein, C.A. O'Sullivan, A.J.S. Coats, D.G. Gibson. *Royal Brompton Hospital, London, UK*

Severe tricuspid regurgitation (TR) is well recognised as a long term complication of rheumatic mitral valve replacement (MVR), impairing the functional results of surgery. However, its exact basis remains unclear and its management is unsatisfactory. We therefore studied 22 patients, 17 female, age 67 ± 10 yrs, 8 ± 2 years after MVR by transoesophageal echo (TOE) with 3 D reconstruction. All had normal mitral prosthesis function but 15 had impaired exercise tolerance and marked fluid retention. In them transthoracic echo-Doppler showed enlarged right atrium (RA) and right ventricle (RV), a mean RV-RA pressure drop of 15 ± 4 mmHg and apparently normal cusp anatomy. TOE and 3D reconstruction, however, demonstrated abnormal cusp anatomy in all patients, with restricted cusp motion in 10, cusp shortening and thickening in the remainder, and dilatation of tricuspid ring suggesting rheumatic involvement. Although diastolic transtricuspid velocities were increased in all patients due to increased stroke volume (peak 1.0 m/s), significant tricuspid stenosis was present in 2 patients (mean gradient 4 and 3 mmHg). Histopathology confirmed leaflets vascularisation and extensive fibrosis in 2 patients who underwent tricuspid valve replacement.

Conclusion: Rheumatic cusp involvement contributes to severe tricuspid regurgitation occurring long term after mitral valve replacement, although overt stenosis is uncommon. Knowledge of the structural basis of this condition may thus improve its long term management.

P2904 Changes in echocardiographic left ventricular performance following mitral valve repair or replacement for pure mitral regurgitation

G.R. Ciliberto, E. Lobiati, A. Alberti, A. Moreo, G. Cataldo, E. Taglieri, E. Vitali, A. Pellegrini. *Cardiology Department, Niguarda Hospital, Milan; Department of Cardiothoracic Surgery, Niguarda Hospital, Milan, Italy*

Mitral Valve (MV) repair compared with replacement has been associated with lower mortality and better Left ventricular (LV) function. Aim of this study was to compare the effects of MV repair or replacement on postoperative LV performance in pure mitral regurgitation (MR).

Methods: We retrospectively analyzed 106 consecutive patients who underwent surgery for pure MR: 78 MV repair (Group A) and 28 MV replacement (group B). All patients underwent 2D echocardiographic study (ECHO) preoperatively and 1 year after surgery in order to obtain LV function parameters. Group A and B were devided on the basis of preoperative LVEF >= 60% (subgroup A1 and B1) or <60% (A2 and B2) and LVedD >= 65 mm (A3 and B3) or <65 mm (A4 and B4). Baseline ECHO parameters were substancially homogeneous within each subgroup (A1 vs B1, ...).

Results are reported in the following table.

Subgroups	LVEF %			LVedD (mm)		
	Preoper.	Postoper.	P	Preoper.	Postoper.	P
A1	68.1 ± 4.8	58.2 ± 7.1	0.001	59.1 ± 7.1	50.6 ± 6.1	0.001
B1	68.5 ± 4.7	56.8 ± 10.4	0.01	61.2 ± 7.3	54.1 ± 6.3	0.001
A2	55.7 ± 2.8	49.7 ± 14	ns	62.4 ± 6.3	52 ± 2.9	0.001
B2	53.4 ± 2.8	41.1 ± 8.7	0.01	65.8 ± 12.4	63.5 ± 9.6	ns
A3	65 ± 10	54.8 ± 10	0.05	69.4 ± 4.6	54.8 ± 10	0.001
B3	58.6 ± 10.6	45.1 ± 10.3	0.05	70.8 ± 7.3	63.1 ± 8.8	ns
A4	65.7 ± 6.3	58.1 ± 7.5	0.001	56.1 ± 5.6	49.1 ± 5.5	0.001
B4	65.5 ± 6.1	57.1 ± 8.2	0.001	56.6 ± 4.9	53.7 ± 7.2	ns

In pts with LVEF > 60% or LVedD < 65 mm, postoperative parameters are favourable independently of the type of surgery. If preoperative LVEF is <60% or LVedD > 65 mm, postoperative changes are still favourable after repair, while after replacement LV dimensions remain high with a significant decrease in LVEF.

Conclusions: These data suggest that in pts with significant MR, surgery should not be delayed, even if replacement is expected, as in pts with LVEF < 60% or LVedD > 65 mm favourable results can usually be obtained only with MV repair.

P2905 Valvular heart disease is associated with Chinese herbs and appetite suppressants intake

P. Unger, J. Nortier[1], M.-C. Muniz[1], J.L. Vandenbossche[2], D. Plein[2], Y. Goffin[3], P. Vereerstraeten[1], J.L. Vanherweghem[1]. *Cardiology; [1]Nephrology Departments, Erasme Hospital; [2]Cardiology Department, Saint Pierre Hospital; [3]Pathology Department, Brugmann Hospital, Université Libre de Bruxelles, Brussels, Belgium*

Chinese herbs nephropathy (CHN), described in 1993 in women under slimming regimen, has been attributed to inadvertent replacement of *Stephania tetrandra* (ST) by *Aristolochia fang chi*. Cases of aortic regurgitation (AR) were reported in these patients. However, factors such as aging and metabolic or hemodynamic disturbances of end-stage renal disease could contribute to valvular abnormalities.

Methods: We assessed the prevalence of Doppler-detected valvular regurgitation in 40 CHN women with terminal renal failure (currently dialysed or transplanted) and in 32 age-matched control women with nephropathy of other origin (CTRL). Total cumulative doses of ST and appetite suppressants were reviewed and compared in CHN patients with and without valvular heart disease, defined as ≥ mild AR and/or ≥ moderate mitral or tricuspid regurgitation.

Results: 21 out of 40 CHN patients presented AR as compared to 6 out of 32 CTRL (P < 0.01). One CHN patient underwent aortic valve replacement in 1995 for recent onset of severe AR. All remaining AR were mild or moderate. There were no significant differences between CHN and CTRL with regard to mitral and tricuspid regurgitations. The mean (±SD) total cumulative doses of ST and fenfluramine (FEN) were higher in patients with (n = 23) compared to patients without (n = 17) valvular regurgitation (ST: 225 ± 17 vs 164 ± 19 g, P = 0.023; FEN: 19.0 ± 2.6 vs 10.9 ± 1.8 g, P = 0.020).

In conclusion, transplanted and dialysed CHN patients present an increased prevalence of valvular regurgitation, which is associated with a higher intake of ST and FEN. The respective role of these substances remain to be determined.

P2906 Is human myocardial Na^+/Ca^{2+} exchanger transcription altered according to the level of myocardial adaptation to chronic volume or pressure overload in patients with valvular heart disease

C. Piper[1], A. Dörner[2], J. Bilger[2], E.-M. Henrichs[2], H.-P. Schultheiß[2], D. Horstkotte[1]. *[1]Department of Medicine, Heart Center North Rhine-Westphalia, Ruhr University Bochum, Bad Oeynhausen; [2]Department of Medicine, University Hospital Benjamin Franklin, Free University of Berlin, Germany*

A significant upregulation of Na^+Ca^{2+} exchanger (EXCH) gene expression was found in explanted hearts from patients with end-stage heart failure. As a change of the EXCH expression is one of the signs of disturbed myocardial calcium homeostasis, we investigated in patients with chronic valvular heart disease whether and in case at which level of myocardial adaptation to chronic pressure and/or volume overload the EXCH transcription is altered.

Methods: To determine the EXCH mRNA copy number in small biopsy samples, we established a quantitative PCR method using an internal RNA standard. Endomyocardial biopsy from the interventricular septum (IVS) of 11 patients (P) with aortic stenosis (AS), 5 P with aortic regurgitation (AR) and 6 P with primary mitral regurgitation (MR) were examined. The patients' left ventricular pump function was assessed by cardiac catheterization: Cardiac index (CI) varied between 1.8 and 4.5 l/min/m^2 and left ventricular ejection fraction (EF) between 34 and 70%. In addition, endomyocardial tissue (IVS) from explanted hearts of 13 P with end-stage heart failure were examined. As controls served endomyocardial tissue (IVS) from 4 P, in whom cardiac disease could be excluded.

The average level of EXCH mRNA in controls (2.2 ± 1.3 amol/ng total RNA) was not different from those in P with AS (1.8 ± 1.4 amol/ng total RNA) or in P with AR/MR (2.0 ± 1.5 amol/ng total RNA). The EXCH transcription showed no alterations parallel to the severity of valvular dysfunction nor to the impairment of left ventricular (LV) pump function. However, patients with end-stage heart failure (CI 2.4 plus EF < 30%) had a fourfold increase in EXCH mRNA level (8.9 ± 1.9 amol/ng total RNA).

LV pump function	CI (l/min/m^2)			EF (%)	
	>3.5	3.5-2.4	<2.4	>50	≤50
EXCH (amol/ng total RNA)	1.4 ± 1.1	2.5 ± 1.8	1.8 ± 1.0	1.9 ± 1.8	1.9 ± 0.9

In conclusion, an alteration of the EXCH transcription in humans seems to occur only after manifestation of end-stage heart failure and seems to indicate an irreversible myocardial damage. The EXCH transcription is therefore no marker to detect the exhaustion of myocardial adaptation to chronic overload.

P2907 Transseptal left heart catheterization: modification to the technique using venous puncture only

H. Kandil. *Cardiology Dept, Cairo University, Cairo, Egypt*

Background: Transseptal left heart catheterization (TSC) is the key to successful balloon mitral valvotomy (BMV). Different fluoroscopic projections are used for TSC. It is usually done in the postero-anterior or right anterior oblique view using femoral arterial and venous punctures. Arterial puncture is used primarily for direct blood pressure monitoring, diagnostic purposes and to guide some operators during atrial septal puncture.

Methods: We performed TSC using femoral venous puncture only in 92 adult patients with tight mitral stenosis referred for BMV. Standard Mullin's dilator and Brockenbrough needle were used in all patients. Positioning of the Mullin's dilator with the Brockenbrough needle in the innominate vein was done using standard steps over a straight guide wire in the postero-anterior view. Interatrial septal puncture was done under fluoroscopic guidance only in the non magnified mode in the lateral view (90°) with the curve of the Brockenbrough needle directed straight towards the patient's left side. Puffs of concenterated dye are injected during needle withdrawal over the interatrial septum to verify interatrial septal bulge. Before transseptal puncture mild septal staining is done by injection of 1 ml of concentrated dye at the puncture site. The preferred puncture site is at the horizontal level of the body of the 8th thoracic vertebra. In this lateral view the aorta is anterior to the left atrium and away from the interatrial septum. After transseptal puncture by the needle tip, puffs of concentrated dye are injected into the left atrium to confirm correct needle position. Prior to mullin's dilator advancement and before I.V heparin injection, the brockenbrough needle is connected to pressure monitor to record left atrial pressure and to confirm proper needle site.

Results: TSC was successful in all patients. No complications occurred apart from transient vagal reaction in one patient.

Conclusion: The use of (90°) lateral view with the curve of the Brockenbrough needle straight at the level of the body of the 8th thoracic vertebra, appears to allow safe interatrial septal puncture. Only a single right femoral venous puncture is needed for this technique.

P2908 Effects of balloon mitral valvuloplasty on left atrial energetics

E. Tsiamis, J. Dernellis, C. Stefanadis, C. Stratos, C. Tendolouris, P. Toutouzas. *Department of Cardiology, University of Athens, Athens, Greece*

Total mechanical energy of the left atrium (LA) can be quantified by a specific area in the pressure-area (P-A) diagram that is bounded by the end-systolic and end-diastolic P-A relations and the systolic P-A trajectory. In mitral stenosis (MS), LA afterload is increased because resistance is increased at the mitral valve.

Methods: We studied the effects of acute alterations in LA afterload on LA energetics caused by dilatation of the stenotic mitral valve by means of retrograde nontransseptal balloon mitral valvuloplasty (RNBMV). RNBMV is a technique developed in our institution for dilating stenotic mitral valves without any damage to the interatrial septum. LA pressure-area relations were obtained in 8 patients with mitral stenosis who were in sinus rhythm before and after RNBMV as well as in 8 controls (C). LA pressure was recorded by a catheter-tip micromanometer introduced retrogradely into the LA. LA area was simultaneously recorded using acoustic quantification. The total mechanical energy was quantified by the systolic P-A area (PAA). The PAA consists of two smaller areas: one is the area for external work (EW), determined by the LA A loop, and the other is the area for mechanical potential energy (PE) between the end-systolic and end-diastolic P-A relation curves. Furthermore, LA contractile efficiency (Ef) was determined as the ratio of EW/PAA.

Results:

	Controls	$MS_{pre\ RNBMV}$	$MS_{after\ RNBMV}$
PAA, mmHgcm^2	11.8 ± 1.7	23.9 ± 2.7***	13.7 ± 2.8***
EW, mmHgcm^2	7.5 ± 1.8	5.5 ± 0.8**	8.6 ± 2.3**
PE, mmHgcm^2	4.3 ± 0.5	18.5 ± 2.2***	5.2 ± 0.6***
Ef, mmHgcm^2	0.63 ± 0.07	0.23 ± 0.02***	0.62 ± 0.05***

$^{**}p < 0.01$, $^{***}p < 0.001$ controls vs $MS_{preRNBMV}$ and $MS_{preRNBMV}$ vs $MS_{afterRNBMV}$.

Conclusions: The mechanical efficiency of LA reduces in MS while following RNBMV, there is a significant increase. This efficiency varies as a function of afterload.

P2909 Increased platelet activation and endothelial dysfunction in patients following percutaneous balloon mitral valvuloplasty

I.R.A. Goldsmith[1,2], F.L. Li-Saw-Hee[1], A.D. Blann[1], G.Y.H. Lip[1]. [1]*HTVBU, University Dept of Medicine, City Hospital, Birmingham;* [2]*Cardiothoracic Surgical Unit, Walsgrave Hospital, Coventry, UK*

Immediately following percutaneous balloon mitral valvuloplasty (PBMVP), patients have a 3% risk of systemic thromboembolism. This may be due to increase in coagulopathy, platelet activation and endothelial dysfunction. To investigate this we measured indices of platelet activation (soluble P-selectin, sP-sel, ELISA), endothelial dysfunction (von Willebrand factor, vWf, ELISA) and coagulation (fibrinogen, modified Clauss) in 16 patients (15 females; mean age 59 years ± 10) admitted for PBMVP and 16 healthy age and sex matched controls. Peripheral venous blood samples were obtained prior to PBMVP, immediately following PBMVP and 24 after PBMVP. Arterial blood samples were obtained prior to and post-PBMVP.

Results, analysed using Wilcoxon sign test and expressed as mean (standard deviation) are:

Index	Pre-PBMVP	Post-PBMVP	24 hours
sP-sel (ng/ml)	73.4 (37)	92.8 (35)*	121.1 (51)*
vWf (IU/dL)	148.8 (24)	150.9 (34)	161.0 (15)*
Fibrinogen (g/l)	4.2 (0.8)	3.9 (0.9)	4.1 (0.9)

$^{*}P < 0.05$

Following PBMVP there was a significant increase in venous sP-sel levels immediately post-procedure and at 24 hours afterwards and arterial levels correspondingly increased post-PBMVP (p = 0.01). There was a significant increase in mean venous, but not arterial levels of vWf at 24 hours post-PBMVP. There was no significant changes in mean venous or arterial fibrinogen levels following PBMVP.

Conclusions: The increased levels of sP-sel immediately post-procedure ant at 24 hours, in association with increased vWf levels at 24 hours after PBMVP, is in keeping with increase in platelet activation and endothelial dysfunction following PBMVP. These changes may contribute to the increased risk of thromboembolism following PBMVP and suggest the need for adequate antiplatelet therapy and anticoagulant therapy following PBMVP.

GRADING OF VALVULAR STENOSIS

P2910 Reliability of different indexes of aortic stenosis severity in low flow states

F. Antonini-Canterin, F. Macor, D. Pavan, E. Cervesato, F. Ribichini[1], V. Ferrero[1], P. Faggiano[2], A. Cassin, C. Burelli, G.L. Nicolosi. *Cardiology Dept. ARC, Pordenone;* [1]*Cuneo;* [2]*Brescia, Italy*

Background. New indexes of aortic stenosis (AS) severity have been recently introduced in addition to the transvalvular gradient and to the traditional "flow-corrected" indexes (continuity equation valve area; aortic valve resistance). These indexes can be defined as "function-corrected" (fractional shortening-velocity ratio = fractional shortening/4V max^2; ejection fraction-velocity ratio = ejection fraction/4V max^2) and "pressure-corrected" (stroke work loss = mean gradient/mean gradient + systolic blood pressure). Little information however is available about the reliability of each of these indexes for identifying patients with severe AS in low flow states.

Methods. We analyzed 161 patients with AS (96 males, 65 females, aged 68 ± 9 years) and low cardiac output (thermodiluition cardiac index < 2.5 l/m^2). All pts underwent cardiac catheterization and Doppler-echocardiography within 48 hours one of the other. Hemodynamic Gorlin valve area was used as gold standard. Echocardiographic indexes were measured by an investigator unaware of hemodynamic findings.

Results. Mean Gorlin valve area was 0.7 ± 0.3 cm2; cardiac catherization allowed to identify 129 patients with severe AS (Gorlin valve area ≤ 0.8 cm^2) and 32 with mild-to-moderate AS (area > 0.8 cm^2). Respective values of sensitivity and specificity are reported for each echocardiographic index (using previously suggested cut-off values of severity).

	Cut-off value	Sensitivity	Specificity
Mean Doppler Gradient	≥50 mmHg	55%	100%
Continuity Equation	≤0.8 cm^2	83%	90%
Mean Aortic Valve Resistance	>240 d s cm^{-5}	77%	97%
Percent Stroke Work Loss	≥23%	84%	84%
Ejection Fraction-Velocity Ratio	≤0.8	87%	88%
Fract. Shortening-Velocity Ratio	≤0.5	88%	78%

Conclusion. Our study confirms the inadequate sensitivity of Doppler gradient alone in the assessment of AS severity in patients with decreased cardiac output. The simple "function-corrected" and "pressure-corrected" indexes (in particular ejection fraction-velocity ratio and percent stroke work loss) provide a good diagnostic accuracy as well as "flow-corrected" indexes.

P2911 Non invasive assessment of pure mitral stenosis: role of dobutamine stress echocardiography (DSE) and cardiopulmonary test (CPX)

C.A. Greco, M. Morello, R. Casoni, A. Fubini, E. Brscic, L. Mangiardi, G.P. Trevi. *Cardiologia Universitaria, Molinette Hospital, Turin, Italy*

Patients with mitral stenosis may present severe symptoms although basal echocardiographic data show only moderate mitral stenosis.

The aim of this study was to correlate the functional impairment (as evaluated by CPX) with DSE data in patients with pure moderate mitral stenosis.

Twenty-three consecutive symptomatic patients (21 women, mean age 50 ± 12 years, NYHA class 2.3 ± 0.5) with pure moderate mitral stenosis [mitral valve area (MVA): 1.4 ± 0.2 cm^2, mean valvular gradient (MVG): 8 ± 2 mm Hg] were evaluated. Eleven patients had atrial fibrillation.

CPX data included maximum oxygen uptake (max VO_2), max VO_2 % of predicted maximal oxygen uptake [ratio Wassermann (RW)].

DSE was performed increasing dobutamine by 5 mg/kg/min every 3 minutes until either maximal heart rate or symptoms occurred. MVG, MVA, pulmonary artery pressure (PAP) and cardiac output (CO) at rest and at peak stress were obtained.

Results: according to CPX data patients were divided in two groups: group A with impaired cardiopulmonary fitness (12 patients, RW = 0.61 ± 6, max VO_2 = 15 ± 3 ml/kg/min) and group B with normal cardiopulmonary results (11 patients, RW = 0.99 ± 17, max VO_2 = 19 ml/kg/min). Baseline clinical and echocardiographic data were similar in the two groups. At peak stress, PAP was significantly higher in group A (72 ± 2.1 versus 43 ± 7.2, p = 0.005) than group B, while MVG (15 ± 6.6 versus 15 ± 3.9) and CO (5.8 ± 1.1 versus 7.3 ± 2.2, p:0.06) increased in a similar manner in the two groups.

Conclusions: CPX and DSE are useful for assessment of mitral stenosis in patients with discrepancy between symptoms and baseline echocardiographic data. Patients with moderate mitral stenosis and impaired functional capacity show a disproportionate increase of PAP compared to the change of MVG, during stress. A pulmonary mechanism may be responsible of the poor functional capacity in these patients.

P2912 Aortic valve area and resistance in the evaluation of aortic stenosis: a dobutamine echocardiographic study

G. Sarasso, L. Airoldi, G. Marti, G. Francalacci, C. Piccinino, E. Occhetta, C. De Gasperis[1], C. Vassanelli. *Divisione Clinicizzata di Cardiologia, Università "A. Avogadro", Novara; [1]Divisione di Cardiochirurgia, Ospedale Maggiore, Novara, Italy*

In the evaluation of aortic stenosis (AS), Aortic Valve Area (AVA) and Resistance (AVR) have been suggested to be less flow-dependent than gradients, but presently few data are available. Aim of the study was to compare AVR to AVA for assessment of AS and normal LV function, at baseline and after dobutamine echo (DOB). We studied 15 pts with calcified AS, in sinus rhythm, without other valvular or coronary heart disease. Etiology was rheumatic (4) or degenerative (14 pts). Age was 68 ± 11 years. A standard DOB protocol was used. AVA was calculated with different echo methods: 1) Gorlin formula, 2) Continuity equation ($(Cross\ sectional\ area_{LVOT} * (V_x^{LVOT}/V_x^{aorta}))$, using for V_x either, V_{max}, V_{mean} or Flow Integral from LVOT; Stroke Work Loss (SWL) was also computed.

Results are summarized:

	Ao area V_{max}	Ao area V_{mean}	Ao area FVI	Ao area Gorlin	AVR	SWL %
Baseline	0.88 ± 0.3	0.82 ± 0.2	0.89 ± 0.3	0.93 ± 0.3	234 ± 115	23.1 ± 7.1
DOB	0.87 ± 0.3	0.84 ± 0.3	0.88 ± 0.3	0.91 ± 0.3	299 ± 139	30.6 ± 7.4
Change	−1.4 ± 14%	+6.4 ± 22%	−3.9 ± 23%	−2.2 ± 25%	+28 ± 44%	+37 ± 30%
p	ns	ns	ns	ns	<0.05	<0.001

No patient experienced major symptoms or arrhythmias during DOB. A good inverse linear correlation was found between G_{max} and V_{max}-calculated AVA (r = −0.80) at baseline. After DOB, AVA calculated with either method remained unchanged. However, relatively large interindividual variations were found. During DOB, 3 pts (21%) developed a significant intraventricular (IV) pressure gradient (mean 35 mmHg) that prevented calculation of AVA in two. In these subjects, LVOT flow at baseline was slightly higher (mean 108.3 cm/sec) than in the remaining pts (mean 74 cm/sec). Among the different methods, V_{max}-calculated area was the most flow-independent and showed the least interindividual variations while SWL and AVR were significantly flow dependent. AVR has been previously found to be the most flow-independent measure of AS severity in subjects with low-flow, low-gradient critical AS. In our pts with normal LV function, AVR increased significantly more than AVA. In conclusion, DOB proved to be a useful test for assessing AS even in pts with normal LV function. In comparison to AVR and SWL, V_{max}-calculated AVA was the most flow-independent parameter. Development of IV pressure gradients was a frequent and often misleading finding. DOB could unmask latent intraventricular gradients as a potential cause of misinterpretations of measurements of AVA.

P2913 Plasma N-terminal proBNP and cardiotrophin-1 in aortic stenosis

S. Talwar, P.F. Downie, I.B. Squire, J.E. Davies, D.B. Barnett, L.L. Ng. *Dept of Medicine & Therapeutics, Leicester University, Leicester, UK*

Echocardiography with doppler examination of the aortic valve provides a very accurate assessment of the transvalvular gradient across the valve and is used to monitor progression of disease. Plasma BNP has been shown to correlate with end-systolic wall stress in patients with aortic stenosis (AS). We hypothesized that plasma N-Terminal proBNP (NT) and a newly identified cytokine Cardiotrophin-1 (CT-1) are elevated in patients with AS and correlate to the trans-valvular pressure gradient (TVPG).

Method: We compared plasma NT and CT-1 in15 AS patients (5 males, mean age 79 years [range 60–94], mean TPG 39.3 mm Hg [20–100]) with 10 echocardiographic normal controls (mean age 55.9 years [40–79]). None of the patients had Left ventricular systolic dysfunction (i.e. wall motion index < 1.4) or significant mitral regurgitation. Two competitive immunoluminometric assays using a methyl acridinium ester to label the peptides and an in-house polyclonal antibody to amino acids 65–76 of the prepro BNP sequence and 105–120 of the CT-1 sequence were developed. Results are expressed as medians [ranges] and comparisons were by the Mann-Whitney test.

Results: NT levels were elevated in AS patients when compared to the controls (242.9 fmol/ml [79.2–541.8] Vs 144 fmol/ml [73.7- 206.3], p = 0.001 Vs controls]. Also CT-1 levels were elevated in AS patients when compared to the controls (53.9 fmol/ml [33–86.3] Vs. 25.3 fmol/ml [7.6–37.2], p = 0.0001 Vs controls). Both NT and CT-1 levels correlated to the TVPG (r = 0.63 & r = 0.68, p = 0.01 & p = 0.005, respectively). Furthermore NT and CT-1 levels in the AS patients were weakly correlated (r = 0.49, p = 0.06). On best subset analysis the strongest correlate with TVPG was CT-1 (R2 = 42.8). The addition of NT improved diagnostic accuracy (R2 = 51.1).

Conclusion: These results suggest NT and CT-1 levels increase in proportion to the TVPG and could potentially be used to monitor progression of disease. These markers may be used to better identify the optimum time for surgery in AS.

P2914 Differences between Doppler and catheter gradients in aortic valve stenosis: related factors

F. Calvo, V. del Campo, X.A. Fernández, R. Mantilla, R. Claro, E. Ponce, J.L. Escribano, R. Ruiz, J. Pasalodos. *Hospital do Meixoeiro, Vigo, Spain*

In the assessment of aortic valve stenosis, discrepancies between Doppler (D) and catheterization (©) gradients have been reported. The aim of the study was to investigate the frequency and possible related factors in the overestimation by D of mean aortic gradient obtained at ©.

Methods: We examined 75 consecutive patients (p) with aortic valve stenosis in sinus rythm. Mean age was 69 ± 10 years and D was performed 1 hour prior to ©. Relevant overestimation (RO) was defined if D mean gradient exceeded >10 mmHg that one obtained in catheter pull-back from left ventricle to the aortic root.

Results: Pearson correlation coefficient between D and © in those 75 pts was 0.90. RO was founded in 19 p (25%) and main results in univariate analysis were:

	RO n = 19	NO n = 56	p
Female sex	12 (63%)	23 (41%)	0.09
Height < 160 cm	7 (75%)	8 (46%)	0.04
Hemoglobin (hg), g/dl	12.5 ± 1.4	13.9 ± 1.3	0.003
Aortic root diameter, cm	2.9 ± 0.3	3.2 ± 0.3	0.004
Aortic root (A) < 3 cm	17 (81%)	21 (38%)	0.0001
Valve regurgitation (VR) > 2+	6 (32%)	6 (11%)	0.04
Mean D gradient, mmHg	80 ± 24	61 ± 23	0.004
D Heart rate, beats per min.	77 ± 12	72 ± 11	0.06

No other significant differences were seen attending to different clinical and echocardiographic variables including medications and selected acoustic window. Entered in a multiple logistic regression analysis, only A < 3 cm (OR 22) and VR > 2+ (OR: 9.7) were identified as independent predictors of RO. In this model, RO was predicted with 59% sensibility and 96% specificity.

In conclusion, in the setting of adult aortic valve stenosis, echocardiographic and clinical variables, mainly an aortic root diameter below 3 cm, may be useful to predict relevant discrepancies between Doppler and catheter gradients.

P2915 Aortic stenosis: role of contrast Doppler echocardiography

A. Almeida, L. Sargento[1], H.M. Gabriel, J. Marques da Costa, J. Morais, F. Madeira, C. David, J. Oliveira, J. Correia da Cunha, M. Celeste Vagueiro. *Serv. Cardiologia, Hosp. Santa Maria, Lisbon; [1]Hosp. Santa Maria, Serv. Cardiologia, Lisbon, Portugal*

Objective: The aim of this study is to compare the severity of aortic stenoses assessed by conventional and contrast Doppler echocardiography, with the "gold-standard" of cardiac catheterization.

Methods: We evaluated 21 consecutive patients referred to catheterization study for aortic stenosis, 12 men and 11 women, aged 39 to 94 years old (68 ± 14). All were submitted to conventional Doppler echocardiography, contrast Doppler echocardiography with Levovist® and catheterization study. Doppler measurements included: peak aortic velocity (V2) and velocity time integrated (VTI2), left ventricular outflow tract velocity (V1) and VTI (VTI1), peak aortic gradient (MxGr), mean aortic gradient (MnGr), aortic valve area. Catheterization measurements: peak and mean aortic gradients (C-MxGr and C-MnGr).

Results: Compared with conventional Doppler measurements, the use of contrast yielded: 1. Aortic flow – increased V2 (p < 0.001), MxGr (p < 0.001), MnGr (p < 0.01), VTI2 (p < 0.01). 2. Left ventricle outflow tract flow – increased V1 and VTI1, without statistic significance. 3. No statistic difference between aortic valve areas.

Doppler measurements vs. catheterization data: A positive significant correlation was found between C-MxGr and MxGr without contrast (r = 0.73, p < 0.001) and a stronger one between C-MxGr and MxGr with contrast (r = 0.89, p < 0.001). MxGr with contrast was higher (p < 0.01) than the C-MxGr (81.5 ± 27 vs. 70.5 ± 32).

Conclusion: In the evaluation of aortic stenosis, Doppler echocardiography has an excellent correlation with catheterization study. The use of contrast is a reliable method for the evaluation of aortic stenosis, having a better correlation with hemodynamic study than the conventional Doppler.

INFECTIVE ENDOCARDITIS

P2916 Embolization after adequate antibiotic treatment in infective endocarditis

C. Graupner, I. Vilacosta, J.A. San Román[1], J.V. Sanmartín[2], O. Sanz[1], C. Sarriá[2], R. Ronderos[3], C. Fernández, D. Echazarreta[3], W. Stoermann[3]. *Hospital Universitario San Carlos, Madrid; [1]Hospital Universitario de Valladolid; [2]Hospital de la Princesa, Madrid, Spain; [3]Hospital de San Juan de Dios, La Plata, Argentina*

Aim and Methods: Assess embolization of patients (P) with infective endocarditis (IE) once an adequate antibiotic treatment has been initiated based upon prospective clinical follow-up.

The study group consisted of 143 episodes (ep) of left sided endocarditis (138 P, 92 men, mean age 56 ± 14 years) studied by transesophageal echocardiography (TEE). According to Duke criteria, 132 ep had definitive and 11 probable IE. These P were clinically followed (mean time follow-up was 144 days). Forty nine ep were on prosthetic valves and in 43 ep the P was on anticoagulants. Characteristics of the vegetations were analyzed by TEE.

Results: There were 27 embolic events in 22 ep (15.4%, group I). Thirteen of these embolic (48%) involved the central nervous system. Seventy five percent of these emboli occurred during first two weeks after TEE and adequate antibiotic treatment The remaining 121 ep did not embolize (group II). There were no significant differences between microorganisms of group I and II (*staphylococcus aureus:* 20 in 4 gI and 16 gII, *staphylococcus coagulase negative:* 21 in 4 gI and 17 gII. No significant differences among the infected valves were found. Anticoagulation was present in 18% in gI and 32% in gII (p = NS), and atrial fibrillation was detected in 22% in gI and 25% in gII (p = NS). Previous emboli was not a risk factor for embolization after treatment (8 gI and 29 gII, p = NS). TEE showed no differences in vegetation detection rate (91% gI and 86% gII). Comparing the vegetation size by TEE there were no statistical differences between both groups: ≤9 mm (16.7% gI and 29.2% gII), 10–20 mm (61.1% gI and 53.9% gII), ≥21 mm (22.2% gI and 16.9% gII). Surgery (41% gI and 54% gII, p = NS) and in-hospital mortality (41% gI and 31.5% gII, p = NS) was not different for both groups.

Conclusion: 1. Embolization after adequate antimicrobial therapy is frequent and most emboli occur during the first 2 weeks of treatment. 2. Vegetation size does not predict systemic embolism. 3. Embolic events do not appear to be predicted neither by the type of microorganism nor the clinical profile.

P2917 Active infective endocarditis. Prognosis of patients with initial medical treatment

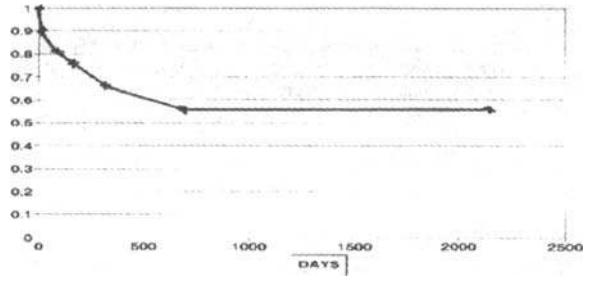
A. Hershson, O. Andrin, E. Gabe, C. Nagel, A. Torino, H. Casabe. *Cardiology Dept, Fundacion Favaloro, Buenos Aires, Argentina*

Background: Infective endocarditis is fatal if untreated. Despite microbiological cure, actuarial curves after admission show a significant number of late surgery or death.

Objective: To analyze the prognosis of patients with Active Infective Endocarditis (AIE) non requiring surgery during hospitalization.

Material and Methods: From June 1992 to January 1999, 129 patients (p) were included. During hospitalization, 83 p required surgery. Of the remaining 46 p treated medically, 44 were contacted during the follow-up interval [mean of 648 days (2–2145)]. Survival free of events (surgery or death) was performed by the Kaplan-Meier method.

Results: Mean age was 52.3 ± 17 years; male sex 67%. AIE affected native valves in 47.8% and prosthetic valves in 52.1%. In 15 cases Staphylococci were involved, Streptococci in 22, other in 3 and hemocultures were negative in 4. The echocardiogram showed vegetations in 68%. Emboli were present in 10 p (22.7%). During follow-up 10 p died (22.7%) and 7 required valvular surgery (15.9%). One patient is in NYHA FC IV and the remaining 26 in NYHA FC I.



Survival curve free of events.

Conclusions: In this group of p with AIE non requiring surgery during hospitalization: 1) Survival free of events at mid term follow-up was 56%. 2) Most of the events occurred early after microbiological cure. 3) 96% of survival patients are in NYHA FC I.

P2918 Time-related occurrence of neurological complications in patients with infective endocarditis submitted to surgical treatment

A.J. Mansur, V.S. Issa, J. Fabri Jr., M. Grinberg, P.M.A. Pomerantzeff. *Heart Institute (Incor), University of São Paulo Medical School, São Paulo, Brazil*

Neurological complications of infective endocarditis modulate decisions regarding cardiac surgery. We studied the time-related occurrence of neurological complications and surgery in patients with infective endocarditis.

Methods: we studied 144 (24.9%) patients with 145 episodes of infective endocarditis with 161 neurological complications, among 579 patients with 641 episodes of endocarditis. The ages ranged from 2 months to 83 (33.5 ± 17.5) years; 89 (61.4%) episodes occurred in men and 56 (38.6%) in women. Mortality was higher in patients with neurological complications (44.1% vs. 19.1%; $p < 0.01$).

Results: In 95 (65.5%) episodes, patients were submitted to medical and in 50 (34.5%) to surgical treatment. Neurological complications were pre-operative in 38 (76%) episodes and post-operative in 12 (24%). Neurological complications preceded surgery from 2 to 132 (39.4 ± 32.9) days; after operation neurological complications occurred up to 16 (4.3 ± 4.9) post-operative days. Post-operative neurological complications were: neurological disability, toxic psychosis and meningitis in 1 episode each; seizure in 2 episodes; cerebral embolism, cerebral haemorrhage and stroke in 3 episodes each. Forty-nine (51%) patients submitted to medical treatment and 15 (30%) operated upon died ($p < 0.05$).

Conclusion: neurological complications of patients submitted to surgical treatment of endocarditis were more frequently pre-operative. The post-operative neurological complications occurred early after surgery. Mortality was higher in patients with neurological complications submitted to medical treatment than in those operated upon.

P2919 Unexpectedly high incidence of embolic events with the St. Jude Silzone valve

A. Ionescu, A.G. Fraser, E.G. Butchart[1]. *Dept. of Cardiology, University Hospital of Wales, Cardiff; [1]Cardio-Thoracic Surgery, University Hospital of Wales, Cardiff, UK*

Background: The incidence of thromboembolism (TE) following heart valve replacement is determined by patient-related factors, anticoagulant control and possible thrombogenicity. In a prospective study designed primarily to investigate patient-related factors, patients with both St. Jude Silzone (SZV) valves (silver-coated sewing ring) and standard St. Jude Medical valves (SJM) were included. Because of an unexpectedly high incidence of TE in patients with SZV, a comparison was made between SZV and SJM in this study.

Methods: We compared 51 patients (21 M) who had an SZV implanted between October 1997 and July 1998 with 118 patients (59 M) who had an SJM implanted between June 1995 and October 1997. All patients were anticoagulated with Warfarin to a mean INR of 2.5 for aortic, and of 3.0 for mitral and double valve replacement.

Results: Patients in the SZV group were younger (mean age [SD] 61[10] vs. 65[9] years, p = 0.01); they had 32 (63%) aortic, 13 (25%) mitral, and 6 (12%) double valve replacements, and 9 had CABG (42%). The SJM group had 72 (61%), 35 (30%), and 11 (8%) replacements respectively, and 36 (46%) CABG (ns). The proportions with atrial fibrillation, heart failure, hypertension, diabetes mellitus, previous stroke and smoking were similar. Follow-up was 98% in the SZV group and 96% in the SJM group, totalling 31 (mean 0.6; range 0.03–1.1 years) and 244 patient years (mean 2.1, range 0.03–3.6 years) respectively. The linearised rate of stroke/RIND/peripheral embolism was higher in patients with SZV (Table).

Linearised rates (%/year) of endpoints

Endpoints	SZV	SJM
Death	12.9	4.5
Stroke/RIND/embolism	22.6	0.8
TIA	22.6	9.4
Endocarditis	3.2	0.0

SZV – St. Jude Silzone valve; SJM – standard St. Jude valve; RIND – reversible ischaemic neurologic deficit; TIA – transient ischaemic attack.

Conclusions: The incidence of major embolic events after implantation of the St. Jude Silzone valve is significantly much higher than that of the St. Jude Medical valve, raising concern about the thromboresistance of the silver-coated ring. These findings need to be investigated in other studies.

P2920 Analysis of the interval between preoperative neurologic events and valve operations in patients with acute infective endocarditis

S.M. Tugtekin, W. Rohrer-Park, M. Taha, M. Knaut, T. Jost, V. Gulielmos, S. Schueler. *University Dresden, Cardiovascular Institute, Dresden, Germany*

Background: In patients with acute infective endocarditis and complicating cerebrovascular events due to embolization the duration of the interval between neurologic event (NE) and the valve operation (VO) is still discussed controversially. An interval of more than three weeks is supposed to be essential to prevent the impairment of the neurologic status by the use of extracorporal circulation. In the following we present our experience and results after valve replacement (VR) for acute endocarditis in patients with preoperative NE with particular concern of the interval between the NE and VO.

Methods: From 5/95 to 1/99, 88 patients (54 ± 13 years, range 20–82 y.) underwent VR or valve reconstruction for acute left heart valve endocarditis at our institution (64 patients with aortic VR, 13 patients with mitral VR, 7 patients with double VR, 3 homograft implantations and 1 mitral valve reconstruction). In 20 patients (23%) a preoperative NE required delayed VO. The interval between NE and VO ranged between 2 days and 22 days, respectively, with a mean of 9 ± 3 days.

Results: The overall perioperative survival of patients without preoperative NE was 94%, in patients with preoperative NE 90%, respectively. A new NE occurred in two patients without preoperative NE. In patients with preoperative NE no impairment of the neurologic status occurred.

Conclusions: The data demonstrate that valve operations in patients with acute infective endocarditis and preoperative NE can be performed safely within an interval of 9 days with good clinical results. In conclusion, decision making for the time of operation should be based mainly on the risk of further embolization.

P2921 A rapid molecular assay for the detection of antibiotic resistant organisms in infective endocarditis

J.E. Moore, B.C. Millar, X. Yongmin, M. Crowe. *Bacteriology Dept., Belfast City Hospital, Belfast, UK*

The cornerstone in the treatment of infective endocarditis (IE) has been traditionally based on the culturable anitibiotic susceptibility assay. However, this method may be unreliable with culturable agents of IE, in that it may be difficult to ascertain the modal action of resistance to a given antibiotic, as this may only be determined genotypically. In addition, as it is not possible to evaluate phenotypically the susceptibility of non-culturable causal agents of infective endocarditis (IE), genotypic detection of antimicrobial gene resistance loci employing molecular techniques offers both the opportunity to examine the susceptibility of the causative agent to antibiotics, as well as to reduce the time required for institution of definitive therapy. The aim of this study was to develop a rapid molecular assay for the detection of such resistance loci in organisms causing IE. As the majority of agents responsible for IE are Gram-positive, the following antimicrobial classes were examined: aminoglycosides, glycopeptides and B-lactams, targetting the aacA-aphD, aphA3, aadC for the aminoglycosides; vanA, van B, van C-1, van C-2 for the glycopeptides and mecA for the B-lactams. Three patients with IE due to Staphylococci (1 MRSA, 1 S. aureus & 1 CNS) were examined with respect to methicillin resistance, both by conventional and molecular means. Identical resistance profiles were obtained by both methods, however the molecular detection was completed within four hours, as opposed to the three days required for conventional workup. As it is not possible to evaluate phenotypically the susceptibility of non-culturable causal agents of IE, genotypic detection of antimicrobial gene resistance loci employing molecular techniques offers both the opportunity to examine the susceptibility of the causative agent to antibiotics, as well as to reduce the time required for institution of definitive therapy. In conclusion, rapid detection may reduce the use of inappropriate agents or enable the use of combinations of antibiotics, other than those that would normally be prescribed empirically for IE., viz. a combination of a b-lactam e.g. penicillin G and an aminoglycoside e.g. gentamycin. Detection of antibiotic gene resistance loci by molecular-based technologies,namely polymerase chain reaction (PCR) will allow for a more directed antibiotic therapy and may also provide opportunities for early identification of resistant organisms. This work was funded by the British Society for Antimicrobial Chemotherapy and the British Heart Foundation.

P2922 Brucella infective endocarditis: successful combination of medical and surgical treatment

L. Hadjinikolaou, S.H. Stamou[1], I. Rizos[2], S. Foussas[3], M. Zairis[3], P. Toutouzas[2], E. Chlapoutakis[4], P.J. Asimacopoulos. *Department of Cardiac Surgery, University of Athens, Athens; [1]Department of Cardiac Surgery, Athens; [2]Department of Cardiology, University of Athens, Athens; [3]Department of Cardiology, Tzanio Hospital, Piraeus; [4]Department of Cardiac Surgery, Hippokration Hospital, Athens, Greece*

Brucella endocarditis is an under-diagnosed complication of human brucellosis, associated with high morbidity and mortality. We report the successful treatment of seven consecutive cases of Brucella infective endocarditis, based on high suspicion of the disease.

Methods: Seven patients with infective Brucella endocarditis were treated over the last 20 years. The native aortic valve was involved in 4 cases, the native mitral valve in two and the native aortic and mitral valves simultaneously in one. The early suspicion of Brucella infective endocarditis relied on reported professional contact with sheep and goats and clinical features. The standard tube agglutination titter on admission was >1:320 in all cases and blood cultures were positive in 1 patient. Valve cultures were positive in 1 patient. They both grew Brucella mellitensis. All patients were successfully treated with a combination of aggressive medical and early surgical therapy. Medical treatment included preoperative administration of co-trimoxazole, doxycycline and streptomycin. During the postoperative and follow-up period all patients received co-trimoxazole and doxycycline. All affected valves were replaced within one week from admission. There were neither operative deaths nor recurrence of infection. One patient died two years after the operation due to a massive cerebrovascular accident.

Conclusion: Brucella endocarditis is a rare entity. Its optimum management should be a combination of aggressive medical treatment and early surgical intervention. High degree of suspicion in areas with high incidence of the disease leads to early treatment, which may provide the best results.

P2923 Infective endocarditis in HIV infection

A. Chinaglia, E. Cecchi, F. Pomari, B. Demichelis, R. Trinchero. *Cardiology Dept, Ospedale Maria Vittoria, Torino, Italy*

Infective endocarditis (IE) is one of the HIV infection related cardiac diseases. It is uncertain whether advanced disease (AIDS) is characterized by a higher incidence of IE. The present study aimed at assessing if HIV infection represents an independent risk factor for IE.

Subjects and methods: all the HIV infected patients referred to the echocardiographic laboratory because of IE suspicion between 1992 and 1998 were considered (n = 68). The echocardiographic study was performed with HP Sonos 1000, 2000, 2500 or 5500. Diagnosis of IE was based on Duke University criteria, and patients were followed up for at least 6 months.

Results: diagnosis of IE was confirmed in 22 (IE+) out of 68 patients. In the remaining 46 patients (IE-) an alternative diagnosis was made and/or follow up was negative. Among the 22 EI+ patients 1)21 were drug abusers and 1 was affected by mitro-aortic disease, 2)12 were affected by AIDS, 10 asymptomatic HIV carriers. EI+ and EI− patients did not differ by mean age and sex distribution, while drug dipendence was more frequent in EI+ group. Echocardiogram was positive for IE in 17/22 patients, consistent with IE in 5/22. Positive blood cultures were found in 19/22 patients (S. Aureus in 12 cases). Tricuspid valve was involved in 15 cases, aortic valve in 5, mitral valve in 4. A left heart valvular involvment was shown in 7/12 AIDS patients and only in 2/10 HIV carriers. Two patients died in hospital (both were affected by AIDS). Four patients were submitted to cardiac surgery (1 AIDS patient). Long term mortality was mainly due to non-cardiac disease and was higher in IE- patients (11% vs 28%).

Conclusions: in our series IE was related to known predisposing factors; AIDS was not an adjunctive risk factor for IE, but in these patients left heart involvment and in-hospital mortality were more frequent; medical and, in selected cases, surgical treatment was effective.

P2924 Expression of E-selectin and VCAM-1 on aortic heart valves

A.M. Müller, C. Cronen[1], I. Kupferwasser[2], K.M. Müller, C.J. Kirkpatrick[1]. *Inst.of Pathol.Univ-Clin.Bergmannsheil, Bochum; [1]Inst.of Pathol.Univ.-Clinic, Mainz; [2]II.Dep.Intern.Medicine, Univ.Clin, Mainz, Germany*

Shear stress causes endothelial cells (EC) to undergo functional alteration. While the expression of adhesion molecules by EC of large vessels has been widely studied, to our knowledge there are no such studies on EC of heart valves. As heart valves – like large vessels – are exposed to extreme shear stress we characterised immunohistochemically the expression of the adhesion molecules E-selectin and VCAM-1 (vascular cell adhesion molecule-1) on degenerated aortic valves and aortic valves with acute endocarditis. This knowledge might be important for the understanding of etiologic aspects of (recurrent) local inflammations but also for the development of new bioprosthetic heart valves.

Methods: 18 degenerated aortic valves (with no microscopical signs of inflammation) and 6 aortic valves with acute endocarditis were stained immunohistochemically with antibodies against E-selectin and VCAM-1. The FVIII-related antigen – constitutively expressed in EC – was used as an identification marker for the control staining reaction for EC. All valves were excised during prosthetic valve operation.

Results: There was a positive staining of the EC of all 6 aortic valves with antibodies against E-selectin and VCAM-1. The EC on 12 of the degenerated valves showed a positive reaction for E-selectin. 14 degenerated valves showed a positive staining of the EC with antibodies against VCAM-1.

In conclusion there is an expression of E-selectin and VCAM-1 not only on aortic valves with acute endocarditis (as expected) but also on degenerated aortic valves with no morphological evidence of inflammation. These findings might explain why patients with degenerated aortic valves are susceptible to recurrent endocarditis. Further investigations will show if the expression of E-selectin and VCAM-1 has to be regarded as pathogenetic similarity to the expression of these molecules in atherosclerosis.

PROSTHETIC VALVES – VARIOUS ASPECTS

P2925 Influence of left ventricular mass in the haemodynamic profile of bileaflet mechanical aortic protheses assessed by Doppler echocardiography

S. Martins, R.M. Soares[1], M.R. Rasteiro, J. Abreu, L. Bernardes, N. Castelão[2], J.M.S. Ramos, C. Salomão, J. Roquette[2], A.M. Antunes. *Cardiology Dept., Hospital de Santa Marta, Lisbon; [1]Cardiology Dept., Hospital de Santa Marta, Lisbon; [2]Cardiothoracic Surgery, Hospital de Santa Marta, Lisbon, Portugal*

Purpose: to evaluate the influence of left ventricular (LV) mass (LVM) in the hemodynamic profile of different sized bileaflet mechanical aortic protheses (BMAP), assessed by Dopppler echocardiography.

Methods: we studied 52 patients (pt) with normofunctional BMAP, sinus rhythm, 23.5 ± 8.4 months after surgery, divided in two groups (Gr) according to the size of the implanted protheses (P) – gr I: P 19 or 21 mm – 26 pt, 8 men, 61 ± 10 years, 14 with Carbomedics (CM) and 12 with St.Jude Medical (SJ) P; gr II: P 23 or 25 mm – 26 pt, 19 men ($p < 0.05$ vs gr I), 57 ± 13 years (NS), 13 CM and 13 SJ P (NS).

We analysed, at rest: maximal (Gmax) and mean (Gmean) transprothesic pressure gradients, P area (PA), P resistance (PRes), and PRes index (PResI). Gradients were calculated using the Bernoulli equation, PA using the continuity equation, PRes as 1333.Gmean.SEP/SV (SEP = systolic ejection period; SV = stroke volume), and PResI as PRes.BSA (BSA = body surface area). LVM was calculated using the ASE/Devereux method and LVM index (LVMI) as LVM/BSA.

Results: functional class, ejection fraction and time after surgery were comparable for the two Gr. There were no differences between CM and SJ P.

Gr I vs. GR II – Gmax: 21 ± 7 vs 19 ± 7 mmHg (NS); Gmean: 11 ± 3 vs 8 ± 4 mmHg (NS); PA: 1.3 ± 0.2 vs 1.8 ± 0.4 cm^2 ($p < 0.001$); PResI: 123 ± 22 vs 95 ± 29 dynes s cm^{-5} m^2 ($p < 0.001$); LVMI:158 ± 50 vs 176 ± 47 g.m-2 (NS).

In Gr I, but not in Gr II, we found a significant correlation between LVMI and PResI ($r = 0.65$). LVMI was independent from other analysed variables. Gr I PResI median was 119 – for pts with PResI < 115 (40th percentile) LVMI = 128 ± 27 and for those with PResI > 124 (60th percentile) LVMI = 184 ± 66 ($p = 0.03$).

Conclusions: PResI correlates with LVMI in pts with smaller sized BMAP. This is perhaps related to the influence of LVM in LV outlet flow dynamics, particularly in pts with smaller LV outflow tracts. The way LVM contributes to the magnitude of protheses resistance concept deserves further investigation.

P2926 Benefit of exercise training in patients with valve protheses and chronic heart failure

D. Gaita, I. Branea, S.T.I. Dragulescu, I. Socoteanu, M. Gaspar, S. Dragan, B. Mut, C. Dina, S. Pescariu, A. Gaita. *Cardiac Rehabilitation, Cardiology Centre, Timisoara, Romania*

In patients with chronic heart failure, exercise training improves ventilation and exercise capacity, but training programme has some particularities in patients with valvular disease. We studied the efficiency of exercise training in patients with valve protheses.

We evaluated 46 patients with mechanic valves (18 mitral, 23 aortic, 5 mitral and aortic; 29 males, 17 females; 54 ± 7 years old) 2 months after replacement of heart valves, with similar clinical features: left ventricular ejection fraction < 40%, NYHA class II-III, in relatively stable condition. In random order 23 patients underwent 12 weeks of conditioning by exercising (Group A) and 23 patients underwent 12 weeks of activity restriction (Group B). 4 patients in Group A and 2 patients in Group B did not complet the study. All patients performed six-minute walk test and cardiopulmonary exercise test before and after 12 week period. Exercise training protocol consisted of "interval training" (120 s work/60 s recovery) using mixed isometric and isotonic exercises at a maximum heart rate corresponding to 80% of maximum oxygen uptake (or at level 15 – hard – according to the Borg scale) 30–45 minutes, 3 times a week. Symptomes from daily activities were assessed by "Minnesota Living with Heart Failure Questionnaire" (score 0–105) and by the dyspnea-fatigue index (DFI) (score 0–12).

	6-min walk (m)	VO_2 max (ml/kg/min)	Minnesota	DFI
Baseline				
Group A	338 ± 36	14.8 ± 1.6	64 ± 12	6.5 ± 1.9
Group B	327 ± 38	13.9 ± 2.3	59 ± 16	6.3 ± 1.4
p value	NS	NS	NS	NS
Final evaluation				
Group A	405 ± 31	18.2 ± 2.3	36 ± 18	9.2 ± 1.4
Group B	342 ± 26	15.2 ± 2.1	54 ± 14	6.9 ± 2.1
p value	<0.01	<0.01	<0.001	<0.05

No major medical incidents occurred during the training programme. Patients with aortic protheses had a greater exercise performance than patients with mitral protheses. We noticed a good correlation between maximal oxygen uptake and distance ambulated during six-minute walk test ($r = 0.71$, $p < 0.001$).

In conclusion, exercise training is of great importance for the increase of effort capacity and quality of life in patients with valve protheses and chronic heart failure.

P2927 Medium-term left ventricular mass index and systolic function after stentless aortic valve replacement

X.Y. Jin, S. Westaby. *Department of Cardiac Surgery, John Radcliffe Hospital, Oxford, UK*

Background: The haemodynamic benefits of stentless aortic valve replacement (AVR) to the early improvement of left ventricular (LV) function is increasingly recognised. The medium term results, however, remain to be fully defined.

Methods: 140 patients (80 males, age at AVR: 72 ± 6 yr, 40% with Co-CABG) undergoing AVR using a Freestyle stentless valve (valve size 23 ± 2 mm) and with sinus cardiac rhythm were studied from 0.5 month to up to 4 years afterwards. LV ejection fraction (LVEF, %), mass index (LVMI, g/m^2), and mean pressure gradient of stentless valve (mPG, mmHg) were determined by echocardiography. Systemic blood pulse pressure (PBP, mmHg) was also measured.

Results: A total of 540 echoes were analysed, data were shown in mean ± SD.

	0.5 mth	6 mths	1 year	2 years	3 years	4 years
PBP	63 ± 20	63 ± 20	71 ± 25*	77 ± 22*	83 ± 23*	83 ± 26*
LV EF	56 ± 17	61 ± 14	63 ± 14*	64 ± 13*	64 ± 12*	65 ± 14*
LV MI	141 ± 60	116 ± 38*	109 ± 40*	110 ± 41*	114 ± 43*	116 ± 36*
mPG	8.4 ± 5.1	5.2 ± 3.1*	5.4 ± 3.6*	5.9 ± 3.8*	6.3 ± 4.3*	6.4 ± 4.5*

*: different from that of 0.5 mth by 95% CI.

In conclusion: The regression of LV MI and improvement of LV EF were achieved within 6–12 months after AVR, and both then remain stable up to 4 years even though pulse pressure had gone up significantly. Such a sustainable LV rehabilitations in elderly AVR patients may partially be attributed to a very low mPG of the stentless valve.

P2928 Magnetic resonance imaging after prosthetic heart valve replacement, safety and potential hazards

D. Pruefer, P. Kalden[1], W. Schreiber[1], M. Dahm, M. Buerke[2], M. Thelen[1], H. Oelert. *Cardiothoracic and Vascular Surgery, University-Hospital Mainz, Mainz; [1]Dept. of Radiology, University Hospital Mainz, Mainz; [2]II. Dept. of Medicine – Cardiology, University Hospital Mainz, Mainz, Germany*

Because of its potential diagnostic usefulness, nuclear magnetic resonance imaging (MRI) is performed in increased numbers of examinations in patients after cardiac valve replacement. Therefore, the purpose of the present study was to determine potential hazards in NMR imaging by the effects of strength static magnetic fields or radiofrequency pulses for prosthetic heart valves and the patient himself.

Seventeen different common prosthetic heart valves (12 technical valves and 5 tissue valves) were evaluated using an 1.5Tesla high field MRI-System (Siemens Magnetom Vision) in a well established model. The heart valves were suspended by a 35 cm suture. Deflection force was monitored by visual inspection looking for angular deviation and rotation about the suture line. Heat production was measured by submerging each valve in 40 ml of 1/1-electrolyt solution. in plastic containers. The containers were set in a Styrofoam block to isolate and separate each other. In the 1.5T-magnet, the block was imagined twice using a turbo spin echo (TSE) with repetition time (TR) of 5200 ms, echo time (TE) of 138 ms, flip of 180 degree, swap PA and LR and total imaging time of 10 minutes and 30 seconds. To determine heat production, the temperature of each electrolyt solution in the containers was measured just before and immediately after MR-imaging using a digital thermometer.

The examinated cardiac valve prostheses demonstrated no significant deflection in the 1.5 Tesla magnet. This means, that no significant force was exerted on the heart valve prostheses. No significant temperature increase was observed after MR-imaging.

In summary, the presented study demonstrated for the examinated valves no additional hazards to patients undergoing magnetic resonance imaging after cardiac valve replacement. There is no evidence contraindicating MR-imaging for patients with one of the examined prosthetic valves.

P2929 Low molecular weight heparin versus unfractionated heparin after mechanical heart valve replacement

V. Pelletier-Polle, G. Montalescot[1], A. Bellanger, D. Thomas[1]. *Pharmacy Unit, Pitié-Salpétrière University Hospital, Paris[1]Cardiology Dept., Pitié-Salpétrière University Hospital, Paris, France*

Low Molecular Weight Heparins(LMWH) are widely prescribed in Cardiology but almost no data are available on LMWH anticoagulation of patients with mechanical valve prostheses.

Methods: we performed a retrospective analysis of anticoagulation in the postoperative period after heart valve replacement with mechanical prostheses. Anticoagulation with either unfractionated heparin (UH) or LMWH was left to physician preference with a recent increase of LMWH use. Subcutaneous UH (500 UI/kg/day, 3 times daily) was adjusted according to aPTT and enoxaparin (100 UI/kg/12 hours) was controlled with antiXa activity. Oral anticoagulation was started before hospital discharge.

Results: 198 patients were treated (106 with UH vs 92 with LMWH) after aortic (75%), mitral (14%) or double (11%) valve replacement. There were no differences between the 2 treatment groups according to age (57 yrs), sex (69% men), weight, atrial fibrillation (19%), heart failure (11%), prior ischemic stroke (3%), renal failure, echocardiographic left atrial size and left ventricular function, and models of prostheses. There were more diabetes ($p = 0.017$) and more coronary disease ($p = 0.0006$)in the LMWH group. The mean duration of LMWH treatment was 13.2 ± 0.8 days (mean ± esm)with a mean antiXa activity of 0.8 ± 0.05 U. There were no death, no prostheses thrombosis and no thrombocytopenia in the whole population. One ischemic stroke occurred (UH group). There were 4 major bleedings (2 in each treatment group).

In conclusion, LMWH anticoagulation appears feasible after mechanical heart valve implantation. However, time has come now for large randomized trials evaluating this new strategy of anticoagulation in patients with mechanical prostheses.

P2930 Plasma brain natriuretic peptide levels correlate with clinical and cellular markers of cardiac function in patients undergoing surgery for mitral valve incompetence

D.L. Adamson, C.I.O. Brookes[1], M. Kemp[2], J. Hooper[2], S.E. Harding[3], N. Moat[4]. *NHLI, Royal Brompton Hospital, London; [1]Cardiology Dept., Royal Brompton Hospital, London; [2]Biochemistry Dept., Royal Brompton Hospital, London; [3]NHLI, Imperial College School of Medicine, London; [4]Surgery Dept., Royal Brompton Hospital, London, UK*

The poor outcome in patients undergoing surgery for chronic mitral regurgitation (MR) is partly due to previously undetected left ventricular (LV) impairment. Plasma BNP may be useful as a screening tool for asymptomatic LV dysfunction. We investigated the functional and cellular correlates of BNP concentrations in patients undergoing mitral valve repair/replacement (MVR).

Methods: Fourteen patients with chronic non-rheumatic isolated MR had pre-operative BNP measurement and myocardial oxygen consumption (MVO_2) assessment. MVO_2 was expressed both as an absolute value and as a percentage of predicted (%P). At the time of operation, an epicardial biopsy was taken and ventricular myocytes enzymatically isolated. These were then superfused and electrically stimulated at 37°C (1 Hz, 2 mM Ca^{2+} or 0.2 Hz, maximum Ca^{2+}) and contraction monitored.

Results: Patients were aged 38–76 (mean 60.1 ± 2.8) and NYHA: 0/I 9, II/III 5. BNP levels were raised in 13 patients, mean 23.2 ± 6.2 pmol/L,(2.5–54.8) Normal range = 1.6–4.7 pmol/L. MVO_2 levels ranged 13.4–44.4 ml/kg/min (24.5 ± 2.8) with%P 51–137 (85.8 ± 9.0). BNP inversely correlated both to MVO_2 ($p < 0.01$, $r^2 = 0.45$), and%P ($p < 0.02$, $r2 = 0.40$). Contractile myocytes were obtained in 11 patients. Time-to-50% or 90% relaxation (R50, R90) was slowed compared to previous control patients at both 2 mM and max Ca^{2+} and BNP was significantly correlated with R50 ($p < 0.03$, $r2 = 0.50$) and R90 ($p < 0.01$, $r2 = 0.60$) at max Ca^{2+}.

Conclusion: BNP correlated significantly with both clinical (MVO_2) and cellular markers of reduced LV function (impairment of relaxation in isolated myocytes). BNP may therefore be a useful indicator of LV function in patients with MR and may have important implications for the timing of surgery in the future.

VALVULAR HEART DISEASE – EPIDEMIOLOGY AND PROGNOSIS

P2931 The natural history of asymptomatic severe aortic stenosis

R. Rosenhek, T. Binder, G. Porenta, I. Lang, G. Christ, G. Maurer, H. Baumgartner. *Dept. of Cardiology, Univ. of Vienna, Austria*

Recent studies have reported a rapid progression and poor outcome of asymptomatic severe aortic stenosis (AS) independent of age, sex, and other risk factors. These findings raised the question of recommending early elective surgery in these patients. To evaluate whether such an approach is justified and to identify predictors of outcome, we followed 128 asymptomatic or mildly symptomatic pts (69 F, 59 M; age 59 ± 19 yrs) with severe AS who had an echocardiographic examination in 1994. The AV-Vel. was 4.5 ± 0.6 m/s. By August 98 follow-up was 98.4% complete. 22 patients underwent surgery within 90 days although remaining asymptomatic based on the decision of their primary care physician. The remaining 106 patients had a Kaplan-Meier event-free survival, with end points defined as death (n = 8) or aortic valve surgery (n = 67), of 67 ± 4% at 1 yr, 59 ± 4% at 2 yrs, and 32 ± 4% at 4 yrs. CAD, diabetes, mitral annulus calcification were not independent factors of outcome. Outcome was not significantly related to sex, hypercholesteremia, or hypertension. However, age was a highly significant predictor of outcome: for pts 50 yrs old or younger, event-free survival was 94 ± 4% at 1 yr, 85 ± 6% at 2 yrs, and 63 ± 9% at 4 yrs compared with 73 ± 5%, 59 ± 5%, and 23 ± 5%, respectively, for pts older than 50 yrs ($p < 0.0001$). Even after 10 yrs, 52% of the pts younger than 50 years were followed for 5 to 10 years without developing symptoms. 8 patients died, of whom 6 had a cardiac death. 5 of these patients had developed significant symptoms (3 refused surgery, 1 died on the waiting list and 1 had an end-stage cancer). 1 sudden death occurred. Thus, this study confirms that, in pts with hemodynamically significant AS, it is safe to delay surgery until symptoms develop. In particular, pts younger than 50 years may remain free of symptoms or adverse events for many years. Considering that aortic valve replacement does not represent a cure in this disease, the recommendation of early elective surgery does not appear to be justified in these pts.

P2932 Persistent left ventricular hypertrophy after aortic valve replacement for isolated aortic stenosis: implications on morbidity and mortality

Markus Schwerzmann, Renate E. Benz, Dorothy Pfiffner, Beat C. Aeschbacher. *Cardiology, University Hospital, Berne, Switzerland*

Background: In longstanding aortic stenosis [AS], left ventricular hypertrophy [LVH] is a common compensatory response of the left ventricle to increased wall stress. LVH itself increases the stiffness of the myocardium and impairs its relaxation, leading to diastolic dysfunction. After aortic valve replacement [AVR], regression of LVH is expected. The impact of persistent LVH after AVR on morbidity and mortality has not been assessed.

Methods: We retrospectively collected clinical, angiographic and echocardiographic data about patients undergoing AVR for isolated AS. For inclusion, echocardiographic measurement of left ventricular muscle mass had to be performed *at least six month after AVR*. As endpoints, all-cause mortality, cardiac-related morbidity (dyspnea NYHA IV, angina pectoris CCS IV, myocardial infarction, pulmonary embolism, valve replacement, major haemorrhage) and their combination were assessed. Patients were classified into three categories (without LVH [No-H], with persistent LVH [P-H] and with a muscle mass above the 75th sex-specific percentile [MAX-H]).

Results: Of 212 patients (141 men, 71 women), 99 patients (62 men, 37 women) had persistent LVH. During 1967 years of follow-up, 36 deaths (26 men, 10 women) occurred. In *univariate analysis* P-H and MAX-H were associated with increased dyspnea on exertion, angina pectoris and decreased quality of life, assessed by a questionnaire (all $p < 0.05$) and only MAX-H had a significant effect on mortality ($p = 0.01$). A multivariate Cox proportional hazards model (for survival) and multivariate logistic regression (for morbidity) showed (NS: $p > 0.1$, **bold:** $p < 0.05$):

	All-cause mortality	Cardiac-related morbidity	Combined Endpoint
P-H	NS	2.21 (0.90–5.41)	NS
MAX-H	NS	2.08 (0.88–4.86)	2.29 (0.98–5.36)
Age at AVR	*1.85 (1.39–2.47)*	NS	NS
Coronary artery disease	*3.36 (1.31–8.62)*	*2.34 (1.12–5.06)*	2.08 (0.98–4.40)
Current smoking	*4.81 (1.73–13.4)*	NS	NS
	Hazard Ratio (CI)	Odds Ratio (CI)	Odds Ratio (CI)

Conclusions: Persistent LVH itself has no independent effect on survival after AVR, but by impairing diastolic function, it is likely to account for cardiac-related morbidity (dyspnea on exertion, angina pectoris, history of myocardial infarction).

P2933 Aortic stenosis: parameters determining short- and medium-term prognosis after surgery

P. Mota, M. Trabulo, T. Castilho, A.T. Timoteo, A. Mesquita, M. Sousa-Almeida, R. Gouveia, J.M. Aniceto-Silva, J. Queiroz-Melo[1], R. Seabra-Gomes. *Serviço de Cardiologia, Hospital de Santa Cruz, Carnaxide[1] Serviço de Cirurgia Cardiotorácica, Hospital de Santa Cruz, Carnaxide, Portugal*

We reviewed the population of patients (pts) referred to this centre for pure aortic stenosis who had aortic valve replacement (AVR) between 1989 and 1998, aiming to determine which clinical parameters influence perioperative evolution and post-discharge prognosis. The evaluated parameters were: age, gender, complaints of dyspnoea (NYHA class > 2), angina or syncope, presence of diabetes mellitus, left ventricular shortening fraction (LVSF) and peak (Pgrad) and mean (Mgrad) transvalvular gradients determined by echocardiography, presence of coronary artery disease (CAD) on angiography, prosthesis implanted and the complexity of the surgical procedure (concomitant bypass grafting (AVR+CABG) or aortic annulus widening (AoAW)). Population: 305 pts (44% female, 56% male), aged 23 to 85 y (65.1 ± 10.7 y). At the time of surgery 44.7% of pts referred dyspnoea (NYHA class 3 or 4), 29.8% angina and 26% syncope. Average gradients were Pgrad = 91.8 ± 27.3 and Mgrad = 60.5 ± 19 mmHg and LVSF = 35.1 ± 10.6%. Significant CAD was detected in 29.3% of pts and 7.8% had diabetes. 5%(16) were operated on as emmergencies due to refractory angina or heart failure (HF).

Results: types of prostheses implanted were: mechanical (42%); biological (36.4%), homografts (16%) and Ross procedures (5.6%); AVR+CABG in 25.5% of pts and AOAW in 3.6% cases (10 female/1 male). Peri-operative mortality (POPM) was 6.6%. The only factor that influenced POPM was age ≥ 75 y ($p < 0.01$), NYHA class >2 reached marginal significance ($p = 0.06$). Mean in-hospital stay (IHS) was 13.5 ± 11.9 days (IHS ≤1 day was excluded). Duration of IHS was more prolonged for pts ≥ 75 y ($p = 0.01$), diabetics ($p = 0.03$), LVSF ≤ 25% ($p < 0.01$) and AVR+CABG ($p = 0.03$). Mean follow-up for discharged pts was: 3.05 ± 2.69 y (0.044 to 9.875 y) with 7.86% total mortality (information was obtained in 98% of the population). Less than 1% of pts were re-operated on and 2.3% were admitted for suspected infective endocarditis. Mechanical prostheses presented a longer survival than biologicals ($p = 0.01$, after correction for age).

Conclusion: parameters (HF, LVSF, Pgrad/Mgrad, CAD/CABG) traditionally associated with severity and prognosis of aortic stenosis did not influence peri-operative mortality nor medium-term prognosis, bearing their weight in the duration of IHS. Age was a very important prognostic determinant both in and out of hospital. Mechanical prostheses have a better long-term prognosis.

P2934 Complex ventricular arrhythmias and cardiac death in mitral valve prolapse: results of a ten-year prospective follow-up

A. Zuppiroli, F. Mori, S. Favilli[1], A. Mascagni, G. Corti, A. Montereggi, A. Dolara. *Cardiologia 2, Azienda Ospedaliera Careggi, Florence; [1]Cardiologia, Azienda Ospedale A.Meyer, Florence, Italy*

Major complications in Mitral Valve Prolapse (MVP) can be predicted by some clinical and echocardiographic parameters. While palpitations are common in these patients (p) the prevalence of arrhythmias has been variously reported and their prognostic role still needs to be clarified.

Methods: 104 consecutive p with MVP (diagnosed using strict M-Mode and 2D echocardiographic criteria) underwent a 24-hour Holter monitoring at enrollment and were prospectively followed-up for a mean of 127 ± 61 months. Mean age was 38 ± 18 years, 51(49%) were males. Complex atrial and ventricular arrhythmias were present in 6 p (6%) and in 22 p (22%), respectively.

Results: During the follow-up 22 MVP-related major complications occurred in 20 p (17:mitral surgery; 5:cardiac death) (2.0 per 100 patient/years). Cardiac deaths were: sudden (2), due to pulmonary oedema (2) and to cerebral embolism (1). At the univariate analysis overall complications resulted significantly associated with age ($p = 0.007$), male gender ($p < 0.05$, OR = 3.0), presence of a moderate-to-severe mitral regurgitation ($p = 0.002$, OR = 8.6), left atrial ($p < 0.001$) and left ventricular ($p < 0.001$) enlargement; only left chamber enlargement resulted independently correlated at a multiple logistic regression. Cumulated complex arrhythmias showed a weak correlation ($p = 0.05$; OR = 2.8) with overall complications; significance was higher if death only was tested ($p = 0.018$, OR = 12.3). At multiple logistic regression they resulted as the unique independent predictor for death (cumulated complex arrhythmias: $p = 0.049$; complex ventricular arrhythmias: $p = 0.038$).

Conclusions: This prospective ten-year follow-up confirm the previously reported association between some clinical/echocardiographic parameters and overall complications in MVP and seems to confere to complex ventricular arrhythmias a potential role in detecting p at risk of cardiac death.

P2935 Patients with rheumatic mitral stenosis in sinus rhythm show a prothrombotic state and fibrinolytical disfunction

F. Marín, V. Roldán[1], P. Marco[1], J.V. Monmeneu, V. Bodí, J. Luján[2], F. Reyes, J.G. Martínez[2], F. García de Burgos, F. Sogorb[2]. *Cardiology, General Hospital of Elche; [1]Hematology; [2]Cardiology, General Hospital of Alicante, Spain*

Patients with chronic atrial fibrillation have a hypercoagulable state with impaired fibrinolytic function. The aim of our study was to analize if patients with rheumatic mitral stenosis in sinus rhythm have also these abnormalities in the hemostatic markers.

Methods: Tissue type plasminogen activator (tPA), its inhibitor (PAI-1) levels as fibrinolytic markers, and D-dimer (D-D) and modified antithombin III (ATM) levels, as prothrombotic markers, were measured in 24 patients with mitral stenosis in sinus rhythm (SR) and were compared with those found in plasma of 18 patients with rheumatic atrial fibrillation (AF) and 20 healthy subjects. None of them had received anticoagulation therapy. Transthoracic echocardiography was made. Results are expressed as median and 25th–75th percentiles. Statistical analysis was performed by non parametric tests

Results: There were no differences in the severity of mitral stenosis or left atrial diameter between patients in SR or AF.

	SR	AF	Controls
tPA (ng/ml)	2.30 (2.04–2.72)	1.78 (1.43–2.78)	2.92 (1.41–4.80)
PAI-1 (ng/ml)	28.5 (15.5–53.0)	45.9 (24.4–58.9)	7.3 (5.6–9.2)*
DD (ng/ml)	517.8 (272.2–861.9)	550.6 (292.9–737.9)	12.5 (7.2–31.5)*
ATM (ng/ml)	12.1 (8.0–27.2)	30.0 (21.3–152.3)	10.1 (8.2–12.6)*

*$p < 0.05$ between controls and SR or AF groups

Even in those patients of SR group without dilated left atria (diameter ≤ 45 mm), 10 patients, showed an increase in the PAI-1, DD and ATM levels ($p < 0.05$). These increases take more relevant in patients with dilated left atria.

Conclusions: Patients with mitral stenosis in sinus rhythm show also a prothrombotic state and high plasma levels of PAI-1 as those patients in atrial fibrillation, even without left atrial dilatation.

P2936 The "benign mitral leaflet syndrome": how benign is it, and is surgery warranted?

F. Grigioni, M.E. Sarano, H.L. Ling, K.R. Bailey, A.J. Tajik. *Mayo Foundation, Rochester MN, USA*

Background: Patients with mitral regurgitation and absent or minimal symptoms are considered at low risk. The benefit of early surgery in this syndrome has never been directly confirmed.

Methods: To address this issue, we analyzed 340 consecutive patients in NYHA class I or II with MR due to flail leaflets diagnosed between 1980 and 1994 and considered as surgical candidates.

Results: At 10 years the incidence of death or heart failure was overall 52 ± 4%. After the Echo diagnosis of flail, 68 patients (20%) underwent mitral valve surgery within 3 months (Early_S group, 61 ± 13 years, 75% Males), and 272 were conservatively managed (Cons group, 66 ± 12 years, 75% Male). Early_S group at 10 years experienced a lower incidence of death or heart failure than the Cons group (33 ± 10 vs 56 ± 4%, P = 0.004). Moreover, multivariate analysis adjusting for age and ejection fraction and baseline predictors of death and heart failure showed early surgery to be independently associated with a lower incidence of the combined end-point of death or heart failure (adjusted Hazard Ratio [95% C.I] = 0.46 [0.23–0.89], P = 0.02).

Conclusions: These data demonstrate that the "benign mitral leaflet syndrome", i.e. mitral regurgitation due to flail leaflets with no or minimal symptoms, 1) develop a high incidence of death or heart failure, and 2) suggest that in these patients an early surgical treatment is associated with an improved outcome despite the "benign" presentation.

P2937 Frequency components of heart rate variability signal in patients with syncope and mitral valve prolapse

M. Ruchalski, P. Burduk[1], J. Karwowski[2]. *Department of Cardiology, Military Hospital, Bydgoszcz; [1]MSWiA Hospital and INTERCOR, Bydgoszcz; [2]INTERCOR, Bydgoszcz, Poland*

The aim of our study was to assess the relationship between symphatho-vagal balance as a ratio of low to high frequency components of heart rate variability spectrum and occurrence of syncope regardless of its causative factor among patients (pts) with mitral valve prolapse MVP.

Methods: we studied a group of 62 pts (47 females and 15 males), mean age 38.3 years with primary MVP confirmed by echocardiography.Diagnosis of MVP was established according to Perloff's major criteria.The pts were divided in two subgroups: those with syncope in last year (defined as a spontaneously transient sudden temporary loss of consciousness associated with a deficit of postural tone) and those without syncope. The control group consisted of 36 healthy people without any changes in echocardiographic examination, well chosen in relation to age, sex and body surface. Spectral analysis of heart rate variability with the aid of a computerised system using FFT method from 15-minute ECG recordings was performed. All patients, in a drug-free state and a control group, were examined in the same conditions between 08:00 and 10:00 a.m. after half-hour rest. We compared the ratio of amplitude of low frequency component (LF 0.05–0.15 Hz) to high frequency component (HF 0.15–0.4 Hz) (LF/HF).

Results: There were no significant differences in left atrial and left ventricular dimension between subjects with MVP and syncope and those without syncope. Also presence of significant mitral regurgitation in both groups was similar. Comparisons between mean values of LF/HF ratios in MVP subgroups with and without syncope and between control group is shown below (table).

Table

Group	n	LF/HF (mean ± SD)	p value
MVP with syncope	32	0.72 ± 0.37	
MVP without syncope	30	0.48 ± 0.31	0.007*
control group	36	0.47 ± 0.29	0.003**, 0.9***

*MVP with syncope vs MVP without syncope, **MVP with syncope vs control group, ***MVP without syncope vs control group

Conclusions: Patients with MVP and syncope have relatively higher component of low frequency HRV spectrum in relation to the control group and pts with MVP without syncope. It suggests that these pts have increased stimulation of sympathetic nervous system.

P2938 Incidence and prognostic meaning of mild periprosthetic leaks detected early after valve surgery by transesophageal echocardiography

A. Picozzi, F. Santoro, E. Colombo[1], P. Agricola, M.R. Gioffrè, R. Tramarin[1], R.F.E. Pedretti. *Division of Cardiology, IRCCS Fondazione Salvatore Maugeri, Tradate (VA); [1]Division of Cardiology, IRCCS Fondazione Salvatore Maugeri, Pavia, Italy*

Leaks with severe regurgitation usually require surgical correction. On the contrary, little is known about the most appropriate management and prognosis of leaks with mild and subclinical regurgitation. Aim of this study was to assess the incidence of mild periprosthetic leaks detected early after valve surgery by echocardiography and their prognostic meaning in a mid-term follow-up.

Methods: 98 consecutive patients (pts) (61 males, 37 females, mean age 58 ± 8 years) underwent transthoracic (TTE) and transesophageal (TEE) echocardiography within 20 days (mean 14) after valve surgery. After echocardiography, all pts entered a follow-up program to assess subsequent mortality and morbidity.

Results: Among the 98 pts, there were 15 mitral and 12 tricuspidal valve repairs (VR) and 57 aortic, 44 mitral, 1 tricuspidal prosthetic valves (PV); of the 102 PV, 87 were mechanical and 15 biological. Leaks with mild regurgitation were detected in 12 (12.2%) pts at TTE and TEE (8 at TEE only): 7 were in mitral (5 PV, 2 VR) and 5 in aortic site (5 PV). After a follow-up period of 20 months (range 12–31), the following prespecified end-points were observed: cardiac death in 6 (6.1%) pts and non-fatal adverse clinical events (re-intervention, cerebral or peripheral embolism, severe gastrointestinal hemorrhage, severe hemolytic anemia) in 12 (12.2%) pts. 4 of the echocardiographic and clinical variables tested at univariate analysis had a statistical correlation with the end-points considered and were then tested in a multivariate model. Results are shown in the table.

Univariate and multivariate analysis

	Cardiac Death		Non-fatal Events	
	p univ.	p multiv.	p univ.	p multiv.
Leak	0.15	ns	0.0058	0.001
LVEF≤40%	0.06	0.05	ns	ns
LVEDD > 55 mm	0.13	ns	ns	ns
Tricuspidalization	0.13	ns	ns	ns

Conclusions: TEE early performed after valve surgery detected mild and subclinical periprosthetic leaks in 12.2% of the pts, with a better sensitivity than TTE. Only LVEF was predictive of cardiac mortality; however, leak presence was associated with a significantly higher incidence of non-fatal adverse clinical events, independently of other risk markers.

P2939 Preoperative effective regurgitant orifice area is a strong predictor of long-term outcome in patients undergoing surgery for chronic mitral regurgitation

R. Pizarro, P. Oberti, O. Bazzino, J. Krauss, A. Cagide, H. Doval. *Instituto del Corazón, Hospital Italiano de Buenos Aires, Argentina*

Background: Post-operative LV dysfunction after chronic mitral regurgitation (MR) can be predicted by left ventricular size and function, but these variables are only partially reliable for prediction of LV dysfunction or survival. The purpose of the study was to explore the additional value of doppler echocardiographic parameters to identify patients at risk of development of long term postoperative death or LV dysfunction.

Methods: We prospectively evaluated 112 patients (p), (mean age: 62 ± 7 years; 64% male) with organic MR, using transthoracic echocardiography. Baseline ejection fraction (EF) was 58 ± 8%; 82% of p had myxomatous degenerative disease. Fifty-seven p underwent mitral valve (MV) repair (50.9%) and 55 p MV replacement (49.1%). The following parameters were analyzed: LV volumes and diameters, left atrial diameter, regurgitant fraction, regurgitant volume, effective regurgitant orifice area (ERO) and pulmonary systolic pressure.

In order to identify those variables predicting EF < 50% and/or late mortality (combined end-point), we performed univariate analysis and a Cox regression model multivariate analysis, after controlling for the effects of age, gender, atrial fibrillation, New York Heart Association functional class, history of congestive heart failure, type of surgery, etiology, concomitant coronary artery disease and vasodilator treatment.

Mean follow-up was 25 ± 12 months.

Results: Forty-four p (38%) had EF < 50% and 14 p (12.5%) died during follow-up. The reported cut-off point value for the different variables was based on the receiver operating curve (ROC) plotted against the primary end-point. The area of the ROC curve of the ERO for prediction of events was 0.85 (SE 0.056) with a likelihood ratio for a cut-off point of 0.55 cm^2 = 6.2 (CI 95% 2.3–12.5). Kaplan Meier analysis showed a significant difference between survival curves of both groups (p value < 0.001 log rank test). Multivariate analysis identified ERO > 0.55 cm^2 (hazard ratio: 4.7, CI 95%: 2.3–7.8; p < 0.0001); end-systolic diameter > 4.5 cm (hazard ratio: 2.2, CI 95%: 1.2–3.8; p < 0.02) and EF < 60% (hazard ratio: 2.0, CI 95%: 1.1–3.7; p < 0.04) as independent predictors of outcome.

Conclusion: In patients undergoing MV surgery for organic MR, ERO is a strong independent predictor of late ventricular dysfunction or mortality and adds to known prognostic variables such as left ventricular size and function.

P2940 An echocardiographic analysis of the relation between degenerative changes of cardiac valves with aging and their dysfunction in non-rheumatic adult subjects

K. Yamamura, M. Tani, Y. Homma, M. Takayama, H. Hasegawa, M. Kawamura, Y. Ebihara, K. Tamaki. *Geriatric Medicine, Keio University School of Medicine, Tokyo, Japan*

Purpose: Although rheumatic fever had been a primary etiology of valvular heart failure, importance of degeneration, sclerosis and calcification with aging is increasing as a cause of valvular diseases in the elderly in the developed countries. We echocardiographically analysed the relation between valvular deformity, especially, its calcification and valvular diseases in the elderly.

Methods: The mitral and aortic valves were assessed by two-dimensional and Doppler echocardiography in 726 serial adult subjects (average of age; 66.8 ± 13.5 y/o) without congenital heart disease, myocardial infarction, rheumatic valvular disease, or cardiomyopathy. We analysed sites of valvular calcification, pressure gradient across the valve, and degrees of valvular regurgitation in three age groups (middle age group; less than 65 y/o (221 subjects, 50.8 ± 11.6 y/o), old group; 65 to 75 y/o (302 subjects, 69.4 ± 2.8 y/o), super old group; 75 y/o or more (203 subjects, 80.4 ± 4.5 y/o)).

Results: The incidence of aortic valvular calcification was increasing with age (middle age group; 21.3% (47/221), old group; 52.0% (157/302), super old group; 65.5% (133/203), middle age group vs old group; $p < 0.001$, old group vs super old group; $p < 0.01$). In old and super old groups, single calcification of noncoronary cusp of the aortic valve was most frequent (29.0%), followed by calcification of all the three cusps (23.8%). Aortic valvular calcification had statistically significant relation with the presence of aortic regurgitation ($p < 0.01$) or aortic stenosis ($p < 0.01$), and the degree of aortic regurgitation ($p < 0.01$). Seventeen cases of middle age group (7.7%), 52 cases of old group (17.2%) and 49 cases of super old group (24.1%) showed the mitral valvular calcification. The incidence became higher with age (middle age group vs old group; $p < 0.005$, old group vs super old group; $p < 0.05$). Single calcification of posterior leaflet of the mitral valve was 47.5% (56/118), while that of anterior leaflet was less frequent (30.5%, 36/118). The incidence of mitral valvular calcification was higher in women than in men in only old group. Mitral valvular calcification was also related to the presence of mitral regurgitation ($p < 0.01$), mitral stenosis ($p < 0.01$), or atrial fibrillation ($p < 0.02$).

Conclusions: These results suggest that valvular calcification with aging can increase the incidence of valvular diseases and atrial fibrillation, which may result in heart failure in the elderly.

P2941 A prospective investigation of the prevalence of anorexigen induced valvular disease in 353 patients

A.J. Burger, M.P. Notarianni, G.L. Blackburn[1]. *Beth Israel Deaconess Medical Center, Boston MA; [1]Center for Study of Nutritional Med., Boston MA, USA*

Background: Dexfenfluramine and Phentermine-fenfluramine use for weight loss has been previously associated with increased prevalence of valvular heart disease. This association was based on a small number of patients, no control population, and limited data on dose and duration of therapy. Our study involved 353 obese subjects enrolled in a prospective, strict weight loss, research protocol from September 1994 to September 1997.

Methods: All subjects underwent transthoracic echocardiography for significant valvular lesions within a mean of 121 days from the manufacturer's announcement of the withdrawal of fenfluramine and dexfenfluramine. All echocardiograms were interpreted by two independent readers.

Results: The study population included 292 females and 61 males with a mean age of 46.5 ± 9.1 years and mean starting body mass index of 40.1 ± 7.8 kg/m^2. Using the FDA criteria for significant valvular disease, aortic regurgitation was detected in 21 subjects (5.9%) and mitral regurgitation in 3 subjects (0.9%). Only one patient had significant regurgitation of both aortic and mitral valves. No patients had 3+ or 4+ regurgitation. Significant valvular disease did not correlate with the dose or duration of Dexfenfluramine or Phentermine-fenfluramine therapy. There was no statistically significant difference in the prevalence of valvular disease when compared to the patients in the Framingham study who were similar in regards to age, gender, and geographic location.

Valvular Regurgitation

	No regurg	trace regurg	1+ regurg	2+ regurg
Aortic	263 (74.5%)	69 (19.5%)	18 (5.1%)	3 (0.8%)
Mitral	117 (33.1%)	198 (56.1%)	35 (9.9%)	3 (0.8%)
Tricuspid	135 (38.2%)	205 (58.1%)	13 (3.7%)	0 (0.0%)
Pulmonic	274 (77.6%)	76 (21.5%)	3 (0.8%)	0 (0.0%)

regurg = regurgitation

Conclusions: Anorexigen therapy is associated with a low prevalence of significant valvular regurgitation. Valvular regurgitation in our subjects may reflect age-related degenerative changes. Late valvular abnormalities from the use of Dexfenfluramine and Phentermine-fenfluramine await long-term, prospective studies.

ARRHYTHMIA MECHANISMS

P2942 Decremental conduction property in human infarcted ventricular myocardium: correlation with histology

T. Kawara, R. Derksen[1], J.R. de Groot, C.A. Remme, R. Coronel, J.M.T. de Bakker[2], R.N.W. Hauer[1], C.N. Belterman, S. Tasseron, M.J. Janse. *Department of Experimental Cardiology, University of Amsterdam, Amsterdam; [1]Heart Lung Institute, University of Utrecht, Utrecht; [2]Interuniversity Cardiology Institute of the Netherlands, Utrecht, Netherlands*

Decremental properties have been used for risk stratification in patients with hypertrophic cardiomyopathy. The mechanism of decremental conduction in diseased myocardium is unknown. In this study we attempted to elucidate the mechanism of decremental conduction in human infarcted ventricular myocardium.

Methods: We performed high-resolution epicardial mapping (247 terminals, interelectrode distance 0.3 mm) at three left ventricular sites of an explanted human infarcted heart during Langendorff perfusion. Basic (600 ms) and premature stimuli (from 500 ms down to the refractory period) were applied several mm away from the edges of the electrode. Histology of subepicardial layers was correlated with electrophysiology.

Results: Histology showed substantial fibrosis at one recording site but not at the other two. Activation patterns during propagation transverse to the fiber direction were more irregular than during longitudinal propagation. Marked delay was observed in the area with substantial fibrosis during transverse propagation. The activation delay as a function of coupling interval was integrated (s^{-2}) for each series of premature stimuli, and was greatest during transverse propagation in fibrotic tissue (table).

Integrated delay ($\times 10^{-3} s^{-2}$)			P	N	
(1) Transverse	1.44 ± 0.45	<0.05	<0.001	0.74	4
(2) Longitudinal	0.75 ± 0.22	–	<0.001	<0.01	4
(3) Transverse + Fibrosis	5.15 ± 0.59		–	<0.05	2
(4) Longitudinal + Fibrosis	1.56 ± 0.08			–	2
	Compared with	(2)	(3)	(4)	

Conclusion: Decremental conduction in human infarcted ventricular myocardium was mainly caused by propagation transverse to the fiber orientation in the area with substantial fibrosis.

P2943 A new index of cardiac vagal tone assessed in the West of Scotland Coronary Prevention Study population

P.W. Macfarlane, P. Julu, J. Norrie. *On behalf of the WOSCOP Study Group; University of Glasgow, UK*

Background: The West of Scotland Coronary Prevention Study involved 6,595 men, aged 45–64 years on entry, with moderately raised cholesterol who were randomised to placebo or Pravastatin 40 mg daily and followed for 5 years. The primary end-point was coronary heart disease death or non-fatal myocardial infarction. This study group was used to assess a new ECG based index of cardiac vagal tone (CVT).

Methods: All study ECGs were analysed by automated methods. From the baseline ECG, minor changes were defined as moderate amounts of ST depression and/or T wave inversion. CVT was measured by phase demodulation of pulse synchronised delays in RR intervals available from 8 seconds of ECG. 6,281 subjects with ≥4 RR intervals excluding SVES or VES were included. Hazard ratios were derived from both univariate and multivariate Cox proportional hazard models.

Results: The CVT index was skewed (mean 5.55 ± 3.93; 96% range 1.0–17.2) and so log (CVT) was assessed. Univariately for the primary endpoint, (i) for an increment of 0.5, log (CVT) had a hazard ratio of 0.89 (CI 0.82–0.95: $P = 0.0011$); (ii) quartiles 2, 3 and 4 of log (CVT) had increasing levels of risk (0.78, 0.71, 0.61) with respect to quartile 1; (iii) those with CVT ≤ 3 had a hazard ratio of 1.44 (CI 1.17–1.77: $P = 0.0005$) compared to those with CVT > 3. Multivariately, in 2 models involving (i) log (CVT) plus only ECG variables (rate, QT, minor ECG changes), or (ii) log (CVT) plus only clinical variables (treatment, diastolic BP, smoking, etc.), log (CVT) was not independently predictive in each case. Similar results were obtained for all cause mortality.

Conclusion: These data indicate that, even with a standard resting 12-lead ECG recording, information of clinical value relating to cardiac vagal tone can be obtained by analysing heart rate variability.

P2944 Significance of ventricular fibrillation complicating acute myocardial infarction in the thrombolytic era

S. Gottlieb[1], S. Behar, M. Canetti, Z. Rotstein, V. Boyko, A. Medina[1], M. Eldar. *For the SPRINT and the Israeli Thrombolytic Survey Groups; Neufeld Cardiac Research Institute, Tel Hashomer; [1]Bikur Cholim Hospital, Jerusalem, Israel*

Several studies performed in the prethrombolytic era (PTE) showed that ventricular fibrillation (VF) complicating AMI carries high early mortality. We compared the incidence and short- and long-term outcome of primary VF (1°VF) and secondary VF (2°VF) in the hrombolytic era (TE) and the PTE.

Methods: A prospective, nationwide survey of 3321 consecutive pts admitted with AMI in all CCUs in Israel during Jan.–Feb. of '92 and '96 (TE), compared with a previous Israeli study of 5839 AMI pts (SPRINT Registry) in 1981–83 (PTE).

Results: *1° VF:* In the TE the baseline characteristics of pts with 1°VF (n = 85) were comparable to their reference group without 1°VF (n = 2326). The crude and multivariate adjusted 30-day (4.8 vs. 5.0%; OR = 1.01, 95% CI 0.30–2.54) and the 1-yr mortality rates (11.0 vs. 8.0%; HR = 1.46, 95% CI 0.74–2.86) of both groups were similar. The incidence of 1°VF in the TE and PTE (2.6% vs. 2.0%) was similar. The 30-day (4.8 vs. 21.0%; OR = 0.19, 95% CI 0.05–0.60) and the 1-yr mortality rates (11.0 vs. 24.4%; HR = 0.42, 95% CI 0.19–0.93) of 1°VF pts were significantly lower in the TE vs. the PTE.

2° VF: The baseline characteristics of pts with 2°VF in the TE (n = 43) were comparable to their reference group without 2°VF (n = 725). The 30-day (51.2 vs. 14.6%; OR = 6.62, 95% CI 3.44–12.80) and the 1-yr mortality rates (58.1 vs. 26.6%; HR = 3.32, 95% CI 2.17–5.09) of 2°VF pts were significantly higher. The incidence of 2°VF in TE was significantly lower than in the PTE (1.3% vs. 2.5%, $p < 0.01$). The 30-day (51.2 vs. 58.3%; OR = 0.63, 95% CI 0.27–1.46) and the 1-yr mortality rates (58.1 vs. 67.4%, HR = 0.77, 95% CI 0.48–1.25) of 2°VF pts in the TE and the PTE were similar.

Conclusions: 1) In the TE, the outcome of pts with and without 1°VF complicating AMI was similar. Although the incidence of 1°VF in the TE and the PTE did not change, the outcome of 1°VF pts in the TE improved. 2) In pts with 2°VF, their outcome in the TE was significantly worse than in counterparts without 2°VF. Although the incidence of 2°VF in the TE declined, the outcome of 2°VF pts in the TE did not change despite recent advances in AMI pts management.

P2945 1B ventricular fibrillation depends on critical cellular coupling in the isolated regionally ischaemic pig heart

J.R. de Groot, R. Coronel, F.J.G. Wilms-Schopman[1], C.A. Remme, M.J. Janse. *Department of Clinical and Experimental Cardiology, Academic Medical Center, Amsterdam, Netherlands; [1]Interuniversity Cardiology Institute the Netherlands*

Introduction. Ventricular fibrillation during the 1B phase of acute ischemia (1B VF) is associated with the occurrence of cellular uncoupling. We hypothesized that a critical amount of cellular coupling is required for the induction of 1B VF, and that progression of uncoupling terminates the substrate for 1B VF.

Methods. Pig hearts (n = 12) were Langendorff perfused with blood and the left anterior descending artery was ligated to produce ischemia. We recorded epicardial and intramural electrograms at 105 sites in 3 pigs. In 9 pigs attempts to induce VF were undertaken repetitively with up to 3 premature stimuli (PS) (twice diastolic threshold current pulses of 2 ms duration). Tissue impedance was measured with the four electrode technique, difference between baseline and final values is expressed as relative Rt rise (dRt).

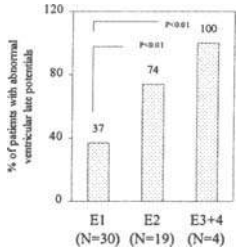
Results. Before coronary occlusion VF could be induced in 0/9 pigs with 3 PS, after ischemia VF could be induced in 8/9 pigs repetitively from 17.0 ± 9.1 min (mean ± SD) up to 55.1 ± 11.4 min. dRt was 0.12 ± 0.09 at the start and 0.54 ± 0.21 at the end of the 1B phase. At dRt up to 0.4, VF inducibility was maximal, VF in 8/9 pigs ($p < 0.001$ vs control). VF was inducible in 4/9 pigs at dRt 0.5 ($p = 0.07$ vs dRt < 0.4, p = NS vs control). At dRt exceeding 0.5, VF induction ranged between 5/8 and 3/9 pigs. At the start of the 1B phase, intramural electrodes showed signs of activation in 48 ± 18% whereas epicardial sites were excitable in 97 ± 5% ($p = 0.01$). At 50 minutes ischemia, 4 ± 3% of intramural sites were excitable vs 22 ± 16% of the epicardial sites (p = NS).

Conclusions. 1B VF is inducible during a distinct period in time, determined by dRt < 0.4 and coincides with a difference in number of excitable sites between epicardial and transmural sites. This study suggests that 1B VF depends on a critical degree of coupling, and that coupling between subepicardium and midmyocardium might play a key role in the genesis of these arrhythmias.

P2946 Ventricular late potentials in myotonic dystrophy: correlation with CTG trinucleotide repeat length

M. Paradiso, A. Mammarella, V. Paoletti, S. Basili, L. Coppotelli, A. De Matteis, C. Cardarello, L. Donnarumma, G. Labbadia, A. Musca. *Department of Medical Therapy, University "La Sapienza", Rome, Italy*

Myotonic dystrophy (MD) is the most common dystrophy in adults characterised by multiple systemic effects. Cardiac involvement is frequent and is manifested as an impairment of the conducting system. Nevertheless, in these patients there is a high incidence of sudden death not always attributable to a conduction block. Spontaneous ventricular tachycardia was also reported raising the possibility that ventricular arrhythmias play a major role in the mortality of patients with MD. Abnormal ventricular late potentials (LP), caused by slowed and fragmented conduction through damaged areas of myocardium, represent a substrate for malignant reentrant ventricular arrhythmias. The aim of the study was to further evaluate the relation between the myocardial involvement, assessed by LP positivity, and DNA analysis. Forty-two MD patients (21 females and 31 males) entered the study. The severity of skeletal muscle involvement was scored as mild (n = 32), moderate (n = 13) and severe (n = 7). An inverse correlation between age at disease onset and CTG expansion ($r = -0.37$, $p < 0.05$) was observed. The subjects were classified into 3 subgroups on the basis of the number of CTG trinucleotide (MD mutation) repeat expansions: $E_1 = 30$ pts. with 0 to 500 CTG repeats; $E_2 = 19$ pts. with up to 1,000 repeats; $E_{3+4} = 3$ pts. with equal or more than 1,500 repeats. Twenty-eight out 52 patients (54%) showed abnormal LP. Sex, age of disease onset, skeletal muscle involvement did not significantly discriminate these patients from remain sample. A significant positive trend between the presence of abnormal LT and number of CTG repeats (figure, $p < 0.01$) was observed. In particular, a significant difference between prevalence of abnormal LP between E1 and E2 groups ($p < 0.01$) was detected indicating that CTG expansion more than 500 repeats is related to a substantial myocardial involvement.

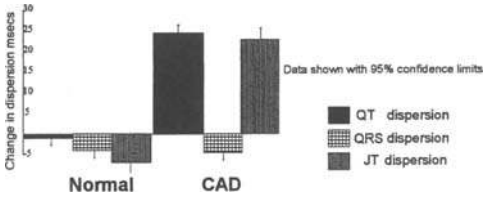


Our findings suggest that in patients with myotonic dystrophy the LP-molecular correlation could provide additional information regarding the morbidity and prognosis in these patients. Prospective study is planned to better understand the predictor value of abnormal late potentials in survival of this kind of patient.

P2947 Mental stress and sudden cardiac death? From anecdote to electrophysiological basis

R. James, P. Taggart, S. McNally, S. Newman, S. Sporton, S. Hardman. *University College London Medical School and Hospitals, London, UK*

Sudden cardiac death (SCD) remains a significant cause of mortality among patients with coronary artery disease (CAD): most deaths are arrhythmic. The association between acute psychological stress and SCD is largely anecdotal. Psychometric testing has been shown to induce psychological stress and regional ischaemia in patients with CAD. Using this technique we have examined the propensity for mental stress to influence QT dispersion (dispersion of repolarisation), JT dispersion (dispersion of action potential duration) and QRS dispersion (dispersion of conduction) in patients with and without CAD. 12 lead ECGs were recorded during psychometric testing from which QT, JT and QRS dispersion were measured. QT dispersion increased in patients with CAD (n = 14) (change = 25 msecs) ($p < 0.001$) but not in those with normal coronaries (n = 7). The increase in QT dispersion occurred by virtue of an increase in JT dispersion ($p < 0.0001$) rather than QRS dispersion.



Psychological stress increases QT dispersion (reflecting JT dispersion) in patients with CAD but not in normal subjects. These findings could be explained by an inhomogeneity of repolarisation secondary to regional ischaemia and provide a link between stress and arrhythmia.

P2948 Analysis of human right atrial conduction properties and velocities during atrial flutter determined by non-contact mapping

R.J. Schilling, N.S. Peters, A. Kadish[1], J. Goldberger[1], D.W. Davies. *Waller Department of Cardiology, St Mary's Hospital, London, UK; [1]Cardiology Department, Northwestern Memorial Hospital, Chicago, USA*

Characterisation of the complex relationship between right atrial anatomy and function may give further insight into the mechanisms and aetiology of human atrial flutter (AFL).

Methods and Results: A non-contact mapping system was used to map the right atrium (RA) of 12 patients (pts) with a history of AFL. The system was used to generate an anatomically based "virtual" endocardial model (VE) onto which reconstructed electrograms were superimposed producing isopotential maps. The Cartesian co-ordinates of points on the VE were used to calculate the tricuspid annulus-inferior vena cava isthmus (IS) length and the CV of the AFL wavefront within the IS, and either side of the crista terminalis (CT) delineating smooth from trabeculated RA. IS was anatomically defined by locator signal labelling of anatomical landmarks using fluoroscopic guidance and the entrance and exit of the IS defined as a distinct narrowing and re-expansion of the mapped wavefront during AFL. The CT was defined as a line of conduction block located in the lateral RA with craniocaudal activation on one side and caudocranial activation on the other. In 1 pt the IS could not be clearly defined and in another a line of block could not be seen in the lateral RA. Ten pts had counter clockwise and 2 had clockwise AFL. The IS length was 50 ± 24.27 mm (mean ± SD) and CV was 0.78 ± 0.35 m/s (range 0.34 to 1.7 m/s). CV was similar for the smooth and trabeculated RA being 1.16 ± 0.48 m/s and 1.22 ± 0.65 m/s respectively ($p = 0.67$). Smooth RA CV was faster than isthmus CV ($p = 0.045$) but trabeculated RA CV was not ($p = 0.06$).

Conclusion: Non-contact mapping has demonstrated that conduction velocity within the IS can be significantly slower than other portions of the RA but that IS conduction velocity varies considerably between pts.

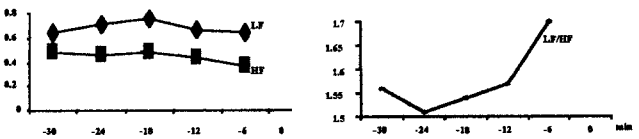
P2949 Initiation of sustained monomorphic ventricular tachycardia originating from the right ventricular outflow tract: sympathetic versus parasympathetic tone activity

A.G. Manolis, A. Katsivas, P. Haikos, D. Karatza, A. Anastasopoulou, N. Louvros. *Hellenic Red Cross Hospital, Athens, Greece*

The relation between autonomic nervous system (ANS) activities and genesis of ventricular tachyarrhythmias is well known. Changes in frequency domain measures of heart rate variability (HRV) preceding the onset of ventricular tachycardia (VT) associated with ischemic heart disease are reported. VT arising from the right ventricular outflow tract (RVOT) is facilitated to occur when sympathetic nervous system is increased, but the role of sympathovagal balance assessed by HRV in the genesis of VT of this particular type has not been thoroughly analysed yet. This study aimed to assess the ANS activity during the last few minutes preceded the onset of episodes of sustained VT originating from RVOT.

Methods: Six pts (2 M, 4 F, 41 ± 8 years) with sustained idiopathic VT, originating from RVOT were enrolled in the study, and underwent a 3 channel 24 hour Holter monitoring (Marquette 8000, 5.8) in a drug free state. We evaluated the ANS activity using spectral analysis of HRV. We measured the normalised units (nu) of power spectrum in the low frequency (LF) (0.008–0.15 Hz) and high frequency (HF) (0.15–0.40 Hz) and the ratio LF/HF of 6 min intervals over a 30 min period before the onset of VT. Twenty episodes of sustained VT from the six recordings formed this study.

Results: The power spectrum in the HF were: 0.47 ± 0.06 nu for the period of 30-24 min and 0.37 ± 0.04 nu for the period of 6-0 min before the onset of VT ($p < 0.05$). There were no differences in the LF in between these periods. The ratio LF/HF was 1.56 ± 0.1 for the period of 30-24 min and 1.7 ± 0.17 for the period of 6-0 min before VT ($p < 0.05$). Therefore, the increase in the LF/HF is caused largely from a decrease in the HF without any significant change in the LF.



Conclusions: There is a significant change of the sympathovagal balance during the period preceding the onset of sustained VT, originating from RVOT. These changes of the autonomic influence on the heart are mainly resulted from decreased vagal activity rather than enhanced sympathetic drive to the myocardium.

P2950 The assessment of cardiac sympathetic innervation in patients with arrhythmogenic right ventricular dysplasia

K. Lefflerová, M. Buncová, J. Bytešník, T. Belšan[1], P. Frídl, V. Vančura. *Institute for Clinical and Experimental Medicine, Prague; [1]Dept. of Radiology, 3rd Medical Faculty, Prague, Czech Republic*

Arrhythmogenic right ventricular dysplasia (ARVD) affecting primarily the right ventricle is clinically characterized by ventricular arrhythmias and/or even sudden cardiac death in patients with no apparent heart disease. Metaiodobenzylguanidine (MIBG) scintigraphy is able to demonstrate the disruption of myocardial sympathetic innervation of the left ventricle. The aim of this study was to evaluate the significance of myocardial sympathetic dysfunction in 10 patients (9 men, mean age 40 ± 14) with ARVD. The diagnosis of ARVD was made by clinical history (9 patients had documented sustained VT, 1 survived sudden cardiac death due ventricle fibrillation), echocardiography, angiography of right ventricle and MRI, electrophysiological study was performed in all patients. Ischemic heart disease was excluded by coronary angiography. All ten patients had normal ejection fraction of left ventricle. The uptake of iodine-123 MIBG was measured as the heart/mediastinum activity ratio 4 hours after isotope administration (H4/M4 index). 123I-MIBG SPECT (single photon emission computed tomography) and thallium-201 SPECT was performed to demonstrate abnormal distribution of MIBG. A group of 10 patients with supraventricular arrhythmias without structural heart disease served as a control group.

Results: H4/M4 index was 1.87 ± 0.31 in ARVD group, and 2.38 ± 0.35 in control group ($p < 0.003$). Thus eight of ten patients with ARVD showed reduced uptake of 123I-MIBG. The abnormal areas were located predominantly in posterior and posteroseptal segments of the heart. The greatest defect was detected in survivor of sudden cardiac death despite of normal ejection fraction of left ventricle. 201 TI-SPECT was normal in all ten patients.

In conclusion: This data suggest that I123-MIBG scintigraphy allows detection of depressed sympathetic innervation of left ventricle in ARVD patients and may be helpful in assessing of the extent of the disease.

P2951 Sport activity in young athletes with documented arrhythmogenic right ventricular disease: which recommandations?

F. Revault d'Allonnes, F. Carré, M. Vauthier, V. Berder, P. Mabo, J.C. Daubert. *Department of Cardiology, University Hospital, Rennes, France*

This study reports the outcome of sport practice in 26 top-level athletes who were referrred for Arrhythmogenic Right Ventricular Disease (ARVD). Diagnosis was based on the criteria of the ESC task-force.

Patient population consisted of males, mean age 29.6 ± 7.8 years, participating in sport competition (cycling: n = 13; running, n = 8; football, n = 3; basketball: n = 1; and rugby, n = 1) with a training time ≥ 10 hrs per week. All pts complained of exercise related symptoms including syncope or near-syncope in 18. Spontaneous sustained VT could be documented in 8.

After ARVD diagnosis pts were recommended to stop all competitive activities and were treated by beta-blockers. After a mean follow-up (FU) time of 5.3 ± 4 years the actual sport status was assessed by questionnaire in the 25 survivor pts. Sport competition was actually stopped in 24 pts. Only 1 pt (racing cyclist) continued and suffered aborted sudden death during competition 3 years after diagnosis. 7 pts (30.4%) definitively resumed sport. Surprisingly the other 16 pts still have regular sport practice of 3.5 ± 2.4 hrs a week. The type of sport stayed the same for all pts, but intensity and duration had decreased. None of these pts experienced further arrhythmic events during FU with optimized medical or non pharmacological (ablation: n = 4; ICD: n = 1) treatment.

These date are consistent with the conclusions of the 26-th Bethesda Conference recommending that "athletes with ARVD don't participate in any sport in competition". Nevertheless, this study suggests that pts with controlled arrhythmias may continue sport practice of low intensity, under condition of regular cardiovascular control.

P2952 Influence of ventricular stimulation and stimulation site on coronary flow and flow reserve

Carel C. de Cock, Linda M.C. van Campen, C.A. Visser. *Medical Center VU, Amsterdam, Netherlands*

To assess the influence of ventricular stimulation and stimulation site on coronary flow and flow reserve 14 consecutive patients were studied. All patients were selected for pacemaker implantation because of symptomatic sick-sinus-syndrome. All had sinus rhythm with normal intraventricular conduction (QRS complex ≤ 120 msec). Intra coronary flow and flow reserve was measured using an intracoronary Doppler flow wire at baseline and during maximal hyperemia using adenosine i.c. All patients had normal coronary arteries. Intracoronary Doppler flow velocity (CF) and coronary flow reserve (CFR) was measured in the LAD and CX coronary artery during inherent rhythm (IR) and during stimulation in the right ventricular apex (RVAP) and outflow tract (RVOT). Pacing was performed in the VDD mode; and AV delay was adjusted 2–5 msec shorter than the AV delay of IR.

		IR	RVAP	RVOT
LAD	CF	21 ± 5	22 ± 6	23 ± 6
	CFR	3.2 ± 0.8	2.5 ± 0.7*	2.0 ± 0.7*#
CX	CF	15 ± 5	17 ± 6	17 ± 7
	CFR	2.8 ± 0.7	2.4 ± 0.6	2.5 ± 0.6

* $p < 0.05$ compared to IR; # $p < 0.01$ compared to RVAP and IR.

Conclusion: ventricular stimulation is associated with impaired coronary flow reserve in the LAD. Right ventricular apex stimulation resulted in a higher flow reserve as compared to outflow tract pacing.

P2953 Comparison of effects of anodic versus cathodic pacing on ejection fraction through in ovo pacing of the chick embryo heart

X. Lyon[1], D. Sedmera[2], E. Raddatz[2], P. Kucera[2], L. Kappenberger[1]. [1]*Division of Cardiology, University Hospital;* [2]*Institute of Physiology, Lausanne, Switzerland*

Background: Anodic stimulation is not classically used to pace the heart because 1) stimulation threshold is higher and 2) refractory period is shorter and could facilitate arrhythmias. Anodic stimulation has regained interest in the emerging era of multisite pacing as in biventricular pacing for heart failure or biatrial pacing for prevention of atrial arrhythmias. Very few experiments were performed in the past to compare anodic to cathodic stimulation and almost none were designed to measure potential haemodynamic modifications.

Methods: We used an experimental setup developed in our laboratory, allowing to study cardiac volume modifications of a chick embryo heart under various pacing modes. Through a microsurgical opening of the thoracic wall, two fine isolated platinum electrodes were placed in ovo over the heart of stage 21 chick embryos. The pacemaker was set to 125% of the intrinsic heart rate at 2 time the diastolic threshold amplitude of the anodic mode. After 2 minutes of control recording, one minute period of either cathodic or anodic stimulation followed. End diastolic (EDV) and end systolic volumes (ESV) were derived from computerized image analysis; stroke volume (STV) and ejection fraction (EF) were calculated accordingly.

Results: In all five cases, EDV, ESV and STV were significantly lower under pacing as compared to sinus rhythm. The heart volume was even more decrease by anodic pacing as compared to cathodic pacing, but EF was unchanged.

Conclusion: The observed differences between pacing and control corresponds to well known observations, the added modification induce by anodic as compared to cathodic stimulation warrants further investigation of this problem. It is concluded that anodic and cathodic stimulation have different effects on LV function and that more investigations has to be done to characterize the properties and understand the intracellular mechanisms of the anodic stimulation that should be considered for further optimizing cardiac stimulation.

P2954 The activation of platelet function, coagulation and fibrinolysis during radiofrequency catheter ablation in heparinized patients

O.-G. Anfinsen, K. Gjesdal[1], F. Brosstad[2], O.M. Orning[1], H. Aass, E. Kongsgaard, J.P. Amlie. *Department of Cardiology, Rikshospitalet, Oslo;* [1]*Arrhythmia Clinic, Ullevaal Hospital, Oslo;* [2]*Research Institute of Internal Med, Rikshospitalet, Oslo, Norway*

Catheter ablation may be complicated by clinical thromboembolism in about 1% of patients.

Methods: We studied the activation of coagulation (prothrombin fragment 1+2 (PF1+2)), platelets (beta-thromboglobulin (b-TG)) and fibrinolysis (plasmin-antiplasmin complexes (PAP) and D-dimer) during RF ablation in 13 patients. They received heparin 100 U/kg i.v. after the initial electrophysiological study, prior to the delivery of RF current; thereafter 1,000 U/hour throughout the procedure.

Results: PF1+2 increased fourfold ($p < 0.001$) during the diagnostic study, but gradually declined to upper reference value during heparin administration. There was a strong correlation between procedure duration prior to heparin bolus (range 39–173 min.) and a) maximal rise of PF1+2 ($r = 0.83$, $p < 0.001$) and b) increase of PF1+2 from baseline to end of procedure ($r = 0.74$, $p = 0.004$). There was no correlation between post-heparin changes of PF1+2 and a) post-heparin procedure duration (range 40–317 min), b) number of RF pulses (range 1–16) or c) RF current duration (range 46–687 s). Plasma b-TG concentration showed similar trends. Fibrinolytic activity increased moderately from baseline until heparin administration; then remained around the upper reference values. PAP at the end of procedure and D-dimer at the time of heparin administration both correlated with pre-heparin procedure duration ($r = 0.70$, $p = 0.007$ and $r = 0.69$, $p = 0.01$, respectively). All parameters were normal the next morning.

Conclusion: Procedure duration prior to heparin administration, and not the delivery of RF current per se, determines activation of hemostasis and fibrinolysis during RF ablation. This study supports the use of heparin in right-sided as well as left-sided procedures.

P2955 Reduced radiation exposure during cardiac electrophysiologic procedures

E. Wever[1], F. Wittkampf[2], C. Vos[2], J. vanderTol[2], E. Robles de Medina[2]. [1]*St Antonius Hospital Nieuwagein;* [2]*Heart-Lung Institute, University Hospital Utrecht, Netherlands*

During cardiac electrophysiologic (EP) studies including catheter ablation procedures, radiation exposure is a serious issue for both patients and operators.

Methods and Results: Since 1996, we took various measures to reduce X-ray exposure. Originally, our biplane fluoroscopy system was 12.5 Hz pulsed in the RAO and continuous in the LAO direction. With an annual load of 170 catheter ablation procedures and 100 diagnostic investigations, the total depth dose of all operator badges was 7.4 mSv per month as measured over a 1.5-year period. In July 1996, two measures were taken. 1) First, both X-ray beams were extra filtered with 0.3 mm copper plus 2 mm aluminum to reduce the amount of soft radiation. This resulted in a slight but for EP procedures acceptable reduction of image quality. Measurements with tissue-equivalent phantom models, however, showed a threefold reduction of skin dose. 2) The second measure was the introduction of the LocaLisa system to allow for real-time non-fluoroscopic display of mapping/ablation catheter positions. In the ensuing 9 months, total badge readings of all operators combined decreased to 1.4 mSv per month, while the annual number of catheter ablation procedures increased to 220. Thereafter, 2 additional measures were taken. 1) The lateral fluoroscopy was upgraded from the continuous to the 12.5 Hz pulsed mode. 2) A lead glass screen was installed to protect the operator against scattered radiation. During the ensuing 11 months, these last 2 measures resulted in a further reduction of the total of all badge readings to 0.3 mSv per month, while the annual number of catheter ablations increased to 250.

Conclusions: Adequate measures resulted in a 25 fold reduction of operator radiation exposure. The use of extra copper-aluminum filters for the reduction of soft radiation alone is an easy measure to achieve an estimated threefold reduction of radiation exposure during cardiac electophysiologic procedures.

P2956 Radiofrequency catheter ablation using a multipolar irrigated-coiled electrode catheter: in vivo studies assessing the induction of linear lesions

C. Weiss, F. Thuneke, M. Antz[1], S. Willems, T. Meinertz. *[1]Depts. of Cardiology, St.-Georg Hospital; University Hospital Eppendorf, Hamburg, Germany*

The induction of continuous linear lesions is prerequisite for successful radiofrequency (RFC) ablation of atrial flutter and fibrillation. Ablation catheters with multiple coiled electrodes seems to be a good tool for it. However the risk for coagulum formation with these electrodes is increased. Irrigation of the coils might reduce this risk. A novel 7 F ablation catheter with 4 irrigated-coiled ablation electrodes (electrode length: 6 mm; interelectrode distance: 2 mm; Medtronic, USA) was investigated in 7 anesthetized sheeps. Irrigation of the electrodes was achieved via 4 holes at both edges of each electrode (10–15 ml/min). The skin over the thigh muscle was incised and raised to form a cradle which was superperfused with heparinized blood (37°C). The catheter was placed along the muscle with standardized 10g contact pressure. RFC energy was delivered sequentially between each ablation electrode and a skin patch for 90 seconds with a power of 10, 20, 30 or 40 Watt (W) respectively. The width and depth of the 87 induced lesions was compared between the different power levels: (*$p < 0.05$ vs. 20 W) Lesions were continuous in all cases except those achieved with 10 W RFC pulses. Coagulum formations were not observed following any RFC delivery.

	10 W (n = 12)	20 W (n = 16)	30 W (n = 31)	40 W (n = 28)
Width (cm)	0.24 ± 0.06	0.82 ± 0.22	0.77 ± 0.14	0.98 ± 0.02
Depth (cm)	0.14 ± 0.07	0.47 ± 0.13*	0.74 ± 0.13*	0.75 ± 0.16*
Continuity	3/12 (25%)	16/16 (100%)	31/31 (100%)	28/28 (100%)

(*$p < 0.05$ vs. 20 W)

Conclusions: Continuous linear lesions could be induced using irrigatied-coiled RFC ablation electrodes with a power of 20–40 W. Lesion depth of more than 0.7 cm developed already with a power of 30 W. Coagulum formation were not observed using power up to 40 W.

P2957 Differences in dual av nodal properties between men and women

Per Insulander, Göran Kennebäck, Eva Stråât, Mats Jensen-Urstad[1], Hans Vallin. *Department of Cardiology, Huddinge University Hospital; [1]Department of Cardiology, Karolinska Hospital, Stockholm, Sweden*

A discontinuous antegrade AV nodal conduction curve (Dual AVN) is a common finding during electrophysiologic studies (EPS). Females are more common in patients referred for catheter ablation of AV nodal re-entry tackycardias (AVNRT). The objective of this study was to determine if Dual AVN was a more frequent finding among women than among men in patients referred for EPS, excluding patients with AVNRT.

Methods: 80 consecutive patients undergoing EPS due to other causes than AVNRT were evaluted. AV nodal conduction curves were determined at two different pacing rates with both single and double extrastimuli with 10-msec decrements.

Results:

	No	Jump	%	FPERP	SPERP	Window
Female	34	20	59	321	248	73
Male	46	28	61	327	292	35
					p = 0.0040	p = 0.0096

FPERP: fast pathway effective refracory period; SPERP = slow pathway effective refractory period

Conclusion: No gender difference in the occurrence of Dual AVN was found. Women, though, have a significantly shorter SPERP, resulting in a wider window (FPERP-SPERP). This increases the possibility that a premature atrial depolarisation results in retrograde activation of the right atrium through the fast pathway and to initiate AVNRT. This finding might be one part of the explanation why AVNRT seems to be more common among women than among men.

P2958 Does gender differ in ventricular repolarization and in response to dofetilide (an I_{Kr}-blocker) in isolated rabbit Purkinje fibres?

H.R. Lu, A. Saels, R. Mariën, F. De Clerck. *Dept. of Cardiovasc. & Pulm. Pharmacol. Janssen Research Foundation, B-2340, Beerse, Belgium*

Woman are known to have a longer QT-interval than man and an increased propensity toward drug-induced "torsades de pointes" (TdP). However, little is known about these gender differences in isolated cardiac tissues. In the present study, we evaluated potential gender differences in the ventricular repolarization in isolated rabbit Purkinje fibers using microelectrode.

Methods: Isolated rabbit Purkinje fibers were perfused in Tyrode solution containing K^+ 4.7 mM and at 37.5 °C in a condition of a normal rhythm (1 Hz) as well as in a extreme bradycardiac rhythm (0.2 Hz) with and without dofetilide (1×10^{-M}).

Results: Female Purkinje fibers (n = 10) tended to have a longer duration of the action potential at 90% repolarization (APD_{90}) than male ones (n = 10): 345 ± 13 ms (mean ± SEM) versus 289 ± 18 ms at 1 Hz (p = 0.047); 611 ± 57 ms versus 449 ± 51 ms at 0.2 Hz (p = 0.06), respectively. Dofetilide (1×10^{-8} M) tended to increased more APD_{90} in female Purkinje fibers (n = 10) than in male (n = 10): 638 ± 39 ms versus 431 ± 64 ms at 1 Hz at 20-min after the infusion (p = 0.02), and 800 ms versus 746 ± 37 ms at 0.2 Hz at the end of 25-min infusion (p = 0.07), respectively. Furthermore, dofetilide (1×10^{-8} M) resulted in a higher incidence of early after depolarizations in female Purkinje fibers than in male ones during 0.2 Hz (100% versus 50%; p = 0.03).

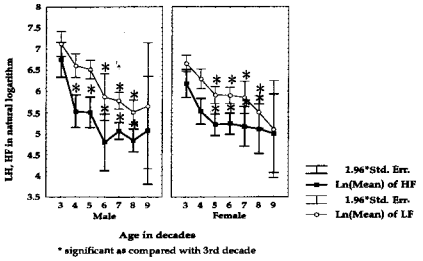
In Conclusion: we conclude that female Purkinje fibers have longer ventricular repolarizations and a higher risk for drug-induced early afterdepolarizations in a slow stimulation rate than male ones. This may contribute to gender difference in QT-interval and to female being a more prone than man to develop drug-induced TdP.

P2959 "Asynchronized" autonomic decline occurs in middle-aged men, not in women

Chi-Jen Tseng, Chia-Ting Chao, Wen-Jer Wang, Kwen-Hsung Chen[1], Cheng-Ju Wu, Chung-Peng Liu, Hung-Ting Chiang. *Kaohsiung Veterans General Hospital; [1]Armed Forces TsoYing Hospital Kaohsiung, Taiwan, China*

Many investigators had shown us that decline in autonomic activities was a naturally aging process. However, the different patterns of the autonomic decline between males and females were not well delineated.

Methods: We carried out power spectral analysis of heart rate variability in 685 healthy, random, eligible subjects (M:F = 408:277, aged 57.75 ± 15.89 years old). We assumed high frequency power (HF, 0.15 ~ 0.4 Hz) to stand for parasympathetic activity and low frequency power (LF, 0.04 ~ 0.15 Hz) for sympathetic activity. The LF/HF ratio stood for balance in sympathetic and parasympathetic activity. The baseline data were not different in males and females. We divided subjects into 7 age groups. We applied an ANOVA test to see the aging effect on decline of LF, HF, and LF/HF.



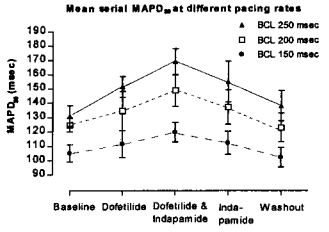
Results: Both age and gender did not influence LF/HF. Age influenced LF and HF significantly. A post hoe analysis disclosed both LF and HF decreased significantly at fourth decade in women. However, in men, LF decreased significantly at fifth decade and HF at third decade (graph).

Conclusion: There exists an asynchronized autonomic decline in men but not in women. The significance remained to be determined.

P2960 Electrophysiological effects of combined block of the rapid (I_{Kr}) and slow (I_{Ks}) components of the delayed rectifier potassium current: potential for excessive prolongation of cardiac repolarization

P. Geelen, B. Drolet, E. Lessard, G.E. O'Hara, J. Turgeon. *Quebec Heart Institute, Laval Hospital, Sainte-Foy PQ, Canada*

The rapid component of the delayed rectifier potassium current (I_K), I_{Kr}, is the target of most drugs that prolong repolarization. Electrophysiological effects resulting from combined block of I_{Kr} and the slow component of I_K, I_{Ks}, still need to be characterized. Studies in isolated, buffer-perfused guinea pig hearts (n = 15) were undertaken to compare lengthening of cardiac repolarization ($MAPD_{90}$) under conditions of I_{Kr} block alone (dofetilide (dof.)), I_{Ks} block alone (indapamide (ind.)), or combined block of I_{Kr} and I_{Ks}. Measurements were taken at basic pacing cycle lengths (BCL) of 250, 200 and 150 msec. Sequential perfusions with dof., dof./ind. and ind. showed significant increases in $MAPD_{90}$ versus baseline after isolated dof. or ind. perfusion at BCL 250 and 200 msec. A further significant rise versus isolated drug perfusions of combined dof./ind. was seen at BCL 250 and 200 msec. At BCL 150 msec only combined dof./ind. caused a significant increase in $MAPD_{90}$ (figure).



Rate-dependent decreases in $MAPD_{90}$ from BCL 250 to 150 msec were not significantly different during the different perfusions (20% decrease at baseline, 26% after dof., 29% after dof./ind. and 27% after ind.).

Conclusions: 1. Combined I_{Kr} and I_{Ks} block may lead to excessive lenghtening of cardiac repolarization and can predispose to proarrhythmia. 2. Reverse-use dependence is maintained in the presence of combined I_{Kr} and I_{Ks} block.

P2961 ST-T variation assessment with a multilayer perceptron network

H.A. Kestler[1,2], J. Wöhrle[1], M. Höher[1]. [1]*Dept. of Medicine II;* [2]*Dept. of Neural Information Processing, University of Ulm, Germany*

Alternans measurements are expressed by a single value. In order to assess the utility of multidimensional variation measurement for categorization, we performed a feasiability study on CAD patients and healthy subjects. High-resolution beat-to-beat ECG's (16 bit, 1000 Hz) were recorded from 51 healthy volunteers (age 24 ± 4.2 ys) without any structural heart disease and no cardiac risk factors and 44 patients (age 61 ± 8.8 ys) with coronary heart disease, a history of myocardial infarction and inducible sustained ventricular tachycardia (>30 s). Microvariability measurement of the ST-T-signal was based on 250 consecutive sinus beats per individual.

ST-T microvariation was measured from the vector of standard deviations of the amplitude of corresponding points of the ST-T-signal. A window of 400 ms starting from the QRS-off point was analyzed. Prior to the quantification of variability, the beats were preprocessed to suppress the main electrical waveform by subtracting each beat from its cubic spline smoothed version. A multilayer perceptron neural net was trained using conjugate gradient descent with line search. Different training runs with variing number of hidden neurons (range: 3–8) were performed. The optimal net consisted of 400 inputs, 3 hidden neurons and 2 output neurons. The network performance using leaving-one-out was (%):

Accuracy	Sensitivity	Specificity	PPV	NPV
81.1	75.0	86.3	82.5	80.0

We conclude that multidimensional ST-T variation assessment gives classification results equivalent to other noninvasive tests. The main advantage of the multilayer perceptron is its capability of forming arbitrary decision boundaries without prior knowledge. The independence of an exact determination of T-wave endpoints together with the inclusion of the complete ST-T wave in the decision process, make this a promising new approach.

P2962 Autonomic tone prior to and following episodes of spontaneous, non-sustained ventricular tachycardia

D. Leftheriotis, E.G. Livanis, P. Flevari, G.N. Theodorakis, E. Evgeniadou, P. Kaperneka, D.Th. Kremastinos. *2nd Dept of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

Spontaneous episodes of non-sustained ventricular tachycardia (NSVT) are preceded by increases in heart rate variability (HRV) in the frequency domain. On the contrary, a decrease in HRV has been observed before episodes of sustained ventricular tachycardia (VT), though results are conflicting. In an attempt to further elucidate the role of autonomic nervous system in ventricular arrhythmogenesis, we assessed HRV changes not only before the onset of NSVT but also following its termination.

Methods: A total of 19 patients with structural heart disease were studied. Arrhythmia substrate was coronary artery disease in 7 and dilated cardiomyopathy in 12. All had 24-hour Holter ECG recordings comprising one episode of spontaneous NSVT. Normalized values of low frequency power (LF), high frequency power (HF) as well as LF/HF ratio were used as indexes of autonomic input to the heart. We assessed 24-hour average measures of these HRV indexes and compared them to 1-hour calculations a) prior to NSVT onset and b) following its termination.

Results: LF and HF power were increased relatively to 24-hour values, not only prior to NSVT initiation (44.3 ± 14.9 and 34.7 ± 18.4 vs 32.4 ± 24.0 and 18.3 ± 13.6 respectively, $p < 0.04$ and <0.004) but, also, following its termination (43.8 ± 13.5 and 39.2 ± 22.4 vs 32.4 ± 18.4 and 18.3 ± 13.6, $p < 0.03$ and <0.004). LF/HF ratio prior to and following NSVT remained unchanged relatively to its 24-hour value. No difference was observed in HRV parameters tested 1 hour prior to NSVT and 1 hour after its termination.

Conclusion: An increase in both sympathetic and vagal modulation of the heart exists not only before the onset of NSVT, but also following its termination. This finding might represent protective autonomic activation against the development of sustained VT.

P2963 Circle maps of respiratory sinus arrhythmia patterns: a new method to differentiate cardiac denervation from vagal modulations after atrioventricular node modification

C. Stellbrink, M. Zarse, K. Markus, M. Schiek[1], F.R. Drepper[1], H. Halling[1], Peter Hanrath. *Department of Cardiology/Internal Medicine, University of Technology Aachen;* [1]*Research Institute Jülich, Germany*

Respiratory sinus arrhythmia, an indicator of vagal cardiac innervation decreases with age and after AV-node modification (AVNM), both suggesting vagal denervation. We hypothesized that AVNM only modulates parasympathetic ganglia, adjacent to the slow pathway ablation site, whereas aging causes chronic denervation. Circle maps (CMs), a new method of analyzing RSA phase dynamics independent of amplitude dynamics can potentially differentiate between both forms of changes in vagal tone. The Kulback information (KI) quantifies differences in CMs, increased KI indicating decreased vagal innervation.

Methods: 12 young (22 ± 4 y, 8 m, 4 f) and 11 old (58 ± 11 y, 5 m, 6 f) healthy probands underwent 24-hour ECG recording (24-R) and a paced breathing protocol (PBP). 10 consecutive patients (46 ± 19 y, 7 f, 3 m) underwent 24-R and the same PBP before and 1 day AVNM. High frequency bands (HF) and HF/LF ratio were analyzed from 24-R. RSA-Amplitudes (A) were analyzed for spontaneous breathing (SB) and PB. CMs were obtained and differences in cardiac dynamics analyzed with the KI.

Results:

ms	HF ms^2	LF/HF	SB-A	SB-KI	PB-A	PB-A KI
Young	908 ± 98*	2.6 ± 04*	92 ± 37*	0.41 ± 0.03*	230 ± 90*	0.4 ± 0.7*
Old	188 ± 100	3.8 ± 1.5	43 ± 16	0.55 ± 0.07	74 ± 24	0.56 ± 0.09
Pre	696 ± 285	1.8 ± 0.6	53 ± 28+	0.34 ± 0.08	138 ± 74	0.45 ± 0.08
p	287 ± 125*	2.8 ± 1.3*	39 ± 21	0.3 ± 0.08	127 ± 860	0.47 ± 0.09

*$p < 0.05$ compared to pre = before young, AVNM, p = post

Conclusions: In contrast to HF bands, CMs can differentiate between vagal modulation by AVNM and vagal denervation by aging.

P2964 Circle maps of respiratory sinus arrhythmia: a new method to fast and reliably determine autonomic cardiac innervation

M. Zarse, K. Markus, M. Schiek[1], F.R. Drepper[1], H. Halling[1], C. Stellbrink, P. Hanrath. *Department of Cardiology/Internal Medicine University of Technology Aachen; [1]Research Institute Jülich, Germany*

Determination of the autonomic tone is essential for risk stratification in cardiac disease. Respiratory sinus arrhythmia is reliably characterized by mean values of time and frequency domain in the 24-hour ECG. Recordings over a few minutes however, show high intraindividual variability (Var) with decreased reliability. Circle maps (CM), a new method to analyze RSA phase dynamics seperated from amplitude dynamics, allow reliable measurements of autonomic tone within 10 minutes.

Methods: 7 young (24 ± 5 years; 3 f, 4 m) and 9 old (58 ± 9 years; 4 f, 5 m) healthy probands (P) underwent a 10 minute paced breathing protocol three times on different days. RSA during spontaneous (SB) and paced breathing (PB) [7.5 s cycle] was characterized by amplitudes in time domain (RSA-A) and phase dynamics of CMs. The intraindividual differences in information of the consecutive CMs were quantified by the Kulback-Information (KI-CM). The 3 obtained measurements of RSA-A and KI-CM were averaged, the standard deviations (SDs) were expressed as % of the average values and defined as normed SDs. The normed SDs were used as parameter for the Var of RSA-A and KI-CM.

Results:

	RSA-A young P	KI-CM young P	RSA-A old P	KI-CM old P	RSA-A all P	KI-CM all P
SB	23 ± 8	8 ± 6*	23 ± 7	10 ± 4*	23 ± 8	9 ± 3*
PB	18 ± 7	7 ± 3*	18 ± 7	9 ± 3*	18 ± 6	8 ± 3*

Normed SDs *p < 0.05 compared with RSA-A

Var of autonomic tone determined by CM of RSA-patterns issignificantly lower than with RSA-A. PB decreases Var of RSA-A, whereas KI-CM is very reliable both during SB and PB.

Conclusions: CMs of RSA pattern provide a new method for determination of the autonomic tone within 10 minutes. Even short measurements are very robust at PB and SB, as opposed to RSA-A.

P2965 Electrophysiologic effects of partial and complete autonomic nervous system blockade in awake dogs

L. Eckardt[1], A. Meißner[2], P. Kirchhof[1], N. Rolf[2], W. Haverkamp[1], M. Borggrefe[1], G. Breithardt[1], H. Van Aken[2]. *[1]Dept. of Cardiology and Inst. of Arteriosclerosis Research; [2]Dept. of Anesthesiology and Operative Intensive Care Medicine, University of Münster, Germany*

Background: The autonomic nervous system plays a major role in arrhythmogenesis. As autonomic influences on repolarization are far from being completely understood we aimed to characterise the electrophysiological effects of sympathetic blockade by means of thoracic epidural anesthesia (TEA) and additional complete pharmacological autonomic nervous system blockade (ANSB).

Methods: In 6 anaesthetized mongrel dogs an epidural catheter and two 6F sheaths in the right jugular vein were percutaneously implanted one day before the electrophysiologic study. Thereafter, in awake dogs two quadripolar monophasic action potential (MAP) catheters were placed in the right ventricle via the sheaths. TEA was performed with lidocaine 0.4 mg/kg through the epidural catheter at the level of Th 2. In the presence of TEA, ANSB was performed by application of propanolol (2 mg/kg), atropine (3 mg/kg), and hexamethonium (20 mg/kg).

Results: No ECG changes were documented in the presence of TEA alone, or both TEA and ANSB. TEA decreased heart rate from 118 ± 24/min at baseline to 108 ± 28/min. Induction of ANSB increased heart rate to 146 ± 31/min. Ventricular pacing thresholds remained constant. TEA resulted in a rate-dependent increase in right ventricular refractory period (RP) (cycle length (CL) 400 ms: +9.7 ± 4%; CL 300 ms +12 ± 2%; CL 200 ms +16 ± 5%). This effect was even more marked after ANSB which led to a 27% and 34% prolongation of RP for CLs of 300 and 200 ms, resp. These changes were paralleled by prolongation of right ventricular MAP duration at 90% repolarization. Thus, no change in postrepolarization refractoriness was observed.

Conclusion: Sympathetic and complete blockade of the ANS prolong repolarization in awake dogs. This may indicate a protective role of blocking the autonomic system with regard to arrhythmogenesis.

P2966 Neurohormonal activation and heart rate variability in cardiovascular diseases

A.J. Manolis[1,2], K. Katsaros[1], A. Pittaras[1], G. Haralambidis[1], G. Hatziioakim[1], G. Psaras[1], C. Rammos[1], S. Foussas[1], M. Bresnahan[2], I. Gavras[2], H. Gavras[2]. *[1]Hypertension and Heart Failure Clinic, Tzanio Hospital, Piraeus, Greece; [2]Hypertension and Atherosclerosis Section, Boston University, School of Medicine, Boston MA, USA*

Neurohormonal activation is reported to accompany various cardiovascular diseases and is believed to contribute to their pathogenesis and complications, including disease progression, arrhythmia and sudden death. In this report, we correlated the hormone profile of 127 "cardiac" patients with their tendency to ventricular arrhythmias.

Methods: We studied 61 patients (pts) with hypertension and left ventricular hypertrophy (LVH), mean age 51 ± 10 yrs (52 ♂, 9 ♀), 42 pts with congestive heart failure (CHF) mean age 62 ± 9 yrs (36 ♂, 6 ♀), and 24 pts with a first acute myocardial infarction (AMI) mean age 57 ± 9 yrs (19 ♂, 5 ♀). We measured plasma renin activity (PRA, ng/ml/hr) arginine vasopressin (AVP, pg/ml), norepinephrine (NE, ng/ml), epinephrine (E, ng/ml), and hemodynamic and functional parameters. We also performed Holter monitoring for arrhythmias, including runs of ventricular tachycardia (VTR) and parameters of heart rate variability (HRV), i.e. SD, SDAN, SDNN and pNN50.

Results: Results are shown in table.

	PRA	AVP	NE	E	SD	SDAN	PNN 50
LVH	1.9 ± 1.8	0.9 ± 7	0.3 ± 1	0.04 ± 0.02	46 ± 15	112 ± 39	6 ± 5
CHF	4.9 ± 6	1.2 ± 9	0.45 ± 2	0.05 ± 0.07	36 ± 10	85 ± 39	3.8 ± 3
AMI	3.3 ± 5	7.7 ± 6	1.15 ± 7	0.2 ± 0.1	50 ± 18	67 ± 28	14 ± 10

PRA levels were higher in CHF vs LVH ($p < 0.005$). AVP levels were higher in AMI vs LVH ($p < 0.0000$) and vs CHF ($p < 0.0000$). NE levels were higher in AMI vs LVH ($p < 0.0000$) and vs CHF ($p < 0.0000$) and in CHF vs LVH ($p < 0.003$). E levels were higher in AMI vs LVH ($p < 0.0000$) and vs CHF ($p < 0.0003$). From HRV parameters SD was lower in CHF vs LVH ($p < 0.05$) and AMI ($p < 0.04$), SDAN was lower in AMI vs LVH ($p < 0.0007$) and in CHF vs LVH ($p < 0.05$) and pNN 50 in CHF vs AMI ($p < 0.0007$) and in LVH vs AMI ($p < 0.0003$). In CHF, PRA levels were correlated with VTR ($r = 0.58$, $p < 0.04$) and NE levels with SD ($r = -0.67$), $p < 0.04$) and E levels with VTR ($r = 0.89$, $p < 0.0002$).

Conclusion: Low HRV parameters (indicating autonomic disequilibrium and propensity to ventricular ectopy) were significantly correlated with high NE and were more pronounced in AMI and CHF. Consistent with this, AMI and CHF had also significantly higher levels of E and PRA, which were significantly correlated with VTR's, in accordance to the known high rates of ventricular arrhythmia and sudden death in these conditions.

P2967 Effect of β-blockade on baroreflex sensitivity and heart rate variability in Ca-channel blocker administered cardiac patients

H. Sato, K. Miyoshi, M. Yamamoto[1], H. Iinuma, T. Aizawa, K. Kato. *Cardiovascular Institute, Tokyo; [1]Miyagi University, School of Nursing, Sendai, Japan*

While Ca channel blocker (CA) has been used widely in ischemic heart disease patients, who do not necessarily improve the prognosis. Sympathetic activation by CA has been supposed as a possible cause of deterioration of prognosis and beta-blockade has been reported to improve the prognosis in ischemic heart disease patients. However, the precise mechanism of improvement of prognosis by beta-blockade still remains to be elucidated. Baroreflex sensitivity (BRS) and heart rate variability (HRV) serve powerful predictors of cardiac sudden death in myocardial patients. In this paper we studied the effects of beta-blockade (atenorol 12.5–50 mg daily) on BRS and HRV in cardiac patients taking CA. Thirteen cardiac patients were enrolled in this study. Resting supine position ECG was recorded for ten minutes, two hours after the morning administration of drugs. Finger arterial blood pressure (BP) was monitored using Finapres. RR intervals, systolic and diastolic BP were filed in the computer for later analysis. For analysis of 5-min. records, RR intervals were analyzed using FFT to calculate HF power (0.15–0.5 Hz). BRS was estimated by the sequential method. The computer selected all sequences of three or more successive heart beats in which there were concordant increases or decreases in systolic BP (SBP) and RR interval. If the coefficient between SBP value and RR intervals had a value less than 0.92, the data was discarded from the analysis. A linear regression was applied to each of the sequences, and an average regression slope was calculated. This slope represents BRS (msec/mmHg).

Beta-blockade	RR interval (msec)	log (HF)	BRS
OFF	833 ± 89	1.46 ± 0.34	5.31 ± 2.07
ON	1037 ± 111*	1.82 ± 0.46*	8.17 ± 4.73*

meam ± SD, *p < 0.01 Beta-blockade OFF vs. ON

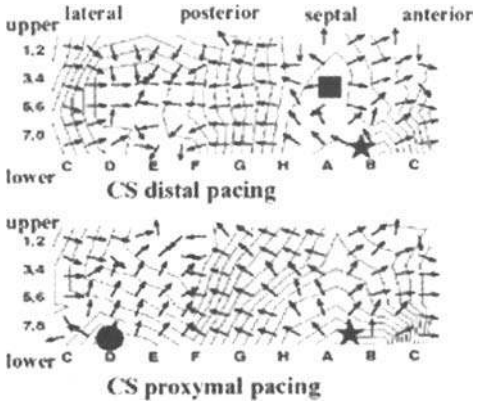
Beta-blockade decreased heart rate and increased HF power and BRS. These beneficial effects on HRV and BRS of beta-blockade might be one of the possible mechanisms of improving the prognosis of ischemic heart disease patients.

P2968 Evidence of three independent inter-atrial conduction systems: observation of the retrograde conduction

Y. Fuda, M. Shoda[1], R. Sugiura[1], K. Kajimoto[1], N. Matsuda[1], H. Kasanuki[1]. *Cardiology Dept, Tokyo Women's Medical College, Tokyo; [1]Cardiology Dept, Tokyo Women's Medical College, Tokyo, Japan*

Electrial preferential connections between the right atrium (RA) and left artium (LA) have been suggested to be located at high inter-atrial septum (Bachmann's bundle), low inter-atrial septum and ostium of the coronary sinus. The purpose of this study is to determine these inter-atrial connections based on their retrograde conduction. Twelve patients without structual heart disease were studied. Activation sequence of the RA during coronary sinus (CS) pacing was examined by a standard basket catheter.

Results: The earliest activation of RA during CS pacing was the low inter-atrial septum (IAS) (stars indicated the locations in the figure) in all patients. In 8 of 12 patients, the activation sequence was clearly changed when the pacing site in the CS was moved. The earliest activation was shifted to the high IAS (box in the figure) during CS distal pacing in 6 of 12 patients and to the low lateral RA (circle in the figure) during CS proximal pacing in 4 of 12 patients.



Conclusions: These findings indicate that there are three different retrograde inter-atrial preferential conduction systems in the low IAS, the high IAS and the low CS ostium.

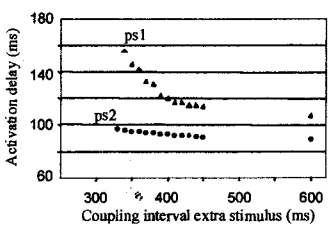
P2969 Site of pacing affects ventricular activation delay after premature stimulation in the explanted human heart

R. Derksen[1], J.R. de Groot[2], T. Kawara[2], R. Coronel[2], J.M.T. de Bakker[3], R.N.W. Hauer[1], M.J. Janse[2]. *[1]Heart Lung Institute, University Hospital Utrecht, Utrecht; [2]Department of Experimental Cardiology, University of Amsterdam, Amsterdam; [3]Interuniversity Cardiology Institute of The Netherlands, Utrecht, Netherlands*

Background: Progressive ventricular activation delay after premature stimulation at a remote site has been used for risk stratification in patients with hypertrophic cardiomyopathy. We hypothesize that decremental conduction properties are present in dilated cardiomyopathy as well and that the site of stimulation importantly affects the amount of decremental conduction.

Methods: In 2 Langendorff perfused human hearts from patients with dilated cardiomyopathy (no antiarrhythmic drugs), ventricular electrical activity was recorded at 194 sites (98 epi- and 96 endocardial sites, homogeneously distributed). Unipolar recordings were made during pacing at different sites with basic (600 ms) and premature stimulation (from 450 ms in steps of 10 ms down to the refractory period). Conduction curves were determined of the main component of the fractionated electrograms.

Results: Conduction curves showed decremental characteristics at virtually all epicardial and endocardial recording sites. Steepest increase of delay occurred for recording sites remote from the site of stimulation. The amount of increase in activation delay was highly dependent on the site of stimulation (see figure).



Conduction curves at one recording site (rs) after stimulation from two pacing sites (ps).

Conclusions: Decremental conduction properties are present in human hearts with dilated cardiomyopathy. The amount of increase of activation delay highly depends on the site of stimulation. The latter has impact when clinically performed conduction curves are used for risk stratification for sudden death.

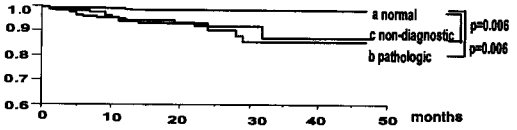
P2970 What is the impact of a non-diagnostic baroreflex sensitivity measurement on mortality in patients with structural heart disease

Harald Schwacke, Axel Drögemüller, Gregor Siemon, Monika Rameken, Jochen Senges, Karlheinz Seidl. *Herzzentrum Ludwigshafen, Ludwigshafen, Germany*

Impaired baroreflex sensitivity (BRS) has been demonstrated to be a valuable method for risk stratification in patients (pts) with structural heart disease (SHD). Though correctly performed measurement of BRS is often non-diagnostic (no correlation between blood pressure and heart rate after norphenephrine administration).

Aim of this study was to evaluate the clinical importance of a non-diagnostic BRS regarding long-term outcome of patients (pts) with SHD. In 634 pts (75% male) measurement of BRS was performed. Mean age was 62 ± 11 years, ejection fraction 38 ± 15%. Organic heart disease was in 82% of pts coronary artery disease, in 14% dilative cardiomyopathy, in 4% others. Follow up was 20 ± 11 months. 17% of pts had diabetes, 37% hypertension. In 481 pts BRS was diagnostic: in 338 pts normal (BRS > 3 ms/mmHg) (a) and in 143 pts pathologic (BRS ≤ 3 ms/mmHg) (b). In 153 pts BRS was non-diagnostic (c).

Results: There were no differences in clinical parameters between pts with normal, pathologic or non-diagnostic BRS. Total mortality was 4.5%. In contrast to pts with normal BRS (mortality 1.5%) mortality in pts with pathologic BRS was 7.7% and in pts with non-diagnostic BRS 7.8%.



Conclusions: 1. In frac14 of pts BRS was non-diagnostic. 2. Mortality in pts with non-diagnostic BRS was as high as in pts with pathologic BRS (7.8% vs 7.7%). 3. A non-diagnostic BRS has the same prognostic impact as a pathologic BRS in pts with SHD.

P2971 Differentiated sympathetic nerve response to acute ACE inhibition in healthy subjects

M. Johansson, B. Rundqvist[1], M. Pettersson[1], S. Gao, P. Friberg[2]. *Clinical Physiology Dept, Sahlgrenska University Hospital, Gothenburg; [1]Department of Cardiology, Sahlgrenska University Hospital, Gothenburg; [2]Clinical Physiology, Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: In patients with hypertension, enalaprilat reduces blood pressure without provoking a baroreceptor-mediated increase in heart rate, muscle and overall sympathetic nerve activity. The aim of the present study was to explore the cardio-renal sympathetic nerve response to acute inhibition of angiotensin converting enzyme (ACE) in healthy subjects.

Methods: We measured mean arterial pressure (MAP), heart rate (HR), pulmonary capillary wedge pressure (PCW, n = 5), arterial angiotensin II plasma concentration (AII, pg/ml), cardiac (n = 12), renal (n = 19) and total body norepinephrine spillover (TB NE sp, pmol/min) in 22 healthy subjects. The isotope dilution technique was used to estimate overall and cardio-renal sympathetic nerve activity. Arterial, coronary sinus and renal vein blood samples were drawn simultaneously at baseline and 30 min after enalaprilat, given intravenously.

Results and Interpretation: Arterial AII plasma concentration decreased by 28 ± 5% (mean ± SEM, $p < 0.01$) after enalaprilat. Renal NE sp increased by 60 ± 20% ($p < 0.01$), whereas HR, cardiac and TB NE sp remained unchanged after enalaprilat. PCW decreased by 40 ± 28% (ns) after enalaprilat and there was a slight reduction in MAP by 3 ± 2% ($p = 0.05$).

Conclusions: Acute administration of an ACE inhibitor to healthy subjects provokes a differentiated sympathetic nervous response, with a selective increase in outflow to kidneys, whereas cardiac and overall sympathetic nerve activity remain unchanged. This differentiated sympathetic response pattern possibly reflects a central nervous effect by ACE inhibition. Given the effect on salt and water excretion by renal nerve stimulation, the elevated renal sympathetic nerve activity after acute ACE inhibition may have clinical implications.

P2972 Risk stratification after individually optimized therapy of acute myocardial infarction: the role of impaired baroreflex sensitivity

Karlheinz Seidl, Axel Drögemüller, Harald Schwacke, Gregor Siemon, Silke Breunung, Jochen Senges. *Herzzentrum Ludwigshafen, Germany, Cardiology*

Methods: In a prospective single center study 365 consecutive patients (pts, mean age 61 ± 12 yrs, 281 male, 84 female) with acute myocardial infarction (AMI, anterior MI 45%) were enrolled after individually optimized acute therapy (acute revascularisation: 87%, aspirin 92%, β-blocker 87%) plus optimised long term treatment (aspirin 88%, β-blocker 81%, ACE-inhibitors 80% and statins 42%). Aim of this study was: which risk indicator (RI) identifies high risk pts best following optimal treatment in the 1990ies? All pts underwent risk stratification at day 7–14. Positive RI were predefined: 1) EF ≤ 40%; 2) Holter ECG positive, if one of the following parameters was positive: a) ≥10 VPB/h, b) ≥4 couplets/24 h, c) ≥1 salves/24 h; 3) late potentials (LP); 4) heart rate variability (HRV) ≤ 75 ms, 5) baroreflex sensitivity (BRS) ≤ 3 ms/mmHg.

Results: The 1-year-mortality in this pt population was 9%. Frequency of RI and pos./neg. predictive values (PPV/NPV) for 1-year-mortality were:

	Incidence	Sensitivity	Specificity	PPV	NPV
EF ≤ 40	30%	50%	72%	15%	94%
Holter positive	21%	50%	82%	19%	95%
LP positive	27%	36%	74%	9%	94%
HRV ≤ 75 ms	13%	19%	87%	16%	93%
BRS ≤ 3 ms/mmHg	24%	50%	78%	16%	95%
EF ≤ 40 + Holter pos	8%	28%	93%	26%	94%
EF ≤ 40 + HRV ≤ 75 ms	5%	6%	95%	10%	92%
EF ≤ 40 + BRS ≤ 3 ms/ mmHg	5%	29%	96%	36%	94%

Conclusions: In the era of acute revascularisation of AMI and adjuvant therapy (including aspirin, betablocker, ACE-inhibitor and statins) high risk pts are best identified by the combination of EF ≤ 40% plus impaired BRS with a PPV of 36%.

P2973 Autonomic cardiovascular regulation in obesity

K. Laederach-Hofmann, L. Mussgay[1], H. Rüddel[1]. *Internal Med and Psychosomatics Dept, Inselspital, University Hospital, Berne, Switzerland; [1]Behavioral Medicine St. Franziska-Stif, Center Psychobiology and Psychosomatic, Bad Kreuznach, Germany*

Objective: Obese persons suffer from an increased mortality risk supposedly due to cardiovascular disorders related to either continuously lowered parasympathetic or altered sympathetic activation.

Method: Our cross-sectional correlation-study establishes the relationship between obesity and autonomic regulation as well as salivary cortisol levels. Three patient cohorts were sampled, covering ranges of body mass index (BMI) of 27.5 to 32 (n = 17), 33 to 39 (n = 12), and above 40 kg/m^2 (n = 12), and stratified for age, sex, and menopausal status. Patients were assessed by cardiovascular activity (ECG), continuous finger blood pressure, and respiratory activity recorded at baseline and during a stress reaction-time task. Salivary cortisol was concurrently collected. Autonomic cardiovascular regulation was assessed by use of heart rate variability and continuous blood pressure recordings; spectral-analytical calculation yields indices of sympathetic and parasympathetic activation and baro-reflex-sensitivity.

Results: 42 patients (18 males, 24 females (15 premenopausal)) with a mean age of 42.7 ± 9.3 years were included. Contrary to expectation, BMI and waist/hip-ratio (WHR) were inversely related to sympathetic activity. This was true for resting conditions ($r = -0.48$, $p < 0.05$; $r = -0.33$, $p < 0.04$ for BMI and WHR respectively) and for mental challenge ($r = -0.36$, $p < 0.03$ for BMI). Resting baro-reflex-sensitivity was strongly related to the degree of obesity at rest (BMI: $r = -0.42$, $p < 0.03$, waist: $r = -0.43$, $p = 0.01$) and for mental challenge (BMI: $r = -0.54$; $p < 0.001$, waist: $r = -0.47$, $p < 0.01$). Salivary cortisol correlated significantly with BMI ($r = -0.33$, $p < 0.05$).

Conclusions: With increasing weight, no overstimulation was found but a depression in sympathetic and parasympathetic activity together with a significant reduction in baro-reflex functioning and in salivary cortisol levels.

P2974 Modulation of baroreflex sensitivity during physical stress

H. Sato, M. Yamamoto[1], H. Iinuma, T. Aizawa, K. Kato. *The Cardiovascular Institute, Tokyo; [1]Miyagi University, School of Nursing, Sendai, Japan*

Decreased baroreflex sensitivity (BRS) has been shown to be a sign of poor prognosis and to reflect an increased incidence of sudden death in patients with cardiovascular disease. BRS is usually evaluated by administering a vasoactive drug that raises arterial pressure, however, this technique is not always applicable in all clinical situations. We studied the modulation of BRS during physical stress, exercise, and the head-up tilt test (HUT), without infusing drugs.

Subjects and Method: Fourteen normal volunteers (7 males and 7 females, 34.4 ± 10.0 yr) performed the exercise test. Submaximal ramp and 50-watt one-step (7 min) exercises were performed. HUT (80 degree for 15 minutes) was assessed in 20 young subjects (10 males and 10 females), whose age was 29.6 ± 4.8 yr. Blood pressure and ECG were monitored continuously during tests. Finger arterial blood pressure was measured by using Finapres. Oxygen uptake was measured during exercise. To analyze 5-minute records at rest and during physical stress, the computer selected all sequences of three or more successive heartbeats in which there were concordant increases or decreases in systolic blood pressure (SBP) and RR interval. If the correlation coefficient between SBP and RR intervals was less than 0.92, the data were excluded from the analysis. Linear regression was applied to each of the sequences, and an average regression slope was calculated. This slope represents baroreflex sensitivity (BRS msec/mmHg).

Results: BRS was decreased during HUT (19.6 ± 6.6→6.8 ± 3.3, $p < 0.01$). The ratio of oxygen uptake during 50-watt exercise to uptake during peak exercise averaged 56%. BRS was lower during exercise (2.6 ± 1.2) than at rest (8.2 ± 2.7). The rate of reduction of BRS during exercise was highly correlated with the ratio of oxygen uptake during 50-watt exercise to uptake during peak exercise.

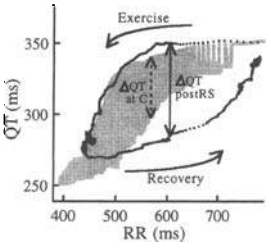
Conclusion: BRS is usually assessed in the supine position and modulation of BRS during physical stress has seldom been investigated. BRS is not constant and can be reduced by ordinary physical stress, such as changes in position and an exercise. During exercise, BRS decreased according as exercise intensity increased.

P2975 Right thoracoscopic sympathicotomy increases QT hysteresis during exercise in man

P. Musialek[1], A. Kardos[1], O. Fojt[1], I. Webb[1], J. Collin[2], J. Johnston[1], B. Casadei[1]. *[1]Dept. of Cardiovascular Medicine; [2]Nuffield Dept. of Surgery, John Radcliffe Hospital, University of Oxford, UK*

An altered adaptation of ventricular repolarisation to changes in heart rate may play an important role in arrhythmogenesis. Experiments in animals have indicated that right stellectomy might promote arrhythmias by uncoupling the QT from the RR interval response to exercise. Whether a similar phenomenon occurs in humans is not known.

Methods and Results Nine subjects (age 22–42 years), referred for thoracoscopic sympathicotomy for idiopathic hyperhydrosis, were studied before (C) and 6 weeks after *right* T1-2 sympathicotomy with T2 diathermy (postRS). High resolution ECG signal (Frank leads) was acquired during supine exercise at 70% VO_{2max} (Ex, 7 min) and recovery (Rec, 15 min), and a newly developed algorithm was employed to measure the RR and QT intervals on a beat-to-beat basis. RR and QT (ms) were increased postRS, both at rest (915 ± 32 *v* 1088 ± 46 and 375 ± 6 *v* 399 ± 7, mean ± SEM, $p < 0.05$) and during steady-state Ex (443 ± 16 *v* 493 ± 19 and 272 ± 5 *v* 291 ± 5, $p < 0.05$). PostRS QT remained shortened during Rec despite the lenghtening of RR, forming a wide hysteresis loop in the QT/RR relationship (typical raw data in Fig, C = shaded). The "width" of the hysteresis loop was taken as $\Delta QT = QT_{Ex} - QT_{Rec}$ (ms), and was measured at $RR = (RR_{Rec} + RR_{Ex})/2$ (see Fig). PostRS Δ QT was markedly higher than ΔQT at C (70 ± 5 *v* 43 ± 4, $p < 0.05$). This was accompanied by an increase in the time lag (s) of QT adaptation to a steady-state RR during exercise (54 ± 6 at C *v* 93 ± 9 postRS) or during recovery (13 ± 3 at C *v* 35 ± 3 postRS, $p < 0.05$).



In summary, we have found that right T1-2 sympathicotomy significantly alters the kinetics of the QT adaptation to changes in cycle length during exercise. These data provide novel insights into the role of the sympathetic nervous system in the regulation of the QT/RR relationship in man.

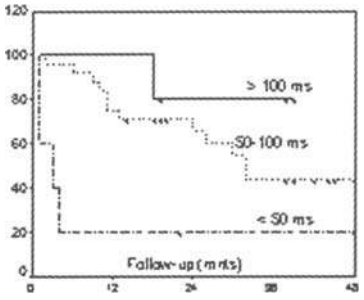
P2976 Risk assessment in patients with systemic amyloidosis is improved by heart rate variability analysis

J. Brouwer, A.K.L. Reyners[1], A.J. Smit[1], B.C.P. Hazenberg[1], E.B. Haagsma[1], H.J.G.M. Crijns. *Thoraxcenter, Dept. of Cardiology, University Hospital, Groningen; [1]Dept. of Internal Medicine, University Hospital, Groningen, Netherlands*

Introduction: In patients with systemic amyloidosis, mortality is high. Cardiac involvement and autonomic neuropathy are considered important risk factors. However, identification of patients at high risk remains troublesome. In this study, we assessed the prognostic value of heart rate variability (HRV) analysis in amyloidotic patients.

Methods: We evaluated 39 patients (mean age 61 ± 10 yr, 17 male, 22 female) with AA- or AL- amyloidosis (n = 18 and 21, respectively). At baseline, patients were hemodynamically stable, those with heart failure NYHA classes III or IV were excluded from participation.

Results: During a median follow up of 19 months (range 1–48), 21 patients died. In 10 patients with a low HRV, defined as a standard deviation of all normal RR intervals (SDNN) less than 50 ms, 8 died after a median follow-up of 4 months. Mortality was 50% in patients with an SDNN between 50 and 100 ms, and 20% in patients with an SDNN > 100 ms (see figure, p = 0.0007). Using the median value of SDNN of 67 ms as cut-off value resulted in a sensitivity of 67% and a specificity of 56% for all-cause mortality. Of 15 patients with probable or definite signs of cardiac amyloidosis on echocardiography, 12 died during follow up. Echocardiography had a sensitivity of 57% and a specificity of 78% for mortality. Combining SDNN with echocardiography increased sensitivity to 71% with a specificity of 78%. Inability to perform some or all Ewing tests resulted in a limited prognostic value of traditional autonomic function testing.



Survival in relation to SDNN.

Conclusion: HRV analysis provides important prognostic information in patients with systemic amyloidosis, especially in combination with echocardiography. This may be useful in identifying patients who may benefit from aggressive additional treatment.

P2977 Selective inhibition of sarcolemmal K_{ATP} channels does not abolish ischaemic preconditioning against myocardial infarction in rabbits

W. Linz, T. Sato[1], O. Jung, W. Jung, B. O'Rourke[1], N. Sasaki[1], H.C. Englert, H. Gögelein, E. Marban[1], B.A. Schoelkens. *Cardiovascular Diseases Hoechst Marion Roussel Frankfurt/Main, Germany; [1]Department of Medicine The Johns Hopkins University Baltimore MD, USA*

Pharmacological findings have implicated mitochondrial ATP-dependent K^+ ($mitoK_{ATP}$) channels rather than sarcolemmal ($surfaceK_{ATP}$) channels as end-effectors of ischemic preconditioning (IPC). To test the role of $surfaceK_{ATP}$ channels in the cardioprotection afforded by IPC, we examined 1) the effects of HMR1883, a novel cardioselective K_{ATP} channel blocker, on $surfaceK_{ATP}$ and $mitoK_{ATP}$ channels in rabbit ventricular myocytes, and 2) the effect of HMR1883 on IPC against myocardial infarction in rabbits.

Methods and Results: HMR1883 (Na^+ salt, 30 μM) inhibited the $surfaceK_{ATP}$ current activated by 2,4-dinitrophenol (100 μM) (from 2.22 ± 0.89 nA to 0.52 ± 0.14 nA, $P < 0.05$), whereas the drug did not blunt diazoxide (100 μ M)-induced flavoprotein oxidation, an index of $mitoK_{ATP}$ channel activity (from 41 ± 8% to 42 ± 9%). Anesthetized rabbits were subjected to 30 min of left anterior descending coronary artery occlusion followed by 120 min reperfusion. IPC with two cycles of 5 min occlusion and 10 min reperfusion significantly reduced infarct mass (TTC staining) as compared to non-IPC group (21 ± 4% of risk mass vs. 41 ± 3%,). Glibenclamide (0.3 mg/kg) given prior to IPC totally reversed the infarct mass reducing effect (42 ± 2%). In contrast, HMR1883 (3 mg/kg) given prior to IPC did not interfere with the protective effect of IPC (21 ± 3%). These results indicate that the selective inhibition of $surfaceK_{ATP}$ channels by HMR1883 did not abolish the infarct mass reducing effects of IPC.

We conclude that selective inhibition of $surfaceK_{ATP}$ channels in rabbits do not interfere with IPC against infarction. The results provide additional evidence that $mitoK_{ATP}$ channels are likely effectors of IPC.

P2978 Is it possible to replace the "heart" connexin43 by the "liver" connexin32? Electrophysiological studies in transgenous mice

A. Hagendorff, B. Schumacher[1], A. Plum[2], K. Willecke[2]. *Dep. of Cardiology, University of Leipzig; [1]Dep. of Cardiology, University of Bonn; [2]Inst. of Genetics, University of Bonn, Leipzig, Germany*

Background. Connexins (Cx) are crucial for gap junctional cell-to-cell communication. In the mammalian heart, connexin (Cx) 37, 40, 43, 45, 46, and 50 were observed. Cx43 is predominantly expressed in the atrial myocardium, the distal regions of the bundle branches, the Purkinje fibres, and the ventricular myocardium. Cx32 has not been found in cardiac tissue, but is expressed predominantly in the liver. Homozygous Cx43 deficient mice are not viable. Heterozygous Cx43 deficient mice have a reduced cardiac conduction velocity. This study was thought to determine the electrophysiological effects of Cx43 replacement by Cx32 in transgenous mice.

Methods and Results: Transgenous mice were generated by gen targeting. Nine homozygous ($Cx43^{32/32}$) and 10 heterozygous ($Cx43^{43/32}$) transgenous mice as well as 10 Cx43 wildtype mice ($Cx43^{43/43}$) were investigated by surface electrocardiogram recordings and by transesophageal atrial stimulation under general anaesthesia with avertin. Following this procedure, the transgenous mice were dissected and underwent macroscopic anatomical evaluation. Heterozygous ($Cx43^{43/32}$) and homozygous ($Cx43^{32/32}$) transgenous mice are viable and did not show differences in the relative heart weight as compared to Cx43 wildtype mice ($Cx43^{43/43}$). In addition, no differences were found between $Cx43^{32/32}$, $Cx43^{43/32}$, and $Cx43^{43/43}$ mice with regard to P wave duration (20 ± 2 vs 20 ± 3 vs 22 ± 2 msec), PQ interval (57 ± 15 vs 65 ± 29 vs 50 ± 5 msec), QRS duration (16 ± 2 vs 16 ± 2 vs 15 ± 5 msec), sinus node recovery time (203 ± 71 vs 181 ± 41 vs 155 ± 30 msec), and 1:1 AV conduction time (100 ± 18 vs 98 ± 26 vs 88 ± 7 msec). In none of the mice, atrial burst stimulation resulted in atrial or ventricular arrhythmias.

Conclusions: Whereas Cx43 deficiency is associated with developmental disturbances and a decreased ventricular conduction velocity, Cx32 can fully replace Cx43 with regard to cardiac development and electrophysiological fuction.

P2979 Upregulation of the sarcolemmal Na^+/Ca^{2+}-exchanger in patients with chronic atrial fibrillation

U. Schotten, M. van Helden, D. Benke, C. Stellbrink, F. Schoendube, P. Hanrath, M. Allessie. *Dept. of Cardiology and Dept. of Thoracic- and Cardiovascular Surgery, University Hospital Aachen, Germany; Dept. of Physiology, Cardiovascular Research Institute Maastricht, Netherlands*

Background: Contractile remodeling after the cessation of atrial fibrillation (AF) has been hypothesised to result from altered intracellular Ca^{2+} handling. The aim of this study was to determine the protein expression of the Na^+/Ca^{2+}-exchanger (NCX) and of calcium transport proteins of the sarcoplasmic reticulum (SR) in atrial myocardium of patients with chronic (≥6 month) AF compared to patients who were still in sinus rhythm.

Methods: In homogenates of right atrial appendages from patients undergoing coronary artery bypass graft surgery (CAB, n = 26) or mitral valve repair (MVR, n = 22) the protein expression of the NCX, the SR Ca^{2+}-ATPase (SERCA), phospholamban (PLB), and calsequestrin (CALS) were measured using Western blot analysis.

Results:

	Mean protein expression ± SEM (10^3 cpm/mg protein)			
	NCX	SERCA	PLB	CALS
MVR sinus rhythm n = 13	3.6 ± 0.4	22.2 ± 1.5	16.6 ± 1.5	26.1 ± 2.2
MVR AF n = 9	5.4 ± 0.6*	24.8 ± 1.7	17.6 ± 3.1	26.4 ± 2.2
CAB sinus rhythm n = 15	2.6 ± 0.2#	25.3 ± 1.7	21.4 ± 2.2	39.0 ± 3.7#
CAB AF n = 11	4.3 ± 0.6*	22.3 ± 1.9	17.2 ± 2.7	34.4 ± 5.7

*: $p < 0.01$ AF versus sinus rhythm. #: $p < 0.05$ CAB versus MVR.

Conclusion: AF-induced atrial contractile dysfunction cannot be explained by changes of SERCA, PLB or CALS protein expression. However, an increased expression of the Na^+/Ca^{2+}-exchanger is a specific change in atrial myocardium of AF patients and might contribute to contractile remodeling.

P2980 Endothelin-1 induced arrhythmias in rat heart: the underlying mechanisms

K.M. Burrell[1,2], M.D. Bootman[1], M.J. Berridge[1], P. Lipp[1]. *[1]Laboratory of Molecular Signaling, The Babraham Institute, Cambridge, UK; [2]Department of Pharmacology, The University of Melbourne, Parkville VIC, Australia*

Endothelin-1 (ET-1), a positive inotroph, has also been identified as a potent arrhythmogenic agent in heart. The levels of endogenous ET-1 are increased in many pathophysiological conditions including acute myocardial infarction, unstable angina and cardiac failure, by which many patients die each year due severe rhythm disturbances and sudden cardiac death. It has been proposed that ET-1 may play an important role in these disturbances, however, the mechanisms underlying the arrhythmogenic effects of ET-1 have yet to be elucidated. Consequently, we have examined the cellular Ca^{2+} and pH regulation in rat atrial myocytes, which may contribute to endothelin induced arrhythmias. Ca^{2+} transients were monitored by the measurement of Indo-1 fluorescence, and pH changes with SNAFL-2, in isolated rat atrial myocytes which were either quiescent or electrically paced (0.3 Hz, 2 ms duration, amplitude 25–40 V).

ET-1 (0.1 μM) caused spontaneous Ca^{2+} transients in quiescent myocytes 5–10 minutes after application. Multiple effects of ET-1 (0.1 μM) application were observed in electrically paced cells. Firstly, the Ca^{2+} fluorescence transient amplitude was increased by 9.08 ± 1.13% (n = 7) after 10 minutes. Secondly, spontaneous Ca^{2+} transients were observed in theelectrically-driven myocytes, with a similar time course to the automaticity observed in non-paced cells. The time course of the spontaneous Ca^{2+} transients resembled that of Ca^{2+} signals causing delayed-after depolarisations (DADs). The non-selective endothelin antagonist SB 209670 (5 μM) blocked both the inotropic and the arrhythmogenic Ca^{2+} transients induced by ET-1. However the two ET_A-selective blockers, BQ123 (1 μM) and A-147627 (1 μM) failed to antagonise the effects of 0.1 μM ET-1, ruling out the involvement an ET_A-receptor in mediating these effects in rat atria.

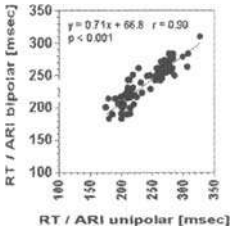
Intracellular pH in response to ET-1 activation in rat atrial myocytes was also monitored. An alkalinisation of the cytoplasm by ~0.25 pH units was observed, this effect occurred prior to the onset of the increase in the Ca^{2+} transient amplitude. This change in pH suggests an increase in Na^+/H^+ exchange activity upon ET-1 activation; Na^+/H^+ exchangers are down-stream targets of protein kinase C (PKC).

In summary, the positive inotropic and arrhythmogenic effects of ET-1 in rat heart are mediated through activation of a non-ET_A receptor subtype, possibly ET_B. ET-1 receptors appear to mediate their effects though activation of several intracellular pathways, in particular, this study suggests a role for the PKC signaling pathway. The most plausible explanation for this is an increase in Na^+/H^+ exchange that would lead to an elevated Na^+ concentration, thereby inducing the Na^+/Ca^{2+} exchanger to operate in reverse mode (causing Ca^{2+} influx). An increased Ca^{2+} load of the sarcoplasmic reticulum would result, thus inducing positive inotropy and generation of arrhythmias.

P2981 A new recording technique of midmyocardial repolarization from isolated rabbit hearts

M. Zabel, M.R. Franz[1], H.P. Schultheiss[2], S. Behrens[2]. *Cardiology, Klinkumm Benjamin Franklin, Berlin, Germany; [1]Cardiology, VAMC and Georgetown University, Washington, DC, USA; [2]Med. Klinik II, Div. of Cardiology, Free University, Berlin, Germany*

Intramural repolarization characteristics are paramount in the genesis of long QT associated arrhythmias, and possibly play a role in the genesis of electrical alternans. A recording technique of midmyocardial repolarization in isolated whole heart models is lacking. In an established isolated rabbit heart model for the evaluation of myocardial repolarization by means of multiple monophasic action potentials (MAPs), teflon-coated Tungsten wire electrodes (76 μm, deisolated at the tip) were spring-mounted onto the contact MAP holders and inserted pairwise (distance 2–3 mm) to the myocardium at prespecified depth. Bipolar recordings from the midmyocardium (4 mm) of the LV and the endocardium (8 mm) of both ventricles were compared to unipolar recordings from each electrode measured against Wilson central terminal (WCT, from volume-conducted ECG). After insertion of the wire electrodes a local injury current ensued, permitting the recording of MAPs against WCT. If the local reference electrode exhibited a neutral potential, ie was free of injury, MAPs were also observed in the bipolar recordings. Because injury at either one electrode was usually not sustained, most signals changed continuously to an electrogram within 15–30 min after insertion. MAPs were measured at 90% repolarization (APD90), electrograms for activation recovery intervals (ARIs) according to standard definitions.



Scatter plot.

The figure shows the correlation scatter plot of all data points generated from a total of 8 isolated rabbit hearts. Correlation coefficients were high both for MAP contact electrodes ($r = 0.93$, $p < 0.001$) and for wire electrodes ($r = 0.83$, $p < 0.001$). In conclusion Tungsten wire electrodes permit the evaluation of midmyocardial repolarization characteristics in an isolated rabbit heart model.

P2982 Inhibition of the ATP-dependent potassium current IK(ATP) by HMR 1883 in human cardiomyocytes

S. Kääb, L. Zwermann, A. Barth, M. Hinterseer, H.C. Englert[1], H. Gögelein[1], M. Näbauer. *Medicine 1, Klinikum Großhadern, Munich[1] Hoechst Marion Roussel, DG Cardiovascular, Frankfurt, Germany*

Purpose: The activation of the myocardial, ATP-dependent potassium current (IK(ATP)) during ischemia causes potassium efflux and shortening of the action potential duration (APD). This increases the dispersion of the repolarisation between ischemic and non-ischemic myocardium and predisposes to arrhytmias including ventricular fibrillation. The novel cardioselective IK(ATP) inhibitor HMR 1883 allows selective block of the sarcolemmal myocardial K(ATP)-channel without effecting the pancreatic K(ATP)-channel (which would cause hyperinsulinaemia and hypoglycaemia) or the mitochondrial K(ATP)-channel (interfering with potentially beneficial preconditioning). Therefore, we studied the concentration and pH-dependence of HMR 1883 in human ventricular myocytes.

Methods: Single cardiomyocytes were isolated enzymatically from the free ventricular wall of human hearts. IK(ATP) was measured with the patch-clamp technique in the whole cell configuration at 35°C. Action potentials were recorded using amphotericin B in perforated patch conditions to maintain the intracellular environment. In voltage clamp experiments, the K(ATP)-channel, which is closed under physiological conditions, was activated by application of 1 μM rilmakalim, a K(ATP)-channel opener. In action potential recordings, 0.1 μM rilmakalim was used.

Results: At physiological pH (pH = 7.3) half-maximal block of the rilmakalim-induced current occurred at 0.6 μM HMR 1883 (at 0 mV membrane potential); under more acid conditions (pH = 6.5), half-maximal block was achieved at markedly lower concentrations (IC50 = 0.3 μM). In current clamp experiments, block of IK(ATP) by HMR 1883 was capable of reversing the action potential shortening induced by rilmakalim, and restored the action potential plateau.

Conclusions: HMR 1883 appears to be useful to prevent IK(ATP)-induced shortening of the action potential in human ventricular myocardium. More acid conditions, as observed in ischemia, increase the sensitivity to HMR 1883, leading to block of IK(ATP) at lower concentrations, indicating a more potent effect in ischemic myocardium. Thus, HMR 1883 may be a useful agent to prevent action potential shortening and dispersion of repolarisation during ischemia, which may protect against ischemic venticular arrhythmias.

P2983 Evidence for membrane potential modulated control of calcium release and reuptake from the sarcoplasmic reticulum in mammalian heart muscle

K.C.R. Patel, V.K. Pabbathi, A.K. Hinde, H.L. Wallis, J.V. Jones, L.A. Arberry, A.J. Levi. *Cardiovascular Research Centre, University of Bristol, Bristol, UK*

Background: Until recently, it has been accepted that calcium (Ca) release from sarcoplasmic reticulum (SR) in cardiac myocytes is controlled through calcium induced calcium release (CICR). In the absence of transmembrane Ca entry we have shown that membrane depolarisation is still able to elicit an intracellular calcium (Cai) transient. We have termed this mechanism 'voltage activated calcium release' (VACR). The mechanisms responsible for termination of Ca release from the SR and therefore relaxation of contraction are not yet known. We investigated whether membrane repolarisation might play a role terminating SR release.

Methods: Experiments were carried out in guinea-pig ventricular myocytes at 370°C, using whole-cell patch clamp. Cells were internally dialysed with a 100 mM cAMP (3′5′ cyclic adenosine monophosphate) Na-free (to abolish reverse mode Na/Ca exchange) pipette solution and held at a post-conditioning potential of −40 mV in the presence of 8 mM Ni (to block Ca entry via L-type Ca channels and Na/Ca exchange). The superfusate was changed to a Na-free (NMDG) solution (to abolish forward mode Na/Ca exchange) containing 8 mM Ni, 4 seconds before a test depolarisation to +20 mV. Cells were repolarised to −80 mV at the end of the test pulse. Cai transients were measured using the fluorescent dye, FURA2.

Results: In the absence of transmembrane Ca entry, membrane depolarisation was still able to elicit Cai release of 70.2 ± 8.0%; (mean ± SEM; n = 8) of total SR Ca content. Repolarisation in the presence of an external Na-free, 8 mM Ni solution elicited a rapid decline of the Ca transient to baseline (t = 211 ± 26 ms; n = 24 cells). This Ca decline could not be due to Ca extrusion via Na/Ca exchange, as this is inhibited by Na-free external solution and also by 8 mM Ni.

Conclusion: We provide evidence that cardiac myocytes dialysed with cAMP possess voltage sensitive mechanisms which are not only able to elicit SR Ca release, but may also terminate SR release directly. We suggest the existence of a voltage sensor which couples the sarcolemma to the SR release channels, enabling depolarisation and repolarisation to gate the opening and closing of SR release channels. The implications of such phenomena are far reaching and may provide us with important information about myocyte behaviour under adrenergic stimulation and in disease states.

P2984 Potential cellular mechanism for the antifibrillatory properties of fish oils: potent blockade of the Kv4.3 encoded transient outward current

C. Singleton, B. Walker, H. Tie, K. Wyse, J. Bursill, S. Valenzuela[1], M. Qiu[1], S. Breit[1], T. Campbell. *Department of Medicine, St. Vincents Hospital, Sydney; [1]Centre for Immunology, St Vincent's Hospital, Sydney, Australia*

The vast majority of human transient outward current (Ito) is encoded by the Kv4.3 gene. The interaction of this current with other plateau phase currents during myocardial ischaemia is implicated in the development of heterogeneity of repolarisation, which predisposes to the development of potentially fatal reentrant tachyarrhythmias. Omega-3 polyunsaturated fatty acids, present in fish oils, have potent antifibrillatory properties and we propose that this effect may in part result from their ability to block the Kv4.3 current.

Methods: We have stably transfected the Kv4.3 gene into the Chinese hamster ovary cell line and using single electrode patch clamp techniques have described the biophysics of the resultant current in this cell line, both at 23°C and 37°C. (All results quoted are at 23°C unless otherwise stated). Modulation of current biophysics was assessed after superfusion with the omega-3 polyunsaturated fatty acids docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), as well as arachidonic acid.

Results: Kv 4.3 current activation and steady state inactivation are voltage dependent, with V1/2 of −6.7 ± 2.3 mV and −48.4 ± 1.0 mV respectively. The current rapidly inactivates with a biexponential course (tau1 = 20.1 ± 1.2 ms and tau2 = 96.6 ± 6.7 ms at +45 mV), and displays rapid recovery from inactivation which is voltage dependent and well fit by a monoexponential function (time constant of 276 ms at −85 mV). Current activation, steady state inactivation and recovery from inactivation are accelerated at 37°C compared to 23°C. The omega-3 fatty acids DHA and EPA block the Kv4.3 current with IC50s of 3.6 ± 1.5 and 2.3 ± 1.5 μmol/L respectively, an order of magnitude more potent than that observed with arachidonic acid.

In conclusion: Omega-3 fatty acids potently block the Kv4.3 current. This property would tend to limit the degree of heterogeneity of repolarisation that develops during myocardial ischaemia, and may in part explain why consumption of at least one fatty fish meal per week has been shown to decrease the risk of primary cardiac arrest by 50%.

P2985 The role of the slow component of the delayed rectifier potassium current in dog ventricular muscle and Purkinje fibre repolarization

A. Varró[1], B. Baláti[1], N. Iost[1], J. Takács[1], L. Virág[1], L. Tálosi[2], D. Lathrop[1], J.G. Papp[1]. *[1]Department of Pharmacology and Pharmacotherapy; [2]2nd Department of Internal Medicine, Albert Szent-Györgyi Medical University, Szeged, Hungary*

Two distinct components of the delayed rectifier potassium current (I_K), i.e. slowly (I_{Ks}) and rapidly (I_{Kr}) activating components have been identified in mammalian heart muscle. Specific blockers of I_{Kr} have been widely shown to lengthen cardiac action potential duration (APD) and this is consistent with their strong antiarrhythmic potency. The lack of specific blockers of I_{Ks}, however, has made it impossible to evaluate directly the physiological role of I_{Ks} in cardiac repolarization.

Methods: Therefore, the aim was to examine the possible role of I_{Ks} in cardiac repolarization using the two recently developed specific I_{Ks} blockers, chromanol 293B (Ch) and L-735, 821 (L). A comparison with the role of I_{Kr} was also made using the specific I_{Kr} blockers d-Sotalol (S) and E-4031 (E). Conventional microelectrode and the whole-cell configuration of the patch-clamp techniques were applied to dog ventricular muscle and Purkinje fibres at 37°C.

Results: S (30 μM) and E (1 μM) markedly decreased the amplitude of I_{Kr} tail current in isolated dog ventricular myocytes. In the same preparations Ch (10 μM) almost completely inhibited I_{Ks} tail current, while L (100 nM) completely abolished this current. Suprisingly, however, Ch and L lengthened APD by less than 7% in dog ventricular papillary muscle and also in dog Purkinje fibres. In contrast, S and E markedly prolonged APD in dog Purkinje fibres (48.2 ± 4.6%, n = 8 and 68.9 ± 8.6%, n = 8, respectively [mean ± SEM]), as well as in ventricular papillary muscle (18.5 ± 2.4%, n = 7 and 20.5 ± 4.2%, n = 6, respectively). In dog ventricular myocytes I_{Ks} activated slowly (τ = 1705.3 ± 110.6 ms, n = 14 at +50 mV) and deactivated rapidly (τ = 78.9 ± 4.6 ms, n = 14 at −40 mV), while I_{Kr} activated rapidly (τ = 53.8 ± 5.8 ms, n = 15 at +30 mV) and deactivated slowly ($\tau 1$ = 360.3 ± 26.3 ms, $\tau 2$ = 3310 ± 280 ms, n = 15 at −40 mV). Calculation of the current density expected to develop during the plateau phase (150 ms at +20 mV) of an action potential, indicated that the activation of I_{Kr} was more than 10 times larger than that of I_{Ks}.

Conclusions: Therefore, our results suggest that I_{Ks} unlike I_{Kr} plays little part in the repolarization of normal cardiac ventricular muscle and Purkinje fibres, and the role of I_{Ks} in cardiac repolarization should be re-evaluated.

P2986 Cardiac electrophysiological and vascular effects of fluoxetine

V. Kecskemeti, P. Pacher, J. Magyar[2], P. Szigligeti[2], T. Banyasz[2], Cs.Z. Ungvari[1], P. Nanasi[2], A. Koller[1,3]. *Depts of Pharmacology; [1]Pathophysiology, Semmelweis University of Medicine, Budapest; [2]Dept of Physiology, University Medical School of Debrecen, Debrecen, Hungary; [3]Department of Physiology, New York Medical College, Valhalla NY, USA*

Fluoxetine is a widely used antidepressant compound having selective serotonin reuptake inhibitor properties. In this study we investigated the effects of fluoxetine (F) on transmembrane action potentials (AP) and ionic currents of rat, rabbit, guinea-pig and canine ventricular preparations and on the vasomotors responses of first order arterioles of rat gracilis muscle

Methods: conventional microelectrode and whole cell voltage clamp techniques were used. The internal diameter of isolated, pressurized arterioles (98 μm at 80 mmHg perfusion pressure) was evaluated by microvideoangiometry.

Results: low concentrations of F (1–10 μM) caused significant shortening of action potential duration (APD) and depression of the plateau phase in guinea pig and rabbit papillary muscles and single canine ventricular myocytes. In rat papillary muscle, APD was not affected by F (up to 100 μM), however, the drug decreased the force of contraction with EC_{50} of 10 μM. F (10 μM) decreased also the maximum velocity of depolarization and the overshoot of AP in each species studied, without changing the resting membrane potential level. In voltage clamped canine ventricular myocytes 10 μM F decreased the amplitude of the peak Ca^{2+} current (ICa) by 55 ± 4.5% at 0 mV (n = 5). F did not alter the gating kinetics (voltage-dependence of activation, steady-state inactivation and time constant for inactivation) of I_{Ca}. The increasing concentrations of F dilated arterioles up to 155 μm with an EC_{50} of 2.5 ± 0.5 μM. Removal of endothelium, application of 4-aminopyridine (4-AP, 0.01–1 mM) or use of glibenclamide (1 μM) did not affect the vasodilatory response to F. Norepinephrine (1 nM–10 μM) and 5-hydroxytryptamine (1 nM–10 μM)-induced constrictions were significantly attenuated by F (1–10 μM). Increasing concentration of Ca^{2+} (0.1–30 mM)-induced constrictions were markedly reduced and abolished by F (2 μM, 10 μM, respectively)

In conclusion these data suggest that fluoxetine may inhibit cardiac Ca^{2+} and Na^+ as well as vascular CA^{2+} channels and this effect may explain most cardiovascular side-effects observed occasionally with fluoxetine.

P2987 P_2 purinoceptors contribute to adenosine-5′-triphosphate-induced inhibition of L-type Ca^{2+} current in rabbit atrial myocytes

T. Yamamoto, Y. Habuchi, M. Nishio, F. Suto, H. Matsuzaki[1], J. Morikawa, H. Tanaka, K. Kashima, M. Yoshimura. *Kyoto Prefectural University of Medicine, Kyoto; [1]Aiseikai General Hospital, Kyoto, Japan*

Activation of P_1 (A_1) purinoceptors by adenine compounds inhibits the L-type Ca^{2+} current (I_{Ca}) in the heart, and produces negative inotropic, chronotropic and dromotropic effects. However, these compounds simultaneously activate P_2 purinoceptors. We therefore elucidated whether or not (and how) P_2 purinoceptor activation modifies the effects of adenosine-5′-triphosphate (ATP) in rabbit cardiac myocytes.

Methods: The perforated patch clamp method was employed on single cells isolated from the rabbit atrium. I_{Ca} was elicited by depolarization from a holding potential of −40 mV to 0 mV.

Results: ATP did not change basal I_{Ca}. In contrast, ATP (0.1 μM–3 mM) consistently inhibited I_{Ca} under prestimulation with isoproterenol (ISO, 30 nM). This inhibition of I_{Ca} was abolished when the cells were dialyzed with 8bromo cAMP, were stimulated by forskolin plus 3-isobutyl-1-methylxanthine, or were pretreated with pertussis toxin (PTX). The concentration response curve indicated that at least two different pathways mediate the I_{Ca} inhibition by ATP. Both 1,3-dipropyl-8-cyclopentylxanthine (DPCPX, A_1 blocker) and suramin (P_2 blocker) partially blocked the ATP-induced inhibition of I_{Ca}, while their co-application completely abolished the effect of ATP. ATP-γS, a non-hydrolyzable ATP analogue, showed a suramin-sensitive inhibition of I_{Ca}. DPCPX did not change the effect of ATP-γS. When the enzymatic degradation of AMP to adenosine was blocked by α,β-methylene-ADP, suramin completely abolished the effect of ATP.

Conclusions: P_2, not only P_1, purinoceptors contribute to the ATP inhibition of ISO-stimulated I_{Ca} via the PTX-sensitive and cAMP-dependent pathway. The P_1 stimulation by ATP results from hydrolysis of ATP to adenosine.

SUPRAVENTRICULAR ARRHYTHMIAS

P2988 Dynamic patterns of high and low-frequency atrial activation potentials recorded at the posterior input to the atrioventricular node using a split-tip electrode catheter and a long stabilizing sheath

G. Senatore, F. Ouyang, M. Volkmer, M. Antz, J. Hebe, K.-H. Kuck, R. Cappato. *A K, St. Georg Hospital, Hamburg, Germany*

Antegrade and retrograde patterns of bipolar local activation at the posterior input to the AV node were investigated in 12 pts with AV nodal reentrant tachycardia (AVNRT) through a custom-made 7 F quadripolar-tip (split-tip) miniaturized electrode ablation catheter (Cordis-Webster). To optimize stability, the catheter was advanced to the target region through a long sheath. Local activation was assessed in all pts during atrial and ventricular programmed electrical stimulation and during AVNRT.

Results. During sinus rhythm, a double potential consisting of a high-frequency (HF) component followed by a low-frequency (LF) component was found in all pts in the midseptal area of Koch's triangle. During programmed atrial stimulation, conduction through the AV node was associated with non-decremental patterns of HF and decremental patterns of LF potentials in all pts; multiple distinct LF potentials (up to 5) were recorded in response to atrial extrabeats resulting in antegrade jump and AV node echoes or AVNRT. The antegrade AV nodal refractory period occurred either before and after LF potential activation. During retrograde slow pathway conduction, LF potentials were recorded before HF potentials. One radiofrequency pulse (range, 1–12) at sites where both HF and LF potentials were recorded successfully abolished AVNRT in all pts.

Conclusions. LF potentials reflect local activation of transitional areas involved in slow pathway conduction. Use of split-tip miniaturized electrodes and long sheaths increases the local resolution and allows an accurate detection of LF-potential dynamic patterns in response to pacing maneuvers and during AVNRT.

P2989 A novel approach to electrocardiographic diagnosis of pre-excited atrial fibrillation

R.K. Pathmanathan[1], S. Talwar[3], E.W. Lau[2], J. Cooper[1], J.D. Skehan[1], P.J. Stafford[1], M.J. Griffith[2]. *Departments of Cardiology; [1]Glenfield Hospital, Leicester; [2]Queen Elizabeth Hospital, Birmingham; [3]Department of Cardiovascular Medicine, Leicester Royal Infirmary Leicester, UK*

Background: Atrial fibrillation (AF) in patients with Wolff-Parkinson-White syndrome (AFWPW) may easily be confused by non-specialist electrophysiologists with AF with bundle branch block (AFBBB) or ventricular tachycardia (VT). Yet essential diagnosis of this arrhythmia is essential to avoid inappropriate and potentially dangerous therapy with atrioventricular nodal blocking agents or class 1B antiarrhythmic drugs. We have applied a simple ECG based criteria to improve diagnosis of this arrhythmia.

Methods: 104 12 lead ECGs (31AFBBB, 41AFWPW, 32VT – latter 2 diagnoses confirmed electrophysiologically) were blindly analysed randomly by a trainee in electrophysiolgy (RKP) and a medical registrar (ST). Three ratios were calculated: 1) 10 successive RR intervals (RR) were measured to the nearest 0.5 mm. The maximum (max) minus minimum (min) value was divided by the widest QRS complex in mm ($RR_{max\text{-}min}$/QRS ratio); 2) 5 successive isoelectric to R wave peak measurements in the lead with the tallest R wave were made. The max minus min value was divided by the min value ($R_{iso\text{-}peak}$ ratio); 3) 5 successive peak to trough measurements in the lead with the largest QRST complex were made. The max minus min value was divided by the min value ($QRST_{peak\text{-}trough}$ ratio). RKP and ST were also asked for a clinical diagnosis of each ECG.

Results:

	Sensitivity	Specificity (AFWPW)
$RR_{max\text{-}min}$/QRS ratio of 0.6–2.0	98%	86%
$R_{iso\text{-}peak}$ ratio of ≥ 0.22	85%	92%
$QRST_{peak\text{-}trough}$ ratio > 0.15	92%	97%
$RR_{max\text{-}min}$/QRS & $QRST_{peak\text{-}trough}$ ratios	95%	91%

Clinical diagnosis – RKP	AFWPW 100%	AFBBB 100%	VT 100%
Clinical diagnosis – ST	AFWPW 78%	AFBBB 100%	VT 56%

Application of both the $RR_{max\text{-}min}$/QRS and $QRST_{peak\text{-}trough}$ ratios (using ST's ECG measurements) to ST's 23 misdiagnosed ECGs resulted in 19 (83%) to be correctly diagnosed.

Conclusions: Application of an easily executable algorithm of RR interval and QRST height variability enables correct diagnosis of AFWPW with high sensitivity and specificity. Application of these criteria would improve the acute and long term management of this potentially life threatening condition.

P2990 Differences in onset of delta wave between different electrocardiographic leads: implications for prediction of accessory pathway location and for catheter ablation

J. Fuertes, J.L. Merino, R. Peinado, J. Pereira, N. Sobrino, J.A. Sobrino. *Lab. Electrofisiologia Cardiaca, Hospital Universitario "La Paz", Madrid, Spain*

Endocardial sites with local ventricular activation time preceding the onset of the delta wave are considered suitable for radiofrequency application in the WPW syndrome. Onset of ventricular preexcitation is occasionally earlier and better appreciated in some ECG leads than in others, and, therefore, it is advisable to chose the optimal ECG lead to reference the endocardial activation time before radiofrequency application. However, it has not been established whether these differences in the recognition of onset of ventricular preexcitation between different ECG leads are significant and related to the AP location.

Methods: 64 consecutive patients were studied prior to the catheter ablation of a single manifest AP. The onset of the delta wave (ODW) – referred to the onset of the P wave – was simultaneously measured in all 12 ECG leads at 200 mm/sec and by electronic callipers. The following variables were studied: ODW in all ECG leads, difference in ODW between the earliest lead and the mean ODW in all 12 leads, and difference in ODW between the latest lead and the mean ODW in all 12 leads. These variables were also analysed according to a left (n = 33), right (n = 15) or posteroseptal (n = 16) location of the AP.

Results: There was a difference in ODW between the earliest and latest leads and the mean ODW of 17.9 ± 8.8 ms (CI 95%: 15.7–20.2) and 43.9 ± 18.9 ms (CI 95%: 39.1–48.6) respectively. The earliest and latest ODW were most frequently recorded in leads V3 and aVL respectively. There greatest difference in ODW between the earliest and mean ODW was found in the right sided AP group (−26.5 ± 10.0 ms) compared with the left-sided (−15.8 ± 10.6 ms) or posteroseptal (−14.2 ± 4.5 ms) AP groups (ANOVA, $p < 0.0001$). The earliest ODW in right-sided AP was recorded in leads V1 and V2 and a difference in ODW between the earliest and mean ODW in V1/V2 greater than 20 ms had showed 81% sensitivity and 98% specificity for right-sided AP.

Conclusions: 1) Differences in recognition of ODW between different ECG leads are often substantial and, therefore, it should be strongly recommended – specially in right-sided AP – to select the appropriated ECG lead for ablation. 2) An ODW recognised more than 20 ms earlier in V1/V2 than in other ECG leads suggests a right-sided location of the AP.

P2991 Differential diagnosis of paroxysmal supraventricular tachycardias by administration of adenosine during sinus rhythm

Z. Csanadi, C. Foldesi, M. Csanady. *2nd Department of Medicine, A. Szent-Gyorgyi Med. Univ., Szeged, Hungary*

Background: Atrioventricular node reentrant tachycardia (AVNRT) represents the most commonly encountered type of paroxysmal supraventricular tachycardias (PSVT). Administration of adenosine-5′-triphosphate (ATP) during sinus rhythm was shown to be a valuable test in demonstration of dual AV node pathway physiology indicated by an at least 50 msec jump in AH interval between two consecutive sinus beats. Adenosine, the end-product of the ATP metabolisation cascade with a very short half-life has been widely used to terminate supraventricular tachycardias with less adverse effects than ATP. The aim of our investigation was to test the potential of adenosine in revealing dual AV node pathway physiology in a consecutive series of patients undergoing invasive electrophysiology study and radiofrequency ablation for PSVT.

Methods: 38 patients (23 female, age: 16–63 years) were enrolled. All patients had documented narrow QRS complex tachycardias and either AVNRT or atrioventricular reentrant tachycardia (AVRT) was confirmed at electrophysiology study. A rapid iv bolus of adenosine was administered at 6 mg and 12 mg doses to all patients prior to atrial stimulation. Dual AV node pathway physiology was defined as a ^{3} 50 msec increment in AH interval between two consecutive sinus beats after adenosine or after a 10 msec decrement in coupling interval during atrial extrastimuli.

Results: AVNRT was diagnosed based on atrial extrastimulus testing in 20 patients. In 14 of these 20 patients dual AV node pathway physiology was revealed with adenosine test. None of the 18 patients with atrioventricular reentrant tachycardia showed signs of dual AV node pathways with adenosine. Adenosine test had a 70% sensitivity and 100% specificity in the diagnosis of dual AV node pathways. No adverse effect of adenosine was found in any of the patients.

Conclusion: I.v. adenosine administration is a safe test with excellent sensitivity and specificity for differentiation of arrhythmia mechanism in patients with PSVT.

P2992 Extrastimuli from two different directions provide the distance between the dual atrioventricular nodal inputs

K. Yamashiro, Y. Ohnishi, A. Takei, K. Adachi, N. Kuroda, K. Okajima, M. Yokoyama. *First Department of Internal Medicine, Kobe University School of Medicine, Kobe, Japan*

We have reported that extrastimuli from two different directions can help to reveal the functional difference between the dual pathways ('98AHA). It is impossible to know the positions of the dual inputs exactly. To evaluate the distance between dual inputs is important to avoid the AV block induced by slow pathway (SP) radiofrequency (RF) ablation.

Methods. Fourteen consecutive patients (pts) with typical AV nodal reentrant tachycardia underwent successful selective SP RF ablation guided by SP potentials or a fractionated atrial electrogram. Steerable electrode catheters were simultaneously positioned anterior (A) to the His bundle catheter and posterior (P) near the coronary sinus ostium before the RF procedure. We applied extrastimuli from either the A or P site in 14 pts [Group1 (G1): transient VA block during SP ablation, 4 pts, Group2 (G2): no VA block during SP ablation, 10 pts]. In all pts, we measured the atrio-His interval from A2 at the stimulating site to H2. A1A2 vs A2H2 conduction curves (CC) were obtained by stimulation applied from either of two different sites. ΔAH (longest A2H2 – shortest A2H2), and MaxAH (maximum increase in A2H2 for a 10 ms decrement in A1AZ), were measured in each CC.

Results: All 14 pts showed a ΔAH (A/P) ≥ 1. ΔAH (A/P) in G2 was significantly larger than in G1.

	ΔAH (A)	ΔAH (P)	ΔAH (A/P)	MaxAH (A)	MaxAH (P)
G1	233 ± 49 ms	220 ± 50 ms	1.07 ± 0.06*	65 ± 36 ms	65 ± 43 ms
G2	248 ± 93 ms†	195 ± 79 ms	1.3 ± 0.19	134 ± 78 ms#	87 ± 70 ms

*$p < 0.05$ vs G2, †$p < 0.01$ vs ΔAH (P) in G2, #$p < 0.05$ vs MaxAH (P) in G2

Conclusions. In patients with a small difference in the ΔAH obtained by extrastimuli from two different directions, the distance between the dual AV nodal inputs was estimated to be short. ΔAH (A/P) provides an electrophysiological marker for the risk of AV block induced by slow pathway ablation.

P2993 Role of an early follow-up electrophysiologic study after acutely successful radiofrequency ablation of accessory pathways and atrioventricular nodal re-entrant tachycardia

F. Freihoff, G. Jakl, O. Merl, C. Wollmann, W. Kaltenbrunner, K. Steinbach. *Ludwig Boltzmann Institute for Arrhythmia Research, III. Med. Dept., Wilhelminenspital, Vienna, Austria*

Background: Recurrence rates of accessory pathway (AP) conduction (cond) and AV nodal reentrant tachycadia (AVNRT) after initially successful radiofrequency ablation (RF) are reported to be up to 8% and 5%, repectively. We report our results of a routinely performed electrophysiologic study (EP study) 4–6 weeks after acutely successful RF for WPW syndrome and AVNRT.

Methods: 263/332 pts (79%) with AVNRT (group I) and 265/340 pts (74%) with WPW syndrome (group II) underwent an EP study a mean of 36 days after the RF session. Studies were performed off all antiarrhythmic drugs for at least 5 half lives with two catheters positioned to record a His bundle electrogram and the HRA and RVA, respectively.

We performed incremental and programmed atrial pacing with up to two extrastimuli and incremental and programmed ventricular pacing with 1 extrastimulus in all patients at baseline and on isoproterenol in pts in group I.

Results: In group I 17 pts (6.5%) had an EP recurrence. Only 5 of them had palpitations suggestive of recurrent AVNRT. 11 of these pts underwent a successful repeat ablation.

In group II 12 pts (4.5%) demonstrated recurrent AP cond either uni- or bidirectionally. Only 2 pts had symptoms suggestive of AVRT since the ablation. 5 of the 12 pts underwent a second ablation procedure, that was successful in all.

Thus, a therapeutic consequence of the early invasive follow-up study resulted in 4.2% of pts with AVNRT and 1.9% of pts with WPW syndrome.

Conclusion: The low recurrence rate of AVNRT and AP conduction after an initially successful RF ablation suggests that in asymptomatic pts an early invasive follow-up study is not warranted.

P2994 A simplified ATP test for the non-invasive diagnosis of dual atrioventricular nodal pathways and the assessment of the results of slow pathway ablation in patients with atrioventricular nodal reentry tachycardia

B. Belhassen, R. Fish, S. Viskin, M. Glikson[1], A. Glick, M. Eldar[1]. *Cardiology Dept, Tel-Aviv Medical Center, Tel-Aviv; [1]Cardiology Dept, Sheba Medical Center, Tel-Hashomer, Israel*

We have recently shown that administration of ATP during sinus rhythm identifies dual AV nodal pathways (DAVNP) in 76% of 41 patients with inducible sustained AV nodal reentry tachycardia (AVNRT (Circulation 1998; 98: 47). In that study, ATP test was considered to be positive for DAVNP only when the results were reproducible once at a given dose of ATP. The present study evaluated the sensitivity of a simplified adenosine triphosphate (ATP) test in the noninvasive diagnosis of dual AV node pathways (DAVNP) and assessment of the results of radiofrequency ablation (RFA) of the slow pathway in a large group of patients with inducible sustained slow/fast AVNRT.

Methods: The value of a single given dose of ATP was studied in 105 patients with inducible sustained slow/fast AVNRT. ATP (10 to 60 mg, at 10 mg increments) was injected during sinus rhythm until ECG signs of DAVNP (>50 ms increase or decrease in PR interval in 2 consecutive beats, or >1 AV nodal echo beat) or 2nd degree AV block were observed.

Results: The test could be completed in 96 patients. DAVNP by ATP test were seen in 72 (75%) of 96 patients. DAVNP by electrophysiologic criteria were demonstrated in 82 (85%) of the 96 patients. DAVNP were present by ATP test in 59 (72%) of the 82 patients with and in 13 (93%) of the 14 patients without DAVNP by electrophysiologic criteria (p = NS). DAVNP by ATP test disappeared in 27 (96%) of 28 patients who underwent slow pathway abolition and in 18(60%) of 30 patients who underwent slow pathway modification. In the 12 patients with persistent DAVNP by ATP test after slow pathway modification, the number of beats conducted over the slow pathway was significantly reduced (2.5 ± 2.2 vs 6.3 ± 3.3, $p < 0.002$).

In conclusion: A single administration of ATP during sinus rhythm at a given dose enables the noninvasive diagnosis of DAVNP in a high percentage of patients with inducible slow/fast AVNRT and reliably predicts the results of RFA of the slow pathway.

P2995 Electrophysiologic and antiarrhythmic effects of a new atrial selective 5-HT4 receptor antagonist in experimental atrial flutter and fibrillation

E. Leistad, M. Rahme[1], B. Cotter[1], M.K. Wadhwa[1], R. Mohabir[2], A.P.D.W. Ford[2], R.P. Eglen[2], G.K. Feld[1]. *Department of Medicine, Lovisenberg Hospital, Oslo, Norway; [1]Cardiovascular Division, UCSD Medical Center, San Diego CA; [2]Roche Bioscience Inc., Palo Alto CA, USA*

Stimulation of the 5-HT4 receptor increases atrial chronotropic and inotropic response, but whether it has other electrophysiologic effects is unknown. In humans and swine the 5-HT4 receptor is present only in the atrium. Therefore, the effects and the antiarrhythmic potential of a new 5-HT4 receptor antagonist, RS-100302, were studied. In order to delineate the role of this receptor in modulating atrial electrophysiologic properties, the partial receptor agonist cisapride was also evaluated.

Methods: In 17 anesthetized, open-chest,pigs, atrial flutter or fibrillation were induced by rapid right atrial pacing with or without a crush-injury of the right atrial free wall, respectively. Atrial effective refractory period (ERP), conduction velocity (CV), wavelength, and dispersion of refractoriness were determined during programmed stimulation via a 56-electrode mapping plaque sutured to the right atrial free wall. Ventricular electrophysiologic parameters were also measured. All electrophysiologic parameters were measured at baseline and following infusion of RS-100302 and cisapride.

Results: In the atrium RS-100302 prolonged mean ERP (115 ± 8 vs 146 ± 7, $p < 0.01$)and wavelength (8.3 ± 0.9 vs 9.9 ± 0.8, $p < 0.01$), reduced dispersion of ERP (15 ± 5 vs 8 ± 1, $p < 0.01$), and minimally slowed CV (72 ± 4 vs 67 ± 5, $p < 0.01$). These effects were all partially reversed by cisapride. RS-100302 produced no ventricular electrophysiologic effects. RS-100302 terminated atrial flutter in 6 of 8 animals and atrial fibrillation in 8 of 9 animals. Re-induction of sustained tachycardia was prevented in all animals.

Conclusions: The electrophysiologic effects of the new atrial 5-HT4 receptor agotagonist RS-100302 suggest that it may have important atrial antiarrhythmic potential, without producing ventricular proarrhythmic effects.

P2996 Predisposing factors, histology and treatment of superior vena cava stricture complicating radiofrequency modification of the sinus node

F.M. Leonelli, G. Tomassoni, E. Pisano[1], J.A. Requarth[2], A. Natale. *Cardiology Dept, University of Kentucky, Lexington KY, USA; [1]Casa sollievo della, Sofferenza, Italy; [2]Charleston Area Medical Center, Charleston, USA*

Radiofrequency modification (RFM) of the sinus node (SN) is an accepted therapy of drug resistant inappropriate sinus tachycardia (IST). During this procedure mapping and sequential ablation of the earliest atrial activation site is continued until the SN response to Isoproterenol infusion (I) is decreased to less than 120 bpm. The only recognized specific complication of this procedure is sinus arrest with junctional escape rhythm neccessitating pacemaker (PPM) implant. We describe superior vena cava (SVC) obstruction as a late complication of RFM, its contributory factors and its management. From Oct. 1997 to May 1998, 14 patients (pts), (12 female) with drug resistant IST underwent RFM of SN. Caudal shift of the earliest atrial activation with a SN response to I of <120 bpm was observed acutely in every pt. PPM implantation occurred in three patients: two prior to the procedure due to complete heart block and one due to complication of the procedure. All three patients developed SVC syndrome at 64 ± 15 day's post RFM. The number of RF applications was similar to the uncomplicated pts. Trans-esophageal echocardiography (TEE) was diagnostic in all cases correctly identifying the stricture at the SVC-right atrial junction. Angiography confirmed a mean gradient of 25 ± 3 mmHg with histology in one pt demonstrating full thickness tissue fibrosis. One pt underwent surgical repair of the stricture while in two, percutaneous transluminal balloon dilation (PTBD) successfully reduced the gradient to less than 5 mmHg. There was no recurrence at 3 ± 1 months.

Conclusion: 1) SVC obstruction is not an uncommon complication of RFM of SN. 2) The presence of PPM may be a strong predisposing factor to this complication. 3) TEE is the diagnostic test of choice while PTBD of the stricture appears to be a successful therapeutic modality.

HEART FAILURE AND HEART TRANSPLANTATION

P2997 Importance of left anterior hemiblock development in inferior wall acute myocardial infarction

K. Ozdemir, Y. Uluca, M. Tokac[1], G. Daný, H. Gök. *Cardiology Dept., Selcuk University, Konya; [1]Cardiology Dept., Selcuk University, Konya, Turkey*

New left anterior hemiblock (LAHB) in anterior wall myocardial infarction (MI) is the most frequent intraventricular conduction defect. On the other hand, the coronary angiographic significance of LAHB development in patients with acute inferior wall MI (AIMI) is known to be less significant. This study was planned to investigate this phenomenon by comparing the patient groups with and without LAHB after AIMI.

Methods: One-hundred and seventy-two patients (141 men and 31 women) between 28 and 84 years of age (mean 55 ± 10) with the diagnosis of AIMI were included in the study. Patients with previous LAHB finding were excluded. Patients were divided into two groups according to ECG criteria: group I – 25 patients in whom an ECG pattern characteristic of LAHB developed; group II-147 patients without this pattern. Patients were placed in group I if there was an axis deviation of <30° of the mean frontal plane to the left with the following pattern: increased S-wave voltage and decreased R-wave voltage in leads II, apparence of deep S-wave in lead II, and terminal positive R wave in lead aVR. Coronary angiography was performed within 1 weeks. A coronary stenosis was considered significant if the vessel diameter was narrowed by >50%. The dominant coronary artery was classified as right and left or balanced. LV ejection fraction (EF) was calculated from the single-plane right anterior oblique 30° projection of left ventriculography.

Results: There was non-significant difference between two groups according to risk factors of coronary disease. The frequency of the left dominant or balanced coronary artery, left anterior descending (LAD) and multivessel coronary artery diseases was found to be significantly higher in group I comparing to group II (44% Vs 17%, $p = 0.018$; 80% Vs 38%, $p < 0001$; 84% Vs 52%, $p = 0.001$ respectively). The average age of patients in group I was significantly higher (58 Vs 54, $p = 0.007$) while the mean LV EF was found to be lower than group II (51% Vs 56%, $p = 0.04$). The peak CKMB values were higher in group I, however the difference was not statistically significant (216 Vs 162, $p = 0.09$).

As a result our study suggest that the LAHB development during AIMI can be an indicator of LAD lesions, multivessel coronary artery diseases and impaired left ventricular systolic function. Therefore the coronary angiography should be considered for these kinds of patients.

P2998 Pacing transplanted patient: 10-year experience

R. Frank, C.E. Guzman, S. Chabrak, L. Romero, J.C. Petitot, A. Pavie[1], V. Bors[1], J.J. Ghoussoub[1], R. Dorent[1], I. Gandjbakhch[1], C. Cabrol[1], A. Cabrol[1]. *Hôpital Jean Rostand, Ivry; [1]Hôpital de la Pitié, Paris, France*

We reviewed the 61 permanent pacemakers implanted in a series of 930 cardiac transplants 6.7%) between 1988 and 1998, 54 sinus node dysfunction (SND), 4 atrio ventricular blocs (AVB) and 3 both. 90% were male, mean age 46 ± 11 years.

All patients had undergone the orthotopic transplantation using the classical Shumway technique. Half of the population (31) were implanted during the first 6 post-operative weeks. The incidence of early implantation ranged from 4 to 8 by year up to 1995, and then decreased to one or none since 1996. The other half (30) were implanted later, between 1 to 10 years, 5 every 2 years.

Pacing mode was VVI (7) for 5 paroxysmal AVB, one unexcitable atrium, and one paroxysmal SND with right bundle branch block. AAI (5) or AAIR (25) for isolated SND without AVB or chronotropic incompetence (3). DDD (15) + DDDR (18) for SND with various degree of AVB, for SND without ventricular escape, or elective.

Mean atrial thresholds were 0.9 ± 0.4 V, with endocardial potential of 3.36 ± 1.38 mV. The only post-implant complications were the early dysfunction of two leads, one atrial and one ventricular, that had to be repositioned.

Two months after implant, 52% were found in normal sinus rhythm, and 48% permanently paced in early as in late implantation.

Mean follow-up was 110 ± 79 months. Survival was 95% at one year, and 75% at five years. The only late complication was the dislodgment of a ventricular lead during a biopsy. No patient with isolated SND developed late AV block.

Pacing in transplanted heart is uneventful, and simple atrial pacing should be considered in most SND.

P2999 Endocardial biventricular pacing through jugular transseptal catheterization in end-stage heart failure

F. Leclercq, J.C. Macia, C.J. Mariottini, J.L. Pasquié, F.X. Hager, R. Grolleau. *Department of Cardiology, Arnaud de Villeneuve hospital, CHU Montpellier, France*

Biventricular pacing may improve functional and hemodynamic status of patients with end-stage heart failure (HF) but transvenous left ventricular (LV) pacing through branches of the coronary sinus can not always be achieved. Endocardial LV pacing may be an alternative to epicardial LV pacing, which requires thoracotomy or thoracoscopy.

Methods: We developed a modified technique for LV pacing, performed with transseptal catheterization through the internal jugular vein. Five patients with end-stage cardiomyopathy and widened QRS linked to left bundle branch block (n = 4) or right ventricular pacing (n = 1) were included in this preliminary study. Transseptal catheterization was achieved via the internal jugular vein using a brockenbrough needle with a more curved tip than the standard model. An unipolar tined (n = 3) or screw-in (n = 2) lead was easily placed in the LV through a flexible long sheath. The proximal tip of the LV lead was tunneled and connected, with a special bipolar connector, to the ventricular channel of a dual (n = 3) or simple (n = 2) chamber pacemaker located in the subclavian area.

Results: Efficient acute sensing (V wave amplitude = 12 ± 3 mV) and pacing (acute pacing threshold = 0.6 ± 0.3 V) were obtained in the 5 patients. Early loss of capture occurred in the 2 first patients requiring lead replacement. At 6 month follow-up, biventricular pacing was maintained in all patients (mean LV threshold 1.1 V) with QRS duration reduction always observed when compared with right ventricular pacing (QRS duration: 140 ± 20 ms *vs* 220 ± 25 ms, respectively; $p < 0.001$). Clinical status improved dramatically and was maintained at follow-up in all patients who were free of clinical embolic event with oral anticoagulant therapy.

In conclusion, endocardial LV pacing can be achieved via jugular transseptal catheterization and could be an alternative to venous or epicardial pacing in end-stage heart failure.

P3000 The role of ischaemia in early sinus node dysfunction after orthotopic transplantation

R. Frank, C.E. Guzman, S. Chabrak, L. Romero, J.C. Petitot, A. Pavie[1], V. Bors[1], G. Ghoussoub[1], R. Dorent[1], I. Gandjbakhch[1], C. Cabrol[1], A. Cabrol[1]. *Hôpital Jean Rostand, Ivry; [1]Hôpital de la Pitié, Paris, France*

We reviewed the 57 permanent pacemakers (PM) implanted in a series of 930 cardiac transplants between 1988 and 1998 for persistent sinus node dysfunction (SND). The mean age was 46 ± 11 years, 90% were male.

All patients had undergone the orthotopic transplantation using the classical Shumway technique. Half of the population were implanted during the first 6 post-operative weeks. The incidence of early implantation ranged from 4 to 8 by year up to 1995, and then decreased to one or none since 1996. The other half were implanted later, between I to 10 years, 5 every 2 years.

To evaluate risk factors for implant, multivariate analysis was performed in the 49 subjects with complete data including biopsies information. They were separated in two group: 20 patients with early SND ≤ 6 weeks without rejection group I, and 29 patients, with early (3) or late SND at a time of rejection (16), and 7 late SND without rejection. Early SND only differed from the other group by aortic cross clamping time (ACCT) (116.6 ± 37.1 vs 91.5 ± 18.8 min; $p = 0.047$) and graft ischemia (GI) (165.93 ± 62.1 vs 126.9 ± 48.2 min; $p = 0.039$).

There was no PM implant in the 45 other patients transplanted between 1996 and 1998 with operative procedure preserving the superior vena cava. In this group, ACCT was 108 ± 21 min, and GI 159 ± 56.

In the absence of rejection, early SND is related to the ischemia of a sinus node damaged by the classical technique. This is suggested by the fact that despite similar ischemic times, there is no more early pacemaker implantation with operative procedures preserving the superior vena cavae as used since 1996. However late sinus node dysfunction can still be found in patients from the older series, especially at time of rejection.

P3001 Multisite pacing with short atrioventricular delays acutely improves diastolic and systolic function in patients with congestive heart failure

C. Stellbrink, O.A. Breithardt, B.H. Diem, O. Baltar, A. Franke, T. Pochet[1], A. Auricchio[2], P. Hanrath. *On behalf of the Path-CHF Investigators; [1]CPI/Guidant, St. Paul MN, USA; [2]Department of Cardiology, University Hospital Magdeburg; Medizinische Klinik I, RWTH Aachen, Germany*

The PATH-CHF study included patients (pts) with CHF, NYHA class III–IV, QRS-width > 120 ms and PR-interval > 150 ms. All pts received 2 DDD pacemakers (PM) allowing VDD pacing either from the right ventricular apex (RV), left ventricle (LV) or both ventricles (BV) at a short (AV-S, 50–130 ms) and long (AV-L, 120–260 ms) AV delay adjusted to the individual PR interval. Pulsed-wave Doppler analysis of transmitral inflow and continuous-wave doppler measurement of aortic outflow velocity time integral (A_{VTI}) was performed in sinus rhythm (SR) and all pacing modes.

Results: 25 pts were analyzed. Mitral inflow velocity time integral (M_{VTI}) acutely increased by 11–19% and A_{VTI} by 3–6% with LV and BV pacing at AV-S compared to SR. RV and AV-L resulted in only minor changes. Similar effects were observed for diastolic filling time (FT) and early filling wave deceleration time (Edt).

		Short AV-delay			Long AV-delay		
	SR	RV	LV	BV	RV	LV	BV
M_{VTI} (cm)	16.2±4.6	17.9±5.1*	18±5.7*	19.3±6.3#	17.1±4.6	17.2±5.2	17.3±4.6
FT (ms)	385±129	406±120*	421±147#	435±141#	390±123	384±128	386±102
Edt (ms)	181±65	222±97*	203±89	236±112#	210±110	197±96	205±110
A_{VTI} (cm)	23.2±5.6	23.7±6.2	24±5.9	24.5±5.7*	23.2±5.5	22.9±4.8	23.6±5.8

* = $p < 0.05$ vs. SR; # = $p < 0.01$ vs. SR

Conclusions: LV and BV pacing with short AV delays acutely improve doppler indices of diastolic function and stroke volume in patients with congestive heart failure compared to SR and RV pacing. Diastolic filling time and Edt are prolonged with an increase in mitral inflow during the early filling phase. There is no significant improvement at long AV delays.

P3002 Long-term performance of a transvenous system for atrio-biventricular pacing in patients with dilated cardiomyopathy and congestive heart failure

H. Oude Luttikhuis[1], D. Gras[2], P. Mabo[3], C. Bucknall[4], T. Tang[5], A. Kirstein-Pedersen[6]. *For the InSync Investigators; [1]St. Sophia Ziekenhuis, Zwolle, Netherlands; [2]Clinique du Val d'Or, Paris; [3]Dep. de Cardiologie et Maladies, Rennes, France; [4]St. Thomas Hospital, London, UK; [5]Ottawa Heart Institute, Ottawa ON, Canada; [6]Skejby Sygehus, Aarhus, Denmark*

The InSync clinical trial is a prospective, non-randomized study evaluating cardiac resynchronization therapy in patients with dilated cardiomyopathy (LVEDD ≥ 60 mm), advanced heart failure (NYHA class III/IV, EF ≤ 35%), and ventricular conduction deficits (QRS ≥ 150 msec).

Methods: All pts were implanted with the InSync system, including the Medtronic Attain Model 2187 unipolar (71 pts) or Model 2188 bipolar (25 pts) transvenous LV leads. 16 centers in Europe and Canada are participating in the study, and pts are followed for 12 months. Data summarizing the performance for the Models 2187 and 2188 leads through 6-months of follow-up are presented here.

Results: 103 pts were successfully implanted with an InSync system out of 118 attempts (success rate = 87.3%). The average LV lead implant time was 52 ± 45 min.; the average total procedure time was 128 ± 76 min. Data shown below represent paired results (to time of implant) for electrical parameters for the Models 2187 and 2188 leads.

Model 2187 LV lead	BiV Thresholds (V) (@0.5 msec)	Impedance (Ω)	R-Wave (mV)
1 month	1.9 (N = 27)	478* (N = 39)	12.2 (N = 29)
3 months	1.9 (N = 16)	499* (N = 29)	11.5 (N = 21)
6 months	2.3 (N = 13)	469 (N = 19)	13.1 (N = 14)

*p value ≤ 0.05

Model 2188 LV lead	BiV Thresholds (V) (@0.5 msec)	Impedance (Ω)	R-Wave (mV)
1 month	2.5 *(N = 10)*	463* (N = 14)	9.6 (N = 13)
3 months	3.0 *(N = 8)*	506* (N = 13)	12.5 (N = 9)
6 months	2.7 *(N = 9)*	527* (N = 13)	11.5 (N = 11)

*p value ≤ 0.05

Conclusions: Stable biventricular (BiV) capture thresholds, sensing, and lead impedances were observed for the Models 2187 and 2188 transvenous LV leads through 6 months following implant of the InSync system. Further studies will contribute to overall experience and success with transvenous lead placement for cardiac resynchronization.

P3003 Right ventricular mural endocarditis after central catheter

C. Braunstein, F. Lacassin[1], D. Ducharme, E. Tarpinian, S. In, Ch. Menager[2], J. Robert. *Cardiology CHT Gaston Bourret Noumea; [1]Internal Medicine CHT Gaston Bourret Noumea; [2]Pediatric CHT Gaston Bourret Noumea, New Caledonia (French)*

Valvular endocarditis is well known and did motivate numerous publications. We report a case of a right mural infective endocarditis in a child.

A 15 years old boy was admitted for acute left schoulder osteitis complicated with septicaemia due to *Staphylococcus aureus* and purulent pericarditis. The evolution was favorable after drainage, lavage of pericardium and schoulder and antibiotics infusion with a central subclavian catheter during 15 days (oxacillin, netromycin, rifampicin). We obtained sterilization of sepsis and total regression of pericardial effusion without constriction at regular echocardiography control.

We removed the central catheter after 15 days. Culture of the tip found coagulase negative *Staphylococcus* with high level of resistance.

Four days after removing the catheter, the transthoracic echocardiography, done to control the pericardium, revealed a large vegetation (17 mm long) on the basal wall of the right ventricule, near from the IV-septum, with a large implantation. The patient felt well without fever. Blood culture were sterile and sedimentation rate was high.

The child received new antibiotics during 6 weeks (vancomycin, pyostacin) with a good evolution on the vegetation's size after one month of treatment, and disappearing of infection signs.

In conclusion: This case report seems to be unusual. It focus on unusual localization of endocarditis and may be explained by satellite lesions due to the jet stream from the catheter striking the right ventricule endocardium.

P3004 Natural course of severe asymptomatic rheumatic mitral regurgitation

F. Maatouk, F. Betbout, M. Ben Farhat, H. Gamra, K. Ben Hamda, T. Lounissi, M. Boyo, S. Hammami, F. Addad. *Fattouma Bourguiba University Hospital, Monastir, Tunisia*

Surgical correction of severe asymptomatic rheumatic mitral regurgitation (MR) remains controversial. The purpose of the study was to determine the natural course of severe asymptomatic rheumatic MR.

Methods. Thirty patients with grade3 and 20 patients with grade4 MR according to Sellers angiographic classification had clinical and echo-Doppler evaluation at baseline and at a mean follow-up (F/U) of 6 ± 4 (range 2–14) years. Mean age was 16.7 ± 7 (4–17) years. The rheumatic origin was assessed according to Jones criteria. The interval between the acute attack and entry in the study was 8 ± 5 (4–16) months. Forty six patients (92%) were in NYHA fuctional class I and 4 patients were in class II. Baseline pulmonary capillary wedge pressure was ≤16 mmHg in all patients.

Results: Functional status remained unchanged in 48 patients (96%), 2 patients evolved to functional class III and underwent surgical correction. Mitral regurgitation decreased to grade2 in 5 patients and to grade1 in 3 patients. It remained unchanged in 42 patients (84%). Left ventricle dimensions (DD = diastolic diameter, SD = systo-lic diameter, FS = fractional shortening) and left atrium (LA) dimension remained unchanged (p = NS):

	DD (mm)	SD (mm)	FS (%)	LA (mm)
Baseline	57 (43–77)	34 (23–51)	40 (28–51)	36 (20–54)
F/U	55 (44–4)	36 (25–51)	36 (30–47)	33 (21–38)

In conclusion: Severe asymptomatic rheumatic MR remains unchanged in the majority of patients. It decreases in few patients. Functional status deterioration is very rare.

Day 5

Wednesday, September 1, 1999

ATRIOVENTRICULAR NODAL RE-ENTRY TACHYCARDIAS

3121 Morphology of the anterior-superior approach region in the light of atrioventricular nodal re-entry tachycardia fast pathway ablation

D. Kozlowski, E. Kozluk[1], A. Stanke, A. Owerczuk[2], M. Grzybiak[2], M. Adamowicz[3], E. Walczak[3], F. Walczak[1]. *2nd Dept. of Cardiology, Medical University of Gdansk, Gdansk; [1]National Institute of Cardiology, Warsaw; [2]Department of Clinical Anatomy, Medical University of Gdansk, Gdansk; [3]Medical University of Warsaw, Warsaw, Poland*

Atrioventricular nodal reentry tachycardia (AVNRT) base on reentry circulation in nodal-perinodal area. The radical treatment of choice is radiofrequency fast or slow pathway ablation. Procedure approached from the anterior-superior (fast) region sufficients a few seconds of energy delivery for succes, however this can result often in a-v block. The possibility that arrhythmias substrate may lie very superficial (succes of ablation) and damage of the normal structures (complication) in the perinodal region must be considered.

In order to confirm this hypothesis we took observation on the autopsy material of 30 normal hearts, both sexes from 18 to 81 years of age (control) and 30 hearts with a-v total block 45–95 years of age (block group). Koch's triangle was divided in the sagittal plane into 3 parts: inferior, central and superior. We paid attention on the morphology of the nodal artery (NA), atrial inputs (AI).

It was observed that NA at the level of central fibrous body was positioned in 94% in the central and in 6% in the inferior part of the Koch's triangle. It was removed from the endocardium 3–6 mm in control and 2–5 mm in block group respectively (no significant). Besides, we observed in 30% of controls small parietal thrombi and in 90% of block group ($p < 0.05$). In the perinodal area we distinguish AI that directly joined the a-v compact node. They composed 2 layers: superficial (right part of the interatrial septum) or deep (left part). The first of mentioned occurred in 100% of controls and in 80% of block groups (NS), and the last in 80% of control group and in 33.3% in block respectively ($p < 0.05$).

Conclusions: 1) the real substrate of arrhythmia in anterior-superior region lies very superficial and far from the conduction tissue 2) NA in examined hearts was laying deep beneath the endocardium 3) ablation of the deep part laing close to the node could result in a-v block

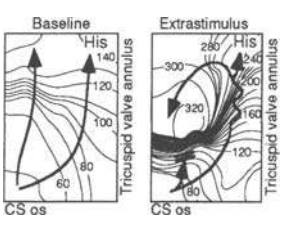
3122 High-resolution mapping of the canine atrioventricular node after endocardial resection reveals functional dissociation: the substrate for re-entry?

Peter Loh[1,2], Jacques M.T. de Bakker[2,3], Günter Breithardt[1], Martin Borggrefe[1], Michiel J. Janse[2]. *[1]Department of Cardiology and Institute of Arteriosclerosis Research, University of Münster, Germany; [2]Department of Experimental Cardiology, Academic Medical Center, Amsterdam; [3]the Interuniversity Cardiology Institute of the NetherlandsAmsterdam, Netherlands*

During atrioventricular (AV) nodal reentry, reentrant excitation is supposed to involve 2 functionally distinct pathways. Since direct mapping of nodal extracellular electrograms could not yet be performed, controversy continues regarding the mechanism and the site of reentry.

Methods: In 8 isolated, blood perfused dog hearts, the endocardium overlying the AV node was carefully resected until AV nodal extracellular signals could be identified with a roving electrode. A 247-terminal electrode (19 × 13) with an interelectrode distance of 0.3 mm, was used to map AV nodal activation during programmed atrial extrastimulation.

Results: Antegrade functioning of the AV node did not change significantly after endocardial resection. In 4 hearts, electrical activation of the AV node revealed functional dissociation. As illustrated, after a shortly coupled atrial extra-stimulus (right panel, S_1S_2 190 ms), block occurred in the anterior area and activity reached the His bundle via the posterior area. The anterior area was then activated retrogradely. However, antegrade conduction delay was never sufficient to allow complete recovery of the anterior area and the occurrence of an atrial echo.



Conclusions: Functional dissociation of the canine AV node in response to premature atrial stimulation gives rise to conduction block in the anterior area and retrograde activation of this area. This can be the substrate for AV nodal reentry.

3123 ATP test: a bedside diagnostic-tool for identifying patients with palpitations who are likely to benefit from electrophysiologic evaluation

S. Viskin, R. Fish, A. Glick, M. Glikson[1], M. Eldar[1], B. Belhassen. *Cardiology Dept., Sourasky – Tel Aviv Medical Center, Tel Aviv; [1]Cardiology Dept., Sheba Medical Center, Tel Hashomer, Israel*

Patients with atrioventricular nodal reentry tachycardia (AVNRT) or AV reentry tachycardia (AVRT) are generally referred for electrophysiologic studies (EPS) because these arrhythmias are curable with radiofrequency ablation. However, AVNRT and AVRT are often short-lasting arrhythmias that elude clinical diagnosis. We showed that administration of adenosine triphosphate (ATP) during sinus rhythm may expose dual AV node physiology (DAVNP) [Circulation 1998; 98: 47]. Also, some data suggest that ATP may unmask a concealed accessory pathway (AP). Thus, we used our "ATP test" to identify AVNRT or AVRT among patients with "palpitations of unclear etiology."

Patients with palpitations were included if: 1) Their history suggested a paroxysmal supraventricular tachycardia, but spontaneous arrhythmias could not be documented. 2) Arrhythmias had been documented (mainly on single-lead recordings) but their mechanism remained unclear. Patients with antegradely conducting AP were excluded.

ATP was given intravenously during sinus rhythm using 10 mg increments. The ATP test was "positive" when signs of DAVNP (a PR "jump" of $^{3}50$ msec in consecutive sinus beats) or concealed AP (induction of AVR echo beats) were disclosed. The ATP test was "negative" when ^{3}IIo AV block without "PR jump" or AVR echoes ensued. These results were correlated with the results of a subsequent EP evaluation.

Sixty six patients were studied (20 with "palpitations but no documented arrhythmias" and 44 with "arrhythmias of unclear mechanism"). A positive ATP test predicted the presence of AVNRT or AVRT with a positive predictive value of 93% (sensitivity = 72%) but a negative predictive value of 29% (specificity = 67%).

A "positive ATP test" is highly predictable of AVNRT or AVRT. This bedside test may be used to select patients with palpitations who will benefit from early referral to EPS.

3124 The slow pathway potential (A_{SP}) indicates the activation of an anatomical input to the atrioventricular node

Hein Heidbüchel, Rik Willems, Jef Adams, Stefan Foulon, Hubert Goethals, Hans Wittockx, Hugo Ector, Frans Van de Werf. *Cardiology, University of Leuven, Leuven, Belgium*

Background: Although the so-called "slow pathway potential" or A_{SP} is often used as target for ablation of AVNRT, it is still a matter of debate in how far this potential represents indeed the activation of a discrete anatomical pathway, or is the functional result of the nonuniform anisotropic conduction properties of the posterior AV nodal inputs. We postulated that if functional properties would determine the A_{SP} morphology, it would depend on the direction of the activation wavefront.

Methods: We recorded A_{SP} during sinus rhythm (SR) and pacing at 3 atrial sites in 33 pts with Slow/Fast AVNRT (28 women; 39 ± 12 y). Pacing was performed from the atrial appendage (RAA), proximal coronary sinus (CS) and dorso-septal right atrium (800 ms). The stability of the A_{SP} was confirmed by comparing its morphology during intermittent SR. Power-controlled RF delivery was directed at the A_{SP} site (20–25 W).

Results: Measurements were not possible in 7 pts due to instability of the Asp recording catheter or absence of a clear A_{SP} potential. In 18 of the 26 remaining pts (69%), the Asp morphology was identical or highly similar during pacing from the different positions, with clear variations in the relative timing of the first (presumably) atrial deflection and the A_{SP} potential. In 8 pts, A_{SP} was different during pacing from at least 1 position. The median number of RF applications for ablation of the slow pathway was 1 respectively 2 in both groups (2.1 ± 2.0 vs. 1.9 ± 0.6: NS).

Conclusion: A similar A_{SP} morphology in the majority of pts indicates that it is not (or not always) generated by functional conduction properties (e.g. nonuniform anisotropy) but that the posterior input to the AV node is entered via the same anatomical corridor. Moreover, since the A_{SP} site results in ablation of AVNRT, the A_{SP} electogram must be due to activation of the reentrant circuit (i.e. AV node extensions or the atrial posterior input), and the small preceding deflection due to far-field atrial potentials or to activation of overlying isolated atrial tissue. Both are generated separately.

3125 Atypical patterns of re-entry in patients with atrioventricular nodal tachycardia

G. Senatore, F. Ouyang, N. Paparella[1], M. Schlüter, P. Alboni[1], K.-H. Kuck, R. Cappato. *AK St. Georg, Hamburg, Germany; [1]Osp. Civile Cento, Cento (Fe), Italy*

Similar or identical His-to-atrium (H-A) intervals during tachycardia (T) and ventricular (V) pacing (P) at the T cycle length (H-AP) ([H-AT]-[H-AP] ~ 0) are suggestive of a lower reentrant circuit turn-around located in close proximity to the proximal His bundle and account for most patterns observed in the typical slow/fast [s/f] form of AVNRT.

Methods: Out of 219 pts with AVNRT, we investigated the [H-AT]-[H-AP] in 29 (13%) pts presenting with an atypical AVNRT. The H-AT was defined as negative if the first retrograde A activation at time of T induction preceded the H deflection of the first T QRS complex.

Results: Seven pts presented with a f/s, 8 with a s/s, 8 with a f/s and a s/f, 3 with a s/s and s/f, and 1 with a s/s, f/s and s/f form; in 2 more pts, retrograde s pathway (p) emerged at the anterior input to the AV node. At time of T induction, the H-AT was negative (−83 ± −28 ms) in 9 and positive (173 ± 76 ms) in 20 pts. H-AP matching retrograde A conduction through the s p as during T were available in all 9 pts of the former and in 13 pts of the latter group. The [H-AT]-[H-AP] was 249 ± 93 ms in pts with negative H-AT and 100 ± 55 ms in pts with positive H-AT at time of T induction. Ablation was achieved in all pts with 2 (range, 1–17) RF pulses delivered at the posteroseptal-to-midseptal A-tricuspid region.

Conclusions: Atypical AVNRT: 1) accounts for ~10% of all AVNRTs referred for RF ablation; 2) is related to a retrograde s p emerging at the posterior and anterior AV nodal input in ~90% and ~10% of cases, respectively; 3) is associated with antegrade f p conduction in ~50% and s p conduction in ~50% of cases. During retrograde s p conduction, H-AT invariably shorter than H-AP are suggestive of a lower turn-around of the reentrant circuit away from the entrance of the compact node into the His bundle.

3126 Site of recording of the His potential in relation to the angiographic triangle of Koch in patients with atrioventricular nodal re-entry tachycardia

J.M. Rubio, J. Farré, C. Chaves, J.A. Cabrera, I. Fernandez-Rozas. *Cardiology Dept, Fundacion Jiménez Diaz, Madrid, Spain*

In a series of 37 consecutive patients (Pts) with AV nodal reentry tachycardia in whom a right atrial angiogram (RA-angio) was performed to disclose the angiographic boundaries of the triangle of Koch (TK), we have measured the amplitude of the atrial (A), ventricular (V) and His bundle (H) electrograms recorded near the anterosuperior vertex of the TK in relation to the distance between the tip of the His bundle catheter (Hbcath) an the angiogaphic margin of the tricuspid valve. Care was taken to place the HBcath at the site of recording of the largest possible H potential. Six Pts were excluded because the H-V interval was <36 ms. Intracardiac recordings obtained at the time of performing RA-angio were filtered between 30–500 Hz. The distance between the tip of the HBcath and the anterosuperior vertex of the TK (as defined with RA-angio) was 2.5 ± 6.9 mm (from +19 mm to −10 mm; negative values were those obtained when the tip of the HBcath was beyond the angiographic limit of the tricuspid valve). Patients were divided into 3 groups (Gr) according to the relation between the tip of the HBcath: Gr A (8 Pts [26%]) with a distance H-vertex of the TK more negative than −2 mm; Gr B (9 Pts [29%]) with an H-vertex of 0 ± 2 mm; Gr C(14 Pts [45%]) with an H-vertex > +2 mm. There was no relation between the site of recording of the His potential and the site of successful ablation of the slow pathway within the triangle of Koch. In no instance ablation resulted in unwanted transient or permanent AV block.

Electrograms in relation to the the TK

Gr	H-vertex mm	A mV	H mV	V mV	H-V ms
A	−4.8 ± 3	0.33 ± 0.25	0.38 ± 0.23	2.4 ± 0.9	47 ± 7
B	0.2 ± 0.9	0.30 ± 0.30	0.15 ± 0.05	2.1 ± 1.0	44 ± 5
C	8.3 ± 5.5	1.10 ± 1.0	0.29 ± 0.16	1.4 ± 0.9	49 ± 6

Gr C had significantly larger A and smaller V than the other 2 Grs.

Conclusions: the relations between the angiographic TK (as defined with RA-angio) and the A-V conduction system (as defined by the HBcath) show a wide variation in Pts with AVNRT. The HBcath is a better marker to avoid unwanted AV nodal-His ablation than the angiographic definition of the triangle of Koch.

ATRIAL AND ATRIOVENTRICULAR NODAL REMODELLING

3127 Right atrial appendage monophasic action potentials for assessment of atrial electrical remodelling in patients with successfully cardioverted chronic atrial fibrillation

E.G. Manios, E.M. Kanoupakis, M.D. Kaleboubas, M.K. Zeaki, H.E. Mavrakis, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

Aim: Conventional electrophysiological studies (EPS) have shown that rapid atrial depolarization rates result in changes of the electrical properties of the atrium. In this study we used repeated monophasic action potential (MAP) recordings in order to assess the changes in atrial electrical behavior in successfully cardioverted chronic atrial fibrillation patients.

Methods: Consecutive chronic atrial fibrillation patients were studied after successful intracardiac low energy conversion to sinus rhythm. Antiarrhythmic drugs were stopped for at least five half lives before procedure. All patients underwent two consecutive electrophysiological studies, the first within fifteen minutes after conversion, and the second 24 hours later. A special catheter, capable of simultaneous pacing and MAP recording, was advanced to within the right atrial appendage and stabilized in a position where it was possible to record satisfactory MAPs and to stimulate the atrium at a low diastolic threshold. Atrial effective refractory period at a basic cycle length of 500 ms and the duration of MAP recordings until 90% of repolarization (MAPd90) were evaluated after one minute of continuous pacing at five separate cycle lengths (600, 500, 450, 400, 350 ms).

Results: Satisfactory MAP recordings were possible in nine out of eleven patients (mean age 68 ± 9, six male) who were initially recruited. The values of the parameters measured in the two studies are given in the table below. All values are expressed as mean ± SD. MAPd90 differed significantly only between the two measurements marked by an asterisk (*).

	A-ERP	MAPd90	MAPd90	MAPd90	MAPd90	MAPd90	p
	500	600	500	450	400	350	
0 h	202 ± 15	232 ± 30*	228 ± 22	224 ± 21	215 ± 20	206 ± 21*	0.03*
24 h	250 ± 26	272 ± 34	274 ± 41	268 ± 29	250 ± 17	243 ± 16	0.26
p	<0.001	0.054	0.132	0.049	0.008	0.004	

Conclusions: These results suggest that MAP duration, similarly to atrial ERP, increases with time after the electrical conversion of chronic atrial fibrillation to sinus rhythm. In contrast, normal adaptation of MAP duration to cycle length was not confirmed.

3128 Is acute "reversed" atrial remodelling a transient phenomenon in man?

P. Spurrell, K. Kamalvand, A. Topham, S. Bland, M. Higson, N. Sulke. *Dept of Cardiology, Eastbourne, United Kingdom Hospital*

Aim: The Atrial Effective Refractory Period (ERP) shortens following episodes of AF (remodelling). The temporal changes in the ERP following DC Cardioversion in patients with persistent AF is unknown.

Methods: The atrial ERP was measured at two sites, the mid lateral right atrium (MLRA) and the right atrial appendage (RAA), at cycle lengths of 600 and 400 ms immediately, 24 hours and 2 weeks post DC Cardioversion. 34 patients (pts) (mean age 67 (SD 9), 57% male) were enrolled. All pts had persistent AF for >1 month prior to cardioversion. All cardioactive drugs were stopped 5 half lives prior to the study.

Results: 32 pts were in SR at 24 hrs and 14 pts in SR at 2 weeks. *24 hrs:* Post cardioversion the ERP was significantly shorter at the RAA site for both cycle lengths when compared to the MLRA ($p < 0.03$). A significant increase in ERP occurred at both atrial sites and cycle lengths from 0 hrs to 24 hrs ($p < 0.0001$). Despite this increase, the RAA ERP remained significantly shorter than the MLRA at 24 hrs ($p < 0.03$).

Site	0 hr	24 hrs	Site	0 hr	24 hrs
RAA600	211 (25)	254 (31)	MLRA600	225 (28)	275 (40)
RAA400	208 (25)	242 (30)	MLRA400	219 (34)	256 (43)

2 weeks: There was a significant rise in ERP at both sites and cycle lengths between 0 and 24 hrs. A significant fall in ERP occurred between 24 hrs and 2 weeks at RAA (600 & 400 ms) and MLRA 600 ms ($P < 0.01$)

	0 hr	24 hrs	2 week
RAA600	214 (21)	256 (40)	221 (43)
RAA400	211 (23)	249 (46)	217 (36)
MLRA600	226 (38)	280 (44)	235 (31)
MLRA400	230 (50)	265 (46)	242 (36)

There was no significant difference in ERP at 0 hrs or 24 hrs between pts who then reverted to AF and those in SR at 2 weeks.

Conclusions: 1) A significant increase in ERP occurs from 0 to 24 hrs post Cardioversion. **2)** The significant difference in refractoriness between the RAA and MLRA persists to 24 hrs. **3)** The change in ERP does not predict post shock duration of SR. **4)** Pts still in SR at 2 weeks show a significant fall in ERP from 24 hr values back to immediate post cardioversion levels. This data suggests that acute 'reversed' remodelling is transient in man.

3129 Atrial electrical remodelling due to dilatation or rapid pacing is diminished by verapamil, but not by glibenclamid or cariporide, in Langendorff-perfused rabbit hearts

M. Zarse, E. Athanatou, C. Stellbrink, P. Hanrath. *Department of Cardiology/Internal Medicine University of Technology, Aachen, Germany*

Atrial dilatation (AD) and rapid pacing (RP) cause electrical remodeling (ER) by reducing atrial effective refractory periods (AERPs). We investigated the effects of Verapamil (Ve), a blocker of the L-type Ca^{2+}-channel (LTCC), Glibenclamid (Gli), a blocker of the ATP-dependent K^+-channel (K^+_{ATP}), and Cariporide (Car), a Na^+/H^+-channel blocker on ER due to AD and RP in a rabbit Langendorff-model of sustained atrial fibrillation (SAF). In 20 hearts basal (b) AERPs were measured under stepwise increase in IAP [cm H_2O] up to 20 cm H_2O. Episodes of (SAF) defined as lasting >10 minutes, were protocolled. After deflation AERPs were measured every 2 minutes for 10 minutes of RP [20 Hz/min]. Then Ve [0.5 mg/l] (n = 7), Gli [0.05 mg/l] (n = 7), or Cariporide [0.3 mg/l] (n = 6) were added to the perfusate and the protocol was repeated.

Results:

cm H_2O	0	6	10	Pre RP	P 4 min	P 10 min
AERP b	83 ± 9	72 ± 15	61 ± 12*	84 ± 9	65 ± 9	54 ± 8*
AERP Ve	69 ± 12#	73 ± 13	79 ± 18+	84 ± 7	79 ± 9	72 ± 15
AERP Gli	89 ± 10	77 ± 4	66 ± 13*	82 ± 10	64 ± 11	60 ± 13*
AERP Car	88 ± 10	79 ± 8	66 ± 7*	81 ± 6	65 ± 3	59 ± 7*

*$p < 0.01$ compared to 0 cm H_2O and pre RP, respectively; #$p < 0.01$, +$p < 0.05$ compared to b, all parameters in ms

ER occurs both after AD and RP. Ve significantly shortens AERP at 0 cm H_2O. However, Ve abolishes ER after AD and significantly reduces it after RP. After Gli and Car, ER both due to RP or AD is not significantly altered. Ve prevented the induction of SAF in all hearts, Gli and Car did not prevent SAF in any heart.

Conclusions: The Langendorff-perfused rabbit heart shows ER both due to RP and AD to a similar extent. LTCC seems to play a crucial role in the process of ER both due to AD and RP, suggesting similar pathophysiological mechanisms. K^+_{ATP} and Na^+/H^+-channel did not influence ER, suggesting that ischemia and acidosis do not play a substantial role in either form of ER in this model.

3130 Electrophysiological remodelling of the atria after internal cardioversion of atrial fibrillation

T. Korte, M. Niehaus, G. Borchert, O. Meyer, J. Tebbenjohanns. *Cardiology Dept, Hannover Medical School, Hannover, Germany*

Early recurrence of atrial fibrillation after internal cardioversion (IC) remains an unsolved problem of the implantable atrioverter. Electrophysiological remodelling of the atria (LA/RA) after IC of chronic (cAF) and intermittent AF (iAF) (AF-duration < 24 h) has not been studied. After IC of cAF in 15 patients (Pt) (AF duration: 64 ± 50 months, LA: 45 ± 5 mm) and iAF (LA: 37 ± 6 mm) in 15 Pt continuous registration and computer analysis of the duration of monophasic action potentials at 90% repolarisation (APD90) in the right atrial appendage was performed and interatrial conduction times (CT) between high RA and coronary sinus (CS) in sinus rhythm (SR) and during stimulation with a cycle length (CL) of 500 ms were measured during a time period of 20 min.

Results: APD90 was prolonged by a mean of 52 ± 30 ms. There was significantly more APD90 prolongation in minute 0–3 with 46 ± 21 ms as compared to minute 3–20 with 10 ± 9 ms ($p < 0.05$). Interatrial CT did not significantly change. APD90 and CT were not significantly different in the 11 Pt (37%) with 3 ± 2 AF recurrences after 3 ± 2 min and comparing Pt with cAF and iAF ($p > 0.05$).

APD90 and CT (ms)

	0 min	1 min	3 min	10 min	20 min
APD90/SR	161 ± 20	199 ± 35	210 ± 32	215 ± 31	213 ± 34
CT/RA– > CS/SR	98 ± 30	81 ± 22	91 ± 26	86 ± 25	98 ± 30
CT/RA– > CS/500		142 ± 35	131 ± 16	130 ± 50	135 ± 21
CT/CS– > RA/500		136 ± 15	135 ± 10	133 ± 19	138 ± 10

Conclusions: (1) There is a significant prolongation of atrial monophasic action potential duration in minute 0–3 after internal cardioversion regardless of AF duration and atrial size. (2) The prolongation of atrial action potentials does not significantly differ between Pt with and without recurrence of atrial fibrillation in the first minutes after internal cardioversion.

3131 Electrical remodelling of atrioventricular conduction in patients with chronic atrial fibrillation

E.G. Manios, E.M. Kanoupakis, M.D. Kaleboubas, M.K. Zeaki, H.E. Mavrakis, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

Aim: Long periods of very rapid atrial depolarizations probably affect the electrical properties of atrioventricular conductive tissue. In this study we looked for such effects of chronic atrial fibrillation on the atrioventricular node (AVN) and the His bundle.

Methods: Fourteen consecutive patients with chronic atrial fibrillation (>3 months duration) electrically converted to sinus rhythm were studied. Their mean age was 67 ± 7 years and nine were male. All were free of antiarrhythmic drugs for at least five half lives. They underwent two electrophysiological studies, the first immediately after conversion, and the second 24 hours later. Basic intervals (AH, HV), right atrial effective refractory period (A-ERP), AVN functional refractory period at a basic cycle length of 500 ms (AVN-FRP) and the Wenckebach point (WP) were evaluated.

Results: The values of the parameters measured in the two studies are given in the table below.All values are expressed in ms and are represented as mean ± SD.

	AH	HV	A-ERP	AVN-FRP	WP
0 h	112 ± 44	49 ± 5.7	202 ± 15	386 ± 78	431 ± 76
24 h	108+46	50+6	250 ± 26	345 ± 92	401 ± 75
p	NS	NS	<0.001	<0.05	<0.05

Conclusion: Electrical remodeling resulting from chronic atrial fibrillation also affects the atrioventricular node, apart from atrial tissue. These changes subside significantly within the first 24 h after conversion to sinus rhythm.

NEW POTASSIUM CHANNEL BLOCKERS

3132 Dose response for azimilide treatment of paroxysmal supraventricular tachycardia

R.L. Page, S.J. Connolly[1], S.R. Marcello[2], D.J. Schnell[2], W.E. Wilkinson[3], E.L.C. Pritchett[4]. *Internal Medicine Dept., University of Texas Southwestern, Dallas TX, USA; [1]Department of Medicine, McMaster University, Hamilton ON, Canada; [2]Procter & Gamble Pharmaceuticals, Cincinnati OH; [3]Dept. of Community and Family Medicine, Duke University Medical Center, Durham NC; [4]Department of Medicine, Duke University Medical Center, Durham NC, USA*

Azimilide (AZ) is an investigational class III antiarrhythmic agent the effect of which on paroxysmal supraventricular tachycardia (PSVT) has not previously been reported. In three randomized, placebo-controlled, double-blind trials, patients with symptomatic PSVT received 35, 75 or 100 mg AZ. The studies were identical in design, except for the duration of follow-up (180–270 days) and the dosage. AZ was dosed generally as an outpatient, twice a day for 3 days (loading phase), and then once per day. In each study the primary outcome variable was the first symptomatic recurrence of supraventricular arrhythmia after completion of the loading phase, as documented using transtelephonic ECG monitoring. Efficacy data from all 3 trials were tested for a trend across doses using a log-rank trend test with placebo = 0 mg and all 3 AZ doses. Data were stratified by trial to control for variation in placebo group event rates. Recurrent arrhythmias were defined by recording trans-telephonic ECG.

Results: A total of 133 patients were enrolled (65% female), aged 58 ± 14.9, with 50 receiving placebo (P) and 83 receiving AZ. Heart failure was present in 8% and coronary artery disease in 23%. The log-rank trend test was statistically significant with chi-square = 6.53 and p = 0.01. There were no cases of torsades de pointes. Thus, AZ showed a positive dose-response relationship over the dose range tested. The 100 mg dose demonstrated a clinically important treatment effect with hazard ratio (placebo:azimilide) of 2.35 (CI 1.18, 4.68) and p = 0.015.

Conclusions: AZ demonstrates a dose-response relationship over the dose range of 35–100 mg daily in patients with symptomatic PSVT. The 100 mg daily dose has both statistically significant and clinically important antiarrhythmic effects.

3133 Dofetilide reduces hospitalisations in patients with atrial fibrillation or flutter and left ventricular dysfunction: a DIAMOND sub-analysis

O. Dyg Pedersen. *On behalf of the DIAMOND Study Group, KAS Gentofte Hospital, Hellerup, Denmark*

Patients (pts) with left ventricular (LV) dysfunction and co-existing atrial fibrillation or flutter (AF/AFl) may suffer substantial morbidity due to impaired haemodynamic function. Dofetilide (D), a class III antiarrhythmic agent, has been shown to be effective in the restoration and maintenance of sinus rhythm (SR). In this DIAMOND (Danish Investigations of Arrhythmia and Mortality ON Dofetilide) sub-analysis of the pre-defined endpoint of hospitalisation with worsening congestive heart failure (CHF), the effect of D therapy on subsequent hospitalisation was assessed in the 506 pts with AF/AFl at baseline. All pts had LV dysfunction (equivalent to left ventricular ejection fraction ≤ 35%).

Methods: Pts were randomly assigned to 250 μg bid D (n = 249) or placebo (Pl) (n = 257) with D subsequently adjusted based on creatinine clearance and QTc interval. Over the course of the study, SR was pharmacologically restored in 112 D (45%) and 35 Pl (14%) pts and electrically restored in 36 D (15%) and 51 Pl (20%) pts. Time to hospitalisation was assessed during the follow up period of 12–42 months.

Results: Both first hospitalisation due to CHF (risk reduction 0.69; p = 0.014) and first hospitalization for all-causes (risk reduction 0.70; p = 0.004) were significantly reduced on D compared with Pl therapy. There was no difference in the number of pts with non-heart failure related first hospitalisations.

Pts hospitalized for CHF N (%)		Pts hospitalized for non-CHF N (%)		Pts hospitalized for All Cause N (%)	
D (n = 249)	Pl (n = 257)	D (n = 249)	Pl (n = 257)	D (n = 249)	Pl (n = 257)
73 (29.3%)	102 (40.0%)	52 (20.9%)	54 (21.0%)	125 (50.2%)	156 (60.7%)

Conclusion: In pts with AF/AFl and LV dysfunction, D therapy significantly reduced the requirement for hospitalisation mediated by an improvement in CHF.

3134 The effect of dofetilide on pharmacodynamics of warfarin and pharmacokinetics of digoxin

Donald J. Nichols, Isobel Dalrymple, Margaret W. Newgreen, Diane Kleinermans. *Pfizer Central Research, Sandwich, Kent, UK; Brussels, Belgium*

Dofetilide (D) is a novel class III antiarrhythmic agent effective in treating a broad range of supraventricular tachyarrhythmias, including atrial fibrillation (AF) and atrial flutter (AFl). Warfarin (W) and digoxin (DIG) are drugs commonly used in the treatment of patients with AF/AFl. This study was performed to assess whether steady-state D treatment altered the pharmacodynamics of W or the pharmacokinetics of DIG.

Fourteen healthy men were randomly assigned to treatment with either D 750 mcg bid or placebo (P) in a two-way crossover design study with a washout period of ≥1 week. A single dose of W 40 mg was administered 2 hours after D or P on day 5 of an 8-day treatment period. Prothrombin time (PT) was measured at specified intervals to 96 hours. Compared with P, D did not significantly affect PT (D-P 0.04 sec; p = 0.69) or the area under the PT time curve (AUECt) [D-P = 13 sec•h; p = 0.78].

After a one-week washout period, 13 men received 250 mcg DIG daily (following loading doses of 1000 mcg on day 1 and 500 mcg on day 2). Serial measurements of plasma DIG concentration were evaluated for C_{trough}, C_{max}, T_{max}, AUC_{0-24}, and renal clearance on day 7. On day 8, subjects were randomly assigned to concomitant treatment with 250 mcg bid D (n = 8) or P (n = 5). DIG pharmacokinetic measurements were repeated on day 12 and compared with the baseline values. Compared with P, D did not affect C_{trough} (D-P = −0.02 nmol/l; p = 0.71), C_{max} (D-P = 0.0 nmol/l; p = 0.97), T_{max} (D-P = −0.7 hours; p = 0.06), AUC_{0-24} (D-P = 0.0 nmol•h/l; p = 0.99), or the renal clearance (D-P = −25 ml/min; p = 0.30) of DIG.

Conclusion: D does not significantly affect the pharmacodynamics of W or the pharmacokinetics of DIG, medications which are commonly prescribed in patients with AF/AFl.

3135 Pharmacokinetics and pharmacodynamics of dofetilide: daily versus intermittent dosing

Donald J. Nichols, Lynn Purkins, Margaret W. Newgreen, Michael J. Allen. *Pfizer Central Research, Sandwich, UK*

This randomized, single-blind, placebo-controlled, parallel-group study assessed the pharmacokinetics (PK) and dynamics (PD) of dofetilide (D). D (1 mg) was given bid for 24 days (daily) or as a single AM dose on days 1, 5, 10, 17 and 24 (int). Daily D resulted in initially rising plasma concentrations (conc.) with peak and steady-state conc. achieved by day 5. PK parameters were unaffected by int D and consistent with low inter- and intra-subject variability.

		Day 1	Day 5	Day 10	Day 17	Day 24
C_{max} ng/mL	Daily	4.79	7.10	6.93	7.08	6.99
	Int	4.61	4.74	4.48	4.69	5.01

Mean renal clearance was stable whether dosing was daily or int. Daily D resulted in increasing prolongation of the QTc interval for the first 2 days with no further increase despite increasing plasma D conc. This attenuation of QTc response stabilized after day 5 up to day 24, as represented by the change in slope of the plasma conc. versus change in QTc from baseline (Δ Slope of PK-PD effect). Int D dosing resulted in consistent changes in the QTc prolongation each time the drug was given.

		B/L	Day 1	Day 2	Day 3	Day 4	Day 5	Day 10	Day 17	Day 24
QTc Max	Daily	373	443	453	450	445	440	441	446	442
(msec)	Int	387	472	406	397	396	467	467	469	458
Δ Slope of	Daily						−5.15	−5.59	−5.38	−5.80
PK-PD	Int						−0.76	−0.69	−0.22	−1.40

In conclusion, this study demonstrates that D has predictable PK and PD when administered daily. The QTc interval prolongs for the first 2 days in response to increasing plasma conc. Thereafter, the QTc response to D is attenuated up to day 5 and does not progress further after day 5 up to day 24. QTc interval should be carefully monitored for the initial 3 days of D therapy.

3136 After one year treatment on dofetilide patients with longer post-cardioversion QT (QTc) interval are more likely to remain in sinus rhythm

R. Lehman, R.A. Greenbaum[1], T.J. Campbell[2], K.S. Channer[3], J.H. Kingma[4], M. Santini[5], K. Theisen[6], L.K. Toivonen[7], H.W. Dalrymple[8]. *For the EMERALD investigators; Ashford Cardiac Clinic, Ashford NSW; [2]St Vincent's Hospital, Darlinghurst NSW, Australia; [1]Edgware General Hospital, Edgware; [3] Royal Hallamshire Hospital, Sheffield; [8]Pfizer Central Research, Sandwich, UK; [4]St Antonius Ziekenhuis, Nieuwegein, Netherlands; [5]Ospedale S Filippo Neri, Rome, Italy; [6]Klinikum Innenstadt, Munich, Germany; [7]HUCH/Meilahti Hospital, Helsinki, Finland*

Dofetilide (D) is a new pure class III antiarrhythmic agent with a linear relationship between dose and QT interval. The relationship between QT interval and clinical efficacy has not been established for class III drugs.

Methods: EMERALD (European and Australian Multicenter Evaluative Research on Atrial Fibrillation – Dofetilide) assessed the efficacy and dose relationship of oral dofetilide (D) [125, 250, 500 mcg bid] and placebo (P), in 534 patients (pts) with atrial fibrillation (AF) in a double blind parallel group design. Patients with a QT interval > 500 msec or an increase over 20% from baseline after the first oral dose were excluded from the study.

Results: By day 3, 431 pts (81%) regained sinus rhythm (SR), pharmacologically or by DC conversion. D cardioverted significantly more pts (up to 29%) in a dose-dependent manner than P (<1%, $p < 0.05$ at all dose levels). At 3, 6, and 12 months, all doses of D maintained significantly more pts in SR than P ($p < 0.05$ at each time point). D was effective in converting patients with AF and maintaining up to 71% in SR at 6 months.

The post-cardioversion QT interval correlated linearly with the efficacy of D in maintaining SR after 12 months ($p = 0.04$). Patients with a QT interval after conversion > 425 msec had a 31% higher chance of staying in SR, compared to patients with a shorter QT.

In conclusion, the efficacy of D to maintain sinus rhythm after conversion of atrial fibrillation was related to the degree of QT prolongation by D.

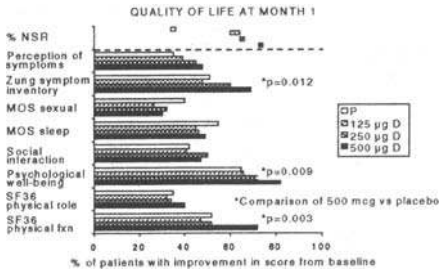
3137 Dofetilide improves quality of life

R.A. Greenbaum, T.J. Campbell[1], K.S. Channer[2], J.H. Kingma[3], M. Santini[4], K. Theisen[5], L.K. Toivonen[6], H.W. Dalrymple[7]. *For the EMERALD investigators; Edgware General Hospital, Edgware; [2]Royal Hallamshire Hospital, Sheffield; [7]Pfizer Central Research, Sandwich, UK; [1]St Vincent's Hospital, Darlinghurst NSW, Australia; [3]St Antonius Ziekenhuis, Nieuwegein, Netherlands; [4]Ospedale S Filippo Neri, Rome, Italy; [5]Klinikum Innenstadt, Munich, Germany; [6]HUCH/Meilahti Hospital, Helsinki, Finland*

Quality of life (QOL) is significantly reduced in patients (pts) with atrial fibrillation or flutter (AF/AFl). The extent to which treatment of AF/AFl improves QOL depends on the effectiveness of the treatment and the side effects of the agents used. Dofetilide (D), a new class III agent has proven effective in the restoration and maintenance of sinus rhythm in pts with AF/AFl. The EMERALD (European And Australian Multicenter Evaluative Research on Atrial Fibrillation and Dofetilide) study was performed to assess the effect of D therapy on QOL.

Methods: Pts with AF/AFl were randomised to twice daily doses of 125 μg D (129 pts), 250 μg D (133 pts), 500 μg D (135 pts), or placebo (P) (137 pts) in a double-blind trial. QOL was assessed at baseline and at 1 month, independent of rhythm status, using MOS Short Form-36 (SF-36) physical function scale; SF-36 physical role limitation scale; Psychological General Well-Being Index; SQOLB Social Interaction Scale; MOS Sleep Evaluation Scale; MOS Sexual Functioning Scale; Zung Symptom Inventory.

Results: Symptom perception was assessed using a numerical scale. Compared to P, D resulted in significantly more patients with improvement in the SF-36 physical function scale, psychological well-being score, and the Zung symptom inventory. A dose response in improvement was also demonstrated for these instruments.



Conclusion: D significantly improves QOL in pts with AF/AFl.

3150 The ACE I/D polymorphism and mortality: a population-based study

T.A. McDonagh, A.D. Cunningham, F. Cambien[1], H.J. Dargie. *Cardiology Department, the Western Infirmary; the MRC CRI in Heart Failure, University of Glasgow, UK; [1]INSERM, Paris, France*

A previous report has suggested an association between the DD genotype of the ACE I/D polymorphism and an increased mortality rate in patients with chronic heart failure. To date, there is no epidemiological work looking at the effect of the ACE I/D polymorphism on mortality in the general population. We report on the association between the ACE I/D polymorphism and all cause mortality in a random sample of 1640 men and women aged 25–74 from a geographical urban population.

1640 attendees were studied in 1992/3. Left ventricular function was assessed by a left ventricular ejection fraction (LVEF) using the apical Biplane Simpson's Rule Method. A LVEF $\leq$ 30% was taken as significant systolic dysfunction (LVD). Ischaemic heart disease (IHD) as defined as a previous history of myocardial infarction or angina, use of nitrate drugs or the presence of a q wave or major ischaemia on the ECG. The ACE I/D polymorphism was determined according to the method of Rigat. The analysis below refers to all cause mortality at 4 years of follow up.

24% (322) of subjects were II, 48% (651) ID and 28% (385) of the DD genotype. These are in Hardy-Weinberg equilibrium. The 4 year all cause mortality rate in the whole cohort was 4.9% (80 deaths). DNA was available for analysis in 63 of these subjects.

Genotype	4 yr. mortality %	(n)	
II	3.1%	10	
ID	4.4%	29	p = 0.0.005 (II vs DD)
DD	6.2%	24	

A trend also existed for the DD polymorphism carrying a higher mortality rate in subjects with IHD (DD-12.4% vs II 7.8%) and in those with LVD (II 3% vs DD 25%). These were not statistically significant, most probably due to the small numbers of deaths.

We have demonstrated a significant association between homozygosity for the D allele of the ACE I/D polymorphism and all cause mortality in the general population

3151 Haemostatic parameters disturbances in patients with essential hypertension: the effect of ACE gene polymorphism

Th. Makris, G. Stavroulakis, P. Krespi, A. Hatzizacharias, G. Anastasiadis, N. Hatzizacharias, C. Tsoukala, M. Kyriakidis. *Cardiology Dept., 2nd Reg. BTC, Haemost. Lab, LAIKON Hospital and Medical School, University of Athens, Greece*

The deletion (D) allele of the insertion/deletion (I/D) polymorphism of the angiotensin converting enzyme (ACE) gene has been implicated in the pathogenesis of a variety of cardiovascular disorders. This study examined the possible association of the ACE gene polymorphism with the fibrinogen (F), fibrinogen degradation products (FDP), D-dimer and plasminogen activator inhibitor-1 (PAI-1) levels in untreated hypertensive patients (pts).

Methods: The I/D polymorphism of ACE gene was determined in 104 hypertensives aged 56 ± 12 yrs. Forty-two pts had DD genotype (Group A), 30 pts had ID genotype (Group B) and 32 pts had II genotype (Group C). The three groups are matched for age, sex and body mass index. The F, FDP, D-dimer and PAI-1 levels were determined (ELISA method) in the whole population.

Results: The results and the comparison between the three groups are shown below:

Parameters	Group A	Group B	Group C
Fibrinogen (mg/dl)	342 ± 54	295 ± 49	298 ± 33
FDP (NV < 250 ng/ml	429 ± 167.5	263 ± 38.7	262 ± 64
D-dimer (NV < 400 ng/ml)	371 ± 73.6	244 ± 85	233 ± 88
PAI-1 (IU/ml)	13 ± 8.8	9.13 ± 6.6	8.84 ± 3.2

F	A–B, $p < 0.001$	A–C, $p < 0.001$	B–C, p = NS
FDP	A–B, $p < 0.0001$	A–C, $p < 0.0001$	B–C, p = NS
D-dimer	A–B, $p < 0.0001$	A–C, $p < 0.0001$	B–C, p = NS
PAI-1	A–B, $p < 0.05$	A–C, $p < 0.01$	B–C, p = NS

Conclusions: Our findings suggest that the DD genotype of the ACE gene polymorphism is associated with significantly increased levels of F, FDP, D-Dimer and PAI-1 in pts with EH, supporting the idea that ACE gene polymorphism plays a crucial role in the haemostatic balance hypertensives.

3152 The 825T-allele at the B3-subunit gene of heterotrimeric G proteins enhances adrenaline-induced platelet aggregation requiring simultaneous activation of gaq by 3′5′adenosine-2-phosphate

C.K. Naber, D. Vietzke, D. Rosskopf, W. Siffert. *Pharmacology Dept., University Hospital Essen, Essen, Germany*

We have recently identified a C825T polymorphism at the gene GNB3, encoding for the beta3 subunit of heterotrimeric G proteins, which is associated with enhanced PTX-sensitive G protein signalling, hypertension, and myocardial infarction (MI). Since platelet aggregation is crucial in the development of MI and involves activation of various G proteins, it is likely, that the 825T-allele, enforces the platelet responses to agonist stimulation.

Methods: Platelet rich plasma was obtained from 37 healthy, male volunteers. Aggregatory responses and changes in intracellular Ca^{2+} (delta$[Ca^{2+}]_i$) were compared according to genotype at GNB3 after stimulation with adrenaline, vasopressin, and thrombin- and thromboxane receptor agonists, respectively. Additionally, 3′,5′adenosin-2-phosphate (ADP), which activates PTX-sensitive (Galphai), and -insensitive (Gaalphaqq) G proteins, was removed from the suspending medium, and replaced by serotonin, which selectively activates Galphaq.

Results: While the response to agonists requiring PTX-insensitive G proteins was not affected, upon adrenaline stimulation, which involves mainly PTX-sensitive G proteins, slope and maximum of the secondary aggregation was higher in 825T-allele carriers, being significant at 1 μM, 2 μM and 10 μM and 2 μM, respectively ($p < 0.05$). The overall response rate to adrenaline, regarding secondary aggregation was throughout higher in 825T-allele carriers($p < 0.05$). Adrenaline induced aggregation was inhibited after removal of extracellular ADP, and restituted after addition of serotonin.

Conclusions: The 825T-allele at GNB3 significantly enhances the response to adrenaline stimulation in human platelets by a mechanism requiring simultaneous activation of Gaq by ADP. These findings may in part explain the observed association of the 825T-allele with MI.

3153 Genetic variants of the human endothelial nitric oxide synthase and hypertension

T. Oethjeng, J. Erdmann[1], E. Fleck, V. Regitz-Zagrosek. *Internal Medicine/Cardiology, Charite, Virchow-Clinic, HU and DHZB, Berlin; [1]Internal Medicine/Cardiology, Berlin, Germany*

A missense mutation of the human eNOS gene (Glu-298-Asp) has been reported to be associated in Japanese patients with essential hypertension (OR = 2.4, CI 1.4–4.0). In addition, the pathophysiological role of promoter variants of the human eNOS gene are discussed.

Hence, this study was undertaken to investigate if there is a similiar association in Caucasian and to search for new genetic variants in the promoter region of the eNOS gene.

We genotyped the BanII polymorphism (Glu-298-Asp) of the eNOS gene in a sample of 207 hypertensive probands and 137 normotensive controls. The same probands were screened for mutations using a non-radioactive SSCP-analysis method.

There is no significant difference in allele frequencies between patients and controls for the BanII polymorphism (0.66/0.34 vs 0.69/0.31).

We identified two new polymorphic sites in the eNOS promoter. At position −739 we found a C to T exchange, which is not associated with hypertension in our sample (0.43/0.57 vs 0.40/0.60), in addition we identified at position −794 a C to T substitution in one hypertensive patient.

Our results do not support the hypothesis that the human eNOS gene contributes essential to the development of hypertension in our Caucasian sample. But it remains the possibility that a genetic variant which is not yet identified, and which is not in linkage disequilibrium with Glu-298-Asp is associated with hypertension in Caucasian. Differences in ethnic background can explain such divergent results.

3154 How selected are families of myocardial infarction survivors? Implications for genetic analysis

S. Engel, C. Hengstenberg[1], S. Holmer[1], H. Löwel[2]. *Coronary Event Registry, Central Hospital of Augsburg, Augsburg; [1]Internal Medicine II, University of Regensburg, Regensburg; [2]GSF – Insitute of Epidemiology, Oberschleißheim, Germany*

Family studies of myocardial infarction (MI) provide the basis to determine familial clustering of diseases and risk factors as a means for differentiating possible behavioural, environmental, and genetic causes and their interactions. Family structure, survival and emotional factors may influence recruitment of such families and may have great impact particularly on genetic analysis. The aim of this study was to examine the availability of family members (siblings) and the criteria for study participation in families recruited from a population-based MI registry (1985–95; 4,976 MIs plus 5,712 sudden cardiac deaths, age 25–75 years).

Methods: 1381 index probands (IPs) having experienced their incident transmural infarction prior to the age of 60 were selected and asked for participation in a family study and for information on survival and positive MI history of their first degree relatives. IPs and living siblings were invited for a standardized interview and an extensive cardiovascular examination.

Results: In 1996/7, 16.7% of the selected IPs were deceased. Of the remaining 1147 IPs, 15.6% had no brothers or sisters, 56% had ever had at least 1 natural sibling, 44% reported at least 1 living sib, and only 26% presented with at least 1 sib who participated in the study. Of these 536 siblings, only 31 were affected with prior MI. Survival of the IPs appeared to be determined by occurrence of anterior MI, diabetes mellitus and medication, but not by parental history of MI (deceased 26%, survivors 25%). IPs who had had a personal interview shortly after their incident MI were significantly more likely to participate in the family study than IPs without a personal interview. Participating IPs reported then significantly more often positive parental history than non-participating IPs (29% vs. 20%). 70% of the designated, non-participating siblings (n = 643) were deceased, located in distant area, or untraceable.

Conclusion: Due to high mortality and unfavourable family structures, only a small number of families can be recruited for a family study from a large MI registry. The actual study sample appears to be positively selected in terms of familial and genetic factors as a result of emotional determinants. For a study design such as an affected sib-pair study, recruitment of a sufficient number of families will depend on collaboration of multiple centers.

3155 The Acute Coronary Event DNA Library project: assesment of feasibility and demographics

N.P. Durham, R.K. Singh, B. Jackson, C. Morrell, J. Stribling, S. Coote, A.J. Balmforth, S.G. Ball, N.J. Samani, A.S. Hall. *Institute for Cardiovascular Research, Leeds General Infirmary, Leeds; Department of Cardiology, University of Leicester, Glenfield Hospital, Leicester, UK*

Background: The familial clustering of coronary artery disease (CAD) and acute myocardial infarction (AMI) have been recognised for some time.

Methods: We have initiated a linked marker approach to studying 2,500 sibling pairs affected prematurely with CAD before the age of 65 years, developing strategies for the identification of affected sibling pairs (ASP's) using hospital discharge coding databases, and local media in combination with a postal screening questionnaire. So far the two co-ordinating centres have identified 300 pairs of siblings affected by premature coronary artery disease (mean age 52 yr). DNA from ASP's is being extracted from whole blood and subjects screened with microsatellite markers (based on polymorphic di-/tri-/tetra-repeat sequences) spaced throughout the genome at an initial spacing of approximately 10 cM. Analysis of allele identity and frequency will then be undertaken using the 377 ABI PRISM Gene Scanner System and GENOTYPER software to seek regions of positive linkage.

Results: Demographic characteristics of the first 505 individuals to be identified are as follows: males 70%; females 30%, pairs 188, trios 20, myocardial infarction 65% (mean age of first event 51 yr), revascularisation 54%, angina 60%. *Historical evidence of risk factors:* current smoking 16%, ex-smoking 61%, type 1 diabetes 4%, type 2 diabetes 7%, hypertension 38%, dyslipidaemia 69%. *Parents:* no affected (CAD < 65 yr) parent 40%, one affected 48%, both parents affected 12%, one surviving parent 16%, two surviving parents 1%. *Siblings:* 1 or more dead affected sisters 8%, 1 or more dead affected brothers 23%.

Conclusions: We have demonstrated that it is possible to identify large numbers of affected sibling pairs through collaborative efforts. Furthermore, some of the demographic characteristics of individuals from families at increased risk of premature CAD have been described.

RISK FACTORS FOR CORONARY ARTERY DISEASE: NEW INSIGHTS

3166 Increased mortality over a 5-year follow-up in diabetics with coronary disease on combined metformin/sulphonylurea therapy

E.Z. Fisman, A. Tenenbaum, A. Benderly[1], U. Goldbourt[1], S. Behar[1], M. Motro. *Cardiac Rehabilitation Institute, Chaim Sheba Medical Center, Tel-Hashomer; [1]Bezafibrate Infarction Prevention Coordinating Center, Neufeld Cardiac Research Institute, Chaim Sheba Medical Center, Tel-Hashomer, Israel*

Purpose. Adverse cardiovascular effects were described for oral antidiabetic drugs. The relationship between different types of antihyperglycemic therapy and mortality rates in non insulin dependent diabetes mellitus (NIDDM) patients with ischemic heart disease (IHD) is uncertain. We aimed to examine the survival in NIDDM patients with IHD receiving various types of oral antihyperglycemic regimens over a 5 year follow-up period.

Methods. The population consisted of 11440 patients aged 45–74 years with previous myocardial infarction or stable angina, including 9045 nondiabetics and 2395 diabetics. Diabetics comprised 4 groups, on the basis of their therapy upon screening: diet alone (n = 990), sulphonylureas (n = 1041), metformin (n = 78) and a combination of a sulphonylurea and metformin (n = 266).

Results. All NIDDM groups were similar with regard to age, gender, hypertension, smoking, heart failure, angina and prior myocardial infarction. Crude mortality rate was lower in nondiabetics (11.21% vs. 21.8%; $p < 0.001$). In diabetics mortality was 18.5% for patients on diet alone, 22.5% for those on sulphonylureas, 25.6% for patients on metformin, and 31.6% for the combined sulphonylurea/metformin group ($p < 0.01$). Analyzing age-adjusted mortality rate and actuarial survival curves, the lowest mortality was found in patients on diet alone and the highest in patients on combined metformin/sulphonylurea therapy. After multivariate analysis, the use of metformin and of combined therapy were associated with increased relative risk (RR) for all-cause mortality of 1.44 (95% CI 0.87–2.38) and 1.41 (95% CI 1.10–1.90), respectively, whereas the use of sulphonylureas alone was not [RR 1.11 (95% CI 0.90–1.36)].

Conclusions. NIDDM patients with IHD receiving metformin, especially in combination with sulphonylureas, exhibited a significantly increased mortality over a 5 year follow-up period Until the results of problem-oriented prospective studies on oral control of NIDDM become available, alternative therapeutic approaches should be investigated for these patients.

3167 Impaired functional and structural properties of saphenous vein conduits in diabetic patients undergoing coronary bypass surgery

R. Lorusso, R. Raddino[1], P. Totaro, P. Fellini, S. Pentiricci, V. Borghetti, T.M. Scarabelli[1], G. Villanacci[2], G. Coletti, M. Zogno. *Cardiac Surgery Division, Civic Hospital, Brescia; [1]Cardiology Division, Civic Hospital, Brescia; [2]IInd Pathology Division, Civic Hospital, Brescia, Italy*

Diabetes (DB) represents a widely recognized risk factor for unfavorable outcome after coronary bypass surgery. Nonetheless, structural and functional properties of CABG conduits in DB patients have been poorly investigated, and represent the aim of this study

Methods: Seventy patients were evaluated fro this study. Diabetes was present in 38 patients (24 pts with NIDD, and 14 pts with IDD), whereas 32 patients had no DB and represented the control group. The excess segments of internal thoracic artery (ITA)and saphenou vein (SV) were collected during elective CABG. Vessel strips were immediately set up in isolated organ-bath and suspended under an isometric transducer. Contractile and vasodilative responses were assessed by infusion of Norepinephrine, Serotonine, and KCl, and subsequently antagonised (Nifedipine, Captopril, TNG). Endothelium-dependent vascular reactivity was also evaluated by Acetylcholine administration during Norepinephrine-induced contraction. Histology was carried out on formaline-fixed specimens, which were processed for light microscopy.

Results: No differences were found between groups in relation to functional and structural properties of ITA segments, which proved to be well preserved. In contrast, significant impairment of endothelium-dependent response of SV grafts was observed in DB patients. Indeed, a significantly reduced inhibitory response to SV graft contraction after Acetylcholine administration was shown (8.7% in DB pts vs 32% in non-DB pts). Histological assessment confirmed significant derangement of SV endothelium of DB patients as compared to control ones (15 DB pts with diffuse intimal hyperplasia vs 2 control pts).

Conclusions: Functional and structural properties of SV graft endothelium are impaired in DB patients undergoing coronary bypass surgery, and may negatively affect the postoperative outcome by enhancing SV graft degeneration.

3168 Hyperhomocysteinaemia is a novel, independent risk factor for coronary heart disease in UK Indian Asians

J. Chambers, O.A. Obeid, H. Refsum, P. Ueland, J.S. Kooner. *National Heart and Lung Institute, Imperial College School of Medicine, Hammersmith Hospital, London, UK*

Premature coronary heart disease (CHD) mortality is 2-fold higher in UK Indian Asians (IA), than European whites (EW), and is not explained by classic risk factors smoking, hypertension and cholesterol. We hypothesised that homocysteine (Hcy) levels are elevated in IA compared to EW, and may account for their increased CHD risk. We studied 551 male CHD patients (257 IA aged 52 ± 7 yrs, 294 EW aged 55 ± 5 yrs) and 1025 age-matched controls (518 IA, 507 EW). Hcy was measured fasting and after a methionine load (100 mg/kg). Subjects were characterised for CHD risk factors, red cell folate, and vitamin B_{12}.

Mean Hcy levels were higher in IA than EW (fasting, 11.2 ± 7.7 vs 10.5 ± 5.4 μmol/l, p = 0.001; post-load, 34.9 ± 12.8 vs 33.2 ± 12.1 μmol/l, p = 0.001). Fasting Hcy levels were elevated in CHD patients compared to respective controls (IA, 12.0 ± 4.5 vs 10.8 ± 3.5 μmol/l, p = 0.001; EW, 11.1 ± 3.9 vs 10.2 ± 2.9 μmol/l, p = 0.001). In contrast, post-load Hcy levels did not differ significantly between patients and controls (IA, 36.1 ± 11.1 vs 34.3 ± 9.5 μmol/l, p = 0.02; EW, 33.9 ± 10.6 vs 32.9 ± 8.8 μmol/l, p = 0.18). The association between fasting Hcy and CHD was independent of conventional risk factors including diabetes, cigarette smoking, hypertension, and hypercholesterolaemia in both racial groups. Hcy levels were inversely related to vitamin B12 (p = 0.001) and folate (p = 0.001). Compared to EW, IA had lower folate (349 ± 160 vs 384 ± 166 ng/ml, p = 0.001), and vitamin B_{12} (270 ± 143 vs 358 ± 158 pmol/l, p = 0.001). The differences in homocysteine concentrations between the two racial groups were explained by lower vitamin B_{12} and folate levels in Asians.

We conclude that elevated fasting Hcy may contribute to theexcess CHD risk in IA compared to EW, and may be amenable to modulation through dietary vitamin supplementation.

3169 Why do Afro-Caribbeans have a low incidence of ischaemic heart disease?

J. Mayet, N. Chapman[1], A.D. Hughes[1], R.A. Foale, S. Thom[1], A.V. Stanton[1]. *Cardiology Dept., St Mary's Hospital, London; [1]Peart-Rose Clinic, St Mary's Hospital, London, UK*

Afro-Caribbeans have a greater prevalence of diabetes, hypertension, left ventricular hypertrophy and obesity compared with White Europeans. In spite of this, they have a lower prevalence of ischaemic heart disease. An increased carotid intima-media thickness (IMT) has recently been found to be associated with the majority of known cardiovascular risk factors, including left ventricular hypertrophy. It is widely believed that intima-media thickening may represent an early marker for the development of atheroma. Afro-Caribbean subjects with their clustering of cardiovascular risk factors may be expected to have an increased IMT compared with White Europeans. In order to test this hypothesis 32 age, sex and blood pressure matched Black and White hypertensives underwent bilateral common carotid and femoral ultrasonography and echocardiography.

The Afro-Caribbean group had a significantly greater left ventricular mass index compared with the White Europeans (mean ± SEM 137 ± 7.3 versus 115 ± 8.5 g/m^2, $p < 0.05$). In spite of this, there were no significant differences in common carotid or femoral IMT between the Black and White groups (0.77 ± 0.02 versus 0.78 ± 0.04 mm and 0.67 ± 0.03 versus 0.66 ± 0.03 mm).

In conclusion, in spite of having a significantly greater left ventricular mass index, the Black subjects had a similar large vessel intima-media thickness compared with Whites. This may indicate that, even though they have a greater clustering of risk factors, Afro-Caribbeans may not have the same propensity for the development of atherosclerosis. This might help explain their lower incidence of ischaemic heart disease.

3170 Characteristics, therapy and prognosis of 952 hypertensive and 1,903 normotensive men with coronary heart disease: long-term follow-up

U. Goldbourt, V. Boyko. *For the BIP Research group; Neufeld Cardiac Research Institute, Tel Hashomer, Israel*

Between 1990 and 1992, 3122 CHD patients (pts) were recruited to participate in the multicenter placebo controlled BIP trial, including 2855 men. Among 952 hypertensive (HT) men, 438 were so classified on the basis of history alone and 514 by history as well as at least one measurement exceeding systolic and/or diastolic levels of 160 and 95 mmHg respectively. Among HT CHD pts so defined, 89% were taking medication at the time of screening. The mean ages were 60.7 among HT and 59.5 in normotensive (NT) pts. The mean screening blood pressure levels were 144/86 among HT and 127/79 in NT pts, respectively. At randomization, and on repeated medical visits after 4 and 8 months, these values changed little (to 141/84 and 128/79 mmHg respectively). Mean BMIs were 27.1 and 26.4 kg/M2 in HT and NT respectively and there were no appreciable lipid level differences. Diabetes was the only condition obviously in excess (12.8% vs. 7.9%) in HT, whereas fewer of them (9.9%) reported smoking than NT (13.5%). Calcium channel blockers (CCB) (56%), beta blockers (48%), ACE inhibitors (22%) and diuretics (19%) were the most common treatment modalities in HT CHD pts. Other than CCB, the above therapies were by far more prevalent among HT than NT. Through 1997 (mean follow up 6 yrs, maximum 7.5) no difference in all-cause mortality was observed between HT (10.4%) and NT (10.3%). Upon multivariate adjustment the adjusted HT mortality hazard was 0.96 (95% CI, 0.75–1.23). HT exhibited a small non-significant excess in incident recurrent MI, unstable angina and invasive cardiac procedures. Only the incidence of stroke (9.9% in HT "qualifying" by elevated BP, 5.5% in HT with controlled BP, 5.2% in NT) was significantly related to baseline hypertension. These results confirm recent findings, from other studies, of little or no excess in cardiac events and mortality among HT CHD patients. An explanation of this apparent paradox remains elusive.

3171 Blood pressure and long-term coronary heart disease mortality in different populations; results from the seven countries study

P.C.W. van den Hoogen, E.J.M. Feskens, N.J.D. Nagelkerke, A. Menotti[1], A. Nissinen[2], D. Kromhout. *Department of Chronic Diseases, the National Institute of Public Health, Bilthoven, Netherlands; [1]Division of Epidemiology, University of Minnesota, Minnesota, USA; [2]Department of Community Health, University of Kuopio, Kuopio, Finland*

It is unclear whether the strength of the relationship between blood pressure and mortality from coronary heart disease (CHD) varies among populations. We compared the relationship of systolic (SBP) and diastolic (DBP) blood pressure with CHD mortality in 6 different populations, and examined the effect of blood pressure measurement error.

Methods: Blood pressure was measured at baseline in 12,268 middle-aged men in the United States, Northern and Southern Europe, Serbia and Japan. During 25 years of follow-up there were 1,397 deaths from CHD.

Results: For a SBP of 140 mmHg, CHD mortality rates varied more than threefold between populations and for a DBP of 85 mmHg, there was a fivefold range. High rates were observed in the US and Northern Europe and low rates in Japan and Mediterranean Southern Europe. The relative risk (RR) for CHD mortality for a given increase in blood pressure was similar in all populations. The overall RR for CHD mortality per 10 mmHg increase in SBP was 1.15 (95% confidence interval: 1.13–1.19) and per 5 mmHg increase in DBP 1.13 (1.10–1.15), and became 1.26 and 1.29 respectively after adjustment for measurement error.

Conclusions: The relative increase in CHD mortality for a given increase in blood pressure is similar in different populations. After adjustment for measurement error, the RR of SBP increased by 40 to 80% while that of DBP more than doubled. However, the large difference in absolute risk among populations at a given blood pressure level indicates that other factors, such as diet and physical activity, are also of interest with respect to primary prevention of CHD.

DIAGNOSTIC VALUE OF ELECTROCARDIOGRAM COMPUTER ANALYSIS

3172 Atrial flutter detection by computer

S. Morrison, P.W. Macfarlane. *University Department of Medical Cardiology, Glasgow Royal Infirmary, Glasgow, UK*

Interpretation of arrhythmias is recognised as one of the major problems in automated ECG analysis, and new methods are continuously being investigated to improve the accuracy of this section of the Glasgow Program. As part of this research, a new algorithm has been developed for the detection of atrial flutter.

Methods: The original approach to detecting atrial flutter involves checking for repeated occurrence of opposing gradients in the T-Q interval, in keeping with the saw-tooth configuration of F waves. The new method searches for a regular pattern of detected "P" waves with a high atrial rate. If flutter is not found, further checks are made for a regular pattern of peaks in the first difference of leads II and V1. In each case a regularity index is calculated which takes into account the possibility of undetected or spurious waves. This index, plus the number of detected waves and estimated atrial rate, are used as criteria for atrial flutter. The algorithm was developed using a training set of 422 ECGs including 49 cases of atrial flutter with a variety of flutter wave shapes and varying degrees of A-V block. The remaining rhythms were atrial fibrillation (AF) and sinus rhythm with supraventricular extrasystoles (SVES) and/or ventricular extrasystoles (VES). Optimisation was achieved using a trial and error approach, with various parameters in the algorithm being tuned to maximise sensitivity (84%) without sacrificing specificity (98.1%).

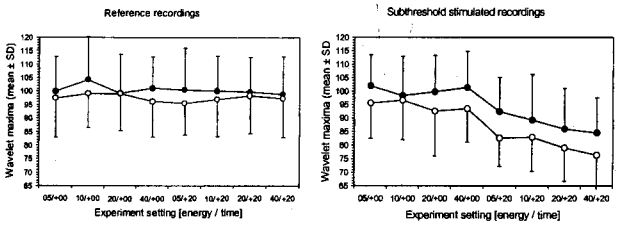
Results: The new algorithm was evaluated and compared to the existing algorithm using a test set of 462 ECGs including 75 showing complex forms of atrial flutter with the remainder having either AF or sinus rhythm with SVES and/or VES. There was a significant improvement in sensitivity (77%) compared to the existing flutter logic (25%) while achieving high specificity (98.4%). If both old and new algorithms were used in combination, a sensitivity of 84% was achieved, with a high specificity of 98.1% being maintained.

Conclusion: Computer interpretation of cardiac arrhythmias can still be improved through careful development and enhancement of basic methods.

3173 Wavelet analysis of subthreshold cardiac modulation in healthy subjects and ventricular tachycardia patients

Katerina Hnatkova, Mark W. Kroll, Stephen J. Ryan, Marek Malik, Thomas M. Munger, Nemer Samniah, Lars Hegrenaes, David G. Benditt, Marshall S. Stanton, Ole Rossvoll, Harold H. Hoium. *Harbinger Medical Inc., Minneapolis MN; University of Minnesota Hospital, Minneapolis MN; St Jude Medical/Daig, Minnetonka MN; Mayo Clinic, Rochester MN, USA; Regional Hospital, Trondheim, Norway; St. George's Hospital Medical School, London, UK*

Subthreshold stimulation without capture reduces the stimulation threshold and changes the action potential of a subsequent stimulation with capture (Wedensky Phenomenon). Patients with EP documented ventricular tachycardia (n = 47, mean age 63 ± 13 years, 83% male) and healthy controls (n = 30, mean age 44 ± 16 years, 60% male) were subjected to a subthreshold external stimulation between precordial and left subscapular patches. Stimuli of 5, 10, 20, and 40 mA were delivered for 2 ms either simultaneously with the R wave or 20 ms after the R wave. 60 to 200 subthreshold stimulated QRS complexes were averaged and compared with non-stimulated complexes (reference). Vector magnitude wavelet decompositions (53 scales of Morlet wavelet, central frequencies 40–250 Hz) were obtained for both stimulated and non-stimulated complexes. Local maxima of the 3D spectral envelopes were counted in 50 ms windows following the subthreshold stimulation and compared in VT patients and controls. In non-stimulated recordings (left figure), they were no statistical differences between VT pts (filled circles) and controls (unfilled circles). In subthreshold stimulated recordings, the local maxima decreased (3D envelopes are more smooth). This decrease was greater in healthy controls and with stimulation after the R wave (right figure – all differences but in 10/00 experiment were significant – $p < 0.001$).



Hence, subthreshold external stimulation makes the depolarisation wave more uniform, mainly in healthy controls.

3174 Temporal changes in fractal and spectral characteristics of heart rate variability in patients with coronary artery disease

V. Jokinen, K.E.J. Airaksinen, H.V. Huikuri. *Dept. of Med., Div. of. Card., University of Oulu, Oulu, Finland*

Background: Spectral and fractal measures of heart rate (HR) variability are altered and provide prognostic information in patients with coronary artery disease (CAD), but there are no data from longitudinal studies on the determinants of temporal changes in HR behavior. This study evaluated changes in the 24-hour measures of HR variability in patients with CAD undergoing repeat Holter recordings 32 months after the baseline recordings.

Methods and Results: Non-spectral, spectral and fractal measures of HR variability were analyzed from the baseline 24-hour ECG recordings and from recordings performed 32 months later in 110 patients participating in the multicenter trial (LOCAT) evaluating the angiographic progression of CAD. Several laboratory variables, including lipid, glucose and insulin levels, exercise tests and quantitative computer-assisted analysis of coronary artery stenoses were also assessed at baseline and after 32 months's follow up. None of the traditional non-spectral or spectral measures of HR variability changed significantly during the follow-up. The power-law slope of R-R interval variability decreased from -1.28 ± 0.12 at baseline to -1.36 ± 0.23 ($p < 0.001$) and short-term fractal scaling exponent of R-R intervals from 1.29 ± 0.14 to 1.22 ± 0.19 ($p < 0.001$) during the time course. Changes in the measures of HR variability were not related to changes in any of the laboratory variables, exercise capacity, clinical ischaemic events or angiographic progression of CAD.

Conclusions: This longitudinal study shows that fractal analysis techniques are more sensitive than traditional analysis methods in documenting temporal changes in HR behavior of patients with CAD. Altered fractal characteristics of HR behavior are related to aging itself, but not to progression of CAD or to changes in the risk factors of CAD.

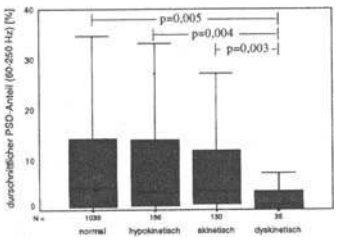
3175 No reduction of high frequency contents in power spectra of epicardial electrograms in regions with moderate contraction abnormalities in patients with chronic ischaemic myocardium

H.-J. Bruns, F. Janssen, T. Fetsch, D. Hammel[1], T. Wichter, M. Borggrefe, G. Breithardt. *Dept. of Cardiology; [1]Dept. of Cardiovascular Surg., University of Münster, Germany*

Purpose: The aim of the present study was to assess the influence of the severity of regional myocardial dysfunction on high frequency components of epicardial electrograms in patients with chronic myocardial ischaemia.

Methods: During elective coronary artery bypass surgery, intraoperative epicardial mapping was performed in 21 patients. Using a sock electrode, 102 bipolar electrograms were simultaneously recorded from the epicardial surface of the heart during sinus rhythm. In a 200 ms time window around center of local activation, the relative part of the power spectrum density [PSD] was calculated in a frequency band of 60–250 Hz. The severity und extent of regional myocardial dysfunction was assessed from preoperative biplane angiograms. The results were projected to the grid and intraoperative position of the sock electrode.

Results: Epicardial electrograms and regional contractile function were analysed in 1390 left ventricular segments (n = 186 hypokinetic, n = 130 akinetic, n = 35 dyskinetic). In contrast to previous studies describing a significant decrease of high frequency PSD-components in acute myocardial ischemia, we found a significant decrease of PSD components only in electrograms of dyskinetic areas ($p < 0.01$) Hypo- and akinetic areas, however, showed normal or almost normal PSD-deviations.



Conclusion: The findings indicate differences in the electrical characteristics of acute vs. chronic ischaemic myocardium. Areas of chronic ischaemic myocardium and moderate dysfunction show normal electrical behaviour, possibly indicating myocardial viability.

3176 Comprehensive assessment of QT dispersion in various at risk groups including acute myocardial infarction, unstable angina, hypertrophic cardiomyopathy, idiopathic dilated cardiomyopathy, and healthy controls

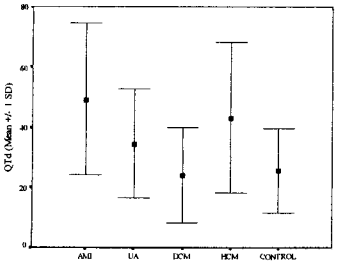
Yee Guan Yap, Gang Yi, Kudret Aytemir, Xiao-Hua Goa, A. John Camm, Marek Malik. *St. George's Hospital Medical School, London, UK*

Background: QT dispersion (QTd) has been proposed as a risk marker of ventricular tachyarrhythmias. However, inconsistent results had been shown on various at risk groups due to various methods used. No comprehensive study has been done to compare QTd in various cardiac conditions using a consistent method to determine its clinical value.

Aim: We compared and determined the value of QTd in various at risk patients and healthy control using a fully automated method.

Methods: We performed QTd on 81 acute myocardial infarction (AMI) patients on the first day *after* AMI (61 male, age 63.1 ± 12.3), 22 unstable angina patients (UA) (17 male, age 62.7 ± 12.8) on the first day *after* admission, 76 hypertrophic cardiomyopathy patients (HCM) (43 male, age 39.6 ± 14.0), 27 idiopathic cardiomyopathy patients (DCM) (18 male, age 48.9 ± 15.7), and 69 healthy controls (30 male, age 50.6 ± 7.4), using Marquette MAC VU equipped with QT Guard software which automatically analysed QTd on digitally stored ECGs.

Results: 1) Using student's t-test, AMI, UA, HCM patients but not DCM had significantly higher QTd than control (AMI: 49.3 ± 25.1 vs. 25.7 ± 14.1, $p < 0.0001$; UA: 34.7 ± 18.1 vs. 25.7 ± 14.1, $p = 0.041$; HCM: 43.3 ± 25.0 vs 25.7 ± 14.1, $P < 0.0001$; DCM: 24.1 ± 15.8 vs. 25.7 ± 14.1, p = N.S.). 2) AMI patients had significantly higher QTd compared with UA (49.3 ± 25.1 vs. 34.7 ± 18.1, $p = 0.004$) and DCM patients (49.3 ± 25.1 vs. 24.1 ± 15.8, $p < 0.001$) but not with HCM patients (p = N.S.). 3) UA patients had significantly higher QTd than DCM patients (34.7 ± 18.1 vs. 24.1 ± 15.8, $p = 0.038$) but not with HCM patients (p = N.S.) 4) HCM patients had higher QTd than DCM patients (43.3 ± 25.0 vs. 24.1 ± 15.8, $p < 0.0001$).



Conclusions: 1) QTd is most increased in AMI and HCM patients, less so in UA patients but no difference in DCM patients compared with controls. 2) Different cardiac condition has different degree of ventricular repolarisation manifested by different QTd values. 3) QTd is useful as a risk stratification tool in most cardiac conditions assessed here but not all. 4) The underlying cardiac condition must be considered when QTd is compared.

3177 ECG detection of acute myocardial infarction by artificial neural networks

H. Öhlin, S. Wallerstedt, M. Ohlsson[1], L. Edenbrandt[1]. *Dept. of Cardiology, [1]Dept. of Clinical Physiology, University Hospital, Lund, Sweden*

Recent reports have demonstrated that artificial neural networks can be used for interpretation of ECG. The purpose of this study was to compare the performance of artificial neural networks, an experienced cardiologist and an intern in detecting acute myocardial infarction in the 12-lead ECG. **Methods:** A total of 960 ECGs from patients with acute myocardial infarction and 11750 control ECGs recorded at an emergency department with computerized ECG were studied. Artificial neural networks were trained to detect acute myocardial infarction by use of measurements of the ST-segments of each ECG together with the correct diagnosis. After the training process the neural networks, an experienced cardiologist and an intern reviewed 200 ECGs from patients with acute myocardial infarction and 800 control ECGs, with and without access to earlier ECGs for comparison. Receiver-operating characteristic (ROC) curves were obained and the area under each curve was calculated. A high value signifies good performance. **Results:** Area under the ROC-curves

	With earlier ECG	Without earlier ECG	p-value
Intern	0.777	0.712	<0.001
Cardiologist	0.805	0.791	0.17
Neural Networks	0.833	0.846	0.07

Conclusions: Neural Networks are able to diagnose acute myocardial infarction in the 12-lead ECG at least as well as an experienced cardiologist and definitely better than an unexperienced ECG reader. Availability of an earlier ECG for comparison is of doubtful help to an experienced ECG reader.

ELECTRICAL CARDIOVERSION OF ATRIAL FIBRILLATION

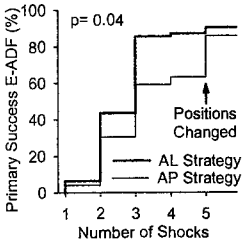
3178 The sequential application of two different paddle positions in external atrial defibrillation

A.E. Tuinenburg, B.A. Schoonderwoerd, I.C. Van Gelder, R.G. Tieleman, P.J. De Kam, H.J.G.M. Crijns. *Thoraxcenter, University Hospital Groningen, Netherlands*

External atrial defibrillation (E-ADF) is a generally accepted method to restore sinus rhythm (SR). Either anterior-posterior (AP) or anterior-lateral (AL) paddle positions are used in E-ADF. However, the effect of application of both techniques sequentially is unknown.

Methods: We investigated primary (SR immediately after E-ADF) and secondary success (SR after 1 month) of E-ADF in 111 consecutive patients with persistent (>24 hours duration) atrial fibrillation (AF). Patients were randomized to either AL (n = 62) or AP (n = 49) positions, with paddle diameters 9 + 9 cm and 8 + 12 cm respectively. Monophasic DC-shock energy was increased stepwise until successful (100; 200; 360 Joules). If this failed, another 360 Joules were delivered. If still ineffective, 360 Joules in the other paddle positions were finally applied.

Results: After the third shock (maximal energy) 85% of the patients in AL strategy were in SR vs. only 59% in AP strategy (p = 0.04; see figure). As to be expected, the fourth shock (maximal energy, same positions) was rather ineffective (AL + 2%, AP + 4%). However, the fifth shock (maximal energy, *positions changed*) was not very effective in AL strategy, but highly effective in AP strategy (AL + 3%, AP + 23%). Eventually, strategies were comparable for primary (AL 90%, AP 86%) and secondary (AL 38%, AP 45%) success of E-ADF. Multivariate analyses confirmed that strategy was neither related to primary nor to secondary success. No heart failure or ventricular (pro-) arrhythmia was observed immediately after E-ADF.



Conclusions: Without a sequential change of positions, AL positions are most effective. A 2nd delivery of 360 Joules in the same positions is rather ineffective. A sequential change of positions should be considered when AP positions are ineffective at 360 Joules.

3179 External cardioversion of atrial fibrillation: a randomized comparative study on efficacy of biphasic versus monophasic waveform shocks

P. Ricard, E. Lakhal, G. Boccara, S. Lévy. *Division of Cardiology, School of Medicine, University of Marseille, France*

Biphasic waveform shocks were found to decrease energy requirements as compared to monophasic waveform in terminating ventricular fibrillation. We compared the efficacy of external cardioversion of atrial fibrillation (AF) using biphasic versus monophasic waveform in a prospective study.

Methods and results: Thirty nine patients (Pts) were randomized to undergo cardioversion using antero-lateral approach either with a defibrillator using a monophasic waveform. (Hewlet Packard, Codemaster) or a defibrillator which delivers an impedance-compensating biphasic waveform (Forerunner, Heartstream Inc). The energy of the first shock with the Codemaster (monophasic waveform) was set at 150 J to match with the energy delivered by the Forerunner (biphasic waveform) and if needed followed by a second 360 J.

Characteristics of patients

	Monophasic (Group I)	Biphasic (Group II)
Number of Pts	19	20
Chronic/Paroxystimal	18/1	19/1
Heart disease	14	12
Size of left atrium (mm)	45 ± 5.2	46 ± 4.8
Duration of treated episode (months)	4.1 ± 7.8	4.3 ± 7.6
Antiarrhythmics	9	12

Sinus rhythm was restored with the first shock in 11 out of 19 Pts (58%) in group I and 18 out of 20 Pts (90%) in group II ($p < 0.05$) However after completion of the protocol the success rate was 94% in group I and 90% in group II. Myocardial enzymes did not show any significant change in both groups. No complication was observed.

Conclusion: This study demonstrates that at an energy at 150J external cardioversion of AF is more effective using biphasic than monophasic shock waveform.

3180 Randomised comparison of electrode pad size and position for transthoracic cardioversion of atrial fibrillation

T.P. Mathew, A. Diamond, M. McIntyre, M.T. Harbinson, A.A.J. Adgey, G.W.N. Dalzell. *Regional Medical Cardiology Centre, Royal Victoria Hospital, Belfast, N., Ireland*

Transthoracic impedance (TTI) is a major determinant of intramyocardial current flow during external countershock. It has been suggested that TTI is lower with larger pad sizes and in anteroposterior (AP) electrode position. We prospectively randomised 119 patients (pts) undergoing transthoracic cardioversion of atrial fibrillation to 3 different pad sizes – standard (S; area 106 cm^2, n = 39), medium (M; area 140 cm^2, n = 40), and large (L; area 221 cm^2, n = 40) and 2 pad positions – anteroapical (AA n = 58) and anteroposterior (AP n = 61). TTI and peak current were measured.

TTI was significantly lower with larger pads (S; 74.8 ± 14.6 Ω, M; 64.9 ± 17.3 Ω, L; 48.5 ± 6.8 Ω, p = 0.0001) with a corresponding increase in the peak current (S; 35.7 ± 10.6 A, M; 40.6 ± 10.7 A, L; 47.9 ± 11.3 A p = 0.0001). Cardioversion success rate was similar in all the 3 different pad sizes (S; 34/39–87%, M; 34/40–85%, L; 36/40–90% p = 0.79). Similarly success rate at low energy shocks (≤200 J) was similar in all the 3 groups (S; 20/39–51%, M; 23/40–58%, L; 23/40–58% p = 0.81). TTI was lower in the AP position (AP 65.8 ± 19.0 Ω, AA 59.4 Ω ± 15.1, p = 0.05). However there was no significant differences in the total success rate (AA 85%, AP 85% p = 0.47) or rate of success at low energy shocks (AA 57%, AP 54% p = 0.76) between the 2 pad positions. Twenty pts crossed over to the alternate route if cardioversion failed in one position and 50% (3/6) succeeded in the AP position and 36% (5/14) in the AA positions (p = 0.55).

TTI is lower with larger pad sizes and AP pad position with corresponding increase in the current. However cardioversion success rate for atrial fibrillation is not related to electrode pad size or position.

3181 Chronic atrial fibrillation: a 3-month course with low-dose amiodarone before electrical cardioversion reduces early recurrences

E. Moreno, R. García, O. Baún, M.J. Aguado, J. Sánchez-Ramos, L. Tercedor, C. García, A. Ramírez, J. Azpitarte. *Dept. of Cardiology, Hospital Universitario Virgen de las Nieves, Granada, Spain*

Electrical cardioversion (ECV) is a an effective and safe procedure to restore sinus rhythm in patients (pts) with atrial fibrillation (AF). However, the high rate of recurrences constitutes a limitation of the procedure. In this study we tested the hypothesis that a low-dose of amiodarone (Amd) before ECV is helpful in order to mantain sinus rhythm after successful ECV

Methods. 106 pts with chronic AF (6 months to 5 years) were randomized to ECV following 3 months of Amd therapy (group A) or to ECV without specific antiarrhythmic therapy (group B). Amd was administered at a loading dose of 100 mg/kg for a week, followed by a maintenance dose of 200 mg daily. All pts were anticoagulated with warfarine, at least for 4 weeks before ECV. After successful ECV, pts in group B initiated Amd therapy (low maintenace dose following a loading dose) while group B pts were mantained in the low-dose regime. All pts were revaluated 3 months after the procedure.

Results. Baseline characteristics (age, % of structural cardiopathy, ejection fraction, left atrium dimension, AF duration, and % of AF longer than 3 years) were similar in both groups. At the time of planned ECV, 7 (13%) Pts of group A had achieved sinus rhythm for none in group B (p = 0.01). The rate of successful ECV was similar in both groups (65% and 75%, respectively). At 3 months follow-up there were 2 (6.7%) recurrences of AF in group A vs 11 (27.5%) in group B (p = 0.03); thus, the RR for recurrences in group A, compared to group B, was 0.2 (95% CI, 0.06 to 1.01). Adverse reactions were seen in 31 (29%) pts; most of them were not serious and were reversed with a dose reduction. Withdrawal of Amd was necessary in 8 (7.5%) pts.

Conclusion. In pts with chronic AF, a low dose of Amd during the 3 months going before ECV, significantly reduces early recurrences. In addition, some 13% of pts can achieve pharmacologic sinus rhytm, making unnecessary the ECV.

3182 Left ventricular dysfunction of chronic atrial fibrillation with controlled ventricular rate is reversed or greatly ameliorated after one year in sinus rhytm

R. García, O. Baún, E. Moreno, L. Tercedor, M.J. Aguado, J. Sánchez-Ramos, A. Navarrete, J.F. Díaz, A. Villegas, J. Azpitarte. *Hosp. Virgen de las Nieves, Granada, Spain*

Atrial fibrillation (AF) with fast ventricular rate can be associated with left ventricular systolic dysfunction (LVSD). It has been shown that the control of ventricular rate or the sinus rhythm restoration can greatly improve the LV function. However, it is not yet proved if a similar benefit could be attained in patients (pts) with chronic AF and controlled ventricular rate. Therefore, we designed an observational study to asses the hypothesis that cardioversion is also advantgeous for pts with chronic controlled AF and moderate or severe LVSD.

Methods: Serial assessment of echo ejection fraction (EF) was performed in 30 pts with chronic AF (>6 months) and baseline EF $\leq$ 0.50 who underwent electrical cardioversion. The ventricular rate was pharmacologically controlled to <100 bpm (Holter assessment) before baseline determination of EF. All pts were anticoagulated for one month prior to cardioversion. A low-dose amiodarone (200 mg daily) was prescribed for all pts who achieved sinus rhythm. This therapy was maintained for one year or until the recurrence of AF.

Results: Cardioversion was successful in 25 (83%) pts and 20 of them (67%) were still in sinus rhythm after one-year follow-up. In these, EF increased from 0.42 $\pm$ 0.7 at baseline to 0.56 $\pm$ 0.11 at one year follow-up ($p < 0.0001$). A normal EF ($\geq$0.55) was achieved in 14 pts (47% of the entire cohort). In contrast, EF did not change (0.38 $\pm$ 0.8 at baseline vs 0.41 $\pm$ 0.9 at one year follow-up) in pts that did not achieve sinus rhythm or have AF recurrence.

Conclusions: Intention to treat analysis of pts with chronic AF and controlled ventricular rate shows that restoration and long-term maintenance of sinus rhythm can completely reverse the associated LVSD in about a half of the pts. Therefore, we firmly advise to attempt sinus rhythm restoration, in spite of a good control of the ventricular rate, in all pts with chronic AF and LVSD.

3183 No cerebral circulating microemboli in patients undergoing electrical cardioversion due to permanent atrial fibrillation

H. Reinecke[1], D.G. Nabavi[2], A. Allroggen[2], V. Kemény[2], D.W. Droste[2], G. Breithardt[1], E.B. Ringelstein[2]. *[1]Dept. of Cardiology and Angiology/Institute for Arteriosclerosis Research; [2]Dept. of Neurology Hospital of the Westfälische Wilhelms-University, Münster, Germany*

Introduction: Electrical cardioversion (CV) in patients (pts.) with atrial fibrillation is known to be associated with an increased periprocedural risk for thromboembolic events. This is due to mobilisation of pre-existent atrial thrombotic material during CV but also to an increased risk for thrombus-formation after CV because of impaired atrial contractility ("stunned atrium"). We analysed pts. undergoing electrical CV for circulating cerebral microemboli (ME), which are known to be predictive for thromboembolic events.

Methods/Results: Pts. admitted for CV were included if they had been on effective anticoagulation with phenprocoumon (INR 2.0–3.0) for at least 3 weeks and gave full written informed consent. They underwent duplex sonography of the carotid arteries and were excluded if a stenosis of $\geq$50% was detected. Finally, 29 pts (22 men, age 54 $\pm$ 13 yrs) were included. Concomitant cardiac anomalies were mitral valves defects (n = 5), coronary heart disease (n = 9) and cardiomyopathies (n = 2), in 13 pts no structural anomaly could be identified. All underwent transthoracal and -esophageal echocardiography without detection of intracardiac thrombotic material. Additionally, 10 pts. with prosthetic left heart valves on phenprocoumon without CV were examined as controls. Unilateral transcranial Doppler (TCD) sonography was performed of the middle cerebral artery through the temporal skull with a two-channel 2 MHz probe using a system from EME/Nicolet. Five one-hour TCD monitorings for ME were performed: (a) 24 h before CV, (b) during and directly after CV, (c) 4–6 h, (d) 24 h, as well as (e) 2–4 weeks after CV. All monitorings were analysed offline in a blinded matter by an experienced investigator. None of the pts. neither with CV nor with prosthetic valves showed any symptoms characteristic for thromboembolic events. No ME were detected before CV and during a total of 115 h of post-CV-monitoring. In contrast, in 6 out of the 10 pts. with prosthetic valves, ME were detected with a frequency of 2 to 15/h.

Discussion: In 29 pts. with effective anticoagulation for at least 3 weeks undergoing electrical CV, no circulating cerebral ME could be detected before, during or after CV, although sensitivity of this technique was confirmed in controls. With regard to the well-known potential of ME to indicate increased thromboembolic activity, large-scale studies are warranted to evaluate the prognostic relevance of this method to improve the peri-procedural management of patients undergoing CV.

MARKERS OF INFLAMMATION, COAGULATION AND MYOCARDIAL DAMAGE IN ACUTE CORONARY SYNDROMES

3188 Inflammation markers and adhesion molecules in acute coronary syndrome: culprit or consequence?

S. Blankenberg, H.-J. Rupprecht[1], C. Bickel[1], J. Lotz[2], N. Meciki[1], G. Rippin[3], J. Meyer[1]. *II. Medical Clinic, University Clinic, Mainz; [1]II. Medical Clinic, University Clinic, Mainz; [2]Clinic for Clinical Chemistry, University Clinic, Mainz; [3]Institute for Medical Statistics, University Clinic, Mainz, Germany*

Introduction: Many studies demonstrated increased levels of C-Reactive Proteine (CRP) and Tumor Necrosis Factor a (TNF-a) in acute coronary syndrom (ACS). Recently elevation of soluble Intracellular Adhesion Molecule 1 (sICAM-1) in ACS could be evidenced. However it remains unclear whether these markers of inflammation and adhesion react as sensitive but unspecific acute phase reactants or if they play a pathogenetic role in development of unstable coronary lesion.

Methods: In 321 patients (pts) with ACS levels of Troponin I (TNI) [ng/ml], high sensitive CRP (hsCRP) [mg/l], TNF-a [pg/l], and sICAM (ELISA technique) [ng/ml] were determined on admission to hospital. Considering TNI as a marker for myocardial injury with subsequent acute phase reaction we divided pts with ACS in TNI+ and TNI− groups (>0.5 = TNI+).

Results: 156/312 (48.6%) pts with ACS had a TNI+ level.

ACS: inflammation markers and ICAM-1

Mean (sem)	TNI−	TNI+	p
hsCRP [mg/l]	13.9 (1.7)	40.4 (3.7)	<0.0001
TNF-a [pg/ml]	26.1 (4.9)	47.8 (5.5)	0.003
sICAM-1 [ng/ml]	298.4 (11.2)	306.9 (13.6)	0.628

Conclusion: We could demonstrate that in pts with ACS levels of hsCRP and TNF-a are significantly higher in TNI+ group than in TNI−. Elevated levels of sICAM-1 in ACS do not differ between both TNI groups. These results suggest that elevated levels of hsCRP and TNF-a in ACS are mainly due to myocardial injury and subsequent acute phase reaction whereas endothelial inflammation documented by elevated sICAM levels are indepently of myocardial injury and are likely to play a causative role in pathogenesis of unstable lesion.

3189 C-reactive protein and fibrinogen in unstable coronary artery disease are related to long-term cardiac mortality

B. Lindahl, H. Toss, A. Siegbahn, L. Wallentin. *Dept. of Cardiology and dept. of Clinical Chemistry, University hospital, Uppsala, Sweden*

Previous studies, including the FRISC substudy, have shown an association between short-term mortality and markers of inflammation such as C-reactive protein (CRP) and fibrinogen, in patients with unstable coronary artery disease (UCAD). The follow-up in FRISC have been extended and we therefore are able to report the long-term influences of CRP and fibrinogen on mortality.

Methods: The patients were participating in FRISC – a double blind, randomised, placebo controlled trial of l.m.w. heparin (dalteparin) in UCAD. Blood samples were obtained at inclusion. CRP was analysed turbidimetrically and fibrinogen by rate nephelometry. The patients were stratified into tertiles based on fibrinogen levels and CRP levels, respectively. Information about death and cause of death during the extended follow-up period was obtained from the national registry on mortality.

Results: The median age at inclusion of the 917 patients were 70 years (25^{th}–75^{th} perc. 63–75) and 65% were males. After 3 years there were 114 (12.4%) deaths of which 91 (9.9%) were cardiac in origin. Cardiac mortality (%) in relation to time and level of the markers:

CRP, mg/L	<2.0	2–9.9	≥10.0	RR (95% CI)†	RR (95% CI)*
1 month	0.6	0.4	3.9	0.6 (0.1–6.4)	10.5 (1.4–80.1)
1 year	3.2	3.3	11.1	1.1 (0.4–2.5)	3.3 (1.6–6.8)
3 years	6.4	6.3	16.2	1.0 (0.5–1.8)	2.6 (1.5–4.3)
Fibrinogen, g/L	<3.4	3.4–3.9	≥4.0	RR (95% CI)†	RR (95% CI)*
1 month	0.3	1.0	4.0	3.1 (0.3±30.0)	4.0 (1.1–13.9)
1 year	4.1	6.3	7.9	1.5 (0.8–3.0)	1.3 (0.7–2.2)
3 years	6.1	11.0	12.9	1.8 (1.1–3.1)	1.2 (0.8–1.8)

†relative risk, second vs first group; *relative risk, third vs second group

Conclusion: Elevated levels of markers of inflammation are associated with both an increased short- and long-term cardiac mortality. Especially high levels of CRP seem to be associated with an increasingly high risk of cardiac death by time after an episode of unstable coronary artery disease.

3190 C-reactive protein and troponin T independently predict mortality in patients with unstable refractory angina

C. Heeschen, C.W. Hamm, J. Bruemmer[1], B.U. Goldmann, M.L. Simoons[2], A. Deu. *Cardiology Dept, University Hospital Hamburg, Hamburg; [1]Clinical Chemistry Dept, University Hospital Hamburg, Hamburg, Germany; [2]Thoraxcenter, Erasmus University, Rotterdam, Netherlands*

Elevated levels of C-reactive protein (CRP) and Troponin T (TnT) are predictive for short and long term cardiovascular outcome in patients (pts) with acute coronary syndrome. We investigated whether elevation of CRP provides prognostic information beside the TnT status with respect to cardiac events (death, AMI) during 6 months follow-up. Included were 561 pts with refractory unstable angina enrolled in the placebo arm of the CAPTURE trial.

Results: CRP was higher among pts who died compared with survivors (25.4 vs 8.6 mg/L, p = 0.003). The probability of elevated TnT levels rose with increasing CRP concentrations (p < 0.0001). Among TnT negative pts, CRP measurements identified a subgroup of high risk patients (CRP > 10 mg/L; 2.7% mortality). In TnT negative pts with CRP levels < 10 mg/L no death was documented during 6 months follow-up (p = 0.003). TnT positive pts with CRP levels > 10 mg/L were at highest risk relative to TnT positive patients with CRP level < 10 mg/L (5.9 vs. 3.6% mortality; p = 0.008). In contrast, CRP measurements did not provide independent predictive value for the incidence of AMI during 6 months follow up (logistic regression analysis; p = 0.32).

Conclusions: Elevated CRP at presentation in pts with unstable angina is correlated with short term mortality and identifies TnT negative pts with increased risk. A combination of CRP and TnT testing more reliably stratifies high risk patients with regard to mortality but not to incidence of AMI.

3191 Long-term cardiac mortality in relation to troponin T level and ECG findings in unstable coronary artery disease

B. Lindahl, P. Venge, L. Wallentin. *Dept. of Cardiology and dept. of Clinical Chemistry, University hospital, Uppsala, Sweden*

The FRISC troponin T-substudy in unstable coronary artery disease (UCAD) showed that maximal levels of tnT < 0.06, 0.06–0.6 and ≥0.6 μg/L identified low, intermediate and high risk groups, respectively, regarding short-term risk of cardiac death. However, no previous study has evaluated the long-term risk. We therefore report the long-term influences of tnT and, in additon ECG findings, on cardiac mortality after extension of the follow-up in FRISC.

Methods: The patients were participating in FRISC – a double blind, randomised, placebo controlled trial of l.m.w. heparin (dalteparin) in UCAD. ECG was obtained at admission, blood samples at inclusion and after 12 and 24 hours. Information about death and cause of death during the extended follow-up period was obtained from the national registry on mortality.

Results: The median age of the 917 patients were 70 years and 65% were males. After 3 years there were 114 deaths of which 91 were cardiac in origin. Cardiac mortality (%) in relation to time and level of the markers:

Max. tnT, μg/L	<0.06 n = 173	0.06–0.6 n = 367	≥0.6 n = 377	RR (95% CI)†	RR (95% CI)*
1 month	0	0.6	3.4	–	4.2 (1.2–14.7)
1 year	0.6	4.4	10.3	7.5 (1.0–56.4)	2.4 (1.4–4.2)
3 years	1.7	9.3	14.3	5.3 (1.7–17.2)	1.5 (1.0–2.3)

†relative risk, second vs first group; *relative risk, third vs second group Both markers provided independent prognostic information in muitiv. analysis.

ST-segment depr.	No (n = 358)	Yes (n = 559)	RR (95% CI)
1 month	0.8	2.3	2.8 (0.8–9.7)
1 year.	2.5	8.4	3.3 (1.7–6.7)
3 years	4.7	13.2	2.8 (1.7–4.6)

Conclusion: Both elevated tnT and presence of ST-segment depression are associated with an increased short- and long-term risk of cardiac death after an episode of UCAD. On the other hand, a normal maximal tnT is associated with a favourable long-term prognosis regarding cardiac mortality.

3192 Antibodies to Chlamydia pneumoniae in unstable angina: results from the CAPTURE trial

J. Kähler, M.L. Simoons, C. Heeschen, P. Schäfer[1], R. Köster, T. Meinertz, C.W. Hamm[2]. *Department of Cardiology; [1]Institute for Medical Microbiology and Immunology, University-Hospital Hamburg; [2]Kerckhoff-Klinik, Bad Nauheim, Germany*

Patients with coronary heart disease frequently have elevated antibody titers against Chlamydia pneumoniae (CP). Whether CP has a causal role in coronary heart disease or is activated as a secondary phenomenon remains unclear.

We examined the sera of 422 patients with unstable angina regarding their titers of CP-IgG, -IgM, C-reactive protein (CRP)- and Troponin-T (TnT) at admission and prior to discharge. CP-titers were measured with specific CP-antibodies by means of rELISA, CRP- and TnT-titers by means of ELISA.

CP-IgG-titers were elevated with average values of 1.6 ± 1.9 (index 1 = titer 1:100) in 42% of the cases at admission and with 1.9 ± 2.2 in 49% of the cases at discharge. CP-IgM-titer were elevated with average values of 0.2 ± 0.3 (index 1 = titer 1:50) and 0.3 ± 0.5 in 2% respectively 4% of the cases. IgG-titers in patients with consecutive events (myocardial infarction or death) had 19% higher titers at admission than patients without subsequent events. IgM-titers were 39% lower in patients with subsequent event. In both groups, titers increased during hospitalization, IgG from 1.8 resp. 1.5 to 2.2 resp. 1.9, on average 21%, IgM from 0.09 resp. 0.15 to 0.23 resp. 0.22, on average 44% (p < 0.01). Patients with an increase of IgG- or IgM-titer of >100% had no increased frequency of consecutive events. IgG- or IgM-titer did not correlate with titers of CRP (r = 0.02/−0.05) or TnT (r = 0.03/−0.05).

Our data indicate that patients with unstable angina have elevated C. pneumoniae-IgG-titers. However, there is no individual correlation between increased Chlamydia titers and coronary events, CRP- or TNT-titers. Patients with myocardial infarction or death during follow-up have higher titers that further increase during hospitalization.

3193 The prognostic value of fibrinopeptide A, cardiac troponin I, myoglobin and myosin light chain in patients presenting to the emergency department with chest pain

B.M. Sasseen, A. Sonel[1], N. Fineberg[2], N. Bang[2], R.L. Wilensky. *University of Pennsylvania Medical Center, Cardiovascular, Philadelphia PA; [1]Pittsburgh VA Medical Center, Medicine, Pittsburgh PA; [2]Indiana University Medical Center, Medicine, Indianapolis IN, USA*

Background: Although cardiac troponin I (TnI), myoglobin (Myo), and myosin light chain (MLC) have been used to risk stratify patients with acute MI or unstable angina, their role in predicting future cardiac events in a general patient population presenting with chest pain is less clear. Fibrinopeptide A (FPA), a marker of thrombin activity, has not been previously evaluated as a predictor of ischemic events. We sought to determine which myocardial markers would accurately predict major adverse events in patients who presented to the Emergency Department (ED) with possible acute coronary syndromes.

Methods: Serial measurements of urinary FPA, serum TnI, Myo and MLC were analyzed from 247 consecutive patients during the first 8 hours after their presentation to the ED. Major adverse clinical events (MACE) were defined as death of any cause, myocardial infarction, unstable angina, and myocardial revascularization. Events during the initial week and at 6 month follow-up were determined. Sensitivity (Sens), specificity (Spec), positive (PPV), and negative predictive values (NPV) were calculated.

Results: All markers predicted MACE at one week by univariate analysis (all p < 0.01). However, by multivariate logistic regression, only an elevated FPA (odds ratio (OR) 4.82, confidence intervals (CI) 1.78, 13.03, p = 0.002) and an elevated TnI (OR 9.41, CI 2.84, 31.17, p < 0.001) were independent significant predictors of adverse outcomes. At six months, excluding the index events, FPA was the only significant marker to predict MACE (OR 9.57, CI 3.29, 27.80, p < 0.001) and was the only marker to determine a shorter event free survival (p < 0.001). The marker predictive values are listed below.

	1 Wk				6 Mon			
	Sens	Spec	PPV	NPV	Sens	Spec	PPV	NPV
FPA	36	83	71	53	51	82	51	82
TnI	34	91	82	52	30	81	39	75
Myo	33	84	71	50	31	77	34	74
MLC	49	68	63	52	38	59	28	72

Conclusion: In this heterogeneous patient group, TnI and FPA were the most significant markers to predict MACE at one week. An elevated FPA was the most accurate marker in detecting events and predicting decreased survival at 6 months.

ARTERIAL HYPERTENSION: AMBULATORY MONITORING AND THERAPEUTIC ASPECTS

3194 The smoothness index, but not the trough-to-peak ratio, predicts changes in carotid artery morphology during antihypertensive treatment

D. Rizzoni, M.L. Muiesan, M. Salvetti, G. Bettoni, M. Castellano, C. Monteduro, C. Corbellini, C. Brun, R. Zulli, E. Porteri, D. Guelfi, E. Agabiti Rosei. *Chair of Internal Medicine, Dept. of Medical and Surgical Sciences, University of Brescia, Italy*

Objective: It has been recently demonstrated that the "Smoothness Index" (SI) [the ratio between the average of the blood pressure (BP) changes computed for each hour of the recording and its standard deviation, High Blood Press 1997], a new, reproducibile and clinically relevant measure of the homogeneity of BP reduction by antihypertensive treatment, has evident advantages over Trough to Peak ratio (T/P) in the prediction of the regression of left ventricolar hypertrophy (J Hypertens 1998). Therefore we considered worthwhile to compare the ability of SI and T/P to predict changes in the carotid artery morphology in patients with essential hypertension.

Design and methods: In 90 patients with essential hypertension [WHO I–II, age range 45–71 years, clinic supine diastolic BP ranging between 95 e 115 mm Hg], 24-hour ambulatory BP and Carotid artery intima-media thickness (IMT) (BIOSOUND 2000 II) were measured after 3 weeks of therapeutic wash-out and after 12 months of antihypertensive treatment (calcium antagonists, diuretics, ACE inhibitors or β-blockers). The homogeneity of the effect of treament over BP was evaluated by computing T/P and SI.

Results:

Correlations vs. (r)	Δ av comm car art IMT	Δ av comm car art IMT far	Δ av bif IMT	Δ max comm car art + bif IMT
SI of systolic BP	−0.25*	−0.28**	−0.38***	−0.32**
SI of diastolic BP	−0.21*,	−0.25*,	−0.34***	−0.27**
T/P of systolic BP	0.16	0.19	0.06	0.11
T/P of diastolic BP	−0.005	−0.18	−0.058	0.03
Δ24-hour systolic BP	−0.12	−0.14	−0.16	−0.15
Δ24-hour diastolic BP	−0.11	−0.12	−0.17	−0.17

*p < 0.05, **p < 0.01, ***p < 0.001. Δ = changes (therapy − basal), av = average, max = maximum, comm = common, car = carotid, art = artery, far = only far wall, bif = carotid bifurcation].

Twenty-four hour BP was significantly reduced by therapy (from 137/86 ± 12.1/9.20 mm Hg to 129/81 ± 9.89/9.05 mm Hg p < 0.001) while, on average, no significant change of indices of carotid artery wall thickness was observed, although in some cases IMT was clearly reduced. Statistically significant correlations were observed between changes in the 4 indices of carotid artery IMT during therapy and SI. No significant correlation was observed between indices of carotid artery morphology and T/P, basal 24 hour BP or changes in BP during therapy.

Conclusions: SI seems to be a better predictor of changes in carotid artery wall thickness than T/P. The information provided by SI is independent from basal BP values. For carotid artery morphology the smoothness of BP reduction is more important than its absolute change.

3195 24-hour ambulatory pulse pressure and left ventricular structural changes in patients with mild to moderate essential hypertension

P. Zelveian, M.S. Buniatian[1], E.V. Oschepkova, A.N. Rogoza[1], L.M. Sergakova[1], G.G. Arabidze. *Arterial Hypertension, Cardiology Research Complex, Moscow; [1]New Diagnostic Methods, Cardiology Research Complex, Moscow, Russian Federation*

The aim of this study was to evaluate the relationship between 24-h blood pressure (BP) profile parameters and left ventricular (LV) structural changes in patients (pts) with mild to moderate essential hypertension (EH).

Methods: We investigated 70 hospitalized males with mild to moderate EH, aged between 30 and 62 (mean age 48 ± 1.0 y). Noninvasive 24-hour BP recordings (SL-90207) was performed with intervals of 15 min in day- and 30 min in nighttime. LV mass was assessed by echocardiography (Devereux) and normalized by body surface area (LVMI). LV remodeling was assessed by the relative wall thickness (RWT), which was calculated as the sum of the posterior wall thickness and interventricular septum, divided by the end-diastolic dimension. The relationship between LVMI and parameters of BP profile was established by: 1) using multiple stepwise linear regression (MSLR) analysis; 2) Pts were divided into two groups (Gr) according median value of pulse pressure (PP): Gr. A (PP > 45 mm Hg, n = 35) and Gr. B (PP≤45 mm Hg, n = 35).We compared the group A with the group B regarding BP profile parameters. Differences in estimated parameters(M ± SE) were tested by Student t-2 test, the prevalence of normal structure of the LV (LVMI≤125 g/m^2 with RWT ≤ 0.45) – by Fisher's exact test. P < 0.05 was considered as statistically significant.

Results: (1) Awake and sleep systolic, diastolic, pulse pressures entered multiple regression analysis to evaluate their ability to influence LVMI. Multiple R was 0.62 (p < 0.0001). A MSLR analysis identified nighttime PP as a significant predictor of LVMI, which was correlate more closely than other parameters (b = 0.78, partial R = 0.37, p < 0.002).

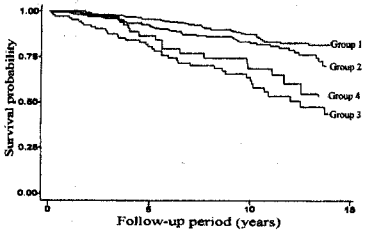
(2) No significant differences was observed between Gr by mean age, body mass index and duration of arterial hypertension. LVMI (134 ± 5 vs 116 ± 3 g/m^2, p < 0.03) and RWT (0.48 ± 0.01 vs 0.43 ± 0.01, p < 0.01) were significantly higher in the Gr.A, comparatively with Gr.B. The prevalence of normal LV structure was significantlty higher in the Gr with nighttime PP < 45 mm Hg (46% vs 14%, P < 0.008).

Conclusion: Our findings demonstrate that nocturnal ambulatory pulse pressure is a powerful and independent risk factor for left ventricular structural changes in patients with mild to moderate essential hypertension.

3196 Dichotomous age-related effect of ambulatory diastolic blood pressure on morbidity and mortality in essential hypertension

R. Khattar, J.D. Swales, R. Senior, A. Lahiri. *Department of Cardiovascular Medicine, Northwick Park Hospital, Harrow, UK*

Population studies have demonstrated age-related changes in diastolic blood pressure. This study compared the prognostic significance of 24 hour ambulatory diastolic blood pressure (DBP) in hypertensives above and below 60 years of age. We followed up 688 patients who underwent pretreatment 24 hour intra-arterial ambulatory BP monitoring, a mean of 9.2 ± 4.1 years earlier; 157 first morbid events were recorded. Patients were divided into 4 groups as follows: group 1 = age < 60 years, DBP < 95 mmHg; group 2 = age < 60 years, DBP ≥ 95 mmHg; group 3 = age ≥ 60 years, DBP < 95 mmHg; group 4 = age ≥ 60 years, DBP ≥ 95 mmHg. Kaplan Meier survival curves after adjustment for sex, race, diabetes, smoking and previous history of cardiovascular disease are shown below:



Whereas DBP ≥ 95 mmhg was associated with reduced survival in the <60 years age group, in those aged ≥60 years, DBP < 95 mmhg was associated with the most adverse outcome. In conclusion, 24 hour diastolic BP has a dichotomous age-related effect on subsequent morbidity and mortality in essential hypertension.

3197 Evaluation of long-term effects of amlodipine and lisinopril on left ventricular mass and diastolic function in elderly, previously untreated hypertensive patients (the ELVERA trial)

W.F. Terpstra, J.F. May[1], A.J. Smit[2], P.A. de Graeff[3], T.K. Havinga[4], E. van der Veur[4], F. Schuurman[4], B. Meyboom-de Jong[5], H.J.G.M. Crijns. *Cardiology Dept., Academic Hospital Groningen, Groningen; [1]Cardiology Dept., Groningen Hypertension Service, Groningen; [2]Internal Medicine, Groningen Hypertension Service, Groningen; [3]Clinical Pharmacology Dept., Groningen Hypertension Service, Groningen; [4]Groningen Hypertension Service, Groningen; [5]General Practice, Groningen Hypertension Service, Groningen, Netherlands*

Meta-analyses by Dahlöf and Cruickshank suggest that ACE-inhibitors reduce echocardiographic left ventricular mass more effectively than diuretics, beta-blockers and calciumantagonists. Little is known about the effects of drug treatment in the elderly hypertensive patient. The ELVERA trial was designed to evaluate the long term effects of the long-acting calciumantagonist amlodipine and the ACE inhibitor lisinopril on left ventricular mass and diastolic function in elderly, previously untreated hypertensives.

Methods: From a population survey 166 newly found, elderly hypertensives (aged 60–75 years) were randomized to amlodipine 5–10 mg or lisinopril 10–20 mg in a two year double-blind randomised comparative trial. Before and after one and two years of treatment left ventricular mass, indexed by body surface area (LVMI) was estimated by 2-D mode echocardiography according to Devereux with use of Penn convention. Early to atrial filling ratio (E/A) was assessed by transmitral flow. Change from baseline of LVMI and E/A ratio was evaluated by repeated measurement analysis of the treatment effect in an intention to treat analysis.

Results: At the end of the study period, in the amlodipine group LVMI decreased by -21.8 g/m^2 (95% CI: -25.3, -18.3) and E/A ratio increased by 0.08 (95% CI: 0.05, 0.11). In the lisinopril group LVMI decreased by -22.4 g/m^2 (95% CI: -25.8, -19) and E/A ratio increased by 0.07 (95% CI: 0.04, 0.10). Blood pressure reduction was equal for both treatment regimens.

Conclusion: The ELVERA trial proves that the long term effects of amlodipine and lisinopril are equipotent with respect to reduction of left ventricular mass and improvement of diastolic function in elderly hypertensive patients.

3198 Effect of angiotensin-converting enzyme inhibitor on fibrogenic activity in hypertensive patients

Ahmed A. El-Hawary, Emad Ismail, Taher I. El-Serafy, Fathy A. Maklady. *Department of Internal Medicine and Biochemistry, Faculty of Medicine, Suez Canal University, Cairo, Egypt*

This study was conducted to evaluate fibrogenic activity in patients with hypertension by measuring serum concentrations of procollagen type I peptide (PIP) and procollagen type III peptide (PIIIP) as biochemical markers of tissue synthesis of collagen type I and type III. Also, to assess the relation between their serum concentrations and left ventricle (LV) structure and functions, and to demonstrate the effect of reduction of blood pressure by captopril on their serum concentrations. We studied 79 hypertensive patients and 50 normotensive control subjects. After clinical evaluation, echocardiography (M-mode, 2D, and pulsed Doppler) was done to evaluate left ventricle structure and function. Serum PIP and PIIIP were estimated by radioimmunoassy. All hypertensives received captopril for 6 months, after which, echocardiograhic and biochemical studies were repeated. Posterior wall thickness, septal thickness, left ventricular mass and mass index were significantly higher in patients than in control. Serum concentrations of PIP and PIIIP were significantly higher in patients than in control (258 ± 57.1 & 3.7 ± 2.2 vs. 167.4 ± 69.8 & 1.91 ± 1.36 μgm/L respectively). In addition PIP and PIIIP were significantly higher in hypertensives with LVH than in those without LVH (270.6 ± 56.8 & 4.03 ± 2.3 vs. 223.4 ± 42.2 & 2.9 ± 0.91 μgm/L respectively). After treatment with captopril for six months left ventricle hypertrophy regressed in 13 out of 68 patients, LV mass index and diastolic dysfunction were normalized in 17 out of 58 patients and in 10 out of 44 patients respectively. Serum concentrations of PIP and PIIIP were diminished significantly after treatment (258.1 ± 57.1 and 3.73 ± 2.16 versus 168.4 ± 62.6 and 2.51 ± 2.19 μgm/L respectively). We concluded that, biochemical monitoring of collagen fibril turnover might provide a potential non-invasive method of assessing myocardial fibrosis and elevated serum PIP and PIIIP may be useful markers of increased collagen synthesis in those patients. Circulating procollagen derived peptides may reflect ongoing myocardial fibrosis in essential hypertension. ACE-I may reduce the excessive synthesis of collagen type I and type III in hypertension.

3199 Effect of losartan on human platelets activation

J.I. Guerra, A.M. Jiménez, J.A. Rodríguez-Feo, F. González-Fernández, M. Montón, M. García-Durán, L. Rico, J. Farré, S. Casado, A. López-Farré. *Nephrology, Hypertension and Cardiovascular Research Laboratory, Fundación Jiménez Díaz, Madrid, Spain*

Previous studies have demonstrated that losartan could block the receptor of thromboxane A_2 (TXA_2) on the vascular wall. The aim of present study was to assess the effect of losartan on human platelet activation.

Design and Methods: Platelets were obtained from 15 healthy men with ages between 26 and 40 years. Platelet activation was measured by the changes in the light transmission of platelet-rich plasma stimulated by the TXA_2 analogue, U46619 (5×10^{-6} mol/L) or ADP (10^{-5} mol/L).

Results: U46619-stimulated platelet aggregation was significantly inhibited by losartan in a dose-response manner. Only a high dose of EXP3174 (5×10^{-5} mol/L), the in vivo active metabolite of losartan, was able to attenuate U46619-induced platelet activation. Captopril (5×10^{-5} mol/L) an angiotensin I-converting inhibitor failed to modify U46619- induced platelet aggregation. Furthermore, the binding of [^{3}H]-U46619 to platelets was competitively inhibited by losartan, whereas only a high dose of EXP 3174 (5×10^{-5} mol/L) reduced the binding of [^{3}H]-U46619. Captopril failed to modify the binding of [^{3}H]-U46619 to platelets. The effect of losartan on platelet activation induced by ADP (10^{-5} mol/L), a platelet agonist partially dependent on TXA_2, was also tested. Losartan reduced ADP-induced platelet activation. In addition, blocking of thromboxane A2 generation by aspirin inhibited ADP-induced platelet aggregation to a similar magnitude as losartan. Exogenous angiotensin II did not elicit any modification of either U46619-or ADP-stimulated platelet aggregation.

In conclusion: Losartan decreased platelet aggregation by a TXA_2-dependent mechanism. EXP3174 showed a lesser potency than losartan to reduce TxA_2-platelet activation. Captopril and exogenous angiotensin II had no effect on human platelet activation. These results suggest that losartan reduced TXA_2-dependent platelet activation independently of Ang II involvement.

NEW DEVELOPMENTS AND APPLICATIONS OF THREE-DIMENSIONAL ECHOCARDIOGRAPHY

3204 Improved accuracy of transthoracic three-dimensional echocardiography with harmonic imaging for assessment of left ventricular volumes: comparison with magnetic resonance imaging

W.Y. Kim, P. Sogaard, B. Ostergaard Kristensen, H. Egeblad. *Department of Cardiology, Skejby University Hospital, Aarhus, Denmark*

Background: Three-dimensional transthoracic echocardiography (3D ECHO) eliminates geometrical assumptions in estimation of left ventricular (LV) volumes and harmonic imaging may improve accuracy because of improved delineation of endocardial borders. We compared 3D ECHO with multislice magnetic resonance imaging (MRI) which is considered a gold standard for LV volume measurement.

Methods: Thirteen consecutive patients undergoing coronary angiography because of heart failure and impaired LV function (11 males, 12 with ischemic heart disease and one with cardiomyopathy) were included in the study. LV volumes were measured independently by MRI and 3D ECHO (GE-VINGMED,System V) using fundamental B-mode and tissue harmonic imaging. Volume calculations were performed by two of the authors in order to assess interobserver variability.The agreement between 3D ECHO and MRI, and interobserver variability for determination of EDV, ESV, and EF were estimated. Thus, the mean difference between the two measurements $\pm$ 2 SD of the differences expressed as a percentage of the average values were calculated.

Results: According to MRI, EDV = 278 ± 82 ml, ESV = 202 ± 82 ml and EF = 0.29 ± 0.08%. Compared with fundamental imaging, tissue harmonic imaging showed closer agreement with MRI and less interobserver variability in estimation of left ventricular volumes (see table).

	Harmonic imaging		Fundamental imaging	
	MRI-3D ECHO	Interobs. variability	MRI-3D ECHO	Interobs. variability
EDV	-1.9 ± 9.7	-0.3 ± 5.6	-10.8 ± 17.5*	5.5 ± 13.9*
ESV	0.4 ± 9.3	0.7 ± 10.8	-6.3 ± 22.0*	0.5 ± 18.7
EF	-1.5 ± 6.3	$-0.7 \pm 0.6.4$	-2.8 ± 12.1	2.6 ± 13.7*

*$P < 0.05$ Harmonic vs. fundamental imaging. Mean $\pm$ 2 SD(%).

Conclusion: Tissue harmonic imaging with 3D ECHO shows low interobserver variability and is a very accurate method for assessment of LV volumes in patients with heart failure and LV dilatation.

3205 Flow quantification with digital three-dimensional Doppler: a potential tool for monitoring cardiac output

X.-N. Li[1], T. Irvine[1], D. Lennon[2], Y. Mori[1], P. Detmer[2], A. Pope[2], G. Schwartz[2], D.J. Sahn[1]. [1]*Oregon Health Sciences University, Portland OR;* [2]*A T L Ultrasound, Bothell WA, USA*

The accuracy of conventional Doppler methods for measuring stroke volume is highly variable especially if the flow in the area of measurement deviates from a circular fixed cross-section and uniform velocity profiles. We have developed a Gauss's Theorem based digital three-dimensional (3D) Doppler method for resolving volume flow rates with minimal angle dependence. We tested the method *in vitro* using a simulated ascending aortic flow model.

Method: 8 pulsatile flows (peak flows 85–200 cm^3/sec, verified with an ultrasonic flowmeter) were pumped through each of three curved, oval-shaped compliant tubes (cross-sectional area 1.75–3.5 cm^2). A rotational 3D scan at 5° intervals was performed with a multiplane transesophageal probe oriented in 2 distinctive views (20° and 40° oblique to the flow direction). ECG triggered digital color Doppler images were obtained synchronized to peak flow. Doppler velocity vectors normal to a selected spherical surface projected within the 3D data (Fig.) were integrated to yield flow rate.

Results: The 3D derived flow rates correlated well to the references for all three tubes at all settings (n = 48, Table). Stroke volume derived from multiple samplings integrated within the pulse cycle (at one flow rate) also yielded results comparable to true stroke volume (56 vs. 50 cm^3).

Tube	Regression (n = 8 each)		r		SEE (cm^3/s)		p	
	20° Oblique	40° Oblique	20°	40°	20°	40°	20°	40°
1	Y = 0.94X + 6.1	Y = 1.25X − 35.2	0.99	0.96	5.6	14.0	<0.001	<0.001
2	Y = 0.99X + 0.2	Y = 0.97X − 4.2	0.98	0.99	8.2	5.5	<0.001	<0.001
3	Y = 0.92X + 10.2	Y = 0.97X − 3.4	0.97	0.99	9.0	3.4	<0.001	<0.001

Conclusion: Our digital 3D Doppler method provides laminar flow volume quantification with little angle dependence and could be applicable clinically for measurements of stroke volume and cardiac output.

3206 Real-time three-dimensional stress echocardiography in assessment of patients with ischaemia; comparison with two-dimensional stress echocardiography

M. Ahmad, T. Xie, G. Abreo, M. Trough, M. Adams, M. Runge. *Cardiology Dept, University of Texas Medical Branch, Galveston TX, USA*

Real-time 3D ultrasound (RT-3D, VOLUMETRICS) displays multiple views from a single acquisition, a major advantage in assessment of LV wall motion (WM). RT-3D images were obtained within a minute of 2D images at baseline and at peak Dobutamine stress echo (DSE) in 179 patients (pts); RT-3D and 2D images were reviewed independently by 2 different observers.

Results: Imaging time per stage ranged from 45 to 60 secs. for RT-3D and 60 to 90 secs. for 2D. Out of 179 pts, technically satisfactory studies for comparisons were obtained in 158 pts. At baseline 41 of 158 pts had abnormal LV WM by RT-3D and 43 of 158 by 2D (84.8% concordance). At peak DSE 62 of 151 pts had abnormal WM by RT-3D compared to 55 of 149 pts by 2D (81.6% concordance, 11 were non-diagnostic by RT-3D and 14 by 2D). WM scores in pts with abnormal WM at peak DSE were 1.52 ± 0.36 by RT-3D and 1.22 ± 0.22 by 2D ($p < 0.0001$). Mean ± SD (ml), LV end diastolic volume (EDV), LV end systolic volume (ESV) and ejection fraction (%) by RT-3D at baseline were 110.9 ± 33.2, 49.3 ± 17.6, 56.1 ± 5.2 and at peak DSE were 101.8 ± 28.7, 34.9 ± 15.4 and 66.5 ± 7.1. LV volume measurements by RT-3D were validated against biplane LV Cine-angiograms in 9 pts with r = 0.9 for EDV and 0.8 for ESV.

In 56 pts with coronary angiographic data, the sensitivity of RT-3D in detection of coronary artery disease was 81.1% compared to 67.6% by 2D.

Conclusions: RT-3D DSE is sensitive in detection of coronary artery disease, provides rapid measurements of LV volumes and offers promise in delineating the extent of ischemia.

3207 Initial experience with real-time three-dimensional echocardiography using ultrafast rotating transthoracic scanner: preliminary human and experimental studies

J.D. Kasprzak[1], S.A.I.P. Trines, R. Krams, N. de Jong, W.B. Vletter, C.T. Lancee, N. Bom, F.J. Ten Cate, J.R.T.C. Roelandt. *Heart Centre Rotterdam, Netherlands;* [1]*Medical University of Łódź, Poland*

Background: Real-time data acquisition for three-dimensional echocardiography (3DE) has been accomplished using a dedicated system with pyramidal scanning capability. The study was designed to determine the feasibility of real-time data acquisition using a newly developed ultrafast rotating transthoracic scanner (URS) in humans and in experimental contrast echocardiographic studies.

Methods: Studies were performed using URS connected to Vingmed System FiVe. 3DE was performed in 3.3 MHz fundamental or 2.9/5.8 MHz harmonic mode with image settings optimized for high 2D frame rates. Data were collected in a digital cine loop during a fast (160–480 rpm) rotation of the URS array without ECG or respiratory gating. After transfer to EchoPAC-3D environment, off-line data analysis was performed. Studies were performed in 4 patients and 2 porcine experiments with imaging before and after the bilateral coronary injection of a deposit agent, Myomap™.

Results: A total of 29 successful acquisitions was performed. Variable rotational speed resulted in datasets collected at 3–15 degree interval with temporal resolution of 6–14 volumes per heart cycle. Successful, geometrically correct datasets were obtained both in fundamental and second harmonic mode. Anyplane and volume-rendered views could be reconstructed. Resolution was sufficient to display anatomical details such as valve orifices or coronary arteries. The deposit contrast agent provided a consistent myocardial opacification, reliably reproduced within 3DE datasets. The main problems were cardiac motion artifacts and resolution limitations resulting from insufficient 2D frame rate.

Conclusions: 3DE real-time data acquisition can be performed with an ultrafast rotating scanner connected to a standard echo system. Resulting datasets are suitable for clinical analysis and may be used for perfusion contrast studies. Increase in maximal 2D frame rate is desirable to improve resolution and widen the imaging sector.

3208 Evidence of reduced regression of left ventricular mass one year after valve replacement for pure aortic stenosis in patients with small prosthetic valves: a three-dimensional echocardiographic study

H.P. Kühl, D. Puschmann, R. Hoffmann, A. Franke, P. Hanrath. *Medical Clinic I, RWTH Aachen, Germany*

We sought to assess the impact of prosthetic valvular size on the regression of left ventricular mass (LVM) in patients with pure aortic stenosis one year after mechanical valve replacement. In 20 patients (mean age 63 ± 10 years) without concomitant coronary artery disease, hypertension or diabetes mellitus LVM was measured using transesophageal three-dimensional echocardiography (3DE) 2 ± 1 days before and 12 ± 1 months after aortic valve replacement. Results of LVM regression were compared for patients with a small prosthetic valve size (23 mm; group I = 10 pts) to those with a valve of >23 mm (range 25 to 31 mm; group II = 10 pts.). 3DE image acquisition was performed in 3° increments using ECG and respiratory gating (HP Sonos 5500). LVM was measured using a previously validated software (Echo-View, TomTec). In addition, regression of LVM was also assessed by M-mode echocardiography according to ASE standards.

Results: Preoperative mean valve area was 0.7 cm^2 in both groups. Before surgery LVM by 3DE averaged 116.9 ± 37.0 g/m^2 in group I and 140.7 ± 33.9 g/m^2 in group II ($p = 0.01$). One year after valve replacement there was a significant difference in the regression of LVM between the two groups (18.5 ± 5.7 g/m^2 or 16.7% in group I vs. 38.7 ± 11.8 g/m^2 or 27.6% in group II; $p < 0.003$). There was no significant association between the regression of LVM and mean transvalvular Doppler gradient after surgery (mean pressure gradient 8.0 ± 4.0 mmHg versus 7.7 ± 2.1 mmHg for group I and II; p = ns). Despite comparable baseline mass values for M-mode (126.0 ± 34.8 g/m^2 and 147.3 ± 23.4 g/m^2; p = ns versus 3DE) no significant difference in LVM regression between groups I and II could be detected (25.8 ± 16.5 g/m^2 or 19.6% vs. 28.9 ± 16.1 g/m^2 or 19.6%; p = ns).

Conclusion: 1) In pure aortic stenosis the regression of LVM is lower for prosthetic valves sized 23 mm as compared to valves > 23 mm at one year. 2) M-mode is an insensitive tool to detect subtle mass changes in patients with small prosthetic valves.

3209 Measurement of mitral valve area using three-dimensional echocardiography: in vitro validation

N. Sutaria, T.R.D. Shaw, K.A.A. Fox[1], S. Pye[2], N. McDicken[2], D. Northridge. *Cardiology Dept., Western General Hospital, Edinburgh; [1]Cardiology, Edinburgh Royal Infirmary, Edinburgh; [2]Medical Physics Dept., Western General Hospital, Edinburgh, UK*

Two-dimensional echocardiography (2DE) is an imperfect tool for the measurement of mitral valve area (MVA) due to limitations of beam alignment and difficulty in locating the precise short axis plane of the orifice at the leaflet tips. Three dimensional echocardiography (3DE) allows careful selection of the optimal plane for planimetry thereby offering a more accurate method for quantitation of mitral stenosis. This technique has yet to be validated.

Methods: 20 porcine mitral valves were isolated and the commissures glued to simulate mitral stenosis over a range of severity. The valves were scanned in a water bath using a 7.5 MHz transoesophageal probe and a rotational 3D data set acquired using Tomtec Echoscan. During off-line analysis a line of intersection was positioned at the tips of the mitral leaflets in the plane of the orifice and a series of parallel cross sections through the valve were generated at 1 mm intervals (paraplane echo). The optimum 2D short axis slice was selected and the orifice area measured by planimetry. 'Actual' mitral valve area was determined by pixel intensity measurement of a digitally scanned image of the valve which had been angulated to project the maximum orifice size.

Results: The digital scanner technique had been validated using 14 cylindrical phantoms of known cross-sectional area, the mean difference between phantom area and area measured by the digital scanner was 0.05 $cm^2 \pm 0.12$ cm^2 (mean $\pm$ 2 SD, Bland Altman), $r = 0.99$, $p < 0.001$. MVA of the prepared porcine valves ranged from 0.3 to 3.6 cm^2. MVA measured by 3DE correlated very well with MVA measured by digital scanning with mean difference 0.1 $cm^2 \pm 0.15$ cm^2, $r = 0.99$, $p < 0.01$.

Conclusions: This invitro study demonstrates that 3DE is very accurate in the measurement of MVA. If these findings are confirmed in clinical studies transoesophageal 3DE could become the gold standard for measurement of MVA

MECHANISMS OF PROGRESSION OF VALVULAR HEART DISEASE

3210 Abnormal aortic elastic properties in patients with bicuspid aortic valve

S. Nistri, M. Sorbo[1], A. Vitolo, C. Basso[2], R. Scognamiglio[1], G. Thiene[2]. *Sanitary Service, Arma dei Carabinieri, Dept. of [1]Cardiology; [2]Pathology, University of Padova, Padua, Italy*

Bicuspid aortic valve (BAV) is frequently associated with abnormalities of the aorta suggesting that this association may reflect a common developmental defect, namely intrinsic medial weakness. Aortic dilatation has been considered to be a clinical correlate of aortic medial weakness, and it has been shown to be present in patients with BAV independently from hemodynamic abnormalities of the aortic valve. In order to evaluate the presence of abnormal aortic elastic properties in patients with BAV, we consecutively studied 42 young male patients with BAV and no or mild aortic regurgitation by means of 2D-echocardiography to assess aortic distensibility and stiffness. We compared our results with data obtained in 44 consecutive normal young males, matched for age and blood pressure. Patients with BAV showed significantly larger aortic root dimensions at annulus (24 $\pm$ 2 mm *vs* 22 $\pm$ 2 mm, respectively, $P = 0.00126$), sinuses of Valsalva (32.6 $\pm$ 3.6 mm *vs* 26 $\pm$ 2.7 mm, respectively, $P < 0.001$), sinotubular junction (28.3 $\pm$ 2.8 mm *vs* 24.7 $\pm$ 1.8 mm, respectively, $P < 0.001$) and ascending aorta (28 $\pm$ 23 mm *vs* 24.9 $\pm$ 1.9 mm, respectively, $P < 0.001$) in comparison with controls. The difference between systolic and diastolic aortic diameters in patients (2.07 $\pm$ 1.24 mm), was significantly lower than the one in controls (2.76 $\pm$ 1 mm, $p = 0.002$). Systolic and diastolic blood pressure and pulse pressure were comparable in patients and controls. Aortic distensibility in patients ($2.61 \pm 1.5 \times 10^{-6}$ $cm^2/dyne^{-1}$) was significantly lower than in controls ($4.6 \pm 2.2 \times 10^{-6}$ $cm^2/dyne^{-1}$, $P < 0.001$), while aortic stiffness index was higher in patients with BAV (10.43 $\pm$ 5.4) than in controls (5.63 $\pm$ 2.9, $P < 0.001$).

In conclusion, patients with BAV and no or mild aortic regurgitation, present larger aortic root dimensions and abnormal elastic properties of the ascending aorta, confirming that aortic dilatation is a morphological correlate of intrinsic medial weakness.

3211 Role of endothelial adhesion molecules in the pathogenesis of degenerative aortic valve disease

N. Ghaisas, B. Foley, D.S. O'Briain[1], P. Crean, D. Kelleher[2], M. Walsh. *Dept. of Cardiology, [1]Dept. of Pathology, [2]Dept. of Clinical Medicine, St. James's Hospital, Dublin, Ireland*

The presence of activated T lymphocytes in degenerative aortic valve (AV) disease suggests that immunnological mechanisms may be important in the pathogenesis. Adhesion molecules play a key role in recruitment of leukocytes to sites of inflammation. We studied the valvular expression of the endothelial adhesion molecules intercellular adhesion molecule 1 (ICAM-1), vascular cell adhesion molecule 1 (VCAM-1) and E-selectin in patients with degenerative AV disease and the relation between endothelial expression and soluble adhesion molecule levels.

Methods: Aortic valves from 23 (adequate endothelium in 22) patients undergoing elective AV replacement were stained for the 3 adhesion molecules by immunohistochemistry. Staining intensity was graded 0–4 independently, a grade of 2 or more was considered positive. Soluble adhesion molecule levels were measured by enzyme linked immunosorbent assay in 16 of the patients without other inflammatory illnesses. Levels of soluble adhesion molecules were correlated with endothelial staining intensity (Spearman's correlation). Six autopsy AV (4 normal, 2 thickened)were also studied.

Results: A high proportion of the diseased valves stained positive for the 3 adhesion molecules (Table 1)while the normal autopsy valves were negative. There was no significant difference between the proportions of valves staining positive between the bicuspid and trileaflet groups. There was a strong association between the intensity of endothelial staining and the soluble molecule levels for E-selectin ($R = 0.724$, $p = 0.002$) but not for ICAM-1 ($R = -0.130$, $p = 0.631$)or VCAM-1 ($R = -0.367$, $p = 0.162$).

Table 1. Adhesion molecule expression on aortic valve endothelium

	ICAM-1 +	VCAM-1 +	E-selectin +
Surgical – trileaflet (n = 16), n (%)	12 (75)	11 (69)	12 (75)
Surgical – bicuspid (n = 6), n (%)	4 (67)	3 (50)	5 (83)
Autopsy – normal (n = 4), n	0	0	0
Autopsy – thickened (n = 2), n	2	2	2

Conclusion: The increased expression of adhesion molecules ICAM-1, VCAM-1 and E-selectin supports an inflammatory component in the pathogenesis of degenerative AV disease. Soluble E-selectin levels may be useful markers of endothelial activation in this condition, while soluble ICAM-1 and VCAM-1 may be derived from sources other than valvular endothelium.

3212 Is Chlamydia pneumoniae aetiologically linked to aortic stenosis?

P. Hilti[1], N. Jander[1], C. Murtin[3], T. Schaffner[3], Ch. Zaugg[1], N. Hess[1], W. Brett[2], P. Hohl[4], H. Matile[4], M. Pfisterer[1]. *[1]Division of Cardiology; [2]Cardiothoracic Surgery; [3]University Hospital Basel; Institute of Pathology, University of Berne; [4]F. Hoffmann-La Roche AG, Basel, Switzerland*

Background: The etiology of nonrheumatic calcified valvular aortic stenosis is unknown. Recent work suggests a possible link to infection with *Chlamydia pneumoniae*. Therefore we tested the evidence for *C. pneumoniae* in calcified aortic valves, and as control in non-calcified aortic and mitral valves.

Methods: We studied 23 patients (pts.) (mean age 68 $\pm$ 13 years, 13 males) undergoing valve replacement because of severe calcified aortic stenosis (AS, n = 17), aortic regurgitation (AR, n = 2) and mitral regurgitation caused by mitral valve prolapse (MR, n = 4). Resected valve tissue was investigated by culture, by immunohistochemistry (IHC) using 2 different monoclonal antibodies (RR-402, CF-2) and by PCR (amplification A and B). In addition IgG serum antibodies against *C. pneumoniae* were analysed by ELISA in 21 pts.

Results: Outcome of serological and non-serological testing differed markedly.

	% positive in pts. with AS	% positive in pts. with AR or MR
IgG serum antibodies	94	100
Immunohistochemistry RR-402	29	0
CF-2	41	0
PCR amplification A	44	33
PCR amplification B	88	67
culture	0	0

Uniformly positive results with both IHC methods and both PCR amplifications were obtained only in 3 pts. (all with AS), and uniformly negative results in only 1 patient (with AR), the latter despite a positive serum IgG titer.

Conclusions: Serological evidence of *C. pneumoniae* is commonly present in pts. with calcified aortic stenosis. However, the only partial detection of *C. pneumoniae* antigen in aortic stenosis by immunohistochemistry, the presence of DNA even in non-calcified valves in pts. with aortic and mitral regurgitation, and the failure to culture *C. pneumoniae* in any of the resected valves cast doubt on a specific causative role of *C. pneumoniae* in calcified valvular heart disease.

3213 Haematological investigation of suspected hypercoagulability in patients with aortic valve disease

I.R.A. Goldsmith[1,2], R.L. Patel[2], A.D. Blann[1], G.Y.H. Lip[1]. *[1]HTVBU, University Department of Medicine, City Hospital, Birmingham; [2]Department of Cardiothoracic Surgery, Walsgrave Hospital, Coventry, UK*

Patients with aortic valve (AV) disease have an increased risk of thromboembolism which may in part be due to increase in coagulopathy. To investigate this we studied indices of platelet activation, endothelial dysfunction and coagulation in 54 patients (20 males, mean age 68 years) with AV disease and 54 age and sex-matched controls. Blood samples were taken from a peripheral vein atraumatically. We measured levels of the soluble adhesion molecule P selectin (sP-sel, ng/ml, an index of platelet activation) von Willebrand factor (vWf, IU/dL, marker of endothelial dysfunction) by ELISA and plasma fibrinogen (g/L) by modified Clauss method. Results, expressed as mean (standard deviation) are as follows:

Index	Controls	Patients	P
Number	n = 54	n = 54	
Age in years (sd)	68.1 (9.8)	67.8 (9.8)	0.46
sP-sel	102.7 (45)	78.1 (40)	0.028
vWf	101.0 (30)	125.6 (32)	0.0001
Fibrinogen	3.0 (0.7)	3.7 (1.0)	0.001

The plasma levels of vWf and fibrinogen were significantly higher in patients with AV disease compared to healthy controls suggesting increased endothelial dysfunction and coagulation in these patients. Conversely, the plasma levels of sP-sel were significantly lower in patients with AV disease. From the total cohort 26 patients underwent mechanical aortic valve replacement (AVR). There was a significant increase in sP-sel ($p < 0.01$) and vWf ($p < 0.01$) but not fibrinogen 3 months post surgery compared to before surgery in these patients.

Conclusions: AV disease is associated with increased endothelial dysfuntion and coagulation but not platelet activation. Following mechanical AVR there is increased endothelial dysfunction and platelet activation. This may contribute to the increased risk of thromboembolism in such patients.

3214 Sudden death in mitral regurgitation due to flail leaflets: when is it unexpected?

F. Grigioni, M.E. Sarano, H.L. Ling, K.R. Bailey, A.J. Tajik. *Mayo Foundation, Rochester MN, USA*

Background: Sudden death (SD) is a catastrophic complication of mitral regurgitation (MR), and its incidence and predictability are undefined.

Methods: To address this issue, we analyzed the occurrence of SD under conservative management in 350 patients (Pts) with MR due to flail leaflets diagnosed echocardiographically from 1980 through 1994.

Results: At diagnosis, patients were age 67 ± 12 years, 74% male, EF 63 ± 10%, and had NYHA class I(61%), II(24%), III(11%), and IV(3%). During a mean medical follow-up of 48 ± 41 months 25 SD death occurred accounting for the 24% of total number of death. Linearized SD rate was overall 1.8%/year. In proportional hazards analysis, independent baseline predictors of SD were NYHA Class ($P = 0.006$), EF ($P = 0.0001$) and atrial fibrillation (AF) ($P = 0.058$). However, among Pts who had SD 9/25 (36%) were in NYHA class I or II (remained so during follow-up) and had an EF > 60%. Moreover, 5 of these 9 were in sinus rhythm and remained so, leading to 5 (20%) completely unpredictable SD. When post-surgical follow-up was considered, multivariate analysis adjusting for NYHA Class, EF, and AF showed surgery performed any time to be independently associated with a reduced incidence of SD (adjusted Hazard Ratio [95% C.I] = 0.22 [0.08–0.58], $P = 0.002$).

Conclusions: 1) Sudden death is a relatively common mode of death in Pts with MR due to flail leaflets. 2) Patients either with severe symptoms, reduced LV function, and AF, are at higher risk of SD, but 3) a notable number of SD are completely unpredictable; 4) Correction of MR appears to reduce the incidence of SD and this effect should be weighed in considering early surgery for MR due to flail leaflets.

3215 Mitral annulus calcification as cause of structural and functional abnormalities in mitral valve and left atrium

D. Mentzikof, J. Parissis, J. Zarifis, K. Merkouris, C. Kefalas, A. Kanapitsas, S. Karas. *First Department of Cardiology, Amalia Fleming Hospital, Athens, Greece*

Background: Idiopathic mitral annulus calcification (MAC) is one of the most common cardiac abnormalities found at autopsy. It has also been reported that severe MAC causes mitral regurgitation (MR). This study investigates the consequences of MAC on mitral valve (MV) and left atrium (LA) in the ederly.

Methods: LA diameter, LA mean surface, MV orifice and MR were measured in 55 patients aged over 60 yrs with MAC by 2D Echo, pulse and color Doppler technique. Patients were classified in three groups according to the severity of MAC: Group A (n = 28, mean age: 72.6 ± 7.1 yrs) with calcification under the posterior leaflet, Group B (n = 17, mean age: 74.7 ± 6.9 yrs) with total MAC and Group C (n = 10, mean age: 75.1 ± 7.9 yrs) with calcification extending to the basal part of the leaflets. Patients with atrial fibrilation, hypertension, aortic stenosis, rheumatic disease and chronic renal failure were excluded from our study.

Results: Echocardiographic study showed that mean LA diameter and surface were in group A 4.2 ± 0.4 cm and 22.7 ± 3.1 cm^2, in group B 4.49 ± 0.6 cm and 25.5 ± 4.2 cm^2 ($p = 0.02$) and in group C 5.1 ± 0.7 cm and 27.2 ± 4.1 cm^2 ($p = 0.01$), respectively. Additionally, there was a minor degree of MV stenosis (mean surface: 1.67 ± 0.7 cm^2) in all patients of group C and two patients of group B (1.68 cm^2 and 1.66 cm^2 respectively). Finally, MR 1^+ was found in 50% of patients of group A, 29% of group B and 30% of group C, while MR 2^+ in 25% of group A, 70% of group B and 60% of group C.

Conclusions: MAC is accompanied by minor to moderate MR in ederly. When calcification invades the basal part of the leaflets, there is a restriction of the MV orifice. Furthermore, LA dilatation is a significant consequence related with the severity and extension of MAC in ederly.

HYPERTROPHY IN RODENTS

3225 AT1 receptor blockade prevents cardiac hypertrophy and myocardial damage in bradykinin B2 receptors knockout mice

R. Maestri, C. Emanueli[1], P. Madeddu[2], D. Corradi, M.B. Salis[1], R. Pacchiana, G. Graiani, N. Bertani, E. Cigola, G. Olivetti. *Pathology Dept., University Medical School of Parma, Parma; [1]National Laboratory, Biostructures and Byosystems, Osilo; [2]Biochemistry and Internal Medicine, University of Sassari, Sassari, Italy*

Transgenic mice lacking bradykinin (BK) B2 receptor develop mild hypertension, cardiac hypertrophy and several foci of replacement fibrosis in the left ventricle similar to that seen in hypertensive cardiomyopathic hearts of humans. These effects have been attributed to the hypertrophying and damaging action of angiotensin II(Ang II) in the absence of balancing protection of BK. To verify this hypothesis pregnant BK knockout (KO) mice were treated orally with a non-peptide antagonist of AT1 receptors (170 μg/kg, A81988, Abbott Laboratories) and the offsprings after weaning continue to receive the same drug in the drinking water until 180 days of age. An additional group of wild type mice was similarly treated. Untreated KO mice served as controls. Arterial blood pressure was monitored by the tail cuff method at regular intervals starting at 40 days of age. At the end of the experiment hearts were arrested in diastole with cadmium chloride. After the measurements of left ventricular chamber length, middle transverse diameters and ventricular wall thickness, the right and left ventricles and septum were dissected free and separately weighted. Transverse slices of the left and right ventricles were embedded in paraffin and examined quantitatively to determine the amount of myocardial damage. No effect on body weight gain, heart rate and arterial pressure was seen in wild type mice with the treatment. In contrast, in KO mice AT1 receptor blockade decreased arterial blood pressure to control values until 3 months of age with no changes in heart rate. Thereafter arterial pressure was similar in treated and untreated mice. At 180 days of age both left ventricular and cardiac weights of treated KO mice were 20% ($p < 0.05$) lower than in untreated KO. No statistically significant differences were seen in left ventricular wall thickness and chamber volume between treated and untreated mice. Interestingly, myocardial damage was almost abolished by AT1 blockade indicating that local Ang II may play a significant role in the genesis of myocardial scar through AT1 receptor. In conclusion, Ang II receptor blockade prevents functional, anatomical and structural alterations characteristic of BK B2 receptors KO mice implying that the balance between Ang II and BK is essential for the maintenance of a normal heart with age. Moreover, the absence of myocardial damage and myocardial hypertrophy in transgenic mice with AT1 blockade in the presence of mild hypertension suggests that local production of Ang II is the major responsible for myocyte death and growth.

3226 The effects of nitric oxide donor, sodium nitroprusside, on the immediate growth response to load in intact adult rat hearts

J. Bartunek[1,2], E.O. Weinberg[2], C.D. Thienelt[2], B.H. Lorell[2]. [1]*Cardiovascular Center, Aalst, Belgium;* [2]*Cardiovascular Division, Beth Israel Deaconess Medical Center, Boston MA, USA*

Nitric oxide (NO) inhibits smooth muscle cell growth *in vitro*, but effects on adult cardiac growth are poorly understood. We have previously shown that the imposition of systolic load in isolated perfused adult hearts induces the acute growth response of new cardiac protein synthesis and proto-oncogene expression. Thus, we used this model to test the hypothesis that the NO donor, sodium nitroprusside (SNP) inhibits the induction of new cardiac protein synthesis and the immediate early gene *c-myc*.

Isovolumic perfused adult rat hearts with constant flow were subjected to the growth stimulus of an acute increase in systolic wall stress for 1 hr by an increment in LV balloon volume. New protein synthesis was measured by the rate of [^{3}H] phenylalanine (Phe) incorporation into LV proteins. LV message levels of *c-myc* were measured by Northern blot analysis. To eliminate confounding effects of changes in coronary flow during SNP infusion, all hearts were studied in the presence of maximal vasodilatation with adenosine (10^{-6} M) at identical coronary perfusion pressure. In the control hearts subjected to elevated systolic load (n = 9), the rate of Phe incorporation was 720.5 ± 65.3 nmol/g protein/hour. Treatment with SNP (10^{-3} M, n = 8) decreased load-induced protein synthesis by 28 ± 6% ($p < 0.05$ vs load alone). In addition, SNP inhibited load-induced LV *c-myc* expression by 55 ± 13% ($p < 0.05$ vs load alone). These effects were associated with an increase in left ventricular cyclic GMP content (7.2 ± 1.1 vs 3.8 ± 0.6 10^{-12} M/g dry weight, $p < 0.01$).

These results demonstrate that the NO donor, sodium nitroprusside, suppresses the acute effects of systolic load on proto-oncogene expression and new cardiac protein synthesis in the intact adult heart.

3227 Angiotensin II increases GLUT-1 mRNA gene expression in rat myocardium

N. Rosenblatt-Velin, M. Brink, P. Delafontaine, R. Lerch. *Cardiology Center, University Hospital, Geneva, Switzerland*

Background and Methods: Indirect evidences suggest that Angiotensin II (Ang II) is involved in development of hypertrophy of surviving myocardium after myocardial infarction. We have previously observed that postinfarction hypertrophy is associated with alterations of the expression of a number of regulatory proteins of metabolism. To study the possible role of Ang II on the expression of regulatory proteins of glucose and fatty acid metabolism, 500 ng/kg/min Ang II was infused in rats for 3 and 7 days by osmotic mini-pumps. mRNA levels of metabolic genes were determined by Northern blot in the left ventricle of hearts.

Results: Blood pressure was increased in Ang II-treated rats (+8%, p = NS and +33%, $p < 0.01$ at 3 and 7 days, respectively) compared to the control group. Hypertrophy of the left ventricle in Ang II-treated rats was detectable at 3 and 7 days with an increase of the left ventricular weight (+21%, p = 0.01 and +12%, $p < 0.05$ at 3 and 7 days, respectively). mRNA expression of both atrial natriuretic factor (+500%, $p < 0.001$ at 3 and 7 days) and α smooth muscle actin (+32%, $p < 0.05$ at 3 days and +27%, $p < 0.001$ at 7 days) was increased during Ang II infusion.

Ang II induced a change in the mRNA expression of the isoform of the glucose transporter with an up-regulation of the foetal isoform GLUT-1 (+25%, p = NS at 3 days and +41%, $p < 0.05$ at 7 days) and a down-regulation of the adult isoform GLUT-4 (−29%, $p < 0.05$ at 3 days and −3%, p = NS at 7 days). Conversely, no alteration of mRNA expression of genes involved in fatty acid metabolism was detected after 3 or 7 days of Ang II infusion.

Conclusion: Development of left ventricle hypertrophy in response to Ang II infusion is associated with an up-regulation of GLUT-1 in rat hearts.

3228 Acute haemodynamic stress induces growth promoting and inhibitory signaling pathways in adult rat heart

Thomas A. Fischer, Stephan Ludwig[1], Egbert Flory[1], Stepan Gambaryan[1], Krishna Singh[2], Peter Finn[2], Marc A. Pfeffer[2], Ralph A. Kelly[2], Janice M. Pfeffer[2]. *Department of Medicine II, University of Mainz;* [1]*Institute of Clinical Biochemistry and Institute of Medizinische Strahlenkunde and Cell Biology (MSZ), University of Würzburg, Germany;* [2]*Brigham and Women's Hospital, Cardiovascular Division, Boston MA, USA*

A role of several parallel extracellular signal-regulated (MAPK) and stress-activated protein kinase (SAPK) pathways in the growth response of cardiac myocytes examined *in vitro* are established, but their importance in response to abrupt changes in hemodynamic load *in vivo* in the adult rat heart is less clear. To address this, we examined the activation of the MAPKs and SAPKs i.e. $p54^{JNK}$ and $p38^{MAPK}$ in left ventricular muscle immediately following aortic banding (AoB) in rat heart. In AoB systolic blood pressure increased from 130 ± 4 to 212 ± 6 and 188 ± 9 mmHg at 15 and 30 min, respectively ($p < 001$ vs SHAM).

Active kinases were immunoprepitated with specific antibodies and we found that AoB increased MAPK phosphorylation by only ~2-fold at 30 min, but increased $p54^{JNK}$ by 5-fold, and $p38^{MAPK}$ activity by 41-fold ($p < 0.01$ vs SHAM). The increase in $p38^{MAPK}$ activity was accompanied by a 2.5- and 6.5-fold increase in the phosphorylation of the p38 substrate MAPKAPK2/3 at 15 and 30 min, respectively ($p < 0.05$ vs SHAM).

Activation of these kinases was accompanied by an increase in phosphorylation of c-Jun and ATF-2 and enhanced DNA binding of activator protein-1 in nuclear extracts, as detected by gel-shift analysis and by phospho-specific antibodies (6.3 ± 2 vs 24 ± 2 arbitrary units vs SHAM; $p < 0.05$). This response to hemodynamic load was also followed by significant increases in mRNA abundance in Northern analysis and protein levels of the MAP kinase phosphatase 1 (MKP-1) in immunoblots at 15 and 30 min following banding (3.9 ± 0.1 vs 14.3 ± 7.0 and 7.3 ± 0.2 vs 24.9 ± 2.9, respectively; $p < 0.05$).

Thus, hemodynamic stress of the adult rat heart results in rapid activation of several parallel kinase cascades, particularly the SAPKs as well as mRNA and protein abundance of a principal counterregulatory phosphatase, MKP-1.

3229 Cell stretch induces the release of growth-promoting factors from cardiomyocytes and fibroblasts

Cindy Ruwhof[1], Janneke M. Egas[1], Annemieke E.T. van Wamel[1,2], Lizet J.M. van der Valk[1], Peter I. Schrier[2], Arnoud van der Laarse[1]. [1]*Dept. of Cardiology;* [2]*Dept. of Clin. Oncology, Leiden University Medical Center, Leiden, Netherlands*

Background An increased workload of the heart stretches the myocardium passively and induces a growth response in myocardial cells. We investigated whether unstretched cells undergo a growth response via paracrine effects of stretched cells.

Methods Myocytes and fibroblasts derived from neonatal rat hearts were subjected to stretch (20%, 1 Hz) for 0 (control), 2, 4, and 6 h. Subsequently, the stretch-conditioned medium (CM2h, CM4h and CM6h, resp) was collected and transferred to unstretched myocytes for 6 h. Protein synthesis induced by CM in unstretched myocytes was assessed by adding ^{3}H-leucine during the final 2 h of incubation. Furthermore, CM of stretched myocytes and fibroblasts (CMmyo and CMfibro, resp) were analysed using size exclusion HPLC.

Results In myocytes incubated with CMmyo, the rate of protein synthesis was increased by 8 ± 8% and by 4 ± 4% versus control (CM4h and CM6h, resp) ($p < 0.05$). The rate of protein synthesis also increased upon incubation of myocytes with CMfibro2h (by 6 ± 4% over control, $p < 0.01$). Furthermore, CMmyo and CMfibro stimulated the expression of ANPmRNA in myocytes. Therefore, these results indicate that CMfibro and CMmyo induce a hypertrophic response in myocytes.

In CMmyo as well as in CMfibro, HPLC detected 6 peaks with molecular weight < 10 kDa, representing proteins released upon stretch. By comparing the chromatograms of CMmyo and CMfibro, two peaks appeared identical, one of which may represent endothelin-1. We found no peak that could represent angiotensin II.

Conclusion Upon stretch of myocytes and fibroblasts factors are released which exert a hypertrophic response in myocytes in a paracrine way. Very likely, one of these growth promoting factors is endothelin-1.

3230 Molecular characterization of myocardial fibrosis during hypothyroidism

Wei-Jan Chen, Kwang-Huei Lin[1], Ying-Shiung Lee. *First Cardiovascular Division, Chang Gung Memorial Hospital; [1]Department of Biochemistry, Chang-Gung University, Taoyuan, Taiwan, China*

The purpose of this study was to gain insights into the underlying mechanism of myocardial fibrosis during hypothyroidism. We evaluated the effect of hypothyroidism on the biological responses of rat cardiac fibroblasts in a defined in vitro system. Treatment of cardiac fibroblasts with a medium lacking thyroid hormone led to a 47% increase in [^{3}H] thymidine incorporation into the cell nuclei compared with that in untreated cells. Northern blot analysis of RNA from cardiac fibroblasts grown in a thyroid hormone depleted medium resulted in a 38% increase in the abundance of mRNA for pro-α1(I) collagen. At the protein level, the amount of type I collagen, as determined by immunoprecipitation, was increased either in the cell lysate (46%) of cardiac fibroblasts grown in a thyroid hormone depleted medium or in the medium (44%). Transient transfection experiments were performed to more precisely define the mechanism whereby thyroid hormone affects type I procollagen gene transcription. The chimeric plasmid, ColCAT 3.6, contains the 5′-flanking region of the rat pro-α1(I) collagen gene (from bases −3520 to +115) fused to the chloramphenicol acetyltransferase (CAT) gene. The plasmid was cotransfected with thyroid hormone receptor (TR) expression plasmid into rat cardiac fibroblasts and COS-1 cells (monkey mesangial cells). Cells transfected with the ColCAT plasmid in the presence of thyroid hormone (100 nmol/L T3) had a significant decrease (39% in fibroblasts, $P < 0.01$; 52% in COS-1 cells, $P < 0.001$) in CAT activity when compared to cells not exposed to thyroid hormone. Transient cotransfection of TR with various pro-α1(I) collagen/CAT deletion constructs showed that T3-dependent repression was preserved with the deletion from 3520 bp of the flanking sequence to a 5′ end point at position −224, indicating that a thyroid hormone- response element (TRE) was localized at the region −224 to +115. The TR-DNA binding assays demonstrated binding of the human TR β 1 to a fragment containing a proposed TRE located between position −35 and +115 in the 5′-flanking region of the rat pro-α1(I) collagen gene.

GENETIC DETERMINANTS FOR RESTENOSIS

3247 Polymorphism of glycoprotein IIb of the platelet fibrinogen receptor and risk of thrombosis and restenosis after coronary stent placement

C. Böttiger, A. Kastrati, W. Koch, N. von Beckerath, J. Mehilli, H. Seidl, M. Gawaz, A. Schömig. *Deutsches Herzzentrum, 1. Med. Klinik rechts der Isar, TU München, Munich, Germany*

Platelet glycoprotein (GP) IIb/IIIa receptor plays a central role in platelet aggregation. While the association between the HPA-1 polymorphism of GP IIIa and thrombosis and restenosis has already been studied, there are no data about the significance of the HPA-3 polymorphism of GP IIb in the outcome of patients undergoing percutaneous coronary interventions.

Methods: The study included 2178 consecutive patients (pts) with successful coronary stent placement with 1-year clinical follow-up in all and a 6-month angiography in 1731 patients (80%). HPA-3 genotype was determined with the aid of polymerase chain reaction. Angiograms were assessed quantitatively.

Results: Of the 2178 pts, 789 (36%) were HPA-3 a/a, 1023 (47%) HPA-3 a/b, and 366 (17%) HPA-3 b/b. There were no significant differences between these groups with respect to clinical, angiographic and procedural parameters. Stent vessel occlusion occurred in 1.7% of the HPA-3 a/a pts, 1.7% of the HPA-3 a/b pts and 1.6% of the HPA-3 b/b pts ($P = 1.0$). Angiographic restenosis (≥50% diameter stenosis at follow-up) was encountered in 37.7% of the HPA-3 a/a pts, 36.2% of the HPA-3 a/b pts and 34.6% of the HPA-3 b/b pts ($P = 0.72$). Late lumen loss was also comparable. In addition, no significant differences were recorded between these 3 groups in the incidence of death, myocardial infarction and target lesion revascularization at 1 year after the intervention. Event-free survival one year after stent placement was 76.1% in HPA-3 a/a pts, 76.5% in HPA-3 a/b pts and 76.4% in HPA-3 a/a pts ($P = 0.97$). One-year survival free of myocardial infarction was 95.8% in HPA-3 a/a pts, 96.9% in HPA-3 a/b pts and 95.5% in HPA-3 b/b pts ($P = 0.32$). No significant difference among the groups was noted either for overall survival one year after stent placement. It was 97.8% in HPA-3 a/a pts, 98.2% in HPA-3 a/b pts and 96.9% in HPA-3 b/b pts ($P = 0.36$).

Conclusions: HPA-3 polymorphism of the platelet membrane GP IIb is not associated with an increased risk of vessel thrombosis or restenosis after coronary stent placement.

3248 The PI A1/A2 polymorphism of the platelet glycoprotein IIIa is not associated with coronary stent restenosis

P. Russo, E. Colajanni[1], G. Steffenino, F. Ribichini, A. Dellavalle, V. Ferrero, A. Vado, S. Guarrera[1], G. Matullo[1], A. Piazza[1]. *Division of Cardiology, Ospedale S. Croce, Cuneo; [1]Institute of Human Genetics, University of Turin, Italy*

Background: platelet glycoproteins IIb/IIIa have a role in platelet aggregation. A common polymorphism of glycoprotein IIIa (PI A1/A2) has been associated with a higher risk of myocardial infarction, and coronary stent thrombosis and restenosis.

Methods: a prospective study to investigate the association between PI A1/A2 and angiographic restenosis (DS ≥ 50% at QCA) at follow-up in non-diabetic patients (pts) after successful placement of a single stent in a single de novo lesion in a native coronary vessel. Seventy-five consecutive pts with restenosis (R) were matched for age, sex, and extent of coronary artery disease, with 75 controls without restenosis (NR). No significant difference was found between R and NR as to conventional risk factors for coronary artery disease, frequency of the D allele of the ACE gene, history of myocardial infarction, left ventricular ejection fraction, focal/diffuse pattern of the original lesion, clinical presentation at PTCA, indication for stent placement, and type of stent used.

Results: overall, in the 150 R and NR pts the PI A2 allele frequency was 0.14, with the following distribution of the 3 genotypes: PI A1/A1 = 73.3%, PI A1/A2 = 25.4%, PI A2/A2 = 1.3%. The PI A2 allele frequency was 0.166 and 0.113 (ns) in the R and NR cohorts, respectively. The distribution of the genotypes PI A1/A1, PI A1/A2 and PI A2/A2 in R vs NR was 68% vs 78.7%, 30.7% vs 20%, 1.3% vs 1.3%, respectively (ns).

Conclusions: our data suggest that, in non-diabetic patients treated with a single coronary stent for a single de novo lesion in a native vessel, restenosis is not associated with significant differences in the distribution of the PI A1/A2 polymorphism of the platelet glycoprotein IIIa.

3249 The 5A6A polymorphism in the promoter of the stromelysin-1 gene as a risk factor for restenosis

P. Amouyel[1,2], C. Bauters[1,2], A. Meirhaeghe[1], L.A. Luong, M.E. Bertrand[2], S.E. Humphries. *[1]INSERM U508, Institut Pasteur de Lille, Lille; [2]University and CHRU de Lille, Lille, France; Centre for Cardiovascular Genetics, Rayne Institute, London, UK*

Intracoronary utrasound studies in humans show that chronic remodeling rather than neointimal hyperplasia is the mechanism of restenosis. Stent implantation limiting this remodeling process has been shown to significantly reduce restenosis. Stromelysin-1 (MMP3), a member of the matrix metalloproteinase family may play a role in this remodeling. A 5A/6A MMP3 promoter polymorphism allowed us to estimate the possible contribution of MMP3 in restenosis.

The 5A/6A MMP3 genotypes were determined in a series of 287 consecutive patients who underwent coronary angioplasty (Balloon) and in a series of 198 consecutive patients who underwent coronary angioplasty successful implantation of a Palmaz-Schatz stent (Stent). All the patients had systematic 6 month angiographic follow-up (fu). Restenosis was estimated with quantitative computer assisted angiography measurements.

Minimal luminal diameters before and after the procedures did not differ significantly among genotype groups. At follow-up, subjects with the 6A6A genotype had an increased risk of restenosis after balloon angioplasty, while stented patients had not.

	5A5A	5A6A	6A6A
Balloon	n = 60	n = 156	n = 71
Diameter stenosis at fu (%)	44 (18)	46 (20)	52 (21)*
Loss index	0.34 (0.69)	0.34 (0.71)	0.53 (0.61)+
Stent	n = 56	n = 92	n = 50
Diameter stenosis at fu (%)	39 (20)	33 (24)	31 (19)
Loss index	0.46 (0.37)	0.42 (0.39)	0.41 (0.37)

means (SD), *p = 0.012, +p = 0.038

Thus, the 6A6A MMP3 genotype (~25% of the population) is a genetic susceptibility factor for restenosis after PTCA without stenting, suggesting an involvement of MMP3 in the remodeling process after angioplasty.

3250 Association between transforming growth factor β polymorphism and coronary in-stent restenosis

H.S. Iee, I.V. Hutchinson[1], V. Pravica[1], C.G. Densem, C. Perrey[1], N.H. Brooks. *Department of Cardiology, Wythenshawe hospital, Manchester; [1]University of Manchester, Manchester, UK*

Following coronary angioplasty (PTCA) and stenting, some patients developed in-stent restenosis and may require further revascularisation procedures. Transforming growth factor beta-1 (TGF) affects vascular remodelling and neointimal formation. Its infusion is known to accelerate neointimal proliferation in animal studies. TGF gene polymorphism influences TGF production with individual being either high or low TGF producers. This study examined the association between TGF polymorphism and the incidence of in-stent restenosis after PTCA. DNA extraction, PCR and subsequent electrophoresis identified TGF genotype. The study population consisted of 77 patients with follow up coronary angiograms after PTCA and 107 control patients with no coronary disease. Restenosis was defined angiographically as >70% renarrowing of the stented coronary segment. Signicantly more of the 36 patients with in-stent restenosis are high TGF producers (High producers 35 patients [97%], Low 1 [3%]) when compared to control patients (87 [81%], 20 [19%] $p < 0.05$). No significant difference was observed between the 41 patients without restenosis (36 [88%], 5 [12%]) and the control patients (p = NS).

Conclusions: High TGF producers are at an increased risk of developing in-stent restenosis. Inhibitions of TGF production may reduce the incidence of in-stent restenosis.

3251 Long-term clinical outcome of coronary stenting: role of the D allele of the ACE gene, and importance of the angiographic pattern of restenosis

F. Ribichini, V. Ferrero, A. Vado, G. Steffenino, A. Dellavalle, P. Russo, G. Matullo[1], E. Colajanni[1], S. Guarrera[1], A. Piazza[1], E. Uslenghi. *Divisione di Cardiologia dell'Ospedale Santa Croce di Cuneo, Cuneo; [1]Istituto di Genetica Umana dell'Universtità di Torino, Torino, Italy*

The D allele of the angiotensin-converting enzyme (ACE) seems to be a risk factor for restenosis after stent placement. A genetic marker may have a priori predictive value, and a permanent interaction with the mechanisms of restenosis, which may influence the prognosis, beyond the conventional 6-month follow-up period.

Methods: we analyzed the angiographic pattern of restenosis of patients treated with coronary stents in our Centre according to their I/D ACE genotype, and the long-term clinical outcome according to the pattern of restenosis. Restenosis (%DS > 50) was observed in 137 (23%) out of 593 patients (pts). After exclusion of pts with total occlusion (19) and focal restenosis at the articulation site of the Palmaz-Schatz 153 stent (5), 113 pts were analyzed. The length and the severity of the restenotic lesion was significantly different for each genotype, as the distribution of a focal (<10 mm) or diffuse (>10 mm) type of restenosis (table).

Restenosis data	DD (56)	ID (48)	II (9)	p
Restenosis length (mm)	14.6 ± 10.5	9.3 ± 11.2	4.5 ± 4.2	0.005
DS% at follow-up	71.4 ± 11.9	65.5 ± 10.5	61.3 ± 7.2	0.004
Focal restenosis (48)	15 (31%)	26 (54%)	7 (15%)	
Diffuse restenosis (65)	41 (63%)	22 (34%)	2 (3%)	0.001

At six months, 27/48 (56%) and 35/65 (54%) pts with focal and diffuse restenosis had a 2° PTCA respectively (p = ns). Subsequent reinterventions on the target lesion were as follows:

Events	Focal restenosis (48)	Diffuse restenosis (65)	p
3° PTCA (8)	0	8/35 (22.8%)	0.01
3° PTCA or CABG (23)	3/48 (6.3%)	19 (29.2%)	0.002

The Kaplan Meier analysis at a 40 months follow-up period showed that 93.7% of pts with focal restenosis and 61.5% with diffuse restenosis were free from new target lesion revascularization, log rank = 9.75, p = 0.001.

In conclusion, the I/D polymorphism is a determinant of the pattern of restenosis, and the latter predicts the long-term outcome after coronary stent placement.

3252 Insertion/deletion polymorphism of the angiotensin I-converting enzyme gene and 1-year angiographic and clinical outcome after coronary stent placement

W. Koch, A. Kastrati, J. Mehilli, C. Böttiger, N. von Beckerath, A. Schömig. *Deutsches Herzzentrum, 1. Med. Klinik rechts der Isar, TU München, Munich, Germany*

The renin-angiotensin system is thought to play a role in coronary thrombosis and restenosis. Plasma angiotensin I- converting enzyme (ACE) activity is associated with an insertion/deletion (I/D) polymorphism in the ACE gene. This prospective study was performed to test the hypothesis that the D allele of the gene encoding ACE is associated with a higher risk for thrombotic and restenotic events over one year after coronary stent placement.

Methods: This prospective study included 1254 consecutive patients with coronary artery disease who underwent intracoronary stent implantation. The determination of ACE I/D polymorphism was performed using polymerase chain reaction amplification. Angiographic control at 6 months was achieved in 80% of the patients and coronary angiograms were assessed with QCA. Clinical follow-up was extended up to 1 year after the procedure. Primary endpoints of the study were 1-year event-free survival and angiographic restenosis; secondary endpoint was the angiographically proven stent thrombosis.

Results: The observed distribution of the ACE genotypes was 19.8% for II, 53.0% for ID and 27.2% for DD. Stent thrombosis occurred in 2.4% of II patients, 1.2% of ID patients and 0.9% of DD patients (P = 0.248). Restenosis rate at angiographic follow-up was 32.3% for II patients, 34.0% for ID patients and 36.0% for DD patients (P = 0.715). Event-free survival one year after stent placement was 78.1% in patients with genotype II, 77.8% in patients with genotype ID and 76.0% in patients with genotype DD (P = 0.737). No independent role for the D allele could be demonstrated also by multivariate analysis.

Conclusions: The ACE DD genotype or D allele does not influence the 1-year clinical and angiographic outcome of patients undergoing coronary stent placement. These data suggest that routine determination of the ACE genotype may not help to identify patients who are at higher risk of thrombosis and restenosis after coronary stent placement.

EXPERIMENTAL RESTENOSIS AND MODULATION OF PROLIFERATION

3253 Temporal and spatial pattern of VEGF and KDR/FLK expression in reendothelialization and neovascularizations after coronary angioplasty

C. Unterberg, J. Stevens, K. Nebendahl, A.B. Buchwald. *Dept of Cardiology, University Clinic, Göttingen, Germany*

Background: Time to complete reendothelialization has been suggested as determinant of neointimal proliferation after coronary angioplasty. VEGF may play a central role in this process.

Methods and Results: Coronary angioplasty was performed in minipigs and injured arterial segments were analyzed after 24 hrs (n = 4), 72 hrs (n = 3), 96 hrs (n = 3), 7 days (n = 4) and 2 weeks (n = 4).

In paraffin embedded tissue we performed in-situ hybridization (ISH) using a probe generated from minipig ovary tissue mRNA by rtPCR (19- and 17-mer sense/antisense primers, chosen to fit the known VEGF- and the human KDR/flk sequence). VEGF ISH for the VEGF receptor showed positive signals beginning 48 hrs after angioplasty in periluminal cell layers. The number of positive cells increased until day 7 after angioplasty in areas of deep arterial injury. ISH for the VEGF receptor KDR/flk showed positive signals with a maximum on day 4. Absolute numbers of positive cells were 198 ± 35/mm^2 (mean + SEM, VEGF day 7) and 38 ± 6/mm^2, (KDR/flk day 4). None of the normal control segments showed a positive signal for either VEGF or KDR/flk. ISH using a probe for the VEGF receptor flt-1 showed no positive signal. Immunostaining with a rabbit polyclonal VEGF antibody was positive in periluminal cells (maximum after 2 wks) and in areas of deep arterial injury, where it co-localized with lectin-positive neovascularizations.

Conclusion: These data support the hypothesis that locally expressed VEGF and ist receptor KDR/flk are involved in reendothelilization and the formation of neovascularizations in deeply injured coronary arteries.

3254 Early spontaneous re-endothelialization does not reduce late intimal thickening

H.M.M. van Beusekom, D.M. Whelan[1], S.C. Krabbendam[1], W.J. van der Giessen[1]. *Experimental Cardiology Ee 2357, Erasmus University Rotterdam, Rotterdam; [1]Experimental Cardiology, Erasmus University Rotterdam, Rotterdam, Netherlands*

Introduction: Early re-endothelialization after PTCA or stenting has often been put forward as an important parameter in enhancing vascular repair and subsequently in attenuating neointimal growth. Most experimental models that study this phenomenon compare denuded to non-denuded segments using Fogarty balloons for de-endothelialization prior to PTCA or stenting. However, Fogarty balloons not only remove the endothelium, but also the basement membrane. As a result, Fogarty denudation induces more intimal hyperplasia than balloon angioplasty. Without the confounding factor of Fogarty denudation, we studied the effect of early spontaneous endothelial regrowth on late intimal hyperplasia in swine coronary arteries, using two different stainless steel stent designs.

Methods: Implantation of stainless steel Palmaz-Schatz (PS) and divYsio (D) stents was performed in normal swine coronary arteries under guidance of QCA to match stent and artery size. The metal to surface area is ± 20% and >15% for expanded PS and D respectively. All animals received aspirin during follow-up. The animals were sacrificed at 5 days (n = 10) for assessment of endothelial regrowth using planimetry of scanning electron microscopy images, and at 12 weeks (n = 8) to assess intimal hyperplasia using light microscopy and morphometry. Only stent struts were taken into consideration for assessment of endothelialization and not the area between the stent struts.

Results: Planimetric analysis showed an endothelial coverage of 60 ± 27% for PS and 91 ± 12% for D ($p < 0.05$) at 5 days after stenting. Morphometric analysis at 12 weeks after stenting showed an intimal thickness of 0.2 ± 0.1 mm for PS and 0.2 ± 0.2 mm for D (p = NS).

Conclusion: Despite a significant difference in the percentage re-endothelialization at 5 days after stenting, there is no significant difference in intimal hyperplasia at 3 months follow-up. Therefore dysfunction of the regrown endothelium or non-endothelium dependent factors are likely responsible for ongoing tissue growth.

3255 Effect of angiotensin II type I receptor antagonist on the remodelling after vascular injury

H. ETO, S. Biro, M. Miyata, K. Orihara, T. Kihara, H. Obata, H. Kaieda, C. Tei. *First Department of Medicine, Kagoshima University, Kagoshima, Japan*

Vascular remodeling is one of the main cause of restenosis following PTCA. Angiotensin II (AT-II) is a major factor to contribute to vascular remodeling, namely to migration and proliferation of smooth muscle cells in the early phase and to extracellular matrix production in the late phase. Although extensive studies have focused on the effect of AT-II on migration and proliferation of smooth muscle cells, little attention has paid to matrix production. Therefore, we first investigated the expression of AT-II and angiotensin II type I receptor (AT1R) in the rat carotid balloon injury model, especially in the late phase, and next examined the effect of AT1R antagonist to vascular remodeling.

Methods: Rat carotid arteries were denuded three times with a 2F Fogarty balloon catheter. Carotid arteries were removed at 2, 5, 7 days and 2, 4, 8, 16 and 24 weeks after vascular injury. Specimens were subjected to immunohistochemistry with AT-II and AT1R antibodies, and to in situ hybridization (ISH) for AT1R mRNA. Rats were divided into three groups. Group A is control (just denudation without treatment). Rats were administrated a AT1R antagonist (TCV-116, 10 mg/kg/day) from one day before denudation for 8 weeks (group B), and from 4 days after denudation for 8 weeks (group C), in which smooth muscle cells (SMC) were allowed to migrate into the intima. At 8 weeks after denudation, they were sacrificed, the carotid arteries were removed and morphometric analysis was performed.

Results: Immunohistochemical analysis showed that immunoreactivity of AT-II were hardly detected in the media of uninjured arteries. Vascular injury induced AT-II immunoreactivity in the intima with a peak at 7 days and returned to the medial level by 4 weeks. On the other hand, ATIR were little stained in the medial SMC of uninjured arteries, however after injury they were well stained in the intimal SMC, even at 24 weeks after injury. Furthermore, ISH revealed that mRNA of AT1R were detected much in the intimal SMC even at 8 and 16 weeks after vascular injury. Treatment with AT1R antagonist (group B) significantly decreased the neointimal area compared to group A (5.0 ± 1.8 square mm vs 8.2 ± 2.2 square mm, $p < 0.001$). In group C, neointimal formation was also significantly inhibited in comparison with group A (5.2 ± 2.7 square mm vs 8.2 ± 2.2 square mm, $p < 0.05$).

Conclusion: Angiotensin II type I receptor was upregulated in the intimal smooth muscle cells even in the late phase after vascular injury and was suggested to play an important role in the remodeling via matrix production in the late phase after vascular injury.

3256 Local photodynamic therapy in stented porcine vessels

G. Valassis, C. Vogel-Wiens, P. Gonschior. *I. Medizinische Klinik, Klinikum rechts der Isar und Deutsches Herzzentrum, Technische Universität München, Munich, Germany*

Photodynamic therapy using local drug delivery (LPDT) was examined in porcine vessels before stent implantation.

Methods: The photosensitizer, Photofrin® (5 mg = 2 ml; QLT, Canada) was delivered with a needle injection catheter (NIC) and activated subsequently by light application (630 nm; 100 J/cm^2). 46 arterial segments from pigs (mean weight 34 kg) underwent stenting (Palmaz-Schatz stents, 16 atm in 3 mm coronary and femoral vessels). Subsequently local photodynamic therapy was performed (therapeutic group 1). The tissue was removed at different time points after the intervention (7, 14 and 21 days). 16 further vessel segments were only stented (control group 2). 12 segments received local drug delivery or monochromatic light exposure after stenting (Group 3 and 4). After explantation, the vessel segments of all groups were embedded in methymetacrylate, serially cut (100 μm) and stained (Lazko-Levai).

Results: *Group 1, therapeutic group:* the stented vessels treated with LPDT showed no inflammation and/or proliferative response (area of tissue hyperplasia 0.3 mm^2). *Group 2, control group:* after substantial vessel injury only, polymorphonuclear leukocyte infiltration and subsequent proliferation of myofibroblasts (maximum after 7d, +365% vs. control) was seen. A myoproliferative response resulted in tissue hyperplasia of 1.8 ± 1 mm^2. *Group 3 and 4:* results did not reveal significant differences to group 2.

In conclusion: LPDT led to a marked reduction of proliferation and tissue hyperplasia in porcine stented vessels.

3257 Reduction of in-stent restenosis in pig coronary arteries by adenovirus-mediated GAX gene transfer

R.A. Tio, T.H. Scheuermann[1], C. Lebherz[1], Z. Luo[1], N. Duverger[2], D. Branellec[2], J.M. Isner[1], K. Walsh[1]. *Thoraxcenter, University Hospital Groningen, Groningen, Netherlands; [1]Cardiovascular Research dept., St Elizabeth Medical Center, Boston, USA; [2]RPR-Gencell, Virty-sur-Seine, France*

Intima hyperplasia is the dominant factor in the development of restenosis after coronary stenting. Inhibition of vascular smooth muscle cell (VSMC) proliferation should theoretically reduce neointima formation. Previous work in our lab has shown that over expression of the GAX transcription factor inhibits VSMC proliferation (Smith et al. Genes and Devel, 1997; 11: 1674–1689), and induces apoptosis in cells that are chronically stimulated with mitogens (Perlman et al. EMBO J 1998, in press). Therefore, we investigated the effect adenovirus mediated GAX overexpression, in a porcine model of coronary in-stent restenosis.

Eighteen male Yorkshire pigs underwent coronary angiography. All pigs received 10.000 units of heparin at the beginning of the procedure, and were treated with 325 mg aspirin and 250 mg ticlopidine daily starting two days before. Nir stents (Boston Scientific; Boston, MA) were placed in a straight segment of the left anterior descending artery (balloon vessel ratio 1.1–1.3). This was followed with delivery (Chanelled balloon; Boston Scientific) of the active drug adenovirus (GAX; n = 9) or control vehicle (CON; n = 9). After 4 weeks a coronary angiogram was performed and analysed off line using the CMS system (Medis; Leiden the Netherlands).

Treatment with GAX significantly reduced in-stent restenosis: GAX 24.4 ± 5.6 versus CON 55.2 ± 7.9% (mean ± SEM p = 0.006). Histologic data of the stented vessels will be presented at the meeting.

Treatment with adenoviral GAX significantly reduces in-stent restenosis in a pig model. Allthough systemic dissemination may pose an important problem, the gene therapeutic approach with GAX is a succesfull approach to prevent restenosis after coronary stenting.

3258 Drug effects after local paclitaxel delivery with different catheter types on experimental atherosclerosis in the rabbit

C. Herdeg, M. Oberhoff, A. Baumbach, A. Blattner, S. Schroeder, A. Kuettner, K.R. Karsch. *Dept. of Cardiology, Div. Of Medicine, University of Tübingen; Tübingen, Germany*

The microtubule stabilizing compound paclitaxel has proven to have potent antiproliferative effects on smooth muscle cells both in vitro and in vivo. It induces cellular modifications that result in reduced proliferation, migration and signal transduction by shifting the cellular microtubule equilibrium towards assembly. We therefore reasoned that a visualization of the altered cytoskeleton could enable an evaluation of the drug effects following local drug delivery.

3 catheters – the porous balloon, the microporous balloon and the double balloon catheter – were chosen for this study representing the spectrum from passive to active, pressure-driven delivery. After the induction of a defined plaque in the right carotid arteries of 40 New Zealand rabbits by electrical stimulation, 32 animals underwent balloon dilatation and 8 animals served as pre-interventional control group with electrostimulation only. In 24 animals (n = 8 in each group) subsequent local paclitaxel delivery (10 μmol/L) was performed. 8 animals served as control with angioplasty only. Vessels were excised 1 week following intervention. Immunohistochemistry with antibodies against bromodeoxyuridine, alpha-actin, macrophages, von Willebrand factor and α-tubulin was performed. Cytoskeletal changes were analyzed by electron microscopy. Tubulin staining and electron microscopy revealed changes with distinct staining patterns for the different catheters. Specific catheter-induced injuries could be identified for the porous and double balloon catheter. Intimal proliferation, percentage of macrophages and extent of injury favor the double balloon catheter for local paclitaxel delivery.

Conclusions: The alterations of the cytoskeleton induced by paclitaxel allowed for the detection of drug action by staining of tubulin and electron microscopy. This enables an evaluation of transfer, distribution and drug effects directly in the vasculature without marker substances. The double balloon catheter appears to be best suited for local paclitaxel therapy.

ADVANCES IN STENT TECHNOLOGY

3259 Effects of stent coatings on platelets and endothelial cells

E. Atalar, F. Özmen, I. Haznedaroğlu[1], G. Kabakçi, K. Övünç, S. Aksöyek, L. Tokgözoglu, H. Özkutlu, N. Nazli, A. Oto. *Hacettepe University, Department of Cardiology; [1]Department of Haematology, Ankara, Turkey*

Background: Selectins and intercellular adhesion molecule-1 (ICAM-1) are important molecules in endothelial cell and platelet functions. Previous studies have documented that particularly P-selectin is a marker of subsequent stent thrombosis after stent placement. The aim of this study was to compare the effects of intracoronary placement of phosphoryleholine-coated (PC), heparin-coated and uncoated stents on platelets and endothelial cells.

Methods: Thirty patients (age 55 ± 10, 27 male) with significant LAD stenosis with Type A or Type B1 lesions were randomized to elective implantation of heparin-coated (Jo-stent), PC-coated (Divysio) or uncoated (AVE stent) stents. After stent placement, intravenous heparin infusion was administered only for 24 hours and aspirin + ticlopidine treatment was applied for one month. Venous blood samples were drawn before stent placement and, repeated 24 and 48 hours after the procedure. Patients were excluded if they had recent myocardial infarction, unstable angina pectoris, CABG surgery within last 6 months, total occlusion, or any illness known to influence platelet function.

Results: None of the patients had stent thrombosis. Platelet activity was uninfluenced in uncoated stents and decreased in PC-coated and heparin-coated stents (p = 0.04). Endothelial activation was present only in uncoated stents (p = 0.04).

	Before procedure	24 hr after procedure	48 hr after procedure
Heparin-coated stent (n = 10)			
sP-selectin (ng/ml)	242.60 ± 45.0	184.3 ± 64.7*	177.0 ± 77.3*
sEselectin (ng/ml)	31.8 ± 14.0	38.8 ± 13.8	27.6 ± 8.19.0
sICAM-1 (ng/ml)	199.5 ± 10.6	208.8 ± 42.1	231.6 ± 84.1
PC-coated stent (n = 10)			
sP-selectin (ng/ml)	255.3 ± 96.1	196.0 ± 65.9*	178.0 ± 72.0*
sE-selectin (ng/ml)	29.1 ± 9.5	26.3. ± 8.9	27.50 ± 9.9
sICAM-1 (ng/ml)	216.3 ± 72.4	233.1 ± 59.7	232.8 ± 54.8
Uncoated stent (n = 10)			
sP-selectin (ng/ml)	242.0 ± 98.8	205.5 ± 105.8	200.9 ± 122.3
sE-selectin (ng/ml)	30.4 ± 6.8	38.80 ± 16.9	43.8 ± 9.4*
sICAM-1 (ng/ml)	213.9 ± 92.9	228.5 ± 105.3	207.5 ± 108.7

*p < = 0.04, vs preprocedure parameters.

Conclusion: PC-coated and heparin-coated stents were found to decrease platelet activity without activating endothelial cells whereas uncoated stents led to endothelial activation without changing platelet activity. These results show that PC-coated and heperin-coated stents can be adventageous in decreasing thrombatic complications and restenosis.

3260 Heparin-coated stents and restenosis

A. Akilli, M. Kayikcioglu, M. Akin, M. Zoghi, A. Altintig, S. Payzin, H. Kültürsay, L. Can, C. Türkoglu. *Cardiology Dept., Ege Univ. Medical School, Izmir, Turkey*

Despite the promising results with coronary stenting, sub-acute thrombosis and complications due to intensive anticoagulation are still restrictive problems. There are recent studies reporting the positive effect of heparin coated stents on restenosis by decreasing the cellular proliferation on long term. This study was designed to evaluate the effect of heparin coated Jo-stents on restenosis.

Seventy-eight patients (pts) were enrolled in the study and randomized into two groups according to the implantation of heparin coated or non-coated Jo-stents. There was no difference between the mean ages, risk factors, clinical characteristics, lesion morphologies, and ejection fractions of the groups. Primary procedural success was also similar. After stent implantation, all pts received heparin (IV 10000 U bolus+ infusion 4–6 hours), ticlopidine (500 mg/day), and aspirin (100 mg/day). All pts were controlled with quantitative coronary angiography after 5.7 ± 1 months. All data was compared with Student t-test. Angiographic restenosis (defined as diameter stenosis >50%) was seen in 16 (41%) pts with heparin coated and in 11 (28%) pts of the uncoated group (p > 0.05).

Results: (1) The early angiograph ic results of heparin coated stents were found similar to the results of uncoated stents. (2) There was no appreciable impact of heparin coating on stent restenosis. (3) These data suggest that compared to uncoated stents, heparin coating does not provide additional benefit to restenose rates.

Comparison of the groups

	Heparin coated (n = 39)	Non-coated (n = 39)	P
Refence luminal diameter (mm)	3.16 ± 0.18	3.12 ± 0.22	ns
Minimal luminal diameter (mm)			
– Preprocedure	0.84 ± 0.26	0.58 ± 0.32	<0.05
– Postprocedure	2.85 ± 0.31	2.80 ± 0.30	ns
– Control	1.73 ± 0.71	1.64 ± 1.02	ns
Acute Gain (mm)	1.96 ± 0.60	2.18 ± 0.43	ns
Late Loss (mm)	1.09 ± 0.76	1.06 ± 0.90	ns
Relative gain (mm)	0.64 ± 0.15	0.69 ± 0.15	ns
Relative loss (mm)	0.36 ± 0.23	0.34 ± 0.30	ns
Gain Index (mm)	0.27 ± 0.28	0.34 ± 0.30	ns

3261 Acute interventional success demonstrates no differences between gold-coated and standard stainless steel stents: first data from a multicentre, randomized trial

J. vom Dahl[1], P.K. Haager[1], E. Grube[2], R. Dietz[3], C.W. Hamm[4], E.P. Kromer[5], H. G. Klues[1]. *[1]Medical Clinic I, University Hospital RWTH Aachen; [2]Cardiology Siegburg; [3]Franz Volhard-Klinik Berlin; [4]University Hospital Eppendorf Hamburg; [5]University Regensburg, Germany*

Gold coated stents (G) seem to have various advantages compared to standard high quality steel stents (S): Higher visibility during fluoroscopy, less thrombogenicity and potentially less neointimal proliferation. To compare acute angiographic and clinical outcome as well as the angiographic longterm effects of both, G and S, a prospective, randomized multicenter trial (5 centers in Germany) was initiated. Primary endpoint is the amount of neointimal proliferation after 6 month measured by intracoronary ultrasound and quantitative angiography.

Methods: Monitored acute data of 196 pts are available at this time. Baseline characteristics (78% male, 19% previous PTCA, 6% previous CABG, 44% previous MI; 55% hypertension, 16% diabetes, 41% family history, 61% dyslipidemia) were not different. All patients underwent routine PTCA, indication for stent implantation was a visually suboptimal result after PTCA in both groups.

Results: Mean stent length G versus (vs) S was 13.0 ± 2.9 vs 12.3 ± 3.3 mm. Additional stent implantation was necessary in 7.5 vs 8.5%. Implantation pressure was 12.6 ± 2.8 vs. 13.8 ± 2.6 atmospheres. Angiographic success (<30% residual stenosis) was obtained in 98% (96 G, 96 S). In cathlab complications occurred in 4 cases: Two stent (S) could not be placed in the lesion, 2 stents slipped off the balloon and could be safely removed (G and S). There were no in-hospital infarctions, CABG, or deaths in both groups. One subacute stentthrombosis was observed within 60 days follow up (G).

Conclusion: These preliminary data indicate no significant difference between the safety and acute clinical outcome in pts receiving G or S. Better visibility did not result in shorter stents used to treat the lesion. Intravascular ultrasound at 6 month will demonstrate the impact off different stent surfaces on neointimal proliferation.

3262 Influence of stent design on one-year outcome after coronary stent placement: a multicentre randomized trial with five stent types

J. Dirschinger[1], A. Kastrati, P. Boekstegers[2], S. Elezi, H. Schühlen[1], J. Pache[1], G. Steinbeck[2], C. Schmitt, K. Ulm[3], F.J. Neumann, A. Schömig. *Deutsches Herzzentrum; [1]1. Med. Klinik rechts der Isar der TU; [2]1. Med. Klinik, Klinikum Großhadern, Ludwig-Maximilians-Universität; [3]Institut für Medizinische Statistik und Epidemiologie der TU, Munich, Germany*

There is experimental evidence demonstrating that stent design may have an impact on the stent-vessel interaction. The objective of this randomized study was to assess whether differences in stent design are translated into different clinical outcomes in patients undergoing coronary stent placement.

Methods: The study included 1147 patients who were randomly assigned to receive one of 5 types of stainless steel stents: Inflow (n = 231), MULTI-LINK (n = 227), NIR (n = 229), Palmaz-Schatz (n = 233) and PURA-A stent (n = 233). Six-month angiography was carried out in 82.7% of the eligible patients. Primary endpoint of the study was event-free survival at 1 year. Secondary endpoints of the study were the incidence of stent thrombosis at 30 days and quantitative angiographic indexes of restenosis such as diameter stenosis, late lumen loss and restenosis rate (≥50% diameter stenosis). All annalyses were performed according to the intention-to-treat principle.

Results: Event-free survival at 1 year was significantly different between the groups (P = 0.003). It varied from 69.0% for patients in the NIR stent group to 82.4% in MULTI-LINK patients. Similarly, freedom from myocardial infarction was also significantly different (P = 0.007) with values between 88.6 to 96.5%. There were no significant differences in the incidence of stent thrombosis. Diameter stenosis at 6 months varied from 38.1 ± 25.0% to 45.6 ± 27.7% (P = 0.046), late lumen loss ranged from 1.01 ± 0.70 mm to 1.20 ± 0.82 mm (P = 0.085) and the incidence of restenosis varied between 25.3 to 35.9% (P = 0.145).

Conclusions: This study demonstrates that stent design has a significant impact on the long-term results after coronary stent placement. These results suggest that optimization of stent design should be the target of future efforts to improve the outcome of patients undergoing coronary stent placement procedure.

3263 A randomized trial comparing a gold-plated stent with a conventional steel stent: angiographic and clinical results after 1-year follow-up

A. Kastrati, J. Dirschinger, J. Mehilli, N. von Welser, J. Pache, T. Schilling, F.J. Neumann, A. Schömig. *Deutsches Herzzentrum; 1. Med. Klinik rechts der Isar, TU München, Munich, Germany*

Stent coating with various agents has frequently been investigated as a strategy for reducing thrombosis and restenosis. We report here the final angiographic and clinical results of the randomized trial that assessed the effects of plating steel stents with a pure gold surface.

Methods: Before the procedure, 731 patients (pts) were randomly assigned to receive either a conventional, non-coated steel stent (SS: 364 pts) or a steel stent with a complete gold surface, 5 μm in thickness (GS: 367 pts). Both stent types were slotted tube stents with identical design. Follow-up angiography at 6 months was performed in 78% of the eligible patients. All angiograms were evaluated with an automated quantitative system. Restenosis was defined as a diameter stenosis ≥ 50% at follow-up angiography. Subacute stent thrombosis, death, myocardial infarction, repeat PTCA or CABG were recorded.

Results: There were no differences in baseline clinical, angiographic and procedural data. The follow-up results are displayed in the table.

	GS	SS	P
Stent thrombosis, %	2.5	0.8	0.08
Diameter stenosis, %	52.3 ± 31.9	44.8 ± 29.3	0.005
Minimal lumen diameter, mm	1.48 ± 1.05	1.70 ± 1.00	0.011
Late lumen loss, mm	1.59 ± 0.97	1.33 ± 0.90	0.002
Restenosis rate, %	48.6	37.8	0.011
Death, %	6.5	4.7	NS
Myocardial infarction, %	2.7	1.1	NS
Repeat PTCA, %	26.4	15.9	0.001
CABG, %	3.0	3.0	NS

Conclusions: This randomized trial demonstrates that plating the steel stent with a gold surface exacerbates the hyperplastic response of the vessel wall after stenting. These findings underscore the relevant impact of stent surface on the process of restenosis after this intervention.

3264 Nickel allergy in patients with in-stent restenosis

R. Köster[1], D. Vieluf[2], M. Kiehn[2], M. Sommerauer[1], J. Kähler[1], T. Meinertz[1], C.W. Hamm[3]. *[1]Departments of Cardiology; [2]Dermatology; University Hospital Eppendorf, Hamburg; [3]Kerckhoff Heart Center, Bad Nauheim, Germany*

In-stent restenosis may be triggered by allergic reactions to nickel, chromate, manganese or molybdenum which are components of stainless steel stents. The purpose of this study was to investigate the incidence of allergic reactions to 316L stainless steel components in patients with in-stent restenosis.

In 131 patients (63 ± 9 years) with 171 stainless steel stents (33 Palmaz-Schatz, 70 AVE, 68 other types) coronary angiography was performed 6.1 ± 2.7 months after stent implantation. The percentage diameter stenosis within the stent was analyzed by quantitative coronary angiography. All patients underwent epicutaneous patch tests using Finn chamber technology for nickel-II-sulfate 2.5% and 5%, potassiumdichromate 0.5%, molybdenum-V-chloride 0.5%, manganese 0.5% and 316L stainless steel platelets. Results of the patch tests were evaluated by independent investigators after 48 h, 72 h and if necessary after 96 h of contact with the potential allergen.

Quantitative coronary angiography revealed in-stent restenoses (≥50% diameter stenosis) in 89 pts; 42 pts had no restenosis. In the group *without* restenosis there was *no* patient with an allergic reaction. *All* pts with positive patch tests (n = 9) were in the group *with* restenosis. In this group the overall incidence of positive reactions was 10%. In 3 pts we observed positive reactions to molybdenum and in 6 pts (3 male, 3 female) to nickel. However, none of the pts with allergic reactions to the standardized test solutions had a positive reaction to the 316L stainless steel platelets.

Conclusions: Patients *with* in-stent restenosis had a higher incidence of patch test reactions to nickel than those without restenosis. These results from this small group of patients suggest that allergic reactions to nickel may trigger in-stent restenosis.

CORONARY INTERVENTIONS IN DIABETICS

3265 Is Doppler-guided balloon angioplasty with conditional stenting a viable option in diabetic patients? A subanalysis of the DESTINI trial

Moussa[1], A. Colombo[2], L. Di Francesco[2], C. Di Mario[2], A. Jain[3], J.S. de Leso[4], L.Y. Chio[5], E. Lawrence[1], A. Rombolotti[2], J.W. Moses[1]. *On Behalf of the DESTINI-CFR Study group; [1]Lenox Hill Hospital, New York NY; [3]West Virginia Hospital, Morgantown VA, USA; [2]Centro Cuore Columbus, Milan, Italy; [4]Hospital Reine Sofia, Spain; [5]Yousei University, Seoul, South Korea*

The DESTINI trial is a prospective randomized evaluation of primary stenting (PS) compared to Doppler-guided balloon angioplasty with conditional stenting (OP/CS). The population of this analysis consisted of all randomized patients who had a single lesion treatment and who had 6 mo clinical follow-up (87% of the total study population). This population was divided to diabetics (DM = 96 pts) and nondiabetics (NoDM = 435 pts). There were more females in the diabetic group (36% vs 22%, p = 0.004). Each group was divided into its two randomized arms.

Angiographic findings and follow-up data are shown below:

	DM		No DM	
	OP/CS N = 52	PS n = 44	OP/CS N = 219	PS n = 216
Baseline				
RD (mm)	2.96 ± 0.39	3.07 ± 0.49	3.08 ± 0.46	3.11 ± 0.45
MLD (mm)	0.90 ± 0.30	0.97 ± 0.32	0.95 ± 0.33	0.95 ± 0.33
Lesion length (mm)	12.96 ± 5.66	12.8 ± 5.86	12.55 ± 5.28	12.53 ± 4.99
Post-procedure				
RD (mm)	2.96 ± 0.42	3.15 ± 0.45	3.11 ± 0.47	3.23 ± 0.43
MLD (mm)	1.98 ± 0.58*	2.94 ± 0.49*	2.05 ± 0.56*	2.93 ± 0.54*
6-mo Follow-up				
Death	1 (1.9%)	0 (0%)	1 (0.5%)	2 (1%)
MI	1 (1.9%)	2 (4.5%)	6 (2.7%)	3 (1.4%)
TLR	8 (15%)	6 (14%)	27 (12%)	25 (12%)

*P < 0.05; RD, reference diameter; MLD, minimum lumen diameter; TLR, target lesion revascularization.

Conclusions: 1) Doppler-guided BA with conditional stenting in diabetic pts yield similar intermediate-term outcome to primary stenting; 2) Furthermore, with similar baseline lesion characteristics, diabetics faired as well as nondiabetics in the first 6-month. Whether there will be a divergence in outcome after 6-month will be determined after the completeness of 1-year follow-up.

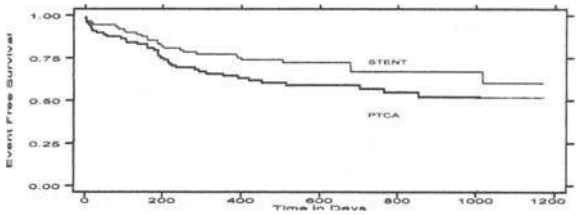
3266 Clinical outcome of stent placement compared to balloon angioplasty in diabetic patients with coronary atherosclerosis

P. Mazeika, N. Prasad, S. Bui, P. Seidelin. *Division of Cardiology, The Toronto Hospital (General Division), Toronto ON, Canada*

Although coronary stenting reduces angiographic restenosis in diabetic patients, its impact on clinical outcome and place in management remains undefined.

Methods: The Angioplasty vs Stenting in Diabetics with Angina (ASDA) study compared the clinical effectiveness of these treatments using a observational historically prospective cohort design. Over 30 months, 176 of 433 diabetics who underwent an intervention, met the inclusion criteria and were enrolled. The 88 patients in each group had similar baseline characteristics and were followed up 22 (8) months later. Assuming an alpha error of 0.05 and a treatment difference of 1.75, a sample size of 176 gave a power of 80%.

Results: Post-procedure MLD was greater with stent placement (2.97 (0.44) *v* 2.24 (0.53) mm; $p < 0.001$). Event-free survival for the composite primary clinical endpoint (death, MI, repeat revascularization, clinical restenosis) favoured stenting (hazard ratio 1.57; 95%CI, 0.95–2.58; $p = 0.08$; see graph). A similar trend was seen for the composite secondary endpoint of target vessel revascularization and clinical restenosis (hazard ratio 1.72; 95%CI, 0.99–2.99; $p = 0.05$). After adjusting for covariates using Cox regression analysis, the results for both primary (hazard ratio 1.62; 95%CI, 0.97–2.69; $p = 0.06$) and secondary (hazard ratio 1.64; 95%CI, 0.94–2.86; $p = 0.08$) endpoints changed only slightly.



Conclusion: A strong and consistent trend favoured stenting for both endpoints, and persisted after adjusting for covariates, Diabetics requiring coronary revascularization who are not surgical candidates should be considered for stent placement rather than PTCA.

3267 The increased restenosis rate after stent implantation in diabetics is independent of the treatment modality for diabetes

J. Schofer, T. Rau, M. Schlüter, D.G. Mathey. *Center for Cardiology Othmarschen, Hamburg, Germany*

The long-term success of coronary stenting in diabetic (DM) pts is impaired by an increased restenosis rate compared to non-DM pts. The influence the treatment modality for DM (insulin vs. oral antidiabetic agents or diet) has not been sufficiently elucidated. We retrospectively analyzed the long-term angiographic outcome after coronary stenting in DM pts treated with insulin (ITDM pts) versus DM pts treated without insulin (non-ITDM pts) and compared the results with those in non-DM pts. The study cohort comprised 1444 pts with a total of 1963 lesions.

Angiographic results:

	Non-DM	Non-ITDM	ITDM	p
Patients (lesions)	1220 (1657)	178 (251)	46 (55)	
Intervention				
Ref. diameter (mm)	2.87 ± 0.44	2.83 ± 0.43	2.72 ± 0.53	0.026
MLD (mm)	0.67 ± 0.42	0.68 ± 0.37	0.73 ± 0.41	0.578
MLD post stent (mm)	2.80 ± 0.37	2.75 ± 0.39	0.65 ± 0.46	0.0032
Stenosis pre stent (%)	77 ± 14	76 ± 13	73 ± 14	0.152
Stenosis post stent (%)	2 ± 12	2 ± 12	2 ± 13	0.771
Follow-Up				
Ref. diameter (mm)	2.79 ± 0.47	2.80 ± 0.46	2.62 ± 0.46	0.024
MLD (mm)	1.80 ± 0.79	1.60 ± 0.80	1.38 ± 0.75	<0.0001
Stenosis (%)	36 ± 25	43 ± 26	48 ± 27	<0.0001
Restenotic lesions	430 (26%)	89 (35%)	22 (40%)	0.0008
Loss index	0.49 ± 0.36	0.57 ± 0.39	0.66 ± 0.42	<0.0001

Conclusions: DM pts have a less favorable angiographic outcome after coronary stenting than non-DM pts, regardless of the treatment modality for DM.

3268 Stenting the coronary vessel in a diabetic: are outcomes comparable with the non-diabetic?

R. Siegel, A. Bhaskaran, B. Barker, P. Underwood, W. Breisblatt, A. Nuttall, Z. Yilma, J. Vermillion, B. Neugart, D. Swanson. *Advanced Cardiac Specialists, Phoenix AZ, USA*

Coronary intervention in the diabetic patient has historically been associated with discouraging outcomes: a) high incidence of restenosis, b) increased need for target lesion revascularization and c) increased long-term mortality. Limited data is available on the impact of diabetes on long term clinical outcomes and restenosis rates following stenting (ST) of coronary lesions. We retrospectively compared procedural, in-hospital and 12-month clinical outcomes following intracoronary ST implantation in diabetic (DM) and nondiabetic (non-DM) patients who underwent transcatheter intervention at our center. From 1/96 to 1/99, 1197 STs were implanted in 1075 native coronary arteries of 934 patients, 199 (21.3%) DM and 735 (78.7%) non-DM. Clinical presentation included acute MI in 25.6%, unstable angina in 47.6% and positive stress test in 22%. Additional co-morbid risk factors included: age > 70, 33.8%; prior MI, 34%; prior CABG, 25.7%; LV dysfunction (EF < 40%), 20.3%; and multivessel disease, 28.7%. The target vessel distribution was the LAD in 38.1%; 7% lesions were ostial. Both groups were well-matched for clinical and angiographic variables. Stented vessels were ≥3.0 mm in diameter. Post-ST high pressure dilatations were performed (mean 16.7 atm). Adjunctive IABP support was used in 19.5%. All patients received oral antiplatelet therapy post-procedure.

Results: Procedural success (≤20% residual stenosis; TIMI 3 flow) was obtained in 98.0% DM and 98.5% non-DM ($p = 0.16$). Acute re-closure occurred in 2.1% of DM and 0.1% non-DM ($p = 0.21$). One non-DM died of worsening heart failure ($p = 0.72$).

	12-Month Follow-Up (96.7% complete; mean 6.72 ± 5.02 mos.)				
	TLR-PTCA	CABG	Death	Event-Free Survival	Mean rise in LVEF (%)
DM	32 (16.1%)	7 (3.5%)	5 (2.5%)	155 (77.9%)	+1.35
Non-DM	38 (5.2%)	19 (2.8%)	12 (1.6%)	668 (90.9%)	−0.95
'p'	*0.019**	0.188	*0.03**	*0.03**	0.89

* 'p' value significant at ≤ 0.05; TLR: target lesion revascularization

Conclusions: (1) In this series of patients treated with ST implantation in obstructed native coronary vessels, acute procedural success was similar in DM and non-DM patients. (2) In-hospital complications were low and infrequent in both populations. (3) The incidence of in-stent restenosis requiring TLR-PTCA showed a *statistically significant* increase and event-free survival was *significantly* lower in the diabetic group. (4) This translated into lower absolute survival rates in the diabetic group, which was *statistically significant.* Our data suggests that stenting is associated with similar acute procedural and clinical success in DM and non-DM patients. DM patients, however, demonstrate increased mortality and a greater need for revascularization for in-stent restenosis, in the long-term. These findings merit further study.

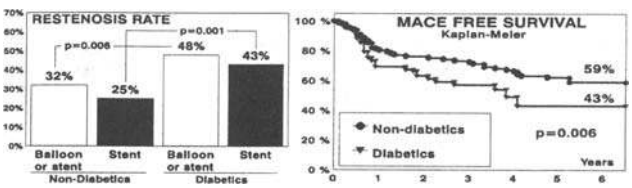
3269 Influence of diabetes mellitus on initial and long-term outcome of stented patients with multivessel coronary disease

E. García-Morán, J.J. Alonso, J.M. Durán, F. Gimeno, B. Ramos, J.C. Muñoz, J. Bermejo, A. Ortiz, O. Sanz, F. Fernández-Avilés. *Hospital Universitario, Valladolid, Spain*

To assess the influence of diabetes mellitus (DM) on restenosis and long-term prognosis after coronary stenting (CS) of pts with multivessel disease, we compared the clinical and angiographic evolution of 94 multivessel pts with DM versus 489 non-diabetic pts.

Diabetics were older (64 ± 8 vs 62 ± 10 yr, $p < 0.01$) and had more number of diseased vessel (2.5 ± 0.5 vs 2.3 ± 0.5, $p < 0.05$) and a higher rate of female gender (23 vs 13%, $p < 0.001$), hypertension (51 vs 40%, $p = 0.01$) and previous heart failure (14 vs 6%, $p < 0.01$). No other clinical or angiographic differences were found. Clinical follow-up (FU) was completed for 94% of pts at 33 ± 18 months.

Coronary stenting was the only revascularization method in 70% of pts, whereas additional ballooning was required in 30% of pts, without differences between diabetic and non-diabetics. Initial clinical success (absence of death, AMI, new revascularization or hospital admission due to angina at 30 days) was similar in both groups (87 vs 87%, p = NS). Likewise, diabetics and non-diabetics had similar long-term survival (84.5 vs 86.4%, p = NS). Nevertheless, diabetics had a higher rate of restenosis and lower rate of freedom from events during FU (figures.).



Thus CS provides similar procedural result and initial outcome in diabetic and non-diabetic pts with multivessel disease. In terms of mortality, late prognosis is also similar. However, events during FU are more frequent among diabetics.

3270 Influence of diabetes in saphenous vein graft stenting: immediate and late outcomes

J.M. Ahmed, M.K. Hong, R. Mehran, M.A. Peterson, G. Dangas, K. Kent, A.D. Pichard, G.S. Mintz, G.W. Stone, M.B. Leon. *Washington Hospital Centre, Washington DC, USA*

Background. Patients with diabetes mellitus have a greater incidence of procedural complications and higher restenosis rates after stenting in native coronary arteries. However the effect of diabetes on immediate and late outcomes in saphenous vein graft (SVG) stenting has not been determined.

Methods. We studied 906 consecutive patients with 1366 SVG lesions treated with Palmatz-Schatz stent implantation. In-hospital and one year major adverse cardiac events (MACE) including death, MI, and any repeat revascularisation were compared among non-diabetics (non-DM, n = 616), and diabetics (DM, n = 290).

Results. DM group had more hypertensives (75.2% vs 60.6%, p = 0.001) and women (28.4% vs 15.6%, p = 0.001). Angiographic findings included similar vessel size (3.3 mm vs 3.4 mm) and lesion length (9.8 mm vs 10.0 mm). Angiographic success (99.5% vs 100%) and final diameter stenosis (7.5% vs 6.1%) were similar between the groups.

	Non-DM (n = 610)	DM (n = 290)	p
In-hospital MACE	1.6%	4.7%	0.04
1 year death	8.6%	12.6%	0.05
1 year MI	0.6%	1.3%	0.27
1 year TLR	18.7%	22.2%	0.14
Late MACE	32.5%	40.7%	0.01

p = NS between NIDDM vs. IDDM; MACE = any death, MI, TLR; TLR = target lesion revascularisation.

Conclusion: As in native coronary arteries, SVG stenting in diabetes is associated with higher in-hospital complications and late cardiac events, mainly due to increased mortality. Potential mechanisms, such as diffuse atherosclerosis and comorbidity, should be further investigated.

BENEFICIAL EFFECTS OF STATIN THERAPY FOLLOWING PERCUTANEOUS INTERVENTIONS

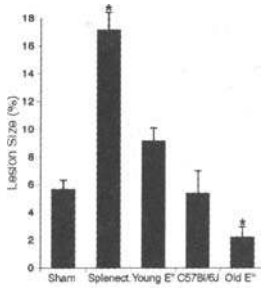
3271 Reduction of atherosclerosis by adoptive transfer of protective immunity in apoE knockout mice

A. Nicoletti, G. Caligiuri[1], G.K. Hansson[2]. *Human Immunopathology Dept, INSERM U 430, Paris; [1]INSERM U 460, Hospital CHU Xavier Bichat, Paris, France; [2]Cardiovascular Research Unit, Karolinska Hospital, Stockholm, Sweden*

Atherosclerotic plaques contain macrophages and T lymphocytes, many of which are immunoreactive against oxidized low density lipoprotein (oxLDL) and immunization with oxLDL reduces lesion in atherosclerotic apoE knockout (E°) mice. However, the role of immune response in atherosclerosis has not been clarified, yet.

Methods: E° mice were immune depressed by splenectomy followed by intavenous transfer of spleen cells deriving from young E° mice that had not yet developed disease, atherosclerotic, old E° mice, wildtype C57BL/6J mice, or buffer alone. Mice were fed a proatherogenic diet for 20 weeks. Lesion size and composition and oxLDL specific cell and antibody immune response were analyzed.

Results: Splenectomized E° mice had three-fold greater aortic root lesions than sham operated mice (*p < 0.01). Transfer of spleen cells from young E° mice or C57BL/6J mice was able to rescue the aggravating effects of splenectomy. As shown in the figure, transfer of spleen cells from diseased mice reduced lesions to half as compared to sham operated mice (*p < 0.01).



Protection was associated with an increase in antibody titers and T cell responses to oxLDL but fewer CD4+ T cells in lesions.

Conclusion: Our data demonstrate that spleen-associated protective immunity in atherosclerotic mice inhibits disease progression.

3272 Statin therapy blocks the excess risk of coronary stent restenosis associated with the NADPH p22 phox polymorphism

D.H. Walter, V. Schächinger, M. Elsner, S. Mach, S. Dimmeler, W. Auch-Schwelk, A.M. Zeiher. *Internal Medicine IV, Div. of Cardiology, University of Frankfurt, Germany*

Background: Oxidative stress in the vasculature has been implicated in the pathogenesis of restenosis after coronary interventions. The NADH/NADPH oxidase system plays a central role for the generation of superoxide anions in vascular smooth muscle cells. A genetic mutation in the gene encoding for the electron transfer element p22 phox, the CC-genotype, has been suggested to increase the susceptibility to coronary artery disease. Statins reduce oxidative stress in the vasculature by lipid lowering, and, in addition, possess antiproliferative and antiinflammatory properties, thereby, potentially interfering with the major processes of stent restenosis.

Methods: We investigated the effects of the p22 phox polymorphism in presence or absence of statin therapy on angiographic outcome in 494 patients following successful coronary stent implantation.

Results: (6 month follow-up)

Stent-Restenosis (≥50%)	No Statin N = 245	Statin N = 249	p-value
TT or TC-genotype	43/132 (31.8%)	34/132 (25.8%)	0.3
CC-genotype	50/113 (44.2%)*	35/117 (29.1%)	0.01

*p = 0.04 vs. TT/TC genotype

Multivariate analysis identified the CC-genotype (p = 0.048), statin therapy (p = 0.02), the minimal lumen diameter immediately post stenting (p = 0.001) and stent length (p = 0.001) as independent predictors for subsequent restenosis development.

Conclusion: Statin therapy substantially reduces the excess risk of coronary stent restenosis associated with the CC genotype of the NADPH p 22 phox polymorphism and thereby may counteract the deleterious effects of oxidative stress on stent restenosis.

3273 The benefit of aggressive lipid lowering: Atorvastatin Versus Revascularization Treatments (AVERT)

W.V. Brown, B. Pitt, D. Waters, L.S. McCormick, L. Shurzinske, D.M. Black. *For the AVERT Investigators. Emory University and the Atlanta VA Medical Center, Atlanta GA, USA*

The AVERT study is the first trial to determine the effect of aggressive lipid lowering with atorvastatin on clinical outcome in patients with stable coronary artery disease (CAD).

Methods: In this open label, multicenter study patients with LDL-C levels > 3.0 mmol/L (115 mg/dL) and ≥1 major coronary artery with at least 50% stenosis were randomized to atorvastatin (80 mg/day) or PTCA followed by usual care (including lipid-lowering therapy if prescribed). The primary endpoint was any documented ischemic event (defined as myocardial infarction, CAD death, unstable angina, CABG or PTCA) over an 18-month period. The major secondary endpoint was the time to the first ischemic event for each patient.

Results: A total of 341 patients were randomized, 164 to atorvastatin and 177 to the PTCA group. The use of anti-anginal drugs did not differ between the two groups. After 18 months, 22 (13%) atorvastatin patients versus 37 (21%) angioplasty patients had experienced ≥1 ischemic event, a 36% reduction (p = 0.048). Furthermore, the time to the first ischemic event was significantly longer (p = 0.027) for the atorvastatin than the PTCA group. Compared with baseline, LDL-C fell 46% from 3.75 to 2.0 mmol/L (145 to 77 mg/dL) with atorvastatin and by 18% from 3.8 to 3.1 mmol/L (147 to 120 mg/dL) with PTCA/usual care. The reduction in the PTCA/usual care group was associated with a lipid-lowering drug, 69% taking a statin by the end of the study. There was a significant correlation between LDL-C reductions and cardiovascular event rates in favour of atorvastatin therapy. Atorvastatin was generally well tolerated. Four patients on atorvastatin 80 mg/day (2.4%) had elevated ALT or AST to values 3× ULN. No patient experienced myopathy during the study.

Conclusions: Atorvastatin not only resulted in a reduction in ischemic events but also a significant delay in the time to first event and was generally well tolerated. AVERT supports the benefits of aggressive cholesterol lowering with atorvastatin in stable CAD patients.

3274 Statin therapy in diabetic patients dramatically reduces proliferation and clinical events after coronary stenting

Mathias Elsner, Dirk H. Walter, Wolfgang Auch-Schwelk, Volker Schächinger, Andreas M. Zeiher. *Medizinische Klinik IV, J. W. Goethe-University, Frankfurt, Germany*

Background: After intracoronary stenting, patients with diabetes mellitus [D] show an augmented proliferative response as compared to non-diabetic patients [ND]. Data on clinical outcome and restenosis rates in D vs. ND are ambiguous and may be confounded by differences in baseline variables and co-medication. Besides effective lipid lowering, statins [S] exhibit antiproliferative, antiinflammatory and antithrombotic properties; thus potentially interfering with all three major processes that initiate in-stent restenosis.

Methods: We performed a comparison of clinical and angiographic outcome at 6 months between 122 D (50 S and 72 /S) and 244 ND matched for statin treatment (100 /144 /S) and also matched for minimal lumen diameter [MLD] post stenting and reference diameter at baseline, two important predictors of restenosis following stent implantation.

Results: (6 months follow-up)

		Baseline Cholesterol	Follow-Up Cholesterol	Restenosis Rate	Diameter Stenosis	Combined Endpoint*
D	S:	256 ± 54	209 ± 37	13 (26%)	35 ± 23%	16 (33%)
	/S:	215 ± 40	204 ± 38	28 (39%)	45 ± 26%	37 (51%)
ND	S:	243 ± 53	209 ± 44	19 (19%)	35 ± 23%	27 (28%)
	/S:	219 ± 37	218 ± 41	50 (35%)	41 ± 24%	53 (37%)
P		<0.001	n.s.	<0.05	<0.05	<0.05

*: Comb. Endpoint: death or myocardial infarction or target lesion revascularization.

Conclusions: In diabetic patients, who constitute a population at high cardiovascular risk, statin therapy dramatically reduces restenosis rates and improves clinical outcome after coronary stent implantation. This beneficial effect of statins is, at least in part, independent of the cholesterol lowering property.

3275 HMG-CoA reductase inhibitor simvastatin inhibits smooth muscle cell proliferation *in vitro* and prevents the neointimal formation after stenting

A. Cioppa, C. Indolfi, C. Coppola, E. Stabile, A. Pisani, C. Perrino, A.M. Stingone, M. Pascotto, M. Chiariello. *Division of Cardiology, University "Federico II", Naples, Italy*

Vascular smooth muscle cell (VSMC) proliferation in response to local stimuli as stent implantation is the major determinant of neointima formation and restenosis. It's well known that Ras proteins are key transducers of mitogenic signals from membrane to the nucleus and Ras farnesylation is essential to activate these proteins. The statins are powerfull inhibitor agents of Ras farnesylation. We tested the effects of Simvastatin (S) on *in vitro* VSMC proliferation and on neointima formation after stent implantation in rat common carotid arteries. S (40 mg/kg/daily) was administered in drinking water from 14 days before the procedure until the animals' sacrifice. NIR 7 cells stents were implanted in common carotid arteries using 1.5 mm PTCA balloon catheter inflated at high pressure (10 Atm) in 12 animals divided into subgroups of 6 rats treated with S or placebo (C). 21 days after stent deployment the arteries were removed. A statistically significant reduction of both neointima (N) (from 0.508 ± 0.035 to 0.362 ± 0.047 mm^2 $p < 0.05$) and neointima-media ratio (N/M) (from 2.00 ± 0.136 to 1.360 ± 0.180 $p < 0.05$) after S administration was found. No difference in the rate of stent thrombosis was observed in the two groups.

fig53475.eps

Thus Simvastatin inhibits VSMC proliferation *in vitro* and markedly reduce the neointima formation after arterial stenting *in vivo*.

3276 Time-dependent changes of arterial distensibility induced by cholsterol and balloon injury: an in vivo intravascular ultrasound study

A. Dorszewski, M. Ribbing, H. Reinecke, G. Breithardt, S. Kerber. *Department of Cardiology, Hospital of the University of Münster, Münster; Institute for Arteriosclerosis Research at the University of Münster, Münster, Germany*

Hypercholesterolemic feeding of rabbits induces formation of early atherosclerotic and stenotic lesions. Balloon injury leads to development of advanced stenotic plaques. The aim of our study was, to analyze changes in arterial distensibility in rabbit aortas revealiing different stages of atherosclerotic plaque formation during cholesterol diet and after balloon injury at different points of time. Newzealand White rabbits (3.5–4.3 kg) received normal chow (I, n = 15) or 1% cholesterol rich diet for 10 weeks (II, n = 14). Balloon injury of abdominal aortas was performed after 4 weeks. 10 segments of the aorta of each animal were evaluated pre and directly post injury, 2 and 6 weeks after trauma with intravascular ultrasound (30 MHz 3.5-F-catheter, introduced via right femoral artery). Acetylcholine was applicated i.a. over 5 minutes to assess arterial reactivity pre and post injury. Corresponding, perfusion fixated segments identified through anatomical landmarks were gained after 2 (n = 49) and 6 weeks (n = 99) for histomorphology. Systolic-diastolic changes of luminal areas of segments served for assessment of vascular pulsatility (vascular pulsatility = [maximum − minimum luminal diameter]/maximum luminal diameter). The inimal index was calculated as follows: plaque area/(luminal + plaque area).

Pre injury vascular pulsatility of aortas of normal fed animals was significantly higher compared to cholesterol fed rabbits (9.0 ± 3.1% vs. 6.7 ± 2.2%; $p < 0.01$). Directly after trauma, there was significant decrease of vascular pulsatility in both groups of 38.4% in I and 42.8% in II ($p < 0.01$ compared to pre injury; p = n.s. for I vs. II directly after injury). After 2 weeks pulsatility was reduced to 3.0 ± 2.2% in I and 3.8 ± 2.6% in II (I vs. II: n.s.), after 6 weeks to 2.2 ± 1.9% in I and 0.7 ± 0.1% in II ($p < 0.05$). There was a significant reduction of vascular pulsatility in both groups after 2 and 6 weeks compared to directly post injury ($p < 0.01$). The intimal index increased from 0% in I and 1.4 ± 0.01% in II pre injury to 1.9 ± 0.02% in I and 17.9 ± 1.8% in II after 6 weeks ($p < 0.01$).

The reduction of arterial distensibility assesed via intravascular ultrasound reveals functional and structural alterations of the arterial wall and corresponds to the depth of vascular injury and plaque development.

CLINICAL PROBLEMS IN ANTITHROMBOTIC THERAPY

3281 Acute effects of high-dose heparin administration on ischaemic threshold in patients with coronary artery disease

G. Fragasso, P.M. Piatti, C. Lu, F. Leonardo, L. Monti, I. Sheiban, A.E. Pontiroli, S.L. Chierchia. *Division of Cardiology, Dept. of Metabolic Medicine, IRCCS, H San Raffaele, Milan, Italy*

Heparin is commonly used as an antithrombotic agent in patients with acute coronary syndromes. However, recent studies indicate that its administration at doses achieved in acute coronary syndromes might decrease endothelial nitric oxide (NO) (nitrite/nitrate) production. In order to investigate the effect of heparin on ischemic threshold, we studied 12 patients (age 63 ± 7 yrs) with a positive exercise test and angiographically documented coronary artery disease. All patients were submitted to a randomized, placebo-controlled trial using i.v. 0.9% NaCl as placebo and i.v. heparin (5000 IU bolus + 1000 IU hour). After both saline and heparin bolus, the infusion was started and, after 10 minutes, treadmill exercise test performed (Bruce protocol). Blood samples for No and free fatty acids (FFA) determination were withdrawn before, at peak exercise and at ECG recovery.

Compared to placebo, heparin significantly decreased time to 1 mm ST segment depression (241 ± 160 vs 303 ± 175 sec, p = 0.003) and prolonged exercise recovery (573 ± 177 vs 441 ± 195 sec, p = 0.003), while total exercise duration was similar. Accordingly, rate-pressure product (RPP) at 1 mm ST depression was lower after heparin (23035 ± 6624 vs 25466 ± 7304 mmHgxbpm, $p < 0.01$), while it was similar at peak exercise. No significant differences were found for basal and peak heart rate, systolic-diastolic blod pressure and plasma NO levels. Conversely, FFA levels immediately increased after heparin administration and remained significantly higher, compared to placebo, throughout the study period. In conclusion, this preliminary report indicates that in patients with stable coronary disease, heparin may significantly decrease the ischemic threshold. Since RPP at onset of ischemia was lower than that recorded during placebo in spite of similar NO levels, the effect of heparin may be mediated by its known positive action on free fatty acid release which can adversely influence the metabolism of ischemic myocardium.

3282 Low rate of bleeding during oral anticoagulant treatment in a prolonged follow-up of elderly patients attending an anticoagulation clinic

D. Poli, L. Bertini, M. Capanni, L. Chiarugi, I. Simone, E. Antonucci, A. Liotta, A. Rogolino, R. Abbate, D. Prisco. *Clinica Medica Generale e Cardiologia, Centro Regionale Trombosi, Florence, Italy*

Over the last few years, there has been a world-wide increase in oral anticoagulant treatment (OAT). The evaluation of risk/benefit ratio of this treatment is of great importance. A recent large prospective multicenter Italian study (ISCOAT) has demonstrated a lower frequency of bleeding and thrombotic complications in outpatients attending anticoagulation clinics in comparison to that reported in previous observational studies. In ISCOAT 2745 patients were enrolled and followed up for a mean time of 8.8 months (2011 pt-yrs).

The aim of this study was to evaluate if in a more prolonged follow-up a low incidence of OAT complications can be maintained in a population attending an anticoagulation clinic, which uses the same procedures of ISCOAT participating centers.

We studied the frequency of bleeding and thromboembolic events in 530 patients followed at Florence anticoagulation clinic for a mean time of 18.9 months (835 pt-yrs). 76% of patients were receiving warfarin for the first time. Patients were aged as follows: 58% <70 yrs and 42% >70 yrs (ISCOAT: 64.8 and 35.2, respectively), among whom 24.4% were over 75 yrs (ISCOAT 16.8). The time spent within, below and above therapeutic range was 64%, 19% and 17% respectively (ISCOAT: 68, 26.1 and 5.9)

The frequency of major bleeding was 0.84% pt-yrs (ISCOAT: 1.1) and no fatal event was observed (ISCOAT: 0.25). Only in two of seven major events the INR was above therapeutic range. Minor bleedings were 6.34% pt-yrs (ISCOAT: 6.2). The rate of major thromboembolic events was 2.98% pt-yrs and 1.32% pt-yrs were fatal (ISCOAT: 2.9 and 1, respectively). Minor events were 2.64% pt-yrs (ISCOAT: 0.6)

In conclusion, a low incidence of complications was maintained during a prolonged follow-up. The older age of the patients assessed in our study in comparison to ISCOAT may provide an explanation for the slightly higher rate of minor thromboembolic events. These data indicate that also elderly outpatients treated routinely in an anticoagulation clinic may have a very low rate of bleeding complications.

3283 Comparative effects of triflusal and aspirin on cardiovascular inflammatory mediators upregulated by NF-kappaB

A. Fernandez de Arriba, M. Sanchez-Crespo[1], F. Cavalcanti, A. Miralles, M. Merlos, J. Garcia-Rafanell, J. Fom. *Department of Pharmacology, J. Uriach & Cia, Barcelona; [1]Inst. de Biologia y Genética Molecular, CSIC, Fac. Medicina, Valladolid, Spain*

The nuclear transcription factor NF-kappaB regulates the activation of cytokine and adhesion molecule genes that might be involved in the pathogenesis of atherosclerosis, acu- te coronary disease or stoke. Triflusal (2-acetoxy-4-trifluorome-thylbenzoic acid) is an antiplatelet drug displaying structural analogy to aspirin, but showing distinct pharmacological and pharmacokinetic properties. Since salicylates have been found to inhibit NF-kappaB activation, the objective of this study was to test triflusal and its deacetylated metabolite 2-hydroxy- 4-trifluoromethylbenzoic acid (HTB) as inhibitors of NF-kappaB activation and related events.

Methods: Peripheral blood mononuclear cells (PBMC) from healthy human donors and human umbilical vein endothelial cells (HUVEC) were used. TNF-alpha production was assayed by ELISA. Vascular cell adhesion protein (VCAM-1) expression was assayed by RT-PCR amplification. Activation of NF-kappaB was quantified in nuclear extracts by electrophoretic mobility shift assay (EMSA) using a double-stranded 32P-oligonucleotide containing consensus kappaB-binding sites.

Results: Incubation with 3 mM triflusal or HTB inhibited NF-kappaB activation in lipopolysaccharide(LPS)-activated PBMC (87 ± 3 and 85 ± 7%, respectively), whereas aspirin and salicylate produced 48 ± 5% and 35 ± 12% inhibition. Similar results were obtained using TNF-alpha-activated HUVEC (triflusal 85 ± 3%, HTB 81 ± 7%, aspirin 52 ± 12% and salicylate 21 ± 12% inhibition). Incubation of HUVEC with 2 mM triflusal or HTB completely blocked VCAM-1 mRNA expression elicited by TNF-alpha, whereas the inhibition produced by 2 mM aspirin and salicylate was lower than 20%. Triflusal and HTB also inhibited TNF-alpha release by LPS-activated PBMC in a concentration-dependent manner (0.01–1 mM), as compared to a 24 ± 9% and 35 ± 11%inhibition by 1 mM aspirin and salicylate, respectively.

In conclusion, triflusal and its metabolite HTB are more potent inhibitors of NF-kappaB than aspirin and salicylate, thus blunting the induction of both cytokine and adhesion molecule gene products at therapeutic concentrations.Studies are undertaken to assess the therapeutic utility of triflusal on cardiovascular diseases where genes under NF-kappaB control are upregulated.

3284 Triflusal may offer a safer alternative to aspirin in the treatment of acute phase of myocardial infarction: results from the TIM study

J.M. Cruz-Fernández, L. López-Bescós, D. García-Dorado, V. López, A. Cabadés, L. Martín-Jadraque, J. Velasco, A. Castro-Beiras, F. Marfil, F. Torres. *The TIM Investigators; Seville, Spain*

Background: There is firm evidence that treatment with aspirin (ASA) improves the prognosis of patients with acute myocardial infarction (AMI) receiving or not thrombolytic therapy. Triflusal is an irreversible platelet cyclooxygenase inhibitor with negligible effect on PGI2 synthesis.

Objective: To compare the effectiveness of triflusal and ASA in the prevention of cardiovascular events following an AMI.

Methods: In this double-blind, multicentre, sequential design study, patients younger than 80, who had not received ASA or any other antiplatelet drug during the previous 15 days and diagnosed of AMI, were randomised within 24 hours of symptoms onset to receive triflusal 600 mg or ASA 300 mg once daily for 35 days. The primary endpoint was death, non-fatal myocardial reinfarction or non-fatal cerebrovascular event; secondary endpoints were the incidence of these individual outcomes and urgent revascularization.

Results: Baseline characteristics including age (61 ± 12 years), sex (82% males), prevalence of risk factors (smoking 55%, hypercholesterolemia 38%, diabetes 22%, hypertension 38%) or previous history of ischaemic heart disease (40%) or stroke (3%) were similar in both groups. No differences were observed in the treatment administered during the index event, including fibrinolytic drugs in 71% of patients and full-dose heparin in 67%. No difference between treatments was accepted with 80% power after recruiting 2124 eligible patients (triflusal, n = 1056; ASA, n = 1068) (adjusted odds ratio 0.882 [95% CI 0.634–1.227]). Non-fatal cerebrovascular events were significantly less frequent with triflusal (0.364 [0.146–0.908]; p = 0.030). There was no significant difference between treatments in mortality (0.816 [0.564–1.179]), incidence of non-fatal reinfarction (1.577 [0.873–2.848]) nor revascularisation (0.864 [0.644–1.161]). Generally, both drugs were well tolerated, although a trend towards fewer bleeding episodes and significantly fewer central nervous system bleeding episodes were observed in triflusal-treated patients (0.27% vs 0.97%; p = 0.033)

Conclusion: Triflusal and ASA have similar efficacy in preventing further cardiovascular events after AMI, but triflusal showed a more favorable safety profile. Triflusal significantly reduced the incidence of non-fatal cerebrovascular events compared with ASA.

3285 Antagonism of captopril by aspirin in severe heart failure: haemodynamic and neurohormonal demonstration

P.R.N. Viecili, M. Park, S.R. Santos, D. Pamplona, J.A.F. Ramires, P.L. da Luz. *Heart Institute (InCor), University of São Paulo, Brazil Medical School*

ACE inhibitors are established treatment for congestive heart failure (CHF); however, simultaneous aspirin use could invalidate their beneficial effect due to pharmacologic antagonism. To objectively test this possibility we analysed hemodynamic and neurohormonal effects in 30 severe CHF patients (pts).

Methods: Pts were hospitalized for 5 days to receive fixed regimens of furosemide, nitroprusside and digitalis in the first 3 days. They were then randomised into 3 treatment groups: 1-captopril 150 mg/day orally; 2- aspirin 100 mg/day and, 3- captopril plus aspirin. Hemodynamic measurements with Swan-Ganz catheters were performed at baseline and 1 h after captopril administration twice a day/2 days. Noradrenaline (NA), by liquid chromatography analysis, was measured daily. Data were analysed by a repeated variance analysis. All data were expressed as mean ± SEM.

Results: Condensed hemodynamic results are shown on the table.

	Captopril (n = 10)		Aspirin (n = 10)		Cap-Asp (n = 10)	
	before	1 h	before	1 h	before	1 h
CI L/min/m^2	2.0 ± 0.06	2.5* ± 0.03	2.0 ± 0.02	1.9 ± 0.01	1.8 ± 0.02	2.0 ± 0.1
SVR dynes·s·cm^{-5}	2019 ± 87	1595* ± 32	2138 ± 40	2234 ± 40	2404 ± 84	2286 ± 138
PCWP mmHg	17 ± 1	14* ± 0.6	21 ± 0.2	21 ± 0.3	20 ± 1	19 ± 0.9

*$p < 0.001$

NA decreased significantly ($p < 0.001$) in captopril treatment pts, but remained unchanged in the other groups.

In conclusion: Results suport the notion that concomitant administration of aspirin and captopril in CHF, significantly abates both hemodynamic and metabolic effects of captopril.

3286 The use of protamine when administering abciximab after coronary stenting

G.S. Ledley, G. Crespo, R. Maraj, M. Fraifeld, W.S. Hirsch, S. Yazdanfar, M.N. Kotler. *Cardiology Department, Albert Einstein Medical Center, Philadelphia PA, USA*

Background: Recent studies have demonstrated that Abciximab reduces ischemic complications after coronary stenting. However, hemorrhagic complications are associated with elevated activated clotting times (ACT) after infusions of IV heparin and abciximab. Reluctance exits to partially reverse the effect of IV heparin with IV protamine, due to the possibility of producing thrombotic complications.

Methods & Results: 20 consecutive pts receiving abciximab during coronary stenting, and receiving IV protamine, were evaluated. The mean age was 64 y-o (55–80) and 55% were male. 45% of pts were admitted with unstable angina, 35% with MI, and 20% with stable angina. 40% of pts had an intracoronary thrombus and 55% of pts had post-balloon coronary dissection. The mean ACT's prior to, after abciximab infusion, and after protamine were 229 ± 56 s, 326 ± 64 s and 223 ± 41 s, respectively. The mean dose of protamine was 12 ± 3 mg. There were no thrombotic complications during the procedure. There were 3 hemorrhagic complications, including one CVA and 2 large inguinal hematomas. These pts had higher ACTs than the mean.

ACT's Post Abciximab & Protamine.

Conclusion: The use of IV protamine in pts undergoing coronary stenting with abciximab can effectively reduce the ACT. There were no thrombotic complications associated with this treatment strategy. IV protamine used to regulate the ACT, may reduce hemorrhagic complications in this patient population.

ASSESSMENT OF MYOCARDIAL DYSFUNCTION: NEW NON-INVASIVE MODALITIES

3295 Clinical and experimental study on micron-order myocardial layer function by novel Doppler device

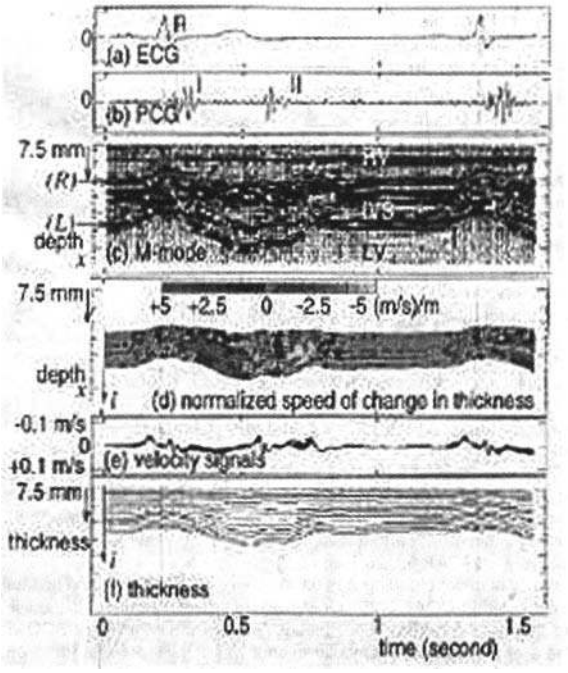
K. Hideichi, Y. Koiwa, K. Shirato, H. Kanai, K Sugiura, F Tezuka, Y Saito. *Tohoku University and Sendai National Hospital, Sendai, Japan*

It was reported that the micron-order vibration (>0.5 μm/sec) was to be measured precisely by novel Doppler analysis (IEEE, 1997).

We aimed to clarify whether a quantitative evaluation of the myocardial layer function (MLF), i.e. thickening of a myocardial layer of 0.75 mm thickness across the wall could be of use to determine the early damage induced by doxorubicin (Dox) injection.

Method: (1) Ten age matched normal subjects (20 ± 5 y.o.) and 40 patients with acute lymphoblastic leukemia and malignant lymphoma (25 ± 7 y.o.; male, 25; female, 15) under Dox treatment were examined for left ventricular function by routine echo/Doppler method and MLF by the developed method (Rf; 9 kHz sampling fr: 1 Mhz, Doppler fr: 3.5 MHz). (2) The quantitative relation between histological damage and MLF was examined in 5 control and 12 Dox injected rabbits (2-weeks injection group = 2, 5-weeks = 3, 8-weeks = 5, 10-weeks = 2).

Result: In normal subjects, MLF across the septal wall showed homgenous distribution of thickening during the cardiac cycle. However, MLF in patients was characterized by 1) the decrease in the peak thickening and thinning rate, 2) the appearance of a nonfunctioning layer across the wall, 3) MLF showed strong correlation to the histological damage induced by Dox injection when examined at the intraventricular septum of the rabbit.



Color code of normal subject myocardium. The changing view of the thickening or thinning rate of each myocardial layer during the cardiac cycle. From top to bottom: (a) ECG; (b) heart sound on the chest wall; (c) M-mode image of the septum; (d) superposition of velocity signals from each sampling point at different depth (0.75 mm); and (f) the thickening of each layer, where the right ventricular surface of the septum was set as no movement for easy realization of the difference among layers.

Conclusion: By the novel ultrasonic Doppler device, we could evaluate quantitatively MLF in Dox treated patients. This noninvasive method may be useful for long term medical management of such patients, providing new insight concerning the MLF at the micron-order level.

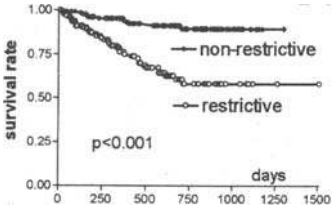
3296 Prognostic value of transmitral flow patterns in patients with chronic congestive heart failure

A. Hansen, C. Zugck, C. Krueger, R. Kell, S. Hardt, D. Mereles, M. Haass, H.F. Kuecherer. *Dept. of Cardiology, University of Heidelberg, Germany*

Background: Risk stratification of patients with end-stage heart failure is necessary for planning therapeutic strategies. The purpose of this study was to determine whether transmitral flow patterns are related to cardiac mortality.

Methods: A total of 328 patients (mean age 56, 276 males) with ischemic (n = 86) or dilated (n = 215) cardiomyopathy or valvular heart disease (n = 27) and left ventricular EF by radionuclide angiography <40% were prospectively studied. Peak early (E) and late (A) transmitral flow velocities and E-wave deceleration time (DT) were obtained using pulsed-wave Doppler echocardiography. Patients were assigned to groups with restrictive (E/A > 2 or DT < 140 ms) or non-restrictive (E/A < 1 or DT ≥ 140 ms) filling patterns. Patients with atrial fibrillation (n = 53) or inadequate Doppler tracings (n = 10) were excluded.

Results: During a mean follow-up period of 256 days (range 5–1509 days) 75 patients had died and 40 patients underwent heart transplantation. In the restrictive group (n = 128) survival rate was lower than that in the nonrestrictive group (n = 137), along with a lower LV-EF (19% ± 10 vs. 25% ± 12, p < 0.0001), higher NYHA scores (2.5 ± 0.7 vs. 2.1 ± 0.7, p < 0.0001) and lower peak VO_2max (13.2 ± 4 vs. 15.8 ± 6 ml/kg/min, p < 0.0001).



Conclusion: Mitral inflow patterns provide important information related to prognosis and functional status of patients with heart failure.

3297 Relation of transmitral flow velocity patterns to left ventricular end-diastolic pressure: new insights from combined haemodynamic and Doppler echocardiographic study

M. Rugină, E. Apetrei, C. Macarie, C. Ginghină, M. Macarie, D. Deleanu, L. Zarma. *National Institute of Cardiology, Bucharest, Romania*

The aim of the study was to investigate whether, deceleration time of A wave (Adt) identifies patients with elevated left ventricular end-diastolic pressure (LVEDP).

Material: 90 pts., 71 men (79%), mean age 54.53 ± 11.44 years with coronary artery disease: stable angina (25.5%), unstable angina (27%), and myocardial infarction (44.5%) were enrolled in this study. None had evidence of mitral stenosis, severe mitral regurgitation, atrial fibrillation or conduction disturbance such as second- or third-degree heart block.

Methods: Diastolic transmitral flow variables were recorded with pulsed-wave Doppler using 3.5 MHz transducer in apical four-chamber view with the sample volume placed 1 cm below the plane of the mitral annulus between the tips of the mitral leaflets and apical five-chamber view for isovolumetric relaxation time (IVRT). The measurement of LVEDP was done by left heart catheterization. Doppler traces were analyzed and the following variables were measured: peak E and A velocities (cm/s), E wave deceleration time (Edt, ms), A wave deceleration time (Adt, ms), IVRT (ms), E/A ratio, E/Edt, A/Adt and E/Adt ratio.

Results: LVEDP was 8 to 42 mmHg. Close negative correlation was found between LVEDP and Adt ($r = -0.77$) in total study pts. According to the Doppler transmitral flow velocity profile, as expressed by the E/A ratio, the study pts. were assigned to the following three groups: group 1 with E/A $\geq$ 2 representing "restrictive" filling pattern (8 pts., 9%); group 2 with E/A $\geq$ 1 and <2 which may signify a normal or "pseudonormal" filling pattern (34 pts., 38%) and group 3 with E/A < 1, impaired relaxation filling pattern (48 pts., 53%). There was a good correlation between LVEDP and Adt in all groups: group 1 ($r = -0.88$), group 2 ($r = -0.71$) and group 3 ($r = -0.78$). In all the study pts. Adt $\leq$ 70 ms predicted LVEDP 18 mmHg with a sensitivity of 98% and specificity of 94%. We find a good correlation between LVEDP and A/Adt ($r = 0.64$) in group 1; between LVEDP and E/Adt in group 1 ($r = 0.82$) and group 2 ($r = 0.68$).

Conclusions: A shortened Adt (70 ms) is useful marker of elevated LVEDP (18 mmHg). We found a good correlation between LVEDP and Adt in all three patterns of diastolic flow. Elevated LVEDP with shortened Adt are useful in differentiating a real normal from "pseudonormal" filling pattern. The E/Adt ratio has close correlation with LVEDP in "restrictive" and "pseudonormal" filling pattern.

3298 Mitral flow derived Doppler indices of left ventricular function in a general population: the Tromsø study

H. Schirmer, P. Lunde[1], K. Rasmussen[1]. *Epidemiology and Statistics Dept., Institute of Community Medicine, Tromsø[1] Dept. of Cardiology, Institute of Clinical Medicine, Tromsø, Norway*

Background: Left ventricular (LV) diastolic dysfunction has been proposed as the basis of heart failure with normal LV systolic function. Doppler indices of mitral inflow have been shown to correlate well with increased LV end-diastolic pressure in patients with cardiovascular disease and to change with age. We wanted to establish age specific criteria for normality of these indices in a large population based healthy reference sample.

Method: In our sample of 3287 subjects aged 25–85 years, 3186 had pulsed Doppler measurements of mitral inflow velocities and passive inflow deceleration time. The association of these indices to age and gender were established in a healthy reference sample of 1021 subjects from the total cohort.

Results: Age specific percentiles showed significant decline by age for peak passive mitral inflow velocity and the ratio of peak passive and active inflow velocities (E/A), whereas passive inflow deceleration time (DT) and peak atrial inflow velocity showed a significant increase by age. According to current criteria for diastolic dysfunction, the prevalence in the general population decreased by age, contrary to what would be expected. Restricting the analysis to subjects with signs or history of cardiovascular disease, did not alter this finding. Only 6% of the variance of DT was explained by cardiovascular disease or risk factors. For E/A, however, 37 and 48% of the variance were explained, for men and women, respectively.

Conclusion: Our data document a significant effect of age and gender on mitral Doppler indices of diastolic dysfunction. Age and gender specific criteria for normality is provided. Current guidelines for diagnosis of diastolic dysfunction do not seem to be applicable in a general population below the age of 50 years.

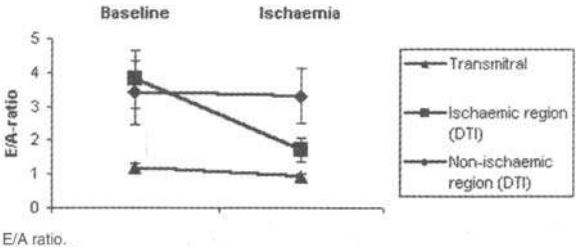
3299 Doppler tissue imaging expresses non-uniformity of left ventricular diastolic function during regional ischaemia

T. Edvardsen, S. Urheim[1], K. Steine[1], H. Ihlen, O.A. Smiseth[1]. *Dept. of Cardiology, National Hospital, Oslo; [1]Inst. for Surgical Research, National Hospital, Oslo, Norway*

The diagnostic value of transmitral Doppler in diastolic dysfunction is limited by substantial overlap with normals. Possibly, regional filling by Doppler tissue imaging (DTI) could be a better marker of diastolic dysfunction. The aim of this study was to determine whether regional myocardial ischaemia causes non-uniformity of myocardial diastolic velocities and to compare myocardial and transmitral velocities.

Methods: In eleven open-chest anaesthetised dogs with inflatable occluders on the LAD, global LV filling was measured by transmitral pulsed Doppler and regional LV filling by DTI.

Results: Transmitral peak early (E) velocity decreased, atrial-induced (A) velocity increased, and the E/A-ratio decreased modestly ($p < 0.05$) after LAD occlusion. In the ischaemic septal region myocardial E-velocities decreased ($p < 0.05$), A-velocities were unchanged, and the E/A ratio decreased substantially ($p < 0.05$). However, along the non-ischaemic lateral wall regional E/A-ratio was unchanged.



E/A ratio.

Conclusion: Regional E/A-ratio measured with DTI could differentiate between ischaemic and non-ischaemic areas in the left ventricle. DTI may represent a new method for assessment of diastolic function, which could be more sensitive than global indices of diastolic function.

3300 Relationship between plasma natriuretic peptide concentration and left ventricular systolic and diastolic function in patients with old myocardial infarction: assessment with gated cardiac blood pool scintigraphy

H. Okayama, T. Sumimoto, H. Kawada, T. Higaki, K. Kikuchi. *Department of Cardiology, Kitaishikai Hospital, Ehime, Japan*

It has been reported that the levels of plasma atrial and brain natriuretic peptide concentration (ANP and BNP) increased in patients with various cardiac disorders. However, the relatioship between left ventricular systolic and diastolic function and the levels of plasma ANP and BNP is not fully understood. The purpose of this study is to clarify the relationship between plasma concentrations of ANP and BNP and parameters of left ventricular systolic and diastolic function assessed by gated cardiac blood pool scintigraphy.

Methods: Equilibrium gated blood pool scintigraphy at rest was performed in 45 patients with old myocardial infarction. Parameters of systolic (ejectoin fraction (EF; %), peak ejection rate (PER; end-diastolic count (EDC)/sec), time to peak ejection (TPE; msec)) and diastolic function (peak filling rate (PFR; EDC/sec), time to peak fillig (TPF; msec) and filling fraction in the first third of diastole (1/3 FF; %)) were obtained from time activity curve and its first derivative. A blood sample was taken from the brachial vein at the same time.

Results: Correlation coefficients (r) between both natriuretic peptide levels and left ventricular systolic and diastolic function were as follows:

	EF	PER	TPE	PFR	TPF	1/3 FF
ANP	-0.68^{***}	-0.59^{***}	-0.45^{**}	-0.55^{***}	-0.05	-0.41^{**}
BNP	-0.63^{***}	-0.51^{***}	-0.31^{*}	-0.51^{***}	-0.32^{*}	-0.56^{***}

$^{*}P < 0.05$; $^{**}P < 0.01$; $^{***}P < 0.001$

For detecting systolic dysfunction (EF < 45%), the sensitivity and specificity for plasma ANP (cut off value > 25 pg/ml) were 87% and 56%; for plasma BNP (cut off value > 40 pg/ml) were 87% and 67%. For detecting diastolic dysfunction (PFR < 1.50 EDC/sec), the sensitivity and specificity for plasma BNP (cut off value > 25 pg/ml) were 76% and 57%; for plasma BNP (cut off value > 40 pg/ml) were 81% and 76%.

In conclusion, these data suggest that ANP and BNP were useful diagnostic marker to estimate both systolic and diastolic functions.

SELF-DEFENSE MECHANISMS OF THE JEOPARDIZED MYOCARDIUM

3310 "Electro-mechanical mismatch" in hibernating myocardium: normal local activation in areas with moderate myocardial dysfunction

H.-J. Bruns, T. Fetsch, F. Janssen, D. Hammel[1], H.H. Scheld[1], G. Breithardt, T. Wichter. *Interdisciplinary Center of Clinical Research, Dept. of Cardiology; [1]Dept. of Cardiovascular Surgery, University of Münster, Germany*

In 21 patients with regional left ventricular dysfunction and an indication for coronary bypass-surgery, multipolar epicardial mapping of local activation was performed during sinus rhythm. For simultaneous recording of the local electrograms, a sock electrode with 102 bipolar leads was used. Severity and extent of myocardial dysfunction were assessed from preoperative angiograms and projected on the grid of the intraoperative position of the sock electrode. This enabled regional comparison of electrical activation and mechanical function in a total of 1390 left ventricular areas (186 were hypokinetic, 130 akinetic and 35 dyskinetic).

For the characterization of local activation, amplitude [AMP], duration of activation [DUR] and the percentage of high-frequency components in the power spectrum [PHF, 50–250 Hz] were calculated for each signal using custom-made automated computer-algorithms.

	Normal	Hypokinetic	Akinetic	Dyskinetic
AMP [mV]	8.5 ± 7.2	8.5 ± 6.7	7.5 ± 5.8	*4.2 ± 4.5**
DUR [ms]	29.2 ± 19.1	29.3 ± 19.3	28.8 ± 17.5	*48.6 ± 28.2**
PHF [%]	10.8 ± 13.2	10.5 ± 15.0	8.1 ± 10.4	*4.1 ± 6.0***

(mean ± SD, *$p < 0.001$ and **$p < 0.01$ compared to all other groups)

Dyskinetic areas showed a distinct change in signal characteristics with reduction of local amplitudes, prolongation of signal duration and a shift of deviation in power spectrum density. Despite an impaired mechanical function, hypo- and akinetic areas showed normal or almost normal signal characteristics, indicating an electro-mechanical mismatch.

Conclusion: In patients with chronic ischaemic myocardium, an "electro-mechanical mismatch", defined as a mismatch between mechanical function and local electrogram characteristics, was observed in hypokinetic and akinetic areas. Thus, the identifiation of normal epicardial electrograms in regions of myocardial dysfunction by be an indicator for myocardial viability.

3311 High-energy phosphate metabolism in human preconditioning by magnetic resonance spectroscopy

R. Kalil, J.C. Nicolau, R.G. Weiss[1], C.P. Albuquerque, C.V. Serrano, R.R.C.V. Giraldez, J.A.F. Ramires. *Cardiology Dept, InCor-HCFMUSP, Sao Paulo, Brazil; [1]Cardiology Dept, Johns Hopkins Hospital, Baltimore, USA*

The ischemic preconditioning (IP) protects the myocardium by limiting infarct size in animal models. Its pathophysiology is uncertain. A paradigm of IP in humans involves the evaluation of patients with episodes of chest pain a day or two prior the infarction.

Methods: We studied 21 patients after a mean of 40 days period after anterior myocardial infarction (MI). All patients were submmited to a succesfull trombolytic treatment within six hours of the onset.The patients were divided in two groups: patients that presented with prior chest pain less than 48 hours before MI (IP group,n = 11, mean age 56) and 10 patients with no pain before MI (NIP, mean age 59). They underwent nuclear magnetic resonance imaging for measurement of left ventricle contractility. Image selected localized 31 P spectroscopy (MRS) of the antero-septal region was carried out on a 1.5 T imaging-spectroscopy Philips system using the ISIS technique. The acquisition time was 25 minutes. Cardiac PCr/ATP ratios were corrected for partial saturation and blood contamination.

The preconditioning group presented higher levels of PCr/ATP ratio than NIP group (1.64 ± 0.10 vs 1.38 ± 0.12, p = 0.008). The infarct area wall motion score trend better in IP group (1.4 ± 0.61 vs 1.84 ± 0.9, p = 0.3)

In conclusion: This preliminary study suggests that chest pain prior to infarction as a model of human ischemic preconditioning is associated with higher cardiac PCr/ATP ratios.

3312 Effect of nicorandil, an ATP-sensitive K-channel opener, on QT dispersion during coronary angioplasty

T. Kato, Y. Maruyama, T. Kamiyama, K. Takahashi, M. Kirimura, M. Kato, H. Ito, S. Tanaka, N. Yoshimoto. *Saitama Medical Center, Saitama, Japan*

Background. Activation of myocardial ATP-sensitive K channel (K_{ATP} channel) has been shown to mimic ischemic preconditioning. The aim of this study was to assess the effect of nicorandil, a K_{ATP} channel opener, on acute increase in QT dispersion (QTd) induced by repeated coronary occlusions at coronary angioplasty (PTCA) and to evaluate its cardioprotective effect against ischemia.

Methods. We studied 34 consecutive patients without previous myocardial infarction undergoing PTCA; 10 patients (NIC+) were taking nicorandil (5 mg orally tid) and 24 (NIC−) were not. PTCA consisted 4 of balloon inflations each lasting 2 min. Collateral filling of diseased coronary arteries was absent at diagnostic angiography in all cases. QTd were measured at baseline and immediately after each balloon deflations.

Results. QTd at baseline were not significantly different between 2 groups. After the first coronary occlusion. QTd increased significantly from the baseline value in NIC− group. The increase was not observed in NIC+ group. The following inflations did not significantly increase QTd in both groups.

	Baseline	1st	2nd	3rd	4th
NIC− QTd (msec)	28 ± 8	50 ± 8*	38 ± 11	28 ± 4	28 ± 4
NIC+ QTd (msec)	23 ± 6	37 ± 6**	37 ± 6	27 ± 12	27 ± 6

*$p < 0.005$ (vs. Baseline) and **$p < 0.05$ (vs. NIC−)

Conclusions. QTd was increased by ischemia during the first balloon inflation but not during subsequent ones; i.e., ischemic preconditiong. Nicorandil may prevent the increase of QTd at the first inflation by pharmacologically mimicking ischemic preconditiong.

3313 Activation of ATP-sensitive potassium channels is the common cardioprotective link between preconditioning and natural hibernation

S. Kevelaitiene, E. Kevelaitis[1], C. Mouas[2], J. Peynet[3], P. Menasché[4]. *Clinic of Cardiology; [1]Dept. of Physiology, Kaunas Medical University, Kaunas, Lithuania; [2]INSERM U-127; [3]Dept. of Biochemistry; [4]Dept. of Cardiovascular Surgery, Hôpital Lariboisière, Paris, France*

The tolerance of hibernating mammals to extended periods of cold hypoxia is related to a plasma factor which is chemically similar to agonists of δ-opioid receptors. The present study was designed to assess whether an activation of δ-opioid receptors could reproduce the cardioprotection conferred by ischemic preconditioning (IPC).

Methods: Isolated isovolumic buffer-perfused rat hearts were arrested with and stored in Celsior solution at 4°C for 5 hr before being reperfused for 2 hr. They were divided into four groups (n = 8, each group). Group 1 hearts were served as controls. In group 2, hearts were pharmacologically preconditioned with a 15-min infusion of the δ-opioid receptor agonist D-Ala^2-D-Leu^5-enkephalin (DADLE, 200 μmol/l) before arrest. In group 3, IPC was elicited by two 5-min global ischemia periods interspersed with 5 min of reperfusion before arrest. Group 4 hearts underwent a similar protocol to group 2, except that the infusion of DADLE was preceded by a 5-min infusion of the K_{ATP} blocker glibenclamide (50 μmol/l). End points included recovery of left ventricular (LV) systolic and diastolic function, including pressure-volume (P-V) curves assessed by linear regression analysis of the end-diastolic pressure (LVEDP) data, total release of creatine kinase (CK) over the first 45 min of reperfusion, endothelium-dependent coronary vasodilation to 5-hydroxytryptamine (10^{-7} mol/l) under constant perfusion pressure or to acetylcholine (10^{-6} mol/l) under constant flow and myocardial water content.

Results: Preischemic functional parameters were not different among the four groups. Main poststorage data (mean ± SEM) are summarised below:

Group	Slope of P-V cure (mm Hg/ml)	LVEDP (mm Hg)	CK release (IU/g dry weight)	Water content (%)
1	694 ± 27	37.8 ± 2.5	548 ± 79	81.23 ± 0.23
2	485 ± 19**	23.6 ± 1.6**	379 ± 62*	79.46 ± 0.37†
3	474 ± 20**	24.7 ± 1.6**	345 ± 54*	79.88 ± 0.22†
4	703 ± 27	39.9 ± 2.9	453 ± 43	80.90 ± 0.13

*$p < 0.05$ vs group 1; **$p < 0.001$ vs groups 1 and 4; †$p < 0.005$ vs groups 1 and 4

Neither recovery of contractile indices nor endothelium-dependent coronary vasodilatory responses to 5-hydroxytryptamine/acetylcholine were different among the four groups.

Conclusion: Activation of δ-opioid receptors, as occurs during natural hibernation, improves recovery of cold-stored hearts to a similar extent as IPC. These endogenous protective effects have a common pathway characterised by an opening of K_{ATP} channels.

3314 Hydroxylradicals increase calcium sensitivity of cardiac muscle

O. Zeitz, A. Rahman, G. Hasenfuss, P.M.L. Janssen. *Cardiology and Pneumology, University of Göttingen, Göttingen, Germany*

Hydroxylradicals are involved in the etiology of postischemic reperfusion injury. Exposure of intact contracting cardiac muscle preparations to exogenous produced hydroxylradicals leads to an increase of diastolic tension. It is well known that oxidative stress causes a mitochondrial dysfunction with ATP-depletion as a consequence. It is also reported that hydroxylradicals directly attack the sarcoplasmic reticulum calcium-ATPase and reduce its activity. Both these effects synergistically lead to disorder of intracellular calcium handling with a subsequent increase of the free calcium concentration in the sarcoplasm. A third mechanism of oxidative damage which is currently under discussion is the direct attack of hydroxylradicals on the myofilaments. Changes in calcium sensitivity induced by oxidative stress have to date not been studied on the actin-myosin matrix directly.

Therefore we first exposed contracting muscle preparations (n = 9) of rabbit hearts to hydroxylradicals generated by H_2O_2 and Fe^{3+}-NTA (Fenton reaction). A brief hydroxylradical-exposure induces a rigor-like contracture; 15 min after application of hydroxylradicals we observed an increase in diastolic force from 5.40 ± 1.65 mN/mm^2 to 23.93 ± 5.70 mN/mm^2 ($p < 0.05$) and additionally after 30 min a loss in developed force (15.33 ± 2.74 mN/mm^2 to 8.24 ± 1.96 mN/mm^2; $p < 0.05$), while all twitch parameters in sham preparations (similar protocol except the exposition to free radicals; n = 8) were stable over the same time. Secondly, 45 min after hydroxylradical exposure muscle preparations were transferred to a solution containing 1% v/v Triton X-100 to access the myofilament matrix directly. 16–20 hours later we measured the force-pCa-relation. The $pCa_{50\%}$ under control conditions was 5.54 ± 0.10 vs. 5.79 ± 0.04 in the hydroxylradical-group ($p < 0.05$). Cooperativity and maximal developed force remained unchanged (3.33 ± 0.58 vs. 2.45 ± 0.38, p = 0.21; 55.05 ± 10.21 mN/mm^2 vs. 57.22 ± 9.21 mN/mm^2, p = 0.87).

We conclude that hydroxylradical exposure sensitises the myofilaments, which can contribute to the rise of diastolic tension. There are several substances with protective but unexplained effects on free radical exposed cardiac muscle. A possible mechanism of action of these compounds could be a desensitising effect on the myofilaments.

3315 Repetitive myocardial stunning in pigs is associated with an increase in the expression of inducible and constitutive nitric oxide synthases

C.S.R. Baker[1], O. Rimoldi[3], P.G. Camici[3], E. Barnes[1], M.R. Chacon[2], T.Y. Huehns[1], D.O. Haskard[1], J.M. Polak[2], R.J.C. Hall[1]. [1]*Departments of Cardiology;* [2]*Histochemistry;* [3]*MRC Cyclotron Unit, Imperial College School of Medicine, Hammersmith Hospital, London, UK*

Nitric oxide (NO) has complex effects on myocardial function particularly following ischaemia-reperfusion. The goal of this study was to examine the result of repetitive myocardial stunning on myocardial NO release and expression of inducible (iNOS) and constitutive NO (eNOS) synthases.

Methods and Results: Propofol anaesthetised pigs underwent ten, 2-minute episodes of circumflex artery occlusion (n = 6) or acted as sham operated controls (n = 4). Measurements of segment shortening demonstrated a fall in function in the ischaemic territory to 52.5 ± 7.3% (mean ± SEM) of baseline shortening 30 minutes after the stunning stimulus, recovering to 92 ± 8.7% 5 ½ hours later. Function remained stable in sham controls. Local myocardial NO production fraction (local coronary venous [NO] – aortic [NO]/aortic [NO] × 100) increased in the stunned group vs. sham controls 6 hours after the final reperfusion (15.1 ± 5.7% vs. −6 ± 3.8%, p = 0.001). Western blotting and band optical density used to compare tissue from stunned territory (S), non-ischamic territory (NI) and sham control animals (C) demonstrated this was associated with an increase in the expression of both iNOS (S: 93 ± 13.4, NI: 37 ± 2.4 and C: 25 ± 4 [arbitrary units], $p < 0.01$ & p = 0.031) and eNOS (S: 104 ± 7.4, NI; 62.5 ± 7.4 and C; 75.7 ± 0.6, $p < 0.03$ & $p < 0.01$). Immunocytochemistry localised iNOS reactivity to vascular smooth muscle cells and cardiomyocytes in stunned tissue and eNOS reactivity to endothelial cells in all groups.

Conclusion: Recovery from repetitive myocardial stunning is associated with the increased expression of both iNOS and eNOS and would be compatible with a protective role for both these enzymes. This finding has possible relevance for both the late window of ischaemic preconditioning and myocardial hibernation.

MECHANISMS OF REMODELLING AFTER MYOCARDIAL INFARCTION

3316 Role of urokinase-type plasminogen activator in ventricular wall rupture, scar formation, and cardiac function after myocardial infarction

S. Heymans[1], D. Nuyens[1], E. Cremers[2], L. Moons[1], J.P.M. Cleutjens[2], M.J.A.P. Daemen[2], J.F.M. Smits[3], D. Collen[1], P. Carmeliet[1]. [1]*The Center for Transgene Technology and Gene Therapy, KU Leuven, Belgium;* [2]*The Depts of Pathology;* [3]*Pharmacology, Universiteit Maastricht, Netherlands*

Remodeling of the extracellular matrix may play a role in cardiac rupture, healing and function after myocardial infarction.

Methods: The role of proteolysis in these processes was studied after coronary artery ligation in mice lacking urokinase-type plasminogen activator (u-PA$^{-/-}$), tissue-type plasminogen activator (t-PA$^{-/-}$) and wild type (WT) mice. Healing of the infarct was studied at 2, 4, 7, 14 and 35 days after ligation by immunohistochemistry, electron microscopy and zymography. Cardiac function was analyzed by high fidelity pressure and cardiac output measurements, and by electrocardiographic recordings 2 weeks after ligation.

Results: About 1/3 of male wild type (10/27) and t-PA$^{-/-}$ (3/10) mice died of cardiac rupture within 4 days, associated in time with infiltration of macrophages expressing u-PA and matrix metalloproteinase-9 (gelatinase-B) in the ischemic zone. Rupture was not observed in u-PA$^{-/-}$ mice (0/18), nor in WT mice after adenoviral transfer of plasminogen activator inhibitor-1 (0/19). Deficiency of u-PA significantly reduced macrophage infiltration, removal of necrotic cardiomyocytes, neovascularization and collagen deposition in the infarct. Importantly, this impaired infarct healing in u-PA$^{-/-}$ mice lead to persistent ischemia 14 days after ligation. In addition, it depressed myocardial contractility, induced arrhythmogenicity, and increased mortality after adrenergic stress.

Conclusion: These data thus provide genetic evidence for an essential role of u-PA mediated proteolysis in cardiac wound healing and rupture following MI. Hence, exaggerated proteolysis mediated by leukocyte-generated u-PA may predispose to wall rupture. Transient inhibition of u-PA may prevent cardiac rupture after myocardial infarction, whereas prolonged inhibition of healing may impair cardiac functional recovery.

3317 Selective aldosterone receptor antagonism attenuates ventricular dilatation and reactive fibrosis but does not affect wound healing following myocardial infarction

J. Delyani, C. Womack, R. Wang, G. Frierdich, B. Kekec, E. Blasi, Y. Yu. *Cardiovascular Discovery Dept, Monsanto, St Louis MO, USA*

Introduction: Aldosterone receptor antagonism can prevent maladaptive reactive cardiac fibrosis during hyperaldosteronism in animals. However, the effect of aldosterone receptor antagonism on cardiac reparative fibrosis and wound healing is unknown and may have important clinical consequences. Purpose: To evaluate the effect of eplerenone, a selective aldosterone receptor antagonist, on myocardial wound healing and ventricular remodeling following infarction.

Methods: 78 rats survived left coronary artery ligation to produce myocardial infarction (MI) or sham MI. Following surgery sham MI rats received vehicle (VEH) and rats suffering MI received either eplerenone (EPL; 300 mg/kg/day, po) or VEH for 3, 7 or 28 days. Infarct thinning (width of the free wall:septal wall), infarct and noninfarct collagen volume fraction (%), and the diastolic pressure/volume relationship were determined.

Results: At day 3 (a time when there is a transition from edema to thinning and replacement of necrotic tissue), the thinning ratio of the MI EPL treated group (0.7 ± 0.1), but not the MI VEH treated group (0.9 ± 0.1) was significantly less than sham MI control (1.0 ± 0.1), suggesting that eplerenone may have altered the edematous transition. However, the thinning ratio of the two MI groups did not differ at days 7 or 28, indicating equivalent thinning of the healed infarction. The collagen volume fraction of the infarcted zone in animals receiving VEH and EPL at day 3 (5.2 ± 0.8 vs 4.6 ± 0.6), day 7 (48.1 ± 4.0 vs 48.3 ± 5.0), and day 28 (59.5 ± 3.1 vs 57.9 ± 4.4) was similar. In contrast, at day 28 the VEH treated animals (3.2 ± 0.4), but not the EPL treated animals (2.1 ± 0.4) had a significantly greater collagen volume fraction in the noninfarcted region than animals undergoing sham MI (1.7 ± 0.2). Moreover, the pressure/volume relationship revealed signficant left ventricular remodeling following MI in VEH treated rats but not EPL treated rats at day 28.

Conclusion: These data demonstrate that EPL does not adversely affect wound healing or infarct expansion following myocardial infarction, but rather that EPL attenuates maladaptive reactive fibrosis and left ventricular remodeling.

3318 The significance of free insulin-like growth factor-1 activation in the process of remodelling in patients with acute myocardial infarction

K.I. Kapetanios, E.V. Economou, C.I. Stefanadis, C.E. Pitsavos, D.M. Farmakis, K. Vassiliadou, M.G. Toutouza, P.K. Toutouzas. *Cardiology Dept. University of Athens, Athens, Greece*

The IGF-1 autocrine system was found to be activated in the viable ventricular myocytes shortly after experimental coronary occlusion in rats, while exogenous administration of IGF-1 induced a physiological form of cardiac hypertrophy, thus preserving cardiac function. The aim of our study is to elucidate the role of free IGF-1 (fIGF-1) in acute myocardial infarction (AMI) patients.

Methods: 27 patients with first attack of AMI, and no previous history of any other disease, were examined for plasma levels of fIGF-1, measured by ELISA, and compared to corresponding levels of 20 Normal controls (NC) with mean values: 7.81 ± 0.15 ng/ml. All pts were divided in 2 sex and age-matched groups Group A: pts with limited infarct size, EF > 45% and no subsequent LV dysfunction. Group B: pts with extensive AMI EF < 45% and residual heart failure. Plasma samples were collected at the time of hospital admission (0 hours) and 6 h, 12 h, 18 h, 24 h, 48 h, 3 days, 4 d, 5 d, 7 d, 15 d, 30 d thereafter.

Results are expressed as mean values ± SEM in ng/ml as follows:

Pts	0 h	6 h	12 h	18 h	24 h	48 h	3 d	4 d	5 d	7 d	15 d	30 d
A (13)	21.7 ± 2.8 ◇	22 ± 2.34 ◇	23.5 ± 2.8 ◇	24.8 ± 2.9 ◇	26.5 ± 3.8 ◇	24.3 ± 2.5 ◇	24.0 ± 2.6 ◇	24.3 ± 2.8 ◇	24.5 ± 2.9 ◇	23.5 ± 2.3 ◇	23.6 ± 2.4 ◇	24.4 ± 2.9 ◇
B (14)	8.04 ± 0.4 NS	8.7 ± 0.61 NS	8.56 ± 0.7 NS	8.66 ± 0.4 NS	9.41 ± 0.6 NS	9.15 ± 0.4 NS	9.11 ± 0.4 NS	8.7 ± 0.35 NS	8.58 ± 0.3 NS	8.55 ± 0.4 NS	8.56 ± 0.5 NS	8.48 ± 0.5 NS

p < 0.05 compared to corresponding values of: a) NC (◇) b) the relevant first plasma sample (*). NS = non statistical compared to NC (Wilcoxon test).

Conclusions: Plasma levels of fIGF-1 exhibited a progressive increase that became statistically significant 24 h after AMI in pts with limited infarct size and no LV dysfunction. All these samples were significantly raised compared to NC. This marked elevation of fIGF-1 may be associated with adaptive hypertrophy, thus leading to a "good quality" remodeling and preserving cardiac function. On the other side fIGF-1 remained inactivated in pts with large infarcts, probably because of the smaller amount of viable ventricular myocytes, thus leading to maladaptive hypertrophy and heart failure. fIGF-1 may prove to be a major factor in modifying the process of remodeling, following AMI, in the future.

3319 Left ventricular remodelling after myocardial infarction can be predicted by plasma brain natruretic peptide

A. Hirayama, K. Kodama, M. Uematsu, H. Yamamoto, K. Kashiwase, Y. Mizuno. *Cardiovascular Division, Osaka Police Hospital, Osaka, Japan*

Background: Plasma brain natriuretic peptide (BNP) secreted from the infarct and the noninfarct segments after myocardial infarction (MI) reflects the left ventricular function as well as provides the prognostic information of patients. Left ventricular remodeling has been shown to be associated with the clinical worse outcome and predicts the poor prognosis. In this study, the relationship between these two prognostic factors was studied.

Methods: Plasma BNP level at aortic root (A) and anterior interventricular vein (AIV) were measured by the radioimmunoassay in 81 patients with first anterior MI, whose infarct-related artery were successfully reperfused within 24 hours from the onset and patent during the study period. Hemodynamic variables were measured by Swan-Ganz catheter. Left ventricular (LV) volume and global LV function were calculated with the area-length method, and regional LV function was assessed by the centerline method, using LV grams at 1 M and 6 M. Infarct size was calculated by Tl-201 SPECT at 1 M.

Results: Among the parameters obtained at 1 M, the increment of percent change of EDVI from 1 M to 6 M has significant correlations with PCWP ($r = 0.319$, $p < 0.05$), EDVI ($r = 0.269$, $p < 0.05$), ejection fraction ($r = 0.321$, $p < 0.05$), regional wall motion ($r = 0.256$, $p < 0.05$), and plasma BNP level ($r = 0.418$, $p = 0.0006$), but not the difference of plasma BNP level between A and AIV representing BNP level secreted from the infarct segment. Multiple regression analysis revealed that only plasma BNP level significantly correlated with the increment of percent change of EDVI from 1 M to 6 M among infarct size, time form the onset to reperfusion, LV functions at 1 M, hemodynamic variables at 1 M and medications including ACE inhibitor.

Conclusion: Plasma BNP level secreted form both the infarct and the noninfarct segment correlates the magnitude of LV remodeling after myocardial infraction, although LV remodeling has been influenced by many factors such as infarct size, infarct location, infarct arterial patency and medications, so on. This suggested that progressive LV remodeling is accompanied with the augmentation of BNP release from both the infarct and noninfarct segment of LV, and BNP level at 1 M is a biochemical marker for the prediction of progressive LV remodeling.

3320 Angina pectoris prior to myocardial infarction protects against subsequent left ventricular remodelling: the Healing and Early Afterload Reducing Therapy trial (HEART)

S. Solomon, S. Greaves, R. Glynn, G. Lamas[1], J. Rouleau[2], G. Timmis[3], F. Menapace[4], M. Arnold[5], C. Hennekens, M. Pfeffer. *Cardiovascular Division, Brigham and Women's Hospital, Boston MA; [1]Cardiology Dept., Mt. Sinai Hospital, Miami FL, USA; [2]Montreal Heart Institute, Montreal, Canada[3]William Beaumont Hospital, Royal Oak MI[4]Geisinger Medical Center, Danville PA, USA[5]Victoria Hospital, London Ontario, Canada*

To investigate the hypothesis that prior angina pectoris confers protection from remodeling following myocardial infarction, we analyzed echocardiograms from the Healing and Early Afterload Reducing Therapy Trial (HEART). 352 patients were randomized to receive one of three dosing regimens of ramipril. Echocardiograms were obtained within 24 hours of myocardial infarction, at 14 days and at 90 days. Left ventricular dilatation from day 0 to 90 was used as a measure of LV remodeling. LV volume change in patients with angina ($n = 111$) during the three month period prior to MI was -0.73 ± 25.5 ml over the 90 day period, compared with 6.8 ± 25.5 ml for patients ($n = 174$) without angina ($p = 0.016$). In contrast, there were no differences in change in ejection fraction based on prior angina. In addition, maximal CK was significantly lower in patients with prior angina (2093 vs. 2743, $p = 0.004$). In a multivariate model, prior angina remained predictive of less remodeling after adjusting for age, sex, baseline ejection fraction, killip class, history of diabetes, baseline end-diastolic volume, and drug treatment group ($p = 0.042$).

Conclusion: Ischemic symptoms prior to anterior myocardial infarction may protect against left ventricular remodeling, and may be associated with less enzymatic release. These protective effects may be secondary to recruitment of collaterals or ischemic preconditioning of the myocardium.

DIRECT PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOPLASTY: IMPROVING BLOOD FLOW

3331 Is TIMI 2 flow after primary PTCA in acute myocardial infarction a successful procedure? Results from the Stent PAMI randomized study

T. Lefèvre, M.-C. Morice, E. Garcia, F. Kiemeney, M. Pieper, C. Macaya, G.-A. Van Es, L. Mattos, A. Schulz, C. Grines. *On behalf of the Stent PAMI study investigators; Institut Cardiovasculaire Paris Sud, Massy, France*

Results from the Gusto trial have shown that one-month mortality after acute MI treated by thrombolysis is related to TIMI flow at 90 min. with a clear difference between TIMI 2 and TIMI 3 flow. These results have changed the definition of successful thrombolysis.

The purpose of this study was to compare the outcome of pts with "successful" PTCA (TIMI 2 or 3 flow and residual stenosis < 50%) included in the Stent PAMI randomized trial according to the final flow (TIMI 2 or 3).

Of 1,458 pts in whom informed consent was obtained, 900 were randomized, 452 to stent and 448 to balloon. Procedural success was obtained in 98.5% of cases (Corelab analysis) with a 15.1% cross-over to stent in the balloon group.

Results are summarized below:

	TIMI 2	TIMI 3	p value
Balloon arm (%)	7.3	92.7	<0.001
Stent arm (%)	9.0	90.4	<0.001
Stent and Bail-out stent (%)	10.6	88.6	<0.001
Death up to 210 days (%)	9.1	2.9	<0.001
MACE up to 210 days (%)	23.4	16.6	<0.001

Death rate at 210 days was not statistically different in pts with TIMI 2 flow treated either by balloon or stent (respectively 8.3 vs 9.8%).

In conclusion, outcome of pts with with TIMI 2 flow after primary PTCA in acute MI is significantly worse than in pts with TIMI 3 flow, whatever the treatment applied. PTCA success must be redefined and all efforts must be made to obtain a TIMI 3 flow at the end of the procedure.

3332 Impact of vessel size and lesion length on outcomes after primary stenting versus primary angioplasty in acute myocardial infarction: results from Stent PAMI

Alexandra J. Lansky, Gregg W. Stone, Roxana Mehran, George Hanzel, Natama Summers, Ahn Bao Bui, Marie-Claude Morice, Luis Mattos, David Cox, Martin B. Leon, Cindy L. Grines. *Washington Hospital Center, Washington DC, USA*

Long lesions and small vessels have an additive effect on target lesion revascularization (TLR) after elective intracoronary stenting. The comparative benefits of primary stenting versus primary angioplasty after acute myocardial infarction (AMI) acording to lesion length and vessel size are not known. PAMI Stent randomized 900 pts presenting within 12 hours of AMI to primary PTCA or stenting with the Cordis heparin coated stent. We reviewed the clinical outcomes of 868/900 pts randomized to PAMI Stent with available follow-up, according to varying lesion lengths and vessel sizes (<2.75 mm, N = 212; 2.76–3.25, N-332, >3.25 mm, N = 278). Independent angiographic core analysis with follow-up was available in 565 of 900 patients. Results by randomization arm are presented in the table.

% Restenosis

Vessel Size	LL ≤ 10 mm N = 339		LL 10–20 mm N = 304		LL > 20 mm N = 119	
	PTCA	Stent	PTCA	Stent	PTCA	Stent
≤2.75 mm	39.5	33.3	38.2	27.8	22.2	80.0†
2.76–3.25 mm	30.4	13.3†	31.9	13.3†	42.9	35.3
>3.25 mm	18.8	17.5	42.1	20.1†	16.7	40.0

†p < 0.05

Target vessel revascularization (TVR) was lower with stenting in patients with vessel sizes of 2.76–3.25 mm and lesion length < 10 mm (0% vs 10.1%, p = 0.02) as well as lengths of 10–20 mm (8.8% vs 18.6%, p = 0.08).

We conclude that after primary PTCA or stenting for acute myocardial infarction, restenosis rates increase with longer lesions in smaller vessels, with a greater variation occurring in the stent group. Primary stenting reduces restenosis and TVR in patients with intermediate (2.76–3.25 mm) vessel sizes, with no apparent additive benefit over PTCA in patients with smaller (<2.75 mm) or larger vessels (3.25 mm)

3333 Angiographic and clinical reasons for the higher in-hospital mortality in diabetic patients with acute myocardial infarction treated with primary angioplasty

R. Moreno, E. García, J. Soriano, M. Abeytua, E. López de Sá, J. Elízaga, J. Botas, J.F. Portales, J.R. Rey, J. Acosta, R. Rubio, J.L. López-Sendón, J.L. Delcán. *Dept. of Cardiology, Hospital Gregorio Marañón, Madrid, Spain*

Diabetes mellitus (DM) is a strong risk factor for a worse outcome in patients (pts) with acute myocardial infarction (AMI). The objective of this study was to identify the reasons for the high in-hospital mortality in DM pts with AMI treated with primary angioplasty (PTCA).

Methods: 713 ptswith AMI were treated with PTCA within the first 12 hours after the onset of symptoms in our institution from 1.991 to 1.998. The in-hospital outcomes were compared between DM (n = 165; 23%) and non-DM (n = 548; 67%).

Results: The angiographic success rate was not statistically different between both groups, and coronary stenting was used more frequently in DM. However, DM pts had a higher in-hospital mortality (20.9% vs. 11.3%, p = 0.0023). After adjunsting by Killip class, mortality was not statistically different between DM and non-DM: 4.2% vs. 3.0% (NS) in Killip I, 21.9% vs. 20.8% in Killip II–III and 74.1% vs. 61.2% (NS) in Killip IV, in DB and non-DM pts, respectively. DM patients had an angiographic and clinical higher risk profile in comparison with non-DM patients:

	DM	NoDM	p
Re-AMI	4.9%	2.4%	NS
Death/Re-AMI	24.5%	13.3%	0.0010
Free wall rupture	2.4%	2.3%	NS
Angio. success	89.9%	93.2%	NS
Coronary stenting	58.8%	47.9%	0.0161
Proximal occlusion	55.6%	44.7%	0.0190
No. vessels	1.9 ± 0.8	1.6 ± 0.7	0.0003
LVEF	0.41 ± 0.14	0.46 ± 0.14	0.0416
Cardiogenic shock	18.4%	8.2%	0.0005
Age (years)	68 ± 10	62 ± 13	<0.0001
Female gender	31.1%	17.0%	0.0002
Hypertension	52.2%	42.0%	0.0221

Conclusion: Despite mechanical reperfusion with primary PTCA, a high angiographic success rate (90%) and a more frequent utilization of coronary stents, DM patients with AMI are at a high risk. However, this may be mainly explained by the worse clinical profile and more adverse angiographic findings in these patients.

3334 Is primary angioplasty of venous bypass grafts for acute myocardial infarction as effective as in native vessels?

B. Frilling, R. Zahn, R. Schiele, K. Dönges, B. Mark, B. Fraiture, J. Senges. *Herzzentrum Ludwigshafen, Kardiologie, Ludwigshafen, Germany*

Objective: Success rates in primary angioplasty of native vessels are beyond 90%. A small proportion of acute myocardial infarction (AMI) is related to acute closure of venous bypass grafts (CABG). AMI after CABG appears to be a well delineated entity and patency rates of >85% have been reported. However data on functional parameters like TIMI flow and reflow are limited.

Methods: In a retrospective study 8 cases of primary angioplasty of venous bypass grafts were analyzed concerning initial treatment, angiographic outcome and clinical course.

Results: Out of 380 primary angioplasties in 1995–1998, 8 patients (2.1%) were diagnosed with AMI related to acute closure of a venous bypass graft. Stents were used in 1 patient, glycoprotein IIb/IIIa antagonists were used in 3 patients. Intracoronary fibrinolysis was applied in 7 patients.

Patient	Age	Sex	Residual stenosis	TIMI flow	No reflow	Death
1	46	f	0%	2	No	No
2	72	m	25%	2	Yes	No
3	64	m	0%	2	Yes	No
4	60	m	80%	3	No	No
5	54	f	30%	3	No	No
6	60	m	100%	0	–	No
7	55	m	60%	2	No	No
8	70	m	60%	0	–	yes

Conclusion: Incidence of AMI with a venous bypass graft as infarct-related artery is low (2.1%). Although patency of the IRA was achieved in 6 out of 8 cases (75%), TIMI III flow was achieved in only two cases. 50% of the patients with TMI II flow showed no reflow despite documented vessel patency.

3335 Primary angioplasty and stenting in acute myocardial infarction: predictors of acute and sub-acute stent thrombosis

C. Loubeyre, R. Kumar, T. Lefèvre, M.-C. Morice, P. Dumas, Y. Louvard, J.-F. Piéchaud. *Institut Cardiovasculaire Paris Sud, Massy, France*

Background: At a time of widespread use of stents and ticlopidine for the treatment of acute myocardial infarction (AMI), predictive factors of acute and sub-acute stent thrombosis (ASAT) have not been precisely determined.

Methods: Since January 1995, over 735 pts have undergone primary angioplasty in our institution within 24 hrs of symptom onset. 647 pts (88%) received a stent. All were treated with aspirin and ticlopidine after stent implantation. ASAT occurred in 1.54% of pts (acute in 4 pts and sub-acute in 6 pts). Clinical and procedural variables were analysed in order to determine predictors of ASAT.

Results: Cardiogenic shock was the only clinical predictive factor associated with ASAT (present in 40.0% vs 11.4% in non ASAT pts, p = 0.02). Procedural variables identified multivessel stenting (30.0% vs 4.2% in non ASAT, p = 0.002), multiple stents (2.0 ± 0.5 vs 1.4 ± 0.7 stent/pt, p = 0.007) and residual stenosis (6.7 ± 11 vs 1.4 ± 7%, p = 0.01) as predictive factors significantly associated with ASAT. ASAT rate was found to be higher when non tubular stents were used (AVE or Cook stent) compared to tubular stents (NIR, Bestent, Crown, Palmaz Schatz, Multilink): 4.65 vs 1.16% (p = 0.01).

Conclusion: (1) Elective stenting with ticlopidine and aspirin in AMI is associated with an acceptable (1.54%) rate of ASAT. (2) Except for cardiogenic shock, predictive factors are mainly related to procedural variables. (3) Tubular stents may be preferred to coil or multicellular stents.

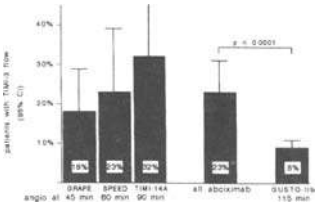
3336 Emergency room infusion of abciximab speeds up reperfusion in acute myocardial infarction eligible for primary PTCA

F.W.A. Verheugt[1], E.M. Ohman[2], E.M. Antman[3]. [1]*Heartcenter, University Hospital, Nijmegen, Netherlands;* [2]*Duke University, Durham NC;* [3]*Harvard Medical School, Boston MA, USA*

Background: Glycoprotein receptor antagonists have been shown beneficial in patients undergoing PTCA including those with acute myocardial infarction (AMI). Little is known about their potency of inducing reperfusion in AMI.

Methods: We analysed the 3 angiographic trials with abciximab *alone* given to patients in the emergency room: the GRAPE (Glycoprotein Receptor Antagonist Patency Evaluation, n = 60) study, the SPEED (Strategies of Patency Enhancement in the Emergency Department, n = 26) trial and the TIMI-14A (n = 31) study. TIMI 3 flow grade was core lab read in the 3 trials (all abciximab, n = 117) and compared to the core lab reading of the angioplasty arm (n = 511) of the largest primary PTCA trial, GUSTO-IIb Angioplasty Substudy.

Results:



Conclusion: Abciximab *alone* given in the emergency room is associated in a time dependent manner with TIMI-3 grade reperfusion in up to 32% of patients at 90 minutes, which is the usual door-to-balloon time in primary PTCA. Larger AMI trials with abciximab given early in-hospital or prehospital are warranted.

PROGNOSIS AND FOLLOWINGS AFTER INTERVENTION

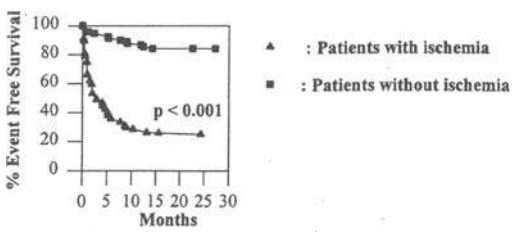
3337 Prognostic value of thallium-201 single-photon emission computed tomographic myocardial perfusion imaging after intracoronary stenting

Y. Cottin, K. Rezaizadeh, C. Touzery[1], O. Ressencourt[1], I. Barillot[1], S. Prevot[1], P. Louis, F. Brunotte, J.E. Wolf[1]. *From the of Department of Cardiology;* [1]*Department of Nuclear Medecine, Centre Hospitalier Universitaire, Dijon, France*

In patients with stable angina, normal thallium SPECT imaging indicates a low risk patient, and the extent of myocardial defect is an important prognostic predictive factor. However, its prognostic value has not been studied yet in a population of patients after coronary stenting. This study was designed to assess the value of thallium-201 SPECT imaging in patients after intracoronary stenting. and to examine the relation, if any, between the presence and extent of myocardial defect and future fatal or non fatal cardiovascular events (revascularization, myocardial infarction, unstable angina, death).

Methods. From September 1994 to September 1996, 201 patients received 204 intracoronary stents. Stress thallium imaging was performed 6 months after stenting on 155 asymptomatic patients and we followed-up patients during 16 ± 12 months.

Results. Fifty four patients suffered cardiac events during the follow-up: seventeen of the one hundred five patients after normal thallium SPECT imaging (16%), and thirty-seven of the fifty patients with ischemia scintigraphy (74%). The mean time to recurrence was respectively 21 ± 9 months for patients in group I and 8 ± 10 months in group II. The relative risk of cardiovascular events was 9.72 [4.6; 20.3]: $p < 0.001$.



Conclusions. In patients after coronary stenting, absence of ischemia on thallium SPECT imaging at six months indicates a low risk patient for cardiovascular events. These results have important implications in patient management and cost health delivery.

3338 Increased prognostic value of gated-SPECT studies with Tc-99m tetrofosmin, in patients with high, medial and low pre-scan likelihood of coronary artery disease

M. Pabón, D. Paez. *Nuclear Medicine Dept., Foundation Valle of Lili Medical Cente, Cali, Colombia*

Background: This research was undertaken to evaluate the correlation between the pretest probability (PSL) of myocardial disease with the single photon emission computed tomography (SPECT) gated studies with Technetium-99m (Tc-99m) labeled Tetrofosmin at our Institution.

Methods and Results: We selected 2,538 consecutive patients who underwent stress/rest gated-SPECT studies between October 1994, and May 1998, and were followed up for the presence of major cardiac events (M.C.E) (cardiac death, myocardial infarction or revascularization) over a mean follow up period of 25.3 months. The pretest probability of myocardial disease was also calculated for each patient using the Bayes Theorem. 648/2538 (25.6%) of the patients were classified as having low probability (≤20% for myocardial disease), 1346/2538 (53%) as a intermediate probability (21 to 80%), and 544/2538 (21.4) as high probability (more than 80%). The following table shows the correlation between the PSL, SPECT study result, and the development of M.C.E., during 25.3 months of follow up:

SPECT Study	Low Probability		Intermediate Probability		High Probability	
	M.C.E.(+)	M.C.E.(−)	M.C.E.(+)	M.C.E.(−)	M.C.E.(+)	M.C.E.(−)
Abnormal	44/217	173/217	339/652	313/652	130/348	218/348
(20%)	(80%)	(52%)	(48)	(37%)	(63%)	
Normal	24/431	407/431	45/694	649/694	5/196	191/196
(5.5%)	(94.5%)	(6.5%)	(93.5%)	(2.55%)	(97.45%)	

Among the 2,538 patients who underwent gated-SPECT, 648 had a low PSL for CAD, 1346 were classified as intermediate and 544 as high PSL. Of the 648 patients with low PSL 217 had an abnormal SPECT and 45/217 had a M.C.E., but only 24/431 with normal SPECT developed a M.C.E. On the other hand of the 544 patients with high PSL, 348 had an abnormal study, and in that particular group, 130/348 developed some M.C.E during de follow up. In the group with high PSL 196/544 patients had a normal SPECT, and only 5 developed some M.C.E at the end of the study. The interobserver agreement was 65% (kappa coefficient 0.3). The NPV in high probability patients was 97.9% and PPV 37.4%. In the low probability group the NPV was 94.7% and PPV 20.7%. In the intermediate probability group the PPV was 51.2% and the VPN 93.4%.

Conclusions: In patients evaluated for CAD, Gated-Spect studies with Tc-99m-tetrofosmin provide reliable prognostic value and can be used for risk stratification. The pretest probability alone is not a good prognostic indicator. The high incidence of mayor cardiac events in the low probability group was probably due to underestimated patient risk classification.

3339 Prognostic value of Tc-99m-sestamibi myocardial perfusion SPECT for the prediction of cardiac death or myocardial infarction

C.R. Kühn, S. Kasischke, C. Fünsterer, Th. Rau, D. Mathey, J. Schofer. *Center for Cardiology and Dr. Pressler/Fünsterer; Hamburg, Germany*

99m-Technetium-Sestamibi myocardial perfusion single photon emission computed tomography (MIBI-SPECT) has become a routine testing technique for coronary artery disease. It has a high sensitivity and specificity. However there is little information about its prognostic value.

Methods: 1000 patients underwent MIBI-SPECT (Orbiter or MultiSpect 3, Siemens) and coronary angiography (DCI, Philips) in our institution for suspected or proven coronary artery disease between 1991 and 1994. Follow-up was obtainable in 800 subjects (223 female, 577 male). Follow up time was 44 months (maximum 71 months, minimum 24 months). Information was obtained by records and telephone interviews.

Results: According to the different results of MIBI-SPECT [discrete (discr.), severe (sev.), fixed (fix) or stress dependent = mismatch (mism.) perfusion defects] the following percentages of events were noted:

SPECT	n	All deaths	Cardiac death	AMI	PTCA	CABG
Normal	66	3.0	0	1.5	13.6	0
Discr. fix.	195	4.1	1.5	1.5	5.6	11.6
Discr. mism.	172	4.1	2.3	2.9	11.6	4.1
Sev. fix + mism.	150	7.3	5.3	3.3	33.3	13.3
Sev. fix + mism.	106	9.4	8.5	10.4	35.8	20.8
Sev. mism.	111	11.7	9.0	7.2	45.9	33.3

The difference between discrete and severe defects was highly significant for cardiac deaths, the combined rate of cardiac deaths and infarctions, PTCA and CABG ($p < 0.0001$). The difference between normal scintigraphic results and discrete defects was not significant ($p = 0.548$).

Conclusions: Patients with severe fixed or stress dependent perfusion defects in MIBI-SPECT had a worse prognosis than patients with discrete abnormalites. Patients without defects had an excellent outcome.

3340 Gated Tc-99m SPECT is superior to biochemical and inflammatory markers for predicting adverse cardiac events in patients presenting with acute chest pain

J. Swinburn, P. Stubbs, U. Raval, R. Senior, P. Collinson, A. Lahiri. *Northwick Park Hospital, Harrow, UK*

Technetium-99m sestamibi gated SPECT (SPECT) is an established method for risk stratification in acute chest pain. However, it is not known whether the biochemical markers Troponin T (TnT) and Troponin I (TnI) and the inflammatory markers CRP, Interleukin-6 (IL6) and Tissue Necrosis Factor alpha (TNF) have independent or additive value as predictors of adverse cardiac events in patients admitted with non-ST-segment elevation acute coronary syndromes (ACS).

Method: 80 patients were studied within 6 hours of chest pain (mean 175 mins). 70% had an abnormal ECG, 20% had previous revascularisation, and 39% had previous MI. Venous samples were taken at admission and at 24 hours and batch assayed for CRP, IL6, TNF, TnT and TnI. Gated SPECT was performed, and perfusion (PER) and wall motion (WM) were scored as abnormal or normal. The other variables were scored as abnormal if they exceeded their upper reference range. The cohort was followed up for subsequent cardiac death, myocardial infarction and coronary revascularisation for a median of 227 days (154–298). Univariate analysis revealed that SPECT WM ($p = 0.01$), PER ($p = 0.03$) and previous MI ($p = 0.01$) were significant predictors of events. However combined WM and PER was the best predictor ($p = 0.0095$) in the univariate model, and the only significant predictor in the multivariant Cox model ($p = 0.01$, RR 3.8 (CI 1.3–11.1)). Thus, early gated SPECT is superior to the other markers measured for the early risk assessment of patients with acute chest pain.

3341 Specificity of exercise-dipyridamole Tc-99m-tetrofosmin myocardial tomography early after successful coronary stent implantation

J. Rodés, E. Domingo, J. Candell, I. Anívarro, J. Angel, J. Castell, A. Soto, F. Padilla, E. Larrousse, J. Soler-Soler. *Hospital General Universitari Vall d'Hebron, Barcelona, Spain*

A high number (30–40%) of "false positive" ischemic defects early after coronary balloon angioplasty have been reported. However, the presence of reversible defects early after optimal coronary angioplasty (PTCA) with stent implantation has not been investigated. The purpose of our study was to evaluate the specificity of maximal exercise-dipyridamole 99mTc-tetrofosmin myocardial single-photon emission computed tomography (SPECT) early after coronary stent implantation. Inclusion criteria were: presence of myocardial ischemia before PTCA, one vessel coronary disease, absence of previous MI and successful PTCA (<30% of residual stenosis) obtained with stent implantation. After discontinuation of antianginal drugs, a maximal exercise 99Tc-tetrofosmin myocardial SPECT combined with intravenous administration of dipyridamole (0.56 mg/kg) if the level of exercise was insufficient, was performed within the week after PTCA. To date, 25 pts have been included (7 women, mean age of 57 years), and distribution of coronary disease was: LAD = 16 cases, LCX = 5 cases and RCA = 4 cases. Reference diameter of the vessels dilated was 3.11 ± 0.54 mm, with minimal lumen diameter and percent stenosis of 0.9 ± 0.36 mm and 68.2 ± 12.6% before PTCA, and 2.85 ± 0.46 mm and 9.6 ± 9.5% after PTCA. Exercise test was performed at 6.1 ± 0.8. days after PTCA and 3 pts received dipyridamole. Reversible myocardial defects were observed in 3 cases (12%): 1 LAD, 1 LCX and 1 RCA (specificity = 88%) and there were no differences in the extent of reversibility (rest uptake-exercise uptake > 10%) in polar map between patients with stent in LAD (5.46 ± 5.68%), LCX (5.36 ± 5.76%) and RCA (4.37 ± 7.78%) and a control group of 74 individuals (49 women, mean age of 55 years) with normal coronary angiography (9.4 ± 12.9%, 7 ± 9% and 11 ± 13%).

Thus, our study demonstrates a high specificity of maximal exercise-dipyridamole 99mTc-tetrofosmin myocardial SPECT early after successful coronary stent implantation.

3342 Determinants of positive follow-up Tl-201 perfusion imaging in asymptomatic patients without restenosis

F. Beygui, C. Le Feuvre, J.P. Metzger, C. Maunoury, G. Helft, A. Vacheron. *Cardiology Department, Necker Hospital, Paris, France*

Discordance between positive Tl-201 stress tomography (SPECT) and absence of angiographic restenosis in asymptomatic patients, is a frequent clinical situation after PTCA. The aim of our study was to identify the determinants of positive SPECT in such situations.

Methods: We studied the results of exercise-redistribution SPECT performed in 123 patients, remaining asymptomatic, 6 ± 2 months after successful PTCA of 132 vessels. Coronary angiography performed, 1 to 7 days after SPECT revealed absence of restenosis in all patients (% diameter stenosis < 50%).

Results: factors significantly associated with positive (n = 31 vessels) compared to negative SPECT (n = 101 vessels) are reported in the table.

	SPECT+ (n = 31 vessels)	SPECT− (n = 101 vessels)
Pre PTCA ejection fraction	64 ± 14%*	70 ± 13%
Incomplete revascularization	51.6%†	20.8%
Infarct-related vessel PTCA	41.9%*	21.8%
FU % diameter stenosis	35 ± 11%*	29 ± 12%

*$p < 0.05$, †$p < 0.001$, positive compared to negative SPECT

On multivariate analysis only incomplete revascularization ($p = 0.007$) and infarct-related vessel PTCA ($p = 0.03$) were associated with positive SPECT.

Conclusions: Myocardial ischaemia due to incomplete revascularization and persisting myocardial sideration or hibernation after infarct-related vessel angioplasty could cause reversible perfusion defects interfering with the detection of restenosis by Tl-201 perfusion imaging in asymptomatic patients.

NEW MODALITIES IN STRESS ECHOCARDIOGRAPHY

3343 The quantitative and semi-quantitative evaluation of low-dose dipyridamole-dobutamine stress echocardiography

F. Szabóki, P. Andrássy[1], K. Heltai, I. Palásti, A. Sárközy[1], I. Märcz, K. Zámolyi[1]. *Hungarian Railways Hospital, Budapest; [1]Bajcsy-Zsilinszky Hospital, Budapest, Hungary*

The **aim** of our study was to compare the long axis M-mode (LAM-m) parameter changes with the accepted semi-quantitative wall motion scoring system for the evaluation of myocardial viability with low-dose Dypiridamole (DPD)-Dobutamine (DBA) stress echocardiography (DDSE).

Methods: The DDSE was performed in 105 patients (88 male, mean age 54.8 ± 9.2 years) on the 30th (±2.2) day of myocardial infarction (MI). Infusion of 0.28 ug/kg DPD over a 4 minute period, than 5 ug/kg/min DBA for 3 minutes and 10 ug/kg/min DBA for another 3 minutes were administered. The mitral annulus was sectioned at four different places by the M-mode cursor (four chamber view: infero-septal, antero-lateral; two chamber view: anterior, inferior). Each section represented three segments (apical, mid, basal). There were regional wall motion abnormality in 224 sections of the obtained 420. The section viability was defined as an improvement of at least I grade according to the 4 grade scoring system during the DDSE. The following LAM-m parameters were measured at rest: the total excursion of the mitral annulus *(d1)*, the mean velocity of the mitral annulus systolic movement *(v1)*; and also on the 10th minute of DDSE: *(d2, v2)*. The *d2/d1* and *v2/v1* quotients were calculated.

Results: There were 149 viable *(A group)* and 75 non-viable sections *(B group)* according to the semi-quantitative scoring system. We found significant differences between the two groups in the values of *d2, v2, d2/d* and *v2/v1*.

	d1 (cm)	d2 (cm)	v1 (cm/s)	v2 (cm/s)	d2/d1	v2/v1
A group	1.02 ± 0.29	1.37 ± 0.35	3.37 ± 1.12	4.82 ± 1.41	1.38 ± 0.27	1.50 ± 0.41
B group	1.12 ± 0.31	1.15 ± 0.34	3.72 ± 1.3	4.1 ± 1.6	1.04 ± 0.2	1.12 ± 0.24
p <	NS	0.0001	NS	0.001	0.00001	0.00001

The best parameter to distinguish viable from non-viable was d2/d1 (chisquare = 73.6, Wilks lambda = 0.72, sensitivity: 78.4%, specificity: 81.1%, positive predictive value: 89.2%, negative predictive value: 65%, accuracy: 79.3%).

Conclusion: Examination of LAM-m parameter changes during DDSE is a simple method. The evaluation of post-infarction viability can be quantified by this method with a high positive predictive value.

3344 Time course of myocardial systolic velocity changes during a dobutamine challenge in normal and infarcted myocardium: a Doppler myocardial imaging study

F. Jamal, K. Zámolyi[1], M. Perinetti, L. Sebbag[1], S. Guérard, J. Beaune, X. André-Fouet[1], M. Ovize[1]. *Service d'échocardiographie, Hôpital Louis Pradel, Lyon[1] Service de Cardiologie, Hôpital Louis Pradel, Lyon, France*

Quantitative assessment of myocardial wall motion during stress echocardiography (SE) is still an unsolved issue. In experimental studies, systolic myocardial velocity measured with pulsed Doppler Myocardial Imaging (DMI) correlates closely to systolic function assessed with sonomicrometry. Therefore, DMI may improve the diagnostic accuracy of SE. In order to test this hypothesis, a standard 4 stages SE examination was performed in 16 patients: after a recent posterior myocardial infarction (MI) in 10 patients (58 ± 12 years) and for atypical chest pain (CP) diagnosis in 6 others (54 ± 10 years) considered as the control group (C). Myocardial systolic velocities (S) in basal (B) and mid (M) segments of the posterior wall (PW) were measured from an apical 2 chambers view using pulsed mode DMI at baseline, low dose, maximal dose of dobutamine, and recovery. Myocardial velocity gradient (MVG) was calculated as the difference between peak S velocities in basal and mid segments.

Results: All patients reached 85% of the maximal heart rate with no severe side effects. Controls had a normal ECG and no wall motion abnormalities during dobutamine perfusion. All patients of the MI group were found to have an abnormal wall motion of the PW in both basal and mid segments (severe hypokinesia to akinesia). At baseline, S velocity in B segment and MVG were significantly lower in the MI group. At low dose, S velocity in B segment and MVG increased significantly in controls by 41% and 60% respectively but not in the MI group. At maximal dose, S velocity in B segment increased in both groups (83% and 65% in C and MI group respectively), but MVG increased only in control group (table).

	Heart rate (b/min)		S basal (cm/sec)		S mid (cm/sec)		MVG (cm/sec)	
	C	MI	C	MI	C	MI	C	MI
Baseline	62	75*	8	5.8*	6	4.8	2	1*
	±11	±12	±1.4	±1.5	±1.2	±0.9	±0.9	1 ±1.2
Low dose	69	80	11.3#	7*	8.2	6.1	3.2#	0.9*
	±21	±23	±2.7	±1.9	±1.8	±1.4	±1.6	±1.7
Max dose	150#	149#	14.7#	9.6*#	7	7.1#	7.7#	2.3*
	±28	±16	±4.1	±3.6	±1.9	±2.1	±3.2	±2.6
Recovery	96#	96#	8.8	6.1	6.2	5.6	2.7	0.5*
	±12	±18	±1.5	±1.8	±1.2	±1.7	±1.7	±1.4

*$p < 0.05$ MI vs. C, #$p < 0.05$ vs. baseline

In conclusion, pulsed DMI may identify infarcted and normally contractile myocardium and offers a clinically useful approach of wall motion and myocardial systolic function quantification in stress echocardiography.

3345 Which off-line tissue Doppler parameters can be used to diagnose myocardial ischaemia during stress?

N. Payne, R. Grocott-Mason, B. Kursten[1], M. Wutte[2], A. Ionescu, B. Lind[3], B. Janerot-Sjoberg[4], A.G. Fraser. *Cardiology Dept, University of Wales College of Medicin, Cardiff, UK; [1]Cardiology Dept, University Hospital Benjamin Franklin, Berlin, Germany; [2]Cardiology Dept, Vienna University Medical School, Vienna, Austria; [3]Cardiology Dept, Huddinge University Hospital, Huddinge; [4]Faculty of Health Sciences, Linkopings Universitet, Linköping, Sweden*

Tissue Doppler echocardiography (TDE) is a very sensitive technique for quantifying changes in regional left ventricular (LV) function. Experimental studies during ischaemia have shown rapid and major alterations of both systolic and diastolic parameters, but the application of TDE to stress testing in patients has been limited by the time needed to sample data from every region 'on-line'. This difficulty has been overcome by the development of the Vingmed System Five which allows acquisition of digital TDE data from every region of the LV during a stress echocardiogram, at the same time that the grey-scale images are acquired. The digital data can then be analysed off-line after the stress test.

As part of the MYDISE study (Myocardial Doppler in Stress Echocardiography), we assessed the feasibility and reproducibility of measuring such data obtained during standard dobutamine stress echocardiography (DSE). Peak systolic velocity V (excluding isometric contraction), time-to-peak systolic velocity TTP, systolic velocity-time integral VTI, peak E and A diastolic velocities and E/A ratio, were measured in each of 16 segments (ASE model). 7 observers in 5 centres analysed the same 8 DSE studies in order to assess reproducibility.

At baseline, the mean coefficients of variability (CV) in 5 basal segments (4 from apical views, plus basal posterior from parasternal long-axis) for the 3 systolic parameters were 11, 13 and 13% for V, TTP, and VTI. For the diastolic parameters E, A, and E/A the mean coefficients were 17, 12 and 27%. As an example, detailed results for all indices from the basal inferior segment (apical 2-chamber view) are shown in the table.

TDE data

	V cm/s	TTP ms	VTI mm	E cm/s	A cm/s	E/A
Mean	7.2	125.6	1186.2	−6.7	−8.5	1.1
Pooled SD	0.6	16.0	84.1	0.9	0.9	0.3
CV (%)	8	13	7	13	11	27

TDE data for basal inferior segment (from A2C)

We conclude that in basal LV segments, systolic function can be accurately quantified off-line with good reproducibility, using V, TTP, and TVI. Diastolic parameters are less reliable, perhaps reflecting sub-optimal frame rates. Until signal averaging is available, myocardial ischaemia during stress echocardiography should be characterised from off-line quantification of changes in systolic indices.

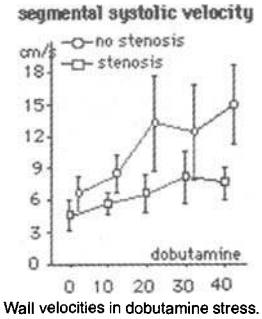
3346 Automatic border detection in dobutamine stress echo: how do normal and ischaemic segments behave objectively and quantitatively?

P.R. Hunziker, L. Schöb, M. Lefkovits, U. Füllhaas, S.I. Yoon, H. Bosch, T. Cron, M. Pfisterer, P. Buser. *Cardiology Dept, Univ. Hospital Basel, Basel, Switzerland*

Analysis of dobutamin stress echo (DSE) is associated with significant interobserver variability. Objective, quantitative analysis of DSE may overcome these problems. Because few quantitative data are available about the pathophysiology of segmental wall motion DSE, we used automatic border detection to determine in nonischemic and ischemic segments the behaviour of segmental wall velocities at rest, during incremental dobutamine doses, and at peak dobutamine stress.

Methods: Using a previously validated ABD algorithm (Echo-CMS, MEDIS, Holland), segmental wall velocities were determined during DSE (0–40 μg/kg/min dobutamine) in 300 segment stages. Segments perfused by stenosed (>70% narrowing) coronary arteries and control segments in patients with and without coronary artery disease were compared.

Results: (Fig) In nonischemic segments, velocities increased early to reach a plateau of 14 ± 6 cm/s at 20–40 μg/kg/min dobutamine. In ischemic segments, velocity increases were also observed, but velocities at peak dobutamine were significantly lower (5.9 ± 3.7 cm/s) compared to normal segments ($p < 0.0001$). A biphasic response was often observed in ischemic segments at the last stage. The best cutoff value for discrimination of ischemic and nonischemic segments was 10.5 cm/s at peak dobutamine.



Wall velocities in dobutamine stress.

Conclusion: Quantitation of segmental wall velocities by automatic border detection in DSE is feasible and allows diagnosis of myocardial ischemia by objective, quantitative parameters. Normal values as well as a best cutoff for detection of ischemia are described. The frequently used ischemia criterion of worsening wall motion versus baseline appears not justified in quantitative DSE using segmental wall velocities, as a small velocity increase often occurred despite ischemia.

3347 Is strain rate better than myocardial Doppler velocity to quantify wall motion during exercise echocardiography?

Agnes Pasquet, Guy Armstrong, Curtis Rimmerman, James Thomas, Thomas Marwick[1]. *Cleveland Clinic, Cleveland OH, USA; [1]Univ of Queensland, Brisbane QLD, Australia*

The strain rate or rate of deformation of a myocardial segment through the cardiac cycle can be derived from myocardial velocities obtained by tissue Doppler imaging; normal segments (sgts) are compressed during systole, so the strain rate is negative. We sought to determine if peak systolic strain rate (SR) can differentiate changes in contractile state during exercise echo (ExE) more accurately than myocardial Doppler velocity (MDV).

Methods. 107 pts (27F, age 60 ± 12, EF 64 ± 14) underwent ExE to evaluate known or suspected CAD; 2D echo and color myocardial Doppler were acquired at rest and post Ex. SR and peak systolic MDV were measured off line in basal and mid segments of the 3 apical views (Echopac 6.0). Sgts were classified as normal (n = 919), ischemic (n = 39) or scar (n = 114) according to results of 2D echo. ExE sgt score obtained at rest and stress was compared to MDV and SR using ANOVA. ROC curves were constructed for SR and MDV.

Results: MDV and SR were obtained in 1087/1284 sgts (85%). Scar sgts had lower SR and MDV than Normal at rest and stress ($^*p < 0.001$). Ischemic segments had lower SR and MDV at Ex and less ΔSR and ΔMDV (diff stress – rest) ($^*p < 0.001$). Area under ROC curve for SR (0.85) exceeded that for MDV (0.71). At optimal thresholds of MDV (6 cm/s) and SR (–1.42/sec), sensitivity of SR exceeded MDV (78% vs 68%), as did specificity (79% vs 66%).

	Normal	Ischemic	Scar
Rest MDV (cm/s)	4.5 ± 1.5	4.4 ± 1.3	3.8 ± 1.2*
Peak ex MDV (cm/sec)	8.4 ± 3.3	5.5 ± 2.9*	5.3 ± 3.2*
ΔMDV (cm/sec)	3.9 ± 2.7	1.1 ± 2.2*	1.7 ± 2.5
Rest SR (1/sec)	–1.1 ± 0.3	–1.0 ± 0.4	–0.6 ± 0.4*
Peak ex SR (1/sec)	–1.9 ± 0.9	–1.0 ± 0.8*	–0.8 ± 0.9*
ΔSR (1/sec)	–8 ± 0.8	–0 ± 0.7*	–0.2 ± 0.7

Conclusions: SR and MDV can differentiate scar and ischemic sgts during ExE but SR appears more accurate.

3348 Can ultrasound strain and strain rate imaging provide additional information on myocardial contractile reserve in patients with ischaemic cardiomyopathy?

T. Kukulski, L. Hubbert[1], U. Dahlstrom[1], B. Wranne, G.R. Sutherland[1]. *Department of Clinical Physiology, University Hospital, Linköping [1]Department of Cardiology, Linköping Heart Centre, Linköping, Sweden*

Background: Strain Rate (SR) and Strain (S) imaging, based on Colour Myocardial Doppler (CDMI) data, potentially allow regional myocardial deformation to be characterised in real time. Since myocardium is, in theory, incompressible the longitudinal strain of a segment will correspond inversely to any change in wall thickness. Thus alterations in inotropic state should modify segmental longitudinal S and SR values.

Aim of the study: A study was designed to characterise the regional response of chronically ischemic myocardium to low dose inotropic stimulation by comparing 2D imaging data with S and SR indices.

Methods: A 5.10 μg/kg/min Dobutamine (D) infusion protocol was performed in 20 pts (6F,aged 39–70 y) with dilated ischemic cardiomyopathy (LVEDD-5.99 ± 0.99 cm, LVESD 4.82 ± 0.88 cm, LVFS-18.2 ± 6.15%). Grey scale, DMI and SRI data sets (50–60 fps) were acquired at rest and during inotropic stimulation. Dysfunctional, but potentially viable, mid septal, mid lateral and mid RV wall segments were chosen for regional motion, velocity and strain analysis. Peak systolic velocity, velocity integrals, peak systolic Strain rate(SR) and systolic Strain(S) were calculated for both rest and 10 ug D echo studies. Based on visual assessment of inotropic response (one phasic response) the dysfunctional segments were divided into segments with (Gr.I, n = 28) and without inotropic improvement. (Gr. II, n = 16).

Results: see table.

Table

Segments	Improved rest	Improved dobutamine	Non-improved rest	Non-improved dobutamine
Peak Strain rate [Hz]	–2.05 ± 0.93**	–2.87 ± 1.01	–1.44 ± 0.86#	–2.28 ± 0.69
Systolic Strain	0.33 ± 0.15#	0.43 ± 0.18	0.21 ± 0.14	0.31 ± 0.09
Peak Velocity [cm/s]	4.11 ± 2.19*	5.39 ± 2.74	3.14 ± 1.33	5.01 ± 3.31
Velocity Integr	0.37 ± 0.39	0.45 ± 0.41	0.46 ± 0.21	0.63 ± 0.39

**p = 0.0007, * p = 0.03, # p = 0.02 rest vs dobutamine

Rest SR was lower in Gr.II segments compared to Gr.I (2.05 ± 0.93 vs 1.44 ± 0.86, p < 0.05)

Conclusions: At rest, systolic S and SR better characterised ischemic segments in both groups when compared to velocity data. Dobutamine infusion caused an increase in segmental velocities, S and SR in both Groups. The increase both in S and SR values was highly significant in Gr. I segments but was greater for SR. Thus SR imaging may offer a new approach to the quantitation of low dose Dobutamine studies for viability.

MYOCARDITIS: IMMUNOLOGY AND OTHER ASPECTS

P3367 No nested PCR evidence of enteroviral infection in hearts explanted from patients with dilated cardiomyopathy

M.G. Crespo-Leiro, M. Hermida-Prieto, F. Peña, F. Portela, R. Rey-García, N. Vazquez-González, J. Muñiz, L.F. Hermida, A. Juffé-Stein, A. Castro-Beiras. *Area del Corazón, Hospital Juan Canalejo, La Coruña, Spain*

Although it has long been thought possible that enteroviruses can be involved in the pathogenesis of dilated cardiomyopathy (DCM), few cases of entervirus-infected hearts with DCM have been convincingly documented. In this study we used nested PCR to detect the presence of enteroviral RNA in the miocardia of hearts explanted from heart transplant (HT) donors and receivers so as to compare the prevalence of infection in DCM patiens

Methods: Myocardial muscle samples were collected from the atria of 70 donor hearts and from 68 hearts explanted from patiens with DCM (22 cases), coronary artery disease (42), amyloidosis (1), myocarditis (1) or valve disease (2). All samples were snap frozen for molecular analysis. RNA was extracted by Chomzynski and Sacchi method. To check the quality of the extratcted RNA, each sample was subjected to RT-PCR with primers specific for *abl* protooncogen; which is expresed from all human RNA samples. A high sensitivity nested RT-PCR with specificity for all enterovius was used to amplify the 5'noncoding region. Sequencing: PCR products were isolated from agarose gel bands, purified and sequenced in a automatic sequencing apparatus (*Pharmacia Biotech*).

Results: *abl* protooncogen was correctly amplified from all the RNA samples. All the controls were correctly amplified. All heart tissue samples from cardiac biospses were negative for enterovirus. Incidentaly, one enterovirus-specific PCR produc was obtained; but upon sequencing it was found to be identical to the positive control and corresponding to poliovirus type 3.

Conclusions: In our sample of hearts explanted from HT patients, nested RT-PCR showed no evidence of the presence of enteroviral RNA. This suggests that if enterovirus had a role in the genesis of DCM, this role does not require or lead to the persistence of the virus in myocardial tissue.

P3368 Elevated levels of tumor necrosis factor-a in the peripheral blood and coronary sinus of patients with myocarditis and their correlation with an increased gene expression in the myocardium

P. Schwimmbeck, C. Hohmann, D. Hohmann, N. Schwimmbeck, U. Rode, U. Kuehl, M. Pauschinger, H.-P. Schultheiss. *Department of Internal Medicine, Benjamin Franklin Hospital, Berlin, Germany*

Pro-inflammatory cytokines seem to play an important role both for the induction and persistence of human myocarditis (MC). The local concentration of cytokines in the myocardium is of major importance, however, their levels cannot be determined directly due to the small size of the human endomyocardial biopsies.

Methods: We analysed the gene expression of tumor necrosis factor-a (TNF-a), which is an indicator of an activated immune system and can induce apoptosis, in endomyocardial biopsies of patients with MC and compared these results with the protein levels of TNF-a in the peripheral blood and the coronary sinus. Gene expression was measured in the biopsies of 19 patients with immunhistologically proven MC and 12 patients with suspected MC, however, having normal biopsies using quantitative PCR with a plasmid as internal standard. For the serological studies we analysed the sera of 58 patients with MC and 36 patients without MC with a quantitative photometric assay for the levels of TNF-a in the peripheral blood and the coronary sinus.

Results: Patients with immunhistologically proven MC had significantly elevated levels of TNF-a in the peripheral blood (102 ± 29.5 pmol/l) and the coronary sinus (87.6 ± 25.4 pmol/l) compared to patients without MC (7.7 ± 1.5 pmol/l, p < 0.05). The gene expression of TNF-a was significantly elevated in the myocardium of patients with MC (1.18 ± 0.56 attomol/μg RNA) compared to the normal controls (0.5 ± 0.1 attomol/μg RNA, p < 0.01).

Conclusion: Patients with immunhistologically proven MC have significantly elevated protein levels of TNF-a in the peripheral blood and coronary sinus. The elevlated gene expression of the TNF-a in the myocardium suggests a pathogenetic significance of pro-inflammatory cytokines in human MC and may offer a specific approach for an immunmodulatory therapy.

P3369 T-cell-dependent immune response protects human heart tissue from a virus-mediated alteration in the ADP/ATP carrier isoform transcription

A. Dörner, M. Pauschinger, U. Kühl, P. Schwimmbeck, H.-P. Schultheiss. *Department of Cardiology, Benjamin Franklin Hospital, Free University Berlin, Germany*

We recently reported that the myocardial adenine nucleotide translocator isoform transcription pattern (ANTitp) is altered in patients with myocarditis. Myocarditis is known to be induced by enteroviral infection. The aim of the present study was to evaluate the relevance of the enteroviral infection and the intramyocardial T-cell immune response for the alteration in the ANTitp.

Methods: The ANTitp was analyzed in endomyocardial biopsies from 52 patients with clinically suspected myocarditis (csMC). Explanted heart tissue from 22 patients with ischemic cardiomyopathy, already shown to have a normal ANTitp, served as controls. Enteroviral RNA was detected in the biopsies using the PCR technique. T-lymphocyte subtypes ($CD3^+$, $CD45R0^+$, $CD4^+$ and $CD8^+$) were quantified using immunohistochemistry.

Results: The ANTitp was altered in 21 patients with csMC. Enteroviral genome was found in the heart specimens of 15 of these 21 patients (71.%). Only 6 of 25 virus-negative patients (24%) were affected by the shift in the ANTitp ($p < 0.021$). The infiltration with $CD3^+$, $CD45R0^+$ and $CD8^+$ was substantially lower in myocardial specimens showing an altered ANTitp than in biopsies with a normal ANTitp ($CD3^+$: 6.1 ± 1.0 vs. 11.9 ± 2.4 cells/mm^2, $p < 0.011$; $CD45R0^+$: 2.3 ± 3.2 vs. 7.9 ± 3.2 cells/mm^2, $p < 0.024$ and $CD8^+$: 3.3 ± 0.6 vs. 8.5 ± 2.6 cells/mm^2, $p < 0.026$); the infiltration with $CD4^+$ cells was only tendentially lower (2.5 ± 0.4 vs. 5.7 ± 2.6 cells/mm^2, $p < 0.45$). Combining the data, it was found that virus-positive biopsies with an altered ANTitp were significantly less infiltrated with lymphocytes (5.9 ± 1.3 $CD3^+$/mm^2) than virus-positive biopsies with a normal isoform transcription (13.7 ± 5.25 $CD3^+$/mm^2, $p < 0.05$).

Conclusion: Changes in the ANTitp is linked to the presence of enteroviral genome in the myocardium. The shift is however not caused by the virus-induced T-cell response but appears moreover to be prevented by an active T-cell dependent immune process.

P3370 Selective induction of CXC- and CC-chemokines in experimental autoimmune myocarditis

U. Eriksson, M. Kurrer, J.-Y. Yang, F. Follath, U. Widmer. *Department of Medicine, University Hospital Zurich (USZ), Zurich, Switzerland*

Chemokines are cytokines with chemoattractant properties for leukocytes. They may play a critical role in directing leukocytes to the myocardium in myocarditis and provide a target for therapeutic intervention. Experimental autoimmune myocarditis (EAM) was induced in 12 week old BALB/c mice by immunization with a synthetic peptide corresponding to amino residues 614–643 of heart myosin heavy chain alpha, control animals received CFA only (N = 5 each). On days 14 and 21 after immunization left-ventricular expression of several cytokine and chemokine genes was measured by quantitative reverse transcription-PCR assay using the TaqMan fluorogenic detection system. Values were corrected for RNA content using GAPDH expression and are expressed as ratio between mRNA levels in immunized versus control mice. Cellular infiltrates were scored on histology slides and cardiac necrosis was assessed by ELISA of troponin-T in serum. Spearman rank order correlations between Infiltrate scores and troponin-T values were highly significant ($p < 0.005$). In EAM mice transcript levels for the CC-chemokines MIP-1a and MCP-1 were modestly elevated on day 14 (5.7x and 2.3x, respectively) and markedly elevated on day 21 (159x and 52x, respectively). The CXC-chemokines IP-10 and MIG were induced in EAM mice on day 14 (11x and 15x, respectively) but they were not significantly elevated on day 21. TNFa and IL-10 were slightly induced on day 14 (2.3x and 2.4x, respectively) and they were strongly induced on day 21 (45x and 372x). The temporal expression pattern of chemokines in EAM with the appearance of CXC chemokines (which attract predominantly neutrophils) followed by CC-chemokines (with a preference for mononuclear leucoytes) might determine the histological picture. Experiments in chemokine-knock-out mice should further characterize the role of chemokines in EAM.

P3371 Quantitative assessment of the myocardial Na^+/Ca^{+2} exchanger transcription in inflamed heart tissue

A. Dörner, J. Bilger, C. Piper, E. Henrichs, U. Kühl, D. Horstkotte, H.-P. Schultheiss. *Department of Cardiology, Benjamin Franklin Hospital, Free University of Berlin, Germany*

An upregulation of the sarcolemmal Na^+/Ca^{+2} exchanger (EXCH) expression is one of the characteristics of disturbed myocardial calcium homeostasis in end stage heart failure due to ischemic (ICM) or dilated cardiomyopathy (DCM). The aim of this study was to evaluate whether changes in the EXCH transcription occurs also in inflammatory heart disease (infHD), leading under special conditions to DCM.

Methods: We established a quantitative PCR method using an internal RNA standard for the determination of the EXCH mRNA copy number in small biopsy samples. Right ventricular biopsies of 13 patients with infHD and 16 patients with end stage heart failure due to ICM or DCM were analyzed. Myocardium from 4 individuals without heart disease served as controls.

Results: The EXCH mRNA level of the controls amounted to 2.2 ± 1.3 atmol per ng total RNA. The amount of EXCH mRNA from patients with infHD was similar to the level of the controls making up 2.3 ± 1.6 atmol/ng total RNA. However, patients with end stage heart failure showed a significant increase in the EXCH mRNA level to 9.5 ± 2.0 atmol/ng total RNA ($p < 0.003$). No correlation between the EXCH transcription and the grade of inflammation was found.

Conclusion: An alteration in the myocardial EXCH transcription is not related to an inflammatory process in the heart tissue. The switch in the EXCH transcription appears to be a phenomenon of end stage heart failure.

P3372 Prognostic significance of left-ventricular aneurysms with normal global function caused by myocarditis

A. Frustaci, C. Chimenti, M. Pieroni. *Institute of Cardiology, Catholic University, Rome, Italy*

Left ventricular aneurysm may result from idiopathic or viral myocarditis. The prognostic significance of this entity, when associated with a normal global cardiac function, is unknown, as a long-term follow-up on a consistent number of patients is actually not available.

Methods: Among 352 patients (pts) with a histologic diagnosis of myocarditis, from January 1989 to November 1998, 11 pts (3.1%) had single or multiple localized left ventricular (LV) aneurysms (size 10.6 ± 3.1 in length and 7.4 ± 4.2 in width) with normal global LV function. Presenting symptoms were: ventricular tachyarrhythmias in 8 pts (sustained ventricular tachycardia (VT) in 4, non sustained VT in 4) and unexplained chest pain in 3 pts. All pts underwent laboratory tests (including serologic tests for cardiotropic viruses and immunologic studies), non invasive (ECG, Holter monitoring, exercise stress testing, 2D-echocardiography) and invasive cardiac exams (cardiac catheterization, biplane left and right ventriculography, coronary angiography, biventricular endomyocardial biopsy, electrophysiologic study in patients with sustained VT). Serology suggested a viral infection in 3 pts, an immunologic disorder in 2 pts while it was negative in 6 of them. In all patients LV endomyocardial biopsy showed a lymphocytic myocarditis (in 1 pt with vasculitis and in 5 with fibrosis) with focal myocytolysis more evident in the fragments from the area closest to the aneurysm, while was non diagnostic in RV specimens in 8 of 11 pts. Treatment included antiarrhythmics (propafenone, sotalol, amiodarone and/or metoprolol) in 8 pts with VT, beta-blockers in 1 pt with chest pain, immunosuppression (prednisone and azathioprine for 5 months) in 4 pts (2 with chest pain and 2 with VT) with active myocarditis.

Results: Long-term follow-up (mean 56.3, range 12–120 months) including clinical examination, Holter monitoring, 2D-echocardiography, cardiac NMR, LV angiography and LV endomyocardial biopsy, showed normal LV volumes and function in all pts, LV aneurysm occlusion in 2 pts with histologic evolution to a healed myocarditis. All pts were asymptomatic, no VT recurrence or major clinical events were registered and none required implantable electrical devices or a surgical intervention.

Conclusions: LV aneurysms with normal global function caused by myocarditis are an uncommon benign entity where major therapeutic regimens are usually unnecessary.

P3373 Active versus borderline myocarditis: can a differential diagnosis predict the clinical outcome?

A. Angelini, F. Calabrese, M. Crosato[1], G.M. Boffa[1], V. Calzolari[1], M. Valente, F. Maddalena[1], R. Chioin[1], G. Thiene. *Department of Pathology, Univ. of Padua, Padua; [1]Department of Cardiology, University of Padua, Padua, Italy*

Myocarditis is an inflammatory disease of the myocardium characterized by polymorphic clinical presentation, evolution to dilated cardiomyopathy and high mortality. The histological diagnosis based on the Dallas criteria allows a classification between active (AM) and borderline myocarditis (BM). We reviewed,among the 419 endomyocardial biopsy (EMB) performed at our institution from 1991, 48 (11%) EMB that were diagnostic for myocarditis according to histologic criteria. On bioptic samples immunohistochemistry and polymerase chain reaction (PCR) for a panel of viruses were performed. Clinico-pathological correlations were also carried out. The mean age of the patients was 34 ± 19 years (range 1–77); the histologic diagnosis was AM in 33 cases (69%), lymphocytic in 27 (82%); BM in 15 cases (31%).Clinico-pathologic correlations between AM and BM revealed no differences in terms of number of fragments analyzed, amount of fibrosis, NYHA class at the time of symptoms onset and at follow-up, LVEF and mortality. We found a statistically significant difference time intercurring between onset of symptoms and EMB execution (AM: 113 ± 232 days vs BM: 802 ± 175 days $p = 0.03$); LVEDV (AM: 85 ± 39 vs BM: 131 ± 57 $p = 0.002$) and degree of inflammatory infiltrates (score 0–4) (AM: 2 ± 1.1 vs BM: 1 ± 0 $p = 0.001$)were also different. PCR analysis detected a positivity for viruses in 40% of AM cases and 25% form BM cases. Enteroviruses were detected in 43% of PCR positive cases. BM seems to encompass ongoing forms with a less aggressive inflammatory infiltrate composed mainly by macrophages. The absence of myocytes necrosis does not predict a more favourable prognosis in terms of death/CHF. Our data suggest that a new classification of myocarditis is required. Besides histologic, immunohistochemical and molecular findings, clinical criteria should also be used for diagnosis.

P3374 Chronic chagasic cardiomyopathy, but not dilated cardiomyopathy, presents overexpression of adhesion molecules and induction of class I HLA on the cardiomyocytes

L.A. Benvenuti, M.L. Higuchi, M.M. Reis. *Heart Institute (InCor), University of São Paulo, Brazil Medical School*

Heart failure and cardiac enlargement occur in both chronic chagasic cardiomyopathy (CCM) and dilated cardiomyopathy (DCM). Although significant chronic lymphocytic myocarditis is usually present in CCM, but not in DCM, autoimmunity is considered to be involved in both cardiomyopathies. Since the expression of adhesion molecules modulates the inflammatory reaction, and class I HLA is usually enhanced in autoimmune reactions, we performed immunohistochemistry for differential analysis of ICAM-1, VCAM-1, LFA-1, and class I HLA in myocardial biopsies from patients with CCM and DCM.

Methods: Frozen sections of 12 ventricular biopsies from patients with CCM, 9 ventricular biopsies from patients with DCM, and 8 right atrial appendage biopsies from patients submitted to graft coronary surgery (control group) were incubated with the following monoclonal antibodies: anti-CD8+ T cells, anti-ICAM-1, anti-VCAM-1, anti-LFA-1, and anti-class I HLA. The mean number of CD8+ T cells per high power field was used to evaluate the intensity of the inflammatory infiltrate in each case. The evaluation of adhesion molecules and class I HLA immunoreactivity was conducted in a semi-quantitative fashion. The scores (0 to 3) were attributed independently for the endothelial/interstitial (E/I) cells and the cardiomyocytes.

Results: Significant lymphocytic inflammatory infiltrate was present in CCM group, but not in DCM and control groups. ICAM-1 and class I HLA were detected on E/I cells in all cases. VCAM-1 was distinct only at the inflammatory sites of CCM group, located on the endothelial cells. CCM group presented higher scores for both ICAM-1 on E/I cells and VCAM-1 than DCM and control groups. ICAM-1 was detected on the cardiomyocytes in 2/12 cases of CCM group, but not in DCM and control groups. Class I HLA was detected on the cardiomyocytes in all cases of CCM group, in 2/9 cases of DCM group, but not in the control group. CCM group presented higher score for class I HLA on the cardiomyocytes than DCM and control groups. LFA-1 was present only on lymphocytes.

In conclusion, CCM presents overexpression of both ICAM-1 on E/I cells and VCAM-1. Additionally, CCM presents induction of class I HLA on the cardiomyocytes. These findings are probably related to the high levels of cytokines at the inflammatory sites of CCM. The induction of class I HLA on the cardiomyocytes should not be considered an irrefutable evidence for autoimmunity in CCM. There is no significant myocardial inflammation in DCM, that presents expression of ICAM-1, VCAM-1 and class I HLA similar to the normal myocardium, differently from CCM.

P3375 E-selelctin-dependent adhesion of leukocytes is induced by CD40-CD40 ligand interaction on human vascular endothelial cells

M. Gräfe, P. Eschenhagen, V. Henn[1], R.A. Kroczek[1], K. Graf, E. Fleck. *Dept. of Medicine/Cardiology, German Heart Institute & Charité Campus Virchow Klinikum, HU, Berlin; [1]Robert Koch Institut Berlin, Germany*

CD40 is a receptor on B-lymphocytes, monocytes with high homology to the TNF receptors and was found recently to be expressed also on endothelial cells. Ligands for CD40 (CD40L) are expressed on activated CD4+ lymphocytes and activated platelets. In the current study we investigated the effects of CD40 stimulation on endothelial cells on expression of adhesion molecules, secretion of chemokines and adhesion of leukocytes.

Expression of the adhesion molecules E-selectin, VCAM-1 and ICAM-1 on endothelial cells, derived from umbilical cords (EC), was assessed by flow cytometry. Secretion of the chemokines IL-8 and MCP-1 by ELISA. Adhesion of HL60 cells, with high expression of sialyl $Lewis^x$, ligands for E-selectin, was measured with an adhesion assay under flow conditions (wall shear stress 0.6–2.6 dyne/cm^2). Stimulation of EC with CD40L induced an increase in expression of E-selectin, VCAM-1 and ICAM-1 which reached about 50–70% of TNFα-induced effects. Adhesion of HL60 cells increased from 4 ± 2 (control) to 41 ± 10 cells per high power field ($n = 5$, $p < 0.01$). The CD40L induced adhesion reached 51% of the TNFα induced effects. The E-selectin dependence was demonstrated by adhesion blockade with anti E-selectin antibodies (BBA2). CD40L and TNFα induced comparable MCP-1 and IL8 secretion in EC. All CD40L induced effects could be blocked by anti CD40L antibodies (anti-TRAP).

In conclusion, CD40-CD40L interactions induce the expression of adhesion molecules, secretion of chemokines and induce E-selectin-dependent adhesion to endothelial cells. CD40 may augment and prolong inflammatory responses locally in addition to its effects in the immune system.

P3376 Is troponin I of prognostic value in the detection of anthracyclin cardiac toxicity?

E. Ferrari, P. Ferrari[1], A. Talbodec[2], M. Baudouy. *Dept of Cardiology, Nice; [1]Biochemistry Dept, Hopital St Roch, Nice; [2]Cardiology Dept, Hopital Pasteur, Nice, France*

Aim of the study: Antracyclin drugs have allowed tremendous progress in the medical treatment of certain solid tumors. One of the most limiting side effects is undoubtedly cumulative cardiac toxicity.

The aim of our study was to assess in a prospective study the value of troponin I in the detection of early anthracyclin cardiac toxicity and compare it to the standard widely used criteria for the definition of cardiac toxicity ie; Echocardiographic and isotopic Systolic LVF parameters.

Method: From January 95 to April 97 we prospectively included 32 patients who have to be treated with an anthracycline drug. All patients were checked before the begining of the anti-cancer treatment, in particular, with echocardiography and isotopic left ventricular examination. In addition, blood samples were collected in order to assay troponin I before treatment (Sanofi-ERIA pasteur). After commencement of the anti-cancer treatment, the same examinations and sampling were performed after the 2nd the 6th and the final course. In addition, samples for troponin I assay were collected before and after each course

Results: 32 patients were included and followed for a sufficient period to allow comparisons.

Using our criteria (A drop of at least 10% in LVEF between 2 investigations occurring during the cancer treatment both at echocardiography and isotopic examination), 7 patients (toxic group) over 32 reached the definition of a cardiac toxicity assessed with echocardiography and isotopic examinations:

Troponin value: With cut-off positivity at >0.1 ng/ml, we found 18 positive assays over 167. When comparing the 2 patiens groups, positive troponin assays were not more frequent in the toxic group. In the non toxic group 88 assays were negative vs 11 positive; in the toxic group 61 assays were negative vs 7 positive: ($X2 = 0.028$; $p = 0.867$).

Conclusion: Troponine I, at least when measured with a common non ultra-sensitive method, cannot predict the occurrence of cardiac toxicity in patients treated with anthracyclin.

NOVEL MOLECULAR AND CLINICAL ASPECTS OF HYPERTROPHIC CARDIOMYOPAHTY

P3377 Disarray as a marker of risk in patients with hypertrophic cardiomyopathy

A. Varnava, P.M. Elliott, S. Sharma, M.J. Davies, W.J. McKenna. *London, UK*

Hypertrophic cardiomyopathy (HCM) is characterised by hypertrophy with myocyte disarray. Many patients die prematurely and yet the histological determinants of these deaths are not well defined. We studied the clinical profiles of patients with HCM and related these details to the degree of myocyte disarray.

Methods: The symptoms, echo data, risk profile and an ischaemia score (according to presence of typical chest pain, ST depression on exercise and reversible defects on thallium scanning) were noted in 68 HCM patients who had suffered sudden cardiac death (SCD), cardiac failure leading to death or transplantation, or death due to other causes. Each heart was quantitatively assessed for% disarray at the base, mid-level and apex of the LV, Intraventricular septum and RV (total of 18 sections).

Results: Patients with premorbid symptoms of chest pain exhibited significantly more disarray than those without (% disarray 29.8% vs. 17.3%, p = 0.006), as did patients with abnormal vascular response to exercise compared to those with an appropriate rise (30% vs. 18%, p = 0.03), and patients diagnosed or presenting with symptoms before the age of 18 years compared to those presenting in adulthood (26% vs. 18%, p = 0. 03 and 28% vs. 17%, p = 0.02 respectively). A weak, but positive correlation was seen between disarray and a family history of sudden premature cardiac death (r = 0.4, p = 0.006), and disarray and ischaemia score (r = 0.4, p = 0.04).

No association was seen between disarray and syncope, or disarray and episodes of non sustained VT.

Conclusion: Myocyte disarray was greater in patients with chest pain and a high ischaemia score. The known risk factors of a family history of sudden premature death, an abnormal vascular response to exercise, and onset of symptoms or diagnosis during childhood were all associated with significantly more disarray.

The relation between risk and disarray did not appear to relate to arrhythmic markers (i.e. NSVT) and suggests that marked disarray may predispose to sudden death by mechanisms other than arrhythmogenesis.

P3378 Hypertrophic cardiomyopathy: inverse relation of subclinical skeletal myopathy with sudden death in the family

A. Anastasakis, N. Karandreas[1], P. Stathis[1], A. Rigopoulos, A. Theopistou, P. Elliott[2], E. Karvouni, C. Stefanadis, P. Toutouzas. *Department of Cardiology, University of Athens, Athens; [1]EMG Laboratory,Department of Neurology, University of Athens, Athens, Greece; [2]Cardiological Sciences, St. George's Hospital Medical School, London, UK*

Background: Hypertrophic cardiomyopathy (HCM) is a heterogeneous disorder caused by mutations in proteins of the cardiac sarcomere. Some mutations (b-myosin heavy chain) may be associated with skeletal muscle (SM) fibre dysfunction.

Methods: This study determined the prevalence of subclinical skeletal myopathy in 46 unrelated consecutive patients (pts) with HCM (26 male, 49 ± 18 years) using conventional and quantitative electromyography (EMG) of deltoid, quadriceps, tibialis anterior and soleus muscles. No pt had clinically detectable muscle weakness.

Results: Myopathic EMG findings were demonstrated in 12 (26%) pts, 25 pts had normal studies and 9 pts had indeterminate recordings. The relation of abnormalities to clinical parameters were:see table.

	Myopathic EMG	Normal EMG	p	Indeterminate EMG
Age (years)	53.6 ± 20.3	47.0 ± 16.3	NS	54.3 ± 19.5
Interventricular septum (cm)	1.85 ± 0.3	1.92 ± 0.4	NS	1.9 ± 0.4
Posterior wall (cm)	1.22 ± 0.2	1.22 ± 0.3	NS	1.22 ± 0.2
NYHA (I-II-III) (n)	3-6-3 /12	7-15-3 /25	NS	2-5-2 /9
LVOT obstruction (n)	8/12 (67%)	11/25 (44%)	NS	4/9 (44%)
Syncope (n)	3/12 (25%)	4/25 (16%)	NS	0/9
Nonsustained VT (n)	0/12	3/25 (12%)	NS	0/9
Sudden death in the family (n)	0/12	9/25 (36%)	<0.05	1/9 (11%)

Conclusion: A substantial minority of pts with HCM show evidence of subclinical skeletal myopathy. The higher prevalence of a family history of sudden death in pts with normal EMG may reflect a higher prevalence of high risk mutations that are not expressed in SM (e.g. troponin T).

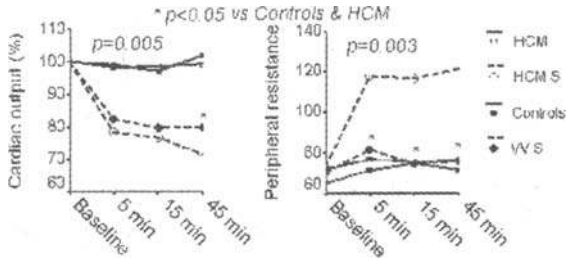
P3379 Haemodynamic determinants of syncope in hypertrophic cardiomyopathy

F. Manganelli, S. Betocchi, Q. Ciampi, M.A. Losi, G.C. Tocchetti, A. Cuocolo[1], G. Storto[1], A. Violante, R. Lombardi, M. Chiariello. *Medicine & Cardiovasc. Sciences, Federico II University, Naples; [1]Radiological Sciences, Federico II University, Naples, Italy*

Background: Syncope (S) occurs in about 1/4 of patients with hypertrophic cardiomyopathy (HCM); its hemodynamic mechanisms, however, are not well established. Ambulatory radionuclide monitoring device (VEST) allows a reliable, noninvasive evaluation of left ventricular (LV) function during exercise or volume changes. Tilting test is an useful tool for identifying patients with vasovagal S (VV S).

Methods: To assess the hemodynamic determinants of syncope, we studied 25 HCM patients without history of S (age 39 ± 14 years, 21 men), 7 HCM patients with S (38 ± 9 years, 5 men [HCM S]), 9 controls (age 36 ± 14 years, 6 men), and 6 patients with VV S (age 34 ± 7 years, 4 men); all underwent head-up tilt at 70° for 45 minutes during VEST. VEST data were averaged for 60-second intervals, and analyzed at baseline and after 5, 15, and 45 minutes of tilting. LV end-diastolic and stroke volumes (SV), and cardiac output (CO) were expressed as% of the baseline values.

Results: All VV S patients and 3 patients with HCM S experienced a positive response to tilt test. VV S patients and HCM S patients showed a similar, significant decrease in SV and CO compared to HCM and control group (Figure, left); a marked increase in peripheral resistance was observed only in HCM S (Figure, right).



Conclusions: Both patients with HCM S and with VV S have a fall in CO and SV with tilting. In the former group, however, the primary mechanism appears to be a decrease in filling of a stiff left ventricle secondary to acute volume unloading, associated with reflex peripheral resistance increase; patients with VV S, in contrast, do not exhibit compensatory vasoconstriction to CO fall.

P3380 Improvement in exercise haemodynamics after transcoronary ablation of septum hypertrophy for hypertrophic obstructive cardiomyopathy

F.H. Gietzen, Ch.J. Leuner, J. Hegselmann, C. Strunk-Mueller, H.J. Kuhn. *Dept. of Cardiology, Bielefeld Hospital, Bielefeld, Germany*

Transcoronary Ablation of Septum Hypertrophy (TASH) is a catheter interventional treatment for hypertrophic obstructive cardiomyopathy (HOCM). Major results – reported in the literature – are a reduction of septal thickness and outflow obstruction and an improvement of NYHA functional class and exercise capacity.

To evaluate objectively the hemodynamic effects of TASH serial left heart and exercise right heart catheterization were performed before as well as 2 weeks, 7 months and 21 months (n = 9) after intervention. The study population consists of 39 pts. with HOCM and severe symptoms (57 ± 14 years, 24 men). In all pts the long-term benefits of TASH on subjective improvement, NYHA functional class, intraventricular gradients, exercise capacity, pulmonary artery mean pressure at workload, cardiac index at workload and peak oxygen consumption were estimated.

43% of the pts. were marked improved, 49% were improved and 8% were unchanged. None of the pts. reported on a further deterioration of symptoms and no late deaths occurred. NYHA functional class improved from 3.0 ± 0.2 to 1.8 ± 0.5 (p < 0.001), exercise capacity increased from 74 ± 31 to 92 ± 36 watts (p < 0.001), peak oxygen consumption from 14.8 ± 4.9 to 16.8 ± 5.7 ml/kg/min (p = 0.015), cardiac index from 6.1 ± 1.9 to 6.5 ± 2.4 l/kg/min (n.s.) and pulmonary artery mean pressure from 44 ± 8 to 36 ± 10 mmHg at identical workloads (p < 0.001). The improvement in NYHA functional class and exercise capacity were significantly correlated to a decrease in pulmonary artery mean pressure at workload and to an increase in peak oxygen consumption.

Conclusion: During long-term follow-up TASH induced reductions of symptoms were accompanied by significant improvements in exercise hemodynamics.

P3381 New mutations in MyBP-C gene associated with hypertrophic obstructive cardiomyopathy (HOCM)

S. Dyachenko, J. Erdmann[1], C. Haberl[2], G. Schmidt[2], H. Kallisch[2], E. Fleck[2], V. Regitz-Zagrosek[2]. *Internal Medicine/Cardiology, Charite, Virchow-Clinic, HU and DHZB, Berlin; [1]Internal Medicine/Cardiology, Berlin; [2]Internal Medicine/Cardiology, Charite, Virchow-Clinic, HU and DHZB, Berlin, Germany*

Hypertrophic cardiomyopathy (HCM) is a primary and heterogenous cardiac disease, and is caused by defects in genes encoding for sarcomeric proteins. A number of disease causing mutations in cardiac myosin binding protein C (MyBP-C) have been identified in patients with a relatively benign clinical course and late disease manifestation.

To search for new mutations in the MyBP-C gene and to analyze genotype/phenotype correlations we screened 71 patients with HCM for mutations in the MyBPC-gene.

Diagnosis of HCM was based on echocardiography (LV hypertrophy, septal hypertrophy $\geq$ 13 mm), RV and LV angiography and hemodynamics and/or preceeding myectomy. DNA was PCR amplified with intronic primers and SSCP-analysis was performed at 4°C and RT. Aberrant PCR-products were directly sequenced on a DNA sequenzer (ABI377).

We identified 5 mutations. Two of them have already been described (insAA1042 and insG791) and three mutations were newly identified. The first new mutation is a 1-bp del in codon 1047 (delG1047) in a 39 y old turkish mother, her father (66 y) and her son (17 y). This mutation leads to a MyBPC-product lacking titin and myosin binding sites and thus affects protein structure and function. The second mutation is a Val-896-Met substitution and was identified in a 28 y old woman from greece. The third mutation identified was a Gln-1233-Ter substitution in exon 34 leading to a protein which lacks parts of the functionally important myosin-binding site. All patients with MyBP-C mutations presented with the typical features of HOCM (one after myectomy, all with septal thickness >15 mm, and ventricular arrhythmia).

We identified a wide spectrum of MyBP-C mutations (two deletions, one insertion, 2 aminoacid exchanges) that affect protein structure and function. In contrast to previously decribed patients with MyBP-C mutations, one family presented with typical HOCM and an early disease manifestation.

P3382 Chronotropic incompetence is an important determinant of functional limitation in hypertrophic cardiomyopathy

S. Sharma, P.M. Elliott, N.G. Mahon, A. Varnava, M.S. Virdee, W.J. McKenna. *Cardiological Sciences, St George's Hospital IMedical School, London, UK*

Patients (pts) with hypertrophic cardiomyopathy (HCM) have reduced peak oxygen consumption (pVO_2). Failure to augment stroke volume is contributory but there are few data on the effect of heart rate response. This study assessed the effect of chronotropic incompetence (CI) on pVO_2.

Methods: One hundred and thirty four HCM patients (29% with a left ventricular outflow gradient > 30 mmHg) with a mean left ventricular wall thickness (LVWT) of 19 ± 5 mm; 9–47 mm underwent upright cardiopulmonary exercise off all medication (except amiodarone) prior to the test using a bicycle ramp protocol. Heart rate (HR) and pVO_2 were measured at 10 second intervals. CI was defined as a peak HR of less than 80% predicted for age and pVO_2 was expressed as a percentage of the maximal predicted VO_2.

Results: Forty nine (36%) pts had CI. Eleven were taking amiodarone. There was no significant difference in peak HR between pts taking amiodarone and those not taking the drug. CI was associated with a lower % pVO_2 than a normal HR response (46.7 ± 14.3 v 68.3 ± 16.8; $p < 0.001$). The V02 versus HR relationship in pts with CI demonstrated two distinct patterns of HR response: Type 1. a steep increase in HR which stopped abruptly on cessation of exercise, and Type 2. a progressive increase in HR which plateaued at least 60 seconds before peak exercise. Pts with a type 2 response were thought to have unequivocal CI whereas pts with a type 1 response may have stopped due to the onset of limiting symptoms rather than failure to increase HR. 29 (21.5%) patients had a type 2 response. In univariate anlaysis there was no correlation between LVWT and pVO_2 but there was a correlation between left ventricular outflow gradient and pVO 2 ($r = 0.5$; $p < 0.0001$) and between CI and pVO_2 ($p < 0.0001$). In multivariate analysis including left ventricular wall thickness, outflow gradient and CI in the model only CI was an independent determinant of pVO_2 ($p < 0.0001$).

Conclusion: Over 20% of HCM patients have CI which appears to be an important cause of exercise intolerance.

P3383 Familial hypertrophic cardiomyopathy. A phenotype–genotype analysis: prognosis depends rather on mutation than on gene

J.M. Langlard, M. Burban, P. Richard[1], B. Hainque[1,5], O. Dubourg[2], M. Desnos[3], P. Charron[4], M. Komajda[4], K. Schwartz[5], J.B. Bouhour. *Department of Cardiology, Hospital Laënnec, Nantes; [1]Biochemical B Laboratory, Hospital Pitié-Salpêtrière, Paris; [2]Hospital Ambroise Paré, Boulogne; [3]Hospital Boucicaut, Paris; [4]Hospital Pitié-Salpêtrière, Paris; [5]INSERM Unit, Hospital Pitié-Salpêtrière, Paris, France*

Familial hypertrophic cardiomyopathy (FHC) is a heterogeneous genetic disease with autosomal dominant inheritance. The highly variable clinical course has been suggested to be related to affected gene, *MYBPC3* mutations seeming to be more benign than β-MHC mutations.

Methods: seven informative families were recruited from French western region. Informed consent, clinical, 12 lead-ECG, echocardiographic data and blood samples were collected for phenotype (P) and genotype (G) analysis. Major cardiac events such as heart failure (HF), heart transplantation (HTx) and cardiac death (CD) were analysed. Microsatellite haplotyping, single-strand conformation polymorphism analysis, and DNA sequencing were used to assess genotype.

Results: 193 patients (pts) were genotyped; among the 60 carriers of mutation (G+), 36 were phenotypically affected (G+/P+). We identified 4 missense mutations in the *β-MHC* gene (Asn232Ser, Arg453Cys, Asn479Ser and Gly768Arg) and a splice donor site mutation of *MYBPC3* gene exon 6 (SDS mut). On 2 occasions, 2 families, suggesting a founder effect, carried the same mutation (Asn232Ser and Asn479Ser). Three of these mutations have been previously described (Asn232Ser and SDS mut as benign; Arg453Cys as severe). Numbers of subjects (G+, G+/P+) carrying each mutation and major cardiac events are listed in table below. *β-MHC* mutations were associated with variable clinical course and the *MYBPC3* mutation with a high penetrance and a poor prognosis.

Gene	Mutation	pts G+/pts G+P+	HF/HTx (age)	CD (age)
β-MHC	Asn232Ser	10/7	0/0	2 (18 y, 38 y)
β-MHC	Arg453Cys	3/2	0/1 (27 y)	0
β-MHC	Asn479Ser	34/16	1/0	1 (33 y)
β-MHC	Gly768Arg	7/6	1/0	1 (47 y)
MYBPC3	SDS mut	6/4	1/1 (41 y)	1 (18 y)

Conclusion: clinical course of FHC seems to be related rather on mutation within the gene than gene itself when *β-MHC* and *MYBPC3* mutations are compared.

P3384 Age-related changes of exercise capacity in patients with hypertrophic obstructive cardiomyopathy

P. Ziemssen, L. Faber, H. Seggewiss, W. Meyners. *Department of Cardiology, Heart Center NRW, Bad Oeynhausen, Germany Ruhr-University Bochum*

Pts. with HOCM often report on decrease in vitality. Left ventricular outflow tract (LVOT) obstruction and diastolic dysfunction may be the main causes. Objective parameters of exercise capacity can be determined by spiroergometry (SE).

77 consecutive pts. (50 ± 16 years, 45 men), underwent SE using a bicycle ergometer ramp protocol (Δ 10 watts/min). We measured peak oxygen consumption (pVO_2), % of maximal predicted oxygen consumption (%VO_2), anaerobic threshold (AT), oxygen pulse (O_2 pulse), maximal work load, and by echo left atrial diameter (LA), LVOT-gradient (LVOTG) at rest and at Valsalva.

Only 35% of pts. with HOCM reached normal %VO_2 values (≥80%). Pts. ≥60 years achieved a higher %VO_2 than youngers (117 ± 71 vs. 69 ± 17; $p < 0.01$) normal %VO_2-values (71% vs. 21%). Details are listed in the table.

Table. Results of SE and echo Doppler study

(n)	<40 years (23)	40–59 years (33)	≥60 years (21)
Peak VO_2 [ml/kg/min]	$27.1 \pm 7.2^{(1)(2)}$	$20.1 \pm 5.2^{(1)(3)}$	$18.2 \pm 5.5^{(2)(3)}$
%VO_2 [%]	$69 \pm 17^{(4)}$	$68 \pm 17^{(5)}$	$117 \pm 71^{(4)(5)}$
AT [ml/kg/min]	$17.1 \pm 3.6^{(6)}$	$15.1 \pm 4.2^{(7)}$	$13.3 \pm 3.5^{(6)(7)}$
LVOTG at rest [mmHg]	48 ± 21	46 ± 28	60 ± 38
At Valsalva [mmHg]	102 ± 52	110 ± 47	110 ± 54
NYHA	$2.5 \pm 0.5^{(8)}$	$3.0 \pm 0.4^{(8)}$	2.9 ± 0.4

(P-value <: $^{(1)}$0.01, $^{(2)}$0.001, $^{(3)}$0.05, $^{(4)(5)}$ 0.01, $^{(6)(7)(8)}$ 0.05).

There is no correlation between LVOTG and pVO_2, %VO_2, AT, and O_2 pulse. In a multivariate regression analysis only LVOTG at rest influences %VO_2 (OR 0.6, $p < 0.01$).

Conclusions: The majority of younger pts. with HOCM have reduced exercise capacity, whereas pts. ≥60 years of age reached more often normal values of %VO_2. Furthermore, only a small influence of LVOT gradient on exercise capacity is detectable.

P3385 Long-term morphological evolution of familial hypertophic cardiomyopathy caused by Arg92Trp mutation in the cardiac troponin T gene

N. Fujino, M. Shimizu, H. Yoshio, K. Okeie, Y. Emoto, T. Matsuyama, M. Yamaguchi, H. Kokado, H. Itoh, H. Mabuchi. *The Second Department of Internal Medicine, Kanazawa University, Kanazawa, Japan*

Familial hypertrophic cardiomyopathy (FHCM) can be caused by a mutation in the cardiac troponin T (cTnT) gene. Previous report suggested that mutations in the cTnT gene were notable because they were associated with a particulary poor prognosis but only mild hypertrophy. However, long-term morphological evolution of FHCM caused by cTnT gene mutations are unknown. We studied two families with the Arg92Trp mutation in the cTnT gene.

Methods: 140 probands with FHCM were screened for mutations in the cTnT gene. The Arg92Trp missense mutation was found in two probands. The two families were analyzed genetically and clinically.

Results: Ten (4 males, 6 females, mean age 49 ± 15 yrs) were affected with the Arg92Trp mutation. Distributions of morphology on ultrasound cardiogram (UCG) were dilated cardiomyopathy-like features (D-HCM) (left ventricular end-diastolic dimension: LVDd > 55 mm, fractional shortening: FS < 25%) in three, asymmetric septal hypertrophy (ASH) with normal LVDd (LVDd ≤ 55 mm) in five, ECG abnormality without UCG abnormality in one male (32 yrs), and non penetrance in one female (27 yrs). Disease related sudden death was seen in three individuals in their family history (1 yrs female, 14 yrs female, and 53 yrs male). The three D-HCM patients were followed up for 6 to 19 years, respectively. LVDd/left ventricular end-systolic dimension (LVDs) of the 65 yrs D-HCM female was 45/32 (mm) in 46 yrs, and dilated to 65/59 in 60 yrs, 67/59 in 65 yrs. Left ventricular hypertrophy with ASH decreased in the course (interventricular septal wall thickeness/posterior wall thickness: 29/13 to 7/10). LVDd/LVDs of the 56 yrs D-HCM male was 60/52 in 50 yrs, and 66/59 in 56 yrs. LVDd/LVDs of another 54 yrs D-HCM male was 52/40 in 45 yrs, and 68/55 in 54 yrs. Considering gender, the five ASH patients were younger than D-HCM patients (a 26 yrs male and four female from 49 to 64 yrs).

Conclusion: There is a tendency to develop into D-HCM in their fifties in male and in their sixties in female in FHCM patients with Arg92Trp mutation in the cTnT gene.

P3386 Ischaemia during daily life in hypertrophic cardiomyopathy

M. Boccalatte, S. Betocchi, R. Gottilla, C. Briguori, L. Adinolfi, M.A. Losi, E. Pezzella, R. Lombardi, Q. Ciampi, M. Chiariello. *Medicine & Cardiovasc. Sciences, Federico II University, Naples, Italy*

Background: Myocardial ischemia is common in hypertrophic cardiomyopathy (HCM) and it appears to be linked to symptoms and sudden death. The impact of spontaneous ischemia in non selected patients with HCM has never been investigated. To address this issue we evaluated the presence and duration of ischemia during daily life using ECG monitoring (EM).

Methods: We recorded 24 hour EM of 70 patients with HCM. Total ischemic burden (TIB) was calculated as the sum of the duration in minutes of each ischemic episode (ST segment shift from the baseline >1 mm and lasting >1 min). By echocardiogram, we measured the extent of left ventricular (LV) hypertrophy (EH) by adding maximal thickness in 4 left ventricular segments, and left atrial fractional shortening (LAFS), an index of passive diastolic function. By upright exercise test with the analysis of expired gases, we measured maximal oxygen consumption (VO_2 max ml/kg/min).

Results: Calculation of TIB was possible in 57 patients (84%) who had good quality recordings; 17 of them had significant ischemia (TIB>30 min) during EM. The 2 groups did not differ for age and basal ejection fraction. Compared to patients without ischemia, patients with ischemia had a worse diastolic function (LAFS 19 ± 6 vs 24 ± 7%, p = 0.016) a lower exercise tolerance (VO_2 max 21 ± 4 vs 26 ± 7 ml/kg/min, p = 0.009), an higher NYHA functional class (1.68 ± 04 vs 1.34 ± 0.5, p = 0.02), a greater extent of LV hypertrophy (EH 59 ± 13 vs 70 ± 19 mm, p = 0.04) and a higher LV outflow tract obstruction (8 ± 22 vs 29 ± 40 mmHg, p = 0.012). Ischemia was a determinant of NYHA functional class and VO_2 max also in the subset of 40 nonobstructive patients.

Conclusion: Myocardial ischemia can be assessed by a non invasive method. Prolonged ischemia during daily life is associated with a lower exercise tolerance and worse diastolic function. LV outflow tract obstruction and high extent of hypertrophy are determinants of ischemia.

P3387 Long-term follow-up of hypertrophic cardiomyopathy

R. Maier, B. Eber, K. Stoschitzky, F.M. Fruhwald, N. Watzinger, B. Rigler[1], W. Klein. *Cardiology Dept, Med. Univ.-Klinik Graz, Graz; [1]Cardiac Surgery, Chir. Univ.-Klinik Graz, Graz, Austria*

Objectives: Aim of this retrospective study was the clinical evaluation of our patients with hypertrophic cardiomyopathy (HCM) receiving medical and/ or surgical treatment, and the calculation of cumulative survival rates.

Patients and Methods: 85 patients – 56 males and 29 females – with HCM have been followed up for 1–26 years (mean 10 years). Mean age at the initial diagnosis was 46 (7–77) years. 79 patients received medical treatment, predominantly verapamil. Six patients – three males and three females – with typical (subaortic) hypertrophic obstructive cardiomyopathy underwent transaortic septal myectomy/ myotomy and were treated with verapamil subsequently. Patients' examination included history, physical examination, ECG and echocardiography. Cumulative survival rates were calculated by life table analysis.

Results: Of those patients treated medically, clinical improvement occurred in 37%, no changes were found in 29%, 15% deteriorated, and 15 patients (19%) – twelve males and three females – died up to 26 years (mean 8 years) after the initial diagnosis. Clinical improvement was obtained in all patients that were treated surgically, lasting up to 15 years postoperatively in five patients. One patient showed clinical deterioration eleven years after initial myectomy; remyectomy was performed, but did not ameliorate symptoms. 10- and 20-year survival rates of medically treated patients were 88% and 63%, respectively (annual mortality rate 1.8%). Survival rate of surgically treated patients with subsequent verapamil-therapy was 100% over a mean follow-up period of 10 (5–18) years.

Conclusions: Medical treatment yielded clinical improvement in about one third of patients. Long-lasting clinical improvement occurred in all patients following myectomy/ myotomy, but recurrence of symptoms could not be avoided completely. Long-term outcome appears to be best in patients treated surgically with subsequent verapamil-therapy. However, DDD pacing as well as percutaneous transluminal septal myocardial ablation were not yet available for our patients.

P3388 Utility of metabolic exercise testing in the differentiation of physiological hypertrophy of athlete's heart from hypertrophic cardiomyopathy

S. Sharma, P.M. Elliott, N.G. Mahon, A. Varnava, M.S. Virdee, W.J. McKenna. *Cardiological Sciences, St George's Hospital, Medical School, London, UK*

The echocardiographic and electrocardiographic distinction between physiological left ventricular hypertrophy (LVH) in highly trained athletes and mild (13–16 mm) LVH in HCM is difficult. We evaluated the role of cardiopulmonary exercise in differentiating the athlete's heart from HCM with mild hypertrophy.

Methods: 8 recreational male athletes with genetically proven HCM (6 = troponin T and 2 = b myosin heavy chain mutations) and mild LVH (<16 mm) were compared with 8 elite male athletes matched for age and body surface area with LVH of similar magnitude, 8 elite athletes without LVH and 12 healthy recreational sportsmen without LVH. All subjects exercised to the point of exhaustion using a maximal ramp cycle ergometer exercise test with simultaneous gas exchange analysis. Peak oxygen consumption(pVO_2), anaerobic threshold (AT) and oxygen pulse (O_2 pulse) were measured.

Results:

Parameter	HCM	Athletes with LVH	Athletes without LVH	Recreational Sportsmen
Age (years)	24.7 ± 6.3	23.9 ± 3.9	24.8 ± 4.3	25.4 ± 5.4
LVWT (mm)	13.7 ± 1.4	12.8 ± 1.0	10.7 ± 0.7	9.9 ± 1.0
PVO_2 (ml/kg)	34.2 ± 8.9	67.2 ± 4.9	66.7 ± 5.1	45.6 ± 3.2
AT (%pred VO_2 max)	41.4 ± 7.0	55.4 ± 12.6	62.1 ± 6.5	46.8 ± 2.8
O_2 pulse (ml/beat)	14.3 ± 2.6	29.1 ± 12.6	27.4 ± 6.2	16.8.0 ± 2.1

Highly trained athletes with and without LVH had significantly greater pVO_2, AT and O_2 pulse when compared to active HCM patients with mild LVH and normal healthy recreational sportsmen ($p < 0.001$). Athletic HCM patients had significantly lower metabolic parameters compared with healthy recreational sportsmen ($p < 0.001$).

Conclusion: Cardiopulmonary exercise testing is a useful non invasive method of differentiating physiological LVH in highly trained athletes heart from HCM with mild hypertrophy.

P3389 Dispersion of repolarisation in hypertrophic cardiomyopathy and hypertensive cardiac hypertrophy

A. Dabrowska-Kugacka, A. Lubinski, A. Baczynska, M. Szolkiewicz[1], B. Rutkowski[1], G. Swiatecka. *II Department of Cardiology, Medical University, Gdansk; [1]Department of Nephrology, Medical University, Gdansk, Poland*

Background: QT disspersion in the 12-lead ECG reflect the disspersion of cardiac repolarisation (DCR). In order to check the hypothesis that DCR in HCM is mainly due to structural abnormalities but not cardiac hypertrophy the extend of DCR in patients with hypertrophic cardiomyopathy (HCM) and hypertensive left ventricular hypertrophy (LVH) was compared.

Methods: The study group consisted of 15 patients with HCM, 25 with LVH and a control group of 15 patients without cardiac disease. DCR was assessed in each patient by measuring the duration of QT interval in the standard 12-lead ECG. The following parameters were calculated: 1) QT disspersion (QTd) as the difference between the longest and the shortest QT, 2) QTc disspersion (QTcd) as the difference between the longest and the shortest QTc. Left ventricular mass corrected for body surface area (LVmass/BSA) was estimated during echocardiography. QT and QTc disspersion index, defined as QTd/(LVmass/BSA) and QTdc/(LVmass/BSA), was also calculated.

Results: All the calculated DCR parameters were significantly longer in the HCM group, compared to the LVH or the control group. QT and QTc disspersion index was significantly bigger in the HCM group, while there was no difference between the LVH and the control group.

	HCM	LVH	Control	p value between HCM & LVH
QTd [s]	51 ± 29	23 ± 14	14 ± 8	< 0.001
QTcd	56 ± 29	28 ± 16	17 ± 9	< 0.001
LVmass/BSA [g/m^2]	221 ± 55	182 ± 42	120 ± 27	< 0.05
QTd/(LVmass/BSA) [s/(g/m^2)]	0.24 ± 0.13	0.12 ± 0.8	0.11 ± 0.3	<0.01
QTcd/(LVmass/BSA) ['/(g/m^2)]	0.27 ± 0.14	0.15 ± 0.1	0.14 ± 0.4	< 0.01

Conclusions: 1) Disspersion of repolarisation is significantly prolonged in HCM compared to LVH or control, 2) The prolongation of DCR in HCM is not a result of cardiac hypertrophy but is mainly due to structural abnormalities.

P3390 Novel mutations in the cardiac myosin binding protein C gene in patients with hypertrohic cardiomyopathy

A. Perrot, M. Hasbach, I. Szangolies, M. Reinke, C. Brückner, I. Poepping, A.E. Ellmer, S. Cordini, R. Dietz, K.J. Osterziel. *Charite/Franz-Volhard-Klinik, Humboldt-Universität zu Berlin, Germany*

Hypertrophic Cardiomyopathy (HCM) is characterized by left and/or right ventricular hypertrophy leading to arrhythmias and sudden cardiac death. HCM is the most frequent genetic disorder of the myocardium. The disease is inherited as an autosomal-dominant trait. Seven different disease genes are known. All these genes encode for proteins of the myofibrillar apparatus. This shows that familial HCM is a disaese of the sarcomere. Mutations in the cardiac myosin binding protein C (MYBPC3) are responsible for about 15% of cases.

Methods: 145 unrelated patients with HCM were evaluated using physical examination, ECG and echocardiography. DNA was extracted from blood. Screening of the 34 coding exons of the MYBPC3 was done using PCR, single strand conformation polymorphism analysis (SSCP), and automated sequencing.

Results: We detected 9 novel mutations in the MYBPC3. 5 missense mutations leading to an aminoacid exchange were found. One mutation leading to a stop codon is predicted to produce a truncated protein. Hot spots were detected in the exon 6 and exons 24–27. Furthermore we identified 3 deletions and one insertion in the exons 29–33 leading to a frameshift. The clinical phenotype of these genotyped patients showed no significant differences to the phenotype described for other HCM disease genes.

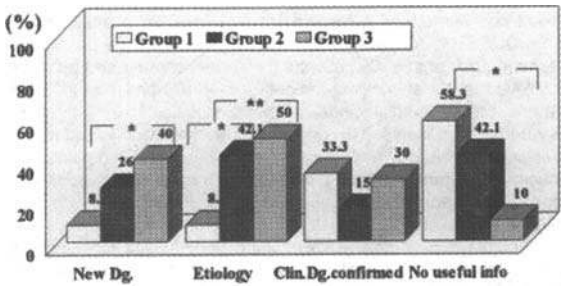
Conclusion: The described mutations in the MYBPC3 confirm the wide allelic heterogeneity of HCM.

PERICARDIUM IN HEART DISEASE: AN UPDATE

P3391 Diagnostic value of pericardial biopsy: improvement with aggressive sampling enabled by pericardioscopy

P.M. Seferovic, A.D. Ristic, P. Petrovic, R. Maksimovic[1], M. Ostojic, B. Obrenovic, S. Simeunovic, P. Djukic, D. Simeunovic, D.D. Zamaklar. *University Inst. for Cardiovasc. Dis., Belgrade; [1]University Inst. for Radiology, Belgrade, Yugoslavia*

Diagnostic value of pericardial biopsy (PB) is still a matter of debate. To elucidate this issue, we compared PB results using fluoroscopy (Group 1: 12 pts, 66.7% males, mean age 46.7 ± 12.2 yrs, 3–6 samples/pt, mean 5.2) and aimed PB performed using flexible percutaneous pericardioscopy (PCS) with standard and aggressive sampling (Group 2: 19 pts, 52.6% males, mean age 52.3 ± 11.2 yrs, 4–6 samples/pt, mean 5.9 (range 3–6))(Group 3: 10 pts, 60% males, mean age 42.3 ± 14.6 yrs, 18–20 samples/pt, mean 19.2). All pts initially underwent pericardiocentesis due to a pericardial effusion (PE) >2 cm or imminent tamponade. In Group 1 left lateral PB was performed, using 9F sheath and Olympus FB-43ST forceps. In Group 2 and 3 aimed PB with FB-43ST forceps were enabled by PCS with Olympus HYF-1T 16F endoscope. Sampling efficiency was better in Groups 2 and 3 in comparison to Group 1, 86.2% and 87.3% vs. 43.7% respectively ($p < 0.01$). Sensitivity of the histology findings was 41.7% in Group 1, 57.9% in Group 2, and 90% in Group 3, while specificity was 100% in all groups. No major complications occurred in either group, while in Groups 2 and 3 short run VT (1/19), pain during dilatation (11/19 and 7/10 pts), and transient fever (8/19 and 4/10 pts) were noted. Patohistology revealed (Group 1 vs. 2 vs. 3)(%): Planocellular Ca 8.4/10.5/10; Adeno Ca 0/15.7/0; Mesothelioma 0/0/10; Plasmocytoma 0/5.3/0; M. Hodgkin 0/5.3/10, Tuberculosis 0/5.3/20. Nonspecific inflammation 33.3/15.7/40. Diagnostic values of the procedures are depicted in the figure.



Conclusion: PCS with Olympus HYF-1T enables excellent visualization, superior extensive pericardial sampling, offering better diagnostic value especially regarding establishing the new diagnosis and etiology of the pericardial disease.

P3392 Effect of pericardial pressure on human coronary circulation

E.I. Skalidis, G.E. Kochiadakis, N.E. Igoumenidis, S.I. Chrysostomakis, E.A. Zacharis, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

Despite the fact that pericardial pressure (PP) has been clinically diagnosed since the 19th century and numerous reflexes and systemic cardiovascular effects have been well described, only a very few studies have dealt with the effects on coronary blood flow and these used experimental animal models. The aim of this study was to assess the effects of PP on human coronary circulation.

Methods: We studied 4 patients (3 men), mean age 53 ± 8 years, programmed for percutaneous balloon pericardiotomy because of rapid pericardial fluid accumulation due to extracardiac malignancy. A 0.014" 15 MHz guide wire was used to record coronary blood flow velocities in the left anterior descending coronary artery at increasing PP achieved by infusion of warmed normal saline at a rate of 30 ml/min. All patients received 200 μg intracoronary nitroglycerin before the procedure. Time-averaged peak velocity (APV) was measured before (R) and after (H) administration of 18 μg intracoronary adenosine, to achieve maximal hyperemia. Coronary flow reserve (CFR) was calculated as the ratio of APV-H to APV-R. Measurements were made at the beginning and at the end of the study. The study was terminated at the onset of any symptom.

Results: After infusion of 166 ± 36 ml of normal saline, the pericardial pressure was 16 ± 3 mm Hg. The coronary blood flow velocity data are given in the table below.

Table

PP (mm Hg)	APV-R (cm/s)	APV-H (cm/s)	CFR
2 ± 1	25.7 ± 6.1	53.2 ± 11.4	2.1 ± 0.2
16 ± 3	14.5 ± 2.6*	31.2 ± 5.4*	2.2 ± 0.4

p < 0.05 vs. low PP

Conclusion: With increasing pericardial pressure there is a decline in coronary blood flow and an unaffected coronary flow reserve. The maximal hyperaemic flow is far less under increased pericardial pressure than at normal pressure, which implies an augmented susceptibility to myocardial ischaemia.

P3393 New concept in pericardiocentesis: preliminary experimental and clinical experience with protected needle and vacuum device

P.M. Seferovic, A.D. Ristic, P. Petrovic, R. Maksimovic[1], M. Ostojic, D. Simeunovic, D.D. Zamaklar. *University Inst. for Cardiovasc. Dis., Belgrade; [1]University Inst. for Radiology, Belgrade, Yugoslavia*

Percutaneous approach to normal pericardium was until recently unrealistic. Objective of present study was to evaluate feasibility and safety of a new instrument for percutaneous access to the pericardium with small or no effusion (PerDUCER®, Comedicus Inc., USA), both in experimental and clinical setting.

Key feature of the device is a distal view tube with a side hole cavity, where pericardium is captured by vacuum and tangentially punctured by introducer needle. The device was studied in four animal experiments (two F1 white pigs in general anesthesia, mean weight 28.6 kg) as well as in five patients with pericardial disease in local anesthesia (two males, mean age 50.4 years, pericardial effusion 0.8–2.2 cm, mean 1.6 cm). The procedure was performed under fluoroscopic control and includes two distinct techniques: 1) access to the mediastinal space and, 2) pericardial capture, puncture, and insertion of the 0.018" guidewire. Access to the mediastinal space includes the introduction of the blunt cannula, 0.038" guidewire, dilator-introducer sheath set and insertion of PerDUCER®. Access to the mediastinal space was possible in 4/4 animal experiments, and in 4/5 patients. Pericardial capture and puncture were also achieved in 4/4 animal experiments and in 4/5 patients. Insertion of the guidewire and pericardial catheter was accomplished in 3/4 animal experiments and in 0/5 patients. The procedure was very well tolerated. No major complications developed, while minor complications included pain at the dilator-introducer sheath entry site (5/5) and the mild transient fever (2/5).

Conclusion: Both in animal and clinical setting the PerDUCER® was successful regarding access to the mediastinal space, pericardial capture and puncture. Insertion of the pericardial guidewire and catheter was achieved only in animal experiments. Further studies and presumably minor modifications are needed to improve efficacy in patients with small or no pericardial effusion.

P3394 Transient left ventricular remodelling as a measure of left ventricular compression in patients with cardiac tamponade

M.S. Feinberg, B.A. Popescu, A.C. Popescu, M. Jonas, Z. Vered, B. Rabinowitz, E. Kaplinsky, E. Di Segni, E. Schwammenthal. *The Heart Institute, Sheba, Israel Medical Center*

Transient left ventricular remodeling characterized by increased wall thickness, decreased cavity size and normal left ventricular mass has been observed clinically and experimentally in cardiac tamponade but its exact diagnostic value is not known. The purpose of this study was to establish the quantitative relationship between the degree of LV remodeling and cardiac tamponade. The study population consisted of 70 consecutive patients (age: 50 ± 16, range: 17–84; F:M; 29:41) with large or moderate pericardial effusion. Symptomatic patients who underwent pericardiocentesis were considered to have cardiac tamponade (n = 33). The receiver operating curve (ROC) of left ventricular relative wall thickness [(LVRT%) = (PW thickness) * 100/(LVEDD/2)] as a marker of cardiac tamponade showed the best accuracy using LVRT ≥ 50%. The diagnostic value of LVRT ≥ 50% was compared to other known echocardiographic signs of cardiac tamponade.

	RA↓	RV↓	IVC↓	Res Var↑	LVRT ≥ 50%
Sensitivity	73%	73%	83%	90%	76%
Specificity	76%	78%	45%	35%	84%
Accuracy	74%	76%	63%	61%	80%

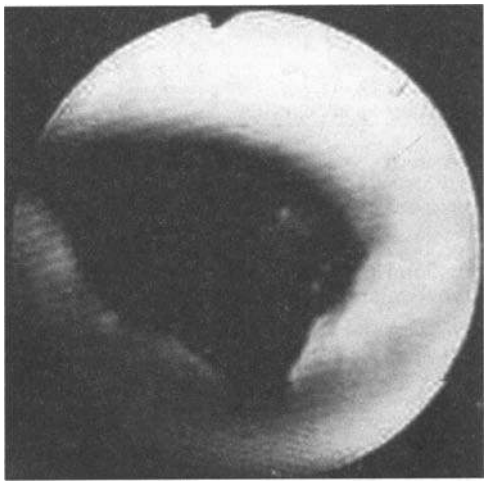
RA↓; right atrial collapse, RV↓ right ventricular collapse, IVC↓ reduced variations of inferior vena cava, Res Var↑ increased respiratory variations of left ventricular flow

Conclusion: Transient left ventricular remodeling emerged as a powerful predictor of cardiac tamponade. The highest accuracy was achieved with a threshold value of ≥50% of LVRT.

P3395 Pericardioscopy after percutanous balloon pericardiotomy: facilitated endoscope placement and verification of the pericardial window

P.M. Seferovic, A.D. Ristic, P. Petrovic, R. Maksimovic[1], M. Ostojic, B. Obrenovic, P. Djukic, S. Stojkovic, D. Simeunovic, D.D. Zamaklar. *University Inst. for Cardiovasc. Dis., Belgrade; [1]University Inst. for Radiology, Belgrade, Yugoslavia*

Placement of a large sheath-dilator set for percutaneous pericardioscopy (PCS) is often tedious and painful despite proper analgesia and local anesthesia. Since the introduction of percutaneous balloon pericardiotomy (PBP), controversial issue of its mechanism of action emerged. In order to elucidate this issue we selected 6/22 pts in whom PBP was performed (66.7% males, mean age 58.6 years) for PCS with Olympus HYF-1T, 16F flexible endoscope. Gradual dilatation of entry site from the 9F size needed for PBP to 16.5F for PCS was performed over a J 0.038" guidewire. Procedure was successful in 5/6 pts, while in one pt it was aborted before the advancement of the endoscope. Dilatation of the entry site was facilitated after PBP with no significant pain in 5/5 pts in comparison to other 24/29 PCS procedures performed without previous PBP (painful procedure in 75% of pts)($p < 0.01$). PCS in all five cases confirmed the triangularly shaped appearance of the pericardial window due to the type of the balloon catheter applied for PBP (Schneider Trefoil-Meier) (figure). There were no complications in five pts included in the study. However, in the sixth pt the procedure had to be canceled due to the cardiac perforation by a 9F dilator. That was the consequence of the sheath dislocation after PBP and further pericardial dilatation over a thin PBP guidewire. Cardiac perforation was successfully treated by surgery.



In conclusion, PCS was facilitated by previous PBP due to the pericardial dilatation with a large size balloon catheter. PCS can successfully visualize the pericardial window created by PBP. To avoid complications, it is essential to keep the PBP sheath in place and to exchange the guidewire used for balloon catheter with a thicker J wire for PCS introducer set.

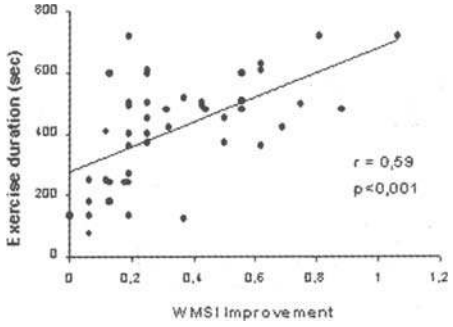
EMERGING CONCEPTS IN DILATED CARDIOMYOPATHY

P3396 Contractile reserve identified by dobutamine stress echocardiography predicts maximal exercise tolerance in patients with dilated cardiomyopathy

P. Otasevic, Z. Popovic, D. Bojic, S.D. Boskovic, M. Bojic, L. Pratali[1], A.N. Neskovic. *Cardiovascular Research Center, Dedinje Cardiovascular Institute, Belgrade, Yugoslavia; [1]CNR, Pisa, Italy*

In order to investigate the relationship between contractile reserve, identified by dobutamine stress echocardiography (DSE), and maximal exercise tolerance (MET), we have evaluated 48 pts with dilated cardiomyopathy (DCM) who underwent DSE and maximal bicycle ergometry. DSE was performed using 5, 10, 20, 30 and 40 mcg/kg/min infusions, in progressive stages lasting 5 minutes each. Contractile reserve was assessed using improvement between resting and peak DSE left ventricular (LV) wall motion score index (WMSi). WMSi was calculated according to the 16-segment model. Bicycle ergometry was performed in 25 W increments, lasting 2 minute each, until 150 W or until MET was reached. LV end-systolic (ESVi) and end-diastolic (EDVi) volume indexes, as well as EF, in rest and peak DSE, were calculated using Simpson's biplane formula.

Results: Mean exercise duration was 410 ± 167 sec, whereas mean improvement in WMSi was 0.34 ± 0.24 ($p < 0.001$, vs. baseline). Cardiac index improved from 2.25 ± 0.85 to 3.51 ± 1.35 L/min/m^2 ($p < 0.001$). Similarly, ESVi and EDVi decreased in peak DSE compared to baseline (90.3 ± 30.8 vs. 82.2 ± 32.4 ml/m^2, $p < 0.001$, and 110.1 ± 30.4 vs. 108 ± 30.6 ml/m^2, $p < 0.05$, respectively), whereas EF increased (19.2 ± 8.4 vs. 25.8 ± 12%, $p < 0.001$). Univariate analysis, that included DSE induced changes in EF, ESVi, EDVi, WMSi, and CI, revealed that exercise duration correlated with change in WMSi ($r = 0.59$, $p < 0.001$) (figure) and change in EF ($r = 0.49$, $p < 0.001$). However, multiple linear regression showed that the only predictor of maximal exercise duration was change in WMSI ($p < 0.001$).



Conclusion: Our data indicate that contractile reserve assessed by DSE is a good predictor of MET in pts with DCM, suggesting that DSE may be a valid alternative for pts who can not exercise.

P3397 Depressed heart rate variability is associated with poor prognosis in non-ischaemic dilated cardiomyopathy

M. Karcz, L. Chojnowska, W. Zaręba[1], J. Grzybowski, W. Ruzyłło. *National Institute of Cardiology, Warsaw, Poland; [1]University of Rochester, Rochester NY, USA*

Prognostic value of heart rate variability (HRV) in patients with non-ischaemic dilated cardiomyopathy (DCM) is not as well established as in post-infarction pts or pts with heart failure of various etiology.

Methods: HRV analysis was performed using 24 hr digital Holter recordings in 69 DCM pts (age 40 +– 12 yrs, 60 M, mean EF 31 +– 10%, 19 pts in NYHA III/IV) who were then followed for mean 20 (6–35) months. Also analysed were arrhythmia, 12 lead ecg, demographic, clinical and haemodynamic variables.

Results: during follow-up cardiac events occurred in 18 (26%) pts (10 deaths, 8 transplantations). Age, gender, arrhythmia, duration of symptoms, history of syncope were not significantly associated with prognosis both in multi- and univariate Cox proportional hazards analysis. Parameters significantly associated with prognosis are given in the table:

	Cox univariate		Cox multivariate	
Parameter	OR (95% CI)	p value	OR (95% CI)	p value
Bundle branch block	5.24 (2.05–13.42)	0.006	–	NS
NYHA III or IV	8.44 (3.00–23.70)	<0.00005	–	NS
EF (per 10% increase)	0.29 (0.15–0.57)	0.0003	0.18 (0.07–0.45)	0.0003
SDNN (per 10 ms increase)	0.72 (0.62–0.84)	<0.00005	0.67 (0.55–0.81)	<0.00005

Conclusions: HRV is independently associated with prognosis in non-ischaemic DCM pts.

P3398 Usefulness of cardiac natriuretic peptide as a neurohumoral marker of impaired coronary microcirculation in patients with dilated cardiomyopathy: relationship between coronary flow reserve and neurohumoral factors

S. Yanagi, K. Hirota, J. Yoshikawa[1], M. Teragaki[1], T. Ota, T. Hasegawa, K. Nagae. *[1]Division of Cardiology, Fuchu Hospital, Osaka; 1st department of internal medicine, Osaka city university, Osaka, Japan*

The abnormalities of coronary microcirculation and augmentation of neurohumoral factors, including atrial and brain natriuretic peptide (ANP and BNP), and Norepinephrine (NE) has been described in pts with dilated cardiomyopathy (DCM). The neurohumoral factor is receiving growing attention as a non-invasive marker for the failing left ventricular (LV). However there was no reports of the association between neurohumoral factors and coronary circulation. This study was designed to investigate the relationship between neurohumoral factors and the myocardial blood flow reserve in pts with DCM, using a Doppler flow wire (DFW).

Methods; We studied coronary flow velocities in 12 pts with DCM using a 0.014 inch Doppler guide wire in the proximal portion of the left anterior descending coronary artery at rest and during adenosine (AD)-induced (intravenous 150 ug/kg/min adenosin tri-phosphate infusion) hyperemia. Coronary flow reserve (CFR) was calculated as the ratio of AD-induced APV/based APV (APV; averaged peak velocity). Hemodynamic parameter of the LV was estimated as pulmonary capillary wedge pressure (PCW), measured by Swan-Ganz catheter, ejection fraction (LVEF) and end-diastolic volume index (LVEDVI) by leftventriculogram. Plasma levels of NE, ANP and BNP were sampled simultaneously. The pts was divided into two groups, group N (CFR > 2.0, n = 7) and L (CFR ≤ 2.0, n = 5), according to CFR value.

Results; Although hemodynamic parameter of the LV were similar with two groups, plasma levels of neurohumoral factors were significantly higher in group L than in group N. Plasma level of neurohumoral factors were significantly increased in group L. In group N, the plasma level of BNP is moderately elevated despite normal ANP and NE.

	CFR	Norepinephrine	ANP	BNP	LVEF	LVEDVI	PCW
Group N	2.90 ± 0.87	270 ± 81	30 ± 37	99 ± 174	39 ± 20	138 ± 72	16 ± 14
Group L	1.67 ± 0.35	521 ± 24	202 ± 102	572 ± 301	31 ± 15	162 ± 51	10 ± 5
P value	0.016	0.002	0.002	0.006	0.48	0.54	0.34

(mean ± SD.)

These data indicate that low CFR was associated with highly elevated neurohumoral factors, suggesting impaired coronary microcirculation and poor prognosis.

Conclusions, The abnormal neurohumoral factors may predict low CFR, indicating microciculatory disturbance in pts with DCM. The pts with normal CFR may have solely damaged myocardium because of moderately elevated BNP. The current study provides new insights into the interplay between the CFR and cardiac natriuretic peptide system in pts with DCM.

P3399 Mitochondrial haplotypes associated with idiopathic dilated cardiomyopathy

S.S. Khogali, B.M. Mayosi, J.M. Beattie[1], H. Watkins, J. Poulton. *University of Oxford, Oxford; [1]Birmingham Heartlands Hospital, Birmingham, UK*

Dilated Cardiomyopathy (DCM) is a recognised manifestation of mitochondrial disease (MTD) and in some cases the only clinical abnormality. Although specific mtDNA mutations affecting tRNAleu have been identified in MTD associated with DCM, it is not known whether underlying variations in mitochondrial DNA predispose to isolated DCM. In other disorders ancestrally related founder mitochondrial haplotypes associate with disease susceptibility (eg type 2 diabetes). Clustering of particular mitochondrial haplotypes with idiopathic dilated cardiomyopathy would suggest possible pathogenic founder mutations of mtDNA.

We evaluated mitochondrial variants within the variable non-coding region of mtDNA in 24 unrelated South African DCM patients aged 16–79 yrs and 19 age-matched normal South African controls. There was no apparent MTD, autosomal dominant inheritance, or diabetes. Echocardiography and right and left heart catheterisation was used to confirm diagnosis. A 400 bp hypervariable region in the large noncoding region of mtDNA was amplified from leucocyte DNA from DCM patients and controls using PCR and the products sequenced with an automated sequencer.

Sequence analyses confirmed 4 different African haplotypes in both DCM patients and controls. A polymorphism at position 16189 which is associated with diabetes was equally prevalent in DCM patients and controls. However, there was a significantly higher prevalence ($p = 0.046$) of an uninterrupted long C-tract associated with the 16189 polymorphism which frequently gave rise to length variation in DCM patients (n = 11; 46%) compared to controls (n = 3; 16%).

The co-segregation of the long C-tract haplotype with DCM suggests that there may be a founder mitochondrial DNA haplotype which predisposes to DCM and that variation in this region of mtDNA may subtly affect mitochondrial function.

P3400 Removal of cardiodepressant factor(s) in dilated cardiomyopathy by immunoadsorption

Alexander Staudt, Thomas Spielhagen, Wolf V. Dörffel, Verena Stangl, Peter Bramlage, Gert Baumann, Stephan B. Felix. *Department of Internal Medicine, Charité, Humboldt University, Berlin, Germany*

Six patients with dilated cardiomyopathy (DCM) received immunoadsorption (IA) therapy. During IA, the cardiac index increased from 2.3 to 2.9 l/min/m^2 ($p < 0.05$), and systemic vascular resistance decreased from 1373 to 1028 dyne*s*cm^{-5} ($p < 0.05$). The underlying mechanisms of these haemodynamic effects as mediated by IA remains unclear.

Methods: In-vitro experiments were performed to determine the influence of factor(s) (>100 KD) eliminated by IA in DCM patients on the intracellular cytoplasmatic calcium transient ($[Ca^{2+}]_{i\ syt}$-$[Ca^{2+}]_{i\ dia}$) and on myocyte shortening of isolated, fieldstimulated (1 Hz; 2 ms; 10–30 V) rat cardiac myocytes. IA was also performed with the blood of 6 healthy donors (controls). We investigated the effects of factor(s) (>100 KD) in the irrigation solution (IS) of IA columns on myocyte shortening and on calcium transient of myocytes loaded with CA^{2+}-sensitive fluorescent probe, (Fluo-3AM). IS was dialysed (MWCO 100 KD, 1:100, 1:1000) and heated (56°C for 30 min) for inactivation of complement. After incubation of cardiac myocytes with IS (1:30; 1:20; 1:10; 1:5; 1:2), myocyte shortening and calcium transient were analysed by confocal laser scanning microscopy (125 images/sec).

Results: IS of DCM patients (n = 6) caused immediate and dose-related decrease of calcium transient (1:30: 88.3%; 1:2: 65.7% – $p < 0.05$) and of myocyte shortening (1:30: 80.3% 1:2: 64.8% – $p < 0.05$). In contrast, IS of controls (n = 6) did not influence calcium transient and myocyte shortening of cardiac myocytes. In IS, different cytokines (e.g., TNF-alpha, interleukin 6, 8 and 10) were not detectable.

In conclusion, IA eliminates cardiodepressant factor(s) in DCM.

P3401 Tumor necrosis factor-alpha (TNF) expression in idiopathic dilated cardiomyopathy (IDCM): correlation to extend of myocardial inflammation

H. Sigusch, M.H. Lehmann, U. Schnittler, D. Reinhardt, O. Gastmann, H.R. Figulla. *Internal Medicine Dept., University of Jena, Jena, Germany*

Cardiac overexpression of TNF in transgenic mouse models resulted in a phenotype of systolic dysfunction with or without infiltration by inflammatory cells. In these models myocardial expression of TNF regulated the extend of inflammatory cell infiltration.

To investigate the relationship of myocardial inflammation and TNF we determined TNF expression (mRNA and protein) in 14 consecutive patients with IDCM who underwent endomyocardial biopsy. Two groups were compared: A group of patients (n = 8) without inflammation by immunohistological evaluation and a group (n = 6) with inflammation. Myocardial TNF mRNA expression was determined by competitive RT-PCR, TNF protein was detected by immunohistochemistry, TNF serum levels were determined by ELISA. Results are summarized in the table.

Results:

	IDCM with inflammation (n = 6)	IDCM without inflammation (n = 8)	P-value
Age (yrs)	50.8 (2.7)	46.6 (5.1)	0.487
Sex (female/male)	1/5	1/7	
Ejection fraction (%)	39 (8)	43 (8)	0.711
TNF serum conc. (pg/mL)	3.0 (0.55)	1.35 (0.20)	0.017
TNF mRNA (arbitrary unit)	1.54 (0.22)	0.81 (0.09)	0.020

Data are given as mean (SEM) and were analyzed using unpaired two-tailed t-test. A $P < 0.05$ indicated that significant differences existed.

In conclusion, TNF expression and serum levels were linked to the extend of inflammatory activation within the myocardium. In analogy to transgene models, it can be speculated that TNF itself might regulate the recruitment of inflammatory cells in human idiopathic dilated cardiomyopathy, too.

P3402 Cytotoxic perforin+ and TIA-1+ infiltrates are associated with cell adhesion molecule expression in dilated cardiomyopathy

M. Noutsias, C. Badorff, P.L. Schwimmbeck, U. Kühl, H.P. Schultheiss. *Cardiology Dept., University Hospital Benjamin Franklin, Berlin, Germany*

Dilated cardiomyopathy (DCM) is etiopathogenically linked to inflammatory cardiomyopathy (InfCM), being characterized by cardiac failure with evidence for intramyocardial inflammation. We recently reported that the diagnosis of InfCM based on CD3+/CD2+ infiltrates does not reflect cytotoxic T lymphocytes (CTLs: perforin+ and TIA-1+ phenotypes).

Methods and Results: Immunohistochemically stained endomyocardial biopsies obtained from n = 97 DCM patients were evaluated for various phenotypes of infiltrates and expression of endothelial cell adhesion molecules (CAMs). Biopsies superceding >7.0 CD3+/CD2+ lymphocytes/mm^2 were considered positive for InfCM (n = 45, 46%) and those with concurrent abundance of >3 endothelial CAMs (n = 63, 65%) positive for CAMs, the two diagnostic approaches correlating significantly with one another ($p = 0.0002$). Whereas CTLs did not correlate with the InfCM criteria (perforin+: $p = 0.78$; TIA-1+: $p = 0.37$), perforin+ ($p = 0.0002$) and TIA-1+ CTLs ($p < 0.0001$) correlated with CAMs evaluation. CTLs did not correlate with CD3+, CD2+, CD4+, CD8+ lymphocytes and Mac-1+/27E10+ macrophages ($p > 0.05$), but with CD18+, LFA-1+, VLA-4+ lymphocytes and CD57+ NK-cells ($p < 0.02$). Except for HLA class I and HLA DR, CTLs correlated with endothelial CAMs (ICAM-1, VCAM-1, LFA-3, CD29, CD62E and CD62P; $p < 0.01$).

Conclusions: In contrast to the diagnosis of InfCM based on immunologically naive CD3+/CD2+ lymphocytes, the CAMs based approach does also reflect perforin+/TIA-1+ intramyocardial infiltrates in DCM. These CTLs coexpress adhesion related lymphocyte activation phenotypes (b2-integrins, VLA-4) and NK-cellular antigens. Our data are in accordance with current immunological concepts repealing the formerly postulated dichotomy of adhesion and secretory events in the lethal attack exerted by CTLs.

P3403 Human endothelial cells as tool for the detection of β1 mimetic autoantibodies in patients with dilated cardiomyopathy

D. Mueller, K. Plötze, T. Christ, R. Henssge. *University Dresden, Cardiovascular Institute, Dresden, Germany*

Background: Autoantibodies (AA) of β1 receptors are thought to play a pathogenic role in patients with dilated cardiomyopathy (DCM).

The β1 receptor stimulation leads to an increased level of cAMP resulting in a raised heart rate. The measurement of the modulation of beating frequency in cultured animal myocytes was used to detect the absence or presence of β1 AA. Up to now, no system was aviable which allows to test human β1 AA in human cells. It was shown that human umbilical vein endothelial cells (HUVECs) carry β1 receptors.

The aims of our study are wheather the β1 receptors in HUVECs are functionally coupled to the intracellular cAMP level and wheather in the serum of DCM patients an autoantibody could be detected which imitates a β1 stimulating effect.

Methods: We used sera from 10 human donors, 3 healthy volunteers and 7 DCM patients with markedly reduced left ventricular function (LVEF < 20%). The IgG fraction was isolated by ammonium sulfate precipitation (saturation of 33%). The precipitates were washed, dissolved in physiological buffer and dialyzed for 72 h. HUVECs of the 2nd passage were incubated with the IgG fractions for 5 min in the presence of phosphodiesterase inhibitors (IBMX 10 μM, RO-20–1724 10 μM). The cAMP level was measured by a commercial enzyme immunoassay kit. As internal standard we used isoprenalin (1 μM, 5 min), as selective β1 antagonists bisoprolol or metoprolol (1 μM, 15 min prior to stimulation).

Results: Isoprenalin stimulates the cAMP-production in HUVECs in a concentration dependend manner and is reduced to the control level by coincubation with metoprolol. The IgG fraction from 6/7 DCM patients lead to a distinct increase of the cAMP levels. The stimulation of cAMP production is reduced by preincubation with the antagonists bisoprolol or metoprolol. The IgG fraction of 2/3 healhty volunteers has no stimulating effect on the cAMP level, however, in one case an increase of cAMP level was observed.

Conclusion: A stimulating effect of β1 agonists (drugs) on the cAMP level can be measured in human endothelial cells. Therfore this cell type offers a tool to evaluate the β1 mimetic effect of AA. Indeed, IgG fractions from serum of DCM patients show distinct stimulating effects on the cAMP levels mediated by β1 receptors. These findings demonstrate in human cells for the first time the β mimetic effects of autoantibodies in DCM patients.

P3404 Polymorphisms in the β1-, β2- and β3-adrenergic receptor genes among patients with congestive heart failure

Y. Magnusson, M. Börjesson, E.L. Kärrstedt, A. Hjalmarson[1], B. Andersson[1]. *Wallenberg Laboratory, Gothenburg; [1]Cardiology Dept, Sahlgrenska University Hospital, Gothenburg, Sweden*

Genetic polymorphisms have previously been defined in the β2- and β3-adrenergic receptor (βAR) genes, whereas no polymorphisms have been described in the β1AR gene. We searched for possible polymorphisms in the β1-receptor gene by PCR amplification and automated sequencing of DNA from peripheral leucocytes, and found two previously undetected mutations. 185 patients with heart failure and 76 healthy controls were genotyped for the novel β1-polymorphisms and for defined β2- and β3- polymorphisms by RFLP and hybridization. The association with long-term survival was investigated.

Results: See table.

Genotypes in patients with heart failure

	β1AR		β2AR		β3AR
	aa N-term	aa C-term	aa16	aa27	aa64
Wildtype (n)	122	10	25	54	167
Mutation (n)	61	174	159	126	18
Survival	p = 0.004	n.s.	n.s.	n.s.	n.s.

aa = aminoacid, Mutation = mutation in its heterozygote and homozygote forms

The allele frequency was not significantly different between patients and controls for any of the polymorphisms.

Conclusion: We have discovered two novel genetic mutations in the β1-receptor gene, one of which was significantly associated with improved 5-years survival. A possibly defect in the function and decreased sensitivity of the β1-receptor might explain this unexpected association.

P3405 Association of preformed IgG3 antimyosin antibodies to endocardial infiltrates after heart transplantation for patients with idiopathic dilated cardiomyopathy

R.S. Warraich, A. Pomerance, N. Banner, A. Khaghani, M.J. Dunn, M.H. Yacoub. *Department of Cardiothoracic Surgery, NHLI of Imperial College, Royal Brompton and Harefield Trust, Harefield Hospital, Middlesex, UK*

The significance and the mechanisms of endocardial infiltrates (EI) in cardiac allografts remains uncertain. Dilated cardiomyopathy patients (DCM) with statistically raised levels of preformed autoantibodies against myosin heavy chain (mhc) have previously been shown to be have a greater frequency of rejection episodes following cardiac transplantation (Tx). The relationship of these antibodies to the incidence of EI in endomyocardial biopsies (EMB) in patients has not been evaluated.

The **Objective** of the study was to determine whether the frequency of EI was related to the indication for Tx, the rejection status and to ELISA levels of preformed antimyosin antibodies at class and subclass level.

Results: - Detection of EI (no. and frequency) in EMB from patients Tx for DCM, (n = 64) was higher than in patients with IHD (n = 53); 61%, 1.54 ± 0.58 *vs* 45%, 0.90 ± 0.37 respectively. Frequency of EI in pts with and with rejection was different in the two groups; 1.86 ± 0.64 *vs* 0.58 ± 0.33, $p < 0.05$ in the DCM group and 0.9 ± 0.49 *vs* 1.0 ± 0.47, p = NS in pts transplanted for IHD. Association of patients with EI to preformed antibody +ve or −ve status in the DCM group differed from IHD patients. Frequency of EI between IgM antibody positive and negative patients did not differ in the groups transplanted for DCM or IHD. A select group of patients transplanted for DCM had a higher activity of preformed IgG3 Abs. Incidence of EMB with EI to IgG3 positive DCM patients was significantly higher than IgG3 negative pts. IgG3 Ab positive patients also had a greater incidence of ISHLT grade 3 as the initial episode of rejection than did Ab negative patients: 50% (5/10) *vs* 15% (6/40), $p < 0.05$.

Conclusion: Pro-inflammatory characteristics of preformed IgG3 Abs in serum of patients with DCM may influence the immunological response to the development of EI and the rejection process after cardiac transplantation.

P3406 Allosteric effects of domain-specific human, rabbit, and monoclonal mouse antibodies on β1-adrenergic receptor function

R. Jahns, V. Boivin[1], T. Krapf[1], F. Boege, M.J. Lohse[1]. *Med.Poliklinik; [1]Institute of Pharmacology, University of Würzburg, Germany*

Purpose: Antibodies capable of modulating the response of certain G protein-coupled receptors have been found in several human autoimmune diseases. The aim of our study was to further elucidate the possible pathophysiological significance of (auto-) antibodies targeting the *human* β1-adrenergic receptor (anti-β1-AR), which is still discussed controversially.

Methods: To investigate the possible effects of anti-β1-AR on receptor function, we generated *heterologeous* antibodies to selected domains (amino-, carboxyterminus, and 2nd extracellular loop) of the human β1-AR in rabbits (polyclonal) and mice (monoclonal). Their immunological and functional properties were characterized using synthetic receptor-peptides as well as intact recombinant *human* β1-AR, and compared with those of selected anti-β1-AR autoantibodies (n = 8), representative for a previously defined subgroup of cardiomyopathic patients.

Results: Rabbit, mouse and human antibodies targeting the 2nd extracellular receptor domain (EC_{II}) preferentially bound to a native receptor conformation, and all of them impaired radioligand [^{3}H]-CGP 12177 binding to the receptor. However, their effects on receptor-mediated signaling differed considerably: rabbit and mouse anti-β1-EC_{II} decreased both basal *and* agonist-stimulated intracellular cAMP-production (and corresponding protein kinase A activities) in a concentration-dependent manner; in contrast, all patient autoantibodies increased basal, and most of them (n = 6/8) even further increased agonist-stimulated receptor activity, *i.e.* acted as receptor-sensitizing agents. Besides, we also detected some partial agonist-like human anti-β1-EC_{II}, which *in*creased basal but *de*creased agonist-simulated receptor activity (n = 2/8).

Conclusion: Antibodies recognizing a same small epitope of the β1-AR can have very divergent allosteric effects on the full scale from inhibitory to agonist-promoting activities. Human anti-β1-EC_{II} might activate cardiac β-AR also *in vivo* and thus be of pathophysiological significance in certain heart diseases.

P3407 Dobutamine stress echocardiography in patients with dilated cardiomyopathy

C.M. Schannwell, F.C. Schoebel, G. Plehn, R. Marx, S. Heggen, M. Schmitz, Ch. Perings, M. Leschke, B.E. Strauer. *Clinic of Cardiology, Heinrich Heine University Düsseldorf, Germany*

Background: Dilated cardiomyopathy (DCM) and coronary artery disease are the most common causes of congestive heart failure. Dobutamine stress echocardiography (DSE) is routinely used to evaluate the contractility in patients (P) with ischemic heart disease. The aim of this study was to investigate whether contractile reserve evaluated by DSE is a powerful prognostic predictor of P with DCM.

Methods: Therefore 41 patients (49 ± 7 years) with DCM and congestive heart failure (NYHA III) were examined. After optimal medical treatment (vasodilators, diuretics) and avoiding inotropic or β-blocking drugs for one week echocardiography (at rest and under low-dose infusion) was performed. Using M-mode echo-cardiography morphological parameters and systolic function (fractional shortening FS; %) were determined. LV diastolic function was assessed by Doppler-echocardiographic analysis of the diastolic transmitral flow: the maximal early (V_E) and late velocity of diastolic filling; the E/A-ratio; the deceleration (DT) and the isovolumetric relaxation time (IVRT). To determine the contractility reserve we measured the ejection fraction (EF), LV enddiastolic and endsystolic volume at rest and during DSE. The contractility reserve index" was calculated according to the formula: EF_{stress} minus EF_{rest} divided by the EF_{rest}. The result is multiplicated with 100.

Results: Impaired FS (15 ± 2%), increased LV cavity size (LV enddiastolic diameter: 69 ± 5 mm), diastolic dysfunction were documented in all P. After a follow-up period of 25 ± 4 months the clinical conditions were unchanged in 16 P, improved in 8 P and worsened in 17 P (2 P died of sudden cardiac death). Multivariate stepwise logistic regression analysis showed that the only the "contractility reserve index" was independently related to the prognosis of P with DCM.

Conclusion: P with DCM and a poor β-adrenergic contractile reserve ("negative contractility reserve index") had an unfavorable outcome. "Contractility reserve index" was evaluated by DSE seems to be prognostic significant in P with DCM.

P3408 Alterations in circulating plasma adenosine in dilated cardiomyopathy: a baseline and dipyridamole stress study

A. Pingitore, L. Pratali, C. Petersen, F. Guideri[1], F. Laghi Pasini[1], A. Varga, E. Picano. *Institute of Clinical Physiology, Pisa; [1]Internal Medicine Department, Siena University, Siena, Italy*

Dipyridamole is a popular vasodilator stress which acts through accumulation of endogenous adenosine mainly produced by the myocardium. Heart failure is characterized by chronically increased adenosine levels, which have been putatively involved in the initiation and progression of disease.

Aim of the study was to assess whether patients with dilated cardiomyopathy (DC) have an abnormal response in terms of endogenous plasma adenosine (ADO) accumulation, to an adenosinergic stress as high dose dipyridamole when compared to coronary artery disease (CAD) patients.

Two groups of patients were studied: I (n = 9 pts, mean age 66 ± 6 years) with idiopathic DC, dyspnea NYHA class 2 to 4, EF < 35%, and II (n = 15 patients, mean age 55 ± 10), with EF>50% and known or suspected CAD. The 2 groups differed in plasma ADO at baseline (I = 281 ± 25 vs II = 211 ± 9 nM/l, $p < 0.0001$) and at peak stress (I = 422 ± 124 nM/l vs II = 756 ± 105 nM/l, $p < 0.0001$), with DC patients showing a blunted% increase in plasma ADO after dipyridamole (I = 123 ± 21% vs II = 367 ± 67, $p < 0.0001$) and an earlier time to peak stress (I = 2' vs II = 12' from onset of infusion).

In conclusion, a profound derangement in adenosinergic system is detectable in patients with DC in whom plasma adenosine levels are abnormally elevated at baseline and dipyridamole-induced plasma adenosine increase shows an earlier peak, a flat response and a lower plateau when compared to CAD patients.

P3409 The elusive link between coronary flow and myocardial contractile reserve in idiopathic dilated cardiomyopathy: a transthoracic and transoesophageal echo study

L. Pratali, A. Pingitore, C. Petersen, E. Adamo, A. Varga, E. Picano. *Institute of Clinical Physiology, Pisa, Italy*

A defect in systolic myocardial function and impairment in coronary flow reserve due to microcirculatory disturbances characterize idiopathic dilated cardiomyopathy (DC).

Aim of this study was to assess the interrelationship between contractile reserve and coronary flow reserve (CFR), assessed by TTE and TEE stress echo respectively, during dipyridamole test in DC patients.

Two groups of pts were evaluated: I, with idiopathic DC (24 patients), dyspnea NYHA class 2–4, EF < 35%, age 60 ± 13 years; and II, healthy controls (11 subjects) with EF >50%, age 57 ± 8, angiographically normal coronary arteries and chest pain syndrome of non-cardiac origin. All patients underwent transthoracic and transesophageal echocardiography monitoring during dipyridamole (DIP) infusion, up to 0.84 mg/kg over 10'. Wall Motion Score Index (WMSI) was calculated at rest and peak stress in a 16 segment model of left ventricle, each segment ranging from 1 = normal to 4 = dyskinetic. CFR was reduced in DC (Group I = 2.1 ± 0.8 vs II 3.2 ± 0.9, $p < 0.002$). Within group I there was no interpatient correlation between changes in CFR and left ventricular contractile response ($r = 0.4$, p = ns). Of the 7 functional non-responders (rest-stress variation in WMSI <0.44), 4 also were physiologic non-responders (CFR < 2); of the 17 functional responders (WMSI > 0.44), 11 also were physiologic non-responders (CFR < 2).

In conclusion, DC patients as a group show a significant impairment in coronary flow reserve in spite of normal coronary arteries. At individual patient analysis, contractile myocardial response and physiologic flow response to DIP stress are substantially heterogeneous and asymmetrically affected in DCC patients.

P3410 Stable improvement of left ventricular function after partial left ventriculectomy during medium-term follow-up: results of an invasive study

Z. Popovic, M. Miric, M. Bojic, P. Otasevic, A.N. Neskovic. *Cardiovascular Research Center, Dedinje Cardiovascular Institute, Belgrade, Yugoslavia*

While partial left ventriculectomy (PLV) efficiently reduces left ventricular (LV) volumes and increases EF, the duration of this effect is not known. We report medium-term effects of PLV on LV function in 16 patients (mean age 47, 13 men) with end-stage heart failure due to non-ischemic dilated cardiomyopathy. Right heart catheterization and ventriculography were performed preoperatively and at early (range 10–18 days) and medium-term (range 6–9 months) follow-up (F/U).

Results: LV end-diastolic (EDVi) and end-systolic (ESVi) volume indexes, EF, systolic LV major-to-minor axis ratio (L/D ratio) and pulmonary capillary wedge pressure (PCWP), before PLV (preOp) and at early and medium-term F/U are shown in the Table. EDVi, ESVi, EF and L/D ratio did not change between early and medium-term F/U ($p > 0.05$, for all).

Early and medium-term effects of PLV

	EDVi (ml/m²)	ESVi (ml/m²)	EF (%)	L/D Ratio	PCWP (mmHg)
Preop	166 ± 30	127 ± 25	24 ± 7	1.44 ± 0.27	20 ± 10
Early F/U	100 ± 22*	60 ± 15*	40 ± 11*	1.93 ± 0.32*	15 ± 5*
Mid-term F/U	102 ± 15*	63 ± 12*	38 ± 8*	1.86 ± 0.28*	19 ± 8

*, $p < 0.05$ vs. preop

Conclusion: PLV leads to reduction of LV volumes and stable improvement in EF and LV geometry during medium-term F/U.

P3411 Left ventricular inotropic reserve predicts improvement in ejection fraction after long-term carvedilol therapy in non-ischaemic cardiomyopathy

T. Ramahi, M. Longo[1], K. Rohlfs, K. Engles, S. Carolan, F. Wackers. *Cardiovascular Medicine Dept., Yale School of Medicine, New Haven CT, USA; [1]Cardiologia, Ospedale Di Rivoli, Rivoli, Italy*

In non-ischemic cardiomyopathy (NICM) chronic beta-blocker therapy is associated with significant improvement in left ventricular (LV) ejection fraction (EF). The purpose of this study was to determine whether higher baseline LV inotropic reserve, defined as the increase in LVEF in response to intravenous dobutamine infusion (DoDEF), predicts the improvement in LVEF after long-term carvedilol therapy in patients with NICM. Fifteen patients underwent baseline assessment of LVEF, at rest and after a 10-minute intravenous infusion of dobutamine at 10 microgm/kg/min, using equilibrium radionuclide ventriculography technique. Age 46 ± 12 yr, 9 males, functional class (FC) 2.6 ± 0.5, duration of CHF (Dur) 60 ± 34 mo, LVEF 18 ± 6%, DoDEF 9 ± 8. Carvedilol was started and up-titrated to the maximally-tolerated or target dose, 62 ± 30 mg daily, and maintained for 13 ± 7 mo. Resting LVEF was measured after this follow-up period. Resting LVEF increased to 29 ± 12%. Patients were divided into 2 groups based on baseline DoDEF: above and below mean. Patients with higher than average baseline DoDEF (group 2) had a significantly higher improvement in LVEF (DEF 19 ± 8) compared to patients with lower than average baseline DoDEF (Group 1, DEF 8 ± 8), p = 0.02, despite comparable other baseline characteristics.

Group 1:	n = 11			
Baseline:	Dur 68 ± 36,	EF 17 ± 5,	DoΔEF 6 ± 3,	FC 2.5 ± 0.5
Follow-up:	Dose 57 ± 30,	EF 25 ± 10,	ΔEF 8 ± 8,	p = 0.03 for EF increase
Group 2:	n = 4			
Baseline:	Dur 40 ± 19,	EF 22 ± 7,	DoΔEF 19 ± 12,	FC 2.5 ± 0.6
Follow-up:	Dose 75 ± 29,	EF 41 ± 11,	ΔEF 19 ± 8,	p = 0.03 for EF increase

Inter-group comparison: p = NS for Dur, baseline EF, FC, and dose; p = 0.02 for follow-up EF and p = 0.04 follow-up ΔEF.

Conclusion: NICM patients with higher LV inotropic reserve derive higher improvement in LVEF from carvedilol therapy.

P3412 Mutation analysis of cardiac and skeletal actin genes in dilated cardiomyopathy

B.M. Mayosi, S.S. Khogali, B. Zhang, H. Watkins. *Department of Cardiovascular Medicine, John Radcliffe Hospital, Oxford, UK*

Idiopathic dilated cardiomyopathy (DCM) is a syndrome characterised by enlargement and impaired contractile function of the heart without a definable cause. It is a major cause of heart failure, and one of the most common indications for heart transplantation. DCM is familial in about a quarter of cases, suggesting that genetic factors play an important role in its aetiology.

Recently, missense mutations in the gene for cardiac actin have been identified in members of 2 small unrelated families with DCM, and a causal role postulated. However, the frequency of cardiac actin mutations in patients with DCM is unknown. Furthermore, cardiac and skeletal alpha actin genes are co-expressed in the sarcomere of cardiac myocytes; and given the predominant expression of the skeletal actin isoform in the adult human heart, we postulated that the skeletal actin gene was now implicated as a candidate gene in DCM.

Using single strand conformation polymorphism (SSCP) analysis and direct sequencing of abnormal conformers, we screened all exons of the cardiac and skeletal actin genes for mutations in 11 affected subjects from 8 families with autosomal dominant DCM, and 46 unrelated probands with idiopathic DCM. Although a number of silent polymorphisms were identified, no missense mutations were detected in either actin gene.

These results suggest that cardiac actin gene mutations are not a major cause of idiopathic DCM, and provide no support for the possible involvement of the skeletal actin isoform in this disease.

P3413 Impaired coronary vasodilating capability is a mechanism for worsening of left ventricular function during stress in early stage dilated cardiomyopathy

D. Neglia, M. Gallopin, M.G. Trivieri, A. Giorgetti, M. Bartoli, G. Sambuceti, P. Salvadori, N. Nista, O. Parodi, A. L'Abbate. *CNR Institute of Clinical Physiology, Pisa, Italy*

Patients with early stage dilated cardiomyopathy (DCM) show a blunted myocardial blood flow (MBF) response to atrial pacing tachycardia (Pac) and i.v. dipyridamole (Dip) possibly due to coronary microvascular dysfunction. Aim of the present study was to assess whether an abnormal coronary vasodilating capability is also associated with an impaired left ventricular (LV) functional response to stress in these patients.

Methods: The study population consisted of 17 DCM patients (age 43 ± 10, 13 males) (NYHA class I-II, angiographically normal coronary arteries, LV EF < 50%) and of 8 normal subjects (age 46 ± 8, 4 males). LV function was assessed at rest (R) and durimg Pac by equilibrium radionuclide angiography. Global LV EF as well as regional LV EF in the septal (S) and in the postero-lateral (PL) walls were measured. On the same day, absolute global and regional MBF were also obtained by 13N-Ammonia and positron emission tomography at R, during Pac and after Dip (0.56 mg/kg in 4 min).

Results: Heart rate, mean arterial pressure and rate pressure product at R and during Pac were not significantly different between patients and normals. Patients, as compared to normals, showed a similar global MBF at R (0.85 ± 0.24 vs 0.91 ± 0.14, ns) but a lower MBF during Pac (1.22 ± 0.58 vs 1.96 ± 0.72, $p < 0.01$) and after Dip (2.02 ± 0.76 vs 3.64 ± 0.75, $p < 0.01$). Patients also showed a decrease of global LV EF during Pac (from 36 ± 9 to 32 ± 9, $p < 0.01$) which was not seen in normals (from 58 ± 5 to 60 ± 6, ns). There was a significant correlation between regional MBF increase (Pac/R MBF) and regional LV EF change during pacing (Pac-R LV EF) in the S ($r = 0.65$, $p < 0.01$) but not in the PL wall ($r = 0.21$, ns).

Conclusions: Impaired coronary vasodilating capability is a mechanism for worsening of regional and global LV funcion during stress in patients with early stage DCM.

P3414 Mild dilated cardiomyopathy: benign or malignant disease?

G. Draganic, P.M. Seferovic, A.D. Ristic, D.D. Zamaklar. *University Inst. for Cardiovasc. Dis., Belgrade, Yugoslavia*

It was suggested that mild dilatation of left ventricle (LV) or slightly decreased LV ejection fraction (EF) are the major features of mild dilated cardiomyopathy (MDC). Furthermore, it was believed that its natural history, as well as the long-term outcome are advantageous in comparison to the advanced disease. In order to elucidate this issue we studied 40 pts, 80% males, mean age 50.4 ± 12.2 yrs, LV enddiastolic dimension 6.3 ± 0.8 cm, LV endsystolic dimension 4.9 ± 1.0 cm, LV EF = 48 ± 8.9%, mean symptom duration 36.3 ± 26.5 months. At initial assessment all pts underwent extensive clinical work-up, cardiac catheterization and EMB and were followed for 132 (34.8 ± 26.3) months, considering cardiac death and heart transplantation as end-points. Complete follow-up (FU) data were obtained for 20 pts (50%); 4/20 pts (25.0%) died and none was transplanted. According to LVEF (echocardiography) at the end of FU, pts were classified into four categories: improved, stable, deteriorated, and nonsurvived. At the end of FU improved, stable, deteriorated, and non-survived pts were found in 25%, 35%, 20%, and 20%, respectively. The analysis of LVEF differences in all four groups at the entry, did not demonstrate statistical significant difference ($F = 1.5$, $p > 0.05$). Improved IDC patients had initial LVEF 47.4 ± 5.0%, while at the end of FU 58.6 ± 6.8% ($t = -3.4$, $p < 0.05$). In stable IDC patients LVEF at the entry, and at the end of FU was 48.4 ± 9.3% and 48.6 ± 9.5%, respectively ($p > 0.01$). In IDC group who deteriorated the LVEF values were 53.0 ± 7.9% at the start of the study and 40.0 ± 8.3% at the end ($t = 3.9$, $p < 0.05$). LVEF of the patients who did not survive FU was 42.2 ± 1.9% at the entry.

In conclusion, this study MDC demonstrated that MDC is malignant disease.with significant number of patients who deteriorated or died. LVEF at the entry could not predict clinical outcomes, and therefore a different mechanism in the ominous clinical course e.g. arrhythmic, need to be considered.

P3415 Existence of a third chromosomal loci responsible for pure familial dilated cardiomyopathies

N. Sylvius, L. Mangin[1], C. Gayet[2], P. Charron, A. Benaiche, M. Peuchmaurd, L. Duboscq Bidot, J. Beckmann[3], F. Tesson, M. Komajda. *Pavillon Rambuteau, Lab. Genetique et Insuff. Card., Paris; [1]Service de Pharmacologie Clinique, Hopital Henri Mondor, Creteil; [2]Service de Cardiologie, Hopital de la Croix Rousse, Lyon; [3]Centre National de Genotypage, Evry, France*

Dilated cardiomyopathies (DCM) represent the first cause of heart transplantation. At least 25% of cases have a familial inheritance. Previous studies have demonstrated the genetic heterogeneity of the disease. Indeed, eight chromosomal locations accounting for pure forms (1q32, 9q13-22) or associated with cardiac and/or muscular disorders (1p1-q1, 2q11-22, 3p22-25, 6q23, 10q21-23) have been identified as well as mutations in cardiac actin gene in two unrelated families. Genetic linkage analysis were carried out on eight families from the French panel (157 individuals including 39 affected members and 25 unknown) with 26 microsatellite markers located in the eight known morbid loci in order to check the potential linkage between these loci and the disease in the families. Two families (18 and 15 members) are potentially linked to the 10q21-23 locus and one family (10 members) to the 3p22-25 locus. A linkage to the markers analyzed in the 6q23 and 9q13-22 regions was excluded for the eight families. For two families (21 and 45 members), all the known morbid loci can be excluded. Moreover, the involvement of the cardiac actin gene in the disease was excluded by SSCP analysis in these eight families. We can, therefore, conclude that there is at least one new chromosomal region responsible for DCM. So, a genomewide scan was carried out with 342 microsatellite markers on the most informative family (45 members including 10 affected). Ninety percent of the genome of this family has been excluded. The identification of the third locus responsible for pure DCM is ongoing.

P3416 Immunohistochemical changes in dilated cardiomyopathy during immunoadsorption therapy

Alexander Staudt, Wolf V. Dörffel, Verena Stangl, Michael Sachse, Karl Stangl, Gert Baumann, Stephan B. Felix. *Department of Internal Medicine, Charité, Humboldt University, Berlin, Germany*

Seven patients with dilated cardiomyopathy (DCM) received a immunoadsorption (IA) therapy. During IA, the cardiac index increased from 2.2 to 2.8 l/min/m^2 ($p < 0.05$). The aim of this study was to analyse changes of chronic inflammatory process in myocardium induced by IA.

Methods: 7 patients with dilated cardiomyopathy (NYHA III–IV, ejection fraction <30%, stable medication) received one-time IA therapy at one-month intervals until month 3. Before and after (<7 d) IA therapy five right ventricular biopsies were obtained from all patients from the interventricular septum. Biopsies were fixed in 4% formalin and embedded in paraffin. The sections were 1 μm thick. In all cases, we excluded acute myocarditis according to the Dallas criteria. In addition to conventional histology, immunohistochemical staining was performed. The immunohistochemical staining procedure with the Labelled StreptAvidin-Biotin (LSAB) method was used for identification of inflammatory cells. The number of the cells were counted under high power magnification (400×) by two observers. The number of cells (cells/mm^2) was described as the mean value of ten counted high power fields. The following antibodies were used: anti CD3; -CD4; -CD8, CD45RO, HLA-DP.

Results:

	CD 3	CD 4	CD 8	CD45 RO
Pre IA	4.6	1.5	2.4	23.7
	(SE 1.2)	(SE 0.4)	(SE 0.6)	(SE 10.0)
Post IA	1.3	0.3	0.8	9.5
	(SE 0.4)	(SE 0.15)	(SE 0.2)	(SE 5.8)
	$p < 0.05$	$p < 0.05$	$p < 0.05$	$p < 0.05$

The reduction of inflammatory cells was paralleled by a decline of HLA-DP activation.

In conclusion, IA reduces the inflammatory process in myocardium of DCM patients.

P3417 Probing the immunological properties of the extracellular domains of the human beta1-adrenoceptor

R. Mobini, Y. Magnusson, A. Hjalmarson, J. Hoebeke. *Cardiology, Wallenberg Laboratory, Göteborg, Sweden*

The human beta1-adrenoceptor is an immune target for autoantibodies with functional activity in cardiovascular disease such as idiopathic dilated cardiomyopathy and Chagas' disease. Different epitopes on the extracellular domains are involved. To study the immunological and pharmacological properties of three different epitopes on the extracellular domains of the human beta1-adrenoceptor, rabbits were immunized with peptides corresponding to a large domain in the N-terminal part of receptor and to its first and second extracellular loops. In contrast to the two other peptides, the first extracellular loop did not have immunogenic properties but acted as a hapten. Antibodies, affinity-purified with the three synthetic peptides were able to significantly ($p < 0.001$) immunoprecipitate the solubilized receptors from transfected Sf9 cell membranes, confirming that they recognize the target receptor. While antibodies against the N-terminal domain did not inhibit the binding of a radiolabeled antagonist to the receptor, those against the first and second extracellular loop showed non-competitive inhibition ($p < 0.05$). Similarly, only the two latter antibodies against the first ($p < 0.01$) and second ($p < 0.001$) extracellular loops of the receptor exerted a specific agonist-like effect on the receptor as assessed on neonatal rat cardiomyocytes in culture. Our results are in accordance with those found for human anti-receptor autoantibodies with functional effects. We conclude that not all extracellular epitopes give raise to functional autoantibodies. We also suggest that the cross-linking between the loops is necessary for functional activity.

P3418 Angiotensinogen gene polymorphism in Caucasian probands with hypertrophic cardiomyopathy

F. Coccolo, P.M. Elliott, N.G. Mahon, C. Baboonian, S. Jeffrey[1], L. Bacchi Reggiani[2], C. Rapezzi[2], A. Branzi[2], B. Magnani[2], W.J. McKenna. *Cardiological Sciences, St George's Hospital Medical School, London; [1]Medical Genetics Unit, St George's Hospital Medical School, London, UK; [2]Institute of Cardiovascular Diseases, University of Bologna, Bologna, Italy*

Genetic polymorphisms in components of the renin angiotensin system (RAS) have been implicated in the expression of several cardiovascular diseases. The angiotensinogen (AGT) gene mutation with methionine to threonine substitution at codon 235 (M235T) has been associated with left ventricular hypertrophy in hypertension and in Japanese patients with non-familial hypertrophic cardiomyopathy (HCM). The aim of this study was to determine the effects of this polymorphism on Caucasian probands with HCM.

Methods: We conducted an allelic association study for angiotensinogen gene M235T polymorphism in 204 unrelated patients with HCM (44.6 ± 14.6 years, 40.2% females). Of these 92 (45%) had familial disease and 112 (55%) had no family history of HCM. As a control population we studied 244 healthy volunteers, without hypertension or left ventricular hypertrophy, matched to cases by ethnicity, age and gender. DNA was extracted from peripheral blood leukocytes and the exon 2 region of the AGT gene was amplified by PCR using allele-specific oligonucleotide primers, followed by restriction endonuclease digestion and gel electrophoresis.

Results: The AGT genotypes TT, MT and MM were present respectively in 18.6%, 49% and 32.4% of patients with HCM and in 17.2%, 52.9% and 29.9% of controls. The mean maximal left ventricular wall thickness of the three groups was 21.7 ± 5.6 mm, 20.7 ± 5.9 mm and 21.9 ± 6.3 mm respectively, p (ANOVA) = 0.348. Compared with a frequency of 44% among controls, the T allele frequency was 43% among all patients with HCM (chi2 = 0.024, p = 0.89), 45% in patients with non-familial HCM (chi2 = 0.041, p = 0.84) and 42% in subjects with familial HCM (chi2 = 0.111, p = 0.74) There was no significant difference between T allele frequency in patients with and without familial disease (chi2 = 0.242, p = 0.62). The T allele frequency in patients with HCM and a family history of hypertension was 27% vs 44% in patients with HCM and no family history of hypertension, chi2 = 1.671, p = 0.20. The relative risk of HCM between subjects with the TT genotype vs either the TM or MM genotype (odds ratio) was 1.1 [95% CI 0.6–1.7] for all HCM patients, chi2 = 0.1 and 0.9 [95% CI 0.5–1.8], chi2 = 0.001 in patients with familial HCM.

Conclusions: (a) Among Caucasian patients the M235T variant of the AGT gene is associated neither with familial nor non-familial HCM.

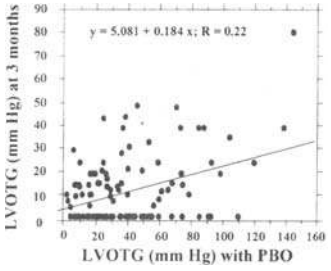
(b) The M235T polymorphism does not influence the degree of hypertrophy in Caucasians with HCM.

P3419 Intra-procedural myocardial contrast echocardiography: a routine procedure in catheter treatment for hypertrophic obstructive cardiomyopathy

L. Faber, H. Seggewiss, P. Ziemssen, A. Meissner, D. Horstkotte. *Department of Cardiology, Heart Center NRW, Ruhr-University of Bochum, Bad Oeynhausen, Germany*

Introduction: Catheter treatment (PTSMA) for HOCM requires the exact definition of the septal myocardium to be ablated. We compared the predictive value of MCE and probatory balloon occlusion (PBO) of the presumed target vessel (TV) in 128 patients (pts.) in whom both approaches were used.

Results: A satisfactory reduction of the left ventricular outflow gradient (LVOTG) was achieved in 117 of these pts. (91%; from 59 ± 33 to 13 ± 15 mm Hg; $p < 0.0001$). LVOTG with PBO was 40 ± 30 mm Hg ($p < 0.001$). There was only a weak correlation between the LVOTG with PBO and the LVOTG after 3 months (See figure). PBO-induced reduction of the LVOTG was >30% in 76 pts. (65%) and >50% in only 55 pts. (47%). In 2 pts. the TV had to be changed after MCE because of echo contrast remote from the septal target area, i. e. papillary muscles or left ventricular free wall segments.



Conclusions: In case of a positive intra-procedural MCE study, PBO adds little information with respect to target vessel selection in PTSMA for HOCM. Furthermore, MCE is able to exclude alcohol necrotization of myocardium remote from the septal target area.

RESULTS OF OPERATIONS AND INTERVENTIONS IN CONGENITAL HEART DISEASE

P3420 Predictors of the right ventricular failure in patients after atrial switch for complete transposition

B. Lubiszewska, P. Hoffman, E. Gosiewska, W. Szaroszyk, W. Piotrowski, J. Rółałski, W. Rułyło, K. Kubicka, J. Stodulski. *National Institute of Cardiology, The Children's Memorial Health Institute, Warsaw, Poland*

Systolic function of the anatomic right ventricle (RV) to sustain systemic pressure long term after Mustard or Senning procedure in patients (pts) with TGA is a main concern in long-term follow-up.

Aim: To assess RV impairment, and to find factors predicting RV failure in pts. with TGA after atrial switch.

Material and methods: 61 asymptomatic pts aged 8-25 years with simple TGA, in mean time 10.5 ± 2.6 years after Mustard or Senning procedure. In all pts chest X-ray, 12-lead ECG and 24-hour ECG Holter monitoring, 2-D and colour coded Doppler echocardiography were performed. Systemic RV function was assessed by radionuclide first-pass angiography; exercise capacity by treadmill test according to modified Bruce protocol.

Results: Mean rest RV ejection fraction (EF) was 36.1 ± 7.7% and left ventricular EF was 52.1 ± 9.4%. 17 pts had rest RVEF < 32% (mean 27.4%) and 44 pts had RVEF ≥ 32% (mean 39.6%). Exercise capacity in both groups was good (mean 10 METs). Univariate analysis showed that pts with lower RVEF (<32%) had enlarged heart size on X-ray (CTR 0.50 vs 0.47, p = 0.03) longer QRS duration (111.3 vs 96.8 ms, p = 0.006), and more frequently rhythm disturbances (nodal rhythm, atrial flutter, paced rhythm) (p = 0.009). Also the group with RVEF < 32% more often had moderate or severe tricuspid regurgitation. There was no correlation with LVEF, age at the surgery, follow-up time, exercise capacity. Multivariate logistic analysis revealed close correlation with rhythm disturbances (p = 0.009) and QRS duration (p = 0.026, odds ratio-0.95, and 95% confidence interval 0.91–0.99).

Conclusions: RV function is significantly impaired in more than 1/3 of asymptomatic pts after atrial redirection procedure for TGA.

The best variables predicting RV failure were rhythm disturbances and QRS duration.

P3421 Exercise capacity, ventricular function and myocardial perfusion 10-years after arterial switch operation

A. Kühn, M. Hauser, S. Braun, M. Beckmann, M. Schwaiger[1], J. Hess. *Department of Pediatric Cardiology, Deutsches Herzzentrum, Munich; [1]Nuklearmedizinische Klinik der Technischen Universität, Munich, Germany*

22 children (age 12.3 ± 2.2 years) with transposition of the great arteries (TGA) were investigated in mean 11.2 ± 2.9 years after arterial switch operation. Spiroergometry (treadmill, Bruce protocol) was performed in all patients; there was no significant difference in cardiopulmonary exercise capacity (anaerobic threshold, max. oxygen uptake) between patients and normal matched volunteers. On stress echocardiography there was a normal exercise induced increase of ventricular function in all patients; two of them had dyskinetic areas within the left ventricular myocardium. There was a significant increase of glycogenphosphorylase activity as a marker for myocardial ischaemia after exercise in five patients; four of those had adenosine induced perfusion defects in positron emission tomography (PET). Coronary flow reserve (CFR) was significantly reduced on PET scanning in all patients compared to normal healthy volunteers.

Conclusion: Children after arterial switch operation have a normal cardiopulmonary exercise capacity; nevertheless exercise induced ischaemia is apparent in some patients, whilst being clinically asymptomatic. Coronary insufficiency, reduced CFR and exercise induced perfusion defects may cause major problems in adulthood.

P3422 Evaluation of cardiac anatomy and function after long-term surgical repair of tetralogy of Fallot by magnetic resonance imaging

G. Casolo[1], S. Favilli[2], L. Rega[1], I. Pollini[2], A. Manetti[2], N. Villari[1]. *[1]Department of Clinical Physiopathology, University of Florence; [2]Paediatric Cardiology, Hospital Meyer, Florence, Italy*

Magnetic Resonance Imaging (MRI) represents a particularly useful diagnostic tool for the evaluation of cardiac malformations. After surgical repair, Tetralogy of Fallot (TOF) patients show several anatomical and functional abnormalities that mainly involve the right ventricle (RV) and therefore are not easy to be studied by conventional imaging tools. MRI seems to represent an ideal technique for the follow-up of such patients.

Methods: We studied 15 pts (11 males, 4 females), aged 22 ± 11 years (range 5–30), who were operated on 16 ± 8 years (range 2–21) before. All of them had been treated by a transannular patch. We also studied 15 age-matched controls. MRI was performed by using a conventional 0.5 T scanner. The study protocol included a spin-echo anatomical study, a gradient-echo functional evaluation of both ventricles, and a flow sensitive sequence positioned through the ascending part of the pulmonary artery. The functional examination included the evaluation of RV volumes, ejection fraction (EF) and mass.

Results: In all the pts MRI depicted the cardiac anatomy with an high image quality. Significantly higher RV volumes and masses than normals were seen in TOF pts. RV EF was preserved in 8 out of 15, while severely depressed function was seen in 4. These also had the greatest RV mass and exhibited a significant residual infundibular stenosis. Pulmonary regurgitation was a common feature (10 out of 15 pts) but was significant only in 3 pts (>1 Lt/min).

	Patients	Controls	p
RV diastolic volume (ml/m^2)	107 ± 41	83 ± 24	0.001
RV mass (g/m^2)	61 ± 8	28 ± 4	0.001
RV EF %	45 ± 11	58 ± 6	0.001
LV diastolic volume (ml/m2	86 ± 28	82 ± 18	0.05
LV EF %	58 ± 6	59 ± 3	0.05

Conclusions: Several unique anatomical and functional information can be detected by MRI in surgically treated TOF patients. RV function and mass appear to be strictly related to the degree of residual pulmonary stenosis and presence of pulmonary regurgitation.

P3423 Influence of surgical closure of atrial septal defects in adults on tachyarrhythmias

M. Vogel, F. Berger, A. Kramer, V. Alexi-Meshkishvili, P.E. Lange. *Congenital Heart Disease, Deutsches Herzzentrum, Berlin, Germany*

There is controversy about the benefit of surgery for atrial septal defects (ASD) in adults and its effect on the incidence of atrial flutter/fibrillation.Surface and 24 Holter ECGs before, early (3–7 days) and late (>6 months) after ASD closure performed at age 42.2 (18.5–74.9) years in 211 patients were examined.All consecutive patients seen for a 10 year period with ASD and pulmonary to systemic flow ratio >1.5:1 were reviewed.The age of ASD patients with no preoperative dysrhythmia was 39 ± 13 years, those with flutter were 54 ± 12 and those with fibrillation 59 ± 8 years old (p < 0.05).38 (19%) had atrial flutter/fibrillation as presenting symptom. There was no correlation between shunt size and incidence of flutter/

fibrillation. 4 patients (2 with flutter and 2 with fibrillation) had a stroke before ASD closure and 2 with fibrillation had transient ischemic attacks. The number of patients with atrial flutter decreased from 18 to 10(p = 0.04), whereas ASD closure did not lead to significant decrease in atrial fibrillation (28 before versus 21 patients after ASD closure). 1 patient with fibrillation had a stroke after ASD closure.Irrespective of rhythm ASD closure lead to an improvement in NYHA functional class (p = 0.001) but was associated with a 1% mortality.

Our data show that ASD closure in adults leads to signifanct decrease of atrial flutter and is thus beneficial as the risk for stroke is also decreased. In patients with atrial fibrillation, however, ASD closure late in adult life does not reduce incidence of atrial fibrillation so that in selected adults a right-sided Maze procedure at time of ASD closure may be warranted.

P3424 Transcatheter occlusion of the patent ductus arteriosus using the Amplatzer duct occluder: immediate and indermediate-term results

F. Hakim[1], Y. Goussous[1], A. Hiari[1], E. Basta[2], A. Zarayelyan[2], G.S. Tsaousis[2], B.V. Thanopoulos[2]. *Departments of Pediatric Cardiology; [1]"Queen Alia" Heart Institute, Amman, Jordan; [2]"Aghia Sophia" Childrens' Hospital, Athens, Greece*

In this study we report our immediate and intermediate-term results of transcatheter closure (TC) of patent ductus arteriosus (PDA) with the Amplatzer Duct Occluder (ADO). The design of other devices is not ideal for this purpose and their use has been associated with several drawbacks, especially in large PDA's.

Methods: Forty patients (pts), aged 4 months to 33 years, (mean = 6.4 ± 6.7 years) with a moderate to large, type A to E, PDA underwent attempted TC using the ADO. The device is a plug-shaped repositionable occluder made of 0.004 in nitinol wire mesh. It is delivered through a 6F long sheath. The mean PDA diameter (at its pulmonary end) was 3.9 ± 1.1 mm (range = 2.2–6.2 mm). All pts had color flow echocardiographic follow-up (FU) (6–24 months) at 24 hours, 1 and 3 months after closure, and at 6 month intervals thereafter.

Results: The mean ADO diameter was 5.9 ± 1.4 mm (range = 4–8 mm). Complete angiographic closure was seen in 26/40 (65%) pts. The remaining pts had a trivial angiographic shunt through the ADO. At 24 hours color flow mapping revealed no shunt in all pts. An 8F long sheath was required for repositioning of a misplaced into the pulmonary artery. 8 mm device. The mean fluoroscopy time was 7.8 ± 1.4 min (range = 4.6–12 min). There were no complications. No obstruction of the descending aorta or the pulmonary artery branches was noted on Doppler FU studies. Neither thromboembolization nor hemolysis or device failure was encountered.

Conclusions: Our data support previous preliminary experience that ADO is an effective and safe device for TC in the majority of pts with patency of the arterial duct.

P3425 Where are the limits of transcatheter closure of atrial septal defects with the Amplatzer septal occluder?

P. Gavora, J. Masura[1], U. Mazic[2]. *Cardiology and Cardiac surgery Center; [1]Children's Hospital, Bratislava, Slovakia; [2]Pediatric Cardiology Ljubljana, Slovenia*

Purpose: The secundum type of atrial septal defect (ASD) is open to transcatheter closure techniques using different investigational devices. When attempting the transcatheter closure technique it is very important to recognize the variability in morphology of the defects to avoid incorrect outcome of the procedure like device embolization, residual shunting or AV valves incompetence. We report 114 patients who underwent transcatheter closure of secundum ASD with the Amplatzer septal occluder (ASO), 75 of these pts (85%) presented with morphological variation of secundum defect.

Patients: Between September 1995 and January 1999 114 pts (age 0.9–43 years, median 10) underwent transcatheter closure with ASO. 39 patients had centrally placed, fossa ovalis type of defect. 75 pts had morphological variations of secundum defects: 56 pts had partial (<3 mm) or total deficiency of antero-superior septal rim. 8 pts with multiple ASD's, 7 patients with aneurysm of atrial septum associated with single communication and 4 pts with multiperforated aneurysm.

Methods: All defects were closed with the Amplatzer septal occluder (ASO), the implantation procedure was monitored by transoesophageal echocardiography (TEE).

Results: The diameter of the defect measured by TEE ranged from 4–26 mm (median, 12) mm and balloon stretched diameter from 4–35 mm (14) mm. Size of implanted devices ranged from 4–34 (15) mm. Reexamination after one month (114 pts) one year (67 pts) and two years (28 pts) showed all defect closed except for two trivial leaks being of no hemodynamic significance.

Conclusion: ASO significantly extends the limits of usual criteria for transcatheter treatment and allowed to close majority (up to 80%) of all secundum atrial septal defects.

ANATOMIC AND FUNCTIONAL ASSESSMENT BY IMAGING

P3426 Atrioventricular function long after Mustard operation for transposition of great arteries: influence of atrial flutter

Wei Li, Michael Y. Henein, Jane Somerville. *Jane Somerville GUCH Unit, Royal Brompton Hospital and Imperial College School of Medicine, London, UK*

Right ventricular (RV) failure and atrial flutter are known long term complications and thus contribute to mortality after Mustard repair for transposition of the great arteries. There is no uniform definition for the resulting RV dysfunction but the qualitative assessment of 2D echoes.

Methods: Electromechanical atrial and ventricular function was assessed in 22 (female 10) patients aged 27 ± 5 years, 10–29 (mean 24) years after initial Mustard operation using transthoracic Doppler echocardiography. Patients were divided into 2 groups: *Group I* included 12 patients with previously recorded atrial flutter and *Group II* involved 10 patients without history of atrial arrhythmia. All patients were studied while in sinus rhythm except 3 (2 in *Group I* and 1 in *Group II*) who were paced for complete heart block and 2 in *Group II* with junction rhythm.

Results: There was no difference in age, gender or age at surgery between the 2 patient groups. RV end diastolic dimension was increased in both groups while left ventricular fraction shortening was reduced (20 ± 10%) only in *Group I* patients. Although right sided total long axis excursion was equally reduced in the 2 patient groups (1.0 ± 0.3 cm), that of atrial 'A' wave of the same side was reduced only in *Group I* patients (0.14 ± 0.13 cm vs 0.26 ± 0.09 cm), $p < 0.01$. Total long axis excursion of the left (1.35 ± 0.37 cm) and septal (0.63 ± 0.23) sides were both significantly reduced in *Group I* patients compared to *Group II* patients (1.8 ± 0.3 cm, 0.95 ± 0.31 cm), $p < 0.05$, $p < 0.001$ respectively as was septal 'A' wave (0.11 ± 0.10 vs 0.33 ± 0.12 cm), $p < 0.001$. The onset of right atrial shortening was significantly delayed in *Group I* compared to *Group II* (110 ± 14 ms vs 84 ± 25 ms, $P < 0.001$), but that of left atrial shortening was not different in the 2 patient groups.

Conclusion: Biventricular dysfunction may occur in patients long after Mustard correction for transposition of great arteries. The consistent association of atrial flutter with the disturbed atrial and ventricular electromechanical behaviour suggests a causal relation with atrial arrhythmia.

P3427 Mitral regurgitation, T-wave abnormalities and development of impaired left ventricular function after treatment with anthracyclines

J. Allen, J.D.R. Thomson, J.L. Gibbs. *Cardiac Ultrasound Dept, The Yorkshire Heart Centre, Leeds, UK*

It is well documented that the anthracycline antibiotics are cardiotoxic. However, with current cardiac monitoring it is not possible to detect early changes that may be predictive of myocardial damage. Current practice in our department includes serial 12 lead electrocardiogram(ECG)and echocardiography for the assessment of left ventricular function. During routine examination mitral regurgitation was noted as a new finding in a number of cases with normal fractional shortening. The purpose of this study is to investigate the development of mitral regurgitation and its relationship to other indicators of myocardial damage in patients receiving anthracycline chemotherapy.

Patients and Methods: 333 patients (169 males, 164 females). Ages ranged from 2–31, median 13 years. All were treated with anthracyclines for childhood malignancy. Cumulative doses of anthracyclines were between 80–450 mg/m^2,median 180 mg/m^2. Left ventricular function was assessed using both M mode echocardiography (systolic and diastolic internal dimensions and fractional shortening) and 12 lead ECG. Mitral regurgitation was detected using colour flow Doppler.

Results: 33 patients (10%) developed ultrasound detectable mitral regurgitation which was not apparant clinically. All had normal systolic function. 15 of these patients developed non specific T wave abnormalities. Subsequently 3 of these patients developed impaired left ventricular systolic function. This occurred at 5, 11 and 20 months following the initial finding of mitral regurgitation.

Conclusion: The combination of subclinical mitral regurgitation and non specific electrocardiographic changes could be an early predictor of anthracycline cardiomyopathy.

P3428 Three-dimensional images of congenital heart disease using electron beam CT

S. Tsukano, H. Sawada, H. Doi, H. Endo, Y. Arakaki, S. Echigo, T. Kamiya, H. Uemura[1], T. Yagihara[1], M. Takamiya[2]. *Department of Pediatrics, National Cardiovascular Center, Suita; [1]Department of Cardiovascular Surgery, National Cardiovascular Center, Suita; [2]Department of Radiology, National Cardiovascular Center, Suita, Japan*

The purpose of this study is to assess usefulness of three-dimensional (3D) images of congenital heart disease using electron beam CT (EBT). Ninety cases including eleven bronchial abnormalities were studied.

Method: After injection of contrast medium from peripheral vein, ECG-synchronized scanning was started in early phase. The scan time was 100 msec in all cases and the slice thickness was 3 or 6 mm with 2–7 mm of the table movement. Two-dimensional (2D) images obtained by EBT were transmitted to workstations on line. It took about twenty minutes to reconstruct a 3D image from 2D images. The 3D images were compared with the angiograms and the echocardiograms.

Result: The position of ventricular septal defect, two great arteries, infundibular septum and atrioventricular valves were showed clearly in the sections of the 3D images. They were useful to estimate a route from the left ventricle to the aorta in order to perform a biventricular repair in complex heart disease such as Double outlet right ventricle and corrected transposition of great arteries. They were also useful for evaluate possibility of separation in univentriculr heart. The relationship between the lesions and the surroundings were easily showed in pulmonary sling, abnormal origin of coronary artery and bronchial abnormality. The 3D images of Peripheral pulmonary stenosis and pulmonary valvular stenosis after external conduit repair were showed more apparently than the angiograms observing the sections at various angles.

Conclusion: The 3D image using EBT gave us new information and was useful to understand anatomy of congenital heart disease and decide a surgical method.

P3429 Echocardiographic parameters of left ventricular systolic and diastolic function in infants, children and adolescents with congenital aortic valve defects before and after cardiosurgery

A. Siwińska, B. Mroziński, W. Bobkowski, W. Musiałkiewicz[1], M. Wojtalik[2], D. Podstawska[3], R. Kalawski[3], J. Maciejewski. *Karol Marcinkowski University of Medical Sciences in Poznań, Clinic of Pediatrics, Department of Cardiology; [1]Department of Pediatric Cardiosurgery; [2]Department of Pediatric Intensive Care; [3]Department of Cardiosurgery of City Hospital in Poznań, Poland*

The analysis of left ventricular (LV) systolic and diastolic function has diagnostic and prognostic values in patients with congenital aortic valve defects.

Methods. The purpose of this investigation was Doppler echocardiographic (ECHO) quantify LV systolic and diastolic function in 141 patients aged between 3 and 24 with aortic stenosis (AS; n = 92) and aortic stenosis + aortic insufficiency (AS + AI; n = 49) before and 6 years after cardiosurgery. ECHO measurements were performed according to the guidelines of the American Society of Echocardiography. This parameters were compared with similar variables in healthy children (N; n = 150).

Results. Before surgery. The diastolic function parameters were the peak mitral flow velocity in early diastolic (E) (AS – 83.9 ± 6.0 cm/s; AS + AI – 79.7 ± 13.1 cm/s; N – 88.1 ± 8.9 cm/s), peak mitral flow velocity in late diastole (A) (AS – 81.2 ± 6.8 cm/s AS + AI – 89.3 ± 9.9 cm/S; N – 45.3 ± 6.3 cm/s), ratio of peak early to late atrial filling velocity (E/A) (AS – 1.04 ± 0.08, AS + AI – 1.03 ± 0.02; N – 1.96 ± 0.17), isovolumetric relaxation time (IVRT) (AS – 100 ± 10 ms; AS + AI – 96 ± 32 ms; N – 71 ± 6 ms) and deceleration time (DT) (AS – 237 ± 14 ms, AS + AI – 222 ± 97 ms; N -149 ± 21 ms). The systolic function parameters were LV shortening fraction (LVSF) (AS – 44.5 ± 2.8%; AS + AI – 28.8 ± 3.1%; N – 34.4 ± 2.9%), LV ejection fraction (LVEF) (AS -79.9 ± 1.9%; AS + AI – 57.0 ± 10.9%; N = 61.2 ± 2.9%).

After surgery. The diastolic function parameters were E (AS – 82.4 ± 7.1 cm/s; AS + AI – 81.2 ± 8.8 cm/s; N – 88.1 ± 8.9 cm/s), A (AS – 77.8 ± 7.1 cm/s; AS + AI – 81.7 ± 9.8 cm/s; N – 45.3 ± 6.3 cm/s); E/A (AS – 1.0 ± 0.5, AS + AI – 1.0 ± 0.4; N – 1.96 ± 0.17), IVRT (AS – 91 ± 5 ms; AS + AI – 89 ± 10 ms; N – 71 ± 6 ms) and DT (AS – 231 ± 28 ms, AS + AI – 197 ± 53 ms; N – 149 ± 21 ms). 2 patients died after cardiosurgery. Their diastolic function parameters were E (94.2 ± 5.4 cm/s). A (49.8 ± 3.4 cm/s), E/A (1.89 ± 0.06), IVRT (69 ± 11 ms), DT (117 ± 28 ms). The systolic function parameters were LVSF (AS – 42.0 ± 2.8%; AS + AI – 30.9 ± 2.1% N – 34.4 ± 2.9%), LVEF (AS – 70.3 ± 4.2%; AS + AI – 59.5 ± 4.0%; N – 61.2 ± 2.9%).

Conclusions. In AS and AS + AI patients the disturbances of LV diastolic function were observed both before and after cardiosurgery. These disturbances should be indication for early cardiosurgery. Pseudonormalization of LV diastolic function parameters was observed in patients that died. The parameters of LV systolic function were worse in AS + AI patients than in AS patients both before and after cardiosurgery.

P3430 The use of ultrasound in the evaluation of cyanosis following bi-directional cavopulmonary shunt

Bernardo A. Vidne, E. Birk, M. Berant, S. Diamant, A. Matitiau, E. Bruckheimer, R. Fogelman, L. Blieden. *Schneider Children's Medical Center of Israel, Petach Tikva, Israel*

Some of the major causes of increasing cyanosis in children who have undergone bidirectional cavo-pulmonary shunt (Glenn) operation include: 1) the development of pulmonary arteriovenous fistulas; 2) development of upper to lower body venous communications and 3) the normal relative decrease in pulmonary blood flow in relation to the child's growth. We suggest that contrast echocardiography can easily identify the relevant mechanism for decreasing saturation.

Methods: A contrast injection of agitated saline into an intravenous catheter in the upper extremity was performed in 5 patients (aged 1–12 yrs) evaluated for gradually increasing cyanosis during 1998. All patients had undergone the Glenn operation 1–10 yrs earlier. When microbubbles were identified in the heart, an attempt was made to identify the cardiac connections of the vessels carrying the microbubbles.

Results: 4/5 patients were found to have microbubbles in the heart. In two patients, the contrast fluid entered the heart via the pulmonary veins and left atrium, indicating the presence of pulmonary arteriovenous fistulas. In one patient the contrast entered the heart via the Inferior Vena Cava, indicating the presence of upper to lower body venous communications. This diagnosis was verified on cardiac catheterization and the collaterals occluded with multiple coils. One patient was found to have contrast in both systemic and pulmonary venous systems, indicating the presence of pulmonary arteriovenous fistulas as well as upper to lower body venous communications. One patient was found to have neither, again this diagnosis was verified on cardiac catheterization.

Conclusions: The use of contrast echocardiography facilitates easy and accurate definition of the mechanism leading to desaturation following the Glenn operation.

P3431 The prevalence and characteristics of physiological left sided regurgitation in children and adolescents

J.D.R. Thomson, J. Allen, J.L. Gibbs. *Paediatric Cardiology Dept., Leeds General Infirmary, Leeds, UK*

Most studies of valve regurgitation in normal subjects have been in adults.In this study we aimed to prospectively determine the prevalence of echocardiographically detectable left sided valvular regurgitation in normal children and adolescents.

Patients and Methods: Healthy volunteers between the ages of 3 and 18 years were recruited from a local school.The study group consisted of 324 subjects (192 males, 132 females).Mitral and aortic flow was assessed using colour and continuous wave doppler techniques.Regurgitation was said to be present when high velocity colour flow, directed into the proximal chamber was detected after valve closure.

Results: The prevalence of mitral regurgitation for the whole group was 1.85% (6/324 subjects,age range 7–18 years).In each case mitral regurgitation was confined to the proximal half of the left atrium. In all but one case(83%)the regurgitant jet arose from the posteriomedial aspect of the mitral valve.The mean jet area was 1.4 cm^2 (range 1.1–1.9 cm^2). None of these patients had clinically detectable valve regurgitation.In addition to the above,one patient had mitral regurgitation on colour doppler but a continuous wave trace that was not holosystolic. The prevalence of aortic regurgitation was 0.3% (one female, 11 years). The jet was confined to the immediate region of the valve and was 0.44 cm^2 in area.

Conclusion: True left sided physiological regurgitation in the paediatric population is rare.Previous studies in normal adults have reported prevalence rates for aortic and mitral valve regurgitation of up to 71 and 89% respectively. This supports the popular theory that valve regurgitation is a wear and tear phenonenon becoming more common with advancing age.

P3432 Dobutamine stress echo in patients repaired with Fontan

S. Brili, C. Aggeli, C. Hantzos, C. Chrysochoou, C. Pitsavos, C. Stefanadis, P. Toutouzas. *Cardiology Dept, University of Athens, Hippokration Hos, Athens, Greece*

Several investigators have reported that patients (pts) after the Fontan procedure (FP) have a subnormal cardiac output (CO) including those doing well clinically. Dobutamine stress echocardiography (DSE) has been used as an alternative stress test for detecting the cardiac reserve in coronary and valvar heart disease as well as in cardiac failure. In this study we aimed at clarifying the hemodynamic response during DSE in pts after FP.

Methods: The study group was comprised by 10 patients (pts) (22 ± 4 years old, 14 ± 6 years s/p FP), and by 10 sex, age and body surface (BS) matched controls (C). Five of the pts were on sinus rhythm (SR) and the other five on atrial fibrillation (AF) and on digitalis. All pts and C were evaluated by 2D and doppler echo at rest and at peak of (5, 10, 20, 30, 40 μg/kg/min) 3 minute period of dobutamine infusion. End terminating point for stopping dobutamine infusion (DI) was the target of 130 beats/min. Stroke volume (SV), CO and CO index (COI) were estimated for all subjects using the equations: SV = LVOT cross sectional area X velocity time integral of LVOT, CO = SVx HR and COI = CO/BS.

Results Mean dose of DI for pts and C was (26 μgr/kgr/min, 35 μgr/kgr/min) respectectively. Systolic blood pressure (SBP) increased slightly but statistical significant (SS) in both C and pts In pts, SV, CO and COI at rest throughout the exercise were SS lower compared to C ($p < 0.001$) No SS difference was found between pts with and without AF. The% increase in SV, CO and COI from rest to the peak of exercise was higher in C than in pts ($p < 0.05$)

Conclusions: Pts s/p FP who are asymptomatic have lower CO at rest and show a less favorable hemodynamic response to DI than C. Although, pts with AF do not differ compared to those without AF.

PAEDIATRIC CARDIAC SURGERY

P3433 Pulmonary blood flow distribution after the total cavopulmonary connection

Masao Tayama, Nobuaki Hirata, Tohru Matsushita[1], Tetsuya Sano[1], Norihide Fukushima, Yoshiki Sawa, Tsunehiko Nishimura[2], Hikaru Matsuda. *First Department of Surgery; [1]Department of Pediatrics; [2]Tracer Kinetics in Biomedical Research Center, Osaka University Medical School, Osaka, Japan*

Background Although the total cavopulmonary connection (TCPC) has been proposed as a rational alternative to atriopulmonary connection for Fontan operations, pulmonary blood flow distribution after TCPC is unkown.

Methods To clarify the pulmonary blood flow distribution after TCPC, we selected 11 patients (8.1 ± 10.1 yrs) performed TCPC and achieved the lung scanning by administrating ^{133}Xe saline solution from their arms, and then from their legs. Radionuclide counts on both lungs were obtained. Because TCPC candidates have many anatomical variations, we divided them into 3 groups. Group R: SVC-PA anastomosis is right side to the site of in IVC-PA anastomosis in 4 patients. Group L: SVC-PA is left in 3. Group B: IVC-PA is between bilateral SVC in 4.

Results The right to left ratio when ^{133}Xe was perfused from SVC was 77.9%:22.1% (±11.6), that from IVC was 45.1%:54.9% (±6.3), and SVC flow speed is equal to IVC's in Group R. That ratio from SVC was 23.6%:76.4% (±11.2), that from IVC was 70.8%:29.2% (±11.6), and SVC to IVC flow ratio is 0.9:1 in Group L. That from the right arm was 75.6%:24.4% (±1.5), that from the left arm was 33.8%:66.2% (±28.4) and that from IVC was 54.4%:45.6% (±10.3) in Group B.

Conclusion ^{133}Xe perfusion scan could reveal pulmonary blood flow distribution quantitatively in the patients after TCPC. The pulmonary blood flows from SVC and IVC perfused to the each anastomotic side predominantly. In the patients whose SVC-PA is left side to IVC-PA, the right and left balance of the pulmonary blood flow distribution was more even than another option, and less mixing of pulmonary blood flow was obtained.

P3434 Acute peritoneal dialysis after surgery for congenital heart defects

J. Janousek, V. Tomek, V. Chaloupecky, P. Vojtovic, M. Kostelka, T. Tlaskal, B. Hucin. *Kardiocentrum, University Hospital Motol, Prague, Czech Republic*

In patients (pts.) with acute renal failure after surgery for congenital heart defects (CHD) peritoneal dialysis (PD) is the preferred elimination method because of limited vascular access, risks given by anticoagulation, frequent hemodynamic instability and technical simplicity. The purpose of this study was to evaluate risks and benefits of PD in this patient population.

Methods: From 1991 to 1997 PD was used in 70/2437 (2.9%) pts. after surgery for CHD. Data were available from 68/70 pts. aged 1 day–25.1 years (median 1.8 months). 54/68 pts. (79.4%) were infants. Preoperative renal dysfunction was present in 16 pts. (23.5%). At time of PD initiation 32 pts. (47.1%) had low cardiac output (LCO) and/or adrenaline >0.1 mcg/kg/min., 25 (36.8%) had capillary leak syndrome and 19 (27.9%) an open chest. PD was started because of refractory fluid retention in 67 pts. (98.5%, anuria in 25/67 pts.), hyperkalemia in 12 pts. (17.6%) and high urea level (>30 mmol/L) in 2 pts. (2.9%). Some pts. had more than 1 indication. Average PD duration was 3.4 (<1–14) days.

Results: 39/68 pts. (57.4%) died in the intensive care unit (ICU). In this group, LCO and/or adrenaline support >0.1 mcg/kg/min. were more frequent than in survivors (61.5 versus 27.6%, $p < 0.01$). Main causes of death were heart failure (25 pts.), multiorgan failure (6 pts.) a sepsis (5 pts.). In terms of PD fluid removal there was no difference between survivors and non-survivors (42.3 ± 32.1 versus 50.4 ± 54.7 mL/kg/day, NS). There was, however, a significant difference in total fluid balance during PD between both groups (−7.3 ± 55.8 versus +38.2 ± 76.9 mL/kg/day, $p < 0.05$). PD was functional (removed fluid >20 mL/kg/day) in 46/59 pts. (78%) with PD duration > 24 hours. PD was complicated by catheter block necessitating exchange in 27 pts. (39.7%), positive peritoneal cultures in the absence of PD related sepsis in 10 pts. (14.7%) and leak around catheter in 4 pts. (5.9%). Renal function was assessed in 26/29 pts. discharged from ICU and was normal in 24 (92.3%) and slightly decreased in 2 (7.7%).

In conclusion, drug refractory fluid retention was the main indication for PD after surgery for CHD. High mortality of dialysed pts. was caused by intractable heart failure and its sequelae. In surviving pts. PD helped to maintain a negative fluid balance and led probably to lower morbidity and mortality caused by hyperhydration. No serious PD complications were observed. Renal function recovered in the survivors.

P3435 Aortic root replacement with pulmonary autograft in the young age group

V.T. Tsang, C. Schreiber, O. Miller, M.J. Elliott, M.R. de Leval. *Department of Cardiothoracic Surgery, Great Ormond Street Hospital for Children NHS Trust, London, UK*

Pulmonary autograft has been considered to be the preferred aortic valve replacement in the young age group because no anticoagulation is required; no degeneration; excellent haemodynamics; and growth. The operation is technically demanding, and we therefore reviewed the results of pulmonary autograft procedure at Great Ormond Street over the last 5 years.

Methods: The records of 36 patients, aged 18 days to 26 years (median age 178 months), were reviewed. All the patients underwent root replacement with coronary reimplantation. Follow-up was complete (median 24.5 months, range 1 month to 5 years). Echocardiographic assessment at late follow-up was available in all the patients.

Results: Aortic stenosis was the primary diagnosis in 2, aortic insufficiency in 4, a combination of these in 26, and aortic stenosis with left ventricular outflow tract obstruction in 4 patients. 33 patients had previous aortic valve interventions (26 valvuloplasties, 17 open valvotomies, 1 valve replacement). There were 2 early deaths and 1 late death (arrhythmia). There were no reoperations for autograft or homograft dysfunction, or valve-related events. Echocardiographic evaluation of the autograft revealed no significant obstruction, moderate insufficiency was found in one, and severe insufficiency in another patient. Evaluation of the homograft showed mild stenosis in 2, and mild insufficiency in 6 patients. All patients have a normal, active lifestyle.

Conclusions: The results are encouraging and the use of tile pulmonary autograft in children requiring aortic valve replacement appears to be justified.

CATHETER INTERVENTION IN CONGENITAL HEART DISEASE

P3436 Intravascular ultrasound assessment of morphologic changes of coarctation of the aorta following balloon angioplasty

Jou-Kou Wang, Mei-Hwan Wu, Hung-Chi Lue. *Department of Pediatrics and Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, China*

Balloon angioplasty has been widely accepted as a procedure-of-choice for the treatment of coarctation of the aorta. The morphologic changes of arterial wall in the coarcted segment following angioplasty has seldomly been reported. We conducted this study to investigate the morphologic changes of the arterial wall following balloon angioplasty using intravascular ultrasonography (IVUS).

Methods: During a 28-month period, angioplasty for coarctation of the aorta was performed in 22 patients, of whom 12 underwent IVUS study to assess the morphologic changes of arterial wall. A 8 F, 10 or 20 MHz IVUS (CVIS) catheter were used. The IVUS imagings was performed prior and immediately following balloon angioplasty. Of the 12 patients, their ages ranged from 4.5 to 18 years. Three had Turner syndrome and 3 had recurrent coarctation following surgical angioplasty. Of the 12 patients, the pressure gradient reduced significantly from 35.8 ± 7.3 to 8.7 ± 7.2 mm Hg ($p < 0.01$). Intimal tear and dissection were detected with IVUS in all 12 patients, which were seen in 3 patients on angiogram. All had dissections less than one fourth of the vessel circumference. No one had aortic aneurysm on IVUS images or angiogram. The mean narrowest diameter increased from 8 ± 2.4 to 12 ± 2.5 mm following angioplasty. ($p < 0.01$) After a follow-up period ranging from 4 to 32 months, the mean pressure gradient estimated with echocardiography was 13.3 ± 4.3 mm Hg.

In conclusion: Intimal tears and dissections were generally present in patients with effective angioplasty for coarctation of the aorta. IVUS is useful in evaluation of morphologic changes following balloon angioplasty.

P3437 Transcatheter closure of large atrial septal defect in adults

J. Masura, P. Gavora[1], V. Fridrich[2], G. Fischer, H.H. Kramer[3]. *[1]Children's Hospital Bratislava; [2]SUSCH Bratislava, Slovakia; [3]Christian-Albrechts University, Kiel, Germany*

Introduction: Transcatheter closure of atrial septal defect (ASD) with Amplatzer Septal Occluder (ASO) was well documented and become treatment of choice in selective patients.

The aim of our two centers study was to determine feasibility of ASO for closure of large ASD more than 20 mm in diameter, in children and adults.

Patients and Methods: From 9/95–01/99, 188 patients (age 5.1–58.9, median 25) with ASD underwent transcatheter occlusion with ASO. Among them 34 with stretched diameter larger than 20 mm.

Results: The median size of the ASD measured by transesophageal echocardiography (TEE) was 19.5 mm (range, 14–26 mm) and the median stretched diameter was 24 (19–35 mm). Size of implanted devices ranged from 20–36 mm (25 mm). All patients had RV volume overload with a median Qp/Qs of 2.59 (1.7–3.27). The median fluoroscopy time was 14 min (6.8–60 min). As assessed by TEE and cine, there was immediate complete closure (C) in 9/34 (25%). At 24 hour follow-up transthoracic echocardiogram with color revealed C in 24/34 (70%), 27/30 (90%) at one month and at 3 months follow up 29/30 (96%) had C. There has been no major complications related to the closure. On median follow up interval 10 months (range, 1 week–3 years), there has been no episodes of endocarditis, thromboembolism or wire fracture. Only one patient was treated due to premature atrial extrasystoles.

Conclusion: We conclude that the new self-expandable, repositionable ASO is effective method to close large secundum ASD's with C in the majority of patients. Further clinical trials are underway.

P3438 The results of the repair of atrial septal defect with or without partial anomalous pulmonary venous connection in patients over 40 years old

L. Paluszkiewicz, M. Jemielity, B. Perek, P. Buczkowski, A. Szyszka[1], W. Dyszkiewicz. *Department of Cardiac Surgery, Institute of Cardiology, Poznań[1] I Department of Cardiology, Institute of Cardiology, Poznań, Poland*

Objective: We aimed to determine the value of surgical closure of atrial septal defect (ASD) and partial anomalous pulmonary venous connection (PAPVC) in patients (pts) over 40 years of age.

Methods: We analyzed 88 consecutive pts over 40 years of age operated because of ASD (76 pts) and PAPVC (12 pts) and followed up for 1 to 17 years. Patient quality of life, clinical status, NYHA class, ecg, chest x-ray and echocardiography were studied before operation and at the end of follow up.

Results: There were 16 men and 72 women aged 40–62 (mean 46.5 ± 6.8 years). Before operation 64% of pts were in III and IV NYHA class, 7 pts had atrial fibrillation. Antiarrhythmic drugs were used in 37% of pts, diuretics in 34% and anticoagulants in 5% of pts. The average pulmonary to systemic flow ratio was 2.48 ± 0.61.

We noted 1 operative and 3 late deaths during follow up. On examination 82% of pts were in I and II NYHA class. The clinical improvement was quantified as significant by 69% of pts. No improvement or deterioration was reported by 12% of pts. Antiarrhythmic drugs were used in 51%, diuretics in 11% and anticoagulants in 12% of pts. 11 pts suffered from atrial fibrillation. Echocardiographic examination revealed significant decrease of the right ventricular diastolic diameter in both groups (4.15 ± 0.89 vs 3.02 ± 0.35 cm, $p < 0.001$ in ASD pts and 3.99 ± 0.86 vs 2.91 ± 0.58 cm, $p < 0.05$ in PAPVC pts), decrease of tricuspid insufficiency and maximal velocity of tricuspid diastolic flow as compare to preoperative examination.

Conclusion: Surgical repair of ASD with or without PAPVC in pts over 40 years of age can significantly improve the clinical status as well as prevent the right ventricular dilatation and insufficiency.

P3439 Neonatal aortic balloon valvuloplasty – early and intermediate results(up to 9 years)

J.D.R. Thomson, G.R. Veldtman, J.M. Parsons, J.L. Gibbs, D.F. Dickinson, M.E.C. Blackburn. *Paediatric Cardiology Dept., Leeds General Infirmary, Leeds, UK*

Primary balloon valvuloplasty was performed in 27 consecutive neonates with severe aortic stenosis. Approach was via the axillary artery(23),femoral artery(3)or antegradely via a ventricular septal defect (1). Median age was 4 days (range 1–30), median weight 3.6 kg (range 1.1–4.5). Balloon: aortic annulus ratio was 1.01 ± 0.12. Valvuloplasty significantly reduced the peak systolic pressure gradient from 58 ± 38 to 20 ± 15 mmHg, whilst increasing aortic regurgitation by a mean of 2.2 ± 1.2 grades. Overall mortality was 41%(7 early and 4 late deaths-after 1 month), but was higher in the subgroup of 17 neonates undergoing valvuloplasty in the first week of life (53% vs 12%). Arterial complications occurred in 4 patients (femoral avulsion-2, femoral thrombosis-1, axillary thrombosis-1). 10 children have required 1 or more reinterventions; Ross proceedure (3 and 43 months),homograft valve replacement (6 months), open valvotomy (1 and 3 months) and repeat balloon valvuloplasty (1, 1, 1 and 8 months). Of the 14 children requiring angioplasty in the first week of life and surviving 1 month, 38% required reintervention compared with 25% of the group requiring angioplasty after 1 week of life. The median Doppler gradient at follow up was 33 mmHg (range 9–50).

Conclusion: Neonatal balloon valvuloplasty is technically successful in terms of gradient reduction. However the mortality in those requiring treatment in the first week of life appears to exceed the mortality rate for alternative therapies such as the Norwood proceedure. Reintervention is common in those surviving (38%). This high mortality is contrasted with a much better prognosis in patients treated afer the first week of life, who have a survival rate of 88% and a reintervention rate of 25% at a median follow up of 76 months (range 6–106).

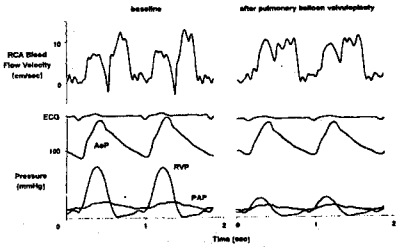
P3440 Reduction of right ventricular systolic pressure results in disappearance of retrograde right coronary artery systolic flow in patients with pulmonary valve stenosis

I.E. Kallikazaros, C.P. Tsioufis, C.G. Stratos, C.I. Stefanadis, P.K. Toutouzas. *Hippokratio Hospital, Department of Cardiology, Athens, Greece University*

Previous studies in animals have shown an alteration of right coronary artery (RCA) blood flow as a result of elevated right ventricular systolic pressure (RVSP) secondary to pulmonary artery constriction or pulmonary emboli. The impact of the elevated RVSP and its changes on the RCA blood flow have not been well studied in humans.

Methods: Towards this end, in 9 patients with severe isolated pulmonary valve stenosis (mean age 30.8 ± 10.6 years), proximal RCA blood flow velocity (BFV) was measured, using an intracoronary Doppler velocimeter, along with hemodynamic parameters before and after pulmonary balloon valvuloplasty (PBV).

Results: The pre-valvuloplasty phasic RCA BFV pattern was predominantly diastolic with an obvious systolic retrograde (SR) wave (Fig. Left panel). The level of RVSP had a negative correlation with the peak systolic antegrade (SA) BFV (r = −0.71), the SA RCA BFV curve area (r = −0.73) and the volumetric RCA flow (r = −0.83) and a positive correlation with the SR BFV curve area (r = 0.97). PBV caused a significant reduction in both the transvalvular pressure gradient (by 59 ± 29 mmHg) and the RVSP (by 55 ± 19 mmHg). The peak SA BFV, the SA BFV curve area, the ratio of total systolic to diastolic BFV curve area and the RCA volumetric flow increased significantly while the SR BFV curve area decreased significantly (Fig. Right panel). The decrease of RVSP had a negative correlation with changes in the peak SA BFV (r = −0.60), in the ratio of peak SA to diastolic BFV (r = −0.51) and in the RCA volumetric flow (r = −0.53) and a positive correlation with changes in the SR RCA BFV curve area (r = 0.91).



In conclusion, RCA BFV pattern is strongly dependent on the RVSP level and its changes after PBV. PBV-induced reduction in RVSP results in a dissapearance of retrograde systolic componet of the RCA BFV pattern.

P3441 Atrial septal defect in the adult: is routine surgical closure always beneficial?

S. Favilli, A. Zuppiroli[1], F. Mori[1], G. Santoro[1], A. Manetti, A. Dolara[1]. *Cardiologia, Azienda Ospedale A.Meyer, Florence; [1]Cardiologia 2, Azienda Ospedale Careggi, Florence, Italy*

Atrial septal defect (ASD) can be recognized firstly in adult age, mostly in asymptomatic or mildly symptomatic patients (p), in whom benefits of surgical closure are still debated.

Methods: Clinical histories of 87 p with first diagnosis of ASD when older than 30 years (59 females-68%; mean age 50 ± 13 years, range 30–81) observed at our Institution since 1978 for a mean follow-up of 96 ± 69 months (range 12–240) were revised. Clinical decision (medical treatment:48 p, 55%, group A; surgery;39 p, 48%, group B) resulted either from individual cardiologist's opinions and indications and/or from patients' personal choices. At first evaluation, group A and B did not differ significantly for any clinical, echocardiographic or hemodynamic parameter; p of group A were older (54 ± 14 vs 45 ± 11 years; $p < 0.0001$); 46 p in group A (95%) and 36 p in goup B (92%) were in I-II NYHA class.

Results: During follow-up NYHA class worsening was observed in 4 p (8%) in group A and 3 p (8%) in group B. Major complications (cardiac death, cerebral emboli, infective endocarditis, severe mitral regurgitation, re-operation) were virtually the same in the two groups: 8 p (16%) in group A and 8 p (20%) in group B. New onset complex supraventricular arrhythmias occurred less frequently in group A (5 p, 12%) vs group B (15 p, 38%; $p < 0.01$).

In conclusion, in a population of adult p with ASD, most of whom mildly or a-symptomatic at first evaluation, serendipitous indication to surgery seeems to be uneffective on mid-term mortality and morbidity.

P3442 Which ASD secundum are not suitable for transcatheter closure?

U. Mazic, P. Gavora[1], J. Masura[1]. *Cardiology Dept., University Children Hospital, Ljubljana, Slovenia; [1]Cardiology and Cardiac Surgery Center, Children's University Hospital, Bratislava, Slovakia*

Amplatzer septal occluder (ASO) is new self-centering device for transcatheter closure of ASD secundum. The purpose of the study was to determine the echocardiographic characteristic of ASD secundum that can not be closed with ASO.

Between 9/95 and 6/98 we examined 220 patients with ASD at median age 6.7 (range 9 months to 43 years) and median weight 32 kg (range 6.9 to 82 kg). We found with TTE 14 (6%) patients, with TEE 23 (11%) patients and during catheterization one patient that were not suitable for transcatheter closure. 91 (27 male/55 female) had the implantation of ASO and the others are on waiting list.

The characteristic of the ASDs not suitable for transcatheter closure with ASO were: 1) ASD secundum with rims < 5 mm (19 pts), 2) ASD secundum with PAPVD (4 pts), 3) associated sinus venosus with PAPVD (13 pts) and 4) ASD secundum with diameter > 30 mm (1 pts). We found 43 patients with insufficient rims: 12 inferior rim (rim toward IVC), 7 posterior rim (direction toward coronary sinus) and 24 anterior-superior rim (toward aorta), but all patients with insufficient anterior-superior rim had successful ASO implantation.

Conclusions: 18% of ASDs are not suitable for transcatheter closure with ASO. TEE is essential for patients' selection. It allows better detection of defect's location, rims length and PAPVD. The most important are rims towards the IVC, SVC, right upper pulmonary vein and AV valves that should be at least 4 mm. Aortic rim is not important for ASO deployment. We also found that inferior and posterior defects are not suitable for transcatheter closure with ASO.

P3443 Severe hypoxaemia due to atrial right-to-left shunt in adult patients with normal pulmonary artery pressure. percutaneous transcatheter occlusion

F. Godart, C. Rey, A. Chmaït, A. Vincentelli[1], C. Francart, G.M. Brevière, A. Prat[1]. *Departments of Paediatric Cardiology; [1]Cardiac Surgery, University of Lille, France*

Hypoxemia due to atrial right-to-left shunt through a patent foramen ovale (PFO) and/or atrial septal defect (ASD) with normal pulmonary artery pressure is an uncommon diagnosis. We report here 8 consecutive cases.

From August 1995 to September 1998, 8 patients (age: 59–78 years), were referred to our institution for severe hypoxemia (oxygen saturation of 70–85%) and dyspnea due to an interatrial right-to-left shunt. Half of the patient had platypnea and orthodeoxia. In 5 patients, symptoms were present for a period of 1 month to 3 years. In 3 patients, hypoxemia appeared suddenly: 2 after surgery (1 pneumonectomy and 1 ventral hernia). The diagnosis was confirmed in all by contrast transoesophageal echocardiography.

Cardiac catheterization revealed normal right-sided pressures. Angiography in the inferior vena cava showed the right-to-left shunt through a PFO (n = 4) or a small ASD (n = 4) and rotation of the heart in a counterclockwise direction distorting the position of atrial septum relative to caval inflow. This latter was explained by enlargement of the ascending aorta noticed in 7 patients or heart tilting secondary to pneumonectomy.

All patients underwent percutaneous occlusion of the PFO/ASD under local anaesthesia using the inverted Sideris device (n = 5), the Cardioseal device (n = 2) and the Amplatzer device (n = 1). Immediately after implantation, a significant rise in oxygen saturation was observed (oxygen saturation > 95%). The closure succeeded in all patients but one. In one patient, the introducing sheath could not be advanced due to tortuous inferior vena cava and patient remained hypoxic. Two complications were observed after closure: 1 atrial fibrillation and 1 transient cerebrovascular accident. During follow-up (1 to 30 months), the 7 patients had no oxygen desaturation or dyspnea and contrast echocardiography showed no atrial shunt (n = 6) and tiny residual shunt (n = 1).

Hypoxemia due to interatrial right-to-left shunt without pulmonary hypertension is an uncommon pathology that is probably underestimated due to the prevalence of PFO in the general population. Correction can be easily performed by percutaneous closure. This latter should be regarded as the treatment of choice for the occlusion of PFO/ASD and a good alternative to surgical closure.

PATHOPHYSIOLOGY AND DIAGNOSIS OF CONGENITAL HEART DISEASE

P3444 Echocardiographic morphologic and geometric variations of the left ventricular outflow tract: possible role in the pathogenesis of discrete subaortic stenosis

E. Tutar, S. Atalay, S. Turkay, H. Gumus, A. Imamoglu. *Pediatric Cardiology Dept., Ankara University, Medical School, Ankara, Turkey*

Although the clinical features and natural course of discrete subaortic stenosis (DSS) are well defined, the etiology remains speculative. The purpose of this study was to identify the echocardiographic morphologic and geometric variations of the left ventricular outflow tract associated with DSS in children and to determine whether these variations had role in the pathogenesis of DSS. The aortoseptal angle (ASA), mitral-aortic valve separation (MAS), and the size of the aortic annulus were determined in two groups of children. Group 1 comprised 11 patients with isolated DSS, who were compared with an age- and body surface area- (BSA) matched healthy children (Group 1A, n: 20). Group 2 comprised 10 patients with DSS and ventricular septal defect (VSD). Group 2 was compared with an age- and BSA- matched patients with isolated perimembranous VSD (Group 2A, n: 22). Measurements were carried out from previously recorded echocardiographic studies. The ASA was steeper (119.3 ± 6.1° vs 137.5 ± 5.6°, $p < 0.001$), and the MAS was wider (6.1 ± 1.6 mm vs 3.2 ± 0.7 mm, $p < 0.001$) in patients with isolated DSS than in healthy control subjects. Similar differences were found between patients in Group 2 and Group 2A; the ASA was steeper (122.2 ± 6.5° vs 141.3 ± 5.0°, $p < 0.001$), and the MAS was wider (5.8 ± 1.5 mm vs 3.8 ± 1.1 mm, $p < 0.001$). The size of the aortic annulus was not different among four study groups. Although the MAS was significantly wider in patients with DSS there was significant overlap in MAS between patients and controls. However, if an ASA < 130° was chosen as a predictive variable, it was found to be highly sensitive, specific, and positive predictive marker for the development of DSS. This study demonstrates that DSS is associated with a steeper ASA, and a wider MAS, in patients with or without associated VSD. These morphologic abnormalities, especially a steeper ASA may be risk factors for the development of DSS.

P3445 Tilt training for neurocardiogenic syncope in paediatric patients

T. Reybrouck, H. Ector, B. Eyskens, M. Gewillig, F. Van de Werf. *University Hospital Gasthuisberg, 3000 Leuven, Belgium*

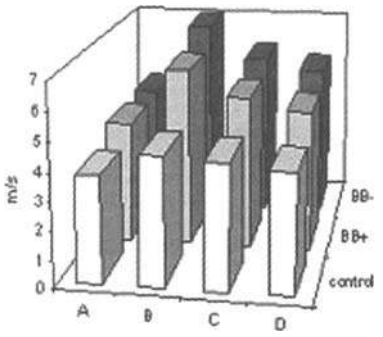
Head up tilt testing is a standardised and sensitive test for diagnosing neurally mediated syncope in patients with a history of syncope. In adult patients who underwent repeated diagnostic tilt tests, we have observed an improved tilt tolerance. Therefore we hypotesised that repeated and prolonged exposure of the cardiovascular system to orthostatic stress might have therapeutic effects in the management of patients with this disorder. The purpose of the present study was to analyse whether the same results could be obtained in pediatric patients with neurocardiogenic syncope. **Methods:** 12 pediatric patients (mean age: 12.7 ± 3.7, min 6 years) with a history of syncope and positive tilt test, performed a program of tilt training. 6 patients were diagnosed as vasodepressor type of syncope, 4 with cardio-inhibitory (CI) type and 2 with mixed type. In the patients with the cardio-inhibitory type of syncope the duration of asystole ranged from 10 to 15 s (mean 12.4 ± 2.5). The patients were tilted daily until syncope occurred or until 45 min. After discharge from the hospital the patients continued tilt training at home for 1 or 2 periods of 30 min per day. They were instructed to lean against a vertical wall, under the supervision of a family member. **Results:** A significant increase in tilt duration was observed during one week of in hospital therapy, with disappearance of syncope in all patients (tilt duration during diagnostic test: 21 ± 13 min (minimum: 3.5 min) vs >45 min at discharge from the hospital. After 2 to 6 sessions all patients were able to sustain the tilt test for 45 min. In the patients with the CI type of syncope, asystole during tilt disappeared within 2 days. In all pts syncope during daily life disappeared completely. **Conclusion:** A daily program of tilt training is a satisfactory therapy also for pediatric patients with neurocardiogenic syncope, since it abolishes the abnormal and excessive autonomic reflex activity.

P3446 Young adult Marfan patients: aortic stiffness and the influence of beta-blocker medication

M. Groenink, A. de Roos[1], B.J.M. Mulder, B. Verbeeten Jr[2], J. Timmermans[3], E.E. van der Wall[4]. *Cardiology Dept, Acad. Medical Centre, Amsterdam; [1]Radiology Dept, Leiden Univ. Medical Centre, Leiden; [2]Radiology Dept, Acad. Medical Centre, Amsterdam; [3]Cardiology Dept, Nijmegen Univ. Hosp., Nijmegen; [4]Cardiology, Leiden Univ. Medical Centre, Leiden, Netherlands*

Objective: To investigate aortic stiffness in young adult Marfan patients with and without β-blocker medication.

Methods: 69 Marfan patients (age range 18–40 yrs) without a history of aortic aneurysms necessitating surgery and 21 matched controls were studied with magnetic resonance velocity mapping, perpendicular to 4 levels in the aorta: 1) ascending aorta, 2) descending aorta (level: pulmonary bifurcation), 3) descending aorta (level: diaphragm), and 4) (level: above the aortic bifurcation). Modulus/phase image pairs with a spatial resolution of 1 mm/pixel, at a temporal resolution of 25 ms, were generated. Aortic flow curves at the 4 levels were calculated. Flow wave velocity (FWV) was calculated from the onset of the flow waves and the distances between two levels. FWV from (A) level 1 to 2, (B) level 2 to 3, (C) level 3 to 4, and (D) level 1 to 4 were compared between 21 controls, 48 Marfan patients using and 21 Marfan patients not using β-blockers.



Results: Significant differences in FWV between Marfan patients and controls were demonstrated in all segments (A: 4.3 ± 1.1 vs 3.8 ± 0.7 ms^{-1}, B: 6.5 ± 2.2 vs 4.5 ± 0.8 ms^{-1}, C: 5.5 ± 1.6 vs 4.4 ± 1.0 ms^{-1}, D: 5.1 ± 0.8 vs 4.2 ± 0.5 ms^{-1}, respectively,$p < 0.03$. Significant differences in FWV between Marfan patients using and not using β-blockers (5.0 ± 0.7 vs 5.4 ± 0.9 ms^{-1}, $p = 0.04$) and between the both groups and the controls (4.3 ± 0.5 ms^{-1}, $p < 0.0001$) could be demonstrated in segment D. Furthermore, a significant difference in mean blood pressure between the groups using and not using β-blockers was demonstrated (78 ± 7 vs 83 ± 8 mmHg, $p = 0.02$).

Conclusions: Young adult Marfan patients show increased stiffness of the entire aorta. Aortic stiffness differences between patients using and not using β-blockers may be related to a reduction in blood pressure.

P3447 Mechanisms for aortic arch gradients unmasked by isoprenaline

N. Sreeram[1], E.D. Silove[2]. *[1]Wilhelmina Children's Hospital, Utrecht, Netherlands; [2]Birmingham Children's Hospital, Birmingham, UK*

Purpose: A subgroup of patients have persistent upper limb hypertension at rest, and left ventricular hypertrophy (LVH) following coarctation repair, despite the absence of resting pressure gradients. The aim of the study was to assess the changes in catheter pullback pressure gradients following iv isoprenaline infusion.

Methods: In 14 pts (7 M, 7 F; median weight 12 [range 5–70] kg; median age 13.9 [3–192] months) who had previously undergone aortic arch repair (coarctation N = 10; interrupted arch N = 2; Damus procedure N = 2; interval from surgery to catheterization 6 [3–48] months), iv isoprenaline (0.1 mcg/kg/min) was administered at cardiac catheterization. Indications for catheterization were resting hypertension (N = 5), echo-Doppler gradients of >30 mm Hg at rest or during exercise (N = 7), or prior to planning further surgery (N = 2).

Results: During isoprenaline infusion, the median heart rate increased from 93 [70–140] to 130 [110–165] beats/min. The pullback gradient across the repaired segment increased from 10 [0–35] to 43 [13–75] mm Hg ($p < 0.05$). In all 5 patients with resting upper limb hypertension there was an exaggerated increase in gradient from 18 [0–35] mm Hg at baseline to 55 [35–75] mm Hg. In 3 others, all with LVH, upper segment hypertension was recorded only during isoprenaline infusion. In these patients, this was the mechanism for the development of a pressure gradient across the aortic arch. The remaining 6 patients had normal upper segment pressures during isoprenaline infusion, but developed gradients (median 5 [2–10] mm Hg at baseline to 24 [13–48] mm Hg with isoprenaline), due to a decrease in distal vascular resistance.

Conclusion: Two distinct mechanisms (increased degree of obstruction with upstream hypertension, or decreased distal vascular resistance and impaired pulse transmission) account for the development of pressure gradients following aortic arch repair. Isoprenaline may unmask clinically significant arch obstruction following previous aortic arch reconstruction.

CORONARY ARTERY PROBLEMS IN CONGENITAL HEART DISEASE

P3448 Myocardial perfusion and coronary flow reserve in children with transposition of the great arteries 10 years after anatomical correction

M. Hauser, A. Kühn, F. Bengel[1], M. Beckmann, M. Schwaiger[1], J. Hess. *Department of Pediatric Cardiology, Deutsches Herzzentrum, Munich; [1]Nuklearmedizinische Klinik der Technischen Universität, Munich, Germany*

Children after anatomical correction of TGA are subsequently largely asymptomatic. However, the final outcome and possible coronary insufficiency remains unclear. It has been considered that coronary flow reserve (CFR) may be reduced in this population.

Methods: Myocardial blood flow (MBF) was assessed at rest and during maximal hyperemia using N-13 ammonia PET before and after intravenous adenosine infusion in 22 children (mean age 12 ± 2 years). MBF and CFR were compared with a group of healthy volunteers.

Results: A stress-induced perfusion defect was noted in 4 patients. Mean resting MBF was higher in patients than in volunteers (0.97 ± 0.27 vs. 0.74 ± 0.14, $p = 0.04$), while stress MBF was reduced (2.74 ± 0.44 vs. 3.48 ± 0.59, $p = 0.001$). CFR in patients was significantly lower than in controls (2.96 ± 0.60 vs. 4.75 ± 0.81, $p < 0.0001$). Myocardial vascular resistance (MVR) was lower at rest in patients (97.87 ± 21.3 vs. 125.08 ± 25.06, $p = 0.006$), while stress MVR tended to be higher.

Conclusion: Patients with surgically corrected TGA show reduced coronary flow reserve compared with healthy young adults. Quantitative PET assessment of CFR may thereby reveal functional abnormalities in these patients prior to the appearance of perfusion defects.

P3449 Coronary anatomy and long-term outcome of the arterial switch

Paul A. Hutter, Ilse B. Raes, Lamise Ay, Thijs H. W. Plokker, Ger B. W. E. Bennink, J. François Hitchcock, Erik J. Meijboom. *University Hospital/Wilhelmina Children's Hospital Utrecht, Netherlands*

Background: Abnormal coronary artery anatomy (CAA) is thought to have a significant influence on mortality and late coronary morbidity after the arterial switch (ASO) and an alarming incidence of late coronary obstruction is reported. This study determines the impact of CAA on the long term outcome of the ASO and occurrence of late coronary obstruction.

Methods: CAA of 147 pts after ASO (1977–98) was determined based on operative reports and pre-operative angiograms. Current status and coronary related morbidity were evaluated using EKG's, echocardiograms, scintigraphy and post-operative coronary angiograms.

Results: In 117 pts CAA consisted of an anterior descending (LAD) and circumflex artery (Cx) from the left cusp and the right coronary artery (RCA) from the right or posterior cusp, 12 pts had LAD from the left and Cx and RCA from the right cusp, 7 LAD and RCA from one cusp and Cx from the other, 4 pts had single ostium and 3 pts had 3 separate ostia. 3 pts had complex patterns with double branches, one of whom had double Cx arteries from either cusp, crossing over in the myocardium and one pt had supra commisural coronary. Overall mortality was 20%. Late coronary related incidents were seen in 3 pts: 2 arrhythmia (1 fatal) and 1 severe LV dysfunction. All 3 pts had the most common anatomy, ischaemia was noted in the early postoperative period. In 2 of these pts coronary angiograms are normal, suggesting failure of myocardial protection during ASO. The 3rd pt has obstructed left ostium. 1 pt has asymptomatic stenosis of the right coronary ostium, and 1 pt has multiple tortuous collaterals from all 3 main coronary branches without stenosis. No significant difference was found between CAA and early mortality as well as late morbidity.

Conclusions: Contrary to previous reports did CAA prior to ASO not influence outcome in our patients. Late coronary abnormalities were found in 3 pts, two of whom are asymptomatic.

P3450 Thrombi in the heart and in coronary arteries in children: successful thrombolytic therapy with rt-PA

G. Kowalik, E. Wiatrowska, K. Kubicka, M. Tomyn, W. Kawalec, G. Brzezińska, J. Książyk, H. Łukasiewicz. *Department of Cardiology, The Children's Memorial Health Institute, Warsaw, Poland*

The aim of the study was to evaluate the effectiveness of thrombolytic therapy with rt-PA in cardiac thrombi and coronary arteries thromboses in children.

Material: 13 children aged 3 month (mo) to 17 years (y), (9 boys, 4 girls) were diagnosed in Department of Cardiology between 1996–1998. 5 patients (pts) had myocarditis/dilated cardiomyopathy (CMP) and severe heart failure (SF = 6.8–16%), 1 patient (pt) was after pacemaker implantation because of complete atrioventricular heart block, 2 pts with mechanical prosthetic valve (St. Jude) in mitral position, 2 pts with Kawasaki disease and 3 pts with complex congenital heart disease. In all pts localization of thrombi were evaluated by echocardiography: LV – 6 pts, LV and LA – 3 pts, RA – 1 pt, in coronary arteries – 2 pts (LPA and RPA – 1, RPA – 1), SV – 1 pt. All pts were treated with rt-PA (Actylise) in doses 0.03 to 0.1 mg/kg/h given to systemic vein or directly to occluded coronary arteries in 3 boluses of 1 mg. Duration of treatment was from 1 to 9 days. The PT, PTT, fibrynogen, FDP levels and complete blood cell count were monitored during thrombolytic therapy. Size and localization of thrombi were monitored by echocardiography. After completed rt-PA treatment heparine or Fraxiparine and Sintrom were given.

Results: Very good results – complete resolving of thrombi were achieved in 9 pts (69.2%), in 4 pts with myocarditis/CMP size of thrombi decreased but persisted until death.

Conclusions: 1. Rt-PA (Actylise) is very effective and safe thrombolytic drug in children with cardiac and coronary arteries thromboses given in dose 0.03–0.1 mg/kg/h to systemic vein or directly to coronary arteries in bolus 2. Short time bleeding from respiratory tract was the only complication observed in 1 pt.

P3451 Anomalous origin of the left coronary artery from the pulmonary artery: diagnosis and postoperative follow-up

E. Birk, J. Katz, E. Erez, M. Berant, A. Matitiau, R. Fogelman, L. Blieden, O. Dagan, B.A. Vidne. *Schneider Children's Medical Center of Israel, Petach Tikva, Israel*

Purpose: to review our experience with the diagnosis of anomalous left coronary artery (ALCA) from the pulmonary artery (PA) and to assess short to midterm surgical results.

Methods: between 1992 and 1998, 12 infants and children (2 mo to 15 yrs) were treated for ALCA at the SCMCI. Eight were diagnosed during the first year of life; 4 were diagnosed later, the oldest being 15 years of age. Eleven patients (pts) were operated on in order to establish dual coronary artery system: 6 underwent the Takeuchi procedure and 5 reimplantation of the ALCA.

Results: All pts diagnosed during the first year of life were symptomatic and had severe dysfunction of the left ventricle. One died shortly after diagnosis before surgical repair was attempted from multiorgan failure and severe neurologic damage. Older pts had preserved myocardial function. Echocardiographic diagnosis was accepted only if flow was clearly demonstrated within the LCA and into the PA. Using these criteria, 5/12 required catheterization to establish diagnosis (one infant and all older patients). Surgery was performed shortly after diagnosis and surgical technique chosen to best fit the anatomy. There were no operative or late deaths on follow up. Three pts needed additional surgery. The most recent evaluation revealed good global LV function in all patients operated on until November 1998, with normal fractional shortening as assessed by M-mode; 2 pts are still within recovery phase showing gradual improvement

Conclusions: (1) a diagnosis of ALCA can be established echocardiographically when flow is documented from the LCA into the MPA, (2) the preferred surgical method appears to be reimplantation of the ALCA and (3) even though global LV function recovers to a great extent, abnormal myocardial features can be identified even years after surgery.

CONGENITAL HEART PROBLEMS IN ADULTS AND ADOLESCENTS

P3452 Long-term results (30 years) after coarctation of aorta repair

J. Popelová, P. Dostálová, T. Belšán, M. Voříšková, T. Honěk, F. Köbel. *Department of Internal Medicine, University Hospital Motol, Prague, Czech Republic*

Backround: Even after successful operation of coarctation of aorta (COA) the patients are not cured.

Methods: We examined 21 pts (mean age 41 ± 9 years) who were operated for COA in the age of 11 (3–18) years, 30 ± 8.7 years ago. The type of operation was in 95% resection and anastomosis end-to-end, one patient had Dacron graft. We performed clinical examination, echocardiography, exercise test and MRI.

Results: Bicuspid aortic valve was present in 63%, in 19% with moderate or severe dysfunction, in 28% with mild dysfunction, mitral valve disease was found in 19%, one patient had Ebstein anomaly of tricuspid valve, one patient aneurysm of ascending aorta. Left ventricle hypertrophy ≥ 12 mm was in 57%, left ventricle systolic dysfunction with EF ≤ 50% was found in 14%. Rest hypertension had 48% of patients, exercise hypertension ≥ 200 mmHg 57% of patients. Recoarctation with arm-leg pressure gradient ≥ 20 mm Hg was in 19%, stenosis > 30% on MRI was in 52%. Most patients (67%) were in functional class NYHA I, 14% in NYHA II, 19% in NYHA III. Patients with stenosis > 30% on MRI had NYHA 1.8 ± 0.87, patients with stenosis ≤ 30% with exclusion of moderate or severe valvular disease were all in functional class NYHA I ($p < 0.01$). Hypercholesterolemia > 5.5 mmol/l was found in 38%.

Conclusion: In spite of good clinical outcome, there are many residual findings in patients 30 years after COA repair. With respect to the increased risk of coronary artery disease and progression of valvular disease, these patients should be followed up closely.

P3453 Effect of phlebotomy on haemostatic parameters in adults with cyanotic congenital heart disease

E. Oechslin, D. Harrison[1], G. Webb[1], E. Yeo[1], S. Siu[1]. *Divisions of Cardiology, University Hospital, Zurich, Switzerland; [1]The Toronto Hospital, Toronto ON, Canada*

Hemostatic abnormalities affecting both platelets and coagulation factors are known in patients (pts) with cyanotic congenital heart disease (CCHD) and are associated with an increased risk for bleeding. Phlebotomy (P) has been recommended to reduce the perioperative risk of serious bleeding. The aim of this study was to evaluate the impact of P on hemostatic parameters in pts with CCHD.

Methods: 13 pts (3 females), mean age 36.0 ± 11.5 yrs, oxygen saturation 82.5 ± 3.6%, underwent 20 P because of hyperviscosity symptoms. Isotonic saline (750 ml) was administered prior to withdrawal of 500 ml of whole blood. Whole blood was collected in sodium citrate tubes adjusted for packed cell volume (PCV) before P, 100 and 200 minutes after the end of P (E100, E200) and on day 3 and 10. Hemoglobin (HB, g/L), PCV (%), platelet count (PLT, bil/L), international normalized ratio (INR), activated thromboplastin time (aPTT, sec), thrombin time (TT, sec) and fibrinogen (F, g/L) were measured. Parameters before P were compared to those after P.

Results:

HB	PCV	PLT	INR	aPTT	F	
Before P	221 ±18	68 ± 6	140 ± 52	1.14 ± 0.09	31.3 ± 3.3	3.3 ± 0.7
E 100	209 ± 23*	63 ± 7*	140 ± 55	1.16 ± 0.10	35.9 ± 23.8	3.0 ± 0.6†
E 200	209 ± 23*	63 ± 7*	144 ± 54	1.15 ± 0.10	31.5 ± 3.1	3.1 ± 0.8
Day 3	206 ± 20*	62 ± 6*	149 ± 51	1.12 ± 0.08	30.3 ± 2.6	3.3 ± 0.8
Day 10	204 ± 20*	63 ± 6*	169 ± 52#	1.12 ± 0.07	29.3 ± 3.7‡	3.7 ± 0.6‡

TT is comparable: 16.6 ± 1.9 *vs* 16.3 ± 1.6 *vs* 16.8 ± 2.1 *vs* 16.9 ± 2.0 *vs* 16.7 ± 1.3 sec. p-value *vs* before P: *p < 0.001; #p = 0.013; ‡p = 0.003; †p = 0.001

Conclusion: Phlebotomy results in a mild increase in platelet count and fibrinogen and in a slight decrease in aPTT on day 10. Extrinsic coagulation pathway is not affected by P. P may be justified at least 10 days before major surgery in this population to improve hemostasis and to donate autologous blood.

P3454 Prevalence, risk factors and clinical consequences of thrombus formation detected by transoesophageal echocardiography after "Fontan type" operations

Manfred Vogt, Gunter Balling, Harald Kaemmerer, Andreas Eicken, Walter Sebening, John Hess. *German Heart Center, Department of Pediatric Cardiology and Congenital Heart Defects, Munich, Germany*

Intracardiac thrombus formation in patients after "Fontan-type" operations are well known as a risk factor. We performed serial transoesophageal echoexaminations (TEE) in such patients, as transthoracic echocardiography (TTE) often does not detect thrombus formation. To evaluate risk factors for thrombogenesis we compared age, sex, underlying cardiac malformation, type of Fontan operation, clinical-, laboratory-, echo- and haemodynamic data between the thrombus and non thrombus group.

Results: 67 TEE's were performed in 43 patients, mean age 19.4 years (range 7.3 y), mean age at operation 9.0 y (range 5.5 y). 16 patients showed thrombus formation in the right atrium, in one of them a thrombus was suspected on TTE. After a mean interval of 5.3 months in five patients the thrombus was resolved, 3 had a residual thrombus and in five thrombus was unchanged despite thrombolytic therapy with alteplase and consecutive oral anticoagulation. There was no difference in age at operation, sex distribution, age at TEE, underlying cardiac malformation and presence of arrhythmias between both groups. Laboratory (Hct, albumine, pTT, protein C and S), echocardiographic (spontaneous echocontrast, ventricular function, atrioventricular- and/or semilunar regurgitation)- and haemodynamic findings (right atrial pressure, pulmonary artery pressure, transpulmonary gradient, systemic and pulmonary flow ratios systemic and pulmonary resistance) did not differ between thrombus and non thrombus group.

Conclusion: All patients with "Fontan-type" operations seem to be at risk for thrombogenesis and therefore should have serial TEE. As there are no predictive risk factors concerning laboratory, haemodynamic and echocardiografic findings all patients should have oral anticoagulation lifelong.

P3455 Prevalence and clinical outcome of hepatitis C infection after cardiac surgery in childhood

M. Vogt, J. Hess, Th. Lang, Ch. Klingler, A. Zeller, G. Frösner. *Department of Pediatric Cardiology, German Heart Center, University Children's Hospital, Max v. Pettenkofer Institute Munich, Germany*

Hepatitis C (HCV) has been known as the main cause of posttransfusion hepatitis since 1989. Worldwide very few data exist on the prevalence of HCV-infection in pediatric patients after major cardiac surgery. We revaluated a study population comprising 486 pts. (mean age 18 years) under medical attendance of the German Heart Center Munich, having undergone operation before 1990. Since 1991 all blood products are routinely tested for anti-HCV.

Method: Serum samples werde collected and examined for anti-HCV antibodies by means of enzyme immuno assay (Abbott EIA II) and westernblot (Mikrogen, Munich) and directly for HCV-RNA by RT-PCR. In addition RNA positive samples were genotyped (RFLP) and quantitated (HCV Amplicor Roche). In all seropositive pts. tests for liver enzymes and auto-antibodies were performed.

Results: Of the 486 pts. examined 14.8% were anti-HCV positive after a mean interval of 17.5 years after the operation compared to 0.65% in an age and sex matched control group. In 55% of the patients HCV-RNA could be detected. Genotype distribution was as follows: 1 a (acc. to Simmonds) 40%, 1 b – 60%, 3 a < 1%. RNA concentration ranged between 250 000 and 1,200 000 genome equivalents/ml. All pts. were clinically stable with only slightly elevated liver enzymes (ALT, AST < 60 U/L) in the positive group.

Summary: These results show a anti-HCV prevalence among the cardiac surgery pts. being 18 times higher than in the normal German population. Despite beeing clinically well in the moment, these pts. are considered to be at risk for chronic liver disease

P3456 Emergency hospital admission of adults with congenital heart disease

H. Kaemmerer, E. Oechslin[1], S. Fratz, S. Brodherr-Heberlein, J. Turina[1], R. Jenni[1], J. Hess. *Abtl. f. Angeborene Herzerkrankungen, Deutsches Herzzentrum Munich, Munich, Germany; [1]Abteilung Kardiologie, Universitatsspital Zurich, Zurich, Switzerland*

The number of patients (pts) with congenital heart disease (CHD) reaching adulthood is continuously growing. Naturally also the emergency hospital admission quantity in this patient population is rising. The aim of this study was to determine the reason and the nature of the emergency situation that lead to an unscheduled hospital admission into a specialized centre.

During 11 consecutive months a total of 61 pts aged 16 to 58 ys (median 27.0 ys) were acutely admitted to the hospital. The distribution of the underlying CHD was as follows: Fallot's Tetralogy/pulmonary atresia (n = 21), univentricular heart after Fontan procedure (n = 15), atrial switch in complete transposition of the great arteries (n = 10), Eisenmenger syndrom with atrioventricular septal defect (n = 1), truncus arteriosus, or ventricular septal defect (n = 4), congenitally corrected transposition of the great arteries (n = 3), atrial septal defect (n = 2), others (n = 5). 51 of the admitted pts had been previously operated.

The reasons for hospital admission (more than one reason possible) were: atrial or ventricular arrhythmia (n = 31), acute heart failure (n = 16), transient cerebral ischemia or cerebral abscess (n = 3), syncope (n = 3), acute abdomen (n = 2), dissecting aortic aneurysm (n = 1), resuscitation (n = 1), respiratory failure (n = 1), suspected pulmonary embolism (n = 2), endocarditis (n = 1), infected pacemaker electrode (n = 1).

All pts needed immediate emergency care. 18 cases had to be admitted directly to the intensive care unit, 9 pts underwent urgent surgery (heart, brain, or gastrointestinal surgery). 9 pts died. The survivors were hospitalized for 12 ± 10 days.

In conclusion: adults with CHD can experience a broad number of serious emergency situations. Therefore management of this patient population is just successful if all associated specialities cooperate in a supraregional full service referral centre.

ARRHYTHMIAS AND ELECTROPHYSIOLOGY

P3457 Signal-averaged electrocardiography in healthy children: influence of age, gender and anthropometric data

J. Gehrmann, F. Müller[1], M. Hellmich[2], D. Kececioglu[1], H.G. Kehl[1], T. Fetsch[3], J. Vogt[1]. *Cardiology Dept, Children's Hospital, Boston MA, USA; [1]Westfälische Wilhelms-Universität, Paediatric Cardiology Dept, Münster[2]Biostatistics Dept, Westfälische Wilhelms-Universität, Münster; [3]Cardiology Dept, Westfälische Wilhelms-Universität, Muenster, Germany*

Signal-averaged electrocardiographic (SAECG) abnormalities provide valuable information in risk stratification of children with various heart diseases culminating in fatal arrhythmias and heart failure. Childhood cancer therapy was also shown to be associated with increased incidence of SAECG abnormalities. Establishing normative data for the pediatric age groups therefore is imperative.

We determined the influence of body characteristics such as height, weight, body surface area (BSA), left ventricular mass, age and gender on SAECG signals and obtained normative data for standard SAECG parameters in a healthy pediatric population.

One hundred healthy children (52 females, 48 males) aged 10.4 ± 3.9 years were studied with high resolution ECG. The study group was divided into three age groups; each age group was divided in two subgroups according to gender. Parameters studied were the signal-averaged QRS duration (QRSd), the duration of the terminal portion of the QRS < 40 micro V of amplitude (LAS40), the root-mean-square voltage of the total QRS complex (RMS-QRS), and the root-mean-square voltage of the last 40 ms (RMS40). Means, standard deviations, minimum and maximum values were determined for each parameter at 25–250 and at 40–250 Hz filtering for the six subgroups. The relation between SAECG parameters and anthropometry was determined by linear regression analysis.

QRSd is significantly influenced by BSA (r = 0.58, p = 0.0001), height (r = 0.58, p = 0.0001), weight (r = 0.56, p = 0.0001),left ventricular mass (r = 0.56, p = 0.0001) and age (r = 0.51, p = 0.0001). There is a weak positive correlation between LAS40 and BSA (r = 0.27, p = 0.01), height (r = 0.26, p = 0.007), weight (r = 0.27, p = 0.01), left ventricular mass (r = 0.27, p = 0.006) and age (r = 0.26, p = 0.01). RMS40 and RMS-QRS are negatively correlated to anthropometric data. QRSd, LAS40 and RMS-QRS are significantly influenced by gender. In boys, LAS40 is influenced by weight (p = 0.04) and left ventricular mass (p = 0.02), in girls by age (p = 0.005), BSA (p = 0.03) and height (p = 0.02). The relation between SAECG parameters and body characteristics is more pronounced in females. Significant differences exist when results are compared to adult normal values.

These data provide a basis for interpretation of SAECG in children. Parameters are influenced by body surface area, height, weight and left ventricular mass. Age and gender also contribute significantly to the variation of some SAECG parameters. In the analysis of SAECG in children, adjustments of results for anthropometric characteristics, age and gender are mandatory.

P3458 Radiofrequency catheter ablation for all types of tachyarrhythmias in children and in patients with congenital heart disease

J. Papagiannis, V. Vassilikos, T. Maounis, E. Livanis, G. Kyrvassilis, A. Nikolaidis, D. Katritsis, S. Rammos, G.N. Theodorakis, A.S. Manolis. *Onassis Cardiac Surgery Center, Athens, Greece*

Since 1995, we have treated pediatric patients, and patients with congenital heart disease of any age with recurrent tachyarrhythmias (TA), with radiofrequency ablation. The purpose of this study was to present the results of this mode of therapy for all types of TA. Seventy four patients (pts), 48 males, 26 females were treated. There were 68 children, {2.5–18 (mean 12.09 ± 3.8) yrs} and 6 adults (21–45 yrs). Types of TA included: AV nodal reentry tachycardia (AVNRT) in 19 pts, AV reentry tachycardias (AVRT) in 43 pts (20 left, 6 right and 20 septal-3 pts had two pathways), ectopic atrial tachycardia (EAT) in 4 pts, ventricular tachycardia in 6 pts {idiopathic right ventricular (RV) tachycardia in 4, postoperative tetralogy of Fallot (TOF) in 1, RV dysplasia in 1} junctional automatic tachycardia (JAT) in 1 and incisional atrial reentry tachycardia (IART) in 2 pts. One pt had both AVNRT and EAT. Congenital heart disease was present in 12 pts (Ebstein's anomaly in 5, postoperative TOF in 2, and congenitally corrected transposition, common AV canal, tricuspid atresia, transposition of the great arteries after Senning operation, and crisscross heart in 1 each). General anesthesia was used in 38 patients and conscious sedation in the rest. Success rates were 100% for IART, 95% for AVNRT and for AVRT, 75% for EAT, 50% for VT and the procedure was unsuccessful in the JAT pt. Fluoroscopy time was 8–117 min (mean 33.7 ± 27.4). Tachycardia reccurred in 11 pts (14%) and a successful repeat procudure was performed in 6 pts, whereas the rest are controlled with medications. Permanent complete AV block occurred in 1 pt (1.4%) with AVNRT and transient AV block in a pt with a posteroseptal accessory pathway. During follow-up of 1–40 months no other complications were noted.

In conclusion, radiofrequency catheter ablation is a highly efficacious form of therapy for pediatric and congenital heart patients that can be applied to all types of TAs. Highest success rates are expected for supraventricular TAs. The number of acute complications is extremely low and most can be avoided with careful technique. Medium term follow-up is remarkable for paucity of late side effects.

P3459 The effects of cisapride on ventricular repolarization in children

E. Tutar, A. Kansu[1], A.G. Kalayci[1], S. Atalay, N. Girgin[1], A. Imamoglu. *Pediatric Cardiology Dept., Ankara University, Medical School, Ankara; [1]Pediatric Gastroenterology Dept., Ankara University, Medical School, Ankara, Turkey*

Life-threatening ventricular arrhythmias mainly attributed to QTc prolongation have been reported in adults and children using cisapride, a prokinetic agent that facilitates gastrointestinal motility. We prospectively studied infants and children receiving cisapride without any concomitant drug, to analyze the time-related effects of cisapride on ventricular repolarization.

Standard 12-lead resting ECGs were obtained from 20 patients (mean age: 6.1 ± 4.1 years; range 2 months–13 years) before cisapride (0.8–1.2 mg/kg per day) therapy, and after 3rd, 7th days and 1 month of therapy. The corrected QT interval (QTc) was calculated by the method of Bazett. Dispersion of QT and QTc (QTD, QTcD) were defined as the difference between the maximum and minimum QT and QTc intervals occurring in any of the 12 leads. Data from these patients were compared with a control group of 372 normal children.

Baseline QTc, QTD and QTcD measurements were not different from control group. Mean QTc values at 7th day and 1 month of cisapride therapy were significantly higher from control group ($p < 0.01$ and < 0.001). Mean QTc at 7th day and 1 month of therapy were also found significantly higher than that of baseline value ($p < 0.05$ and < 0.01)). Mean QTD and mean QTcD values during the cisapride treatment were not different from baseline values and controls. Only two patients (2 and 8 months old) had prolongation of QTc (>450 ms) at 1 month of therapy.

The results of this study suggest that cisapride treatment may cause prolongation of ventricular repolarization without causing increased heterogeneity of repolarization (QT dispersion). Small infants may be more vulnerable to this effect because of reduced activity of p-450 enzyme system. However, clinical significance of these findings is unclear, because all the patients in this study group have been asymptomatic without signs of arrhythmia.

P3460 Ventricular arrhythmia, late potentials, QT dispersion and heart rate variability 5 to 18 years after surgery of tetralogy of Fallot: an increase of risk factors?

P. Jędrasik, D. Wojciechowski[1], Z. Lewandowski[2], H.A. Kowalski[3], M. Wróblewska-Kałużewska. *Dept. of Pediatric Cardiology, Warsaw University of Medicine, Warsaw; [1]Dept. of Clinical Bioengineering, Wolski Hospital, IBIB PAS, Warsaw; [2]Dept. of Epidemiology, Warsaw University of Medicine; [3]Institute of Computer Science, Warsaw, PolandUniversity of Technology*

Sudden death (SD) due to late complex ventricular arrhythmia (cVA) is important problem in patients (pts) after surgical repair of Tetralogy of Fallot, and may increase with longer interval after operation. We thus investigated, whether longer (≥10 years) time after surgery can have influence on occurrence of factors, which were proposed to be related to the risk of SD, i.e. cVA, late potentials (LP), QT dispersion (QTd) and heart rate variability (HRV).

Methods: We distinguished 2 groups of pts: group A (<10 years after operation, mean 7.6 [± 1.3] years) – 21 pts, aged 7 to 12 years (mean 7.9 ± 1.5 years), and group B (≥10 years after operation, mean 12 [± 2.6] years) – 23 pts, aged 13 to 20 years (mean 16.3 ± 2.4 years). All subjects were in good hemodynamic status assessed by clinical and non-invasive examination. In all pts standard resting, ambulatory (48 h), exercise, signal-averaged ECGs, and short-term ECG for HRV spectral analysis were performed. According to HRV standards: total power (TP), low-frequency (LF), high-frequency (HF), and additionaly power coherent with respiration (CRP) were calculated by Berger's and validated by the autoregressive method. Statistical evaluation was performed by use of logistic and linear regression analyses.

Results: In pts operated more than last decade the risk of occurrence of cVA (couplets in 7 pts, a non-sustained VT in 1 pt) was more than 3-times higher (odds ratio = 3.2, $p > 0.13$, 95% confidence interval 0.71 ÷ 14.42) and risk of occurrence of LPs was 5-times higher (odds ratio = 4.7, $p > 0.07$, 95% confidence interval 0.84 ÷ 25.77) than in those operated less than 10 years. There were significant ($p < 0.05$) correlations between time from repair and QTd (r = 0.30), LF/HF (r = 0.42), normalized HF power (r = −0.42) and CRP (r = −0.43).

Conclusion: Accumulation, with time after surgery of Tetralogy of Fallot, of risk factors having influence on the electrical stability of the heart were observed in pts operated more than last decade.

P3461 Usefulness of the P-wave triggered signal-averaged ECG in predicting risk of paroxysmal supraventricular arrhythmias among children with atrial septal defect

W. Banasiak, H. Telichowska, A. Telichowski, A. Fuglewicz, M. Piepoli[1], A.J.S. Coats[1], P. Ponikowski. *Cardiac Department, Clinical Military Hospital, Wroclaw, Poland; [1]Clinical Cardiology, NHLI, London, UK*

Paroxysmal supraventricular arrhythmias (SVA) often complicate the natural history of atrial septal defect (ASD). In a group of 50 consecutive children and adolescents (age: 11 ± 7 yrs) with ASD we applied the P-wave triggered signal-averaged ECG (ASAECG) to investigate atrial electrophysiologic properties and to assess whether this method could be useful in detection those at risk of the development of SVA. Eighteen sex- and age-matched healthy children (age: 12 ± 5 yrs) formed a control group (C). The following ASAECG parameters were calculated: the root-mean-square voltage for the terminal 10, 20, 30 ms of filtered P-wave (RMS10, 20, 30) and time duration of filtered P-wave (PWD).

Results. In the whole group of ASD pts we found longer duration of the PWD and lower values of RMS10 compared to controls (106 ± 13 vs 94 ± 14 ms, 5.2 ± 2.1 vs 6.4 ± 2.0 μV, ASD vs C, $p < 0.05$). None of the ASAECG parameters significantly correlated with the baseline clinical characteristics, the right ventricle diameter (RVD) and the ratio of pulmonary to systemic flow (Qp:Qs). Eight (16%) ASD pts revealed paroxysmal SVA (atrial fibrillation in 8 pts and supraventricular tachycardia in 2 pts) on 24 h Holter monitoring. They demonstrated more compromised haemodynamic status (table), but also a decreased value of RMS10 and RMS20 compared to pts without paroxysmal SVA. The PWD and RMS30 did not differ between groups.

	PWD (ms)	RMS10 (μV)	RMS20 (μV)	RVD (mm)	Qp:Qs
SVA+ (n = 8)	109 ± 11	3.8 ± 1.0*	6.3 ± 1.6	24 ± 6*	2.9 ± 1.0*
SVA− (n = 42)	106 ± 14	5.5 ± 2.2	8.0 ± 3.0	20 ± 5	1.7 ± 0.6

*- $p < 0.05$ SVA+ vs SVA−; $p = 0.09$ for RMS20

Conclusions. Children and adolescents with ASD and paroxysmal SVA demonstrate unfavourably altered atrial electrophysiologic properties which do not simply reflect impaired haemodynamic status. P-wave triggered SAECG could be a useful technique for detecting children with ASD at risk of paroxysmal SVA.

P3462 Management and outcome of atrial flutter in the perinatal age group

Lukas A. Lisowski, Paul M. Verheijen, Avraham A. Benatar, Rogier Schade, Philip Stoutenbeek, Erik J. Meijboom. *Wilhelmina Children's Hospital/UMC, Utrecht, Netherlands*

Background: Perinatal atrial flutter is a potentially lethal arrhythmia. Management of this rhythm disorder in the perinatal period is difficult and controversial.

Methods: A group of 44 pts with documented atrial flutter was studied retrospectively.

Results: Atrial flutter was diagnosed prenatally in 43 fetuses and immediately postnatally in one neonate. Fetal hydrops was seen in 19 pts, of whom 16 received matemal therapy. Two were delivered and one not treated, because of a severe non-treatable cardiac malformation. In the non-hydropic group of 24 pts 16 were treated and the remaining 8 were delivered immediately. In the hydropic group 10 received single-drug therapy (digoxin or sotalol), 6 multiple-drug therapy. In the non-hydropic group 12 received a single drug (digoxin or sotalol) and 4 multiple drugs. One pt with rapid 1:1 atrio-ventricular conduction (heart rate 480/min) died in utero. Of the 43 liveborn infants 12 were in atrial flutter at birth. Electrical cardioversion was successfull in 8 of 9 pts. Transvenous overdrive atrial pacing was successfull in one of 2 pts where it was used. No recurrences in atrial flutter have occurred beyond the neonatal period. Neurological damage of prenatal origin, however, was encountered in 4 pts, including ischaemic damage, intra-ventricular hemorrhage and infarction.

Conclusions: Fetal atrial flutter is a serious and threatening rhythm disorder and particularly when it causes hydrops. It may be associated with fetal death or neurological damage. Treatment is required primarily aimed at reaching an adequate ventricular rate and preferably conversion to sinus rhythm. Digoxin failed in prevention of recurrence at time of delivery in a quarter of our pts, while with sotalol no recurrence of atrial flutter has been reported. Therefore class III agents may be the future therapy. Once fetuses with atrial flutter survive without neurological damage, their future is good and prophylaxis beyond the neonatal period is unnecessary.

P3463 Haemodynamically optimized temporary cardiac pacing after surgery for congenital heart defects

J. Janousek, P. Vojtovic, B. Hucin, T. Tlaskal, V. Chaloupecky, M. Kostelka, O. Reich. *Kardiocentrum, University Hospital Motol, Prague, Czech Republic*

Disturbance of normal AV synchrony and dyssynchronous ventricular contraction may have deleterious effect on pts with otherwise compromised hemodynamics. This study evaluated the effect of hemodynamically optimized temporary dual-chamber pacing in pts after surgery for congenital heart disease.

Methods: Pacing was performed in 23 children with various postoperative dysrhythmias, low cardiac output and/or high inotropic support aged 5 days to 7.7 years (median 7.3 months) and optimized to achieve highest systolic and mean arterial and lowest mean central venous and/or left atrial pressures. Following pacing modes were used: 1. Atrial triggered or AV sequential pacing with individually optimized AV delay in 12 pts with 1st–3rd° AV block. 2. AV sequential pacing using transesophageal atrial pacing in combination with a temporary VAT pacemaker for atrial tracking and ventricular pacing in 2 pts with 3rd° AV block and poor signal and exit block on atrial epicardial pacing wires. 3. R wave triggered atrial pacing in 8 pts with junctional ectopic tachycardia and impaired antegrade AV conduction precluding the use of atrial overdrive pacing. 4. Atrio-biventricular sequential pacing in 2 pts. Implantable pulse generators customized for temporary pacing were used to improve atrial sensing and allow for high synchronization rates combined with long AV delays necessary for R wave triggered atrial pacing.

Results: Optimized pacing led to a significant increase in arterial systolic (mean) pressure from 71.5 ± 12.5 (52.3 ± 9.0) to 80.5 ± 12.2 (59.7 ± 9.1) mmHg ($p < 0.001$ for both) and decrease in central venous (left atrial) pressure from 12.3 ± 3.4 (10.5 ± 3.2) to 11.0 ± 3.0 (9.2 ± 2.7) mmHg ($p < 0.001$ and < 0.005, resp.) (compared to spontaneous rhythm, VVI pacing or dual-chamber pacing with empirically set AV delays at identical heart rates). Optimal AV delay settings during AV synchronous pacing ranged from 15 to 140 ms (15–50 ms in 13/16 pts). Atrio-biventricular pacing added further hemodynamic improvement to AV sequential univentricular pacing in both evaluated pts.

In conclusion, individually optimized temporary dual chamber pacing was successfully used to improve hemodynamics in pts with poor ventricular function and various dysrhythmias after congenital heart surgery. Very short AV delays during AV synchronous pacing were necessary in the majority. Biventricular pacing carried an additional hemodynamic benefit to optimized AV synchrony. Technical limitations could be overcome by customized pacing equipment.

P3464 Fetal complete atrioventricular block: perinatal outcome

D. Dimeski, V. Jani[1], Z. Elizabeta[1]. *Skopje; [1]Department of Fetal Cardiology, University St. Cyril and Methodius, Skopje, FYROM*

The clinical course and outcome with complete atrioventricular (AV) block detected prenatally were studied to identify factoes that affect the natural history of this lesion.

Methods: We used Fetal echocardiography to study complete AV block. The study included 27 fetuses with complete AV block between 19–38 week's gestation. In 14 fetuses (52%) complete AV block was associated with complex structural heart defects, usually left atrial isomerism (n-8) or discordant AV connection (n-3). The other 13 fetuses had normal cardiac anatomy; in 9 cases the mother had connective tissue disease or tested positive for antinuclear antibodies. Three fetuses showed progression from sinus rhythm or second degree block to complete AV block. Of the 27 pregnancies, 3 were terminated and 12 fetuses or neonates died; at the and of the neonatal period 13 fetuses were still alive. Fetal or neonatal death correlated significantly with the presence of structural heart defects (2 of 14 surviving, $p < 0.001$), hydrops (0 of 11 surviving, $p < 0.001$), an atrial rate < 120 beats/min (1of 6 surviving, $p < 0.005$) or a ventricular rate < 55 beats/min (1 of 10 surviving, $p < 0.001$). Mean atrial and ventricular rates were higher in surviving than in nonsurviving fetuses (142 ± 8 vs. 127 ± 21 beats/min, $p < 0.002$; 64 ± 6 vs. 52 ± 8 beats/min, $p < 0.001$, respectively). A slow atrial rate, however, was frequently associated with left atrial isomerism. In fetuses without left isomerism, mean atrial rate was not significantly different in surviving and nonsurviving fetuses (142 ± 8 vs. 144 ± 15 beats/min, $p = 0.66$), whereas ventricular rate remained different (64 ± 8 vs. 53 ± 8 beats/min, $p < 0.001$). In two cases transplacentar treatment by administering sympathomimetic drugs to the mother was attempted. Although ventricular rate increased variably, only one of these four fetuses, which had no additional structural defect, survived. Effective forms of fetal therapy are not established. A postnatal prmanent pacemaker was implanted in 6 neonates; 4 survived the neonatal period.

In conclusion: Fetal echocardiography must be considered a useful in the study of greater undestanding factors that influence the natural history of fetal complete AV block.

CONGENITAL HEART DISEASE IN FOETUSES AND NEWBORNS

P3465 Impact of fetoscopic versus open fetal surgery on fetoplacental blood flow and outcome in human foetuses

T. Kohl, D.B. McElhinney[1], J. Farrel[2], H.H. Scheld[3], J. Vogt, M.R. Harrison[2], N.H. Silverman[4]. *Department of Pediatric Cardiology, University of Münster Medical School, Münster, Germany[1] Department of Paediatric Heart Surgery, University of California, San Francisco CA[2]Department of Paediatric Surgery, University of California, San Francisco CA, USA[3]Department of Cardiovascular Surgery, University of Münster Medical School, Münster, Germany[4] Department of Paediatric Cardiology, University of California, San Francisco CA, USA*

Introduction: The outcome of human fetal cardiac interventions may be influenced by the impact of the operative approach on fetoplacental blood flow. Therefore, the purpose of our study in human fetuses was to assess the effects of a fetoscopic versus an open operative approach on fetoplacental blood flow, neurological damage and fetal demise.

Methods: Fetoplacental blood flow was studied in 21 human fetuses before and on the day after fetoscopic (n = 6) or open (n = 15) fetal surgery for a noncardiac lesion by 2-dimensional and pulsed-Doppler ultrasound. Hemodynamic variables measured or calculated were umbilical arterial (UA) systolic, diastolic and mean flow velocities. Neurologic damage was assessed with prenatal head ultrasound and/or postnatal evaluation. Variables were analyzed using Bonferroni's paired samples t-test and individual samples t-tests and are presented as mean and SD considering a $p < 0.05$ as significant.

Results: Before fetal surgery, systolic, diastolic and mean umbilical arterial blood flow velocities were similar in the fetuses undergoing fetoscopic versus open fetal surgery (systole 40.0 ± 7.0 cm/sec vs. 36.2 ± 5.0 cm/sec, $p = 0.17$; diastole 11.3 ± 5.1 cm/sec vs. 9.7 ± 1.7 cm/sec, $p = 0.31$; mean 22.3 ± 5.3 cm/sec vs. 21.8 ± 3.1 cm/sec, $p = 0.82$). On the day after fetal surgery, systolic, diastolic, and mean umbilical arterial flow velocities were significantly higher after the fetoscopic than the open operative approach (systole 43.1 ± 13.1 cm/sec vs. 28.2 ± 8.4 cm/sec, $p = 0.009$; diastole 16.1 ± 15.0 cm/sec vs. 6.3 ± 2.8 cm/sec, $p = 0.047$; mean cm/sec 26.9 ± 12.1 vs. 14.2 ± 4.2 cm/sec, $p = 0.005$). There was a strong trend to lower mortality and less neurological damage after the fetoscopic approach versus the open operative group (29% vs. 64%, $p = 0.12$; 14% vs. 43%, $p = 0.2$).

Conclusion: In human fetuses, a fetoscopic operative approach preserves fetoplacental blood flow better than an open one. This finding may explain the trend for lower mortality and less neurological damage following the minimally invasive fetoscopic approach and strengthens its value for fetal cardiac interventions.

P3466 Homeometric autoregulation enables the right ventricle of the newborn animal to maintain cardiac output during infant respiratory distress syndrome and subsequent partial liquid ventilation

R.H. Lopes Cardozo[1], P. Steendijk[2], H.A.A. Brouwers[3], M. De Vroomen[2], J. Baan[2], F. Van Bel[1,3]. *Departments of [1]Paediatrics; [2]Cardiology, Leiden University Medical Centre; Department of [3]Neonatology, Wilhelmina Childrens Hospital, University Hospital Utrecht, Utrecht, Netherlands*

Infant Respiratory Distress Syndrome (IRDS) causes increased pulmonary vascular resistance with a raised afterload. Subsequent Partial Liquid Ventilation (PLV) improves respiratory conditions but may further raise pulmonary vascular resistance. We investigated the effects of artificially induced IRDS and subsequent PLV on RV and LV systolic pump function and on pulmonary and systemic hemodynamics in the newborn lamb.

Methods: IRDS was induced by lung lavages in nine newborn lambs that were subsequently treated with PLV for 30 min (PLV-30) and 60 min (PLV-60). RV and LV contractilities were assessed using indices derived from RV or LV end-systolic pressure-volume relations, obtained by micromanometric and conductance catheters during inferior vena cava occlusion.

Results: Pulmonary function deteriorated during IRDS with a significant decrease in P_AO_2/FiO_2 whereas pulmonary artery pressure (P_{AP}) and pulmonary vascular resistance increased significantly. Cardiac output (CO) and stroke volume (SV) did not change. RV contractility showed a significant increase during IRDS: the slope of the end-systolic pressure-volume relation ($RV\text{-}E_{ES}$) increased while its volume intercept at 5 kPa ($RV\text{-}V_5$) decreased. Pulmonary function recovered during PLV whereas P_{AP} and pulmonary vascular resistance remained high. RV contractility showed a sustained significant increase. Indices for LV pump function and contractility were always unchanged.

	Baseline	IRDS	PLV-30	PLV-60
P_AO_2/FiO_2	0.60 ± 0.13	$0.10 \pm 0.06^*$	$0.35 \pm 0.13^\#$	$0.26 \pm 0.16^\#$
P_{AP} (kPa)	2.22 ± 0.58	$3.60 \pm 1.32^*$	$3.40 \pm 0.86^*$	$3.52 \pm 0.84^*$
$RV\text{-}E_{ES}$ (kPa/ml)	1.22 ± 0.58	$1.88 \pm 0.64^*$	$2.07 \pm 0.71^*$	1.69 ± 0.86
$RV\text{-}V_5$ (ml)	1.88 ± 0.64	$0.91 \pm 0.46^*$	$1.15 \pm 0.35^*$	$1.01 \pm 0.63^*$

$^*P < 0.05$ compared with baseline. $^\#P < 0.05$ compared with IRDS

Conclusion: IRDS increases pulmonary vascular resistance and right ventricular contractility without significantly changing left ventricular contractility. With subsequent partial liquid ventilation, lung function improves but pulmonary vascular resistance remains high with no further change in cardiac performance. It is shown that with the increased pulmonary vascular resistance, the right ventricle of the newborn heart is able to maintain cardiac output through homeometric autoregulation.

P3467 Prenatal diagnosis of congenital heart disease prevents pre-operative lact-acidosis in the newborn patient

Paul M. Verheijen, Lukas A. Lisowski, Philip Stoutenbeek, Ger B.W.E. Bennink, J. Francois Hitchcock, Erik J. Meijboom. *University Hospital/Wilhelmina Children's Hospital, Utrecht, Netherlands*

Background: Duct-dependent congenital heart disease may not cause problems during fetal life but can in immediate postnatal life. Prenatal detection and immediate postnatal care, including prostaglandin administration, might improve management of the disease, lead to better blood gas control and thus prevent severe pre-operative lact-acidosis.

Methods: Patients operated upon for congenital heart disease during the first 31 days of life (n = 164) were studied retrospectively, 16 were diagnosed prenatally (group A) and 148pts had not been diagnosed prenatally (group B). The prenatally diagnosed pts were delivered within the University Hospital, received prostaglandin immediately and were intubated and ventilated if needed. The other 148 pts were all born in outlying hospitals or at home and were transported in after congenital heart disease was suspected.

Results: differences were noted in post-op intensive care duration (group A vs. B: 4.40 ± 1.54 vs. 9.51 ± 2.29 days, $p = 0.48$), pre-op pH (7.30 ± 0.03 vs. 7.27 ± 0.01, $p = 0.30$), BE (-5.10 ± 0.78 vs. -6.16 ± 0.55 mmol/l, $p = 0.54$) and *lactate* 3.14 ± 0.57 *vs.* 6.33 ± 0.58, $p < 0.001$), indicating a significant difference in blood lactate in favor of the prenatally diagnosed group.

Conclusions: Prenatal diagnosis of congenital heart disease and the resulting immediate postnatal care prevent lactate increase in the pre-operative period of these patients. This decreases the risk of cerebral damage and brings the patient in better condition at surgery.

P3468 Electron microscopic and morphometry data does not correlate with the functional and haemodynamic response to growth hormone in patients with dilated cardiomyopathy

F.M. Habib, N.J. Hayat[1], H. Romansca[2], C.S. Thomas[1], K. Varghese[1], G. Cherian[1]. *Cardiology Dept, Al Safat; [1]Cardiology Dept, Chest Diseases Hospital, Kuwait, Kuwait; [2]Pathology Dept, RPMS Hammersmith Hospital, London, UK*

Seven men with idiopathic dilated cardiomyopathy were selected on the basis of normal angiography, normal growth hormone secretion, HYHA Class II-III, and an ejection fraction of less than 40%. All patients had hormonal, functional (gated blood pool scan to assess LVEF and exercise test), haemodynamic (right heart catheterization) and endomyocardial biopsy (EMB) (myofibrillar volume/cell volume%) at baseline, 3 momths therapy with human growth hormones at 14 IU/per week.

Results: Administration of growth hormone improved clinical symptoms and exercise capacity in all the patients. LVEF% improved from 35 ± 1.3 to 48 ± 1.7, $p < 0.001$) and decreased both SVR and PVR (2580 ± 1200 to 1929 ± 500 dyne/s/cm^{-5}, $p < 0.001$ and 200 ± 120 to 158 ± 108 dyne/s/cm^{-5}, $p < 0.01$)respectively. There was no change in PCWP. However, electron microscopy and morphometry of 7 EMB showed no change in myofibrillar content before and after 3 months of GH administration (myofibrillar volume/cell volume, from 29 to 32%).

Conclusion: The myofibrillar content of myocardium from patients with dilated cardiomyopathy does not change in response to GH administration inspite of functional and haemodynamic improvement. The efficacy of GH administration in patients with dilated cardiomyopathy should be revised and mechanisms other than increased myofibrillar content should be explored.

CORONARY VASOREACTIVITY AND FLOW RESERVE

P3469 Effects of simvastatin and enarapril on vasomotion of resistance coronary artery

T. Murakami, S. Mizuno. *Cardiology Dept., Fukui Cardiovascular Center, Fukui, Japan*

Background: Management for hypercholesetrolemia and/or hypertension to prevent coronary artery disease, has great clinical significance, but remains to be pathophysiologically investigated. This study was conducted to evaluate clinical effects of simvastatin and/or enarapril upon vasomotion of resistance coronary artery.

Methods: Thirty-seven hypercholesterolemic and/or hypertensive patients were enrolled into the study to test the effects of simvastatin (S) and/or enarapril (E) on vasomotion of coronary artery and randomized to the four groups, where the patients were treated with S (Group-S, n = 8), with E (Group-E, n = 10), or with S and E (Group-SE, n = 7), and followed without S or E (Group-C, n = 12). We administered S, E, S and E (5–10 mg per day) for more than 6 months. We quantified endothelium-dependent or -independent response to acetylcholine (Ach) or ATP into the study left coronary artery (coronary flow reserve (CFR): maximal hyperemic flow – baseline flow/baseline flow), by coronary angiography and intracoronary doppler guidewire. Changes in flow reserve were evaluated in the four study groups.

Results: CFR to Ach or ATP showed no significant change in Group-C (CFR to Ach: from 55 ± 28% to 52 ± 28%, CFR to ATP: from 200 ± 66% to 204 ± 63%, n.s.). CFR to Ach not ATP was significantly improved in Group-S (from 35 ± 19% to 56 ± 22%, p = 0.03, from 198 ± 61% to 202 ± 62%, n.s., respectively). CFR to not ACh but ATP was improved in Group-E (from 50 ± 23% to 73 ± 38%, n.s., from 170 ± 64% to 198 ± 56%, p = 0.03, respectively). CFR to Ach and ATP were improved in Group-SE (from 34 ± 23% to 83 ± 54%, p = 0.02, from 149 ± 84% to 198 ± 115%, p = 0.01, respectively).

Conclusion: This study suggests that simvastatin and enarapril, alone or together, improve vasomotion of resistance coronary artery and may have beneficial potentials for management of coronary artery disease.

P3470 Unexplained myocardial lactate production as an acute result after intracoronary calcium-antagonist application in patients with syndrome X

O. Oldenburg, D. Baumgart, J. Schaar, K. Brauck, H. Eggebrecht, A. Gutersohn, R. Erbel. *Cardiology Dept., University Hospital, Essen, Germany*

Calcium-antagonists are often used in patients with chest pain and normal coronary angiograms. The acute coronary and myocardial reactions of calcium-antagonists in patients with syndrome X remain unclear.

Methods: Average peak flow velocity (APV) in the LAD was in-vestigated 12 patients with Syndrome X (mean age: 50 years [range 25 – 69 years]). Lactate concentration and oxygen saturation (SaO_2) were measured in the aorta (A) and coronary sinus (CS) simultaneously before and after an intracoronary bolus of the calcium-antagonist verapamil (1 mg).

Results: After verapamil APV increased from 16.0 ± 4.4 cm/s to 40.17 ± 11.2 cm/s ($p < 0.001$). Besides a difference in lactate concentration in A and CS before and after verapamil application, there is a change from an initial myocardial lactate consumption to a lactate production after verapamil (table 1). At the same time SaO_2 increased significantly in the CS due to a decrease in O_2 extraction.

table 1

	SaO_2 baseline	Lactate baseline	SaO_2 verapamil	Lactate verapamil
A	94.9 ± 3.2#	1.09 ± 0.36*	96.4 ± 1.5#	0.89 ± 0.43*
CS	40.2 ± 19.4***	1.03 ± 0.39*	73.3 ± 3.0***	1.21 ± 0.36*
A-CS	54.8 ± 19.1***	0.07 ± 0.24***	23.2 ± 2.4***	−0.31 ± 0.30***

#not significant, *p < 0.05, ***p < 0.001; SaO_2 [%], Lactate [mmol/l]; A-CS: Difference in lactace concentration between aorta (A) and coronary sinus (CS)

Conclusion: There is an unexplained increase in coronary sinus lactate concentration after verapamil in patients with syndrome X. These findings have not been reported before and may be due to an altered myocardial metabolism with lactate production during ischemia, a wash out effect, or steal phenomenon.

P3471 Can intravenous administraiton of adenosine produce the maximal hyperaemic response in patients with acute myocardial infarction? Comparison to intracoronary adenosine during Doppler flow wire

S. Yanagi, K. Nagae, K. Hirota, T. Hasegawa, T. Ota. *Division of Cardiology Fuchu Hospital, Osaka, Japan*

Studies have shown that intracoronary and intravenous administration of adenosine produces a similar augmentation in coronary blood flow in normal coronary circulation. This study was designed to compare the hyperemic response between intracoronary (IC) and intravenous (IV) adenosine tri-phosphate (ATP) in the reperfused legion of myocardial infarction (MI) using a Doppler flow wire (DFW).

Methods: Coronary flow reserve (CFR) was obtained using DFW from 25 patients (pts) with MI who underwent reperfusion therapy by direct percutaneous transluminal coronary angioplasty. A 0.014-inch DFW was placed in the distal portion of the reperfused coronary artery lesion immediately (Group A), 3 weeks (Group R) and 3–6 month (Group O) after reperfusion. A CFR of non-infarcted artery was also measured in the pts with MI (Group N). The hyperemic response to IC and IV ATP was compared (150 μg/kg/min intravenous vs. 50 μg in LCA or 25 μg in RCA intracoronary injection). A CFR was calculated as the ratio of ATP-induced to baseline averaged peak velocity (APV).

Results: Immediately after reperfusion (Group A), IC ATP produced greater hyperemic response than IV ATP. Hyperemic response between IC and IV ATP was similar both in non-infarcted (Group N) and in infarcted coronary artery 3–6 month (Group O) after reperfusion. The pts were devided into two groups according to the ratio of IC to IV CFR, group L (IC/IV CFR < 1.5) and group H (IC/IV CFR ≥ 1.5). Group H has significantly smaller basal APV than group L (APV; 9.8 ± 2.1 vs. 17.5 ± 6.8, p = 0.012).

	Group A	Group R	Group O	Group N
CFR (iv)	1.62 ± 0.50	1.98 ± 0.46	2.33 ± 0.64	2.76 ± 0.85
CFR (ic)	2.25 ± 0.95	2.25 ± 0.64	2.47 ± 0.67	2.87 ± 0.77
P value	0.016	0.086	0.52	0.48

(mean ± SD.)

Conclusions: IC ATP produced greater hyperemic response than IV ATP in the infarcted coronary artery bed immediately after reperfusion in pts with MI. Intravenous ATP could not produce maximal hyperemia in the reperfused coronary circulation specifically with low coronary flow velocity derived by DFW. These results indicate that intravenous drug administration for detecting flow reserve is inadequate route for pts with MI immediately after reperfusin, especially with low flow velocity.

P3472 Computational fluid dynamics analysis in a coronary artery bifurcation stenosis model

G.D. Giannoglou, J.V. Soulis[1], T.M. Farmakis, G.E. Louridas. *AHEPA General Hospital, Thessaloniki; [1]Democrition University of Thrace, Xanthi, Greece*

Background: A Computational Fluid Dynamics (CFD) analysis of a coronary bifurcation model, under different stenoses, was performed, using a 2D, steady, laminar, unstructured grid. The effects of stenoses on the static pressure, wall shear stress, velocity and molecular viscosity were examined.

Methods: An unstructured grid program was used to analyze the non-Newtonian blood flow in a LAD bifurcation with several degrees of stenosis. The initial geometry coordinates were taken from a normal subject. The stenoses coordinates follow the traces of low velocity and low shear stress regions. Various blood flow velocities were applied namely 0.17 m/s, 0.34 m/s and 0.68 m/s which correspond to rest condition, moderate and strenuous exercise, respectively. Static pressure, wall shear stress, velocity and molecular viscosity distribution were computed for all three branches and for all available stenoses.

Results: From the CFD analysis of the normal coronary bifurcation model results show that low wall shear stress and low velocity values occur at regions opposite to the flow divider result which agrees with preferred sites of atherosclerotic lesions in human. In the stenosis region, as the flow velocity increases, the pressure decreases and subsequently the wall shear stress increases. In the maximum degree of tested stenosis (over 70.0%) and under the maximum inflow velocity, 0.68 m/s, the maximum wall shear stress value was 225.0 N/m^2, which far exceeds the reported experimental value of 37.9 N/m^2 for endothelial denudation. Under all stenoses tested cases, static pressure distribution in the upstream to the flow divider area, increases at high blood velocities.

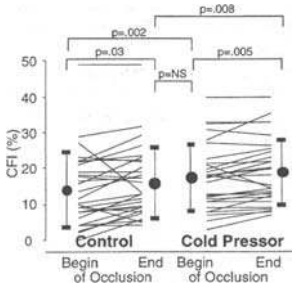
Conclusion: The wall shear stress increases with stenosis. At extreme flow velocity (rigorous exercise) the wall shear stress value far exceeds the endothelial denudation point.

P3473 Sympathetic stimulation using cold pressor test increases coronary collateral flow

S.F. de Marchi, M. Billinger, S. Windecker, M. Fleisch, A. Garachemani, F.R. Eberli, B. Meier, C. Seiler. *Cardiology, University Hospital, Berne, Switzerland*

Background/Methods: Little is known about the function of coronary collateral vessels. The purpose of this study was to examine the collateral flow under a strong sympathetic stimulus (cold pressor test, CPT). In 30 patients (62 ± 12 years) with coronary heart disease two coronary occlusions were performed. In a randomized order, a CPT was performed in one occlusion. Two minutes before and during the 1 minute-occlusion, one of the patient's hands was submerged into ice water. For the calculation of a perfusion pressure-independent collateral flow index (CFI), the aortic (Pao), the central venous (CVP) and the coronary wedge pressure (Poccl) were measured (CFI = (Poccl − CVP)/(Pao − CVP)).

Results: The CPT lead to an increase of Pao from 98 ± 14 mmHg to 105 ± 15 mmHg (p = 0.002). CFI increased during occlusion from 14% ± 10% to 16% ± 10% and from 17% ± 9% to 19% ± 9% without and with CPT, respectively.



Conclusions: During ballon occlusion collateral flow increases due to collateral recruitment independently of sympathetic stimulation. The CPT additionally increases collateral flow. This may reflect a coronary collateral vasodilation mediated by the sympathetic nervous system. This collateral flow increasing effect is comparable to the effect of the occlusion itself.

P3474 Effects of electrical neurostimulation on coronary haemodynamics

G.A.J. Jessurun, R.A. Tio, M.J.L. de Jongste, P. den Heijer, H.J.G.M. Crijns. *Thoraxcenter, University Hospital Groningen, Netherlands*

Neurostimulation reduces anginal complaints and myocardial ischemia in patients with angina pectoris refractory to conventional strategies, putatively by altering the microcirculation in the heart. To test this hypothesis, we studied 14 patients, scheduled for an elective angioplasty (PTCA) with single vessel disease in the left anterior descending coronary artery (LAD). Prior to the PTCA the effect of Transcutaneous Electrical Nerve Stimulation (TENS; Lifecare LTD, Shnuel Israel) was studied on average peak flow velocity (APV; Doppler flow wire, Flomap, Cardiometrics, Mountainview, Ca USA) and coronary diameter (quantitative coronary angiography, QCA) simultaneously in the stenotic LAD and smooth circumflex coronary artery (LCX) (10 patients). Four patients served as a control group. Volumetric flow was calculated from these measurements.

Results (mean ± S.E.M.):

	LAD		LCX	
	Baseline	Sham	Baseline	Sham
QCA (mm)	2.95 ± 0.02	2.94 ± 0.03	2.60 ± 0.16	2.65 ± 0.19
APV (cm/s)	27.7 ± 8.5	27.9 ± 8.7	20.6 ± 4.8	20.0 ± 4.9
Flow (ml/min)	89.8 ± 26.7	90.6 ± 27.5	48.4 ± 5.1	48.2 ± 5.5

	LAD		LCX	
	Baseline	Tens	Baseline	Tens
QCA (mm)	2.92 ± 0.18	2.80 ± 0.15*	3.24 ± 0.26	3.41 ± 0.23*
APV (cm/s)	25.2 ± 3.5	24.4 ± 3.3	21.6 ± 2.8	21.5 ± 3.0
Flow (ml/min)	49.9 ± 8.1	44.8 ± 7.4*	54.5 ± 11.5	60.5 ± 11.2*

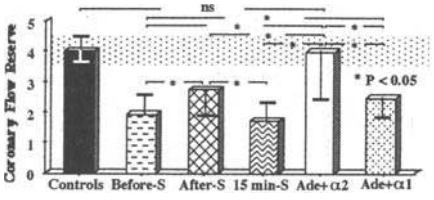
*$p < 0.05$ versus baseline

TENS increased coronary flow in the non-stenotic artery and decreased flow in the stenotic coronary artery. Considering that neurostimulation reduces ischemia, the beneficial effect is likely to be explained by an improvement of micro-collateral flow to the ischemic myocardium.

P3475 Post-ischaemic coronary flow reserve impairment and changes induced by α1- and α2-adrenergic blockade

L. Gregorini[2], J. Marco[1], M. Kozàkovà[3], C. Palombo[3], I. Bossi[1], I. Marco[1], M. Bernies[1], B. Cassagneau[1], G. Anguissola[2], J. Fajadet[1], G. Heusch[4]. *[1]Clinique Pasteur, Toulouse; [2]Cardiovascular Science Department, Ospedale Maggiore, IRCCS, Milan; [2,3]Clinical Physiology Institute; [3]CNR, Università di Milano e Pisa; [4]Pathophysiologie, Universit ätsklinikum, Essen, Italy*

The capacity of coronary arteries to dilate is impaired in the presence of ischemia, and it is controversial whether coronary flow reserve (CFR) may normalize shortly after coronary stenting (S). Accordingly in 30 patients undergoing S for an 85 ± 5% stenosis and in 15 normal controls we evaluated CFR with intracoronary flow wires (Cardiometrics) and 24-μg IC adenosine (Ade). In addition we investigated if α 1-(urapidil 10-mg IC) or α 2- (yohimbine 2-mg IC) adrenergic blockade superimposed to 140-μg/kg for 5 min IV adenosine infusion might improve or normalize CFR. CFR was measured in patients before-S, soon after-S, 15-min later (15 min-S) and after superimposing α1- and α2-blockers on top of adenosine IV infusion. Epicardial coronary diameters were measured at the level of the wire tip by quantitative angiography. The results are shown in figure (mean ± SD).



Conclusions: Coronary stenting transiently improved but did not normalize CFR (2.73 ± 0.9). CFR became normal only superimposing α2-adrenergic blockade (4.09 ± 1.4) on top of Ade, i.e. inducing additional microvascular dilation, whereas the higher increase in blood flow obtained with α1-blockade as compared with α2-blockade was mainly due to conduit coronary arteries dilation.

P3476 Coronary collateral flow and its protective potential against future myocardial infarctions

Michael Billinger, Patrik Kloos, Martin Fleisch, Ali Garachemani, Franz Eberli, Bernhard Meier, Christian Seiler. *Cardiology, University Hospital, Berne, Switzerland*

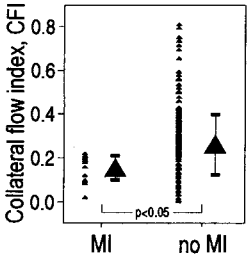
Purpose: The purpose of this prospective study was to determine whether collateral flow has a protective function against future myocardial infarctions.

Methods: In 263 patients (pts) the occurrence of myocardial infarction (MI) was monitored during a follow-up period of 3 to 34 months following invasive study of collaterals. All the pts underwent coronary angioplasty (PTCA) and a collateral flow index (CFI) determination using intracoronary (i.c.) pressure- or Doppler-guidewires. Mean aortic (P_{ao}) and distal occlusive (P_{occl}) pressure during PTCA or distal flow velocity integral during (Vi_{occl}) and after ($Vi_{0\text{-}occl}$) PTCA were measured continuously. The pressure derived CFI was calculated as follows: $(P_{occl} - 5)/(P_{ao} - 5)$. Doppler-derived CFI: $Vi_{occl}/Vi_{0\text{-}occl}$ The angiographic collateral degree was also assessed accoding to the extent of epicardial coronary artery filling through collateral channels (Rentrop 0–3). Based on the absence or presence of ST-segment changes (< or ≥1 mm) on i.c. ECG during PTCA, the patients were considered to have sufficient or insufficient collaterals.

Results: During the follow-up period (mean 13 ± 5 mounths), 12 patients had a MI.

	Myocardial infarction	No myocardial infarction	P
n	12	251	
Age	64 ± 12	59 ± 10	NS
%-Stenosis	81 ± 12%	82 ± 13%	NS
CFI	0.14 ± 0.06	0.24 ± 0.17	<0.05
Rentrop (0–3)	0.5 ± 0.5	1.1 ± 0.9	<0.05
insufficient	100%	72%	< 0.05

%-Stenosis: %-stenosis before PTCA; CFI: Collateral flow index; insufficient: ST-segment shift during PTCA



Conclusions: In this relatively large population with coronary artery disease and quantitatively assessed coronary collaterals, their effectiveness against future myocardial infarction can be clearly demonstrated.

P3477 Acute effects of intravenous amlodipine on coronary microcirculation in humans. Results from the pressure/flow curve analysis

D. Neglia, M. Gallopin, P. Marraccini, I. Simonetti[1], M. Micalizzi, A. Macerata, M. Marzilli, A. L'Abbate. *CNR Institute of Clinical Physiology, Pisa; [1]Istituto di Clin Med Gen e Cardiologia, Universita di Firenze, Florence, Italy*

Many studies suggest that non-ischemic heart failure is associated with impaired coronary microcirculatory function stimulating much interest on drugs potentially able to dilate the coronary microcirculation. Experimantally, amlodipine (Aml) has powerful coronary vasodilating properties; however, it is not known whether and to which extent it is able to dilate the coronary microcirculation in man. In this study the vasodilating effects of Aml on human coronary microcirculation were tested in comparison with adenosine (Ado), one of the most effective coronary vasodilating agents.

Methods: In 10 normal subjects (4 men, mean age 51 ± 15 yrs, range 25–67), coronary flow velocity (CFV) (Doppler flowire into the left anterior descending coronary artery) and left coronary perfusion pressure (2F Millar catheter at the ostium of the left main) were measured at baseline, during Ado (0.5–2 mg intracoronary bolus) and 30 min after i.v. Aml (10–20 mg according to blood pressure response). Data were acquired on a PC and processed offline. Coronary flow reserve (CFR) was obtained as the ratio of CFV during vasodilation (Ado or Aml) and at baseline. The slope of the istantaneous diastolic CFV/pressure curve (IDVPS) (cm/sec/mmHg) was used to measure coronary conductance which, in the absence of epicardial coronary stenosis, reflected the maximal vasodilation achieved by the coronary microcirculation during Ado and 30 min after Aml.

Results: Mean CFV was 16 ± 7 cm/sec at baseline and significantly increased to 50 ± 12 cm/sec during Ado ($p < 0.01$) and to 22 ± 8 cm/sec during Aml ($p < 0.05$). CFR was higher during Ado than during Aml (3.5 ± 0.8 vs 1.5 ± 0.4; $p < 0.01$). However, the IDVPS was not different in the two study conditions (1.7 ± 0.7 vs 1.4 ± 0.7, respectively; ns).

Conclusions: Aml induces a significant coronary vasodilation in normal subjects. The vasodilatory effect of Aml, in terms of CFR, is lower than that of Ado while the effetcs of the two drugs on diastolic coronary conductance, i.e. their abilities to dilate the coronary microcirculation, are similar. These results suggest that Aml may be beneficial in pts with non-ischemic heart failure due to its powerful vasodilatig effects on the coronary microcirculation.

P3478 Non-invasive measurement of blood flow in the left anterior descending artery and great cardiac vein

W.L.F. Bedaux[1], M.B.M. Hofman[2], A.C. van Rossum[1], C.A. Visser[1]. *[1]Dept. of Cardiology; [2]Clinical Physics & Informatics, University Hospital Vrije Universiteit, Amsterdam, Netherlands*

Purpose: With magnetic resonance (MR) flow mapping it is possible to quantify flow velocity and volume flow in the coronary vessels in a noninvasive way. The close anatomic relationship of the Left Anterior Descending Artery (LAD) with the Great Cardiac Vein (GCV) allows imaging both in one view. We examined the feasibility to discriminate between these two vessels and to measure the flow quantitatively.

Methods: Nine individuals with a normal LAD and 6 patients with a diseased LAD [3 after anterior myocardial infarction (MI) of whom 1 with occluded LAD and collateral supply] underwent MR imaging to quantify the flow in the LAD and GCV. From MR images, using connectivity to the aortic root, differentiation between the LAD and GCV was made. Perpendicular to the LAD MR phase contrast velocity mapping was performed within a breath-hold. A Region of Interest (ROI) was drawn around the LAD, GCV and myocardial tissue, to analyze the flow data.

Results: After correction for cardiac motion of the vessel, differentiation can be made between the GCV and the LAD using the flow pattern. The flow in the GCV is mainly systolic and points in the inverse direction as the flow in the LAD, which is mainly diastolic. These criteria appeared valid in all individual subjects, even in cases of highly stenotic arteries. Volume flow measurements corrected for BSA;

	LAD (ml/min/m^2)	GCV (ml/min/m^2)
Normal (n = 9)	32 ± 17	−24 ± 21
Diseased (n = 5)	26 ± 7	−17 ± 18
Occluded LAD and collaterals	-	−7

Conclusion: Magnetic resonance is a unique tool for noninvasive, simultaneous measurement of the flow pattern and volume flow in the GCV and the LAD. A possible clinical application of measuring venous coronary flow is the assessment of collateral supply.

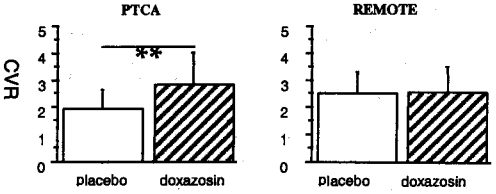
P3479 Impairment of coronary vasodilator reserve after successful angioplasty is prevented by α_1-adrenoceptor blockade

Ornella Rimoldi, Nicos Spyrou, Luisa Gregorini, David R. Hackett, Rodney Foale, Paolo G. Camici. *Hammersmith Hospital and St Mary's Hospital, Imperial College School of Medicine, London, UK*

Background Coronary vasoconstriction after coronary angioplasty (PTCA) is abolished by i.c. phentolamine. An impairment of coronary vasodilator reserve (CVR) has been observed up to 7 days after successful PTCA. To ascertain if pretreatment with the α_1 blocker doxazosin could improve CVR after the procedure, we carried out a randomized, double blind study on 26 patients with >75% single vessel stenosis undergoing PTCA.

Methods G1, (n = 12) received doxazosin od on top of their treatment at: 1 mg for 3 days; 2 mg for 7 days and 4 mg for 7 days before and after PTCA; G2 (n = 14) received matching placebo. Myocardial blood flow (MBF) at baseline (bas) and after iv dipyridamole (dip, 0.56 mg/kg) was measured within 5 days of PTCA using PET with $H_2^{15}O$. CVR was calculated as dip/bas MBF.

Results The main hemodynamic parameters were comparable in the 2 groups at bas and after dip. In the PTCA territory bas MBF was 0.92 ± 0.2 and 1.05 ± 0.3 ml/min/g in G1 and G2 (p = ns). Dip MBF tended to be higher in G1 than G2 (2.46 ± 0.9 vs 1.99 ± 0.6 ml/min/g; p = 0.09). CVR was higher in G1 than G2 (2.78 ± 1 vs 1.95 ± 0.7; ** = $p < 0.01$).



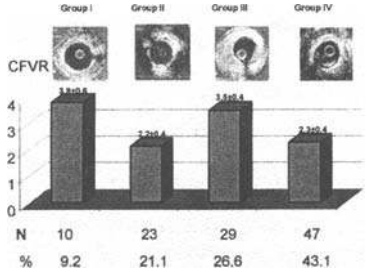
Conclusion Pre-treatment with doxazosin prevented the impairment of CVR after PTCA. We suggest that the reduced CVR, after a successful PTCA, is due to increased α_1 adrenoceptor constriction of coronary resistive vessels.

P3480 Evidence of microvascular dysfunction in patients with normal coronary angiograms

J. Ge, J. Qian, H. Wieneke, D. Baumgart, D. Welge, M. Haude, G. Görge, R. Bhate, R. Erbel. *Dept. of Cardiology, University-GH Essen, Germany*

The purpose of the study was to investigate the incidence and severity of microvascular dysfunction in patients with chest pain but with normal coronary angiograms. A total of 126 patients who showed a normal coronary angiograms were examined with intracoronary ultrasound (ICUS) and Doppler (ICD). A 3.2 F or 2.9 F, 30 MHz ultrasound catheter (CVIS, Boston Scientific) was used for ICUS and a 0.014 inch FloWire (Cardiometrics) was used for ICD. Coronary flow velocity reserve (CFVR) was compared to the presence or absence of plaque formation based on ICUS.

Reduction of CFVR was found in 82/126 (65%) patients. No significant difference of the CFVR was found between patients with and without hypertension (2.69 ± 0.65 vs. 2.73 ± 0.80, p = 0.77). A significant difference exists between patients with and without diabetes mellitus (2.30 ± 0.47 vs. 2.80 ± 0.68, p < 0.05). ICUS was available in 109 patients. Based on the presence and absence of plaque formation on ICUS and with and without reduction of CFVR, patients were divided into four groups.



Conclusion: Microvascular dysfunction exists in a majority of patients with chest pain but with normal coronary angiograms. Among which, a large proportion had early signs of coronary artery disease and only one-fifth had true syndrome X.

P3481 Pressure variability after intracoronary adenosine injection as a pitfall for the determination of fractional flow reserve based on minimum distal pressure

M. Meuwissen, M. Siebes, S.A.J. Chamuleau, K.T. Koch, R.J. de Winter, J.J. Piek. *Cardiology Dept., Academic Medical Center, Amsterdam, Netherlands*

Background: Fractional flow reserve (FFR) is measured at the time of minimum distal pressure(Pd-min) which is assumed to coincide with the time of maximum hyperemia. Pressure variability after intracoronary (i.c.) administration of adenosine may hamper the selection of data for calculation of FFR.

Methods: In 19 intermediate coronary lesions (53.9 ± 10.9% by diameter) we simultaneously measured distal coronary blood flow velocity and pressure with two 0.014" sensor-tipped guide wires. Maximum hyperemia was induced by a bolus of 12–18 mg i.c. adenosine. FFR was calculated from average pressure ratios at different times during the hyperemic response,corresponding to the cycle of Pd-min, maximum pressure drop (dP-max), maximum flow velocity (IPV-max), and the lowest per-beat value of FFR (FFR-min). The mean time difference in beats and the range in beats, of the selected cycle was determined in relation to the beat of IPV-max.

Results: Due to breathing artifacts and a significant decline in aortic pressure (Pao), the timing of Pd-min is more variable than that of dP-max or FFR-min with respect to the time of IPV-max. Because FFR was close to the threshold of 0.75, two of the 19 patients would have been referred to PTCA on the basis of using Pd-min, but not when using FFR-min or dP-max to indicate maximum hyperemia.

Table

Hyperemic parameter	Beats to IPV-max	Range (beats)	Pao	FFR
Pd-min	−0.59 ± 5.1	−10 to 10	90 ± 14**	0.75 ± 0.09
dP-max	0.07 ± 1.27*	−4 to 3	95 ± 14	0.74 ± 0.09
FFR-min	0.07 ± 1.82*	−4 to 4	93 ± 14	0.74 ± 0.09
IPV-max	0	0	96 ± 15	0.74 ± 0.08

** p < 0.03 compared to AOP = 98.7 ± 14.8 at baseline (Student's t-test). *p < 0.05 compared to variance of beats for Pd-min (ANOVA).

Conclusion: After i.c. adenosine, distal coronary pressure is subject to variations that are not induced by flow elevation and Pd-min does therefore not reliably identify the time of maximum hyperemia. Pressure-based evaluation of functional stenosis severity should therefore be based on data at the time of maximum pressure drop or minimum per-beat FFR.

P3482 Coronary flow reserve measurement using the TIMI frame count method: correlation with the Doppler wire (Flowire)

Athanassios Manginas, Plamen Gatzov, Chris Chasikidis, Vassilis Voudris, Gregory Pavlides, Ilia Tomov, Dennis V. Cokkinos. *1st Cardiology Department. Onassis Cardiac Surgery Center, Athens, Greece*

Background: The estimation of the coronary flow reserve (CFR) has significant clinical implications. However, it requires expensive devices.

Methods: We prospectively studied 23 coronary arteries (6 left anterior descending, 7 left circumflex and 10 right coronary arteries) in patients undergoing diagnostic catheterization or coronary angioplasty. Seven arteries had >50% diameter stenosis and 13 had non significant luminal narrowing. All studies were performed following intracoronary administration of 200 μg nitroglycerine. We investigated whether CFR can be calculated by: a) the TIMI frame count (TFC) method (CFR defined as the ratio of the number of frames required to opacify standard coronary artery landmarks at baseline over the number of frames 15 seconds after intracoronary bolus of adenosine) and correlated with, b) The CFR calculated with the 0.014" angioplasty Doppler guidewire (Flowire) with adenosine as hyperemic stimulus (CFR defined as the ratio of averaged peak velocity [APV] in hyperemia over APV at baseline).

Results: The changes of the TFC and APV at baseline and during byperemia were as follows (values mean ± SD):

	TIMI frame count	APV (cm/sec)
Baselne	21.7 ± 10.9	18.7 ± 9.8
Hyperemia	12.0 ± 8.4	40.7 ± 20.0
p	0.001	0.001

A significant correlation was observed between the CFR values obtained by the TFC method (2.2 ± 1.0) and the Flowire (2.3 ± 0.8) (p = 0.0001, r = 0.87). Similarly, the percent changes of TFC and APV from baseline to hyperemia correlated significantly to each other (p = 0.0001, r = 0.89).

Conclusions: The coronary flow reserve during coronary procedures can be easily and reliably estimated using the TIMI frame count method, which is inexpensive, simple and readily available.

P3483 Pressure-derived fractional flow reserve post stent implantation: no difference in epicardial conductance between coil and slotted tube stents

Clara E.E. Hanekamp, Nico H.J. Pijls, Jacques J. Koolen, Rolf H. Michels, B. De Bruyne, Hans J.R.M. Bonnier. *Cardiology, Catharina Ziekenhuis, Eindhoven, Netherlands; Cardiology, Onze Lieve Vrouwen Gasthuis, Aalst, Belgium*

The aim of coronary stenting is restoration of epicardial conductance. Pressure derived Fractional Flow Reserve (FFR) is a specific index of epicardial conductance. In this study, we performed FFR measurements pre and post stent implantation, both in coil and in slotted tube stents.

Methods and Results: A total of 98 stents were implanted, 49 coil stents, 49 slotted tube stents, in 98 patients. The maximum inflation pressure used was 9.8 ± 2.3 for the coil stents and 10.7 ± 3.3 for the slotted tube stents (NS), respectively. FFR improved from 0.53 ± 0.17 before to 0.94 ± 0.06 after the procedure, 0.93 ± 0.06 for the coil stents and 0.94 ± 0.05 for the slotted tube stents (NS). Optimal stent deployment, defined as FFR ≥ 0.94 (equivalent to the absence of any noticeable hyperemic pressure drop across the stent), was achieved in 66% of the coil stents and 69% of the slotted tube stents respectively (NS).

Conclusions: In 67% of the patients optimal stent deployment, according to coronary pressure measurement, was achieved. No differences were observed between coil stents and slotted tube stents.

P3484 Effects of coronary angioplasty on coronary adenosine concentrations

F. Paganelli[1], R. Gelisse[1], S. Levy[1], R. Guieu[2], A. Saadjian[1,3]. *Departments of [1]Cardiology; [2]Biochemistry; [3]INSERM, CHU. Nord, Marseille, France*

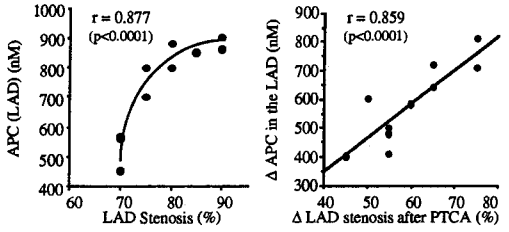
Purpose: We studied the adenosine plasma concentrations (APC) relatively to the degree of coronary stenosis and compared the APC before (B) and after transluminal coronary angioplasty (PTCA).

Methods: APC were mesasured both in the LAD below the stenosis using the PTCA catheter and in the great coronary vein (GCV) in 10 patients presenting a single stenosis of the LAD.

Results:

Stenosis (%)		APC (LAD) (nM)		APC (GVC) (nM)	
B	PTCA	B	PTCA	B	PTCA
79 ± 31	19 ± 1*	736 ± 50	152 ± 20*	846 ± 60	174 ± 22*

(m ± esm), (*P < 0.0001)



Conclusions: We found a close relationship between the stenosis and APC mesured both in the LAD and the GCV. Successfull PTCA is followed by a considerable decrease in APC (ΔAPC) which are linearly correlated with the improvement of the stenosis (Δ LAD).

P3485 Reduction of coronary blood flow during distension of urinary bladder in patients with early atherosclerosis

Tsung-Ming Lee, Sheng-Fang Su, Ming-Fong Chen, Chiau-Suong Liau, Yuan-Teh Lee. *Department of Internal Medicine, Cardiology Section, National Taiwan University Hospital, Taipei, Taiwan; College of Medicine, National Cheng Kung University, Tainan, Taiwan, China*

Coronary blood flow is regulated to a large extent by adrenergic mechanisms. Distension of the urinary bladder reflexly causes an increase in sympathetic and a decrease in vagal fiber activity. The effect of distension of the urinary bladder on the coronary circulation in patients with early atherosclerosis remains unknown.

To assess the effect of bladder distension on coronary dynamics, we measured epicardial and microvascular responses in 40 patients with early atherosclerosis (<50% diameter stenosis). Patients were randomized into two groups on the basis without (group 1, n = 20) or with (group 2, n = 20) pretreatment of α-1 adrenergic receptor blocker (oral doxazosin 2 mg). Percent change in coronary artery diameter was measured by quantitative coronary angiography, and percent change in coronary blood flow was calculated using intracoronary flow Doppler. In response to bladder distension (intravesical pressure 20 mm Hg) coronary diameter was significantly decreased from 3.20 ± 0.46 mm to 2.70 ± 0.42 mm ($P < 0.001$), coronary blood flow from 82.1 ± 25.8 to 62.4 ± 25.6 mL/min ($P < 0.001$), and coronary resistance was increased from 1.40 ± 0.73 to 2.36 ± 1.50 mm Hg/mL/min ($P < 0.001$) compared with baseline values, in group 1 patients. Intracoronary nitroglycerin significantly lessened the severity of urinary bladder distension-induced epicardial coronary vasoconstriction below baseline values ($P < 0.001$). In group 2 patients during bladder distension, although there were significant decrease in epicardial coronary diameter, and increased coronary resistance, coronary blood flow did not show significant changes, compared with baseline values. Rate-pressure product similarly increased during bladder distension in the 2 groups. There were significant differences of coronary diameter ($P = 0.04$), coronary blood flow ($P = 0.01$), and coronary resistance ($P = 0.008$) between the 2 groups during bladder distension.

The present study showed that urinary bladder distension caused a reduction in coronary blood flow that involved mechanisms related to α-1 adrenoceptors. The reduction of coronary blood flow during bladder distension can be relieved after nitroglycerin administration. Pretreated administration of doxazosin had reversed the decreased coronary blood flow during bladder distension towards baseline.

P3486 Patients with elevated large endothelin-1 plasma concentration have increased intimal hyperplasia and decreased blood flow velocity in coronary arteries

P. Wexberg, K. Kiss, G. Steurer, A. Zuckermann[1], C. Springer, J. Bialy, E. Moser, R. Pacher, H.D. Glogar, S. Rödler. *Clinic for Internal Medicine II, Dept. of Cardiology; [1]Clinic for Surgery, Dept. of Cardiothoracic Surgery, University of Vienna, Austria*

Transplant vasculopathy (TVP) is the major limitation of the longterm outcome of heart transplantation (HTx) and can be detected by intravascular ultrasound (IVUS) at a very early stage. Endothelin-1 (ET-1) is a vasoconstrictive peptide found to increase in plasma after HTx. Since it has also been shown to stimulate proliferation of smooth muscle cells we hypothesized that elevated ET-1 levels are associated with both increased intimal hyperplasia and slower coronary blood flow.

Methods: Eighteen patients (pts) (11 to 150 mo after HTx) underwent routine cardiac catheterization. The average peak flow velocity (APV) in the LAD was measured by intracoronary Doppler at baseline as well as after injection of adenosine (peak APV), and the coronary flow reserve (CFR) was calculated as a ratio of both. In IVUS the intimal area (IA) at the most severely affected region of the vessel was measured. The concentration of the precursor peptide Big ET-1 was determined by a radioimmunoassay. Mean IA, APV and CFR were compared between pts with elevated plasma Big ET-1 levels (>2 fmol/ml), and those with normal values by one-way ANOVA.

Results: Pts with elevated Big ET-1 had significantly larger IA than those with normal concentrations (6.79 ± 3.07 vs. 3.28 ± 2.39 mm^2, p = 0.012). They also had lower APV at baseline (15.57 ± 5.31 vs. 20.67 ± 6.71 cm/s, p = 0.08), and a significantly decreased peak APV (41.11 ± 12.24 vs. 57.56 ± 18.91 cm/s, p = 0.04). However, mean CFR did not differ between groups (2.89 ± 0.81 vs. 2.93 ± 1.01, p = 0.92), and was in normal range.

Conclusion: Our data suggest an important role of ET-1 in the development of TVP. Its association with slower blood flow seems to be secondary to intimal hyperplasia, since vasodilatation after adenosine as expressed by CFR was not impaired.

P3487 The superiority of TIMI frame count in detecting flow velocity changes after coronary stenting compared to TIMI flow classification

C. Bickel, H.J. Rupprecht, A. Maimaitimung, I. Welk, F. Krummenauer[1], J. Meyer. *II. Medical Clinic, University Mainz, Mainz; [1]Department of Medical Statistics, University Mainz, Mainz, Germany*

We compared the qualitative, categorical TIMI Flow Classification with a new quantitative method, the TIMI Frame Count, to investigate the differences of both systems in detecting coronary flow velocity changes after stent implantation.

Methods: TIMI Flow grades and the corrected TIMI Frame Counts (CTFC) were determined in 102 patients before, after stent implantation and at 6 months angiography. The qualitative analysis of the TIMI Flow grade was performed following the criteria of the Thrombolysis in Myocardial Infarction (TIMI) Study Group introduced in 1985. The quantitative measurement of CTFC was performed as published by Gibson 1996. The CTFC is defined as the number of cineframes required for the contrast material to reach a standard distal coronary landmark at a film speed of 30 frames per second, corrected by the longer length of LAD compared to the other coronary arteries. The CTFC is calculated by division of the actual measured frame counts of the LAD through a correction factor of 1.7, which was calculated – as described by Gibson – by the division of the mean value of LAD frame count through the mean values for RCA and LCX in a normal collective. The frame counts for the circumflex artery and the right coronary artery are used as measured without correction.

Results: Comparing changes in TIMI flow grades and the CTFC (>5 frames) before and after stent implantation, CTFC measurement detected flow velocity changes in 46% of the patients, which were not detected with the TIMI Flow Classification. Comparing the results after stent implantation and the 6 months angiography, CTFC detected flow velocity changes in 40% of the patients, where TIMI Flow Classification was not able to detect any flow changes. The rate of agreement between TIMI Flow Classification and CTFC is very poor (concordance analysis for the comparison of both methods: kappa value = 0.14 ± 0.06 for CTFC versus TIMI Flow changes before and after stent implantation and kappa value = 0.21 ± 0.06 for CTFC versus TIMI Flow changes after stent implantation and at 6 month control angiography).

Conclusion: The quantitative TIMI Frame Count method is superior to the qualitative TIMI Flow Classification in detecting coronary flow velocity changes. After therapeutic interventions CTFC measurements are able to demonstrate alterations in coronary flow, which are not detected by using the TIMI Flow Classification.

P3488 Coronary Doppler measurements do not predict progression of cardiac allograft vasculopathy: serial intracoronary flow measurements in heart transplant recipients in comparison with dobutamine stress echocardiography and intravascular ultrasound

A. König, C.H. Spes, J. Rieber, E. Regar, P. Überfuhr[1], B. Reichart[1], H. Mudra, K. Theisen, V. Klauss. *Dpt. of Cardiology, Klinikum Innenstadt, University of Munich; Dpt. of Cardiac Surgery, Klinikum Großhadern, Germany*

Coronary flow reserve can be measured by intracoronary Doppler analysis. The aim of this study was to evaluate whether intracoronary Doppler flow measurements are useful to assess the progression of cardiac allograft vasculopathy (CAV). Doppler data were compared to dobutamine stress echocardiography (DSE), a useful non-invasive method to detect functionally relevant CAV. As a reference for morphological assessment of CAV, intravascular ultrasound (IVUS; quantitative analysis of intimal hyperplasia) was used.

Methods: 35 patients (mean age 49 ± 12 years) were serially studied 13 ± 26 months after heart transplantation (baseline) and 1 year thereafter (follow-up) with Doppler, DSE and IVUS. Coronary flow reserve (CFR, max./bas. flow velocity, 16 μg adenosine) was assessed with a 0.014 in. Doppler guide wire. With DSE (5–40 μg/kg/min), wall motion abnormalities (WMA) were analyzed using a 16 segment model. Newly developed or increasing WMA at follow-up were considered a progression of CAV. Mean intimal index (MII, mean intimal area/vessel area) in each patient was determined with IVUS. A 15% increase in intima index was defined as significant CAV progression.

Results:

		Coronary flow reserve	
		baseline	follow-up
DSE progression	(n = 11)	2.7 ± 0.9	3.8 ± 0.8*
DSE no progression	(n = 14)	3.0 ± 1.0	3.3 ± 0.9*
IVUS progression	(n = 12)	2.7 ± 0.7	3.2 ± 0.6*
IVUS no progression	(n = 13)	2.9 ± 0.9	4.0 ± 0.9*

* = $p < 0.05$

In conclusion, the increase in CFR could be observed in all subgroups. Thus, serial intracoronary Doppler flow measurements are not useful to predict morphologic or functional progression of CAV as assessed by IVUS or DSE.

P3489 Coronary flow reserve assessment using transthoracic Doppler echocardiography detects functional status of internal mamaria artery bypass

Harald Lethen, Hans P. Tries, Johannes Brechtken, Heinz Lambertz. *Fachbereich Kardiologie, Deutsche Klinik für Diagnostik, Wiesbaden, Germany*

Transthoracic Doppler echocardiography (TDE) has been used for noninvasive visualization of coronary artery flow. Measurement of flow velocity changes with TDE after coronary vasodilatation in internal mamaria arteries (IMA) after coronary bypass grafting (CBG) could be used for noninvasive assessment of coronary flow reserve (CFR).

Methods: The value of CFR determined by TDE (Acuson, Sequoia) for the noninvasive assessment of the functional status of IMA after CBG was evaluated in 40 patients (pts). From supraclavicular view average maximal systolic-diastolic flow velocity in IMA after CBG was measured at rest and during maximal hyperemia induced by i.v. Adenosine (140 μg/kg/min). CFR was obtained by the ratio of hyperemic to resting flow velocities. All pts underwent coronary angiography after echo studies were performed, CFR was recorded invasively in 17 pts using Flow wires.

Results: Coronary angiography showed stenosis (>50% diameter) of IMA after CBG in 16/36 pts (group I), no relevant stenosis was detected in 20/36 pts (group II). In 9 pts of group I and 8 of group II CFR was measured invasively. IMA CFR could be measured in all pts by TDE.

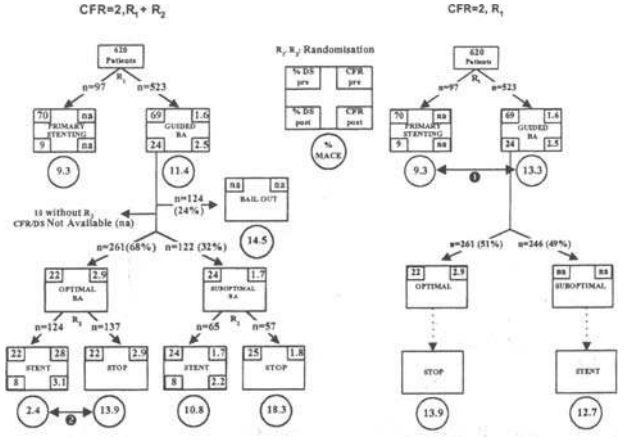
	IMA stenosis	CFR (TDE)		CFR (invasive)	
Group I	>50% diameter	1.5 ± 0.4	⟶ n.s. ⟵	1.4 ± 0.5	} p < 0.05
Group II	<50% diameter	2.7 ± 0.7	⟶ n.s. ⟵	2.5 ± 0.6	

Conclusion: TDE assessment of IMA flow velocity changes after coronary vasodilatation allows noninvasive measurement of CFR in IMA after CBG in all pts. Invasive and noninvasive measurements showed no relevant differences. CFR < 2.0 predicted with a sensitivity of 88% and a specifity of 83% significant stenosis of IMA after CBG.

P3490 DEBATE II: "DESTINI-sation" of the DEBATE II trial data

P.W. Serruys[1], B. de Bruyne[2], O. Gumé[3], N. Pijls[4], J. Belardi[5], G.-A. van Es[8], E. Boersma[6], B. van Hout[7], J.-M. van Sonsbeek[8], G. Steenvoorden[8]. *[1]Thoraxcenter Rotterdam; [4]Catharina Hospital, Eindhoven; [6]Erasmus University Rotterdam; [7]iMTA, Erasmus University Rotterdam; [8]Cardialysis, Rotterdam, Netherlands; [2]Cardiovascular Center, OLV Hospital, Aalst; [3]Hôpital Universitaire de Mont-Godinne, Yvoir, Belgium; [5]Instituto Cardiovascular de Buenos Aires, Argentina*

Abstract: DESTINI and DEBATE II, two contemporary randomised trials addressed the same issue, namely the value of optimal balloon angioplasty (OBA), guided by QCA and intra-coronary Doppler as compared to primary stenting; however, trial design (2nd randomisation in DEBATE II) and CFR criteria for OBA (2 vs 2.5 CFR) differ. Therefore, we have re-analysed our data according to the DESTINI criteria and design.



Conclusions: "DESTINI-sation" of the DEBATE II data confirms that primary stenting and guided balloon angioplasty do not differ in clinical outcome (MACE 9.3 vs 13.3%, p (Fe = 0.32, 1). Implementation of the 2nd randomisation in the DESTINI design also confirms that stenting post-OBA further improves the outcome of OBA (2.4 vs 13.9% = the additional value of stenting, p (FE) < 0.001, 2).

P3491 Colour-coded blood flow – new diagnostic options in intravascular ultrasound: first clinical experience

D.H. Koschyk, K.P. Schaps, C. Brockhoff, T. Hofmann, T. Münzel, T. Meinertz. *University Hospital Eppendorf, Dept. of Cardiology, Hamburg, Germany*

Background: The ChromaFlo is a new intravascular ultrasound technique for color coding of the blood flow. The flow is detected by rating the movement of the tissue as they transverse the ultrasound beam. The faster moving tissue (blood) will be colorized in red, the slower moving tissue (vessel wall) will not. Both color and 2D IVUS will be obtained from the same image plane and is displayed simultaneously. ChromaFlo is available for the Endosonics imaging system and catheter.

Method: We compared the information of standard digital 2D-images, with and without contrast agent injection, versus ChromaFlo of the same region regarding lumen/plaque differentiation and the overall lumen assessment in 65 lesions of 42 pts..

Results: The signal quality of ChromaFlo is depending on various factors. We obtained good signals or a better ratio between true signals and artifact more in: small lumen, high blood pressures, big guiding catheters; that results into a good and more bad ChromaFlo signal. In contrast to small lumen the blood flow close to the outer vessel wall can not be assessed completely in most big lumen. In pts. with a good signal ChromaFlo is helpful in differentiation of lumen vs. plaque, ring down artifact, detection of dissection as well as assessing the overall lumen area, especially in complex lesions. In one case the diagnosis of a resisting flow between a graft stent and the vessel wall due to a not fully apposed stent could only be made by ChromaFlo.

Conclusion: The signal quality of the ChromaFlo is variable from pt. to pt.. In vessels with a good signal the value of information seems to be, in part, superior to standard 2D IVUS with or without contrast injection. ChromaFlo is a promising new technique in intravascular ultrasound for better lumen detection.

P3492 Assessment of flow reserve and patency status of coronary artery bypass grafts by transthoracic Doppler echocardiography

F. Chirillo, A. Bruni, O. Totis, Z. Olivari, E. Franceschini, A. Cavarzerani, A. De Leo, F. Marton, P. Stritoni. *Department of Cardiology, Regional Hospital, Treviso, Italy*

To test the hypothesis that blood flow velocity and flow reserve in coronary artery bypass grafts (CABG) could be recorded by transthoracic Doppler echocardiography 45 consecutive patients with prior CABG (28 internal mammary artery (IMA) to left anterior descending, 33 saphenous vein grafts (SVG) to right coronary artery and 22 SVG to circumflex branches) were evaluated before coronary angiography using an Acuson Sequoia C 256™ platform at rest and after vasodilation induced by dipyridamole (DIP) infusion (0.56 mg/kg/4 min). Detection rate for not occluded IMA was 100% with 100% sensitivity and 100% specificity for graft occlusion. Detection rate for not occluded SVG was 80% with 83% sensitivity and 78% specificity for graft occlusion. Flow velocity parameters of not occluded CABG at baseline and under hyperemia were as follows:

	MA grafts		Saphenous vein grafts	
	Patent	Stenotic	Patent	Stenotic
Baseline SPV	75 ± 38*	78 ± 31*	38 ± 18	11 ± 8
Baseline DPV	41 ± 15*	25 ± 15*	11 ± 15	8 ± 3
DIP SPV	98 ± 25*	131 ± 75*	49 ± 15	18 ± 10
DIP DPV	125 ± 18*†	28 ± 14*	38 ± 17†	7 ± 3
Flow reserve	2.1 ± 1.5†	1.2 ± 0.9	1.9 ± 0.7†	0.9 ± 0.8

* = $p < 0.05$ vs SVG; † = $p < 0.05$ vs stenotic; DPV = Diastolic peak velocity (cm/s); SPV = Systolic peak velocity (cm/s); Flow reserve = DIP DPV/Baseline DPV.

None of the Doppler parameters at baseline could discriminate between patent and stenotic grafts. The best correlation was observed for flow reserve. The calculated flow reserve "cut point" values for patent IMA and SVG were assessed prospectively in a test group of 22 consecutive patients. Flow reserve ≤ 1.9 had 100% sensitivity and 88% specificity for detection of IMA graft stenosis $\geq 70\%$, and flow reserve ≤ 1.6 had 84% sensitivity and 65% specificity for detection of significant SVG stenosis.

In conclusion transthoracic Doppler echocardiography is a feasible and accurate means for obtaining a completely noninvasive assessment of CABG flow reserve and accurately predicts graft patency status.

P3493 Effect of captopril in coronary arterial distensibility as assessed by intravascular ultrasound in atherosclerotic lesions

S.G. Deftereos, E.K. Karvouni, G.A. Lazaros, E.I. Rentoukas, N.M. Kouvousis, A. Tsoukas, J. Giannouleas, A. Karavidas, A.S. Manolis, A.A. Zacharoulis. *Department of Cardiology, Athens General Hospital, 'G Gennimatas', Athens, Greece*

It has been shown that bradykinin contributes to the regulation of coronary vascular tone by causing endothelial release of nitric oxide, which in part may be responsible for normal coronary arterial distensibility. It has also been shown that even mild atherosclerosis decreases arterial distensibility. The aim of the present study was to assess the effect of captopril (which increases bradykinin levels) on arterial distensibility in atherosclerotic coronary vessels.

Methods: We have studied by intavascular ultrasound (IVUS-20 MHz, 3.5 F) 27 patients (16 men and 11 women aged 46.5 ± 7.8 years) having an angiographically non-significant isolated stenosis of the left anterior descending coronary artery (<70%). Lumen and vessel dimensions as well as plaque burden were measured at the lesion site. Coronary artery distensibility (CAD) was assessed by IVUS and simultaneous measurement of intracoronary pressure with a 2 F micromanometer catheter located at the left main coronary artery was performed. CAD was expressed by the coronary distensibility index which was calculated as 10-fold the ratio of luminal area change to intracoronary pressure change during cardiac cycle. All patients included received captopril (12.5 mg twice daily) for a 6-month period and patients were reassessed by IVUS. Statistical elaboration of the results was performed with Student's t-test. P values < 0.05 were regarded as statistically significant.

Results: Our results are shown in the table below.

	Before treatment	After treatment	
% Plaque burden:	47.59 ± 4.1	47.75 ± 4.2	P = NS
Distensibility index:	0.148 ± 0.039	0.154 ± 0.036	P = 0.012
DP*:	5.21	5.17	p = NS

*DP = Difference between systolic and diastolic intracoronary pressure.

In conclusion, captopril seems to improve coronary arterial distensibility in sites of atherosclerotic lesions despite its non significant effect on plaque progression.

P3494 Intracoronary infusion of magnesium sulfate dilates human coronary arteries in vivo

H. Teragawa, M. Kato, Y. Fukuda, H. Hirao, T. Yamada, Y. Muraoka, T. Yamagata, H. Matsuura, G. Kajiyama. *First dept. of Internal Medicine, Hiroshima University, Hiroshima, Japan*

Magnesium (Mg) is considered a natural, physiological calcium blocker, but the vasoresponse of human coronary arteries to Mg is still unknown. Therefore, we performed the present study to examine whether the coronary response to Mg changed in a dose-dependent manner and which segments of the coronary arteries were affected by intracoronary Mg infusion.

Methods: Seventeen patients with normal coronary arteries were enrolled for this study. Magnesium sulfate ($MgSO_4$) (0.02 mmol/min and 0.2 mmol/min over 2 min) was infused into the left coronary ostium. The diameter of proximal and distal segments of epicardial coronary arteries were quantitatively measured and coronary blood flow (CBF) was calculated by quantitative angiography and Doppler flow velocity measurements.

Results: At the dose of 0.02 mmol/min, $MgSO_4$ did not significantly affect the vascular response (percent change from baseline, mean ± SEM, proximal segments: +1.3 ± 0.7%; distal segments: +2.4 ± 0.9%; CBF: +5.8 ± 3.0%). At the dose of 0.2 mmol/min, $MgSO_4$ caused significant dilatation of epicardial coronary arteries (proximal segments: 4.3 ± 0.7%, $p < 0.0001$; distal segments: 8.3 ± 0.9%, $p < 0.0001$) and increase in CBF (31.1 ± 0.8%, $p < 0.0001$).

Conclusions: These findings suggest that Mg may dilate coronary arteries in a dose-dependent manner and the response of coronary arteries to Mg may be more dominant in the resistance coronary arteries than in the epicardial coronary arteries.

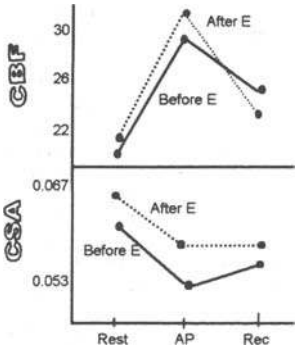
P3495 Favourable modulation of coronary blood flow and vasomotor responses during atrial pacing in postmenopausal women induced by the administration of oestrogen

I. Kallikazaros, C. Tsioufis, P. Zabaras, C. Stefanadis, A. Spanos, P. Toutouzas. *Department of cardiology, Hippokration Hospital, Athens University, Athens, Greece*

Short-term administration of 17 β estradiol (E) has been shown to improve exercise induced myocardial ischaemia in postmenopausal women with CAD.

Methods: In 12 postmenopausal women (mean age 60 ± 5 yrs) with minimal coronary irregularities, as evidenced by angiography or IVUS, we evaluated coronary reactivity and coronary blood flow (CBF) during incremental AP (up to 150 bpm for 3 minutes), before and 20 minutes after the intracoronary infusion of 75 ng/ml E which increased coronary sinus E levels from post- to pre-menopausal levels. The cross sectional area (CSA) and the blood flow velocity of the proximal coronary segments were measured with quantitative coronary angiography and with a doppler flow wire respectively. Measurements were obtained before, during AP and at 7 mins after AP.

Results: Before E administration, AP induced a significant decrease in coronary CSA (from 0.066 ± 0.004 to 0.053 ± 0.003 cm^2) and a significant increase in CBF (from 21.5 ± 2.4 to 27.7 ± 3.3 ml/min). Furthermore, these changes in CSA and CBF remained 7 mins after AP. After E administration, at rest the CSA and CBF did not change significantly (0.067 ± 0.002 cm^2 and 22.05 ± 3.1 ml/min, respectively) but during AP the changes in CSA and CBF were significantly attenuated compared to AP-induced changes before E (by 0.003 ± 0.001 vs 0.013 ± 0.001 cm^2; $p < 0.005$ and by 10.2 ± 1 vs 6.2 ± 1.1 ml/min, $p < 0.005$, respectively) These favorable modulations in CSA and CBF remained at 7 mins after AP.



Conclusion: Acute administration of E reduces the degree of pacing-induced ischemia by attenuating the reduction in coronary CSA and improving the increase in CBF in postmenopausal women.

P3496 Relative coronary flow velocity reserve after optimal balloon angioplasty compared to stenting

M. Haude, D. Baumgart, D. Welge, J. Ge, I. Kantzis, G. Mertes, C. van Birgelen, R. Erbel. *Cardiology Department, University-GHS Essen, Essen, Germany*

Distal coronary flow velocity (CVRd) assessed by intracoronary Doppler guide wires (Cardiometrics, Mountain View, USA) allows to estimate the functional result of a coronary intervention. Despite adequate postinterventional luminal widening CVRd increases to different levels. Instead of using a general cut-off value for CVRd we decided to guide our intervention by the individual measurement of CVRref in an non-stenotic reference artery and to calculate relative CVR (CVRrel) as the ratio of CVRd and CVRref. This approach was used to test whether optimal balloon angioplasty and coronary stenting provide similar results.

In 45 patients (pts) with de-novo LAD stenoses, who underwent optimal balloon angioplasty (PTCA, <20% residual stenosis) followed by stent implantation CVRd and CVRref were measured before and after PTCA and after stenting. CVRd was calculated as the ratio of hyperemic and baseline flow velocity before and after ic injection of 18 μg adenosine. Minimal lumen diameter (MLD) and % stenosis were measured by quantitative coronary angiography.

Results:

	Before PTCA	After PTCA	After stent
CVRd	1.3 ± 0.4	2.7 ± 0.6*	2.9 ± 0.4*§
CVRrel	0.47 ± 0.16	0.94 ± 0.09*	0.89 ± 0.06*§
MLD [mm]	0.89 ± 0.32	2.72 ± 0.18*	3.03 ± 0.16*
% stenosis	71 ± 23	12 ± 6*	3 ± 5*

*p < 0.001 versus before PTCA, §n.s. versus after PTCA

Conclusion: Optimal PTCA provides similar results on CVRd and CVRrel compared to adjunct stent implantation. This approach can be cost-effective since unnecessary elective stenting can be avoided.

P3497 Effect of the potential confounding factors on the thrombolysis in myocardial infarction (TIMI) trial frame count

A. Abaci, A. Oguzhan, N.K. Eryol, H. Arync, A. Ergin. *Department of Cardiology, Erciyes University School of Medicine, Kayseri, Turkey*

The corrected TIMI frame count has been proposed as an objective method to assess coronary blood flow. Although the variability between two consecutive injections appear low, the potential factors that introduce variability into the TIMI frame count has not been systematically investigated. The goal of this study was to determine if nitrate use, rate of dye injection, size of catheter used, the phase of the cardiac cycle dye injected or heart rate affect the TIMI frame count.

Methods: A mechanical electrocardiographic-gated power injector was used to inject contrast dye at rates 3–4 ml/sec in left coronary arteries and 2–3 ml /sec in right coronary artery. In the first 25 pts, injection rate of dye was increased 1-ml/s without any change in the catheter used. In the second 25 pts, coronary angiogram was taken with 6 F catheter, after changing the catheter with 8 F, angiography was repeated in the same dye injection rate. In the third 25 pts, after taking angiogram, 300 microg. intracoronary nitrate was given, and the angiography was performed with the same catheter without any change in dye injection rate. In another 25 pts, after the angiogram taken in basal condition, heart rate increased 25 beat/min over the basal rate and angiography was repeated with same catheter without any change in injection rate. Finally, injection of dye was performed at the beginning of systole and also repeated at the beginning of diastole. The angulation of cinecamera was not varied between repeated studies. The TIMI frame count was measured by counting the number of cine frames (25 frames/sec) during coronary angiography required for the leading edge of contrast to reach predetermined distal landmarks.

Results: The TIMI frame count was not significantly changed by increasing the dye injection rate (28.2 ± 11.4 vs. 27.2 ± 11.5, p = 0.467) or changing the catheter size (25.1 ± 8.7 vs. 25.7 ± 12.4 p = 0.693). With the nitrate administration, the TIMI frame count was significantly increased from 26.4 ± 11.9 to 32.8 ± 13.3 (p < 0.001). The injection of dye at the beginning of diastole or increasing of heart rate significantly decreased the TIMI frame count from 30.1 ± 8.8 to 24.4 ± 7.9 (p < 0.001) and from 30.4 ± 6.1 to 25.3 ± 7.2 (p < 0.001), respectively.

Conclusions: The injection rate of dye and size of catheter have not any effect on the TIMI frame count. However, nitrate use, heart rate, and the phase of the cardiac cycle dye injected have significant effect on the TIMI frame count. Therefore, studies comparing the TIMI frame count need to consider these factors.

P3498 How much coronary collateral flow protects against myocardial ischaemia?

Michael Billinger, Martin Fleisch, Ali Garachemani, Franz Eberli, Bernhard Meier, Christian Seiler. *Cardiology, University Hospital, Berne, Switzerland*

Purpose: The purpose of this study was to determine how much collateral flow is necessary to protect the ipsilateral myocardial area against ischemia during vessel occlusion.

Methods: In 201 patients (pts) undergoing percutaneous transluminal coronary angioplasty (PTCA) an index of collateral flow (CFI) was determined using intracoronary (i.c.) pressure- or Doppler-guidewires. Mean aortic (P_{ao}) and distal occlusive (P_{occl}) pressure during PTCA or distal flow velocity during (Vi_{occl}) and after ($Vi_{0\text{-}occl}$) PTCA were measured continuously. The pressure derived CFI was calculated as follows: (P_{occl}-CVP)/(P_{ao}-CVP), CVP: Central venous pressure = 5 mmHg. The ratio between $Vi_{0\text{-}occl}$ and Vi_{occl} was used for the determination of Doppler-derived CFI. The degree of collateralisation to the vessel to be dilated was also graded angiographically (Rentrop; grade 0–3).

Results: Based on the absence or the presence of ST-segment changes (< or ≥1 mm) on i.c. ECG during balloon occlusion, 50 pts were in the group with sufficient collaterals and 151 pts in the group with insufficient collaterals. There was an overlap of 15/201 data points (CFI) between the 2 groups. By defining a value of CFI ≥ 38% as sufficient collaterals, there were 5 false negative and 10 false positive test results (figure).

	Sufficient Collaterals	Insufficient Collaterals	P
n	50	151	
Age	59 ± 10	58 ± 10	NS
CFI	0.48 ± 0.18	0.17 ± 0.09	<0.0001
Rentrop (0–3)	2.0 ± 0.7	0.8 ± 0.8	<0.0001
AP	9%	91%	<0.0001

AP: Angina pectoris during PTCA, CFI: Collateral flow index

Conclusions: A collateral flow of ≥38% relative to normal flow through the patent vessel predicts protection against myocardial ischemia with 94% specifity and 89% sensitivity.

P3499 L-arginine-induced dilation in stenotic atheromatous plaque is depending to its severity and morphology

D. Tousoulis, C. Tentolouris, T. Crake, G. Goumas, C. Stefanadis, G. Davies, P. Toutouzas. *Cardiology Units Hammersmith Hospital London, UK; Athens University Medical School, Athens, Greece*

Administration of L-arginine may stimulate the release of endothelium derived nitric oxide and improve myocardial ischemia. We sought to examine the effects of L-arginine administration on coronary stenosis vasomotion in patients with coronary artery disease (CAD).

Methods. Intracoronary infusions of normal saline, the receptor mediated nitric oxide stimulant, L-arginine (L-A) (50 and 150 μmol/min) and nitroglycerin (GTN) (250 mcg bolus) were administered in 15 patients with coronary artery disease and stable angina. Coronary stenoses were classified as smooth (smooth with regular borders) or complicated (irregular borders). The diameter of 12 smooth and 10 complicated coronary stenoses and their adjacent reference (R) segment was measured by quantitative angiography. The mean (±SEM)% change from baseline was:

	NS	L-A 50	L-A 150	GTN
Smooth Stenoses	0.9 ± 0.5	6.4 ± 1.4	7.3 ± 2.9	14.9 ± 3.4
R segment	0.7 ± 0.4	4.5 ± 1.4	10.5 ± 2.2	12.3 ± 3.5
Comlex Stenoses	1.0 ± 0.8	7.1 ± 3.2	13.7 ± 2.5*	19.4 ± 2.3
R segment	0.4 ± 0.5	6.3 ± 2.9	10.4 ± 2.4	10.4 ± 2.5

* = p < 0.01 vs smooth stenoses

There was a significant correlation between stenosis severity and L-arginine induced dilation (r = 0.56, p < 0.001).

Conclusions. In patients with CAD, complex coronary stenoses dilate significantly more than smooth stenoses after L-arginine administration. This raises the possibility of partial deficiency of the substrate for nitric oxide synthesis at the site of complicated stenoses. The provision of the substrate significantly enhances nitric oxide activity at the site of irregular and severe stenoses.

P3500 Systemic nature of endothelial dysfunction: association between coronary and peripheral regulation of resistance vessels

V. Schächinger, S. Fichtlscherer, M.B. Britten, A.M. Zeiher. *Dept. of Internal Medicine IV, Div. of Cardiology, J. W. Goethe University, Frankfurt/Main, Germany*

Endothelium-dependent vasodilator function is altered in the presence of risk factors for coronary artery disease. Thereby, risk factors act systemically on all vascular beds, including peripheral vessels as well as coronary arteries, where atherosclerosis develops. However, it is not known whether vascular reactivity of the peripheral microcirculation correlates with regulation of coronary resistance vessels. Thus, in 22 patients, we investigated endothelium-dependent vasoreactivity of the coronary microcirculation by i.c. infusion of acetylcholine (Ach, 10^{-6} M). Coronary blood flow increase was calculated by Doppler measurements and quantitative angiography. Plethysmography was used to measure blood flow increases in the forearm after infusion of Ach (50 μg/min). Endothelium-independent blood flow increase was assessed via i.c. adenosine (2.4 mg/min) or papaverine (7 mg) in the coronary arteries, respectively, by sodium nitroprusside (8 μg/min) in the forearm.

Results: Relative Ach-induced coronary blood flow responses correlated with Ach-induced blood flow responses in the forearm circulation ($r = 0.46$; $p = 0.03$), whereas endothelium-independent coronary and peripheral blood flow responses were not associated with each other. The relation between coronary and peripheral endothelium-dependent blood flow responses persisted after normalization to endothelium-independent responses ($r = 0.52$; $p = 0.013$). No correlation was found between Ach-induced vasoreactivity of epicardial arteries and forearm Ach-induced blood flow response ($r = 0.11$; p = NS).

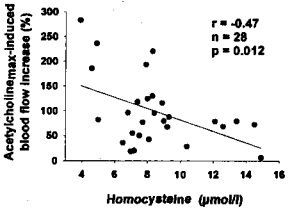
Conclusions: Impaired peripheral endothelial blood flow regulation is a surrogate marker of endothelial dysfunction of the coronary microcirculation.

P3501 Homocysteine impairs endothelium-dependent vasodilation of the coronary microcirculation

V. Schächinger, M. Britten, D. Walter, M. Elsner, W. Auch-Schwelk, A.M. Zeiher. *Dept. of Internal Medicine IV, Div. of Cardiology, J. W. Goethe University, Frankfurt/Main, Germany*

Homocysteine has been shown to play a role for progression of coronary artery disease. Endothelium-dependent vasodilator function of peripheral arteries is impaired in patients with elevated homocysteine levels. However, it is not known, whether homocysteine is associated with impaired coronary endothelial vasodilation. Thus, we investigated the role of fasting homocysteine levels on endothelium-dependent coronary blood flow increase (i.c. acetylcholine, ACH, 10^{-6} M) and endothelium-independent (7 mg papaverine or 2.4 mg/min adenosine) coronary blood flow responses. Coronary microcirculation was tested by quantitative coronary angiography and i.c. Doppler measurements in 28 patients with normal or minimally diseased coronary arteries (<30% focal stenosis).

Results: There is a significant inverse relation between ACH-induced coronary blood flow increases and plasma homocysteine levels (figure). In contrast, endothelium independent coronary blood flow responses were unaffected by homocysteine levels ($r = -0.17$; $p = 0.39$).



Conclusions: Homocysteine seems to be an important risk factor for endothelial dysfunction of the coronary microcirculation. This mechanism might contribute to progression of atherosclerosis in patients with elevated homocysteine levels.

P3502 A study with intracoronary injection of ergonovine in 365 patients: the incidence of coronary spasm in various cardiac disorders

Shozo Sueda, Hideyuki Saeki, Takashi Otani, Naoto Ochi[1], Hitoshi Kukita[1], Kazuaki Mineoi[2], Kazuo Yano[2], Takaaki Ochi[2], Hiroyuki Kawada[3], Tadao Uraoka[3]. *Saiseikai Saijo Hospital; [1]Uwajima Social Insurance Hospital; [2]Takanoko Hospital; [3]Kita Medical Association Hospital, Saijo City, Japan*

We performed selective intracoronary administration of ergonovine for 365 patients to clarify the incidence of coronary spasm in various cardiac disorders in Japanese patients from April 1991 to October 1997. We studied 245 patients strongly suspected of having ischemic heart disease and 120 patients with non-ischemic heart disease. Under no medication for at least 24 hours, ergonovine was injected in total doses of 40 μg into the right coronary artery and 64 μg into the left coronary artery for 4 minutes. We defined spasm as positive with ≥90% luminal narrowing. The result was as follows:

	Rest	Effort	R & E	AMI	OMI	Post PTCA	IHD suspected
No of pts	72	42	22	44	14	51	245
Spasm (+)	43 (60)	16 (38)	10 (46)	15 (34)	3 (21)	24 (47)	111 (45)

	Atypical	Val	DCM	HCM	Other	Non-IHD suspected
No of pts	63	5	5	7	40	120
Spasm (+)	3 (5)	0 (0)	0 (0)	1 (14)	2 (5)	6 (5)

	No	Male	Age	HT	Smoking	HL	DM	Organic (>75%)
Spasm (+)	117	102 (87)	64 ± 10	39 (33)	91 (78)	32 (27)	26 (22)	49 (42)
Spasm (−)	248	127 (51)	63 ± 10	98 (40)	99 (40)	32 (13)	32 (13)	47 (19)
P value		0.01	ns	ns	0.01	0.01	0.05	0.01

(AMI: acute myocardial infarction, OMI: old myocardial infarction, PTCA: percutaneous transluminal coronary angioplasty, IHD: ischemic heart disease, Val: valvular heart disease, DCM: dilated cardiomyopathy, HCM: hypertrophic cardiomyopathy, HT: hypertension, HL: hyperlipidemia, DM: diabetes mellitus, 0: indicates %)

The incidence of provoked spasm in patients with ischemic heart disease was significantly higher than that in patients with non-ischemic heart disease (45% vs 5%). Moreover patients with spasm had significantly higher incidence of habitual smoking, hyperlipidemia, diabetes mellitus and organic coronary stenosis than the patients without spasm. No serious irreversible complication occurred in the procedure.

In conclusion, intracoronary injection of ergonovine is a safe and reliable method. In Japanese patients coronary artrerial spasm occurred frequently in various cardiac disorders.

P3503 Clinical characteristics in patients with provoked coronary spasm by pharmacologic agents, acetylcholine and ergonovine

Shozo Sueda, Hideyuki Saeki, Takashi Otani, Naoto Ochi[1], Hitoshi Kukita[1], Kazuaki Mineoi[2], Kazuo Yano[2], Takaaki Ochi[2], Hiroyuki Kawada[3], Tadao Uraoka[3]. *Saiseikai Saijo Hospital; [1]Uwajima Social Insurance Hospital; [2]Takanoko Hospital; [3]Kita Medical Association Hospital, Saijo City, Japan*

The purpose of this study is to determine the clinical charcteristics in patients with coronary vasospasm induced by acetylcholine (ACh) or ergonovine (ER). We performed spasm provocation tests of both ACh and ER in 57 patients (48 men and 9 women, 63 ± 9 years). These patients, including 23 patients with coronary spasm induced by both ACh and ER, including 14 patients with spasm provoked by only ACh not ER and 20 patients with coronary spasm induced by only ER not ACh were examined. ACh test was performed in incremental doses of 20, 50, 80 μg into the right coronary artery (RCA) and 20, 50, 100 μg into the left coronary artery (LCA). ER was performed in total doses of 40 μg into the RCA and 64 μg into the LCA. Coronary spasm was defined as total or subtotal occlusion. The result was as follows:

	ACh & ER	ACh only	ER only
No of pts (male)	23 (19)	14 (9)	20 (20)
Age (yr)	64 ± 10	64 ± 8	62 ± 9
Smoking	16 (70%)	6 (43%)	20 (100%)*
Hypertension	10 (44%)	4 (29%)	3 (15%)
Hyperlidemia	10 (44%)	3 (21%)	6 (30%)
Diabetes mellites	4 (17%)	1 (7%)	5 (25%)
Mean No of risk factors	1.73 ± 1.03	1.27 ± 1.10	1.74 ± 0.87
T cholesterol (mg/dl)	171 ± 34	168 ± 27	169 ± 27
Triglyceride (mg/dl)	172 ± 101	87 ± 42**	122 ± 36*
HDL-cholesterol (mg/dl)	41 ± 11	44 ± 17	42 ± 9
Organic stenosis (≥75%)	5 (22%)	1 (7%)	13 (65%)*
(RCA: LCX: LAD)	1:1:4	0:0:1	10:0:3
Spasm provocated vessel	29	17	21
RCA	10	7	18
LCX	5	0	0
LAD	14	10	3
Focal vs Diffuse	17 (59%): 12 (41%)	4 (23%): 13 (77%)	20 (95%)*: 1 (5%)

(*: $p < 0.01$ vs other groups, **: $p < 0.01$ vs ACh & ER)

In conclusion, the patients with coronary spasm induced by ER not ACh had significantly higher organic stenosis than other patients. ER is more sensitive to provoke coronary spasm in the RCA than ACh.

P3504 Effects of serotonin and acetylcholine on coronary microcirculation in subjects with coronary spastic angina

K. Kurosawa, A. Hirosaka, J. Goto, N. Komatsu, K. Maehara, Y. Maruyama.
Fukushima Medical University, Fukushima, Japan

Generalized endothelial dysfunction has been speculated in coronary spastic angina (CSA), however, it remains unclarified whether endothelium-dependent vasodilatory response in coronary microvascular beds is impaired. Serotonin (SER) and acetylcholine (ACh) have been known as endothelium-dependent vasodilators, as well as potent inducers of epicardial coronary artery spasm in subjects with CSA. Thus, we investigated coronary microvascular response to SER and ACh in subjects with CSA and angiographically normal coronary artery.

Methods: Eleven subjects with CSA (group S) who were diagnosed by anginal attack with ST elevation and angiographically proved coronary artery spasm induced by SER and/or ACh, and 22 subjects with atypical chest pain without CSA (group N) were enrolled in this study. All subjects had a normal left coronary arteriogram. Doppler tipped flow wire (FloWire) was placed in the proximal left anterior descending coronary artery. Coronary flow (CoF) was calculated by average peak velocity (APV) and quantitative coronary angiography according to the formula; CoF (ml/min) = APV × (coronary cross-sectional area measured by cinedensitometry) × 0.3. Steady flow after intracoronary injection of nitroglycerin (0.2 mg) into left main coronary artery to eliminate the epicardial coronary arterial tone was defined as baseline CoF. Peak CoF responses to acetylcholine (ACh, 50 μg), papaverine (PAP, 10 mg) and SER (10 μg) from baseline were measured.

Results: Baseline CoF in group S and N was 48 ± 5 and 53 ± 6, respectively. There were no differences in peak CoF responses to PAP (group S, 379 ± 37% vs N, 401 ± 23%, N.S.), ACh (group S, 323 ± 33% vs N, 296 ± 15%, N.S.) and SER (group S, 212 ± 20% vs N, 241 ± 21%, N.S.) between group S and N.

In conclusion, coronary microvascular responses to physiological amines, SER and ACh, were normal in subjects with CSA, suggesting that endothelial function is well preserved in coronary microvascular beds.

P3505 Endogenous endothelin contributes to the maintenance of coronary vasomotor tone in humans

P.A. MacCarthy, B.D. Prendergast, N.C. Pegge, A.M. Shah[1], P.H. Groves.
Departments of Cardiology, University Hospital of Wales, Cardiff; [1]Kings College London, UK

Endogenous production of endothelin (ET) contributes to basal human peripheral vascular tone, but its role in the maintenance of coronary vasomotor tone is unknown. We investigated the effect of endogenous ET in the human coronary circulation. An ET_A receptor antagonist, BQ123 (40 nmol/min, 15 min), was infused into the left coronary artery in 9 patients (2 male, mean age 56.8 ± 3.0 yrs) with angiographically normal coronary arteries, undergoing investigation of atypical chest pain. Epicardial coronary diameter was measured by biplane digital cineangiography with off-line quantitative coronary angiography, and coronary flow with a Doppler flow wire in the mid-left anterior descending coronary artery (LAD). Flow-dependent (ic adenosine; 18 μg via infusion catheter) and agonist-mediated dilatation (ic substance P; 20 pmol/min for 2 min via guiding catheter) were assessed at baseline. Endothelium-independent dilatation (ic GTN; 250 μg) was assessed at the end of the protocol. BQ123 caused significant vasodilation in the mid-LAD and an increase in coronary flow (table).

	LAD cross-sectional area (mm^2)			Flow (ml/min)
	Proximal	Mid	Distal	
Baseline	7.91 ± 1.0	5.18 ± 1.0	2.16 ± 0.3	25.8 ± 3.5
BQ123	8.47 ± 1.0	6.34 ± 1.0*	2.4 ± 0.3	30.0 ± 3.6*

All values mean ± SEM. * = P < 0.01 vs baseline

There were no significant changes in ECG or aortic pressure and no correlation between vasodilation following BQ123 and parameters of baseline endothelial function. These data indicate for the first time that endogenous ET plays a role in the regulation of basal vasomotor tone in normal human epicardial and resistance coronary vessels.

P3506 Endothelin-1 and coronary vasoreactivity in unstable angina

A. Gaspardone, C. Ferri, F. Versaci, F. Tomai, A.S. Ghini, P. Gallo, G. Gioffrè, F. Crea, L. Chiariello, P.A. Gioffrè. *Divisione di Cardiochirurgia, Università di Roma, Tor Vergata, Rome, Italy*

In patients with unstable angina (UA) an increased tissue endothelin-1 (ET-1) immunoreactivity has been demonstrated at the site of the culprit lesion (CL) thus suggesting that ET-1 may be involved in the pathogenesis of the enhanced coronary tone. We studied 8 patients with UA (Class IIIB, 6 men, mean age 58 ± 11 years) and 8 patients with stable angina (SA) (CCS II–III, 6 men, mean age 65 ± 5 years) with a single proximal lesion of a major epicardial coronary vessel. Luminal diameter of the CL and of the proximal, middle and distal normal-appearing coronary segments were measured by quantitative coronary angiography at baseline, during cold pressor test (CPT) and after intracoronary administration of nitrate (NTG). ET-1 levels were measured in blood samples obtained proximally and distally to the coronary CL before and after successful stent implantation. Baseline luminal diameter of the CL was 1.0 ± 0.45 mm in UA and 0.92 ± 0.23 mm in SA (p = 0.58). During CPT, the CL in patients with UA constricted more than that of patients with SA (0.78 ± 0.35 vs 0.84 ± 0.19 mm; percent reduction compared baseline −23 ± 8 vs −7.9 ± 10%, p = 0.005). After NTG the CL in patients with UA dilated more than that of patients with SA (1.4 ± 0.45 vs 1.1 ± 0.24 mm; percent increase compared baseline 46 ± 0.22 vs 22 ± 7.5%, p = 0.01). The uninvolved proximal, middle and distal coronary artery segments had similar changes during CPT and after NTG in both patients with UA and SA. Proximal and distal ET-1 levels before stenting were similar in both patients with UA and SA (1.29 ± 0.08 vs 1.24 ± 0.2 pg/ml, p = 0.54 and 1.27 ± 0.20 vs 1.24 ± 0.24 pg/ml, p = 0.79 respectively). After stenting, proximal and distal ET-1 levels significantly increased compared to baseline values both in patients with UA and SA; however the relative increase was higher in UA than in SA patients (1.7 ± 0.26 vs 1.39 ± 0.16 pg/ml, p = 0.015 and 1.70 ± 0.14 vs 1.5 ± 0.3 pg/ml, p = 0.05, respectively). Coronary artery stenting causes a release of ET-1 which is greater in UA than SA. Thus the enhanced potential of the CL to release ET-1 might be responsible, at least partially, for the enhanced vasoreactivity of the CL in patients with UA.

P3507 Transcoronary ablation of septum hypertrophy by selective septal branch injection of ethanol: a 4-year experience in catheter interventional treatment for hypertrophic obstructive cardiomyopathy

F.H. Gietzen, Ch.J. Leuner, J. Hegselmann, C. Strunk-Mueller, H.J. Kuhn.
Dept. of Cardiology, Bielefeld Hospital, Bielefeld, Germany

Since 1995 137 transcoronary ablations of septum hypertrophy (TASH) were performed in 119 pts. with HOCM and severe symptoms (57 men, 58 ± 14 years). Serial left heart catheterization, exercise right heart catheterization, transesophageal echocardiography and electrophysiologic testing were performed before as well as 2 weeks and 7 months after intervention. Clinical information is obtained with a max. of 36 months.

Major results were significant reductions of septal thickness (from 22 ± 4 to 11 ± 3 mm), outflow obstruction (from 53 ± 39 to 11 ± 17 mmHg at rest, from 146 ± 49 to 38 ± 41 mmHg postextrasystolically) and left ventricular filling pressures (from 20 ± 6 to 14 ± 5 mmHg) despite a slightly reduced ejection fraction (from 0.70 ± 0.09 to 0.68 ± 0.10). Peak CK-activity rose to a mean value of 583 ± 376 IU after injection of 3.6 ± 2.2 ml 96% Ethanol. NYHA-functional class improved from 3.0 ± 0.4 to 1.6 ± 0.6, exercise tolerance from 73 ± 30 to 91 ± 34 watts, peak oxygen consumption from 14.8 ± 4.9 to 16.8 ± 5.7 ml/kg/min and pulmonary artery mean pressure from 43 ± 9 to 35 ± 9 mmHg. The induction of sustained ventricular arrhythmias decreased from 9.6 to 4.8% (n.s) in 41 pts. investigated. Permanent high-grade av-block were observed in 14 pts. (12%) and 3 additional pts with severe co-morbidity could not be resuscitated from different emergencies related to the potential of TASH induced AV conduction disturbances. However, there was no late cardiac death after hospital discharge. The risk of a persistent total AV block was correlated to the relief of intraventricular obstruction (r = 0.31 p = 0.001).

Conclusion: TASH leads to a pronounced clinical and hemodynamic improvement that compare favorable with the results of surgical myectomy. However, it should performed only in pts with severe symptoms refractory to drug therapy, as an alternative to surgery.

CARDIOVASCULAR DISEASE IN WOMEN

P3508 The role of aspirin and nonsteroidal anti-inflammatory drugs in the primary prevention of myocardial infarction in women

C. Varas, L.A. García-Rodriguez[1], S. Perez-Gutthann, C. Patrono[2]. *Global Epidemiology, Novartis Pharma, Barcelona; [1]Spanish Pharmacoepide. Research Center, CEIFE, Madrid, Spain; [2]Pharmacology and Medicine Department., University of Chiety., Chiety, Italy*

The antiplatelet effect of aspirin has been found to reduce fatal and nonfatal vascular events in secondary prevention by approximately 15% and 30%, respectively. Data are limited in primary prevention of coronary heart disease (CHD) and even more in women. We conducted a population-based case-control study in order to evaluate the association of acute myocardial infarction (AMI) with the use of aspirin and NSAIDs among postmenopausal women.

Methods: A cohort of women 50 to 74 years old registered in the General Practice Research Database in the UK between January 1, 1991 and December 31, 1995 was identified. Women with a history of MI, other cardiovascular and cerebrovascular disease, neoplasms, coagulopathies, vasculitis, and alcohol-related diseases were excluded from the source population. 1,242 potential MI cases were identified. After the review (blind to exposure status) of medical records and all the available information concerning the acute event, 1,013 first episodes of AMI, 791 non fatal and 222 CHD deaths, were confirmed using WHO adapted criteria. 5,000 women were sampled as controls from the source population. A women was defined as current user when she was taking aspirin/NSAIDs during the month before index date, and as a past user when she stopped aspirin/NSAID ingestion more than one month before index date. Nonusers were women with no aspirin/NSAID prescription in the computerized medical database.

Results: The overall incidence of AMI was 1.6 per 1,000 person-years. The odds ratio (ORs) of AMI associated with prophylactic aspirin use (defined as more than one month of continuous use) was 0.6 (95% CI: 0.3–1.2) afer controlling by age, coronary risk factors, HRT use and comorbidity. Daily doses of 300 mg were not associated with a smaller OR than doses of 150 mg or less. The greatest risk reduction was observed among non-fatal cases of AMI (OR: 0.3; 95% CI: 0.1–0.9). Overall, NSAID use was not associated with a beneficial effect on the risk of AMI. This lack of beneficial effect was also observed after stratification by either duration or daily dose, and neither for fatal and nonfatal AMI events. None of the estimates for individual NSAIDs reached statistical significance.

In conclusion, current and continuous use of aspirin was associated with a 40% reduction on the overall risk of AMI in postmenopausal women, and this reduction was even greater when only nonfatal cases were considered. Chronic use of NSAIDs was not associated with lower risk of AMI in this population.

P3509 Impact of conventional risk factors and the angiotensin-converting enzyme in women treated with coronary stent placement

V. Ferrero, F. Ribichini, W. Wijns[1], G. Steffenino, A. Vado, A. Dellavalle, P. Russo, E. Uslenghi. *Divisione di Cardiologia dell'Ospedale Santa Croce di Cuneo, Italy; [1]OLV Cardiovascular Center, Aalst, Belgium*

Plasma levels of the angiotensin-converting enzyme (ACE) and the deletion (D) allele of the (I/D) polymorphism of the ACE gene are predictors of restenosis (R) after coronary stenting. Women have a lower incidence of coronary artery disease (CAD) before menopause due to the protective effect of estrogen, but post-menopausal women equal the incidence of CAD in men probably because of the cessation of the activity of these hormones and the concomitant increment of the conventional risk factors.

Methods: we analyzed the incidence of R (DS% > 50) in the 141 women treated with coronary stents in our Centers in 1997–98, and the variables associated with CAD shown in the table, including basal plasma ACE level. These variables were also compared to a matched control group of 68 women with normal coronary angiogram and left ventricular function.

	Normal (68)	Non restenosis (112)	Restenosis (29)	p
Age (years)	63 ± 10	67 ± 9	64 ± 8	ns
Hypertension	31%°*	66%°	55%*	<.0001
Diabetes	4%°*	17%°	25%*	<.01
Insulin dependent	3%*	3.5%°	10%°*	<.01
Total cholesterol	200 ± 38	202 ± 58	205 ± 42	ns
Lipoprotein (a)	28 ± 20	35 ± 31	29 ± 23	ns
Apo B	117 ± 27°	124 ± 34	132 ± 35°	<.05
Triglycerides	96 ± 62	98 ± 48	100 ± 65	ns
Fibrinogen	281 ± 59°	348 ± 90°	318 ± 107	<.05
ACE	21 ± 16°	20 ± 16*	37 ± 22°*	<.005

* and ° indicate significant difference between groups.

By multivariate analysis, basal ACE level and insulin dependent diabetes were associated with R, p = 0.006 and p = 0.03 respectively. The comparison between control group vs CAD showed a significant increment of conventional risk factors in the latter, but these were not associated with restenosis.

In conclusion, conventional risk factors in women are associated with CAD but not with R after stenting except for insulin dependent diabetes. The basal level of ACE is an additional risk factor that strongly predicts the occurrence of in-stent R in aged women.

P3510 Aetiology of heart failure in women aged <75 years in the population

K.F. Fox, M.R. Cowie, D.A. Wood, A.J.S. Coats, J.S.R. Gibbs, S.R. Underwood, R.M. Turner, P.A. Poole-Wilson, S.W. Davies, G.C. Sutton. *Imperial College School of Medicine, London, UK*

Background: The Bromley Heart Failure Study is an epidemiological study of the incidence and aetiology of heart failure (HF) in a population of 292 000 within South East London. Uniquely, all incident (new) cases aged <75 were investigated by coronary angiography.

Methods: All new HF cases were identified by in-patient monitoring and from a dedicated rapid access heart failure clinic over a period of 15 months. Cases were assessed by a panel of 3 cardiologists who assigned an aetiology on the basis of the information prior to study angiography. A final aetiology was subsequently assigned combining all clinical, non-invasive and invasive data. We examined the incidence and aetiology of HF in women.

Results: 136 cases were identified aged <75. Angiographic data were available on 99/136 cases (80% of the 124 cases surviving the initial presentation of HF). 91/136 (67%) cases were male and 45 (33%) cases female. The incidence of heart failure in the population aged 25–75 years was 0.78 cases/1000 population/year for men and 0.38 cases/1000 population/year for women. This difference in incidence was dominated by a greater incidence of HF due to CAD in men (0.51 cases/1000 population/year) compared to women (0.09 cases/1000 population/year). The incidence of HF not due to CAD (hypertension, valve disease, arrhythmia, alcohol, idiopathic, other and undetermined) was similar in men (0.26 cases/1000 population/year) and women (0.29 cases/1000 population/year). Prior to angiography no aetiology or an aetiology other than CAD was assigned in 46 cases (29 male and 17 female). Angiography revealed important CAD in 16/29 (55%) of the men compared to only 2/17 (12%) of the women (p < 0.01), both of whom were diabetic.

Conclusions: HF due to CAD is uncommon in women aged <75. If CAD is not suspected from clinical assessment then, in the absence of diabetes, subsequent angiography is very unlikely to reveal important CAD.

P3511 Insulin resistance in postmenopausal women with coronary heart disease

F. Leyva, C. Spencer, A.J. Proudler, I.F. Godsland, C. Walton, P. Collins, J.C. Stevenson. *Rosen Laboratories of the Wynn Institute, St. Mary's Hospital, ICSM; Department of Cardiac Medicine, ICSM at the NHLI, London, UK*

Insulin resistance is associated with coronary heart disease (CHD) and its risk factors. Surrogate measures of insulin sensitivity, such as fasting plasma glucose and insulin levels, are predictors of CHD. Insulin resistance plays a coordinating role in the association of metabolic risk factors for CHD. We explored whether postmenopausal women with CHD are insulin resistant compared to women without CHD.

Methods and results Postmenopausal women (FSH > 40 IU) with angiographically documented CHD (n = 19) and healthy volunteers (n = 30), matched for age and menopausal age, underwent measurement of insulin sensitivity [S_I, intravenous glucose tolerance test (IVGTT)], plasma lipids and body fat (dual-energy X-ray absorptiometry). Compared to controls, CHD patients had a lower S_I [3.96 (−0.59, +0.64) *vs* 5.97 (−0.47, +0.49) 10^5/min/[pmol.l^{-1}], p = 0.012) and a higher IVGTT insulin area [1.92 (−0.21, +0.24) *vs* 1.36 (−0.11, +0.11)] 10^4. (pmol/l).min, p = 0.015). No group differences emerged with respect to fasting glucose and insulin levels, IVGTT glucose area, body mass index, amount of android or gynoid fat or android: gynoid fat ratio. Patients and controls also had similar total and HDL-cholesterol levels and HDL-cholesterol subfractions. Patients with CHD, had higher serum urate levels than controls [287.8 (16.7) vs 229.3 (11.6) μmol/l, p = 0.005]. In multivariate analysis, disease status emerged as a significant predictor of S_I (F ratio = 7.1, p = 0.01), independently of systolic blood pressure and serum uric acid (square multiple R = 0.16).

Conclusions This is the first demonstration that, compared to healthy postmenopausal women of similar chronological and menopausal age, women with CHD are insulin resistant. Further studies are needed to assess the role of insulin resistance in the coordination of metabolic risk factors for CHD in women. The effects of estrogens on S_I warrants further investigation.

P3512 Revascularisation rates in patients with coronary artery disease: no evidence of gender bias

H. Hemingway, A. Crook[1], G. Feder[1], A.D. Timmis[2]. *Academic Department of Public Health, Kensington and Chelsea Health Auth., London; [1]Department of General Practice, Royal Hospitals Trust, London; [2]Cardiology Dept., London Chest Hospital, London, UK*

Background: The previous studies which have shown that women undergo less invasive investigation and treatment of coronary artery disease than men are limited by poor measurement of need.

Objective: To measure whether for a given need (defined by severity of anatomical disease, severity of functional impairment, and numerical ratings of procedure appropriateness) there were sex differences in invasive management of coronary artery disease.

Design: prospective study (24 months mean follow up) of unselected patients undergoing angiography during 12 months from April 1996.

Participants: 1181 women and 2837 men.

Setting: Royal Hospitals NHS trust, London.

Main outcome measures: Rate of coronary angioplasty (PTCA) and coronary artery bypass grafting (CABG) in the presence of coronary artery disease (n = 151 and 192 procedures respectively in women) and survival.

Results: Compared with men, women were older and less likely to have a previous history of MI, exercise ECG or revascularisation ($p < 0.01$ for each comparison). Women were more functionally impaired than men on the CCS, SF-36 and SAQ scales ($p < 0.01$). Amongst patients with significant coronary artery disease there were no overall differences in revascularisation rate; women were however more likely than men to undergo PTCA (hazard ratio 1.34 (95% CI 1.11–1.64). The excess PTCA in women was confined to those deemed inappropriate. There was no difference in mortality.

Conclusion: Women with coronary artery disease were revascularised at the same rate as men and with the same survival. The higher rate of PTCA among women may reflect their greater functional impairment.

P3513 The metabolic syndrome of cardiovascular risk in middle-aged men and middle-aged, postmenopausal women

F. Leyva[1,2], C. Spencer[2], A.J. Proudler[2], I.F. Godsland[2], C. Walton[2], J.C. Stevenson[2]. *[1]Department of Cardiac Medicine, ICSM at NHLI; [2]Wynn Institute of Metabolic Medicine, St. Mary's Hospital, ICSM, London, UK*

Compared to women, men are at an increased risk of early death from coronary heart disease. We explored whether, in middle age, insulin sensitivity (S_I) and other variables that are relevant to the metabolic syndrome differ from those in women.

Methods: Men aged 53.3 (0.8) years [mean (SEM), n = 132] and age-matched postmenopausal women (n = 132, follicle-stimulating hormone > 40 IU) underwent measurement of $S44_I$ (i.v. glucose tolerance test (IVGTT)] and plasma lipids.

Results: Men had a lower S_I ($p < 0.001$), higher fasting glucose ($p < 0.001$), IVGTT glucose ($p < 0.001$) and IVGTT insulin ($p < 0.001$), serum urate levels ($p < 0.001$) and triglycerides ($p = 0.034$), and lower HDL-cholesterol ($p < 0.001$), higher body mass indices (BMI, $p < 0.001$) and blood pressures ($p < 0.001$). Sex was a predictor of S_I [sex: F-ratio 6.60 ($p = 0.011$); BMI: F-ratio = 9.28 ($p = 0.003$); $R^2 = 0.09$; ANOVA, BMI as covariate]. S_I correlated with BMI in women ($r = -0.33$, $p < 0.001$) but not in men; BMI correlated with blood pressure in men ($r = 0.21$, $p < 0.05$) but not in women; and BMI correlated with both triglycerides ($r = 0.25$, $p < 0.01$) and HDL-cholesterol ($r = -0.18$, $p < 0.05$) in men but not in women.

Conclusions: This is the first demonstration that, compared to post-menopausal women, middle-aged men are insulin resistant. The sex-dependent expression of the metabolic syndrome may be important in the increased CHD risk in men. It also emphasises the need to take sex into account in studies of metabolic risk factors for cardiovascular disease.

P3514 Secondary prevention in women with acute coronary syndrome in France: results of the PREVENIR survey

O. Grenier[1], J.P. Cambou[2], J. Ferrieres[2], N. Danchin[3]. *[1]Cardiovascular hospital, Paris; [2]Unité INSERM 518, Toulouse; [3]Cardiovascular hospital, Vandoeuvre-les-Nancy, France*

The aim of the French nation-wide observational study (PREVENIR) was to detail the treatment prescribed at hospital discharge and 6 months later to patients with unstable angina (UA) or myocardial infarction (MI).

Methods. The survey was performed in 77 private and public cardiology centres. All patients admitted to hospital in January 1998 who survived an acute coronary syndrome were included: 1456 patients, MI: 819, UA: 637. Treatment at discharge was collected retrospectively. Data on the ongoing treatment were collected during an out-patient consultation or, by questioning the patient's GP.

Results. Data concerning 355 women alive at 6 month and not lost for follow-up was analysed. Baseline patients' characteristics are comparable with those reported in previous French epidemiological studies (MONICA, USIK, PRIMA). At discharge some treatments [fibrates: 7% (25), omega 3 fatty acid: 1.4% (5), aspirin: 88.2% (313), ACE-inhibitors: 45.4% (161), nicotine-patch: 0.6% (2)] were similar for either male or female patients, whereas the other treatments [statins: 30.4% vs. 39.6%, $p < 0.01$; beta-blockers: 66.2% vs. 73.1%, $p < 0.05$; cardiac rehabilitation: 17.4% vs. 27.2%, $p < 0.001$; oestrogen: 3.4% (12)] were less frequent in women. There were no significant changes in treatment at 6 months, except for statins (40% vs. 30.4%, $p < 0.001$). Six months after discharge, only 4.6% (5) of patients stopped statin therapy. If statin therapy was not initiated in hospital, family physicians initiated it for only 15.8% (39) of untreated patients.

Conclusion. Prescription of aspirin, and ACE-inhibitors after ACS has improved in women in France, while beta-blockers and cardiac rehabilitation are underused and measures against smoking are used sparingly. Whereas in secondary prevention clinical trial had proved a similar effect in men and women, prescription of statins was underutilized in female patients. An older age of women could be an explanation for this difference. Nevertheless, the lessons from recent clinical trials have not yet been completely applied to daily clinical practice.

P3515 Tolerance to oestrogen replacement therapy during long-term treatment: an explanation for lack of clinical benefit?

N. Dawson, A.P. Davie, L. Murray, K.P.J. O'Kane, J.J.V. McMurray. *Departments of Cardiology and Medicine and Therapeutics, University of Glasgow, UK*

Background: Oestrogen replacement therapy is thought to protect against vascular disease in post-menopausal (PM) women. This putative protective effect may result from oestrogen counteracting the actions of vasoconstrictor and mitogenic vascular peptides such as endothelin-(ET-1). In a double blind, randomised, placebo controlled trial, we have studied the effects of oestradiol (E2) on ET-1 induced vasoconstriction in PM women with coronary heart disease.

Methods: 19 women aged 51–77 (mean 66) years were studied on 3 occasions: pre-randomisation and 1 and 3 months after randomisation to E2 2 mg/d or placebo. On each occasion forearm blood flow (FBF) was measured using venous occlusion plethysmography before and during a brachial arterial infusion of ET-1 5 pmol/min for 60 minutes.

Results: % change from baseline in FBF during ET-1 infusion.

	Placebo	Estradiol	p value
Pre-randomisation	−19.4	−16.7	0.31
1 month	−8.6	−21.8	0.002
3 months	−25.9	−23.2	0.22

Conclusion: E2 attenuates the powerful vasoconstrictor action of ET-1 but this action of E2 does not persist over 3 months of therapy. Oestrogen replacement therapy may not have sustained vascular actions during long term treatment. This finding may help explain the disappointing results of a recent controlled trial of hormone replacement therapy in women with coronary heart disease.

P3516 Tamoxifen acutely relaxes rabbit coronary arteries by an endothelium-, nitric oxide, and oestrogen receptor-dependent mechanism

G. Figtree, C.M. Webb, P. Collins. *Cardiac Medicine, National Heart and Lung Institute, London, UK*

Tamoxifen (T) belongs to a group of structurally diverse compounds (SERMS – Selective Estrogen Receptor Modulators) which act as either an estrogen agonist or antagonist depending on the target tissue and hormonal milieu. The effects of T on coronary vascular reactivity have not been investigated. We therefore investigated the effect of T on rabbit coronary arteries in vitro. Epicardial coronary arterial rings of male and female rabbits were suspended in organ baths for measurement of changes in isometric tension. In alternate rings the endothelium was denuded. T (3, 10, 30 mM) induced significant relaxation of rings precontracted with K^+ (30 mM) in a dose-dependent manner (mean ± SEM; 47 ± 8***, 63 ± 8***, 81 ± 7***% respectively; *P < 0.05, **P < 0.01, ***P < 0.001; n = 16) compared to control (3.2 ± 1.5, 4.2 ± 1.5, 5.1 ± 1.5; n = 11). Relaxation to T at lower concentrations (0.3, 1 mM) was not significant. T-induced relaxation at 3, 10, 30 mM was significantly less in rings with no endothelium (29 ± 12, 47 ± 14***, 58 ± 12***%; n = 8), in rings with endothelium incubated in L-NAME (12 ± 4***, 41 ± 9*, 55 ± 9**%; n = 11), and in rings with endothelium incubated in ICI 182,780 (26 ± 4**, 47 ± 5, 61 ± 5*%; n = 9) compared to control. There were no differences between arteries from male or female rabbits. BaCl had no effect on T-induced relaxation. T (10 mM) did not affect the calcium concentration dependent contraction curve. We conclude that T induces significant endothelium-dependent relaxation of isolated rabbit coronary arteries via a NO- and estrogen receptor-dependent mechanism. This effect may contribute to the observed decrease in cardiovascular mortality in female breast cancer patients on Tamoxifen therapy.

P3517 Impact of pregnancy in pulmonary vascular disease: maternal and fetal outcomes

W.S. Avila, M. Grinberg, E.G. Rossi, A.A. Lopes, P.L. da Luz, J.F. Ramires. *Heart Institute HCFMUSP, São Paulo, Brazil*

Pulmonary vascular disease (PVD) and pregnancy are associated with great risk of maternal death. Our aim, was to evaluate the clinical course of pregnant women with PVD and identify possible prognosis factors.

Methods: We followed prospectively 34 pregnancies in 30 pts with PVD who decided carry on pregnancy despite advise of therapeutic abortion. Eighteen pts had Eisenmenger's syndrome (ES), eight with PVD associated to schistomiasis (PS) and four with primary pulmonary hypertension (PH). Their clinical characteristics are depicted below:

	Age (years)	Hb mg.dl^{-1}	Ht%	ST O_2%	PAPmmhg
ES (18 pts)	25.7 ± 5.6	16.5 ± 1.6	52.1 ± 5.1	81.5 ± 7.3	103.0 ± 19.8
PS (8 pts)	26.6 ± 4.5	13.9 ± 13	42.8 ± 2.4	89.1 ± 4.3	92.7 ± 16.4
PH (4 pts)	26.2 ± 4.0	13.1 ± 1.5	41.7 ± 2.2	89.8 ± 4.1	94.8 ± 14.5

Hb – haemoglobin; Ht – haematocrit; ST O_2 – arterial oxygen saturation PAP-degree of pulmonary hypertension (PAP) assessed by echoDoppler.

Prenatal care included bed rest, oxigen therapy and subcutaneous heparin from second trimester of gestation. Drugs therapy were maintained, as indicated.

Results: Only 8 (23.5%) pregnancies had an uneventful course. The events were:heart failure (8 pts; 23.5%), hypoxemia (9 pts; 26.5%), syncope (1 pt; 2.9%), hemoptysis (2 pts; 5.9%), severe arterial hipotension (1 pt, 2.9%), genital haemorragia (3 pts, 8.8%) and genital infection (3 pts; 8.8%). There were 10 (33.3%) maternal deaths due to: sudden death (3 pts), heart failure and/or hipoxemic (6 pts), haemorragia (2 pts) and thromboembolism (3 pts). There were 21 (61.7%) newborns alive, 4 of them died before hospital discharge, 10 spontaneous abortions and 3 stillbirth. ES group was different ($p < 0.01$) from PH and PS groups (combined) in relation to Ht, Hb and St O_2, but not in relation to maternal morbidity or mortality. Regression logistic analyses showed that death probability was not associate to Ht, Hb, or PP degree, in either groups.

Conclusions - PVD is associated to ominous maternal and fetal prognosis, independent of its cause. Predictors of prognosis are still uncertain. Hence, absolute contraindication to pregnancy must be sustained in women with PVD.

P3518 Initial results and long-term clinical and angiographic implications of coronary stenting in women

F. Alfonso, M.J. Pérez-Vizcayno, L. Azcona, R. Hernández, A. Fernández-Ortíz, J. Goicolea, J. Escaned, C. Bañuelos, C. Macaya. *San Carlos University Hospital, Madrid, Spain*

Background: Coronary stenting (ST) is increasingly used during coronary interventions. The influence of gender on balloon angioplasty results has been extensively studied. However, results of coronary ST in women are not well established.

Methods: The initial results and long-term clinical and angiographic follow-up of 158 consecutive women undergoing ST implantation were prospectively compared with those of 823 consecutive men.

Results: Women were older (66 ± 10 vs 59 ± 11 years), and had more hypertension (65% vs 42%) and diabetes (34% vs 16%) than men (both $p < 0.001$). Clinical presentation and number of diseased vessels was similar in both groups. Procedural success angiographic success without complications) was lower (90% vs 95%, $p < 0.01$) and major complications (death, myocardial infarction or surgery) were more common (9% vs 4.3%, $p < 0.05$) in women. Although hospital mortality was higher for women (RR 3, 95% CI 1.2–7.4) this difference disappeared after adjustment for adverse baseline characteristics. However, on multivariate analysis, female gender was selected as an independent predictor of procedural failure or major complications (RR 2.4, 95%CI 1.2–4.8). Clinical follow-up (mean 19 ± 19 months) was obtained in 96% of patients with procedural success. On actuarial analysis event-free survival (death, myocardial infarction or repeat revascularization) at 2 years was similar in both groups (70% men, 69% women, Log Rank p = 0.8). In addition, on systematic late angiography, restenosis rate (evaluated by QCA in 878 lesions, 93% of those eligible) was similar (29% vs 31%, NS) in both groups.

Conclusions: 1) Coronary ST in women is associated with poorer initial results. 2) Women with procedural success have a long-term outcome similar to men 3) Restenosis after ST is not influenced by gender.

P3519 Effect of postmenopausal hormone replacement on atherosclerosis in carotid and femoral arteries : the PHOREA trial

P. Angerer, S. Störk, W. Kothny, P. Schmitt, C. von Schacky. *Kardiologie, Medizinische Klinik, Klinikum Innenst., Munich, Germany*

Many observational studies have found lower cardiovascular morbidity and mortality in women that take estrogens and progestins (hormone replacement therapy, HRT) after menopause. This is commonly attributed to an antiatherogenic potential of HRT. PHOREA is the first large randomized, observer-blind trial that evaluates the effect of HRT on progression of atherosclerosis.

Methods: 321 clinically healthy postmenopausal women with pathological intima-media thickness (IMT) in at least one part of the carotid arteries were randomized to 3 treatment groups: (1) 1 mg 17-beta estradiol daily plus 0.025 mg gestodene on 12 days of every 28 day cycle, (2) gestodene on every third cycle, or (3) no hormone replacement. Using identical ultrasound technique, before and after 48 weeks of treatment images of the maximum IMT in the following arterial segments were recorded: common, internal, and bifurcation of a.carotis, common and superficial a. femoralis. Ultrasound operators and readers were blinded with respect to treatment. History, signs and symptoms, medication, and laboratory values were obtained before and after treatment. The study strictly adhered to the GCP guidelines.

Results: Randomization was successful with regard to all major influencing factors on progression of carotid atherosclerosis (e.g. age, smoking, HDL- and LDL-cholesterol, use of statins etc.). FSH as a marker of medication adherence, and LDL decreased in both HRT groups, but increased with no HRT. There was no difference in progression of IMT of carotid and femoral arteries between the 3 groups, neither in intention-to-treat (n = 264, table) nor valid case (n = 214) analysis.

Table. Change (absolute values) after 48 weeks of treatment, intention-to-treat:

	(1) e+g (m)	(2) e+g (3rd m)	(3) no HRT
FSH (mU/ml)	−19.9 ± 28.9****	−14.1 ± 27.6****	+10.6 ± 27.7
LDL (mmol/l)	−0.15 ± 0.92*	−0.24 ± 0.91**	+0.14 ± 0.67
A. carotis:			
Mean IMT (mm)	+0.03 ± 0.05	+0.03 ± 0.05	+0.02 ± 0.05
Max. IMT (mm)	+0.04 ± 0.13	+0.04 ± 0.12	+0.04 ± 0.13
A. femoralis:			
Mean IMT (mm)	+0.02 ± 0.05	+0.02 ± 0.05	+0.03 ± 0.05
Max. IMT (mm)	+0.04 ± 0.14	+0.04 ± 0.11	+0.05 ± 0.12

*p < 0.05, ** p < 0.01, ****p < 0.0001 compared to no HRT

Conclusion: This sample of postmenopausal women with early signs of atherosclerosis (increased IMT) at baseline, had a slightly accelerated progression of carotid and femoral IMT after 48 weeks, compared to published data. HRT moderately lowered LDL cholesterol, but had no substantial effect on atherosclerosis in these arteries.

P3520 Breast arterial calcification as cardiovascular risk indicator in women undergoing routine mammography for breast cancer screening

I.T.J. Hendriks, B.J.L. Kanters, J.A.A. van Dijck, A.L.M. Verbeek, C. Boetes[1], F.W.A. Verheugt[2]. *Epidemiology (152), University Hospital Nijmegen, Nijmegen; [1]Radiology Dept, University Hospital Nijmegen, Nijmegen; [2]Heartcenter, University Hospital Nijmegen, Nijmegen, Netherlands*

Background: Breast Arterial Calcification (BAC) is commonly seen on screening mammograms, and its frequency increases with age, especially after menopause. Recent studies show a relation between arterial calcifications in the breast and cardiovascular disease (CVD). Whether BAC can be detected in middle-aged apparently healthy women undergoing periodical routine mammography for breast cancer screening, is unknown. This pilot study was performed to determine whether BAC, seen on screening mammograms, may detect silent CVD in women age 50–69 years.

Methods: The setting of this study was the population based breast cancer screening programme of Nijmegen and Barneveld (NL) at the beginning of 1998. In 1500 middle-aged women undergoing routine mammography, analysis for BAC was performed. Questionnaires asking for manifested CVD and CVD risk factors were handed out to the participants at the screening centre.

Results: Questionnaires were returned by 953 women (response: 63.5%). BAC was present in 131 women (13.7%). Documented CVD was significantly more present in women with BAC than in those without BAC (Odds Ratio: 1.61; 95% CI: 1.06–2.45). BAC and CVD risk factors was present in 21 women (2.2%) without documented CVD.

Conclusions: Calcifications in breast arteries seen at routine mammography may detect silent CVD in 1 out of 40 women. The widespread use of routine mammography may contribute to the prevention of CVD manifestations in women. Large prospective studies in this field are warranted.

P3521 Baseline C-reactive protein is higher in women than in men with chronic stable angina

X. Garcia-Moll, E. Zouridakis, D. Cole, J.C. Kaski. *Cardiological Sciences Dept, St George's Hospital Medical School, London, UK*

Background: Increased C-reactive protein (CRP) has prognostic significance in apparently healthy individuals and men with coronary artery disease (CAD). Little information is available regarding whether there are CRP differences between women and men with CAD. We compared CRP concentration in men and women with chronic stable angina.

Material and methods: We prospectively studied 821 consecutive patients (236 women) with typical exertional chest pain. Patients underwent clinical, biochemical and angiographic characterization at study entry. Serum CRP was measured with a highly sensitive assay. Follow-up ranged from 1.0 to 3.7 years. Study end points were: development of unstable angina, myocardial infarction, stroke, and cardiac death. Adjusted CRP values were obtained by multiple regression.

Results: Baseline CRP was significantly higher in women than men (3.0 mg/L [1.3–5.8] vs 2.1 mg/L [1.0–4.2], P = 0.006), even after adjustment for other risk factors. Patients with events had significantly higher CRP levels than patients without events (P = 0.035). Women had fewer cardiac events than men (P = 0.039). After adjustment for confounding variables, CRP in women still was a 16% (CI95% of the difference: 6%-25%; p = 0.002) higher than in men.

Conclusions: CRP levels are higher in women than men despite similar clinical and angiographic characteristics and after adjustment for other variables. Despite higher CRP concentration, women had fewer events than men. These findings may have important pathophysiological and clinical implications.

P3522 Is preeclampsia a risk factor for coronary artery disease in women?

R. Kaaja, H. Laivuori, O. Ylikorkala. *Obstetrics and Gynecology Dept, Helsinki University Hospital, Helsinki, Finland*

Coronary artery disease (CAD) and preeclampsia could share two risk factors known to induce endothelial dysfunction namely insulin resistance and hyperhomocysteinemia.We have earlier demonstrated that a history of preeclampsia 17 years earlier is assoaciated with elevated levels of insulin and testoterone which may contribute to the increased risk of vascular morbidity in such women.

We measured insulin sensitivity (IS) with intravenous glucose tolerance test (Minimal Model technique) in 22 pre-eclamptic patients and 16 normotensive women between 29–39 weeks of gestation and three months after delivery. During the the iv-glucose tolerance test we took blood samples for plasma homocysteine, vitamine B12 and folic acid measurements.

In pre-eclamptic women IS was 37% lower (P = 0.009) than in control women. After delivery IS increased 4- to 5- fold but IS was still 26% lower in pre-eclamptic women (P = 0.04) than in control women. During pregnancy fasting homocysteine levels were significantly elevated in pre-eclamptic women compared to control women (P = 0.0001) and were related to severity of the disease measured by the level of proteinuria. Vitamin B12 concentrations were lower in preeclamptic women, whereas levels of folic acid showed no difference between the groups. IS was in significant negative relation to plasma homocysteine levels in pre-eclamptic women (r = −0.51, P = 0.02), but not in control women. The mean 3-fold increase in glucose and 50-fold increase in insulin levels during iv-glucose tolerance test failed to affect homocysteine levels. After delivery, levels of homocysteine and vitamin B12 increased almost two-fold, but no difference was observed between the goups.

Hyperhomocysteinemia and increased insulin resistance could both induce/worsen endothelial dysfunction during preeclamptic pregnancy. Pregnancy, as an insulin resistant state, could reveal by development of preeclampsia the tendency towards insulin resistant syndromes and CAD. We suggest, that history of preeclampsia should be added to the list of risk factors in women's CAD.

P3523 Evaluation of gender differences in diagnosis and treatment of coronary artery disease from 1981 through 1997: no evidence for a Yentl syndrome

J.E. Roeters van Lennep[1], A.H. Zwinderman[2], H.W.O. Roeters van Lennep[3], H.E. Westerveld[4], A.V.G. Bruschke[1], E.E. van der Wall[1]. *[1]Departments of Cardiology; [2]Medical Statistics, Leiden University Medical Center, Leiden; [3]Department of Cardiology, Oosterschelde Hospital, Goes; [4]Department of Internal Medicine, University Hospital, Utrecht, Netherlands*

Several studies have documented a gender bias in diagnostic procedures and in treatment of coronary artery disease (CAD). This presumed discrimination of women is known as the Yentl syndrome.

Methods: Over a 16-year period (1981 through 1997), we evaluated 1894 consecutive patients (1526 men, 368 women) with angiographically documented CAD (luminal stenosis > 60%). Extent and localisation of the coronary angiographic data and subsequent management (PTCA/CABG) were analysed. The study was divided into the early PTCA years (1981 through 1989) and current PTCA years (1990 through 1997).

Results: No differences in extent and localisation of coronary artery lesions between men and women were found [*extent:* one-vessel disease 42% and 40%, two-vessel disease 27% and 27%, three-vessel disease 26% and 24%, left main 5% and 8%, resp. (pNS); *localisation:* LAD 36% and 39%, RCA 34% and 32%, LCX 27% and 26%, resp. (pNS)]. Over time there was a significant shift from multi-vessel to single vessel disease in both men and women (p < 0.001). As to subsequent management a significant gender difference in favour of women was observed (p = 0.021), which held for both the first and the second PTCA period. Referral to PTCA (n = 353) and CABG (n = 616) in relation to the extent of disease did not show any gender bias in favour of women.

Conclusions: Based on the angiographic findings no gender differences in extent and localisation of CAD was observed. Furthermore, no substantial evidence could be found for under-referral of women to subsequent management. Therefore our study questions the presence of a Yentl syndrome in the current era especially within Europe.

P3524 Relationship between leptin serum levels and common carotid artery intima-media complex in pre-menopausal women

M. Ciccone, G. De Pergola[1], F. Cito, O. Rossi, D. di Noia, S. Scarcella[1], R. Vettor[2], R. Giorgino[1], P. Rizzon. *Inst. of Cardiology; [1]Inst. of Endocrinology, Bari Universlty; [2]Inst. of Medical Semeiotics, Padua, Italy*

Common carotid artery intima-media thickening (IMT) represents an early marker of atherosclerosis. Obese patients show an increase of intima-media complex as compared to a healthy people, but the cause of this thickening is unknown. The aim of the present study was to determine if intima-media thickening correlates with plasma levels of leptin i.e. a marker of adipose tissue accumulation.

Methods: The study was carried out in 70 women with age ranging between 18 and 45 years. Body Mass Index (BMI) was ≤25.0 in 22 women and >25.0 in 48. The following parameters were measured: IMT of the common carotid artery and fasting plasma levels of leptin, insulin, blood glucose, total cholesterol, LDL-cholesterol, HDL-cholesterol and triglycerids. All blood samples were taken during the follicular phase of the menstrual cycle. Blood concentration of leptin and insulin were measured by RIA. IMT was measured by high definition vascular echography.

Results: Leptin plasma concentrations showed a positive correlation with IMT (p < 0.005); BMI (p < 0.001), mean arterial blood pressure (MBP) (p < 0.001), insulinemia (p < 0.001), fasting glycaemia (p < 0.005), triglycerides (p < 0.005) and LDL-cholesterol (p < 0.05) and a negative correlation with HDL-cholesterol (p < 0.001). Stepwise multiple regression analysis confirmed the positive association between leptin (dependent variable) and IMT (p < 0.005), indipendent of age and MBP, insulinaemia, fasting glycaemia, lipids.

Conclusion: We can conclude that progressive adipose tissue accumulation produce high serum levels of leptin and a parallel increase of IMT, which may enhance the risk of developing atherosclerosis.

P3525 Influence of gender on the predictive accuracy of clinical practice guidelines regarding the likelihood of coronary artery disease

E. González-Torrecilla, E. Pérez-David, H. Bueno, J.A. García-Robles, R. Muñoz, J.L. Delcán. *Cardiology Department, Hospital General Universitario "Gregorio Marañón", Madrid, Spain*

Clinical evaluation of chest pain in women continues to be a diagnostic challenge. We prospectively investigate the accuracy of the Agency for Health Care Policy and Research (AHCPR) Clinical Practice Guidelines regarding the likelihood of coronary artery disease (CAD) in women.

Methods: 330 consecutive patients (P) (124 females, 206 males; 66 ± 11 yr) without prior CAD diagnostic testing were admitted because of possible unstable angina. Strict application of AHCPR Guidelines regarding the likelihood of CAD was performed in each P at admission. The P were then grouped as having high, intermediate or low likelihood of significant CAD. Confirmation of ischaemic heart disease was sought by doing coronary angiography (252 P), myocardial perfusion imaging (42 P) or stress-echo (36 P). We consider as erroneous evaluations the misclassifications observed in high and low levels of likelihood.

Results: The prevalences of positive and negative results indicating presence or absence of CAD were:

Likelihood of CAD	Males		Females	
	No CAD	CAD	No CAD	CAD
High	15	107	25	33
Intermediate	33	33	36	17
Low	15	3	12	1
Total	63	143	73	51

Thus, the rates of misclassifications in males and females were 8.7% (16/206) and 21% (26/124), respectively ($p < 0.0001$).

In conclusion, a rigid application of AHCPR criteria results in a rate of misclassifications that is much higher in females. The latter is mainly due to inaccuracy of high likelihood criteria and emphasizes the need for refinement and modification of these guidelines for women.

P3526 Heart failure in women: clinical, epidemiological and prognostic differences in relation with men. Substudy of national survey of heart failure in Argentina (CONAREC VI Study)

D. Tacchi, C.V. Mayans, J.P. Címbaro Canela, G.A. Amarilla, R. Carballido[1], E.R. Perna, E. Farías, M. Alac[2], R. Paz Martín[3], J. Badaracco. *Coronary Intensive Care Unit, Instituto de Cardiología J. F. Cabral, Corrientes[1] Sanatorio Mitre, Buenos Aires[2] Hospital Italiano, Buenos Aires[3] Hospital Córdoba, Córdoba, Argentina*

Objectives: To compare the clinical and epidemiological findings in women (W) and men (M) with chronic heart failure (CFH), as well as prognostic during the hospitalization period.

Methods: Between December 1996 and October 1997, 857 patients (ptes) were included in the National Survey of Heart Failure in Argentina (CONAREC VI Study). They were admitted in 31 centers with a diagnosis of CHF (>30-day evolution) according to Framingham modified criteria. Three hundred and fifty-two of them (41%) were females.

Results: Mean age for female was 67.8 ± 15 years and 64 ± 14 for males ($p = 0.0004$). Regular workers was found less frequently in W than M (13 vs. 29% $p = 0.001$). Risk factors prevalence was different between W and M in the followings: smokers (21 and 48% $p = 0.001$); alcoholism (5 and 18% $p = 0.001$); previous infarct (18 and 28% $p = 0.001$); intermittent claudication (4.8 and 8.7% $p = 0.03$) and COPD (9 and 20% $p = 0.001$). Evolution time of CHF was shorter for W than for M (36 vs. 45 months $p = 0.04$). NYHA class previous was similar for both sexes, but it proved to be higher for W at admission (3.7 and 3.6 $p = 0.01$). During physical examination S3 sound was found in a lower proportion among female patients (22 vs. 31% $p = 0.002$), as well as hepatomegaly (38 vs. 50% $p = 0.001$). ECG registry disclosed a higher rate of atrial fibrillation among women (32 vs. 24% $p = 0.001$). Chest x-ray scan yielded a lower cardiomegaly rate among female (73 vs. 79% $p = 0.02$). Bidimensional echocardiography (2D-Echo) showed that end diastole diameter was smaller for the W group (58 vs. 63 mm $p > 0.001$) as well as atrial size (46.6 vs. 48.7 mm $p = 0.002$) with a higher shortening fraction (27.7 vs. 24.3% $p = 0.001$). Ischemic heart disease was diagnosed less frequently among W (24 vs. 38%) and was observed a higher prevalence for hypertensive heart disease (30 vs. 22% $p = 0.01$) and valve disease (24 vs. 18% $p = 0.05$).

No differences were observed between female and male in incidence of complication (pulmonary or systemic embolism, ventricular or atrial arrhytmias, infections, refractory heart failure, stroke) (15.6 and 17.2%) as well as mortality rate during hospitalization (5.6 and 4.3%).

Conclusion: Women who are admitted because descompensated CHF showed to be older and with shorter time of evolution than men. Physical findings, ECG abnormalities, chest x-ray and 2D-Echo all suggest that diastolic dysfunction is more frequent in W than M, showing a higher prevalence for hypertensive or valvular etiology than for ischemic heart disease. However, in hospital course and death rate were similar for both groups.

SMOKING AND HYPERTENSION

P3527 Smoking affects lipid and thrombogenic factors in postinfarction patients

S.D. Fisher, W. Zareba, A.J. Moss, V.J. Marder[1], C.E. Sparks[2]. *Cardiology, University of Rochester, Rochester; [1] Vascular Medicine, University of Rochester, Rochester, NY; [2] Pathology, University of Rochester, Rochester, NY, USA*

The aim of this study was to determine the effect of current and past smoking on the thrombo-metabolic environment, described by a complex of lipid and thrombotic parameters, in a large population of 1045 post-MI patients.

Methods: In the prospective Thrombogenic Factors and Recurrent Coronary Events (THROMBO) study, blood samples were drawn two months after an index MI to determine levels of the following parameters: fibrinogen, von Willebrand factor, factor VII and VIIa, plasminogen activator inhibitor, D-dimer, cholesterol, apolipoprotein A-1, apolipoprotein B, lipoprotein (a), triglycerides, and HDL cholesterol. Smokers were asked to refrain from smoking for 24 hours prior to blood drawing. The effect of current and past smoking on the above factors was evaluated in univariate and multivariate analyses.

Results: There were 247 current, 443 past, and 349 never smokers. Mean (sd) levels of lipid factors significantly different among three groups were respectively:

ApoB: 129 (31), 121 (26), 121 (28), $p = 0.001$;

Cholesterol: 208 (46), 193 (41), 196 (45), $p = 0.001$;

Triglyceride: 217 (107), 201 (116), 190 (107), $p = 0.019$.

Smoking within 24 hours of blood draw (64 non-compliant patients) resulted in further elevations of ApoB, cholesterol, and fibrinogen compared to smokers who refrained.

Factors in Current and Past Smokers

	Current vs. Never			Current vs. Past		
	OR	95% CI	p value	OR	95% CI	p value
ApoB	2.29	1.51–3.46	0.001	1.64	1.13–2.36	0.009
Cholesterol	2.00	1.33–3.00	0.001	1.76	1.22–2.54	0.002
Triglyceride	1.38	0.92–2.08	0.122	1.41	0.98–2.03	0.068
Fibrinogen	2.20	1.32–3.11	0.001	1.23	0.84–1.79	0.291
FVIIa	1.57	1.04–2.37	0.032	1.33	0.91–1.94	0.147

OR: odds ratios represent the risk of having a blood level in the upper fourth quartile after adjustment for significant covariates ($p < 0.05$): gender, age, race, diabetes, and beta blockers. Fibrinogen and VIIa were not different in univariate comparisons, but were higher in current compared to never smokers after adjustment.

Conclusions: Smoking promotes atherosclerosis via profound lipid altering effects. Smoking cessation favorably modifies the lipid profile but fibrinogen remains elevated. Prothrombotic and atherogenic changes occur immediately after smoking.

P3528 Quitting smoking immediately improves in vivo oxidation injury

H. Sinzinger, A. Oguogho, Susan Meghdadi, H. Kritz, P. Schmid. *Wilhelm Auerswald Atherosclerosis Research Group (ASF) Vienna, Austria*

Isoprostanes (IP) have been identified as reliable in-vivo oxidation injury markers. Cigarette smoking, a major cardiovascular risk factor, together with elevated blood lipids has been shown to be associated with increased 8-epi-prostaglandin (PG)$F_{2\alpha}$ in plasma, serum, urine and vascular tissue. We studied healthy adults (n = 8; 5 m, 3 f; 26–47 a) as well as patients suffering from familial hypercholesterolemia (FH) with various risk factors (n = 27; 15 m, 12 f; 29–50 a) having been smoking at least a pack of cigarettes a day since more than 5 years. Plasma, serum and urinary 8-epi-$PGF_{2\alpha}$ was determined after extraction and purification using a specific immunoassay daily to weekly after quitting cigarette smoking up to 4 weeks. After a few days only, 8-epi-$PGF_{2\alpha}$ significantly drops, reaching a steady state after about 4 weeks (urine: prevalue: 504 ± 71 pg/mg creatinine; 1 week 376 ± 61; 2 weeks 337 ± 59; plasma: prevalue: 56 ± 11 pg/ml; 1 week: 37 ± 9; 2 weeks 33 ± 7). While patients without additional risk factors approach controls (urine: 299 ± 56 vs. 237 ± 37; plasma 24 ± 6 vs. 17 ± 5), values in FH remain higher (urine 357 ± 71; plasma 29 ± 6). Comparable trends are found for the serum values.

These findings indicate a significant in-vivo oxidation injury in cigarette smoking ± FH. Ex-smokers quite fastly are recovering from their enhanced in-vivo oxidation.

P3529 Smoking induces microalbuminuria in essential hypertension

W.F. Terpstra[1,2], J.F. May[1,2], A.J. Smit[1,2], P.A. de Graeff[1,2], H.J.G.M. Crijns[1]. *[1]University Hospital Groningen; [2]Groningen Hypertension Service, Groningen, Netherlands*

Microalbuminuria is thought to reflect endothelial dysfunction in patients with essential hypertension. This study was performed to determine the relationship between traditional cardiovascular risk factors and the occurrence of microalbuminuria in elderly, previously untreated hypertensives.

Methods: From a population survey a group of 178 previously untreated hypertensive patients (4× systolic blood pressure ≥ 160 and ≤220 mmHg and/or diastolic blood pressure ≥ 95 and ≤115 mmHg), mean age 67 (± 4) years, were screened for microalbuminuria. Patients were considered to have microalbuminuria (MA+) when microalbuminuria was between 20 and 300 mg/24 hour. Traditional cardiovascular risk factors were identified by history and bloodsampling.

Results: See table.

Mean (SD)	N	Age (years)	SBP/DBP (mmHg)	% Male	Chol (mmol/l)	DM II	BMI	% Smoke
MA–	162	67 (4)	177 (14)/94 (8)	51	6.0 (0.9)	4	28 (4)	20
MA+	16	66 (5)	183 (14)/97 (7)	69	6.0 (1.1)	2	28 (3)	80*

* = P < 0.001 Chi square; S (D) BP = Systolic (Diastolic) Blood Pressure; Chol = Total cholesterol; DM II = Diabetes Mellitus II; BMI = Body Mass Index.

Logistic regression analysis, including traditional risk factors, duration of hypertension and diabetes, identified smoking as independent variable for the presence of microalbuminuria.

Conclusion: Smoking is a major contributing risk factor for the presence of microalbuminuria in elderly mild to moderate hypertensives. Whether hypertensives with microalbuminuria benefit most of an ACE inhibitor besides cessation of smoking remains to be investigated.

P3530 Hyperhomocysteinaemia is a novel risk factor for hypertension

J. Chambers, O.A. Obeid, A. Thomson, J.S. Kooner. *National Heart and Lung Institute, Imperial College School of Medicine, Hammersmith Hospital, London, UK*

Experimental studies show that hyperhomocysteinaemia causes arterial stiffness, due to degradation of elastin and hypertrophy of smooth muscle cells, and suggest that homocysteine may promote atherosclerosis through elevated blood pressure. We have assessed the relationship between homocysteine concentrations and blood pressure in 299 men with hypertension (mean age 51 ± 6 yrs, SBP > 160, DBP > 90 mmHg), without coronary heart disease (CHD), and in 715 age/sex-matched normotensive controls.

Homocysteine concentrations were measured in the fasting state and after an oral L-methionine load (100 mg/kg). Subjects were characterised for other CHD risk factors.

Homocysteine levels were higher in hypertensive patients compared to controls (fasting 12.0 ± 0.3 vs 10.7 ± 0.1 p = 0.001; post-load 36.6 ± 0.7 vs 34.3 ± 0.4 μmol/l, p = 0.001). Hypertensive patients had higher body mass index (BMI, 28.4 ± 0.2 vs 26.1 ± 0.1, p = 0.001), waist-hip girth ratio (0.98 ± 0.1 vs 0.94 ± 0.1, p = 0.001), fasting glucose (6.1 ± 0.1 vs 5.4 ± 0.1, p = 0.001), fasting triglycerides (2.1 ± 0.1 vs 1.6 ± 0.1, p = 0.001), and lower HDL cholesterol (1.24 ± 0.02 vs 1.29 ± 0.01, p = 0.001) compared to controls. Logistic regression analysis showed that the relationship between elevated homocysteine concentrations and hypertension was graded, and independent of BMI, waist-hip ratio, fasting glucose, triglycerides, and HDL cholesterol.

In summary, elevated homocysteine concentrations are associated with hypertension independently of other risk factors. Our results support the hypothesis that, in part, hyperhomocysteinaemia may promote atherosclerosis through elevated blood pressure levels.

P3531 Calcium antagonists and cardiovascular risk in patients with essential hypertension and non-insulin-dependent diabetes

P. Verdecchia, G. Schillaci[1], C. Borgioni, A. Ciucci, C. Porcellati. *Cardiology Dept., Silvestrini Hospital, Perugia; [1]Citta' della Pieve PG, Italy*

Objective: It is uncertain whether the use of calcium antagonists is associated with an increase in cardiovascular (CV) risk in hypertensive subjects with diabetes.

Methods: We conducted a prospective cohort study in 164 consecutive subjects with essential hypertension, non-insulin-dependent diabetes and no previous cardiovascular (CV) morbid events included in the PIUMA (Progetto Ipertensione Umbria Monitoraggio Ambulatoriale) registry. Subjects were studied before therapy and followed for up to 12 years (mean, 5). The use of calcium antagonists that preceded the event was considered for classification. At entry, the patients who were subsequently given calcium antagonists had a higher clinic (174/98 vs 161/92 mmHg, both p < 0.01) and 24-hour ambulatory blood pressure (150/90 vs 141/84 mmHg, both p < 0.01) than those who were not. During follow-up there were 53 major CV morbid events (6.46 per 100 person-years).

Results: The rate of total CV events (5.6 vs 6.8 events per 100 person-years, relative risk 0.88 [95% confidence interval: 0.47–1.61]) and that of cardiac events (4.0 vs 3.3 events per 100 person-years, relative risk 1.33 [95% CI: 0.62–2.89]) did not differ between users of calcium antagonists (n = 50) and non users. The use of angiotensin converting enzyme inhibitors (n = 66) was unrelated to the risk of CV events (relative risk 1.24, 95% CI: 0.71–2.16). The CV event rate was slightly lower (p = 0.040, log-rank test) among users of calcium antagonists or ACE-inhibitors, alone or combined (5.80 events per 100 person-years) than among the subjects receiving different classes of drugs, mostly diuretics and beta-blockers (10.0 events per 100 person-years). In a Cox multivariate analysis, only age (p = 0.002) and 24-hour pulse pressure (p = 0.04) were independent predictors of CV morbid events.

Conclusions: These findings do not support an association between use of calcium antagonists and increased CV morbidity in subjects with essential hypertension and type II diabetes.

P3532 Validation of three devices for home blood pressure monitoring by comparison with mercury sphygmomanometer and intraarterial pressure measurement

A. Linhart, K. Sedlacek, F. Holm, J. Humhal, T. Janota, M. Aschermann. *IInd Dept. of Internal Medicine, 1st Medical Faculty, Prague 2, Czech Republic*

Oscillometric devices for home blood pressure self-measurement are widely used among patients and clinicians. The aim of our study was to assess precision of these instruments and to compare the results with the standard auscultatory method and with blood pressure (BP) measured invasively.

Patients and Methods: Fifty-one patients (11 women and 40 men, age range 32 to 74 years) undergoing cardiac catheterization for coronary artery disease were included in the study. BP was measured using a fluid filled intraarterial catheter system with the catheter tip placed in the thoracic aorta. Simultaneousy, BP was measured with a calibrated mercury sphygmomanometer and three different types of monitors for home blood pressure self-measurement connected to a single cuff according to recommendations of the protocol of the British Hypertension Society (BHS). Three types of monitors were tested: Omron 711, Omron M4 and Omron HEM-705CP, using two devices of each type in all subjects studied.

Results: Similar correlations were observed between auscultatory and oscillometric measurements and intraarterial BP levels with correlation coefficients ranging between 0.95 and 0.96 for systolic BP (p < 0.001) and between 0.84 and 0.90 for diastolic BP (p < 0.001). Correlations were comparable in all devices tested. The difference between the oscillometric and intraarterial systolic blood pressure ranged from 1.1 ± 9.4 mmHg in Omron 711 to 2.9 ± 9.7 mmHg in Omron M4. Diastolic BP was overestimated by 6.5 ± 6.5 mmHg in Omron 705-CP to 8.3 ± 6.8 mmHg by Omron 711. Differences between the devices did not achieve statistical significance and overestimation of diastolic BP by auscultatory measurement was comparable to the oscillometric method. Comparing auscultatory and oscillometric results using BHS criteria, Omron 711 and M4 were graded A and Omron HEM-705CP was graded B for both systolic and diastolic BP.

Conclusions: BP assessed by the oscillometric method is highly correlated with intraarterial measurements. Systolic BP measured by the two methods is almost identical. In contrast, the oscillometric method tends to overestimate diastolic BP by 6 to 8 mmHg. However, this overestimation is similar to that observed by using the auscultatory method and probably is due to different site of blood pressure measurements (aorta vs. brachial artery). Compared to the auscultatory method, all the tested devices fulfilled requirements of BHS protocol and can be recommended for clinical use.

P3533 Altered circadian rhythm of heart rate variability in normotensive subjects with a family history of hypertension

M.V. Pitzalis, F. Massari[1], R. Romito, M. Iacoviello, E. De Tommasi, C. Forleo, C. Balducci, P. Guida, F. Mastropasqua[1], P. Rizzon. *Institute of Cardiology, University of Bari, Bari; [1]Cardiology Dept., S. Maugeri Foundation, Cassano M, Italy*

Objective: To test whether normotensive subjects with hypertensive parents (H+) have an altered autonomic nervous system activity as compared to normotensive subjects with normotensive parents (H−).

Design and methods: Family history of hypertension was defined when at least one of the parents showed essential hypertension which appeared before the age of 55 years; secondary hypertension was excluded. Thirtyeight H+ (mean age 26+5 years) subjects and 33 sex and age matched H− subjects underwent a 24-h ECG monitoring in order to evaluate the following heart rate variability parameters over the 24 hour, daytime (10.00–16.00, D) and nighttime (00.00–06.00, N) hours: mean RR, SDRR, rMSSD.

Results: All D parameters were similar in the 2 groups, while those evaluated over the 24-h and N were significantly lower in H+ (table).

	H−	H+	p
RR-24 (ms)	834 ± 86	773 ± 90	0.005
SDRR-24 (ms)	180 ± 33	154 ± 40	0.004
RMSSD-24 (ms)	51 ± 14	44 ± 16	0.07
RR-N (ms)	1014 ± 113	911 ± 153	0.005
SDRR-N (ms)	142 ± 41	119 ± 37	0.015
RMSSD-N (ms)	67 ± 23	55 ± 25	0.043

Conclusions: H+ have a different circadian rhythm of HRV parameters from H− which seems to be due to a reduction of cardiac vagal activity during the night.

P3534 Major differences in casual blood pressure in two epidemiologic studies due to minor differences in methodology

S. Rasmussen, T. Drivsholm, H. Ibsen[1]. *Centre of Preventive Medicine, Glostrup County Hospital, Glostrup; [1]Department of Medicine, Glostrup County Hospital, Glostrup, Denmark*

Purpose: Standardisation of minor differences in the methodology of blood pressure measurements between epidemiological studies is hard to overcome. The effect of blood sampling before, respectively after the measurement of casual blood pressure was examined.

Methods: The material comprised of two age-cohorts of 60–62 years old individuals from the same epidemiological center: the first examined in 1993–94 (born 1932, n = 593); the second in 1996–97 (born 1936, n = 695). The two cohorts were chosen on the same criteria and had similar rates of participation. In both studies blood pressure was measured with 2 methods: 1) casual BP by a standard mercury sphygmomanometer with the subject in the sitting position after 5 min. of rest (average of 2 readings); 2) 24-h ABP with the TAKEDA TM-2421 device (both auscultatory and oscillometric readings; only the oscillometric results are presented). The same apparatuses were used in the 2 studies; calibration was performed regularly. One very experienced observer performed all measurements of casual blood pressure at the same time of the day (07:30–11:30 a.m.). Fasting blood samples were taken before the measurements of casual blood pressure in the 1932-cohort, respectively after the measurements of casual blood pressure in the 1936-cohort.

Results: see table.

Results

Cohort	Women		Men	
	1932 (n = 291)	1936 (n = 370)	1932 (n = 302)	1936 (n = 325)
1. Casual BP	133.0/82.3	137.7*/87.8*	136.6/84.3	137.0/90.8*
2. 24-h ABP	126.9/72.5	126.2/71.9	130.7/78.0	129.6/78.2

Results given as systolic/diastolic BP in mmHg. *P < 0.01 for differences between comparable measurements in the two cohorts.

Differences of 5.5–6.5 mmHg and of 0.4–4.7 mmHg were found for the measurements of casual diastolic, respectively systolic blood pressure in the two studies; standard deviations were alike.

Conclusions: The significant differences in casual blood pressure in the two studies could only be explained by differences in the methodology, i.e. the taking of blood samples before, respectively after the measurement of blood pressure. No significant differences were found between ambulatory readings.

Results of casual blood pressure between epidemiological studies should be compared with caution, even when only minor differences in the methodology exist.

P3535 Lack of an association between dopamine D3 receptor gene polymorphism (SER-9-GLY) and essential hypertension

J. Erdmann, H. Kallisch[1], K. Hilgers[2], R. Schmieder[2], E. Fleck[1], V. Regitz-Zagrosek[1]. *Internal Medicine/Cardiology, Berlin; [1]Internal Medicine/Cardiology, Charite, Virchow-Clinic, HU and DHZB, Berlin; [2]Department of Medicine/Nephrology, University of Erlangen/Nuremberg, Nuremberg, Germany*

Recent studies suggest a potential role of the dopamine D3 receptor in the development of hypertension, because disruption of D3 receptor gene in mice causes hypertension. The human dopamine D3 receptor gene contains a polymorphism resulting in a serine to glycine substitution in the extracellular N-terminus of the receptor protein altering dopamine binding.

In order to determine the possible role of the D3 receptor gene in susceptibility to essential hypertension, we determined the frequency of this intragenic polymorphism in a sample of 123 hypertensive patients and 136 normotensive controls. Hypertensive subjects were defined of the individual's blood pressure before starting medications (153 ± 14/89 ± 12 mmHg) and absence of secondary forms of hypertension determined through extensive clinical workup. Control subjects were normotensive anonymous blood donors (123 ± 13/80 ± 6 mmHg) with no anti-hypertensive medications. In a subgroup, with normal or mildly elevated blood pressure (but never treated.for that), we assessed 24-h ambulatory blood pressure (Spacelab 90207), plasma AII and aldosterone concentrations (RIA), 24-h urinary sodium excretion, and LV structure (2D guided M-mode echo).

No significant differences in allele (0.72/0.28 vs. 0.67/0.33) or genotype frequencies (0.54/0.37/0.09 vs. 0.46/0.41/0.13) between a group of hypertensive patients and normotensive controls were found (p = 0.18 and p = 0.5, respectively). A subgroup analysis revealed no significant association between either angiotensin II, aldosterone, and sodium secretion.

Thus, this polymorphism has no major effect on the susceptibility to essential hypertension in our sample of hypertensive patients and is not associated with either angiotensinII, aldosterone, and sodium secretion.

CARDIOVASCULAR DISEASE IN OLDER PERSONS

P3536 Heart failure in the elderly in hospital cardiology units: data from the Italian network on congestive heart failure

G. Pulignano, D. Del Sindaco, A.P. Maggioni, D. Lucci, G. Minardi, M. Gorini, F. Leggio, E. Giovannini, M. Scherillo. *On behalf of IN-CHF Investigators, ANMCO Research Center, Florence, Italy*

Background: Congestive heart failure (CHF) represents a major public health problem with an age-related increasing prevalence. Despite the high incidence of mortality and morbidity in elderly CHF pts, limited epidemiological data are available for development of appropriate prevention and treatment modalities.

Methods: 3327 outpatients consecutively enrolled in the registry of the Italian Network on CHF by 133 cardiological centers were studied. Data were collected using an ad-hoc software. Univariate and multivariate analysis were performed to compare pts <70 and ≥70 yrs-old and to evaluate associations between clinical variables and 1-year mortality.

Results: The 1033 (31%) elderly pts (64.7% M) did not differ from 2294 younger pts with respect to CT ratio, renal dysfunction and history of ventricular tachycardia but were significantly more likely to be female, in NYHA III-IV, to have preserved left ventricular systolic function (EF>40%), an ischemic or valvular etiology and atrial fibrillation/flutter. At baseline visit, elderly pts significantly received ACE-inhibitors, oral anticoagulants and betablockers less frequently than younger ones. One year mortality was significantly higher in pts ≥70 years (22 vs 13.7% p < 0.001). Multivariate analysis, adjusted for main clinical-epidemiological variables showed that age, as a continous variable, is an independent predictor of mortality (RR 1.03; 95%CI 1.021–1.039), with 1-year mortality 3% increase by year of age. At least 1 hospital admission in the year preceding the entry visit (RR 2.11; 95%CI 1.54–2.9), systolic blood pressure (RR 0.98; 95% CI 0.97–0.99) and NYHA class III-IV (RR 1.6; 95%CI 1.22–2.1) were independent predictors of 1-year mortality in elderly pts.

Conclusions: The present study confirms that elderly patients with CHF: 1) have more severe clinical manifestations of CHF; 2) are less likely to receive ACE-inhibitors, betablockers and anticoagulants; 3) have more frequently preserved systolic function; 4) have a worse prognosis. Consequently, there is a need to develop more effective and targeted preventive and management strategies for this increasingly common health problem.

P3537 The impact of coronary stent implantation in reducing event rates and restenosis in elderly population

M. Kayikcioglu, A. Akilli, M. Akin, M. Zoghi, F. Özerkan, O. Yavuzgil, C. Gürgün, L. Can, C. Türkoglu. *Cardiology Dept., Ege University Medical School, Izmir, Turkey*

Percutaneous interventions in elderly patients (pts) is associated with frequent procedural complications and low success rates. Elderly pts are more prone to acute ischemic complications of balloon angioplasty (PTCA). It's reported that coronary stenting improves clinical outcomes and reduces complications of PTCA in younger pts. This study was designed to evaluate the impact of stents in reducing event rates in elderly population. A total of 226 consecutive pts undergoing native coronary artery stenting were enrolled. We performed a prospective analysis of elderly pts (age>65 yrs; n = 44) and compared to younger pts (age < 65 yrs; n = 182) according to risk factors, lesion morphology, primary procedural success, clinical and angiographical stent restenosis rates (follow up = 5.7 ± 1 months). Results are illustrated in table.

Comparison of the groups

	Elder pts	Young pts	P
Age (years)	70 ± 4	50 ± 14	0.0001
Diabetes Mellitus	17(38%)	22(12%)	0.03
Smoking	19(44%)	100(55%)	ns
LAD Lesion	33(79%)	111(61%)	ns
Minimal luminal diameter (preprocedure)	0.81 ± 0.4	0.59 ± 0.4100	0.001
Acute gain (mm)	2.11 ± 0.4	2.35 ± 0.4	ns
Late loss (mm)	1.05 ± 0.9	1.2 ± 0.9	ns
Acute major complications	2 (5%)	11 (6%)	ns
Follow-up: Angina	6 (13%)	22 (12%)	ns
AMI	0	1 (0.5%)	ns
PTCA	7 (16%)	54 (30%)	ns
CABG	7 (16%)	32 (14%)	ns
Death	0	0	ns
Angiographic restenosis	14 (33%)	79 (44%)	ns

Despite a higher risk profile, clinical and angiographical success of coronary stenting in elderly was similar to younger pts. Although not statistically significant, restenosis rates were lower in elderly pts (33% vs 44%). It can be concluded that stents can be implanted safely and successfully in older ages. Age itself should not preclude pts from undergoing coronary stenting.

P3538 Profound reductions in exposure to major risk factors to coronary heart disease (CHD) in 70 year old Danes, surveyed 1967, 1984 and 1991

K.K. Thomsen, M. Schroll[1]. *Cardiology Dept., Odense University Hospital, Odense; [1]Centre of Preventive Medicine, University of Copenhagen, Glostrup, Denmark*

Since 1964 monitoring of levels of risk factors for CHD in random samples of the population in Copenhagen County have been carried out at regular intervals in cross-sectional and in longitudinal designs.

Methods: Standardised methods based on WHO recommendations have been applied since 1964. We report risk factor levels in 3 cohorts, born in 1897, 1914 and 1921; surveyed at age 70.

Results:

Year of survey	1967		1984		1991	
Gender (n)	men (230)	women (209)	men (412)	women (209)	men (201)	women (201)
Smokers (%)	75.6	39.3	51.9	36.7	46.5	29.4
Hypertension (%) ≥160 or ≥95 mmHg	33.0	32.3	15.1	18.8	22.4	19.5
High cholesterol (%) >6.2 mmol/l	98.4	98.1	52.4	72.2	38.7	63.5
BMI ≥ 30 (%)	10.2	22.5	12.2	16.4	13.4	19.9
Syst. blood pressure (mmHg) mean and SEM	146.4/1.7	146.5/1.9	138.0/1.0	140.8/1.0	143.5/1.4	140.8/1.4
S-cholesterol (mmol/l) mean and SEM	8.0/0.10	9.1/0.13	6.2/0.06	7.0/0.06	5.9/0.07	6.7/0.08
BMI (kg/m^2) mean and SEM	25.6/0.23	26.6/0.34	25.2/0.18	25.5/0.25	26.3/0.26	26.5/0.34

Significant reductions in exposure to major CHD risk factors were observed 1967 to 1984. From 1984 to 1991 BMI increased in both genders, systolic blood pressure and the proportion of hypertensives increased in men. The proportion of smokers, and high cholesterol, decreased significantly in both genders. S-cholesterol continued to decrease.

In conclusion: In both genders a significant and continuous reduction in s-cholesterol and smoking prevalence was observed. The prevalence of high blood pressure was almost halved from 1967 to 1984 but no further improvement was observed the following 7 years, whilst BMI increased in both genders. The observed reduction in major risk factors coincided with a 30% decrease in the incidence of myocardial infarction from 1982 to 1991 in people aged 70–74 years of both genders in the same population (Dan-MONICA heart register).

P3539 Dobutamine stress echocardiography after uncomplicated myocardial infarction in the elderly

M.M. de la Torre, J.A. San Román, J. Bermejo, J.L. Vega, J. Paniagua, O. Sanz, G. Pastor, E. García, F. Fernández-Avilés. *Hospital Universitario, Valladolid, Spain*

Background: The elderly are at higher risk for adverse events after myocardial infarction (MI). Thus, risk stratification is mandatory but physical limitations often preclude conventional risk assessment.

Aim: The aim of this study was to assess the prognostic value of Dobutamine Stress Echocardiography (DSE) after an uncomplicated MI in the elderly.

Methods: Fifty seven consecutive patients aged ≥70 years (males 37; age 75 ± 4) underwent DSE within ten days after uncomplicated MI. DSE was carried out following the standard method. Five myocardial responses were identified: 1) negative; 2) sustained improvement of contractility; 3) initial improvement followed by worsening; 4) worsening in the infarcted zone; 5) worsening at a distance.

Results: DSE was well tolerated without any severe complication. Mean follow-up was 14 ± 8 months. There were 26 events: non cardiac death 4, cardiac death 6, AMI 1, heart failure 1, unstable angina 10 and revascularization 4. Clinical and echocardiographic variables were considered, including those previously related to adverse prognosis. Multivariate stepwise regression showed that worsening of contractility in the infarcted zone was the only independent predictor of impaired outcome ($p < 0.001$, relative risk 2.80; 95% confidence interval 1.68 to 4.66).

Conclusion: Ischemia in the infarcted zone detected as worsening in contractility during DSE after uncomplicated MI predicts a poor outcome in the elderly.

P3540 Management of heart failure and atrial fibrillation in older people in the community

Shu F. Ho, M.S. O'Mahony, J. Steward[1], M. Buchalter[2], M. Burr[1]. *University Departments of Geriatric Medicine; [2]Cardiology; [1]Public Health and Epidemiology, Cardiff, UK*

Both heart failure and atrial fibrillation (AF) are common in older people. Improving recognition and care of patients with heart failure has a major impact on morbidity, mortality and heath-care costs. Treatment with angiotensin converting enzyme (ACE) inhibitors can improve survival and quality of life even in those with mild systolic left ventricular (LV) dysfunction. Anti-coagulants are effective in stroke prevention in AF with aspirin being an alternative for those unsuitable for formal anti-coagulation.

Methods: A random sample of 500 subjects was drawn by 2 stage random sampling from 5002 subjects aged 70 years and over living at home. Subjects attended a hospital clinic for clinical assessment. AF was diagnosed by electrocardiography and systolic LV function was assessed qualitatively on echocardiogram as normal, mild, moderate or severe dysfunction.

Results: 452 of the 500 subjects (90%) participated in the study. In total, 351 (78%) received an echocardiographic assessment The population prevalence amongst older people of systolic LV dysfunction was 8% and AF 7%. 32% of those with AF had impaired systolic LV dysfunction compared to 10% of those in sinus rhythm. Those with LV dysfunction were more likely to be prescribed diuretics (50% vs 31%, $p < 0.05$), aspirin (48% vs 26%, $p < 0.001$) and ACE inhibitors (30% vs 9%, $p < 0.0001$). Of those in AF, 34% were taking aspirin, 24% warfarin and 41% were on neither aspirin nor warfarin.

In conclusion, heart failure is under-recognised and under-treated in older people in the community. The majority of those with systolic LV dysfunction are not on ACE inhibitors and a significant proportion of those in AF are not on any treatment for stroke prevention, be it warfarin or aspirin.

P3541 How age does and should influence the management of myocardial infarction

K. Barakat, P. Wilkinson[1], A. Suliman[2], K. Ranjadayalan[2], A.D. Timmis. *Cardiology Dept., London Chest Hospital, London; [1]Dept. of Public Health and Policy, School of Hygeine and Tropical Med., London; [2]Cardiology Dept., Newham Healthcare Trust, London, UK*

Background: Around 75% of patients with acute myocardial infarction (AMI) are aged >70, but they are often treated less vigorously than younger patients. In part this may be because clinicians have misconceptions about their likely prognosis, and give age undue weight in clinical decisions. We have examined how age does and should influence management and risk stratification in AMI.

Methods: Prospective cohort study of the management and outcome of 1225 consecutive patients with AMI.

Results: Older patients were slower to arrive in hospital and less likely to receive thrombolysis or discharge beta-blockers: odds ratios (95% CI) for patients aged >70 years compared to those <60 were 0.63 (0.45–0.88) for thrombolysis and 0.25 (0.16–0.37) for beta-blockers, adjusted for sex, diabetes, previous AMI, Q waves, and left ventricular failure. Left ventricular failure (LVF) was the strongest independent predictor of death within *a* year of infarction (adjusted hazard ratio 4.76 (3.53–6.43)). Its influence was such that patients aged >70 without LVF had significantly better survival at 1 year than patients <60 with LVF. 70.8% (62.2–78.2%) of this older group who survived to hospital discharge were still alive three years later.

Conclusion: Elderly patients with AMI were treated less vigorously than younger patients. Prognosis however was heavily influenced by the development of LVF such that many older patients had a better outlook than younger patients with adverse clinical factors. In planning risk based management, consideration of age independently of clinical status is inappropriate.

P3542 Secondary prevention in elderly patients with acute coronary syndrome in France: results of the PREVENIR survey

J.P. Cambou[1], O. Grenier[2], J. Ferrieres[1], N. Danchin[3]. *[1]Unité INSERM 518, Toulouse; [2]Cardiovascular hospital, Paris; [3]Cardiovascular hospital, Vandoeuvre-les-Nancy, France*

The aim of the French nation-wide observational study (PREVENIR) was to detail the treatment prescribed at hospital discharge and 6 months later to patients with unstable angina (UA) or myocardial infarction (MI).

Methods. The survey was performed in 77 private and public cardiology centres. All patients admitted to hospital in January 1998 who survived an acute coronary syndrome were included: 1456 patients, MI: 819, UA: 637. Treatment at discharge was collected retrospectively. Data on the ongoing treatment were collected during an out-patient consultation or, by questioning the patient's GP.

Results. Data concerning 715 elderly patients (≥65 years) alive at 6 month and not lost for follow-up were analysed. Baseline characteristics are comparable with those reported in previous French epidemiological studies. (USIK, PRIMA). At discharge some treatments [fibrates: 6.9% (49), omega 3 fatty acid: 1.3% (9), ACE-inhibitors: 43.2% (309), nicotine patches: 0.6% (4)] were similar for patients either under or over 65 years, whereas the other treatments (statins: 28.3% vs. 47.8%, $p < 0.001$; aspirin: 88.1% vs. 93.2%, $p < 0.001$; beta-blockers: 65.2% vs. 78.1%, $p < 0.001$; cardiac rehabilitation: 18.7% vs. 31.9%, $p < 0.001$) were less frequent. There were no significant changes in treatment 6 months later, except for statins (35.5% vs. 28.3%, $p < 0.001$). Only 6% of patients (12) with statin at hospital discharge had stopped the medication at 6 month follow-up. Family physicians will initiate statin therapy for only 12.5% (64) of untreated patients.

Conclusion. Rehabilitation and measures to prevent smoking are used sparingly. Statins and beta-blockers are underused compared with younger patients. Whereas, in secondary prevention, statin clinical trials have demonstrated a similar beneficial effect in patients under or over 65 years, prescription remains at a modest level indicating that the lessons for recent clinical trials have not yet been completely applied to daily clinical practice. Our population, however, comprised 12% of patients of more than 85 years, in whom the beneficial effect of statins is not documented to date.

P3543 Exercise conditioning prevents the age-dependent increase in coronary microcirculatory resistance, while arterial hypertension accelerates epicardial artery narrowing

M. Kozàkovà, F. Galetta[1], L. Gregorini[2], G. Bigalli, F. Franzoni[1], C. Morizzo, C. Giusti[1], A. L'Abbate, C. Palombo. *Cardiology Dept., Institute of Clinical Physiology, Pisa; [1]Department of Internal Medicine, Pisa; [2]Clinica Medica, Ospedale Maggiore, Milan, Italy*

Exercise conditioning is supposed to decrease cardiovascular morbidity, while arterial hypertension represents a risk factor for ischemic heart disease. A different susceptibility of coronary circulation to ageing may, at least partially, explain these observations.

Aim of this study was to compare the relation of coronary vasodilator capacity and conduit vessel remodeling with age in 16 healthy sedentary normotensives (NL), 16 highly trained athletes (A) and 16 hypertensive subjects (HT) of comparable age (50 ± 15, 53 ± 18, 58 ± 9 years). By means of TEE-Doppler, coronary flow velocity (CFV) in left anterior descending artery was monitored at baseline and during i.v. dipyridamole infusion (Dip: 0.84 mg/kg/9 min), and left main artery (LMA) diameter was measured in zoomed 2-D diastolic images. Coronary flow reserve (CFR) was calculated as ratio of maximal CFV during dipyridamole and basal CFV, and minimum coronary resistance (MCR) as ratio of mean BP to maximal CFV during dipyridamole.

Results: CFR and MCR were 3.23 ± 0.65 and 0.96 ± 0.23 mmHg*s/cm, respectively, in NL. Compared to NL, not significantly different values were found in A (CFR: 3.60 ± 0.70, MCR: 1.04 ± 0.17 mmHg*s/cm), while HT showed lower CFR (2.31 ± 0.32, $p < 0.01$) and higher MCR (1.21 ± 0.3 mmHg*s/cm, $p < 0.05$). Age was directly related to MCR ($r = +0.63$, $p < 0.01$) in NL and inversely related to CFR in A ($r = -0.56$, $p < 0.02$): such a different pattern was depending in NL on relations of age with dipyridamole BP (direct: $r = 0.61$, $p < 0.01$) and – close to statistical significance – dipyridamole CFV ($r = -0.40$, $p = 0.1$), while in A basal CFV tended to increase with age, paralleling systolic BP and rate-pressure product. No age-dependent changes in LMA area were found in either group. By contrast with NL and A, HT showed a significant inverse correlation of age with LMA area ($r = -0.44$, $p < 0.01$), but not with MCR or CFR.

Conclusions: chronic exercise training counteracts the "physiological" increase of coronary microcirculatory resistance with age, while arterial hypertension seems to accelerate epicardial artery narrowing.

P3544 Stress echocardiography in octogenarians: safety, tolerability and better visualization of the myocardial segments using native harmonics

H. Villarraga, J. Sanchez, M. Badiel, P. Olaya. *Echocardiographic and Hemodynamic Lab, Foundation Valle of Lili Medical Cente, Cali, Colombia*

Introduction: With the gradual displacement of the generational pyramide in the different cultures towards an advanced age, coupled to the fact that this age group has a greater probability of coronary artery disease (CAD). A safe and reproducible exam that can evaluate this entity is of great importance.

Methods: Group 1: 241 pts, range 70–95 yr, Group 2: 788 pts with age less 70 yr. These groups were compared for safety, tolerability and myocardial segment visualization. All patients underwent Dobutamine Stress Echocardiography (DSE). The standard protocol of 3 minute stages of 5, 10, 20, 30, 40 and 50 mcg/kg/min of DBT was used until at least 90% target heart rate (THR) was reached if at 30 mcg/kg/min less than 70% of THR was achieved atropine in boluses of 0.25 mg was used up to a maximum of 2.0 mg.) or Exercise Stress Echocardiography (ESE) until achievment of target heart rate (THR) for age or changes in regional contractility. An Acuson Sequoia C256 (Mountain View, CA) with native harmonics and a H3.5 MHz frequency transducer was used.

Results: Group 1: Was composed of 52.7% women, the mean age of: 75.5 ± 4.8 yr, weight: 65 ± 11.4 kg. ESE was done in 10.5%. The indications were: CAD = 57%, typical angina: 17.2%, atypical chest pain: 4.8%, nonvascular surgery 13.4%, valvular disease:2.7%. THR was achieved in 89.9% with DSE and 95.5% in ESE. 99.5% of the segments were visualized in both groups. The adverse effects between the groups were: None: 90.2% vs 94.3%, Supraventrycular arrythmia:0.5% vs 0.1%, ventricular arrythmia 1.5% vs 0.1%, Bradicardia 0 vs 0.3%, Angina 5.4% vs 4%, Hypotension: 1.5% vs 0.3%, Headeache 1% vs 0.6%, Nausea:0% vs 0.3%. There were no deaths during the examination. A total of 3.836 segmentos were visualized of 3.856 segments possible.

Conclusion: DSE + ESE in octogenarians is a safe and tolerable exam. Adverses effects are comparable to a population of less age. Native harmonic adds the feasibility of visualizing 99.5% of segments allowing a better interpretation of this test modality.

ADVANCES IN PRIMARY AND SECONDARY PREVENTION

P3545 Healthy offspring of men with premature myocardial infarction have significantly elevated factor VII and factor XII plasma levels

Th. Makris, P. Krespi, A. Hatzizacharias, E. Chronakis, C. Tsoukala, D. Xanthis, F. Triposkiadis, M. Kyriakidis. *Cardiology Dept., 2nd Reg. BTC, Haemost. Lab, LAIKON Hospital and Medical School-University of Athens, Greece*

A family history of premature myocardial infarction (PMI) consists an independent cardiovascular risk factor (F) while elevated FVII and FXII plasma levels are associated with increased cardiovascular morbidity and mortality. Aim of the study was to determine FVII and FXII plasma levels in healthy offspring of men with PMI (<55 yrs) and to compare these findings with those of healthy offspring without a family history of cardiovascular disease (CVD).

Methods: Sixty eight (32 M, 36 F) mean age (MA) 18.2 ± 2.75 yrs and body mass index (BMI) 22.5 ± 3.3, kg/m^2 healthy offspring of men with PMI (group A) and 32 (15 M, 17 F) MA 18.45 ± 2.46 yrs and BMI 21.8 ± 3.6 kg/m^2 healthy offspring without family history of CVD, diabetes mellitus or hypertension were studied. Fasting FVII and FXII plasma levels were determined in the whole population (ELISA method).

Results:

	FVII %	FXII %
Group A	163.6 ± 36.9	82 ± 21
Group B	106.2 ± 31.9	72 ± 17
	p < 0.0001	p < 0.01

Conclusions: Our results suggest that fasting FVII and FXII plasma levels are significantly increased in healthy offspring of men with PMI compared to those of healthy offspring without a family history of CVD. This finding may be another mechanism which enhances the cardiovascular risk.

P3546 The effect of weight loss with or without exercise training on large artery compliance in healthy obese men

L.M. Van Bortel, E.J. Balkestein, D.P. van Aggel-Leijssen[1], M.A. van Baak[1], H.A. Struijker-Boudier. *Depts. of Pharmacology; [1]Human Biology, Maastricht University, Maastricht, Netherlands*

Objective: To investigate the effect of weight loss with or without exercise training on compliance of large arteries in healthy obese men.

Methods: Thirty-seven healthy, obese men were studied. Seventeen were randomized to a very low calorie diet (D) for 6 weeks, 20 to a very low calorie diet and an additional exercise program (DE). Subjects were examined before and 12 weeks after start of the study. Systolic (SBP), diastolic (DBP) and mean arterial pressures (MAP) and heart rate (HR) were semi-automatically measured. Cross sectional compliance (CC) and distensibility coefficient (DC) at operating pressures and under isobaric conditions (isoCC and isoDC) were measured with a wall track system at the common carotid artery (CCA) and the brachial artery (BA). Changes between start and end of the study period were analyzed with the Wilcoxon signed ranks test. Differences between interventions (D and DE) were analyzed using the Mann-Whitney test. Results are given as mean ± SEM.

Results: Weight loss averaged 15 ± 1 kg (P < 0.001). Body Mass Index was 32.3 ± 0.4 kg/m^2 before start of the study and decreased (P < 0.001) with 4.7 ± 0.3 kg/m^2. SBP (129 ± 2 mmHg), DBP (81 ± 1 mmHg) and MAP (99 ± 1 mmHg) decreased (P < 0.001) during the study with 9 ± 2 mmHg, 6 ± 1 mmHg and 7 ± 2 mmHg, respectively. HR did not change significantly. DC and CC were 26.2 ± 0.1 10^{-3}.kPa^{-1} and 1.29 ± 0.07 mm^2.kPa^{-1} for the CCA and 5.1 ± 0.5 10^{-3}.kPa^{-1} and 0.12 ± 0.01 mm^2.kPa^{-1} for the BA. No changes between groups were noted for the above mentioned parameters.

Changes (Δ) during the study period are shown in table.

	ΔDC	ΔCC	ΔisoDC	ΔisoCC
BA (n = 34)	1.0 ± 0.8	0.05 ± 0.04*	0.1 ± 1.0	0.04 ± 0.04
CCA (n = 33)	4.7 ± 1.7*	0.18 ± 0.08*	2.2 ± 1.7	0.10 ± 0.09

Δ(iso)DC: 10^{-3}.kPa−1; Δ(iso)CC: mm^2.kPa−1; * = P < 0.05

Conclusion: significant weight loss, with or without exercise, in otherwise healthy obese men decreases blood pressure and increases compliance of the CCA and BA at operating pressures but not at isobaric levels. The increase in compliance at operating pressures is therefore most likely a passive process due to the decrease in mean arterial pressure and is not an indicator of structural changes in the arterial wall in this 12 week period.

P3547 Do we miss the opportunity for effective secondary prevention?

M. Irurita, I. Coello, J.M. Saavedra, R. Vargas, V. Nieto, C. Culebras, J. Irurita, I. Laynez[1], A. Alvarez Calero[1], H. Perez[1]. *Las Palmas; [1]Tenerife, Spain*

The guidelines on the efficacy of secondary prevention after coronary revascularization, based on clinical trials are unequivocal. Many studies have analyzed the cost-effectiveness and the appropriateness of revascularization procedures or drug therapies, but preventive actions appear less attractive.

We studied 700 random patients after revascularization in four public hospitals in the Canary Islands, the Spanish community with the highest coronary heart disease mortality. Revascularization procedures were coronary artery bypass graft in 22%, and non-surgical in 69% (stents 47%, PTCA 20%, atherectomies 2%), 9% underwent multiple procedures. Demographic features and risk factors prevalence were similar in both surgical and non-surgical groups. We found statistically significant differences regarding current smoking (10 vs. 90, p < 0.006) and the number of angiographic studies performed (309 vs. 1344, p < 0.002). In spite of revascularization, 74% of the patients received 3 or more cardiovascular drugs; surgical patients were treated with fewer betablockers (p < 0.003), but more cholesterol-lowering agents than non-surgical patients (p < 0.006).

In conclusion: Revascularized patients have still a great potential of modifiable risk factors. Patients undergoing percutaneous revascularization are more likely to continue smoking and have further angiographic studies. Though non-surgical patients received more cardiovascular drugs on average, especially betablockers, cholesterol-lowering agents were among the least used. A greater effort is needed to enhance patients benefits and rationalize the use of our resources, following the guidelines of clinical trials and avoiding the underuse of simple preventive actions.

P3548 Secondary prevention of patients with acute coronary syndrome in France: results of the PREVENIR survey

N. Danchin[1], O. Grenier[2], J. Ferrieres[3], J.P. Cambou[3]. *[1]Cardiovascular hospital, Vandoeuvre-les-Nancy; [2]Cardiovascular hospital, Paris; [3]Unité INSERM 518, Toulouse, France*

The aim of the French nation-wide observational study (PREVENIR) was to detail the treatment prescribed at hospital discharge and 6 months later to patients with unstable angina (UA) or myocardial infarction (MI).

Methods. The survey was performed in 77 private and public cardiology centres. All patients admitted to hospital in January 1998 who survived an acute coronary syndrome (ACS) were included: 1456 patients, MI: 819, UA: 637. Treatment at discharge was collected retrospectively. Data on the ongoing treatment were collected during an out-patient consultation or, by questioning the patient's GP.

Results. Baseline characteristics of patients with coronary artery disease are comparable with those reported in previous French epidemiological studies (MONICA, USIK, PRIMA). Treatment at hospital discharge included statins: 35.6% (519), fibrates: 6.7% (97), omega 3 fatty acid: 2.7% (40), aspirin: 89.8% (1307), beta-blockers: 68.3% (995), ACE-inhibitors: 41.5% (605), nicotine patches: 0.7% (11), cardiac rehabilitation: 23.8% (347). Data concerning 1290 patients alive at 6 month and not lost for follow-up were analysed. Few patients stopped the medication prescribed at discharge: statins: 4.4% (23), fibrates: 16.5% (16), omega 3 fatty acid: 15% (6), aspirin: 3.8% (49), beta-blockers: 6.1% (61), ACE-inhibitors: 9.4% (57). There were no significant changes in treatment 6 months later, except for a higher prescription of statins (45.7% vs. 35.6%, p > 0.001). When statin therapy was not initiated at hospital, subsequent prescription by the GP or referring cardiologist was uncommon [14.2% (137)].

Conclusion. Prescription of aspirin, beta-blockers and ACE-inhibitors after ACS has improved in France, while cardiac rehabilitation and measures to prevent smoking are used sparingly. The prescription of statins is improving, although it remains at a modest level, indicating that the lessons from recent clinical trials have not yet been completely applied to daily clinical practice.

P3549 A cardiac prevention programme can benefit all patients at first presentation with coronary artery disease in the population

M. Nuttall, P. Devane, B. Arora, E. Dawson, K.F. Fox, S.J. Sutcliffe, D.A. Wood. *Bromley Hospitals NHS Trust and Imperial College School of Medicine at the National Heart and Lung Institute, London, UK*

Background: Traditional cardiac rehabilitation programmes have not included patients with stable or unstable angina unless revascularised, and are usually restricted to patients managed within hospital. This excludes over 50% of patients at first presentation of their coronary artery disease (CAD), despite such patients having mortality benefits from secondary prevention measures. We provided a comprehensive cardiac prevention programme for all patients whose first presentation of CAD was angina or unstable angina in addition to those presenting with myocardial infarction.

Methods: All patients listed with 80/159 (50%) of GPs in Bromley Health Authority (total population 292 000) presenting with CAD were eligible for the new nurse led programme and the other half of patients received usual care. A rapid access chest pain clinic to which GPs referred all suspected new cases of CAD, combined with daily hospital admission monitoring, ensured complete and prompt case identification. Patients were recruited at the time of first diagnosis and visited on the ward and at home within 2 working days. A 3 month programme of lifestyle and risk factor modification including pharmacological treatment of hypertension and hypercholesterolaemia was undertaken. Family screening was offered to first degree relatives. The objective was to achieve defined lifestyle, risk factor and therapeutic targets.

Results: 162 patients (83% of 196 possible cases) were recruited over 15 months with 65% completing the programme. Targets for achieving non-smoking status, blood pressure < 140/90, and total cholesterol < 5.2 mmol/l were achieved in 90%, 73% and 75% respectively and the proportion of patients on aspirin, beta blockers and lipid lowering therapy was 93%, 57% and 62% on discharge to general practice.

Conclusion: A comprehensive prevention programme should be offered to all patients presenting with CAD. A high recruitment rate can be achieved from patients who have not undergone infarction or revascularisation and those normally managed in primary care. Lifestyle and risk factor targets can be achieved with such a programme.

P3550 Long-term course of cardiovascular risk factors following cardiac in-patient rehabilitation

H. Völler[1], S.N. Willich[2], S. Binting[2], B. Rombeck[1], C. Dovifat[1], H. Hahmann, H. Gohlke, G. Klein, K. Bestehorn, K. Krobot. *For the PIN-Study Group; [1]Klinik am See, Rüdersdorf/Berlin; [2]Institute of Social Medicine and Epidemiology, Charité, Humboldt University, Berlin, Germany*

Short-term positive effects on cardiovascular risk factors by altering lifestyle and/or drug therapy have been demonstrated, however, not in the long-term course. In a large cohort we therefore investigated the long-term persistency of risk factor improvements achieved by cardiac inpatient rehabilitation at discharge.

Method: Between January and June 1997 2,441 consecutive CHD patients (22% women, 65 ± 10 years, 78% men, 60 ± 10 years) were enrolled in the study after acute cardiac event (primary diagnosis 38% CABG, 56% MI, 6% PTCA). Standardized questionnaires were completed by the patients and their physicians at admission (A) to and discharge (D) from inpatient rehabilitation as well as after 3, 6 and 12 months.

Results: The percentages of patients with pathologic values of conventionally defined risk factors were:

	A	D	3 mo	6 mo	12 mo	p-value*
BP (>140/90 mmHg)	24	8	19	22	20	0.001
Smoking	39	5	-	10	10	0.001
BMI (>30 kg/m^2)	18	15	17	21	24	0.001
Glucose (>140 mg/dl)	14	11	19	20	24	0.001
Total cholesterol (>200 mg/dl)	59	30	48	51	45	0.001
LDL cholesterol (>100 mg/dl)	87	67	79	78	80	0.006
Triglycerides (>200 mg/dl)	22	15	27	28	29	0.001

• Statistical comparison A vs D and D vs 12 months (mo)

Conclusion: The success of cardiac inpatient rehabilitation in modifying cardiovascular risk factors is not maintained in the long term. Since the patients BMI as well as glucose and triglyceride levels relapsed beyond baseline levels, closer cooperation with the outpatient medical care provider is required.

P3551 Long-term (25 years) efficacy of comprehensive post myocardial infarction rehabilitation program

S. Marcus, I. Orha, E.I. Apetrei, R. Cioranu. *Institute of Cardiology, Bucharest, Romania*

Aim: To assess the effectiveness of a public health approach in rehabilitation and comprehensive secondary prevention after myocardial infarction on 25 years follow-up.

Method: Random allocation of 129 male patients < 65 years, dicharged after acute myocardial infarction during 1973–1975 to either regular care (group C) or a comprehensive program (group I) to reduce risk factors (hypertension, diabetes mellitus, smoking, cholesterol, obesity, alcohol consumption) and regular physical activity, supervised for the first 3 month.

Results: The intervention group (I) comprised 65 p, mean age 52 ± 8 years and the control group (C) 64 p, mean age 53 ± 8 years. The efficacy of intervention was evaluated at 1 year of follow-up: 35% weight reduction, 16.7% blood pressure drop, 22.2% serum cholesterol drop, 40.5% smoking changes, 45.5% alcohol consumption changes, 23.1% improvement in physical work capacity and 6.2% worsened physical work capacity. All cause mortality was 4.9% group I at 1 year vs 7.1% in group C – NS. At 3 year follow-up all cause mortality was 11.9% in group I and 15% in group C – NS. At 25 years all cause mortality was 56.9% in group I and 75% in group C – p = 0.03. Return to work was, at 1 year of follow-up 70.6% in group I and 58.7% in group C – p = 0.02, at 3 years 75.5% in group I and 65.5% in group C – p = 0.04. At 25 years 2 patients in group I were still full-time active.

All cause mortality and return to work

Parameters		Follow-up		
		1 year	3 years	25 years
Mortallty (%)	Group C	7.1	15.0	75.0
	Group I	4.9	11.9	56.9
p		NS	NS	0.03
Return to work (%)	Group C	58.7	65.5	–
	Group I	70.6	75.1	2 pts.
p		0.02	0.04	–

Conclusions: A comprehensive post myocardial infarction rehabilitation program has immediate effect (after 1 year) on risk factor reduction and quality of life (measured by return to work) and on long-term i.e. 25 years reduces all cause mortality by 18.1%.

P3552 Prevention practices in patients with atrial fibrillation and neurological events: evidence for underutilization of anticoagulation

J. Carlsson, E. Flicker, S. Miketic, S. Haun, A. Cuneo, U. Tebbe. *Klinikum Lippe-Detmold, Detmold, Germany*

Background: The purpose of the study was to investigate the primary and secondary prevention practices in patients (pts.) with neurological events (TIA, PRIND and stroke) and atrial fibrillation (AF).

Methods: Between 1/97 and 1/98 all pts. admitted to our hospital with acute neurologic events were prospectively registered and the pts. were stratified according to heart rhythm. Antithrombotic medication on admission and at discharge was recorded.

Results: Of 388 pts. with neurologic events 5 pts. were excluded from the analysis because of subarachnoid hemorrhage as well as 13 pts. because of insufficient ECG data. Of the remaining 369 pts. 82 were in afib (22.2%). The mean age of these pts. was 80.4 ± 7.5 years, 70.7% were female. 15.9% suffered from a TIA, 4.9% from a PRIND and in 79.2% stroke was present. Only 2 pts. had intracranial hemorrhage on admission. In 50 pts. (60.9%) afib was previously known. Of these pts. only 6 (12%) received oral anticoagulation at the time of admission, 26 (52%) were on aspirin or ticlopidine and 18 pts. (36%) received no antithrombotic treatment at all. Of 63 surviving pts. with AF 32 pts. (55.6%) had no absolute or relative contraindications against oral anticoagulation. Of these pts. 14 (40%) were on anticoagulants at discharge, 20 (57.1%) received aspirin or ticlopidine and 1 pt. (2.9%) had no antithrombotic treatment.

Conclusions: In the majority of AF pts. with neurologic events the rhythm disorder had been known before the event, however oral anticoagulation had not been prescribed in 78% of these pts. Only 40% of pts. with AF and no contraindications against anticoagulation were on oral anticoagulants for secondary prevention at discharge. To translate the benefit of oral anticoagulation in preventing stroke in pts. with AF from trials to daily clinical practice, much consequenter adherence to clinical guidelines is needed.

P3553 Adherence to recommendations for prevention in patients with stable angina pectoris: observations from the ACTION (A Coronary disease Trial Investigating Outcome with Nifedipine GITS) study

P.A. Poole-Wilson, J. Lubsen[1]. *On behalf of the ACTION Group; National Heart and Lung Institute, Imperial College of Science, Technology and Medicine, London, UK; [1]SOCAR Research SA, Nyon, Switzerland*

Adherence to current recommendations of the European societies for prevention in patients with established coronary disease was evaluated based on screening data from the ongoing double-blind **ACTION** trial.

Methods: Patients with proven coronary disease and stable angina requiring anti-anginal treatment were recruited in Canada, Israel, Australia, New-Zealand and 15 Western European countries. Patients with heart failure or other conditions that limit life expectancy were excluded, as were patients on a Calcium-blocker that could not be stopped.

Results: Entry characteristics of 78% of randomised patients were:

Total number of patients in data base	5,891 (100%)
Median age in years (range)	63 (35–89)
Male/Caucasian	80%/98%
History of MI or revascularisation	70%
History of claudication, TIA or stroke	12%
Insulin/non-insulin dependent diabetes	2%/12%
Hypertension/hyperlipidaemia treated with drugs	39%/70%
On a beta-blocker/on two or more anti-anginal drugs	80%/52%
Risk factor: current smoker	18%
Risk factor: blood pressure > 140/90 mmHg	36%
Risk factor: cholesterol > 5.0 mmol/l	66%
One/two/three risk factors	46%/30%/4%

18% are still smoking. Despite frequent use of drugs, 36% have a blood pressure > 140/90 mmHg, 66% has a cholesterol > 5.0 mmol/l and 34% have two or three risk factors. There were no differences between patients with (70%) and without a history of MI or revascularisation.

Conclusion: Intensified risk factor management is required to achieve the risk factor goals recommended. This conclusion applies to all countries participating in the ACTION study.

P3554 Lipid treatment goals in patients with atherosclerotic disease

A. Svilaas, H.K. Walsoe[1], L. Ose[2]. *Nymoen Medical Centre, Kongsberg; [1]Parexel Medstat, Lillestrøm[2]Lipid Clinic, Rikshospitalet, Oslo, Norway*

Purpose: Our primary study objective was to evaluate the application of the "5-4-3-2-1" guideline in secondary prevention (total cholesterol [TC] < 5.0 mmol/l, total/HDL-cholesterol ratio < 4, LDL-cholesterol [LDL-C] < 3.0 mmol/l, triglycerides [TG] < 2.0 mmol/l and HDL-cholesterol [HDL-C] > 1.0 mmol/l), recommended in Norway from 1995. After the new European guidelines were presented, with treatment goals of TC < 5.0 mmol/l and LDL-C < 3.0 mmol/l, we added a secondary study objective before opening the database, in intention to explore this optional treatment goal. In addition, we wanted to discuss a treatment criterion of TG < 1.5 mmol/l ("1.5"), since elevated TG are connected with an atherogenic lipoprotein phenotype.

Methods: In 1997/98 in general practice 2134 patients with established atherosclerotic disease on a lipid lowering therapy were monitored. Their mean age was 63 years.

Results: The "5-4-3-2-1" guideline was met in 19.2%, the "3-1.5" goal in 22.5% and the "5-3" guideline in 36.2% of the patients. Our data showed a good conformity between the "5-4-3-2-1" rule and the "3-1.5" rule, also in diabetic patients. Of the patients who achieved the "5-3" guideline approximately 50% still had unfavourable values of HDL-C and TG, while only 15% in those who fulfilled the "3-1.5" criteria had HDL-C ≤1.0 mmol/l.

Conclusions: A treatment goal of LDL-C < 3.0 mmol/l and fasting TG < 1.5 mmol/l seems justified in secondary prevention and can replace the "5-4-3-2-1" guideline. This simple goal of "3-1.5" should also be preferable to the official European guidelines.

P3555 The benefit of clopidogrel over aspirin is amplified in high-risk subgroups with a prior history of ischaemic events

W. Hacke, A.T. Hirsch[1], E.J. Topol[2]. *Neurology Dept., Univ of Heidelberg Medical School, Heidelberg, Germany; [1]Minnesota Vascular Disease Center, Univ of Minnesota Medical School, Minneapolis; [2]Cardiology Dept., The Cleveland Clinic Foundation, Cleveland OH, USA*

CAPRIE showed the superiority of clopidogrel (C) over aspirin (A) in reducing the combined risk of ischaemic stroke (IS), myocardial infarction (MI) or vascular death in patients with recent IS, recent MI or symptomatic peripheral arterial disease (PAD). We performed a multivariate analysis to: 1) define the role of pre-existing symptomatic vascular disease in predicting further atherothrombotic events; 2) test whether such disease defines a high-risk patient cohort; 3) assess the efficacy of C versus A in patients with previous vascular disease.

Methods: A multivariate model was constructed that included all medical variables recorded at patient inclusion. Analysis of established risk factors and the presence of pre-existing vascular disease (previous MI, stable or unstable angina, TIA, RIND, stroke, claudication or amputation) was performed for all CAPRIE patients. Absolute and relative risk reductions (ARRs and RRRs) for C vs A were calculated for the 2 cohorts of patients shown below.

Results: For the combined endpoint IS, MI, hospitalization for angina/ claudication/peripheral ischaemia/TIA/myocardial ischaemia, patients with previous IS, previous MI or previous claudication had risk ratios of 1.23 (p = 0.031), 1.25 (p < 0.001), and 1.44 (p < 0.001), respectively. For the same outcome cluster the following data were obtained in the 2 patient cohorts (see table).

Cohort	Drug	3-year Event Rate	ARR	RRR (p-value)
1. Previous acute events (IS or MI)	C (n = 2249)	32.6%	3.9%	12.4% (0.034)
	A (n = 2247)	36.5%		
Previous vascular disease	C (n = 4421)	30.5%	2.6%	9.3% (0.033)
	A (n = 4433)	33.1%		

Results were consistent for the endpoint IS, MI, or vascular death (ARR = 3.4%, RRR = 14.9% [p = 0.045] for Cohort 1; ARR = 2.8%, RRR = 11.5% [p = 0.05] for Cohort 2).

Conclusions: CAPRIE patients with a prior history of ischaemic events had high event rates, and different disease manifestations represent risk factors for recurrent vascular events. The absolute benefit of C over A is amplified in such high-risk patients.

P3556 Low-dose red wine reduce the risk of upper gastrointestinal bleeding of patients on low-dose aspirin regimens: a prospective case-control study

P. Serrano, A. Lanas, E. Bajador[1], J. Fuentes[1], M. Montoro[2], J. Guardia[2], M. Sanz[3], J.A. Casasnovas, R. Sáinz, I.J. Ferreira. *Hospital Clinico "Lozano Blesa", Zaragoza; [1]Hospital "Miguel Servet", Zaragoza; [2]Hospital "San Jorge", Huesca; [3]Hospital "San Millán", Logroño, Spain*

Low-dose aspirin (<350 mg) and low-dose red wine (<20 gr of alcohol/day) are commonly recommended for patients with ischemic heart disease. Low-dose aspirin increases the risk of upper gastrointestinal (GI) bleeding. Red wine may induce acute gastritis and peptic ulcer bleeding. Objective: to study the influence of red wine on the risk of upper gastrointestinal bleeding in patients who receive low-dose aspirin.

Methods: We prospectively studied 1122 consecutive patients (69% males) with upper gastrointestinal bleeding induced by peptic lesions and 2231 age- and sex-matched controls (1109 hospitalized and 1122 non-hospitalized controls). Data were collected by structured and direct interview with patients/controls and family members during hospitalization or family practitioner outpatient clinics.

Results: Low-dose alcohol was consumed by 11.2% of cases and 14.7% of controls. >97% of the alcohol consumed was red wine. Stepwise conditional logistic regression analysis (Table) identified low-dose aspirin use, moderate-dose red wine and high-dose red wine daily consume as independent risk factor for bleeding, whereas low-dose red wine use was found as protective factor. This protective effect was also observed in patients on low-dose aspirin regimens (OR: 0.52; 95%CI: 0.2–0.9).

Variable	Cases	Controls	OR (95% CI)	p value
Upper GI bleeding history	23.5%	4.1%	5.8 (4.2–8.1)	<0.0001
Ulcer history	35.7%	11.7%	3.4 (2.6–4.3)	<0.0001
NSAID use	46.3%	9.9%	13.1 (10.6–16)	<0.0001
Low-dose aspirin	13.2%	9.9%	2.8 (2.1–3.6)	<0.0001
Low-dose alcohol: ≤20 gr/day	11.2%	14.7%	0.68 (0.5–0.8)	0.0058
Moderate-dose alcohol: 20–50 gr/day	7.9%	6%	1.6 (1.1–2.2)	0.0087
High-dose alcohol: >50 gr/day	5.1%	3.3%	2.4 (1.6–3.6)	<0.0001

Conclusion: Low-dose red wine use is an independent protective factor for peptic lesion-induced upper GI bleeding and reduces the increased risk associated with low-dose aspirin regimens. Moderate or high doses of red wine are independent risk factors for upper GI bleeding.

NUTRITION AND LIPIDS

P3557 Nutrition and frequency of coronary heart disease in Kabardino-Balkarian republic

L.M. Khuranova, R. Medalieva, G.I. Barasbieva, N. Fokicheva, I.S. Zhetisheva, K.H. Shugushev. *Faculty of medicine, Kabardino-Balkarian State University, Nalchik, Russian Federation*

The peculiarities of nutrition and the incidence of CHD have first been investigated at the Kabardino-Balkarian State University in the South of Russia. The research involved 1057 males aged 40–59. They were of different nationalities – Russians, Kabardians, Balkarians; They lived in towns and rural areas of the republic and they had the same economic and social conditions of living. But they all had different food traditions. The epidemiological studies have been performed in according with the international standard methods of investigation. There were significant differences in the incidence of CHD and risk factors which depend on the way of nourishment of Russians, Kabardians and Balkarians in the towns and villages of the Republic. It has been determined that the national nourishment traditions are more stable in the rural areas of Kabardino-Balkaria. The people who leave villages for towns are constantly loosing something in their nourishment traditions. The incidence of CHD (17.4%), arterial hypertension (37%), excessive body mass (33%), hypertriglyceridemia (17%), hypercholesterolemia (14%) are mostly observed among the Russian town-dwellers. The incidence of CHD (5.4%), arterial hypertension (16.2%), excessive body mass (23%), hypertriglyceridemia (9%), hypercholesterolemia (8%) are observed least among the Kabardians who live in rural regions ($p < 0.01$). The food of the first group contains more animal protein, sugar and animal fat. The food of the Kabardians who live in the rural districts of the Republic contain more vegetable proteins, polyunsaturated fatty acids, complex carbohydrates. Such food is nearer to the diet which is recommended by the International Health Organisation for prevention of atherosclerosis. Multiple regression analysis confirmed the connection of CHD and risk factors with the peculiarities of nutrition. The negative connection was found between the incidence of CHD and polyunsaturated fatty acids level ($p < 0.01$). The strongest connection is observed between the caloric value and the body mass index ($p < 0.01$; $R = 0.7$). The increase of systolic and diastolic blood pressure, the level of triglyceridemia of blood directly depend on the content of alcohol and sugar ($p < 0.01$) and indirectly depend on the content of polyunsaturated fatty acids in the diet ($p < 0.01$). It has been statistically proved that the peculiarities of nourishment affect the incidence of CHD and risk factors. This fact is to be taken into consideration in the organisation of primary prevention of cardiovascular and other noncommunicable diseases among the population of the Republic.

P3558 The long-term results of weight reduction in obese coronary patients with different educational programmes and different calorie-restricted low fat diets

Arno A. Schöneberger, Kurt Schmidt. *KVB-Hospital for Cardiovascular Diseases, 61462 Königstein i.Ts., Germany*

The long-term success of weight reduction in obese coronary patients is still unsatisfactory. Therefore, we studied prospectively the influence of two different calorie-restricted low fat diets and two different educational programs on long-term weight loss in 529 obese (BMI = 30.7 kg/m^2) coronary patients (P).

During an inpatient cardiac rehabilitation (CR, 26+ −4 days) P were randomised either to a low fat diet with 1200 kcal (R) or 1800 kcal (M). Additionally each group was subdivided into two different educational programs: one hour session by a physician at the beginning and end of CR (S) or a 10 hour-group-session with psychologists, dietitians and physicians (I). 181 P were in RS, 80 in RI, 194 in MS and 74 in MI. After discharge P continued to weigh themselves for 6 months and returned the results with a questionnaire. 66% of all P responded after 6 months; the intensively educated P showed a better compliance with 73% returns vs 63% of the short-trained P.

The weight loss at the end of CR with 1200 kcal (RI = 4.1 kg; RS = 3.9 kg) was significantly greater ($p < 0.01$) then with 1800 kcal (MI = 3.1 kg; MS = 3.2 kg). However, no difference was found in reduction of body fat mass (BIA). The total weight loss at 6 months after CR amounted to: RI = 5.1 kg, RS = 5.2 kg, MI = 4.5 kg, MS = 4.1 kg. Thus, there was no significant long-term difference between the 1200 kcal and 1800 kcal group. Intensity and duration of educational sessions did not show a short or long-term effect on weight loss.

Obese coronary patients lost successfully and permanently weight with a low fat diet of 1800 kcal and a short educational program. A lower calorie-restricted diet and more intensive education did not induce greater weight loss.

P3559 Plasma homocysteine levels in a cohort of apparently healthy subjects in Northern Italy: relation to age, sex and nutritional status

S. Sassi, B. Cosmi[1], G. Palareti, C. Legnani, G. Grossi[2], S. Coccheri[1]. *Division of Angiology, Ospedale S. Orsola-Malpighi, [1]Division of Angiology, [2]Laboratorio Centralizzato, Ospedale S.Orsola-Malpighi, Bologna, Italy*

Several cross-sectional and prospective studies have indicated that increased levels of total plasma homocysteine(tHCy) are an independent risk factor for cardiovascular disease. Genetic disorders and vitamin deficiencies can lead to a moderate increase in tHCy levels. The definition of normal fasting tHCy is still a matter of debate. The aims of our study were the following: 1) to measure fasting tHCy (tHCy) and determine the correlation with age, body mass index (BMI), sex and levels of folate, vitamin B12 (vit.B12) pyridoxal-5'-phosphate (PLP) in a cohort of apparently healthy subjects in Northern Italy (Bologna); 2) to define reference values for tHCy for the population in the same geographic area.

Methods: Apparently healthy subjects (n = 147; 82 men 65 women, age range: 14–94 y) were selected from the general population in the area of Bologna, Italy. High performance liquid chromatography assays were used to measure plasma levels of the following: 1)tHCy, according to Araki and Sako method (1987) with modifications; 2)PLP according to the method of Sassi et al (1997).Folate and vit.B12 serum levels were measured by automated chemiluminescence assay (Chiron Diagnostics, East Walpole, MA, USA).

Results: The geometric mean (GM) of plasma tHCy levels for the entire group was 9.00 μmol/L. Significant positive correlation was found between tHCy and age (Spearman's r; rs: 0.37; $p < 0.0001$) and tHCy and BMI (rs: 0.22; p:0.041). Significant negative correlation was found between tHCy and folate, and tHCy and Vit.B12 (rs: −0.47, $p < 0.0001$; rs: −0.40; $p < 0.0001$, respectively). No significant correlation was observed between tHCy and PLP. Mean tHCy levels were significantly lower in women than men (GM:8.00 and 9.89 μmol/L, respectively, $p < 0.0023$), but no difference was observed in folate, PLP and Vit.B12 levels in men and women. A significant negative correlation was found between age and folate, age and vit.B12 (rs: −0.16, $p = 0.05$ and rs: −0.37; $p < 0.0001$; respectively), age and PLP (rs: −0.56; $p < 0.0001$). In a stepwise multivariate regression analysis, age and folate levels explained 13% and 7.3% of the tHCy variance, while no significant effect was due to BMI, vit.B12, PLP. We calculated reference values on the basis of sex and age. The 90th percentiles of tHCy for men and women <45 y were 16.38 and 10.33 μmol/L, respectively. The 90th percentiles for men and women > 45 y were: 20.28 and 14.62 μmol/L, respectively.

Conclusions: 1) tHCy levels are influenced by age, BMI, sex and vitamin status 2) reference values for tHCy levels should be expressed according to age and sex.

P3560 Alcohol drinking and cardiovascular disease mortality in Japanese men

S. Choudhury, H. Ueshima, A. Okayama, H. Yanagawa[1], O. Limura[1]. *Department of Health Science, Shiga University of Medical Science, Shiga; [1]NIPPON DATA Research Group, Shiga, Japan*

Moderate drinking is associated with lower CVD death risk in Western populations. The association of alcohol drinking with risk of all cause and CVD death in Japanese men were investigated by analyzing a representative dataset of a 14-year prospective study (NIPPON DATA).

In 1980 a national cardiovascular survey was done in randomly selected subjects and it included information on drinking habit of participants. In 1994, a follow-up survey to ascertain vital status was conducted with a follow-up rate of 91.3%. In this study data of 4044 men aged 30–74 years were analyzed. Age and smoking adjusted relative risk (RR) of death from all causes and CVD death for different drinking categories were calculated by Cox proportional hazard model. Subjects with history CVD were excluded while calculating RR from CVD death.

The age adjusted rates per 100,000 person-year and age and smoking adjusted RR with 95% CI of all causes and CVD death are shown in the table. Occasional drinker had lower death rate and RR of all cause and CVD deaths in comparison to those of non-drinker.

	Non	Ex-drinker	Occas. drinker	Daily drinker
All Death				
No. exposed	784	216	1097	1947
No. death	139	67	103	240
Mortality	1174.9	1365.5	830.8	942.3
RR (95% CI)	1	1.18 (0.88 to 1.58)	0.71 (0.55 to 0.91)	0.84 (0.68 to 1.04)
CVD				
No. exposed	736	177	1033	1868
No. death	46	18	21	70
Mortality	495.5	464.2	145.3	327.8
RR (95% CI)	1	1.16 (0.67 to 2.00)	0.45 (0.27 to 0.76)	0.72 (0.49 to 1.05)

In this cohort of Japanese men occasional alcohol drinking was associated with lower 14-year mortality risk.

P3561 Moderate alcohol consumption is associated with reduced risk for coronary heart disease among women with type 2 diabetes mellitus

C.G. Solomon, F.B. Hu, W.C. Willett, G.A. Colditz, M.J. Stampfer, F.E. Speizer, C.H. Hennekens, J.E. Manson. *Medicine Dept., Brigham and Women's Hospital, Boston MA, USA*

Moderate alcohol consumption has been associated with reduced risk for coronary heart disease (CHD) among general populations. To assess whether moderate alcohol intake is also associated with reduction in CHD among women with Type 2 diabetes mellitus, a population with high baseline risk for CHD, we studied diabetic participants in the Nurses' Health Study, a large prospective cohort study. During 20,370 person years of follow-up among 5103 women reporting a diagnosis of diabetes mellitus at age 30 years or older without a history of prior CHD, we documented 295 CHD events (194 cases of non-fatal myocardial infarction and 101 cases of fatal CHD). As compared with women reporting no alcohol consumption, the age-adjusted relative risk for non-fatal or fatal CHD among women reporting average daily alcohol intake 0.1–5 grams (less than half a typical alcoholic drink) was 0.74 (95% confidence interval [CI], 0.56–0.98), and, among those reporting 5 grams or more daily, was 0.48 (95% CI, 0.32–0.72) (p,trend < 0.0001). After adjusting for body mass index, smoking, family history of MI, and other potential confounders, corresponding relative risks for CHD were 0.72 (95% CI, 0.54–0.96) and 0.45 (95% CI, 0.29–0.68), respectively (p, trend 0.0003). While potential risks of alcohol consumption must be addressed in the setting of diabetes, these data suggest that moderate alcohol consumption is associated with reduced CHD risk in this population and should not routinely be discouraged.

P3562 Relation between the levels of folate in whole blood, homocysteine in serum, and risk for first acute myocardial infarction

D.S. Thelle, B. Christensen[1], J. Ringstad[2], L. Retterstøl[3], S. Djurovic[3], S. Landaas[4], I. Stensvold[1], K. Berg[3]. *Dept. of Epidemiologic Research, University of Oslo, Oslo; [1]Department of Preventive Medicine, Ullevål University Hospital, Oslo [2]Department of Infectious Diseases, Ullevål University Hospital, Oslo [3]Department of Medical Genetics, Ullevål University Hospital, Oslo [4]Department of Clinical chemistry, Ullevål University Hospital, Oslo, Norway*

High level of total homocysteine (tHcy) in plasma is a risk factor for coronary artery disease (CAD). The mechanism underlying the association between tHcy levels and CAD is not known although associations between tHcy, smoking, and other known risk factors including lipoproteins have been observed. While it is known that the intracellular metabolism of the vitamin, folate, is a major determinant for the level of tHcy in plasma, most studies of tHcy levels in CAD include measurements of folate in serum only.

We studied the levels of folate in whole blood and the serum concentration of tHcy, total cholesterol, high density lipoprotein cholesterol (HDLC), and apolipoprotein AI (Apo AI), in 107 patients who were hospitalized with their first acute myocardial infarction (MI) and in 103 controls. The mean level of whole blood folate was lower and that of serum tHcy was higher in cases than in controls. An inverse correlation was observed between the levels of whole blood folate and tHcy. Before adjustment for cigarette smoking logistic regression analysis revealed a significant association between the concentration of whole blood folate or tHcy and risk of first MI. The protective effect of folate remained after adjustment for tHcy concentration, but the effect of tHcy level on risk was not significant after adjustment for folate. Correlations were seen between the levels of whole blood folate and HDLC or Apo AI as well as between tHcy and HDLC or Apo AI. The number of cigarette smokers was significantly higher among MI cases. The level of tHcy was higher and that of whole blood folate was lower in smokers. After adjustment for smoking the risk for MI associated with whole blood folate or tHcy levels was non-significant. The results indicate that cigarette smoking may affect folate status and tHcy level adversely. Low folate or hyperhomocysteinemia may contribute to the risk of MI in smokers. There is evidence for interactive effects of folate, tHcy, and Apo AI in a process associated with the development of CAD.

P3563 Low serum folate levels are associated with an excess risk of acute coronary events: the Kuopio Ischaemic Heart Disease risk factor study (KIHD)

S. Voutilainen, T.A. Lakka, T. Rissanen, E. Porkkala-Sarataho, G.A. Kaplan[1], J.T. Salonen. *Research Institute of Public Health, University of Kuopio, Kuopio, Finland; [1]School of Public Health, Univarsity of Michigan, Michigan, USA*

A number of studies have noted higher levels of plasma total homocysteine concentration (tHcy) in cardiovascular disease patients, suggesting that elevated tHcy is a risk factor for atherosclerosis. Plasma tHcy levels may be elevated due to deficiences of enzyme activity in homocysteine metabolism or deficiencies of folic acid, vitamin B6 or B12, of which folic acid is considered the most important.

The purpose of this study was to test the hypothesis that low serum folate levels are associated with an increased risk of acute coronary events in men free of coronary heart disease. We investigated this association in a population based sample of 734 men aged 46–64 years as part of the Kuopio Ischaemic Heart Disease Risk Factor Study (KIHD).

The mean serum folate concentration was 10.4 nmol/l.We compared men in the highest third of serum folate concentration to those with lower serum folates. In a Cox model including age, examination years, body-mass index, and serum triglycerides, men with higher serum folate had 82.5% reduced (95% CI 25.1 to 95.9, p = 0.019) risk of acute coronary events compared with others. After adjusting for age, examination years and three nutritional factors, men with the higher serum folates had 81.0% reduced (95% CI 17.4 to 95.6, p = 0.027) risk of acute coronary events compared with other men. During the average follow-up of 4 1/3 years, two (0.8%) men with higher serum folates and 23 (4.7%) men with lower folates developed an acute coronary event.

This prospective cohort study in middle-aged men from Eastern Finland indicates that moderate-to-high levels of serum folate are associated with greatly reduced risk of acute coronary events. Although folic acid could lower the risk of coronary disease through reducing plasma homocysteine levels, homocysteine may also be only a marker for folate and vitamin B6 status rather than a causal risk factor. Intervention studies are required to test the effect of folic acid supplementation in the prevention of coronary disease.

P3564 Differentiation of the incidence of risk factors in the variable types of genetic dyslipidaemias

J. Skoumas, C. Pitsavos, M. Toutouza, J. Demellis, S. Paximadas, N. Giotsas, C. Vassiliadou, S. Vaina, C. Stefanadis, P. Toutouzas. *Department of Cardiology, Hippokration Hospital, Athens, Greece University*

Dyslipidemia is a main risk factor for coronary artery disease (CAD). The coexistence of other risk factors aggravate the prognosis. The purpose of the present study was to investigate the incidence of other risk factors in the different types of genetic dyslipidemias.

Method: We studied 831 patients (pts), without treatment. 351 pts with heterozygous familial hypercholesterolemia (hFH), 343 with familial combined hyperlipidemia (FCH) and 137 with familial hypertriglyceridemia (HTGL), mean age: 44.57 ± 10.74, 45.98 ± 8.93, 44.93 ± 9.72 years respectively, P = NS. Lipid plasma levels, thrombogenic factors [fibrinogen (FB) and Lp(a)], and somatometric factors [body mass index (BMI) and waist to hip ratio (W/H)] were measured in all pts. We also evaluated the incidence of arterial hypertension, diabetes mellitus, smoking and CAD.

Results: Somatometric and thrombogenic factors are shown in the table.

	hFH (1) (n = 351)	FCH (2) (n = 343)	HTGL (2) (n = 137)	P
Lp (a) (mg/dl)	41.2 ± 39.74	32.38 ± 36.56	24.89 ± 26.67	1 vs. 2: <0.0001 1 vs. 3: <0.0001 2 vs. 3: = 0.007
FB (mg/dl)	290.13 ± 56.07	293.43 ± 56.53	299.97 ± 65.14	NS
BMI (kg/m^2)	25.47 ± 3.76	27.48 ± 3.29	27.91 ± 3.45	1 vs. 2: <0.0001 1 vs. 3: <0.0001 2 vs. 3: NS
W/H	0.82 ± 0.09	0.88 ± 0.08	0.93 ± 0.07	1 vs. 2: <0.0001 1 vs. 3: <0.0001 2 vs. 3: <0.0001

The incidence of hypertension in the variable genetic types was 13.1% (46/351) in hFH, 37% (127/343) in FCH and 16.8% (23/137) in HTGL, (between groups, P < 0.0001). Respectively, diabetes mellitus was 2% (7/351) in hFH, 11.7% (40/343) in FCH and 24.8% (34/137) in HTGL, (between groups, P < 0.0001). The incidence of smoking was 31.6% (111/351) in hFH, 40.2% (138/343) in FCH and 51.1% (70/137) in HTGL (between groups, P < 0.0001). The incidence of CAD was 21.4% (75/351) in hFH, 16.3% (56/343) in FCH and 10.9% (15/137) in HTGL, (between groups, P < 0.0001),

Conclusion: hFH pts had higher incidence of CAD, but more favorable somatometric factors and lower incidence of arterial hypertension and diabetes mellitus. FCH pts had the highest incidence of arterial hypertension and the HTGL pts had the most unfavorable somatometric factors.

P3565 Medical history of hypercholesterolaemia adversely affects the outcome of pre-hospital cardiopulmonary resuscitation: the "SHAHAL" experience in Israel

A. Roth, M. Golovner, D. Gavish, N. Malov, J. Sender, I. Alroy, E. Kaplinsky, S. Laniado. *Departments of Cardiology and Internal Medicine D, The Tel-Aviv Sourasky Medical Center and Department of Cardiology, the Sheba Medical Center, the Sackler Faculty of Medicine, Tel-Aviv University, and "SHAHAL" Medical Services, Tel-Aviv, Israel*

Purpose: to evaluate the impact selected risk factors for cardiac death may have on the success rate in a large cohort of subscribers to 'SHAHAL' who were resuscitated from out-of-hospital cardiac arrest.

Methods: In this medical facility currently serving 50,000 subscribers, data were prospectively gathered from its establishment in 1987 to December, 1998. The information retrieved from the patient's medical record included a medical history of hypertension, diabetes, hypercholesterolemia (>220 mg/dL), smoking, angina, previous myocardial infarction, and congestive heart failure. The reporting of pertinent time intervals was taken from a form designed for precise listing of the sequences of events and actions taken from the moment of collapse.

Results: A total of 998 patients aged 74 ± 12 years (mean ± 1 SD) were included. Death was announced at the scene for 659 (66%) victims, while 339 (34%) patients were taken to hospital. Of these, 140 (14% of the total cohort) survived and were discharged from hospital.

A comparison of various selected parameters between survivors and non-survivors of resuscitation revealed that survivors were younger, had a higher rate of pulseless ventricular tachycardia/ventricular fibrillation, more were among the arrests witnessed by the 'SHAHAL' team, and that more had a shorter time lag to initiation of cardiopulmonary resuscitation than non-survivors. None of the studied risk factors predicted outcome of cardiopulmonary resuscitation with the exception of hypercholesterolemia, which carried a significantly worse prognosis for cardiopulmonary resuscitation ($p = 0.009$).

In conclusion, history of hypercholesterolemia appears to be an important risk factor which adversely affects the outcome of cardiopulmonary resuscitation.

P3566 Long-term stability of lipoprotein(a) levels in healthy young subjects with parental myocardial infarction: a five-year follow-up

G. Gaeta, S. Cuomo, F. Boeri[1], F. Scotto di Uccio, A. Boccalatte, M. Trevisan[2]. *Cardiologia, Antonio Cardarelli Ospedale, Naples; [1]Laboratorio Analisi Cliniche, Antonio Cardarelli, Naples, Italy; [2]Social and Preventive Medicine Dept, State University of New York, Buffalo, USA*

Background: The "tracking" phenomenon of cardiovascular risk factors (i.e. blood pressure or cholesterol levels) is well understood. Less is known about the stability over time of lipoprotein(a) [Lp(a)], another independent risk factor for cardiovascular disease. Aim of this study was to evaluate, in healthy young subjects with parental myocardial infarction (PMI), the correlation between Lp(a) levels at baseline and five years later.

Method: In twenty-three healthy young subjects with PMI (6 M, 17 F) serum Lp(a) levels were measured at baseline (mean age 15 ± 6 years) as well as after a 56 ± 9 months follow-up (range 46 to 77 months). Lp(a) concentration was determined by a nephelometric assay. Because Lp(a) levels show no normal distribution, values were Log transformed.

Results: There was an high correlation between the Log Lp(a) concentrations at baseline and five years later ($r = 0.918$, $p < 0.001$). All the 12 subjects with Lp(a) levels < 25 mg/dl at baseline had Lp(a) levels < 25 mg/dl at five-year follow-up; moreover, all the 11 subjects with Lp(a) levels > 25 mg/dl at baseline had Lp(a) levels > 25 mg/dl five years later ($p < 0.00001$; diagnostic accuracy: 100%).

Conclusions: In healthy young subjects with PMI, baseline Lp(a) levels were strong predictive of Lp(a) values determined five years later. Therefore, Lp(a) levels are stable over time.

P3567 Gender-related differences in serum levels of lipoprotein(a) in healthy young subjects with a history of parental myocardial infarction

G. Gaeta, S. Cuomo, F. Boeri[1], L. Effuso, F. Scotto di Uccio, A. Boccalatte, M. Trevisan. *Cardiologia, Antonio Cardarelli Ospedale, Naples; [1]Laboratorio Analisi Cliniche, Antonio Cardarelli, Naples, Italy*

Background: The Bogalusa Heart Study demonstrated that lipoprotein(a) [Lp(a)] levels are significantly related to a family history of parental myocardial infarction (HPMI) in white children, without gender-associated differences. Aim of the present study was to determine if Lp(a) serum levels would be different among men and women with HPMI.

Methods: Serum concentrations of Lp(a) and other lipids were measured in 173 healthy young subjects with HPMI (Cases; 81 M, 92 F; mean age 18 ± 6 years; 22% current smokers) and in 173 healthy young subjects without HPMI (Controls) matched for age, gender and smoking status. Because Lp(a) and triglycerides did not show a normal distribution, log transformation was used.

Results: Among men, Cases had higher apo B levels than Controls (94 ± 30 vs. 83 ± 21 mg/dl, $p = 0.006$) while total cholesterol, HDL cholesterol, LDL cholesterol, Log Lp(a), apo A1 and Log triglycerides did not differ between the two groups. Among women, Cases showed not only higher apo B levels (89 ± 25 vs. 81 ± 22 mg/dl, $p = 0.003$) but also higher Log Lp(a) values (1.25 ± 0.44 vs. 1.08 ± 0.48, $p = 0.018$) than Controls.

Conclusions: HPMI is associated with increased Lp(a) levels among women only. These results suggest that in healthy young subjects with HPMI measurement of Lp(a) should be performed only in women.

P3568 Serum lipoprotein(a) in healthy young subjects with family history of myocardial infarction is predicted by parental lipoprotein(a) level

G. Gaeta, S. Cuomo, M.C. Foglia[1], M.L. Genna[1], L. Effuso, F. Scotto di Uccio, A. Boccalatte, M. Trevisan[2]. *Cardiologia, Antonio Cardarelli Ospedale, Naples; [1]Laboratorio Analisi Cliniche, Antonio Cardarelli, Naples, Italy; [2]Social and Preventive Medicine Dept, State University of New York, Buffalo, USA*

Background: High serum concentrations of lipoprotein(a) [Lp(a)] are an independent predictor of premature myocardial infarction (MI). In addition, is now recognized that children of patients with MI (C) deserve aggressive screening. In order to provide the best treatment for primary prevention of MI, aggressive measures should be taken to identify C at major risk.

Methods: We evaluated the serum concentrations of Lp(a) in 36 patients (33 M, 3 F; mean age 48 ± 6 years), at least 6 weeks after an acute MI, and the lipid profile in their 85 healthy C.

Results: Serum Lp(a) was raised (>30 mg/dl) in 13 patients, who had 33 C (C+) admitted to the study (15 M, 18 F; age 19 ± 5 years) and resulted normal in 23 patients, who had 52 C (C−) enrolled in the study (24 M, 28 F; mean age 19 ± 5 years. Total cholesterol, HDL cholesterol, LDL cholesterol, Log triglycerides, apo A1 and Apo B did not differ between C+ and C−. In contrast, C+ showed significantly higher Log Lp(a) levels (1.45 ± 0.46 vs 0.91 ± 0.36, $p < 0.001$) and had more frequently raised Lp(a) levels than C− (17/52 vs 3/33, $p < 0.001$; RR 17.3, 95% CI 4.5–67).

Conclusions: These findings may have clinical implications: high Lp(a) levels in patients with MI seem to be a good predictor for high Lp(a) levels in their C, who may deserve more aggressive preventive measures.

GENERAL ASPECTS OF MYOCARDIAL PERFUSION SCINTIGRAPHY

P3569 The ROBUST study: a randomised comparison of three tracers for myocardial perfusion scintigraphy

A. Kapur, K.A. Latus, G. Davies, P.H. Jarritt[1], M.C. Young, G. Roussakis, D.J. Pennell, P.J. Ell[1], S.R. Underwood. *Department of Nuclear Medicine, Royal Brompton Hospital, London; [1]Institute of Nuclear Medicine, University College Medical School, London, UK*

Background and Methods: There are no large studies available to guide the selection of thallium (Tl), MIBI, or tetrofosmin (Tf) for myocardial perfusion imaging. We have randomised 2540 patients to receive one of the three during routine imaging. A one day stress/rest protocol was used for MIBI and Tf. Tomograms were scored visually in 17 segments and defects were quantified from a polar plot. Quality and artefact scores were assigned (0 to 3), and ratios of heart (H), liver (L), sub-diaphragmatic (S) and lung activity were measured.

Results: The groups were similar in terms of risk factors for coronary artery disease and proportion of abnormal studies. Mean quality scores were Tl 2.13, MIBI 2.29, Tf 2.30 ($P < 0.001$). For attenuation artefact MIBI = Tf<Tl ($P < 0.05$) and for low count artefact Tf<MIBI<Tl ($P < 0.001$). For H/S, Tl>MIBI = Tf, for H/L Tl>Tf>MIBI, and for H/Lung Tf>Tl = MIBI (max $P < 0.02$). Stress defects in the abnormal scans were more severe for Tl than for the other tracers (mean summed score out of 68: Tl 51.8, MIBI 54.7, Tf 55.3, $P < 0.01$), but mean rest scores were similar (Tl 60.2, MIBI 59.1, Tf 58.5, P = NS). In the subset of patients without prior infarction who underwent coronary angiography within 3 months of perfusion imaging, accuracy of each tracer for detecting angiographic disease was the same (sensitivity 90% Tl, 100% MIBI, 95% Tf, specificity 86% for all three).

Conclusion: We conclude that there are technical differences between the tracers. They all perform well in clinical terms, but overall image quality score is superior using technetium.

P3570 A prospective multi-centre comparison of Tc-99m-sestamibi and Tc-99m-tetrofosmin for the assessment of mild to moderate coronary artery disease by dipyridamole SPECT imaging

P. Soman, R. Taillefer, J. Udelson, G.E. DePuey, A. Lahiri. *Northwick Park Hospital, Harrow, UK; Hôtel Dieu de Montreal, Montreal PQ, Canada*

The extraction fraction of Tc-99m tetrofosmin (TETRO) is lower than that of Tc-99m sestamibi (MIBI) and its myocardial uptake may plateau at lower blood flow levels. Whether these biokinetic differences affect the relative ability of these two tracers to detect mild to moderate coronary artery disease (CAD) and reversible ischaemia is unknown. Accordingly, dipyridamole SPECT imaging with both agents was performed in 81 patients with recent (<2 months) coronary arteriographie eveidence of 50–90% stenosis in one or two vessels and 7 patients with <5% likelihood of CAD. Patients with left mainstem or 3 vessel disease and previous myocardial infarction were excluded. The MIBI and TETRO studies were carried out in random order, within a week of each other and reported by a blinded panel using a 17 segment LV model, with the aid of quantitative anaylses.

Results:

	MIBI	TETRO	P value
Sensitivity	63% (51/81)	58% (47/81)	0.09
Specificity	57% (4/7)	57%	ns
Segments with reversible segments	363	285	<0.0001
Defect extent (% LV involved)	15.8 ± 12.3%	12 ± 11.9%	<0.03
Defect severity (Ischaemic/normal wall ratio)	0.60 ± 0.15	0.73 ± 0.14	0.01

Therefore MIBI may be superior to TETRO for the assessment of mild to moderate CAD by dipyridamole SPECT imaging. These findings may have important diagnostic and prognostic implications.

P3571 Does the presence of diabetes mellitus change the predictability of significant coronary artery stenoses by 99m-Tc-MIBI myocardial perfusion imaging?

C.R. Kühn, V. Karnowski, J. Mattes, C. Fünsterer[1], M. Pressler[1]. *Center for cardiology; [1]Dr. Pressler/Fünsterer; Hamburg, Germany*

Patients with diabetes mellitus are prone to diffuse and multivessel coronary disease. Therefore the sensitivity and specifity for detection of coronary artery disease (CAD) by 99m-Tc-MIBI myocardial perfusion imaging (MIBI-SPECT) could be altered in diabetics.

Methods: 1000 consecutive patients (pat.) with suspected CAD underwent MIBI-SPECT and coronary angiography for detection of significant coronary artery stenoses (>70% lumen diameter stenosis). Patients were analyzed as a cohort and regarding the prevalence of diabetes.

Results:

	All	Diabetics	Non-Diabetics	
Number of patients (n)	1000	116	884	
Coronary stenoses > 70% (%)	53	*68*	*51*	*p < 0.001*
Women (%)	27	31	27	
Criterion of ischemia: *any perfusion defects*				
Sensitivity (%)	94.9	94.9	94.9	p > 0.05
Specificity (%)	57.2	56.8	57.2	p > 0.05
Positive pred. value (%)	71.7	*82.4*	*70.1*	*p < 0.02*
Negative pred. value (%)	90.8	84.0	91.4	p > 0.05
Criterion of ischemia: *stress/rest mismatch*				
Sensitivity (%)	74.3	70.9	74.9	p > 0.05
Specificity (%)	83.1	86.5	82.8	p > 0.05
Positive pred. value (%)	83.0	91.8	82.1	p > 0.05
Negative pred. value (%)	74.0	*58.2*	*75.7*	*p < 0.001*

Conclusion: The differences in positive and negative predictive values are due to the higher prevalence of significant CAD in diabetics. The potential of MIBI-SPECT to predict the presence of significant coronary artery stenoses (sensitivity and specificity) is not deminished in patients with diabetes mellitus.

P3572 Cardiac normality in myocardial perfusion imaging: patients with normal coronary angiography are better than healthy volunteers with a low likelihood of coronary artery disease

J. Toft[1,2], D. Lindahl[3], M. Olsson[3], J. Palmer[5], A. Lundin[4], B. Hesse[1], L. Edenbrandt[3]. *[1]Dept. of Clinical Physiology and Nuclear Medicine KF, Center of Engineering, Informatics and Imaging; [2]Dept. of Cardiology, the Heart Center, Rigshospitalet, Denmark; [3]Dept. of Clinical Physiology; [4]Radiology; [5]Radiation Physics, Lund University, Lund, Sweden*

The optimal reference standard in noninvasive stress testing has been disputed for years. Mainly two criteria have been used: patients with a normal coronary angiography (CAG) and subjects with a low likelihood for coronary artery disease (CAD). Especially the criterion based on a normal CAG has been criticized, since the subjects referred to CAG typically usually have some symptoms in spite of a normal CAG, indicating that they may not be representative for the normal population and may represent a "too sick" part of this population. Thereby the criterion for cardiac normality should be too broad. The purpose of the present study was to compare two different criteria of cardiac normality: normal CAG versus low CAD likelihood.

Methods: An artificial neural network was trained on myocardial SPECT studies from 87 patients with angiographically documented CAD and on studies from two different normal groups: 48 patients with no signs of CAD based on CAG or 128 volunteers without any symptoms and a likelihood for CAD less than 5%. The performance of the network trained on either a patient group with a normal CAG or volunteers with a CAD likelihood of less than 5% was then tested on scintigrams from 68 patients referred for CAG without prior myocardial infarction or bypass surgery. CAG was used as gold standard in this group and a diameter reduction of >50% was regarded as significant.

Results: The ROC-area for the network was 94% using patients with a normal CAG versus 74% using subjects with a low likelihood of CAD. $P < 0.01$.

Conclusion: Our results indicate that when the criterion for significant CAD is based on an abnormal CAG a criterion for cardiac normality based on a normal CAG should be preferred, even though theoretical considerations may favorite subjects a low likelihood of CAD. The explanation may be related to the fact that the images of myocardial perfusion and of coronary arteries contain different information.

P3573 Usefulness of exercise tomographic Tc-99m-tetrofosmin imaging for detection of restenosis after coronary stent implantation

A.R. Galassi, G. Iabichella, R. Foti, B. Santangelo, G. Rodi, S. Musumeci[1], C. Tamburino, G. Giuffrida. *Institute of Cardiology, Ferrarotto Hospital; [1]Chair of Nuclear Medicine, University of Catania, Italy*

Background: After coronary stent implantation restenosis rate during the first 6 months still remains between at 20% and 30%. Exercise myocardial perfusion scintigraphy may be a valid alternative to invasive strategies for a close follow-up of such patients. The purpose of the study was to assess prospectively the accuracy of exercise ^{99m}Tc-tetrofosmin SPECT for detecting restenosis in patients after coronary stent implantation.

Methods: In 52 patients (mean age 58 ± 12 years) an exercise ^{99m}Tc-tetrofosmin SPECT scintigraphy was performed prospectively to evaluate 57 vascular territories with stents. The average interval between the stent implantation and the scintigraphic study was 111.9 ± 57.3 days while that from the scintigraphic study to coronary angiography 47.9 ± 14.9 days. A reversible exercise-induced perfusion defect within the segments matched to individual stented vessel was used as the criterion of stent restenosis.

Results: With SPECT scintigraphy, 14/18 vascular territories with 50% angiographic restenosis showed exercise-induced reversible perfusion abnormalities (sensitivity = 78%), while 35/39 territories without restenosis did not (specificity = 90%). Predictive accuracy was 86%. In 24 patients who underwent stenting for complete revascularization sensitivity and specificity for stent restenosis were 9/10 (90%) and 16/18 (89%), while in the remaining 28 patients with partial revascularization 5/8 (63%) and 19/21 (90%), respectively.

Conclusions: Exercise ^{99m}Tc-tetrofosmin SPECT imaging can accurately predict restenosis in patients after coronary stent implantation. This method is most sensitive for evaluating patients who undergo stenting for complete revascularization.

NON-INVASIVE IMAGING OF CORONARY ARTERIES AND CORONARY FLOW

P3574 Correlation of three-dimensional magnetic resonance coronary angiography with selective coronary angiography: impact of the novel motion adapted gating technique

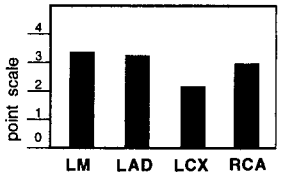
T. Dill, C. Weber, R. Sinkus[2], P. Steiner, P. Börnert[2], T. Meinertz, C.W. Hamm[1]. *University Hospital, Hamburg; [1]Kerckhoff Klinik, Bad Nauheim; [2]Philips Research Laboratories, Hamburg, Germany*

Reliable noninvasive assessment of coronary artery stenoses and occlusions with MRI in patients with known or suspected coronary artery disease would be an advantage. So far, inconsistent breathholding impairs image quality. The impact of the novel respiratory motion compensation (Motion Adapted Gating, MAG) for visualization of coronary arteries (CA) was verified in this study by correlation with selective coronary angiography (SCA) findings.

Methods: 20 subjects (10 patients/10 healthy volunteers), age 52 ± 20 yrs. were investigated. All patients had MRI and CA within 2 weeks. A Philips Gyroscan ACS-NT (Philips Medical Systems, Best, The Netherlands) operating at 1.5 T, equipped with the PowerTrak 6000 gradient system providing 23 mT/m within 0.2 ms, was used. A newly developed MRI protocol consists of a 3D TFE ECG triggered and respiratory motion gated sequence. Repiratory motion was obtained from 3 pencil navigator beams interleaved with one R-R interval. The real-time gating algorithm utilizes the concept of k-space weighing in combination with an automatic analysis of the respiratory motion.

The three main CA and left main (LM) were evaluated. The results of the patient group were compared to SCA. Qualitative analysis of volunteer and patient data was performed by two blinded investigators.

Results: All 80 CA were adequately visualized. Visibility was graded on a four point scale (1 = insufficient, 2 = sufficient, 3 = good, 4 = excellent) (see figure).



Evaluation of coronary artery stenoses (luminal narrowing > 50%) is best in the LM and the proximal part of LAD, LCX and RCA (5/5 stenoses were correctly detected) still of good quality in the middle part (4/5 stenoses were correctly detected) but of less diagnostic accuracy in the distal portion.

Conclusion: MRI with MAG demonstrates to be a promising new technique for noninvasive imaging of CA with high patient comfort (breathholding is not nescessary). Adequate image quality for LM and proximal and middle segments of the main CA was achieved. Stenoses were in 90% correctly assesed. The clinical impact has to be verified.

P3575 Magnetic resonance coronary angiography with targeted volume scans (VCATS): preliminary clinical results

R.J.M. van Geuns, P.A. Wielopolski[1], B.J.W.M. Rensing, H.G. de Bruin[1], P.M.A. van Ooijen, M. Oudkerk[1], P.J. de Feyter. *Cardiology, Thoraxcentrum, Bd 377, University Hospital Rotterdam, Rotterdam; [1]Radiology Dept., Dr Daniel den Hoedkliniek, Rotterdam, Netherlands*

Background: Magnetic resonance coronary angiography (MRCA) with breathhold two-dimensional and respiratory gated three-dimensional (3D) techniques has yielded unsatisfactory results. We developed a new strategy which we refer to as Volume Coronary Angiography using Targeted Scans (VCATS), which uses a small targeted volume to cover one coronary segment in a single breathhold. We report the preliminary clinical results for the detection of stenoses of >50% luminal diameter reduction.

Methods: 34 patients referred for elective coronary angiography (CAG) were examined with several targeted volume scans along the major coronary branches, using a 3D segmented

gradient echo sequence (resolution 1.9 × 1.25 × 1.5 mm)optimal orientations along the coronary arteries were obtained from a single breath-hold 3D localizer scan covering the entire heart. CAG served as the goldstandard for the determination of the diagnostic value of MRCA. Proximal, mid and distal segments of the right coronary artery (RCA), left main (LM) and proximal and mid segments of the left anterior descending (LAD) and left circumflex (LCX) coronary artery were evaluated by a radiologist and a cardiologist blinded for the results of the CAG.

Results: The imaging protocol was completed within 30 minutes. Adequate visualization was obtained in 187 (69%) of the major coronary segments. Overall diagnostic accuracy was 92% with a sensitivity and specificity of 68% and 92%, respectively. Data for the segments in the 3 coronary branches are listed in the table.

	Visualized	Sensitivity	Specificity	PV+	PV−	Acc
LM + LAD	91 (89%)	77%	97%	83%	92%	91%
RCA	68 (67%)	64%	94%	75%	91%	88%
LCX	31 (46%)	50%	100%	100%	93%	94%
Overall	187 (69%)	68%	97%	81%	94%	92%

Conclusion: VCATS adequately visualizes the major coronary arteries in the majority of the patients. The observed accuracy for the detection of significant coronary lesions is encouraging, but should increase before reliable use in a clinical setting is possible.

P3576 Evaluation of coronary bypass grafts by navigator echo magnetic resonance angiography

G. Molinari, F. Sardanelli[1], F. Zandrino[1], D. Bartolini, M.A. Masperone. *Department of Cardiology; [1]Department of Diagnostic Imaging; University of Genoa, Italy*

The development of nonivasive procedures to assess coronary artery bypass grafts (CABGs) is an emergent medical need. The purpose of this study was to validate respiratory gated (navigator echo) magnetic resonance angiography (MRA) in detecting occlusion/patency of CABGs.

Methods: 20 patients with previous history of CABG surgery and recurrent episodes of chest pain were enrolled. Two patients could not be studied (claustrophobia, erratic breathing). Thus, 18 patients with 51 CABGS were examined using a non-velocity-compensated electrocardiographically-triggered and respiratory-gated (navigator echo) three-dimensional gradient echo fat-suppressed sequence: 21 arterial grafts (6 sequential) and 30 saphenous vein grafts (5 sequential). All patients had undergone contrast conventional angiography (CCA) 3–15 days before MRA. The MR data set was analyzed by two independent readers blinded to the CCA results (occlusion of 12 of 51 grafts).

Results: at MRA, 2 CABGs of the posterior descending artery, patent at CCA, could not be visualized because of imaging slab malpositioning. Interobserver concordance was 96% (47/49). After consensus MR reading, MRA and CCA provided identical answers in 47 out of 49 (96%) (of the examined grafts. Eleven out of 12 occluded grafts and 36 out of 37 patent grafts were correctly identified with MR. As far as occlusion is concerned, the sensitivity of MR angiography was 91%, the specificity 97%.

In conclusion, this experience establishes that a 30 minutes outpatient MRA examination without contrast agent administration is highly reliable in determining occlusion/patency of arterial and venous, single and sequential CABGs.

P3577 Magnetic resonance coronary angiography in patients with ST-T changes during exercise

Y. Kondo, M. Nomura, H. Miyajima, T. Nada, M. Yukinaka, S. Ito, Y. Nakaya[1]. *Second Department of Internal Medicine, University of Tokushima, Tokushima; [1]Department of Nutrition, University of Tokushima, Tokushima, Japan*

Purpose: A False positive exercise test represents a serious diagnostic problem and the mechanism by which this results has not been clarified. It is difficult to discriminate between effort angina pectoris (AP) and microvascular angina pectoris (MVA). We evaluated coronary circulation in patients with exercise-induced ST depression using magnetic resonance coronary angiography (MRCA).

Methods: Twenty healthy subjects (N group) and 25 patients showing ST depression greater than 1 mm during a treadmill exercise test were studied. Of these, 18 patients showed significant stenosis (AP group) and 7 did not (MVA group), as evidenced by coronary angiography. MRCA was performed with a Signa Horizon (1.5 Tesla, G.E.). Cross sections of left and right coronary arteries were obtained, and a flow velocity measurement was obtained using segmented k-space fast gradient-echo phase contrast. The washout rate (%WR) was also calculated by 123I-beta-methyliodophenyl pentadecanoic acid myocardial scintigraphy.

Results: Coronary blood flow pattern displayed two peaks, with the diastolic peak velocity being greater than that of systolic in normal subjects. Diastolic peak velocity was not significantly different for the N and the MVA group (24.6 ± 3.4, 21.3 ± 4.8 cm/sec), but was significantly lower in the AP group (17.4 ± 5.5 cm/sec; $p < 0.01$). However, diastolic/systolic velocity ratio was significantly lower ($p < 0.05$) in the MVA group (1.50 ± 1.10), as compared with the N group (1.68 ± 0.19). The%WR were significantly higher in the MVA group, compared to N group (16.4 ± 7.3, 10.0 ± 6.4%, $p < 0.05$).

Conclusion: The patients, who showed ST depression during an exercise test but did not show any significant stenosis in coronary angiography, showed abnormal blood flow velocity of the coronary arteries, suggesting that dysfunction in myocardial microvascular perfusion might be the cause of abnormal ST changes in these patients.

P3578 Non-invasive coronary angiography by contrast-enhanced electron-beam computed tomography in patients after acute myocardial infarction

S. Achenbach, D. Ropers, W. Moshage, G. Muschiol, W.G. Daniel.
Department of Internal Medicine II (Cardiology), University of Erlangen-Nuremberg, Germany

Electron-beam computed tomography (EBCT) is a cross-sectional imaging method which, after intravenous injection of contrast agent, permits non-invasive visualization of the coronary artery lumen. So far, the accuracy of EBCT coronary angiography has been evaluated only in patient groups with a relatively low prevalence of significant stenoses. We therefore investigated the value of EBCT to detect high-grade coronary artery stenoses and occlusions in patients after acute myocardial infarction (AMI).

Methods: 35 patients (28 male, 7 female, mean age: 53 years) were studied 4–70 days after AMI. 40 to 50 axial cross-sections of the coronary arteries were acquired triggered to the ECG in breathhold (3 mm slice thickness, 1 mm overlap, 140–160 ml of contrast agent i.v.). Both the original images as well as thresholded 3-D surface reconstructions of the heart and coronary arteries were evaluated as to the presence of high-grade coronary artery stenoses and occlusions in the proximal and mid sections of the coronary arteries. Results were compared to invasive coronary angiography in a blinded fashion.

Results: A total of 140 coronary arteries had to be assessed (left main, LAD, LCX and RCA in 35 patients). 29 coronary arteries (21%) could not be evaluated due to inadequate image quality caused by motion, severe calcifications, or low contrast-to-noise ratio. In the remaining 111 arteries, sensitivity of EBCT to detect high-grade stenoses and occlusion was 94% (31/33), specificity was 91% (71/78), the negative and positive predictive values were 97% and 82%, respectively.

In conclusion, electron beam CT confirmed its high accuracy for the detection of coronary artery stenoses and occlusions in a patient group with high prevalence of significant coronary artery lesions.

P3579 Assessment of blood flow and flow reserve in coronary grafts using breath-hold phase-contrast magnetic resonance angiography in patients with bypass stenosis

A. Furber, F. Lethimonnier, J.J. Le Jeune, P. L'hoste, A. Tadei, P. Jallet, C. Caron-Poitreau, P. Geslin. *University Hospital of Angers, France*

Direct visualization of coronary bypass graft patency can be obtained non-invasively by MRI. But detection of graft stenosis is not reliably. The purpose of this study was to evaluate the feasibility of MR flow velocity and flow reserve measurements in coronary grafts in order to detect graft stenosis.

Methods. In 17 patients (mean age 65 ± 12 years) 47 coronary grafts (34 vein grafts and 13 internal mammary grafts) underwent conventional angiography and MRI at rest and during intravenous adenosine induced hyperemia. MR imaging was performed on a 1.5 T clinical imager with Torso phased array coil. The phase contrast pulse sequence (FASTCARD PC) was employed in breath-hold with 10 to 25 temporal phases with 4 view per segment, flip angle 20 deg., acquisition matrix 256 × 128, and one excitation. Field of view, TE, TR were 40 × 30 cm, 3.5 ms, 12 ms.

Results. Phase-contrast MR angiography detects coronary graft patency with high sensitivity (93%) and specificity (93%). MR angiography identified only 4 out of 8 graft stenoses. In patients without graft stenosis, mean hyperemic average peak velocity (APV) (11.0 ± 5.3 cm/s) differed from resting APV (6.1 ± 3.1 cm/s). In patients with graft stenosis, the mean APV was 5.6 ± 3.9 cm/s in the basal state and 5.6 ± 3.3 cm/s after pharmacological stress. The coronary flow reserve was higher in patients without graft stenosis than in patients with graft stenosis (2.1 versus 1.0).

Conclusion. Phase-contrast MR imaging is a noninvasive technique which can provide assessment of coronary graft blood flow velocity and vasodilator flow reserve and seems to be able to differenciate abnormal from normal coronary bypass graft.

P3580 Non-invasive haemodynamic assessment of coronary grafts using magnetic resonance imaging

T. Voigtländer, K.-F. Kreitner[1], T. Wittlinger, J. Scharhag, N. Abegunewardene, G. Rippin[2], W. Schreiber[1], M. Thelen[1], J. Meyer. *2nd Medical Clinic; [1]Clinic for Radiology; [2]Institute for Statistics, University Mainz, Germany*

Magnetic resonance (MR) imaging provides techniques for the noninvasive hemodynamic assessment of coronary grafts. We studied changes of flow and flow velocity using adenosin in normal and diseased coronary grafts.

Methods: In 27 patients 32 coronary grafts (10 internal mammary grafts to LAD, 7 vein grafts to LAD, 15 vein grafts to RCA and CX) were investigated. Using MR phase change technique (Siemens 1.5 T; TR 110 ms, BH) measurements of mean velocity, peak velocity and mean flow were performed. The measurements were repeated during adenosin infusion and ratios for each parameter were calculated in order to obtain flow and velocity reserves (CFR). Based on cardiac catheterization performed within 24 hours results were analyzed for normal grafts (n = 27) and compared with the values for grafts with high grade stenosis (>75%; n = 5).

Results: In normal coronary grafts adenosin infusion significantly increased peak and mean velocity and the mean flow:

n = 27	basal	adenosin	p-value
Mean flow	1.15 ± 0.9	2.92 ± 1.4	0.0001
Mean velocity	5.49 ± 4.4	12.1 ± 9.6	0.0001
Peak velocity	7.12 ± 3.2	11.06 ± 4.3	0.0012

CFR based on mean flow measurement was significantly different between normal and diseased grafts (3.59 ± 2.60 vs. 0.75 ± 0.50; $p < 0.0001$) as it was analyzing the mean velocity (3.09 ± 2.12 vs. 0.75 ± 0.50; $p < 0.0001$). CFR based on peak velocity was not significantly different between both groups (1.46 ± 0.55 vs. 0.79 ± 0.35; n.s.).

Conclusion: Normal grafts are characterized by a significant increase of flow parameters during adenosin infusion which is demonstrated noninvasively by MR phase change technique. High grade graft stenosis can be detected by reduced MR mean flow and mean velocity reserve.

P3581 Magnetic resonance flow mapping versus intracoronary Doppler guide wire in the assessment of coronary peak velocity

W.L.F. Bedaux[1], M.B.M. Hofman[2], A.C. van Rossum[1], C.A. Visser[1]. *[1]Dept. of Cardiology; [2]Clinical Physics & Informatics, University Hospital Vrije Universiteit, Amsterdam, Netherlands*

Purpose: Doppler Guide Wire (DGW) measurements during catheterization allow quantifying Averaged Peak Flow Velocity (APFV) in coronary arteries as an indicator for the physiologic significance of coronary artery stenosis. With magnetic resonance (MR) flow mapping it is possible to quantify this flow velocity in a noninvasive manner. We compared these two techniques to assess the APFV in patients known with ischemic heart disease.

Methods: The study included 10 patients all referred for elective diagnostic coronary angiography for evaluation of chest pain. During catheterization the APFV was measured with a Doppler Guide Wire distal from the stenosis and in a healthy reference artery. Within the same week all individuals underwent a MRI. From series of anatomic images the LAD and RCA were visualized. Perpendicular to the vessel MR phase contrast velocity mapping was performed within a breath-hold at the same location as the DGW measurement. A Region of Interest (ROI) was drawn around the vessel and nearby located myocardial tissue, to analyze the flow data and correct for myocardial motion.

Results: Flow measurements were acquired from 21 segments in the RCA and LAD, % stenosis varied from 0–99%. The mean $APFV_{MRI}$ was 21 cm/s (range 8–45 cm/s) and mean $APFV_{DGW}$ was 23 cm/s (range 7–73 cm/s). Bland-Altman analysis showed a mean difference between the two techniques of 2 ± 10 cm/s. There was no significant effect in this comparison depending on the location of the segments.

Conclusion: In patients with coronary artery stenosis noninvasive MR flow velocity quantification provides equivalent data to those acquired with DGW measurements. Assessment of the peak velocity gives an impression of the physiologic significance of coronary artery stenosis.

P3582 Approximation to diastolic coronary flow velocity from illegible recording by transthoracic pulsed Doppler echocardiography

S. Kuriki, M. Nasu, M. Ito, N. Yashima, A. Tashiro, N. Sato, H. Mukaida, H. Yamaguchi, K. Fukami, K. Hiramori. *Second Department of Internal Medicine, Iwate Medical University, Morioka, Japan*

Background: Although recent ultrasound instrument with high-sensitive Doppler enables to visualize epicardial coronary artery, coronary flow velocity is not always recorded completely during a whole diastole by transthoracic pulsed Doppler echocardiography (TPDE). We hypothesized that the deceleration curve of diastolic coronary flow velocity is linear, and that approximate diastolic peak and mean velocity may be measured from the linear deceleration line.

Subjects and method; First, we analyzed thirty complete diastolic envelopes of proximal left anterior descending coronary artery (LAD) flow in 20 patients by TPDE and measured diastolic peak and mean velocity (DPV, DMV) in each envelope. The linear deceleration line (DcL) was derived from two velocities at mid- or late diastolic phase in the envelope. The approximate diastolic peak velocity (ADPV) was measured at the time of aortic valve closing in DcL and approximate diastolic mean velocity (ADMV) was calculated from (diastolic TVI)/(diastolic time). We estimated the relationship between DPV and ADPV and between DMV and ADMV. Secondary, we measured coronary flow reserve (CFR) by Doppler guide wire method (DGW) and by TPDE in 6 other patients.

Results; ADPV agreed well with DPV ($r = 0.99$, $p < 0.001$, mean difference = 2.2 ± 4.5 cm/s), and ADMV also agreed with DMV ($r = 0.99$, $p < 0.001$, mean difference = 1.1 ± 3.9 cm/s). There was a significant correlation between CFR by TPDE (ADMV) and CFR by DGW ($y = 0.90x + 0.25$, $r = 0.84$, $p < 0.001$).

Conclusion; The diastolic coronary flow velocities estimated from illegible envelope by transthoracic Doppler echocardiography could be substituted for true velocities to calculate CFR.

IMAGING OF MYOCARDIAL METABOLISM AND INNERVATION: PET, MRI AND ECHO

P3583 Increased myocardial glucose-uptake after percutaneous myocardial laser revascularisation in patients with end-stage coronary artery disease

F. Stahl, U. Junghans, B. Beuthien-Baumann[1], Regine Kluge[2], B. Lauer, G. Schuler. *Dept. of Cardiology, Heart Center; [2]Dept. of Nuclear Medicine, Univ. of Leipzig; [1]PET-Center Rossendorf, Univ. of Dresden, Germany*

Background: Percutaneous myocardial laser revascularisation (PMR) in patients with refractory angina pectoris due to end-stage coronary artery disease not amenable to angioplasty or bypass surgery leads to improvement of clinical symptoms and increased exercise capacity. Pathophysiological mechanisms are not yet clear.

Methods: 11 patients (P) underwent positron emission tomography (PET) with 18-Flour-Desoxyglucose (FDG) and thallium-scintigraphy before and three months after PMR. FDG- and thallium-uptake in the PMR-target region (TR) were quantitated and compared with the non-treated non-ischemic septum (S).

Results: At baseline FDG-uptake in the TR (19.22 ± 12.2 mmol/100 g/min) was slightly lower than in the S (26.6 ± 13.4 mmol/100 g/min) ($p < 0.08$). 3 months after PMR relative FDG-uptake in the TR increased from 72.2 ± 24.7% to 79.9 ± 20.4% ($p < 0.05$). In P who showed improvement of symptoms (>1 CCS-class) and increased exercise capacity ($n = 7$), relative FDG-uptake in the TR increased from 70.9 ± 25.8% at baseline to 82.4 ± 19.9% after 3 months ($p < 0.05$). In patients without improvement of symptoms and exercise capacity ($n = 4$), relative FDG-uptake did not change (74.6 ± 23.0% to 75.5 ± 21.0% ($p = 0.45$). Thallium-scintigraphy failed to show an increase of relative tracer-uptake in the TR compared to the S in all P (stress: 69.9 ± 16.0% to 68.5 ± 21.0%, rest: 82.8 ± 13.9% to 80.6 ± 16.0%), both, in P who improved clinically after PMR, and in P who did not improve.

Conclusion: Increased FDG-uptake three months after PMR suggests improved perfusion of the myocardium despite unchanged thallium-scintigraphy. However, the amount of perfusion changes seems to be too small to account for the clinical benefit observed after PMR. Therefore, other mechanism may be involved in the pathophysiological process after PMR.

P3584 Left ventricular hypertrophy and insulin resistance

D.P. Dutka, E. Bames, P.G. Camici. *MRC Cyclotron Unit, Imperial College School of Medicine, Hammersmith Hospital, London, UK*

Secondary cardiac hypertrophy is a major cause of cardiovascular morbidity and mortality, and is characterised by a reduced myocardial glucose uptake (MGU) in response to insulin (insulin resistance). This study investigated whether myocardial insulin resistance is also present in primary (genetic) cardiac hypertrophy i.e. in hypertrophic cardiomyopathy (HCM) and the cardiomyopathy of Friedreich's ataxia (FRDA).

Methods: Absolute MGU was measured using ^{18}F-fluorodeoxy-glucose (FDG) and positron emission tomography during euglycaemic hyperinsulinaemic clamp in patients with HCM ($n = 6$) and FRDA ($n = 5$). Asymmetric left ventricular hypertrophy was present in all cases [diastolic septal thickness 1.8 ± 0.3 cm (HCM), 1.4 ± 0.3 cm (FRDA)]. All FRDA subjects were homozygous for the GAA expansion in the frataxin gene without diabetes. Comparison was made with 6 normal control (con) subjects.

Results: Fasting blood glucose ($mmol.l^{-1}$) was 4.46 ± 0.27 (con), 4.51 ± 0.28 (FRDA), 4.48 ± 0.26 (HCM). The whole-body glucose uptake (M, $\mu mol\ kg^{-1}.min^{-1}$) was 39.3 ± 12.7 (con), 33.4 ± 12.7 (HCM) and 18.0 ± 4.7 (FRDA, $p < 0.05$ vs con and HCM). MGU ($\mu mol.ml^{-1}.g^{-1}$) was 0.64 ± 0.04 in con, 0.67 ± 0.10 in HCM and 0.48 ± 0.09 in FRDA ($P < 0.05$ vs con).

Conclusions: The primary myocardial hypertrophy of HCM is not insulin resistant whereas in FRDA myocardial glucose uptake by the hypertrophied heart and whole-body glucose uptake are both reduced. Therefore, cardiac hypertrophy per se is not necessarily associated with myocardial insulin resistance.

P3585 Binding potential of [*amido*-^{11}C]GB67, a new radioligand for assessing myocardial α_1-adrenoceptors *in vivo*

M.P. Law[1], V.J. Cunningham[1], V.W. Pike[1], D. Giardinà[2], P.G. Camici[1]. *[1]MRC Cyclotron Unit, Imperial College School of Medicine, Hammersmith Hospital, London, UK; [2]Dipartimento di Scienze Chimiche, Università degli studi di Camerino, Italy*

Dysfunction of the sympathetic nervous system underlies a number of myocardial disorders. Positron emission tomography (PET) offers a way of assessing receptor function non-invasively in humans but there are no PET radioligands for α-adrenoceptors (AR). We have labelled GB67, a structural and pharmacological analogue of the α_1-adrenoceptor antagonist prazosin, by [^{11}C]methylation of *N*-desmethyl-GB67 (GB99). Studies in rats demonstrated that [^{11}C]GB67 binds to myocardial α_1-AR. Here we assess the binding potential of GB67 and its precursor, GB99.

Methods: [^{11}C]GB67 (0.4 nmol/kg) was injected intravenously into rats together with varying amounts of either unlabelled GB67 or GB99. Rats were sacrificed at 20 minutes after injection and the heart was removed. The uptake index (UI) was expressed as radioactivity per gram of wet tissue divided by the radioactivity injected per gram body weight.

Results: UI decreased as the dose of GB67 or GB99 was increased. The data were fitted to competitive binding model to provide estimates of the maximum number of binding sites (B_{max}) and half saturation doses (IC) for GB67 and GB99 in different myocardial regions. Assuming a tissue protein content of 10%, the values of B_{max} (~13 pmol/g tissue) were similar to those (50–170 fmol/mg protein) reported for myocardial α_1-AR assessed *in vitro*.

	B_{max} (pmol/g)	IC_{GB67} (nmol/kg)	IC_{GB99} (nmol/kg)
R. ventricle	13.1 ± 1.7	1.58 ± 0.29	4.89 ± 0.85
L. ventricle	12.2 ± 1.6	1.46 ± 0.27	4.61 ± 0.80
Septum	13.5 ± 1.6	1.62 ± 0.27	5.04 ± 0.80

Conclusion: [^{11}C]GB67 may be used *in vivo* to quantitate myocardial α_1-ARs. The precursor GB99 has high affinity to α_1-ARs. For PET studies, GB99 should be absent or at a low level that can be included in data analysis.

P3586 Iron in the heart: a cardiac magnetic resonance imaging study

S.I. Mavrogeni, L. Kaklamanis, D. Tsiapras, I. Paraskevaidis, D.V. Cokkinos, L. Vlahos[1], D.T. Kremastinos. *Onassis Cardiac Surgery Center; [1]Areteion University Hospital, Athens, Greece*

Introduction: Although serum ferritin is considered as a valuable index of iron tissue deposition, biopsy is the only way to detect iron in individual organs. The aim of this study was to apply MRI in the assessment of myocardial iron deposition and compare the results with cardiac biopsy data and serum ferritin levels.

Patients and Methods: Twenty patients, aged 22 ± 8 yrs., were studied. ECG-gated spin echo images were obtained from all patients using a 0.5 T superconducting system. Heart T2 relaxation time was calculated using TR = HR and TE = 17 msec in 7 symmetrically repeatable echoes (17–119 msec). Biopsy was performed in all patients within 5 days of the MRI scan. Serum ferritin levels were calculated from the average values of the last 5 years.

Results: All study patients were in heart failure (NYHA II–III). According to biopsy, heart iron deposition was graded as mild (+) or severe (++). Low heart T2 relaxation time was considered as indicative of significant iron deposition. Ferritin > 2500 ng/ml was considered as suggestive of iron overload. Agreement between MRI, ferritin, and biopsy is tabulated:

	Ferritin < 2500 ng/ml	Ferritin > 2500 ng/ml	BIOPSY (+)	BIOPSY (++)
High T2	3	0	2	1
Low T2	0	17	1	16

Heart T2 relaxation time correlated with serum ferritin ($r = -0.88$, $p < 0.001$) and cardiac biopsy results (Spearman's test, Rho = −0.47, $p < 0.04$). Ferritin also correlated with biopsy results (Rho = 0.50, $p < 0.03$)

Conclusion: According to our results, heart T2 relaxation time measured noninvasively by MRI appears in agreement with ferritin levels and cardiac biopsy data. Although there is strong agreement between biopsy and MRI in high heart iron overload, further studies are needed in milder cases.

P3587 Evaluation of myocardial energy metabolism with P-31 spectroscopy in patients with dilated cardiomyopathy

Th. Wittlinger[1], T. Voigtländer[1], K.F. Kreitner[2], S. Genth-Zotz[1], H. Darius[1], J. Scharhag[1], P. Kalden[2], K. Grauvogel[1], M. Thelen[2], J. Meyer[1]. *[1]2nd Medical Clinic; [2]Department for Radiology, University Hospital, Mainz, Germany*

In patients with heart failure due to dilated cardiomyopathy (DCM) cardiac energy metabolism is impaired as indicated by a reduced myocardial phosphocreatinin-to-ATP (PCr/ATP) ratio, which can be measured non-invasively by 31-P-Spectroscopy (MRS). The aim of the study was to evaluate the changes of the PCr/ATP ratio in patients with DCM treated with recombinant human growth hormone (r-HGH) and to show a correlation to data from the heart muscle biopsies.

Methods: We investigated 20 patients with DCM and an ejection fraction < 35% and a NYHA class III. All patients were treated with r-HGH (2 I.E./day, Novo Nordisk) for 3 month or placebo. 31-P-MRS and a heart muscle biopsy were performed at the beginning and after 3 month. In the 2-D chemical shift imaging of the anterior wall of the left ventricle PCr, alpha-, beta- and gamma-ATP were measured. For the controll group we investigated 10 healthy volunteers.

Results: The PCr/ATP ratio in the healthy volunteers was 1.8 ± 0.15. In the patients group before treatment, the PCr/ATP ratio was reduced at 1.6 ± 0.25. At the reevaluation after the r-HGH treatment 11 patients showed a significantly increase of the PCr/ATP ratio to 2.3 ± 0.45. In 9 patients no PCr/ATP increase were observed. There was no increase in the NYHA class or the ejection fraction in all patients due to optimal medical treatment.

Conclusions: Evaluation of the myocardial energy metabolism in human end stage heart failure is faisible non-invasively by 31-P-MRS. The PCr/ATP ratio is significantly diminshed in patients with DCM before treatment with r-HGH. Further studies have to shown, wether the increase of the PCr/ATP ratio after the r-HGH treatment will a good predictor for a possible increase of myocardial contractility. A final assessment will be possible after the correlation of the PCr/ATP-values evaluated with 31-P-MRS and heart muscle biopsies after the unblinding of the study in April 1999.

P3588 Ultrasonic integrated backscatter identifies preclinical myocardial dysfunction in patients with normal ejection fraction and anthracyclines treatment

C. Coletta, M. Renzi, A. Sestili, U. Recine[1], C. Cianti[1], A. Galati, N. Aspromonte, A. Danesi, R. Massini[1], V. Ceci. *Cardiology Division; [1]Internal Medicine Division, S. Spirito Hospital, Rome, Italy*

Based on changes of acoustic properties during the myocardial contraction, cyclic variation of ultrasonic integrated backscatter (CVIB) is a sensitive marker of regional myocardial contractile performance. Aim of the study was to investigate by CVIB the presence of preclinical myocardial toxicity in patients (pts) with normal ejection fraction (EF) treated with anthracyclines.

Methods: Thirteen pts (Group 1, mean age: 54; M = 3, F = 10; breast cancer = 10 pts, non-Hodgkin lynphoma = 3 pts), referred for routine echo evaluation during or shortly after a polichemiotherapic treatment including anthracyclines (3 to 8 cycles, mean: 5.9), were considered for the study. All pts had normal (>50%) EF and all were free of cardiac symptoms. As a control group, 13 consecutive pts (Group 2, mean age: 52; M = 5, F = 8) were considered; in all the presence of major cardiac abnormalities and of any regional or global myocardial dysfunction was excluded. High-quality ultrasonic 2D-IB images (HP Sonos 2500) in parasternal left ventricular (LV) long- and short axis (Lax, Sax) views were digitally stored for each patient through >2 R-R intervals. CVIB was separately analyzed by the same blinded operator within regions of interest (ROI, 31 × 31 or 42 × 42 pixels) in the LV interventricular septum (IVS) and posterior wall (PW). Absolute (peak to peak intensity [PPI], Db) and relative values (PPI/average intensity [AI] × 100) of CVIB were calculated and compared.

Results: EF (56.2 ± 3.9 vs 55.5 ± 6.3%; p = ns) and all basic clinical variables were comparable in the two groups. Group 1 vs Group 2,

	IVS Lax	IVS Sax	PW Lax	PW Sax
PPI (Db)				
Group 1	3.1 ± 1.1**	2.9 ± 1.2**	3.5 ± 1.5**	4.3 ± 1.7**
Group 2	5.7 ± 2.2	4.5 ± 0.9	7.2 ± 2.3	7.7 ± 2.7
PPI/AI (%)				
Group 1	26.5 ± 9.1*	26.3 ± 10.9*	32.8 ± 16.0*	44.6 ± 23.1*
Group 2	45.1 ± 16.6	37.2 ± 11.7	63.6 ± 19.7	64.9 ± 19.1

**: $p < 0.001$; *: $p < 0.03$.

Conclusions: In asymptomatic pts treated with polichemiotherapic regimens including anthracyclines the CVIB is abnormally low in spite of a preserved LV function. The reduced CVIB could represent a preclinical marker of cardiotoxicity.

P3589 Bold-magnetic resonance imaging of the ischaemic myocardium: first clinical results

C.M. Wacker, A.W. Hartlep[1], M. Bock[1], G. van Kaick[1], G. Ertl, L.R. Schad[1], W.R. Bauer. *Kardiologie, Universität Würzburg, Würzburg[1] Radiological Diagnostics and Therapy, German Cancer Research Center, Heidelberg, Germany*

Purpose: The correlation of the apparent transversal relaxation time T2* with the oxygenation state of hemoglobin (BOLD effect) was investigated recently. In the last decade, the BOLD contrast has been exploited in neuro-functional MRI to localize areas of neuronal activity. BOLD magnetic resonance imaging has also been applied to myocardium of healthy volunteers and modulations of the deoxyhemoglobin concentration were detected. In this study, global and regional changes in myocardial oxygenation were evaluated for the first time in patients with coronary artery disease (CAD) by means of magnetic resonance. Moreover, T2* exams were performed before and after coronary revascularization.

Methods: A segmented gradient echo pulse sequence was implemented on a 1.5 T whole body scanner (SIEMENS Vision) to assess myocardial oxygenation. T2*-measurements were done at rest and under stress conditions with dipyridamole (DIP 0.84 mg/kg). 25 patients with CAD were examined. Patients underwent x-ray angiography, stress-echocardiography and MR-exam within 4 days. In 5 patients T2*-measurements were performed before and after coronary revascularization procedures like coronary angioplasty (PTA) or bypass (CABG).

Results: In the MR T2* examination expected ischemic myocardium was detected in 14 cases (10 × LAD, 2 × RCA and 2 × LCX). In these regions, T2* values were significantly reduced when compared to the remaining myocardium ($p < 0.01$). Areas with lower T2* values correlated well with echocardiographic findings of dyskinetic myocardium. In 11 patients (5 × LAD, 4 × RCA and 2 × LCX) ischemic myocardium was not detected due to severe susceptibility artifacts occurring at the infero-lateral border of the heart.

5 patients were reinvestigated after coronary revascularization. Regions with reduced T2* values were clearly delineated before and after PTA. When observing the obtained T2* maps, differences between regions of expected ischemia and regions of normal myocardium were less pronounced than they were prior to PTA. Expected ischemic areas with lower T2* values were not detected after CABG due to susceptibility artifacts.

Conclusion: Our preliminary results show for the first time, that DIP-induced regional changes of myocardial oxygenation in patients with CAD (mainly with a stenosis of the LAD) could be assessed with T2*-exams. T2*-exams may therefore become a promising tool for noninvasive diagnostic and therapy evaluation in patients with CAD.

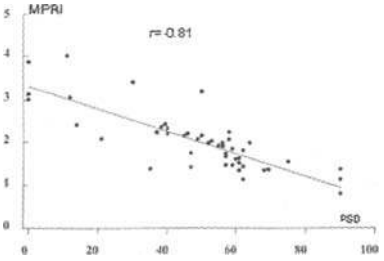
P3590 Relation of coronary artery stenosis severity to a myocardial perfusion reserve index derived from first-pass contrast enhanced magnetic resonance imaging

J. Cullen, M.A. Horsfield[1], D.B. Barnett[2], G.R. Cherryman[3], N.J. Samani. *Cardiology Dept, Glenfield Hospital, Leicester; [1]Division of Medical Physics, University of Leicester, Leicester; [2]Clinical Pharmacology Dept, University of Leicester, Leicester; [3]Radiology Dept, University of Leicester, Leicester, UK*

MRI could be a useful non-invasive tool to assess coronary disease. We evaluated an MRI technique using a quantitative tracer kinetic model to derive a myocardial perfusion reserve index (MPRI) in human volunteers and patients with coronary artery disease.

Methods: 20 patients with angiographically proven coronary heart disease and 5 normal healthy male volunteers, underwent both resting and stress (adenosine 140 mcg/kg/min) first-pass contrast enhanced MRI examinations,using an inversion/recovery turbo-FLASH sequence (TI 300 ms, TR 4.7 ms, TE 2 ms). We computed the unidirectional transfer constant Ki for the myocardial uptake of contrast, a perfusion marker, in each coronary arterial territory. The ratio of Ki for the rest and stress scans was used to estimate the MPRI. A validated QCA package (CAAS 2) was used to measure coronary percent stenosis diameter(PSD).

Results: MPRI was 4.21 ± 1.16 (mean ± SD) in normals and significantly reduced in patients (2.02 ± 0.70, $p < 0.001$). For regions supplied by individual vessels, there was a good negative non-linear correlation of MPRI with PSD of coronary lesions ($r = -0.81$, $p < 0.02$). Importantly, MPRI was significantly different between non-flow limiting lesions (<40%) and "intermediate" lesions (40–59%) (2.80 ± 0.77 and 1.93 ± 0.38 respectively, $p < 0.02$). However even regions supplied by vessels with <40% diameter stenosis had a significantly lower MPRI than normals ($p < 0.01$).



MPRI vs Coronary PSD.

Conclusion: A myocardial perfusion reserve index derived from first-pass MRI studies can distinguish between normal subjects and patients with coronary artery disease. Furthermore, it provides useful functional information on coronary lesions, particularly where the physiological significance cannot be predicted accurately from the angiogram.

P3591 Magnetic resonance perfusion imaging: improvement of myocardial perfusion reserve after PTCA

N. Al-Saadi, E. Nage, M. Gross, B. Schnackenburg[1], A. Bornstedt, C. Klein, E. Fleck. *Internal Medicine/Cardiology, Charité, Campus Virchow, HU Berlin; German Heart Institute, Berlin; [1]Philips Medical Systems, Hamburg, Germany*

Myocardial perfusion reserve (MPR) can be determined with cardiovascular MR. Aim of this study was to assess MPR before and after PTCA with a cut off value of 1.5 that was previously defined in a different study.

30 patients with angiographically significant coronary artery stenosis (≥75%) were examined with a 1.5 Tesla MR tomograph (Philips ACS NT) before and 24 h after PTCA. One short axis image per heart beat was acquired for 70 beats at the base of the papillary muscle with a turbo gradient echo technique (spatial resolution 1.7 × 1.9 × 8 mm, acquisition time 360 ms). A gadolinium DPTA bolus was injected in the superior caval vein (0.025 mmol/kg body weight) before and after dipyridamole infusion (0.56 mg/kg body weight). The signal intensity curves of the left ventricle and 6 myocardial segments were obtained and the upslope was determined using a previously validated linear fit. A correction for the left ventricular upslope (input function) was performed. MPR was calculated as the relative change of the upslope after dipyridamole infusion in comparison to that at rest.

Before PTCA MPR was significantly reduced in segments supplied by a stenotic coronary artery (S+) in comparison to the remaining segments (S−) (1.19 ± 0.24 vs. 2.18 ± 0.43; $p < 0.001$). Sensitivity and specificity for the detection of S+ using the previously defined cut off value of 1.5 were 92% and 87% before and 75% respectively 86% after PTCA. After successful PTCA ($n = 27$) MPR in S+ increased significantly in comparison to pre-PTCA values (1.96 ± 0.56 vs. 1.13 ± 0.25; $p < 0.001$) and did no longer differ from S− (2.11 ± 0.51). If PTCA was unsuccessful or not performed ($n = 3$) MPR remained <1.5 in 12 of 15 S+.

MR perfusion imaging allows a noninvasive assessment of the success of a revascularisation. This technique may be used for the follow up of patients with coronary artery disease and the detection of restenosis.

P3592 Demonstration of impaired myocardial perfusion reserve in patients with syndrome X using magnetic resonance imaging

J. Cullen, G.R. Cherryman[1], N.J. Samani. *Cardiology Dept, Glenfield Hospital, Leicester; [1]Radiology Dept, University of Leicester, Leicester, UK*

Background: Patients with syndrome X may have abnormalites at the microvascular level and impaired vasodilatory response. We therefore investigated subjects with syndrome X using magnetic resonance imaging (MRI) and a quantitative tracer kinetic model, which may be used to estimate myocardial perfusion reserve index (MPRI).

Methods: Five healthy controls and five patients with Syndrome X (classical symptoms of angina, a positive exercise test or reversible ischaemia with stress myocardial scintigraphy and a normal coronary angiogram), underwent both resting and stress (adenosine 140 mg/kg/min) first-pass contrast enhanced MRI examinations,using an inversion/recovery turbo-FLASH sequence (TI 300 ms,TR 4.7 ms, TE 2 ms). Using a modified Kety equation, the unidirectional transfer constant Ki for the myocardial uptake of contrast, a perfusion marker, was calculated for myocardium globally. The ratio of Ki for the rest and stress scans was used derive the MPRI.

Results: (mean ± SD) Global resting Ki (ml/g//min) in patients was not significantly different from that in normals (74.62 ± 30.49 vs 54.24 ± 13.27, $p = 0.21$). However, global MPRI with adenosine was significantly reduced in patients compared with normal subjects (2.21 ± 0.60 vs 4.21 ± 1.16, $p < 0.01$), and the reduction was homogeneously distributed across all vascular beds

Conclusion: Our preliminary data is one of the first demonstrations that global MPRI estimated with MRI is significantly reduced in patients with syndrome X compared with controls, supporting the concept that syndrome X is associated with an impaired microcirculatory vasodilator response. MRI may provide a very useful non-invasive tool to support the diagnosis of syndrome X in patients with angina and normal arteries and the ability to perform longitudinal studies will allow investigation of its mechanisms.

P3593 Myocardial perfusion quantification using dynamic magnetic resonance imaging in patients after angioplasty and brachytherapy

J.P. Vallée, G. Rouault[1], D. Didier, V. Verine[1], P. Chatelain[1], F. Lazeyras, Y. Popowski, L. Bidaut, A. Righetti[1]. *Radiology Dept., Geneva University Hospital, Geneva; [1]Cardiology Dept., Geneva University Hospital, Geneva, Switzerland*

Introduction: Dynamic magnetic resonance imaging (MRI) after injection of a bolus of Gd-DTPA allows the absolute determination of K1, the blood to myocardium constant transfer that is linearly related to the myocardium perfusion at rest. The objective of this study is to measure K1 in normal myocardium and persistent SPECT thallium defect area in patients with stable coronary artery disease.

Methods: 16 patients were studied 6 months after coronary PTCA followed by intracoronary brachytherapy (9 to 18 Gray). A coronary angiography, a rest and stress SPECT 201Tl imaging and a cine MRI coupled with a perfusion study were completed within 28 hours. For the MRI perfusion study, 2 short axis view of the heart were obtained at rest using a Picker Edge 1.5 T MR system with a magnetization prepared FAST sequence after injection of a bolus of Gd-DTPA (Magnevist, Schering AG, Deutschland) in a brachial vein (0.035 mmol/kg). After signal intensity calibration based on external references, blood and myocardium concentration time-curves of 4 sectors (anterior, septal, inferior and lateral) were fitted with a one compartment model for the myocardial perfusion indices: the blood to myocardium transfer constant (K1 in ml/min/g) and the Gd-DTPA distribution volume (Vd in%). From the 3D data set of 201Tl images, 2 short axis slices were reconstructed at the level of the MRI slices for the determination of the status of the 4 sector (normal versus infarct).

Results: All the 16 patients were asymptomatic without ischemia and angiographical sign of restenosis or other coronary obstruction at the time of the study. 7 patients (11 over 128 sectors) had a persistent defect on 201Tl imaging reflecting a previous myocardium infarct. Difference between normal and infarcted myocardium was observed in the wash-in but not the wash-out of the time transit curves. K1 in infarct sectors (0.33 ± 0.11 ml/min/g) was statistically decreased by comparison with normal sectors (0.50 ± 0.09 ml/min/g, $p < 0.0001$). No difference in Vd was observed between normal myocardium and infarct (16.8 ± 3% and 17.3 ± 4.8%, $p = 0.44$).

Conclusion: Quantification of myocardial perfusion using MRI in patients with stable coronary artery disease can differentiate between normal myocardium and infarct. This represents the rational for further studies on the use of MRI derived perfusion index K1 for the assessment of myocardium viability.

P3594 Analysis of the first-pass myocardial perfusion in patients with acute or subacute infarction using ultrafast magnetic resonance imaging

J. Scharhag, T. Voigtländer, T. Wittlinger, S. Petersen, K.-F. Kreitner[1], V. Schröer, P. Kalden[1], M. Thelen[1], J. Meyer. *2nd Medical Clinic; [1]Clinic for Radiology, Johannes Gutenberg, University Mainz, Germany*

The aim of the study was to compare perfusion parameters in infarcted and non-infarcted myocardium after successful revascularization using ultrafast magnetic resonance imaging (MRI).

Methods: 19 patients (55 +− 10 years) with acute or subacute myocardial infarction and angiographic TIMI flow 0 were includud into the study. Successful revascularization with TIMI flow 3 was obtained by PTCA or Stenting within 7.5 ± 6.8 hours in 16 patients. MRI was perfomed within 5.8 ± 1.7 days (Siemens Magnetom Vision 1.5 T, Single Slice, TurboFLASH, breathhold, ECG-gated, Gd-DTPA). The left myocardium was devided clockwise into 16 segments. In each segment following parameters were determined: 1. Normalized Signal intensity (NSI) = SI − Baseline SI; 2. Time to Peak; 3. Slope, 4. Mean transit time (MTT) and 5. Area under the curve (Area).

Results: In all cases central dark zones at the perfusion beds of the infarct-related artery were obvious with significantly different NSI, Time to Peak and Slope (see table). When all segments of the myocardium are compared, the best differentiation between infarct-related and non-infarct-related segments was shown by NSI (κ = 0.83) and Area (κ = 0.98).

	Infarcted	Non-Infarcted	P-Value
NSI	22.5 ± 13.4	41.2 ± 16.4	<0.0001
Time to Peak [sec]	25.4 ± 10.76	19.9 ± 11.31	0.0012
Slope [NSI × 10^{-3}/sec]	0.99 ± 0.69	2.59 ± 1.71	<0.0001

Conclusion: Infarcted myocardium can be distinguished exactly from non-infarcted myocardium. In the infarcted-related segments the perfusion is represented by the diminished SI, the prolonged Time to Peak and the reduced Slope, supporting the concept of the retarded wash-in of the infarcted region. In the differentiation of infarcted-related and non-infarcted-related myocardium NSI and Area are the most robust parameters.

P3595 Variability of regional myocardial blood flow measured by positron emission tomography in 153 normal volunteers

Panithaya Chareonthaitawee, Philipp A. Kaufmann, Ornella Rimoldi, Paolo G. Camici. *MRC Cyclotron Unit, Imperial College School of Medicine, Hammersmith Hospital, London, UK*

Significant variability of myocardial perfusion has previously been demonstrated in animal studies using invasive techniques. Knowledge of the range and regional distribution of normal myocardial blood flow (MBF) in humans is crucial to understanding the contribution of MBF in diseased states. We therefore examined resting segmental MBF in 153 healthy volunteers.

Methods and Results. MBF (ml/min/g) was quantitated by means of positron emission tomography with oxygen-15-labeled water in 117 men (M) and 36 women (F), aged 21 to 86 years. MBF was corrected for rate-pressure product (RPP) by the formula, basal MBF × (mean RPP/individual RPP). T = total population, σ = coefficient of variance.

MBF		Septal	Anterior	Lateral	Inferior Wall
Range	T, uncorrected	0.47–1.79	0.58–2.56	0.56–2.00	0.42–1.56
	σ	0.23	0.30	0.26	0.23
	T, corrected	0.47–1.76	0.52–2.06	0.46–2.26	0.42–1.64
	σ	0.23	0.27	0.25	0.25
	M, corrected	0.47–1.80	0.58–2.56	0.56–1.66	0.43–1.55
	σ	0.22	0.24	0.20	0.26
	F, corrected	0.67–1.60	0.68–2.49	0.69–2.00	0.68–1.51
	σ	0.21	0.25	0.26	0.20
Mean ± SD	M, corrected	0.91 ± 0.19	0.96 ± 0.25	0.95 ± 0.19	0.86 ± 0.19
	F, corrected	1.14 ± 0.23	1.30 ± 0.35	1.13 ± 0.31	1.06 ± 0.20
p, M vs F		<0.0001	<0.0001	<0.0001	

Conclusion. MBF at rest, both uncorrected and corrected for workload, shows considerable variability within each myocardial segment, confirming the pattern previously observed in animals. The significantly higher MBF in women appears to be unrelated to workload.

P3596 Definition of normal and abnormal human myocardial perfusion at rest by venous contrast echocardiography

C. Firschke, R. Blasini, J. Horcher, S. Lange, M. Reeg, S. Martinoff, U. Schricke, M. Schwaiger, A. Schömig. *Deutsches Herzzentrum; 1. Medizinische Klinik der Technischen Universität München, Munich, Germany*

Intermittent harmonic imaging (IHI) combined with digital image processing (DIP) allows for myocardial opacification by venous myocardial contrast echocardiography (VMCE) in humans. How normal and abnormal myocardial perfusion translate into myocardial opacification, however, has not yet been defined.

Therefore, VMCE (IHI, venous infusion of 8 g of Levovist) was performed in 8 patients with a normal TC 99 m sestamibi SPECT (TCSS) scan and normal coronary arteries (group 1). Videointensity (VI) in each of the 10 segments of the 4- and 2- chamber views was quantified after DIP and normalized to the value of the segment with maximal VI. The normalized VI's (mean ± 1 SD) in the 4- chamber view were 0.85 ± 0.06 (basal septum), 0.92 ± 0.07 (mid septum), 0.91 ± 0.07 (apex), 0.92 ± 0.07 (mid lateral) and 0.90 ± 0.08 (basal lateral); in the 2- chamber view, the values were 0.89 ± 0.08 (basal inferior), 0.96 ± 0.09 (mid inferior), 0.84 ± 0.06 (apex), 0.90 ± 0.08 (mid anterior) and 0.79 ± 0.06 (basal anterior). In a second step, VMCE and TCSS were compared in 50 patients with known coronary disease by separate observers. On TCSS (10 segments in the horizontal and vertical long axis), 60/500 segments were visually scored as abnormal. For VMCE, segmental VI's were measured after DIP and normalized as in group 1 patients. Different cut-off values were used to define a segment as ab-normal. Receiver operating characteristic curve analyses identified cut-off values of 3SD beyond the normalized mean VI of the corresponding group 1 segment as optimal contrast echocardiographic criterion for abnormal myocardial perfusion as defined by TCSS (sensitivity 90%, specificity 87%, diagnostic accuracy 89%).

Thus, beyond subjective visual assessment, quantitative criteria for accurate differentiation between normal and abnormal myocardial perfusion at rest can be defined for VMCE.

NON-INVASIVE IMAGING TO SCREEN FOR CORONARY ARTERY DISEASE

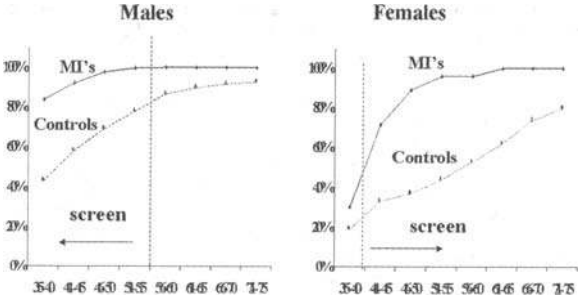
P3597 Screening with electron beam computed tomography to predict hard coronary events: choosing the appropriate age range

P. Raggi, T.Q. Callister, N.J. Lippolis, D.J. Russo. *Clinical Research, EBT Research Foundation, Hendersonville TN, USA*

A controversy exists regarding the predictive value of coronary artery calcification (CAC) discovered on a screening electron beam-CT (EBCT). However, selection of patients (pts) for screening in an inappropriate age range may affect the prognostic significance of CAC.

Method: We studied 2 groups of pts: A) 10,937 asymptomatic pts screened with EBCT, B) 208 consecutive pts (71% men, age 35–75) submitted to EBCT within 6 weeks of suffering an acute myocardial infarction (MI). The age adjusted prevalence of CAC in pts from both groups was plotted separately for men and women (figure). We aimed to identify age ranges where the prevalence of CAC was significantly different in MI pts compared to asymptomatic pts. In these age groups EBCT screening would be most appropriate.

Results: In men >55 y/o the prevalence of CAC in MI pts and controls was very similar (100% vs 90%) and the sensitivity and specificity of CAC for prediction of MI were 100% and 10%. In men ≪55 y/o the prevalence of CAC in MI pts and controls was significantly different (97% vs 56%; P < 0.001) and the sensitivity and specificity of CAC for events were 97% and 44% respectively. In women, the age threshold that identified the best sensitivity and specificity of CAC for events was age >40 (92% and 47% respectively).



Conclusions: In men, EBCT screening of asymptomatic individuals can be conducted as early as 35 y/o, but it should not be done in pts >55 y/o because the specificity of the test becomes poor. For women, screening should begin at >40 y/o and can be continued as late as 75 y/o. These findings carry important implications for the design of future randomized trials intended to study the import of CAC discovered on a screening EBCT.

P3598 Coronary calcification in subjects under age fifty with sudden coronary death as the first manifestation of heart disease

A. Schmermund, R. Schwartz, M. Adamzik, G. Sangiorgi, E. Pfeifer[1], A. Burke[2], A. Farb[2], R. Virmani[2]. *Division of Cardiovascular Diseases and Internal Medicine; [1]Department of Pathology, Mayo Clinic, Rochester, MN; [2]Department of Cardiovascular Pathology, Armed Forces Institute of Pathology, Washington DC, USA*

Sudden coronary death (SCD) under age 50 is a rare but prominent cause of death in adults at the peak of their productive lives. The detection of preclinical coronary atherosclerotic disease has been suggested as a method to predict SCD. However, subjects under age 50 may have little atherosclerosis and still sustain SCD.

Methods: Coronary arteries obtained at autopsy of 28 victims of SCD under age 50 with no prior clinical manifestation of cardiac disease or myocardial scar formation and of 16 age- and gender-matched "healthy" trauma victims were examined. Sections of the complete major coronary arteries were cut in 3- to 5-mm intervals to yield a total of 1,357 histologic sections and analysed using digitised planimetry.

Results: The fraction of sections in categories of cross-sectional area stenosis < 25%, 25–<50%, 50–<75%, and ≥ 75% was 9%, 27%, 37%, and 27%, respectively, in SCD cases and 48%, 37%, 13%, and 2%, respectively, in controls ($p < 0.001$). Plaque area per histologic section was 5.1 ± 2.1 mm^2 in SCD cases and 2.0 ± 0.9 mm^2 in controls ($p < 0.001$). Calcified plaque area per histologic section was 0.18 ± 0.19 mm^2 in SCD cases and 0.02 ± 0.05 mm^2 in controls ($p < 0.001$), providing for separation of the groups with a sensitivity and specificity of 100% and 81%, respectively. On a patient-by-patient basis, calcified plaque area was linearly related to total plaque area. Plaque rupture in SCD cases was associated with a significantly greater presence and amount of calcification compared with apparently stable plaques (univariate analysis).

Conclusions: In young victims of SCD, plaque area was significantly greater than in age-matched controls. Only a small fraction of plaque area was calcified, but calcification was frequently present in plaque rupture. Calcified plaque area was related to total plaque area and provided for good separation between SCD cases and controls.

P3599 Myocardial flow reserve is related with increased carotid intima-medial thickness in healthy men

J. Knuuti, J.O. Toikka[1], H. Laine[2], M. Ahotupa[3], J. Hartiala[1], O.T. Raitakari[1]. *Turku PET Centre, Turku University Central Hospital, Turku; [1]Dept. of Clinical Physiology, TUCH, Turku; [2]Dept.of Medicine, TUCH, Turku; [3]Dept. of Physiology, University of Turku, Turku, Finland*

Reduced myocardial blood flow reserve (MFR) is associated with cardiovascular risk factors in asymptomatic subjects, and has therefore been suggested to represent a marker of increased subclinical atherosclerosis. To test this hypothesis, we examined the relationship between MFR and carotid artery intima-media thickness (IMT), an established marker of subclinical atherosclerosis, in young men free from coronary heart disease.

Methods: Basal and dipyridamole stimulated myocardial blood flow was measured using positron emission tomography (PET) in 55 healthy men aged 36 ± 4 years. MFR was calculated as the ratio of stimulated flow to basal flow. The mean carotid artery IMT was measured using high resolution ultrasound.

Results: MFR decreased across the quartiles of increasing IMT ($p = 0.006$ for trend), and was 5.2 ± 1.9 in the lowest quartile for IMT and 3.7 ± 1.2 in the highest ($p = 0.04$, I vs IV quartile). The association between MFR and IMT remained significant (p 0.01) in multivariate regression model including age, rate-pressure product, left ventricular mass, oxidized LDL, total cholesterol, HDL-cholesterol and triglycerides as covariates. Oxidized LDL (measured as baseline LDL diene conjugation) was the best single bivariate correlate for both IMT and MFR, correlating inversely with MFR ($r = -0.35$, $p = 0.01$) and directly with IMT ($r = 0.51$, $p < 0.001$).

In conclusion, the data support the concept that reduced MFR assessed by dipyridamole PET reflects subclinical atherosclerosis in asymptomatic subjects, and suggest an adverse effect of increased lipoprotein oxidation on early structural and functional atherosclerotic vascular changes.

P3600 Carotid intima-media thickness is increased in healthy young subjects with a family history of hypertension

S. Cuomo, P. Guarini[1], G. Gaeta, M.C. Foglia[2], M. Accadia[1], F. Scotto di Uccio, A. Boccalatte, M. Trevisan[3]. *Cardiologia, Antonio Cardarelli Ospedale, Naples; [1]Cardiologia, S. Maria di Loreto, Naples; [2]Laboratorio Analisi Cliniche, Antonio Cardarelli, Naples, Italy; [3]Social and Preventive Medicine Dept, State University of New York, Buffalo, USA*

Background: We have previously demonstrated that carotid intima-media thickness (IMT) is increased in young subjects with a family history of parental myocardial infarction. However, to our knowledge, the influence of parental hypertension (PH) on carotid IMT in healthy young subjects has not yet been reported. This study examined whether, in young subjects, family history of PH is associated with increased carotid IMT.

Methods: Twenty-four healthy subjects with a family history of PH (Cases; 9 M, 15 F; mean age 23 ± 5 years; 33% current smokers) and 24 healthy subjects, age- and sex-matched, without family history of PH (Controls; 25% current smokers) underwent carotid ultrasonography to measure the sum of carotid IMT (i.e. the sum of common carotid IMT plus carotid bifurcation IMT, recorded for the right and the left-hand sides of the neck). None had family history of parental myocardial infarction.

Results: The sum of carotid IMT resulted significantly higher in Cases than in Controls (1.90 ± 0.35 mm vs 1.68 ± 0.22 mm, $p = 0.012$). A significant relationship was found between the sum of carotid IMT and age ($r = 0.30$, $p = 0.04$), family history of PH ($r = 0.36$, $p = 0.01$) and smoking status ($r = 0.42$, $p = 0.003$). Carotid IMT was not related to blood pressure, total cholesterol, HDL cholesterol, triglycerides, Lp(a), apo A1 and apo B. Multivariate analysis demonstrated that family history of PH and smoking status were independent predictors of carotid IMT.

Conclusions: Family history of PH appears to be a risk factor for increased carotid IMT in healthy young individuals, independent of the effects of age, blood pressure, smoking status and lipid profile.

IMAGING IN THE DETECTION OF MYOCARDIAL ISCHAEMIA: ECHO, NUCLEAR AND MRI

P3601 Comparative study of dobutamine echocardiography and dipyridamole/Tl-201 scintigraphy for detection of coronary artery disease in patiens with left ventricular hypertrophy

E. Prappa, A. Kranidis, M. Efremidis, A. Sideris, S. Patsilinakos, D. Manolatos, D. Kardara, F. Kardaras. *Second Department of Cardiology, Evangelismos General Hospital, Athens, Greece*

The recognition of coexistent CAD in pts with left ventricular hypertrophy (LVH) may be difficult by noninvasive testing. Several studies have shown false-positive results using exercise perfusion scintigraphy while dobutamine stress echocardiography (DSE) has been found to have a better diagnostic potential.

The aim of this study was to compare the ability of DSE and TL-201/dipyridamole SPECT to detect CAD in pts with LVH.

Methods: We performed DSE and TL-201/dipyridamole SPECT in 60 pts with LVH (IVS ≥ 13 mm) who entered the hospital because of chest pain and had known or suspected CAD. All pts were referred for coronary angiography independently of tests results. CAD was defined as ≥50% diameter narrowing in at least one major coronary vessel. Tests were judged to have positive or negative results for myocardial ischemia. Ischemia,in DSE, was defined by stress-induced wall motion abnormalities ranging in severity from dyskinesis and akinesis to grades of hypokinesis.

Results: Documented CAD was found in 46 pts (76.6%). The sensitivity of DSE and TL-201-SPECT was 95.23% and 87.5% respectively ($p > 0.05$).The specificity of DSE was 100% compared with 45.45% of TL-201-SPECT ($p = 0.000$) and their respective accuracies were 96.66% and 63.1% ($p = 0.000$).

In conclusion: This study demonstrates that DSE is a safe and accurate diagnostic method and significantly superior to TL-201/dipyridamole-SPECT for the detection of CAD in pts with LVH.

P3602 Dobutamine stress magnetic resonance is superior to dobutamine stress echocardiography for the detection of wall motion abnormalities: a subgroup analysis for territories and image quality

E. Nagel, H. Lehmkuhl, U. Vogel, C. Klein, S. Schalla, A. Ellmer, E. Frantz, W. Bocksch, E. Fleck. *Internal Medicine/Cardiology, Charité, Campus Virchow, HU Berlin; German Heart Institute, Berlin, Germany*

We have shown previously, that high dose dobutamine magnetic resonance imaging (DSMR) is superior to dobutamine stress echocardiography (DSE) for the detection of stress induced wall motion abnormalities. In this analysis we examined, if these differences can be explained by image quality and related to specific coronary territories.

In 208 consecutive patients DSE (GE VingMed System5) and DSMR (Philips Gyroscan NT, 1.5 T, turbo-gradient-echo technique) were performed before coronary angiography using a standard dobutamine/atropine stress scheme and analysed using a 16 segment model. Significant coronary artery disease was defined as a diameter stenosis of ≥50%. Image quality was graded according to the visibility of the endocardium.

51% echocardiographic examinations and 82% MR examinations ($p < 0.01$) yielded good or very good image quality. In these patients DSMR showed only a tendentially higher diagnostic accuracy, than DSE (85% vs. 89%). In contrast, in patients with suboptimal echocardiographic image quality DSMR was significantly more accurate (59% vs. 85%, $p < 0.01$). Sensitivity with DSMR was superior compared with DSE for all territories ($p < 0.05$, see table).

	Proximal		Medial		Distal	
	DSE	DSMR	DSE	DSMR	DSE	DSMR
LAD	78%	97%	71%	91%	71%	80%
LCX	65%	92%	-	-	62%	84%
RCA	73%	88%	75%	83%	71%	79%

Especially in patients with suboptimal echocardiographic image quality dobutamine stress magnetic resonance imaging is superior to dobutamine stress echocardiography. The largest difference in diagnostic accuracy between the two techniques can be found for the detection of proximal stenoses of the circumflex artery, which is a known limitation of stress echocardiography.

P3603 Identification of myocardial perfusion defects with myocardial contrast echo and MIBI SPECT during dobutamine stress echocardiography

M. Calachanis[3], C. Evdoridis[1], R. Slight[1], E. Adamopoulou[1], D. Chin[2], M. Monaghan[2], P. Nihoyannopoulos[1]. *[1]Cardiology Department, Hammersmith Hospital, ICSM, London; [2]Cardiology Department, Kings College Hospital, London, UK; [3]Institute of Cardiology, University of Chieti, Italy*

MIBI SPECT is an accepted non invasive imaging technique to assess myocardial perfusion. NC100100 (Nycomed) is a new fluorocarbon contrast agent able to opacify the left ventricular myocardium. Aim of this study was to compare MIBI SPECT to NC100100 enhanced echocardiograms with the use of harmonic (H) imaging during dobutamine stress echocardiography (DSE).

Methods: We evaluated 20 patients (pt) (17 males, 3 females, mean age 63 ± 15) with a recent (within six months) positive coronary angiogram. DSE was performed using a standard protocol and NC100100 was given at the dose of 0.03 ml/kg at rest and peak stress. The images were also stored in a digital format. At peak stress MIBI was also injected and peak nuclear images were acquired 1 hour after the end of stress. Rest MIBI SPECT scan was performed 24 h later. Scans were reviewed blindly.

Results: 19 pt had positive DSE + MCE and only 15 had positive MIBI SPECT ($p < 0.001$). If we then consider the ability of the techniques to unmask wall motion and/or perfusion abnormalities in single coronary artery territories then 10 of 12 pts with >50% LAD stenosis were correctly diagnosed with DSE + MCE while 9 were diagnosed with SPECT ($p = 0.08$). All 15 with >50% on RCA or Cx stenosis were diagnosed with DSE + MCE but only 8 had positive SPECT ($p < 0.001$).

Conclusions: While DSE with MCE provides similar diagnostic information to SPECT in patients with LAD disease, it shows a greater diagnostic accuracy in the RCA/Cx territory.

P3604 Dobutamine stress magnetic resonance imaging: a reliable alternative to stress echocardiography in patients with insufficient image quality?

M. Jochims, A. Schmidt[1], J. Crnac, P. Theissen[1], E. Erdmann, H. Schicha[1], F.M. Baer. *Klinik III für Innere Medizin; [1]Klinik für Nuklearmedizin; University of Cologne, Germany*

Approximately 15% of patients admitted to stress-echo have an inadequate acoustic window due to obesity, lung emphysema or sequelae of cardiac surgery. Therefore we studied the potential of dobutamine stress magnetic resonance imaging (MRI) to diagnose coronary artery disease (CAD) as an alternative method for the assessment of ischemia induced wall motion abnormalities in a subset of 30 patients with inadequate image quality by stress echocardiography (>2 segments inadequate for wall motion analysis).

Methods: To evaluate the diagnostic reliability of dobutamine MRI for the detection of CAD MR wall motion analysis was compared to coronary angiography and scintigraphic findings. Each patient underwent MRI at rest and during incremental dobutamine infusion (10, 20, 30 and 40 μg/kg/min + 1 mg atropine) and Tl-201 myocardial scintigraphy at rest and after high dose dipyridamole infusion (0.75 mg/kg over 10 min). MR short axis tomograms and reconstructed Tl-201 short axis tomograms were divided into 8 segments. For evaluation of the MR studies each segment was graded as normal, hypokinetic, akinetic or dyskinetic. Dobutamine-MRI was considered positive if segmental wall motion deteriorated by at least one grade after dobutamine infusion. For comparison with coronary angiography each MR and Tl-201 segment was assigned to a specific coronary artery territory.

Results: MR image quality was adequate in 29 (96.7%) of 30 MRI studies. In one patient respiratory motion precluded evaluation. The average time of examination and wall motion analysis was 62 minutes.

	Sensitivity	Specificity	Diagnostic accuracy
Dobutamine-mri	79%	80%	79%
Dipyridamole-Tl-201	89%	70%	83%

Conclusion: Dobutamine-MRI for the detection of CAD was less sensitive but more specific than Tl-201-scintigraphy with a similar diagnostic accuracy. Therefore dobutamine-MRI using a state of the art fast imaging sequence offers a reliable, clinically safe and feasible alternative to stress-echocardiography in patients with inadequate stress-echo-studies due to an insufficient acoustic window.

P3605 Myocardial perfusion imaging using the effect of stimulated acoustic emissions from SHU 563A, a novel ultrasound contrast agent, reliably identifies perfusion defects during coronary occlusion and after reperfusion

C. Teupe, M. Takeuchi, C. Abadi, J. Yao, T. Fritzsch, N. Pandian. *Tufts, New England Medical Center, Boston MA, USA*

Myocardial perfusion imaging with contrast echo currently involves harmonic triggered, gray scale B-mode [HBM] imaging and requires extensive post-processing to show perfusion in color. We investigated whether the microbubble response to high ultrasound amplitude – the phenomenon of stimulated acoustic emission [SAE]- could be recorded with harmonic triggered power Doppler [HPD] in color to identify perfusion defects. SHU 563A is an air-filled microsphere with a biodegradable cyanacrylate polymer shell, shown in in vitro studies to respond uniquely to high amplitude ultrasound.

Methods: To assess the in vivo potential of this approach, we studied 10 dogs in whom acute myocardial infarction was created by 2–3 hour ligations of either LAD (7) or Cx (3) branches followed by 1 hour reperfusion. After transvenous administration of SHU 563A, imaging was performed with HBM and HPD for SAE recordings. Post-mortem TTC staining was used to verify infarction. HBM images, HPD images and TTC data were analyzed by independent observers.

Results: During coronary occlusion, HBM and HPD showed perfusion defects in all 10 dogs in both short-axis and long-axis views. Correlation between HBM and HPD in assessing hypoperfused bed size was $r = 0.99$, $p < 0.001$. After reperfusion, HPD showed good correlation between perfusion defect size and residual infarct size by TTC ($r = 0.82$, $p < 0.01$).

Conclusion: HPD with SHU 563A identifies perfusion defects during coronary occcclusion as reliably as HBM. After reperfusion, HPD precisely portrays the site and size of residual infarct on line, in color. This approach has excellent potential for clinical application.

P3606 Detection of coronary stenosis in humans using stress contrast echocardiography with pulse inversion harmonic imaging: a comparison with Tc-99m-MIBI SPECT

N.S. Chung, J. Ha, S.J. Rim, K.W. Kwon, H.J. kim, D.H. Choi, Y.S. Jang, S.Y. Cho, T.R. Porter[1]. *Cardiology Div., Yonsei Cardiovascular Center, Seoul, South Korea; [1]Div. of Cardiology, Univ. of Nebraska, Omaha NE, USA*

Harmonic Imaging (HI) which is currently, the most sensitive method for myocardial perfusion imaging using microbubbles, suffer from inferior resolution and poor contrast at low mechanical indices (MI). Pulse Inversion Harmonic Imaging(PIHI) is a new method for imaging nonlinear echoes from microbubbles in which, the phase of alternate transmitted ultrasound pulses is inverted and the subsequent echoes summed to produce a more efficient detection of nonlinear echoes than simple HI. However, the accuracy of MCE with this novel imaging technology in the detection of significant coronary artery disease(CAD) has not been fully investigated. We assessed the ability of PIHI with IV PESDA to produce myocardial contrast echocardiography (MCE) perfusion defects in patients who were suspected to have CAD.

Methods: MCE with PIHI and Tc-99m-MIBI SPECT were performed at the same day during rest and after 0.56 mg or 0.84 mg/kg dipyridamole infusion in 18 patients. MCE and MIBI SPECT were visually assessed for the perfusion defect according to the coronary territory. Coronary angiography was also performed in all patients to determine the degree of stenosis.

Results: Using coronary angiography as the standard, MCE had a sensitivity of 74% and a specificity of 94% for the detection of significant CAD (>70% stenosis) while MIBI SPECT showed a sensitivity of 74% and a specificity of 97%. The overall concordance rate between MCE and MIBI SPECT for the detection of perfusion defect according to coronary territory was 91%.

Conclusion: Stress contrast echocardiography with PIHI is comparable to Tc-99m-MIBI SPECT in accurately identifying significant coronary stenosis and myocardial perfusion abnormalities.

P3607 Value of biphasic response for detecting residual ischaemia after acute myocardial infarction: comparison between exercise and dobutamine echocardiography

E.P. Hoffer, A. Defrance, H. Appeltants, L. Hubin, L.A. Piérard. *Department of Cardiology, University Hospital Sart Tilman, Liège, Belgium*

Detection of contractile reserve (CR) and residual ischemia is clinically important after acute myocardial infarction (AMI). We sought to assess the accuracy of biphasic response (initial improvement followed by worsening) during semi-supine bicycle exercise echocardiography (EE) and dobutamine echocardiography (DE) for detecting residual stenosis and predicting functional recovery (FR) early after AMI.

Methods: 54 consecutive patients (pts) with AMI underwent EE and DE 6 ± 2 days after AMI. Beta-blockers were interrupted for at least 24 h. To assess FR, echocardiography at rest was repeated 1 month later. Regional wall thickening was semi-quantitatively assessed using a 16-segment model. All pts had at least 2 dyssynergic segments at baseline. Ischemia was defined as worsening or extension of baseline dyssynergy with (biphasic response) or without initial improvement in ≥2 contiguous segments. All pts underwent quantitative coronary angiography 13 ± 9 days after AMI. A ≥50% diameter stenosis of the infarct-related vessel (IRV) was considered significant.

Results: Initial improvement of wall thickening was observed in 45 pts (83%) during EE and 47 pts (87%) during DE. In these pts with CR, a biphasic response was found in 29 pts with EE and 30 pts with DE. Among the pts without initial improvement, 2 had worsening in adjacent region during EE and 3 during DE. Functional recovery at 1 month was observed in 45 pts (83%). Sensitivity of EE and DE for detecting significant stenosis of the infarct-related vessel was 65% and 70% respectively, while specificity was 87% with both methods. The positive predictive value of biphasic response to detect residual stenosis of the IRV was 100% with EE and DE. The positive predictive value of biphasic response to predict FR was 97% with both methods.

Conclusion: When observed, a biphasic response of wall thickening during EE or DE is highly predictive of residual stenosis of the IRV and functional recovery early after AMI.

DOPPLER TISSUE IMAGING

P3608 Long axis function of the left ventricle, a comparison of M-mode, pulsed tissue Doppler, colour tissue Doppler and strain rate

A. Stoylen, A. Heimdal[1], T. Skjaerpe. *Cardiology Dept., Univ. Hosp. of Trondheim; [1]Physiology & Biomedical Eng., Univ. of Trondheim, Trondheim, Norway*

Background: Long-axis function of the left ventricle assesses global function. Systolic Mitral Annulus Excursion (MAE) by M-mode and annulus Peak Systolic Velocity (PSV) by Doppler Tissue Imaging (DTI) both correlates with ejection fraction (EF). Velocity Time Integral (VTI) of systolic velocity should reproduce MAE. Synthetic M-mode can also be generated from 2D cine-loops. Tissue velocities are available from pulsed (pw) and colour (c) DTI, the first giving peak, the other mean velocities. Strain Rate Imaging (SRI) assesses regional function from Doppler. The aim of this study was to examine the relation of these variables with each other and EF.

Methods: 19 normals and 19 patients with AMI were examined with a GE Vingmed ultrasound scanner. None excluded for poor echo quality. Cine-loops from two- and four-chamber views were acquired in octave, cDTI and SRI modus. PwDTI and real-time M-mode curves from the mitral ring were obtained from septal, lateral, anterior and inferior points. Synthetic M-mode from octave loops (MAEr) and velocity curves from cDTI loops were generated from the same points. PSSR was averaged from 16 segments. EF was measured by Simpson's method. Measurements were compared for each point, and averages for each ventricle compared to EF.

Results: Comparison is shown in table I.In addition correlation coefficients of EF with the various methods were (95% CI): MAE 0.80 (0.73–0.85), MAEr 0.75 (0.67–0.82), pwVTI 0.66 (0.55–0.75), pwPSV 0.69 (0.58–0.77), cPSV 0.63 (0.51–0.72) and PSSR 0.80 (0.73–0.86).

Table I. Comparison of methods for long axis function

Comparison	BIAS	P	Limits of agreement	4-wall averages
MAE vs MAEr	1.9 mm	<0.0001	−1.9; 5.8	0.1; 4.2
MAEr vs pwTVI	−2.5 mm	<0.0001	−8.3; 3.3	−5.8; 0.5
pwPSV vs cPSV	2.58 cm/s	<0.0001	−1.83; 6.99	−0.41; 5.57

Bases between methods are constant, independent of absolute value.

Conclusions: The present study shows more scatter and weaker correlation than previous reports, probably due to non-selection of patients and early publication bias. Global averages reduce scatter by 30 to 50%, but it is still high. Measurements by different methods are not directly comparable due to biases. The bias between cDTI and pwDTI is to be expected. The bias between real-time and synthetic M-mode may reflect problems with aligning the beam in real-time.

P3609 Study of mitral annulus motion, by Doppler tissue imaging and m-mode echocardiography, for the assessement of left ventricular systolic and diastolic function in patients with coronary artery disease

T. Tsiotika, G. Filippatos, A. Kranidis[1], J. Lekatsas[1], K. Kappos[1], K. Tsilias[1], P. Anthopoulos[1], J. Antonellis, L. Anthopoulos[1]. *Athens; [1]1st Department of Cardiology, Evangelismos Hospital, Athens, Greece*

We compared Doppler Tissue Imaging (DTI) and m-mode echocardiography in the assessment of the systolic and diastolic function of left ventricle (LV), in patients with coronary artery disease (CAD).

Methods: Sixty patients with coronary artery disease (67 ± 12.2 years) were studied. All patients were examined by transthoracic 2D-Doppler echocardiography which included right upper pulmonary vein flow recordings. Tissue velocities in atrioventricular plane by DTI were recorded at five segments (septal, lateral, posterior, inferior and anterior) from the apical views. The velocity of systolic (Smax), diastolic wave (e) and the wave (a) produced by the atrial contraction were recorded. Left atrioventricular plane displacement (AVPD) was examined in the same segments, by m-mode.

Results: Angiographic Ejection Fraction (EF) was 46.4 ± 4.2%. The mean value of Smax in all five sites of the left ventricle was 16.5 ± 3.4 cm/sec and was significantly correlated with the ejection fraction, as assessed by angiography ($r = 0.7$, $p < 0.02$). The waves e, a and the ratio e/a, were significantly correlated with E and A velocities of transmitral flow, as well as with the ratio E/A (respectivelly $r = 0.5$, $r = 0.6$, $r = 05$, $p < 0.01$). e and a were correlated with the diastolic forward and reverse flow velocity of right upper pulmonary vein (0.3 and 0.5, $p < 0.05$)

The mean value of systolic AVPD was correlated with angiographic EF (0.35, $p < 0.01$). Mean AVPD in early diastole and mean AVPD during atrial systole were significantly correlated with E and A velocities of transmitral flow and their ratio (0.3, $p < 0.05$). The early and late diastolic AVPD were not correlated with the diastolic forward and reverse flow velocity of right upper pulmonary vein.

Conclusions: Study of the mitral annulus motion by Doppler tissue imaging is more accurate than m-mode atrioventricular plane displacement, for the assessment of systolic and diastolic function of the left ventricle in patients with coronary artery disease.

P3610 Detection of a pseudonormal Doppler-derived mitral inflow pattern by Doppler tissue imaging

Christian Bruch, Daniela Marin, Stephanie Kuntz, Thomas Bartel, Raimund Erbel. *Dep. of Cardiology, University Essen, Germany*

Background: It was suggested that the assessment of mitral anular dynamics by DTI permits a load-independent evaluation of left ventricular function.

Methods and Results: According to their symptoms of heart failure and their clinical history three groups (g) of patients (pts.) with normal systolic function (EF > 48%) were separated: ten asymptomatic subjects (60 ± 10 y., g A), 15 pts. with coronary artery disease (60 ± 11 y., NYHA class 1.4 ± 0.4, g B) and 15 pts. with arterial hypertension (58 ± 9 y., NYHA class 2.4 ± 0.5, g C). The mitral inflow profile (E, A, E/A) was obtained by pulsed Doppler. Peak diastolic velocities of the septal mitral anulus (E_T, A_T, E_T/A_T) and the time interval from Q in the ECG to the onset of E_T were derived from pulsed DTI. All patients had invasive measurement of left ventricular enddiastolic pressure. (LVEDP).

Group	E (cm/s)	A (cm/s)	E/A	E_T (cm/s)	A_T (cm/s)	E_T/A_T	Q-E_T (ms)	LVEDP (mmHg
A	70	73	0.97	11.7	11	1.11	289	8
(n = 10)	± 17	± 11	± 0.25	± 4.7	± 4.6	± 0.36	± 38	± 3
B	55	65	0.88	8.9	10.7	0.85	302	12
(n = 15)	± 20	± 13	± 0.3	± 5.4	± 6.1	± 0.26	± 40	± 6
C	77	81	1.02	6.9*	10	0.71*	375*	16*
(n = 15)	± 33	± 28	± 0.52	± 4.8	± 6.2	± 0.28	± 55	± 8

$p < 0.05^*$; B/C vs. A, Q-E_T after correction for heart rate. E_T was only poorly correlated to LVEDP ($r = 0.12$, $p > 0.05$).

Conclusion: DTI is a preload-independent tool for the assessment of LV diastolic dysfunction in symptomatic patients with preserved systolic function, a pseudonormal mitral inflow and elevated filling pressures.

P3611 Energy mode Doppler tissue imaging analysis of the left ventricular wall function and intra-myocardial differences between the endocardial and epicardial layers: normal pattern description in a clinical scenario

Pio Caso, Miguel Garcia-Fernandez, José Azevedo, Pablo Puerta, Mar Moreno, Manuel Desco, Javier Bermejo, Juan Luis Delcan. *Laboratorio de Ecocardiografia, Departamiento and Servicio de Cardiologia, Hospital General Universitario "Gregorio Marañon", Madrid, Spain*

Energy mode of the color Doppler tissue imaging (DTI) reflects the Doppler intensity shift of the myocardium and its is a new modality in the non invasive assessment of regional myocardial wall diastolic performance. The advantage and potential clinical applicability of this new imaging method are still unknown. The aim of this study was to analyze the differences between the endocardial (Endo) mesocardial (Meso) and epicardial (Epic) layers during the cardiac cycle in normal individuals using the new energy DTI mode and to establish its normal pattern. After appropriate DTI M-mode energy acquisition using the left ventricular posterior wall and the parasternal long axis view, we divided the cardiac cycle in seven consecutive phases, the QRS complex (Q), the early systole (S1), mesosystole (S2), endsystole (S3), early diastole (D1), mesodiastole (D2) and enddiastole (D3). In a population with 10 normal subjects, for each phase of the cardiac cycle the energy DTI images were quantitatively evaluated in each one of these three myocardial layers (Endo/Meso/Epic) and its correspondent absolute differences (Δ) were also calculated. Our results showed that the more significant statistical differences in intra-myocardial energy mode DTI analysis were obtain always between the Endo and Epic layers, and specially for the Q phase (Δ = 5.7 ± 3.7; p = 0.006), S2 phase (Δ = 4.9 ± 3.6; p = 0.006), D2 phase (Δ = 6.6 ± 6.1; p = 0.008) and D3 phase (8.5 ± 6.2; p = 0.005), a pattern that was constant in all individuals without cardiac pathology.

Conclusion: The regional intra-myocardial energy Doppler tissue imaging analysis of the left ventricle under physiological conditions is feasible in a clinical scenario, registered an heterogeneous pattern within the myocardial wall thickness and during the cardiac cycle, and can establish and quantitate the intra-myocardial differences or gradient between the endocardial and epicardial layers.

P3612 Can assessment of long-axis function differentiate between pathological and physiological left ventricular hypertrophy? A study using tissue Doppler echocardiography

D. Vinereanu, A. Tweddel[1], N. Sculthorpe[1], K. Naka[1], M.R. Stephens[1], A.G. Fraser[1]. *University Hospital of Bucharest, Bucharest, Romania; ; [1]Department of Cardiology, University Hospital of Wales, Cardiff, UK*

In some athletes with an increased left ventricular wall thickness, it is difficult to distinguish between physiological hypertrophy due to athletic training and pathological hypertrophy due to hypertrophic cardiomyopathy (HCM) or coincidental arterial hypertension (HT). This discrimination is clinically important because undiagnosed HCM is one of the most common causes of sudden cardiac death in young athletes.

Methods: We studied long-axis function in 30 patients with different types of left ventricular hypertrophy (LVH) (Gp 1 = 10 pts with HCM; Gp 2 = 10 pts with HT; Gp 3 = 10 weightlifters), and compared these with 10 normal subjects (Gp 4), to identify echo criteria which might differentiate between physiological and pathological LVH. The peak systolic velocities of mitral annular motion by tissue Doppler echocardiography were measured from the apex at 4 sites: lateral – L; medial – M; anterior – A; inferior – I; 4-site average – Mean.

Results: Global EF was normal and similar in all groups (mean: 65%, 65%, 63%, 68% respectively). There were no differences in mean age between groups, apart from Gp 2 who were older (mean: 36, 46, 30, 35 years, respectively). LV mass index (LVMI) and long-axis velocities are shown in the table. A peak systolic < 9 cm/s for mean systolic annular motion differentiated well (sensitivity 85%, specificity 100%) between pathological and physiological LVH.

LV mass index and long-axis velocities

Group	LVMI (g/m^2)	L (cm/s)	M (cm/s)	A (cm/s)	I (cm/s)	Mean (cm/s)
1	169 (58)	8.8 (2)	7.3 (2)	7.5 (2)	8.2 (2)*	7.9 (2)*
2	185 (44)	8.2 (2)	7.6 (1)#	7.9 (2)#	7.8 (1)#	7.9 (1)#
3	181 (34)	10.7 (3)	10.5 (2)*#	10.3 (2)*#	10.8 (2)*#	10.5 (2)*#
4	115 (21)	10.3 (1)	9.6 (1)	10.2 (1)	9.8 (1)	10.0 (1)

*p < 0.05: HCM vs. athletes; #p < 0.05: HT vs. athletes

Conclusion: Long-axis systolic function is decreased in patients with pathological LVH, but preserved in athletes. This simple new echocardiographic parameter may discriminate between pathological and physiological LVH.

P3613 Long-axis parameter changes during low-dose dypiridamole-dobutamine stress echocardiography

P. Andrássy, F. Szabóki[1], I. Balogh[2], A. Sárközy, K. Heltai[1], I. Märcz[1], K. Zámolyi. *Bajcsy-Zsilinszky Hospital, Budapest; [1]Hungarian Railways Hospital, Budapest; [2]Uzsoki Hospital, Nuclear Medicine Department, Budapest, Hungary*

The **aim** of the study was to examine long axis M-mode (LAM-m) parameter changes during combined low-dose Dipyridamole-Dobutamine stress echocardiography (DDSE) for the evaluation of myocardial viability. This method was compared with the accepted Thallium-201 rest and late redistribution scintigraphy.

Methods: DDSE was performed on the 35th day (± 2.2) of myocardial infarction (MI) in 60 patients (48 males, mean age 54.7 ± 10 years). Infusion of 0.28 μg/kg Dypiridamole over a 4 minute period, than 5 μg/kg/min Dobutamine (DBA) for 3 minutes and 10 μg/kg/min DBA for another 3 minutes were administered. The LAM-m pictures of the mitral annulus movement were obtained (depending on the location of MI) in four different sections (infero-septal, anterior, antero-lateral, inferior). We measured in 122 MI sections the following LAM-m parameters at rest: the total excursion of the mitral annulus *(d1)* and the mean velocity of the mitral annulus systolic movement *(v1)*, than we repeated the measurements in the 10th minute of DDSE *(d2, v2)*. The *d2/d1* and the *v2/v1* quotients were calculated to describe the changes during the DDSE. The rest and the late redistribution Th*201* images were done in all patients following DDSE. According to the isotope results the LAM-m sections were divided into viable (group A: 91 regions) and non-viable territories (group B: 31 regions).

Results: We found significant differences between the two groups in the values of *d2, v2, d2/d1, v2/v1*.

	d1 (cm)	d2 (cm)	v1 (cm/s)	v2 (cm/s)	d2/d1	v2/v1
Group A	1.04 ± 0.29	1.41 ± 0.38	3.31 ± 1.04	4.84 ± 1.51	1.38 ± 0.28	1.53 ± 0.46
Group B	1.12 ± 0.37	1.14 ± 0.39	3.52 ± 1.39	3.64 ± 1.61	1.05 ± 0.25	1.05 ± 0.28
p <	NS	0.002	NS	0.0005	0.0001	0.0001

The best parameter to distinguish viable from non-viable myocardium were *d2/d1* (chi square = 29.9, Wilks lambda = 0.778). We determined the discriminant function of *d2/d1* for the evaluation of viability: sensitivity 78.0%, specificity 83.9%, positive predictive value 93.4%, negative predictive value 56.8%, accuracy 79.5%.

Conclusions: The *d2/d1* quotient has a high positive predictive value in the determination of viable myocardium. If the *d2/d1* value does not suggest viability further imaging processes are necessary to exclude it.

P3614 Assessment of left ventricular myocardial viability using mitral annular descent velocity: a study with dobutamine stress pulsed tissue Doppler imaging

Y. Mishiro, T. Oki, H. Yamada, M. Abe, Y. Onose, T. Tabata, S. Ito. *2nd Department of Internal Medicine, The University of Tokushima, Tokushima, Japan*

Systolic mitral annular motion velocity (MAV) usually reflects left ventricular (LV) asynergy corresponding to the infarct regions in patients with myocardial infarction (MI). However, the relationship between MAV and myocardial viability has not been clarified.

Methods: The study population consisted of 24 patients with previous MI who had one major coronary lesion by coronary angiography and 10 normal subjects (mean age 65 ± 12 and 61 ± 14 years, respectively). We performed Tc-99m-methoxyisobutyl isonitrile scintigraphy in all 24 patients, and divided them into the two groups (A group; 13 patients with myocardial viability, B group; 11 patients without viability). Dobutamine was administered intravenously (2, 5, 10, 20 μg/kg/min, 10 minutes intervals), and peak first and second systolic MAVs (Sw1 and Sw2, respectively) were measured at the 6 mitral annular sites (anteroseptal, posterior, inferior, anterior, posteroseptal and lateral sites) by pulsed TDI. LV wall motion score index (WMSI) was determined according to the classification of American Society of Echocardiography.

Results: At baseline, WMSI was significantly greater, and mean systolic MAV was significantly lower in both A and B groups than in the control group, but there were no significant differences between A and B groups. After dobutamine infusion, WMSI improved in only A group. Sw1s and Sw2s at the mitral annular sites corresponding to the infarct regions increased significantly with 2 μg/kg/min and with 5 μg/kg/min, respectively, compared to baseline in group A. However, there were no significant increases in both systolic velocities even with 20 μg/kg/min in B group.

Conclusion: Systolic MAV, especially Sw1, is a useful and feasible parameter for detecting the regional LV myocardial viability using dobutamine stress pulsed TDI in patients with MI.

P3615 The effect of β-blockade on regional myocardial function in patients with coronary artery disease evaluated with colour Doppler myocardial imaging

U.M. Wilkenshoff, B. Janerot-Sjöberg[1], J. Engvall[1], B. Wranne[1], G. Sutherland[1]. *Dept of Cardiology, University Hospital Benjamin Franklin, Berlin, Germany; [1]Dept. of Clinical Physiology, Linköping Heart Center, Linköping, Sweden*

Quantititative assessment of regional myocardial function and the evaluation of β-blockade effects in patients with coronary artery disease (CAD) is of great clinical importance. Currently 2-D echo recognition of wall motion abnormalities (WMA) is based on a qualitative visual assessment of wall motion. With Colour Doppler Myocardial Imaging (CDMI), however, regional myocardial motion can be quantified by measuring peak systolic motion velocities (SVs) within the myocardial wall.

Aim of the study was therefore to evaluate regional myocardial motion with CDMI in patients with CAD and to study the β-blockade effect on normal and less perfused myocardial regions.

Methods: 32 pts with invasive proven CAD (>70% stenosis) and WMA in 2-D-echo were examined with CDMI. 18 pts received a β-blocker therapy. WMA in 2-D echo and SVs of myocardial motion were determined in the 16 standard myocardial segments by 2 blinded observers and compared to normal contracting corresponding segments of 32 age-matched volunteers with regard to normal and less perfused regions and β-blocker therapy.

Results: There was an agreement of 78% between visually assessed WMA by 2-D echo and reduced SVs (below 1 SD of normal segmental SVs) measured by CDMI and an agreement of 85% between angiographically defined stenotic vessel related segments and those with reduced SVs in CDMI. A mean of all SVs derived from 16 segments was significantly lower ($p < 0.001$) in pts with CAD (3.3 cm/s) compared to normals (4.7 cm/s). In pts with CAD mean SVs in segments supplied by stenotic vessels were significantly lower ($p < 0.001$) compared to corresponding segments in normals while mean SVs in segments supplied by non-stenotic vessels were significantly higher ($p < 0.01$). Comparing pts with and without β-blockade mean SVs were lower in normal perfused segments of pts with β-blockade while they were similar in less perfused regions.

Conclusions: CDMI could reliably identify both, segments with reduced contractility in 2-D-echo and segments supplied by angiographically proven stenotic vessels. Furthermore, CDMI allowed quantitative assessment of segmental myocardial motion in pts with CAD which showed reduced systolic motion velocities in regions supplied by stenotic vessels and increased SVs in normal perfused myocardial regions indicating compensatory hypercontractility. β-blocker therapy seems to affect normal and less perfused myocardial regions differently.

P3616 Early postoperative improvement of myocardial systolic velocities assessed by Doppler tissue imaging in patients with significant aortic stenosis

O. Pascal, M. Simon, J. Garot, A. Obratsova, P. Gueret. *Department of Cardiology, Henri Mondor Hospital, Creteil, France*

The aim of this study was to assess changes in myocardial systolic velocities by Doppler Tissue Imaging (DTI) before and after surgery for valvular aortic stenosis (AS). 10 patients (6 M, 4 F), mean age 72 ± 9 y with a significant AS (mean gradient 63 ± 13 mmHg, valve area 0.6 ± 0.3 cm2), good LV function (M-mode echo fractional shortening 34 ± 8%) and no coronary artery desease were studied before and early (6 ± 2 d) after isolated aortic replacement. Radial epicardial, endocardial velocities as well as transmural LV gradient were calculated by M-mode DTI in posterolateral wall (short axis view), and longitudinal LV velocites were calculated by pulsed DTI in inferior wall (apical 2C view).

Systolic radial velocities (cm/s)

	Epicardium		Endocardium		Gradient	
	Before	After	Before	After	Before	After
	1.6 ± 0.7	3.0 ± 1.3	3.6 ± 1.2	7.3 ± 4.9	1.9 ± 1	3.1 ± 2.
p	0.003		0.04		0.16	

Systolic longitudinal velocity (cm/s)

	Before	After
	5.6 ± 1.1	8.2 ± 1.5
p	0.001	

Valvular replacement for aortic stenosis was associated with early improvement in both radial and longitudinal systolic LV velocities, presumably because acute decrease in left ventricular afterload.

P3617 Early changes in left ventricular long axis function following aortic valve replacement for aortic stenosis in patients with left ventricular dysfunction

J. Collinson, M.Y. Henein[1], M. Flather, D.G. Gibson[1], J.R. Pepper[2]. *Clinical Trials and Evaluation Unit, Royal Brompton & Harefield NHS Trust, London; [1]Department of Echocardiography, Royal Brompton Hospital, London; [2]Department of Cardiac Surgery, Royal Brompton Hospital, London, UK*

Chronic aortic stenosis (AS) may cause progressive left ventricular (LV) dysfunction. In many cases, LV function can be salvaged by aortic valve surgery. The best type of valve replacement in this situation is uncertain.

Methods: We studied 19 patients (mean age 64 ± 14 years, 16 males) with significant AS and impaired LV systolic function (fractional shortening < 25%), as assessed by trans-thoracic Doppler echocardiography. No patient had other valvular disease or significant coronary artery disease. Patients were studied pre-operatively and 5 days post-operatively. Patients were divided according to valve received into: Group I – 10 patients receiving a stentless valve and Group II – 9 who had a stented valve.

Results: Before surgery peak aortic gradient was 72 ± 19 mmHg in group I and 67 ± 14 mmHg in group II. Post-operatively, peak aortic gradient was 12 ± 6 mmHg in group I and 38 ± 10 mmHg in group II ($p < 0.001$). Pre-operative LV free wall excursion, peak shortening (SR) and lengthening (LR) rates were not significantly different between the 2 groups. All pre-operative values were lower than values from 21 normals ($p < 0.001$). (See table). Relative to Group II, the increase in LV free wall excursion was 0.2 cm greater in Group I (95% confidence interval −0.2 to 0.7). Increases in peak SR and LR rates were also greater, 1.3 cm/s (−1.7 to 4.3) and 0.9 cm/s (−1.5 to 3.2) respectively.

	Normal Group	Group I (n = 9)		Group II (n = 10)	
		Pre-op	Post-op	Pre-op	Post-op
Excursion (cm)	1.5 ± 0.25	0.8 ± 0.3	1.1 ± 0.4	1.0 ± 0.4	1.0 ± 0.3
SR (cm/s)	8 ± 1.5	3.9 ± 1.6	6.1 ± 2.2	4.5 ± 1.5	5.7 ± 2.4
LR (cm/s)	10 ± 2.5	3.6 ± 2.7	4.9 ± 1.4	3.9 ± 1.4	4.9 ± 1.5

Conclusion: In this small sample of patients, there was a greater early improvement in LV systolic and diastolic function in those receiving stentless valves compared to those receiving stented valves. In patients with poor LV function and AS, this improvement may be clinically important.

P3618 Myocardial velocity gradient as an indicator of regional myocardial contraction after cardiac surgery: a study with tissue Doppler imaging

H. Yamada, T. Oki, Y. Mishiro, M. Abe, Y. Onose, T. Tabata, S. Ito. *Second Department of Internal Medicine, The University of Tokushima, Tokushima, Japan*

Background: It is common finding that ventricular septum (VS) after cardiac surgery indicates a systolic abnormal motion in the M-mode echocardiogram. Recently, it has been reported that the myocardial velocity gradient (MVG) obtained from tissue Doppler imaging (TDI) is useful as a noninvasive index in evaluating myocardial thickening or thinning. We evaluated the systolic MVG in the VS in patients after cardiac surgery.

Methods: We recorded the left ventricular (LV) M-mode color-coded TDI in 20 postoperative patients who showed a systolic abnormal ventricular septal motion in the M-mode echogram and 10 normal controls. There was no evidence of clinically significant abnormal findings following the cardiac surgery in all patients. The myocardial velocity profile in the VS and posterior wall was extracted during a cardiac cycle, and the MVG was measured as the slope of the regression line for each velocity profile across the myocardium.

Results: There was no significant difference in LV ejection fraction determind from the 2-dimentional echocardiogram between the patient and normal groups (60 ± 12 vs $62 \pm 8\%$). The systolic peak MVG derived from the posterior wall showed no significant difference between the two groups (3.0 ± 0.7 vs 3.2 ± 0.9 cm/s/cm). The systolic peak MVG derived from the VS also showed no significant difference between the two groups (1.9 ± 0.7 vs 2.2 ± 0.5 cm/s/cm).

Conclusions: The systolic thickening in the VS is preserved in patients after cardiac surgery despite the abnormal motion in the M-mode echocardiogram. The MVG is a clinically feasible index in evaluating the regional myocardial contraction, which is hardly affected by the translation of the heart.

P3619 Evaluation of myocardial Doppler imaging in the detection of bypass tracts in Wolff-Parkinson White syndrome

J. Forster, M.E.C. Blackburn[1], P. Carter[2], E. McInnes[2]. *Yorkshire Heart Centre, Cardiac Ultrasound Dept, Leeds; [1]Cardiac Ultrasound Dept, Yorkshire Heart Centre, Leeds; [2]Health and Community Studies Dept, Sheffield Hallam University, Sheffield, UK*

Myocardial Doppler Imaging (MDI) provides a new sensitive technique for detecting wall motion and may be useful in characterising the ventricular contraction sequence. In Wolff-Parkinson White (WPW) syndrome there is abnormal premature activation of the ventricles in sinus rhythm and using MDI it should be possible to localise the antegrade conducting bypass tract. Algorithms exist to predict the site of overt bypass tracts from the surface ECG (sECG) but are less useful when pre-excitation is minimal. This study was conducted to evaluate whether MDI could add to non invasive mapping of bypass tracts. The pattern of ventricular activation was studied using MDI in 13 patients with WPW and 35 normal controls to identify the onset and sequence of contraction. The sECGs of the WPW group were analysed to predict the position of the pathway. There was a significant difference in the time interval from onset of atrial depolarisation to earliest onset of ventricular contraction between the WPW group and controls (159 ms vs 210 ms, $p < 0.05$). The sequence of contraction also differed in WPW compared to the controls. In the WPW group, the sECG identified 8 left sided pathways. There was close correlation with MDI data in 2 cases. In a further 5 cases MDI identified a region of myocardium adjacent to the location of the pathway as predicted by the sECG. No correlation was observed in 1 case. The sECG identified 5 right sided pathways and in 4 of these cases the RV was observed to contract prior to the LV. However, precise location of the region within the RV to contract was not possible. In 1 case the LV myocardium, adjacent to the RV insertion contracted first. In WPW, MDI demonstrates early, abnormal activation of ventricular myocardium. Left sided pathways can be predicted more reliably than right sided pathways due to the oblique echocardiographic plane obtained through the RV. However, at present, the predictive accuracy of algorithms to locate bypass tracts from sECGs appears more consistent and accurate than MDI.

MYOCARDIAL CONTRAST ECHOCARDIOGRAPHY

P3620 The influence of parallel beamforming on radio frequency signals – clinical implications

J. D'hooge, B. Bijnens, J. Nuyts[1], J. Thoen[2], P. Suetens[3], F. Van de Werf, G.R. Sutherland. *Cardiology Dept, [1]Nuclear Medicine, University Hospital Gasthuisberg, Leuven; [2]Dept. of Physics, Laboratorium voor Akoestiek, Leuven; [3]Dept. of Electrical Engineering, Medical Image Computing, Leuven, Belgium*

Introduction: Tissue characterization (TC) based on processing radio frequency (RF) data has been investigated by extracting parameters such as integrated backscatter (IB) and its cyclic variation (CV) and by defining statistics of the amplitude distribution of these signals. Recent data has shown that IB is not a simple sinusoidal curve but has multiple reproducable peaks and troughs thoughout the cardiac cycle. This requires data acquisition at frame rates over 100 Hz. This can be achieved by parallel beamforming. However, as this implies different processing of the received signals, the beamforming itself could influence extracted parameters. Our aims were to study the influence of parallel beamforming on the properties of the radio frequency signals.

Methods: A computer simulation environment was used to calculate B-scan images (40 lines, 30 degrees scan angle) of 30 independent, homogeneous, scattering regions (3 cm × 3 cm) with scatterer density of 20, 40 or 80 scatterers/mm^2, imaged with a dynamically focused phased array transducer (64 crystals). The emitted pulse was Gaussian and had a mean frequency of 3.5 MHz and a 100% bandwidth. Each image was calculated 3 times using 1, 2 and 4 parallel beamformers in receive. IB values, skewness and kurtosis of the resulting RF data were calculated within a region of interest of 1 cm × 1 cm. IB values were expressed on a dB-scale using the maximal reflected energy occurring as a reference.

Results: Absolute IB values decreased with increasing number of parallel beams (cf. table). However, this increase was independent of the scatterer concentration. Skewness and kurtosis of the amplitude distribution of the RF signals did not change significantly.

Mean IB values

	1	2	4
20/mm^2	-6.3 ± 0.6	-6.7 ± 0.6	-7.9 ± 0.6
40/mm^2	-3.4 ± 0.6	-3.9 ± 0.5	-4.8 ± 0.8
80/mm^2	-0.5 ± 0.3	-0.9 ± 0.3	-2.2 ± 0.2

Measured IB value (dB) as function of number of parallel beams (columns) and scatterer concentration (rows)

Conclusion: Since absolute IB levels cannot be defined in the clinical setting and have a large intrinsic variability and since changing scattering densities may be an appropriate model for CV, this study shows that parallel beamforming should not influence the measures extracted from RF for TC.

P3621 Experimental studies on an isolated pig heart model: assessment of absolute myocardial blood flow with myocardial contrast echocardiography

E. Helms, M. Janier[1], L. Gerfault[1], E. Canet[1], C. Cachard[1], G. Finet. *Department of Hemodynamics, Cardiovascular hospital, Lyon, France; [1]CREATIS CNRS UMR 5515*

Backround: The measurement of absolute myocardial blood flow (MBF), i.e. in ml/min/g, has gained increasing importance in the evaluation of patients with coronary artery disease. It has been suggested that contrast echocardiography (MCE) can be used to assess changes in myocardial perfusion.

Methods: 5 isolated pig hearts were perfused with a nonrecirculating Krebs-Henseleit solution mixed with blood, containing 15 mM KCl to provoke cardiac arrest. To obtain a reasonable linear relation between bubble concentration and myocardial videointensity, an optimal concentration was defined. 0.01 mg of Levovist® (Schering SA), a saccharide echo contrast agent, was injected as a bolus into the perfusion line through a mixing chamber placed just upstream from coronary arteries cannula. The hearts were imaged in the short-axis with a phased array transducer emitting at a mean frequency of 1.8 MHz and receiving at a mean frequency of 3.6 MHz (second harmonic). Ultrasounds were transmitted once every second (intermittent imaging). Echocardiographic imaging were analysed off line with a videodensitometry software (Sonos 5500, Hewlett Packard Corp). The time-intensity curves from myocardial regions of interest were fitted to a gamma-variate function.

Results: The hearts were studied at different MBF from 0.4 to 3.50 ml/min/g. Excellent correlations were found between myocardial peak videointensity (PMVI), initial slope of the curve, inverse of mean transit time (1/MTT), time to peak contrast effect (TP) and MBF.

	PMVI	Slope	1/MTT	TP
r value	0.92	0.92	0.87	−0.84
p value	<0.0001	<0.0001	<0.0001	<0.0001

Conclusion: Our results suggest that when echocardiographic contrast agent is injected selectively into main coronary arteries, it might be possible to quantify MBF from time-intensity curves.

P3622 Ventricular and supraventricular premature beats induced by contrast echocardiography in an animal model

P.A. van der Wouw, J.T. Vermeulen, A.C.M. Brauns, A. Ouss, C.N. Belterman. *Department of Experimental and Clinical Cardiology, Academic Medical Centre, Amsterdam, Netherlands*

In a phase I ultrasound contrast study in healthy human volunteers, the occurrence of ventricular premature beats (VPB) was observed during end-systolic triggered imaging with high ultrasound output. To study this effect in detail, an animal model was developed.

Methods: Rabbits of 2.5–3.5 kg developed heart failure after a traumatic aortic regurgitation via a catheter was created and the abdominal aorta was partially ligated. Control rabbits did not undergo surgery. Rabbits were anaesthetized and received an intravenous infusion with an ultrasound contrast agent (AIP101, Andaris, Nottingham, UK) at 12 ml/hr in a 1:5 dilution. Before the start of the infusion baseline imaging was done using an ATL HDI 3000 with second harmonic imaging (2.7–5.4 Mhz), at an MI of 1.6, imaging depth of 5.4 cm, and focus 5 cm. Triggering was done end-systole, either every heart cycle, 1:5, and 1:10 heart cycles. During contrast infusion images were made using the same protocol. A one lead ECG was registered on the videotape of the ultrasound machine.

Results: No spontaneous VPBs or SVPBs were registered during baseline. It was possible to induce both VPBs and SVPBs, occurring directly after the trigger pulse that indicated the end of a 2D-sector sweep. With 1:10 triggering, the maximum VPB rate obtained for every trigger was 90% in heart failure rabbits. With 1:5 triggering it was 75%, while with 1:1 triggering the maximum was 7%. In control rabbits, the maximum VPB rate was 42%. The maximum SVPB was 100% with 1:10 triggering.

Conclusion: VPBs and SVPBs can be induced in a rabbit model with ultrasound and an intravenous ultrasound contrast agent, when using a high MI, and end-systolic triggering. The failing heart is more susceptible then the normal rabbit heart. A long trigger interval is necessary to allow refill of the myocardium with contrast.

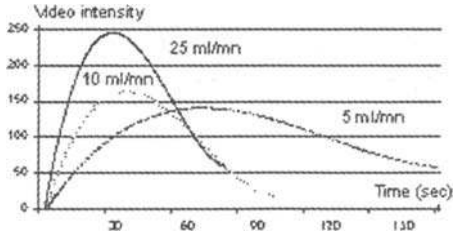
P3623 Improvement of microbubbles detection using NC100100 combined with harmonic power imaging

J.M. Perron, S. Lafitte, S. Garrigue, P. Dos Santos, R. Roudaut. *Bordeaux, France*

NC100100 is a new echocardiographic contrast agent based on a perfluorocarbon emulsion. Harmonic Power Imaging (HPI) has been developed from the Power Doppler technology to increase the stimulated acoustic emission (SAE) which allows high detection of first generation contrast agents. We sought to improve NC100100 detection by the HPI technique inducing a SAE phenomenon. Then, we assessed the effect of flow rate variations on microbubble HPI signals.

Methods: A phantom mimicking myocardial tissue was perfused by saline solution with a constant flow rate. NC100100 was injected by bolus of 0.05 ml. Echocardiography was performed with an HDI3000 system (ATLÒ) equipped with a P3-2 probe. First, the images were acquired in both triggered harmonic imaging and HPI mode for off line videodensitometry analysis and pixel intensities (PI) were compared between the two modalities. Second, flow rate variations (range: 5–20 ml/min) were assessed in terms of PI.

Results: Before NC100100 injection, the mean PI was 22 ± 1.5 with harmonic imaging and 29 ± 0.7 with HPI. The Peak PI was significantly higher in the two modes after the injection of NC100100 but dramatically much more with HPI mode than with harmonic imaging (215 ± 15 vs 55 ± 15, $p < 0.001$). In HPI mode, the peak PI significantly changed depending on the flow rate variations (146 ± 13, 159 ± 21, 248 ± 19) (figure).



HPI NC100100.

Conclusion: HPI mode provides a substantially more sensitive NC100100 detection compared with harmonic imaging. Moreover, the contrast HPI signal is significantly modulated by flow rate variations.

P3624 How does respiration interfere with measuring myocardial signal intensity during contrast studies?

J.U. Voigt, K.W. Temmen, D. Wemer, U. Nixdorff, H. von Bibra[1], W.G. Daniel. *Medical Clinic II, University Erlangen, Erlangen, Germany; [1]Karolinska Institute, Stockholm, Sweden*

Background: Quantification of myocardial perfusion by means of contrast echocardiography is usually based on measurements of myocardial signal intensity (SI) changes. Since those changes may be very small, this study was designed to determine the influence of breathing on the quantitative assessment of contrast effects.

Methods: We acquired ECG-triggered images from an apical four chamber view in 10 healthy volunteers before and during continuous infusion of Levovist® (400 mg/ml, mean infusion rate 100 ml/h) using a HP Sonos 5500 ultrasound system (1.8 MHz, AD Contrast Mode). At least 10 frames were recorded each in apnoea, with intermittent breathing just after the ECG-trigger and with spontaneous breathing. Mid- and endsystolic as well as mid- and enddiastolic ECG-trigger points were used. A total of 1200 myocardial segments was analysed with the HP Acoustic Densitometry software package. In each setting, standard deviation (SD) of the mean SI was used as a measure of the signal variation.

Results: Independent of the selected trigger point, myocardial SI significantly increased with the infusion of contrast by 1.9 ± 2.5 dB ($p < 0.01$). The maximal contrast effect was measured in the septal and lateral apex (2.88 ± 2.1 dB and 3.47 ± 2.7 dB, $p < 0.01$). In the basal lateral wall, however, SI slightly decreased due to attenuation artefacts (−0.67 ± 2.1 dB, n.s.). SD of the mean SI was lowest at apnoea (± 0.49 dB) and not significantly different from SD at intermittent breathing (± 0.58 dB). With uncontrolled breathing, however, SD raised to ± 0.78 dB ($p < 0.001$).

Conclusion: Spontaneous breathing during myocardial contrast studies causes SI changes of more than 40% of the expected contrast effect and may mask this effect completely. The acquisition of images in apnoea or – for longer acquisition periods – with intermittent breathing reduces this source of variance significantly. We therefore conclude that the control of respiration is essential during myocardial contrast studies.

P3625 Incidence of artifacts during myocardial contrast echo and nuclear scintigraphy during dobutamine stress echocardiography

M. Calachanis[3], C. Evdoridis[1], R. Slight[1], M. Ritsou[1], D. Chin[2], M. Monaghan[2], P. Nihoyannopoulos[1]. *[1]Cardiology Department, Hammersmith Hospital, ICSM, London; [2]Cardiology Department, Kings College Hospital, London, UK; [3]Institute of Cardiology, University of Chieti, Italy*

NC 100100 (Nycomed) is a new gas filled contrast agent with the ability of myocardial opacification.

Methods: In this study we compared MIBI SPECT to myocardial contrast echocardiography (MCE) in 20 patients (mean age 63.4 ± 14.6) years with a positive (within six months) coronary angiogram who underwent dobutamine stress echocardiography (DSE). Imaging was performed with an ATL HDI 5000 using only harmonic (H) mode at progressive ECG trigger intervals from 1:1 to 1:6. All patients at peak stress had a MIBI SPECT injection, followed by a resting injection 24 h later. NC100100 was also injected at rest and peak stress at the dose of 0.03 ml/kg in the Ap 4–2 ch and parasternal LAX and SAX views. Images were stored and analyzed in digital format.

Results: MCE correctly diagnosed perfusion defects in at least one of the coronary artery territories involved in 14 out of 20 (70%) patients. Artifacts were seen in 5 patients, involved the lateral wall in both Ap4ch and SAX views and in the inferior walls and were due to rib attenuation and lateral anisotropism. Nuclear scintigraphy correctly diagnosed 15 perfusion defects and showed artifacts involving the anterior wall in 3 patients that were considered as motion artifacts and in the inferior wall in 4 patients that were considered as attenuation from the gut or liver and in one case maybe due to breast apposition.

Conclusion: Artifacts which can mimic perfusion defects can occur with both MCE and SPECT due to a variety of reasons. To avoid false positive results with MCE it is essential to understand these artifacts as nuclear scintigraphy does.

P3626 The effect of optison on sensitivity and specificity of dobutamine contrast echocardiography in technically difficult patients

Melda Dolan, Sanjeev Puri, Kamala Tamirisa, Jeanette St. Vrain, Elena Havens, Jean Flanagan, Mort Kern, Arthur Labovitz. *St. Louis University, St. Louis MO, USA*

Optison, a recently approved echo contrast (C), improves endocardial visualization during Dobutamine Stress Echocardiography (DSE); whether this improvement leads to improvement in sensitivity and specificity of DSE is not well known. Therefore we studied total of 204 patients; 92 with technically difficult studies underwent intravenous contrast adminitration during DSE were compared with 112 patients without contrast. All patients (pts) underwent coronary angiography. Color coded perfusion analysis, regional wall thickening, and percentage of endocardial border visualization (EBV) were performed off-line There were no differences between the groups with respect to age sex, history of myocardial infarction (MI), resting wall motion abnormalities (RWMA) and stenosis severity, extent and location. In the group of DSE with contrast, EBV improved from 52 ± 8% to 87 ± 7% after contrast injection.

	Age	Male%	3 vessel	Hx/MI	LAD	RWMA
DSE with C	62 ± 8	54	40%	42%	59%	59%
DSE without C	60 ± 9	58	38%	40%	64%	54%
p	NS	NS	NS	NS	NS	NS

Sensitivity of DSE for detecting coronary artery disease ≥70% was significantly higher with Optison with additive information obtained from quantitative perfusion and wall thickening analysis performed (65% versus 89%, p = 0.01). Likewise, specificity was significantly improved with echo contrast (72% vs 91%, p = 0.01)

In conclusion, Optison administration during DSE combined with perfusion analysis in technically difficult studies leads to improved sensitivity and specificity as compared to pts with good quality non contrast images.

P3627 Venous myocardial contrast echocardiography can guide clinical decision making in the cardiac catheterization laboratory

C. Firschke, R. Blasini, S. Lange, M. Reeg, U. Schricke, S. Martinoff, M. Schwaiger, A. Schömig. *Deutsches Herzzentrum; 1. Medizinische Klinik der Technischen Universität München, Munich, Germany*

In the experimental setting, venous myocardial contrast echocardiography (VMCE) combined with pharmacological stress has been demonstrated to detect myocardial blood flow mismatch in the presence of coronary stenosis. We therefore hypothesized that, similar to nuclear cardiac imaging, the functional relevance of a coronary stenosis can be detected in patients by VMCE during pharmacological stress.

In 50 patients, coronary stenoses on cardiac catheterisation were considered of uncertain functional relevance. As clinical routine, these patients were subsequently sent for TC 99 m Sestamibi SPECT imaging (SI) at rest and with exercise to determine the need for PTCA in case of stress induced hypoperfusion. Before nuclear imaging, VMCE (continuous infusion of 8 g (300 mg/ml) of Levovist at 200 ml/h) at rest and with pharmacological stress (140 μg adenosine/kg for 5 min) was performed in the 4- and 2-chamber views (5 segments each). Each segment was scored as normal or abnormal for VMCE and SI by two observers blinded to the results of the other method. On SI, 19 patients (68/600 segments) showed abnormal perfusion at rest and deterioration of perfusion with stress was noted in 33 patients (80/600 segments). There was excellent concordance with the findings of VMCE for normal perfusion, reversible and irreversible hypoperfusion for the patient (88%, k = 0.82) and segmental (82%, k = 0.78) comparison. Intra- and interobserver concordance for VMCE was 92% (k = 0.82) and 88% (k = 0.78) respectively. In the 33 patients with positive SI, PTCA of the vessel showing stress induced hypoperfusion was performed.

We therefore conclude, that VMCE is a promising clinical tool for the evaluation of the functional relevance of coronary stenoses. Its impact on the decision between treatment options for coronary lesions can be similar to SI.

P3628 Automatic LV volume and ejection fraction by contrast harmonic color Doppler imaging compared to radionuclide ventriculography

G. Bezante, K.Q. Schwarz[1], X. Chen[1], M. Bertolazzi, P. Spallarossa, G. Villa, C. Brunelli. *Internal Medicine Dept, Cardiology, Genoa, Italy; [1]Medical Center – Cardiology Unit, University of Rochester, Rochester and New York, USA*

Background: Radionuclide ventriculography (MUGA) is a gold standard for measuring LVEF because it is accurate and machine interpreted. Echo LVEF measurements are subjected to variability in image acquisition, interpretation and to the limitations of 2D vs. 3D imaging.

Methods: The LV end diastolic (ED) volume (VOL), end systolic (ES) VOL and LVEF were determined by contrast harmonic color Doppler (CHCD) to MUGA in 35 patients. CHCD 3D VOLs were machine derived from Simpson's rule and an automatic edge detection algorithm that averages the 2D VOL from 3 apical views. The CHCD data was compared to MUGA using linear regression and Bland-Altman analysis.

Results: CHCD produced images with vivid endocardial definition in all patients regardless of precontrast image quality (9% inadequate contrast harmonic 2D) and the exams were completed in less than 3 min. The MUGA LVEF range was 9 to 70% and the MUGA LV VOL ranges from 55 to 320 ml and 20 to 249 ml at ED and ES, respectively. CHCD LVEF showed excellent correlation with MUGA LVEF (regression slope 1.004, R2 = 0.973), as did LV VOL (ED slope 1.17, R2 = 0.92 and ES slope 0.12, R2 = 0.912).

Conclusions: CHCD accurately measures LV VOL and LVEF using machine detected LV borders. Vivid endocardial delineation is seen even in cases that are technically difficult.

P3629 Echo contrast lung transit time: a sensitive new parameter for left ventricular dysfunction

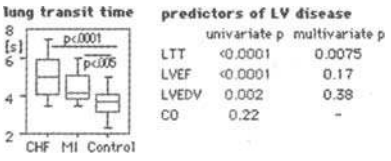
M. Weinbacher, K. Gerber, P.R. Hunziker, P.B. Gordon, M. Scherrer-Crosbie, U. Knutti, M. Pfisterer, P. Buser. *Cardiology Dept, Univ. Hospital Basel, Basel, Switzerland*

Detection and follow-up of left ventricular (LV) dysfunction are important indications for echocardiography. The limited accuracy of echo for systolic LV function, the difficulties of assessing diastolic function, and the subjectivity of the assessment make this task difficult.

Hypothesis: We hypothesized that forward LV failure (increased circulation time) as well as backward failure (increased lung blood pool) prolong the lung transit time (LTT) of echo contrast agents, and that therefore the LTT could serve as a useful quantitative parameter for LV function assessment.

Method: In 74 patients (23 with heart failure [CHF], 20 after infarction [MI] but without CHF, 31 controls), LTT from the right ventricular outflow tract to the left atrium was measured after IV injection of the fluorocarbon echo contrast agent Nycomed NC100100 (0.03 μL/kg). Enddiastolic LV volume (EDV), ejection fraction (EF), and cardiac output (CO) were measured using the biplane method of disks with contrast enhanced endocardial delineation.

Results: LTT was significantly prolonged in LV disease (CHF or MI; figure) compared to controls. In comparison with LVEF, LVEDV and CO, LTT was a stronger and independent predictor of LV disease by univariate and multivariate analysis (table). LTT was inversely correlated with LVEF (p < 0.0001, r = 0.45).



predictors of LV disease	univariate p	multivariate p
LTT	<0.0001	0.0075
LVEF	<0.0001	0.17
LVEDV	0.002	0.38
CO	0.22	-

Lung transit time.

Conclusion: Determination of the echo contrast lung transit time, a novel quantitative application of contrast echocardiography, proved highly valuable in assessing left heart disease and compared favorably with conventional noninvasive parameters. This parameter is rapidly available at bedside and promises improved objective evaluation of LV function.

STRESS ECHOCARDIOGRAPHY – MISCELLANEOUS

P3630 International "Stress Echo Horror Poll" registry: "ad interim" results on 47,858 examinations

A. Varga, E. Cseh, E. Picano. *Institute of Clinical Physiology, Pisa, Italy*

Background: The safety of any test is a major issue in deciding its practicability and cost-effectiveness – yet, many major complications remain transparent to published literature, due to the "file drawer" bias, lack of time ("busy agenda bias") or unfamiliarity with the technicalities of scientific communication.

Aim and Methods: To evaluate the safety of various stress echo modalities in the "real life" an international "Stress Echo Horror Poll" registry was started. Up to January 1999, 33 echo laboratories have reported about 47,858 examinations.

Results: Exercise was used in 13,885, dobutamine in 20,280, dipyridamole in 13,693 cases. Life threatening events occurred in 30 patients: during exercise in 1 patient (event rate: 1/13,885), during dobutamine infusion (low dose for viability or high dose for ischemia) in 20 patients (event rate: 1/1,014) and during dipyridamole stress test in 9 patients (event rate: 1/1,521). Of the 30 patients with complications, 2 died during dobutamine stress test (ventricular fibrillation and cardiac rupture) and 1 following a dipyridamole test (hypotension).

In conclusion, dreadful complications may occur during exercise and, to a greater extent, during pharmacological stress echo. Stress echo should always be performed with an attending physician, with know-how and facilities for basic and advanced life support.

P3631 Safety of ergotaminergic pharmacological stress echocardiography for vasospasm testing in the echo lab: 15 years experience on 543 tests in 529 patients

A. Varga, E. Picano, O. Rodriguez, M. Morelos, R. Sicari, B. Del Negro, A. Djordjevic-Dikic, M.A. Morales, C. Carpeggiani. *Institute of Clinical Physiology, Pisa, Italy*

The safety of pharmacological stress testing for coronary vasospasm when performed outside the cath lab has been vigorously questioned. Aim of the study was to assess the safety of ergonovine/ergometrine stress testing performed in the echo lab. To this purpose, we retrospectively reviewed the data prospectively collected in the echo lab of the Institute of Clinical Physiology from January 1, 1985 up to December 31, 1998 on 543 tests performed by either ergonovine (n = 250) or ergometrine (n = 293) stress echo testing on 529 patients with history of chest pain, consistent with vasospastic angina. Ergonovine or ergometrine maleate was injected up to a total cumulative dosage of 0.35 mg. Interpretable echocardiograms were obtained in all patients during stress. Transient regional myocardial dysfunction occurred in 76 patients (14%). Limiting ischemia-independent minor side effects were present in 16 patients (3%). The overall feasibility was 97%. One patient had non-sustained ventricular tachycardia associated with transient ST segment elevation 30 minutes after the test. Two patients had second degree AV block associated with positive echocardiography test and promptly reversed by nitrates administration. Pharmacological stress echocardiography with either ergonovine or ergometrine is technically simple, highly feasible and can be safely performed in echo lab in properly selected patients in whom coronary vasospasm is suspected.

P3632 Is transesophageal echocardiography a viable option in the stress echo lab? The Pisa experience

L. Pratali, A. Pingitore, A. Varga, R. Sicari, E. Picano. *Institute of Clinical Physiology, Pisa, Italy*

In order to assess the practical domain of application of transesophageal echocardiography (TEE) in the busy reality of a large volume stress echo lab, the Pisa stress echo lab experience from January 1994 to January 1999 was retrospectively reviewed. A total of 2630 transthoracic stress echo studies were performed. Additional 173 stress TEE studies (6.5% of the total stress echo load) were requested for one of the following indications: 1) poor transthoracic acoustic window (n = 26); 2) ambiguous transthoracic stress echo results (n = 10); mapping of mitral insufficiency during low dose dobutamine prior to coronary artery bypass surgery (n = 7); 4) coronary flow reserve assessment in patients with normal coronary arteries and suspected microvascular disease or with left anterior descending coronary stenosis of intermediate severity (n = 135). The total stress time (from preparation to report) was consistently <30 min. In 3 cases the TEE was interrupted for intolerance. In the remaining 170 patients, interpretable images were obtained, yielding an overall feasibility of 98%. TEE stress echo was withheld in 2 cases, in which resting TEE documented a severe left main stenosis – subsequently confirmed by angiography. In 168 patients, pharmacological stress TEE was completed with dobutamine up to 40 mcg/kg/min (n = 21), dipyridamole up to 0.84 mg/kg (n = 76), or adenosine up to 0.14 mg/kg/min for 5 min (n = 71).

In conclusion, stress TEE is a feasible and effective option for versatile assessment of anatomic disease, wall motion abnormalities, functional evaluation of mitral valve and coronary flow reserve. The TEE allows to vanquish acoustically hostile transthoracic windows and flow reserve assessment help to document noninvasively a coronary microvascular disease. Identification of severe left main stenosis in resting TEE is an additional built-in safeguard against contraindicated stress testing.

P3633 Post-stress echo ischaemia in patients with coronary artery disease

M. Zanchi, R. Marazzi, T. Forzani, J.A. Salerno. *University of Insubria, Medical School of Varese; Cardiology Division, Mater Domini Hospital, Castellanza (VA), Italy*

Pharmacological stress echocardiography (SE) has become an important diagnostic tool and/or a follow up study in patients (pts) with coronary artery disease (CAD) because of its feasibility, diagnostic impact and safety. The stress test is interrupted after the appearence of a new wall motion abnormality (WMA) and/or worsening of the baseline WMA. After the interruption of dobutamine or dipyridamole infusion and administration of the antidote, the examination is usually considered terminated. However, we observed in some patients appearence of a new WMA *after* the interruption of the examination and administration of the antidote. We studied the features of patients with this rare phenomenon of post stress-echo ischemia (PSI).

Patients and methods: *SE:* in the period from 1997 to 1999, we performed 794 SE (399 dobutamine-atropine echo test = DOBET, 360 dipyridamole-atropine echo test = DIPET, 35 ergonovine echo test). PSI (i.e. a new WMA or worsening of the baseline WMA 3 to 7 minutes *after* the interruption of the test and administration of antidote – beta blockers, nitrates or aminophilline) was observed in 13 pts: in 12 pts after DOBET (1.5%) and in one pt after DIPET (0.1%). In 9 pts SE was performed as a follow up procedure after the previous PTCA, in 4 pts it was performed before the first (diagnostic) angiography.

ECG during SE: significant changes of the ST segment (≥1 mm) were observed in all pts.

Exercise test: all pts had a positive bicycle exercise test.

Coronary angiography: a) *Diagnostic angiography:* the 4 pts (30.7%) had no significant coronary lesions; b) *control (6 monthes post PTCA) angiography:* 2 pts (15.4%) had no significant intraluminal proliferation and no new lesions, 4 pts (30.8%) had an intraluminal proliferation of the stent or worsening of the coronary stenosis; in 3 pts (23%) no control coronary angiography was performed after the PTCA.

Discussion and conclusions: PSI is a rare phenomenon (only 1.6% of SE), observed almost only after DOBET; it is more frequent in pts with previous PTCA + stent (69% pts); it can be a sign of a severe endoluminal proliferation, but is present also in pts with a good post-PTCA result or without angiographically significant lesions. Although the pathophysiological mechanism is not clear, PSI is probably due to vasospastic effect of dobutamine on damaged and/or previously treated coronary arteries. This study indicates the importance of continuous monitoring of pts' symptoms, ECG and wall motion also after the SE for at least 10 minutes.

P3634 The value of QTC interval increase during dipyridamole stress echocardiography in predicting restenosis after percutaneous transluminal coronary angioplasty

B. Gabrylewicz, A. Wycisk, A. Ochala, P. Garbocz, M. Bartnik, M. Tendera. *3rd Dept. of Cardiology, Silesian School of Medicine, Katowice, Poland*

The aim of our study was to estimate whether provoked myocardial ischaemia during dipyridamole stress echocardiography (DIP-test) causes QTc interval increase in ECG leads: II, V2, V5 and if QTc changes increase sensitivity and specificity of the DIP-test.

Methods: 50 pts(19 women, 31 men) who previously underwent PTCA with recurrent angina: CCS class II – 18 (36%), class III – 29(58%), class IV – 3 (6%). Mean time from PTCA was 12.7 SD = 13.0 mth. DIP-test and elective angiography were performed in all pts. The following parameters: heart rate (HR), ejection fraction (EF), systolic volume (SV) and wall motion score index (WMSI) were measured during TTE at baseline, after the first dose of dipyridamole (0.56 mg/kg/4 min/, after the second dose of dipyridamole (0.28 mg/kg/2 min) and 6 min after termination of drug infusion. QTc intervals increase (at least 40 ms) were measured in leads II, V2, V5 during DIP-test at baseline and after the second dose of dipyridamole. DIP-test was regarded as positive in case of WMSI increase during the test.

Results: QTc increases in lead V5 were the most significant. Among 39 pts with restenosis confirmed by angiography, QTc increase was observed in 33 pts ($p < 0.05$), and positive DIP-test in 27 pts. In 11 pts without restenosis 4 pts had QTc increase and 7 pts had positive DIP-test. In pts without restenosis QTc interval in lead V5 was increased only in subgroup with positive DIP-test ($p < 0.05$), compared with subgroup with negative DIP-test ($p = 0.99$). Combined analysis of QTc increase and positive DIP-test improved the sensitivity from 75% to 89% without changing specificity: 41% vs 42%. Positive predictive value of the combined test was 89% and negative predictive value was 54%.

Conclusion: QTc interval prolongation in lead V5 during dipyridamole stress echocardiography increases DIP-test sensitivity. We suggest that QTc interval prolongation in lead V5 should be considered as an additional marker of the presence of restenosis.

P3635 Dipyridamole induced QTc shortening in Q-wave leads predicts subocclusion of the infarct-related artery early after an acute myocardial infarction

M. Bertella, F. Scalise, G. Eriano, S. Garducci, L. Melchiorre, R. Valentini. *Vimercate, Italy*

Background: At the moment we are not aware of simple noninvasive tests useful in predicting the impaired patency of the infarct related artery.

Purpose: to assess whether an unconventional, but extensively validated, ECG marker of transmural ischemia, i.e. the stress induced shortening of QTc interval, may identify patients (pts) with residual severe stenoses in the infarct related artery.

Methods: 109 consecutive pts (85 men, mean age 61 ± 11 years) underwent dipyridamole echocardiography test (DET) and subsequent coronary angiography within 2 weeks after Q-wave myocardial infarction. Dipyridamole was chosen as "stressor", because the appearance of transmural ischemia (and therefore QTc shortening) during DET needs a horizontal steal, in a collateral dependent myocardial region. The drug was infused up to 0.84 mg/kg over 10 min. The QTc interval was measured at rest and at peak stress, lead by lead, in leads showing ST-segment shift and the fractional difference percentage between the QTc intervals (ΔQTc) was calculated. ECG tracings were analyzed by 2 observers unaware of angiographic results.

Results: On the basis of angiographic findings, 2 groups were identified: pts with infarct related artery stenosis ≥ 95% (group I; n = 53) and with infarct related artery stenosis < 95% (group II,n = 56). The 2 groups were similar for rest WMSI (1.48 ± 0.26 vs 1.45 ± 0.27, P = n.s.) and chest pain during stress (6/53 vs 7/56, i.e. 11.3% vs 12.5%, P = n.s.). A significant difference between group I and II was observed regarding the mean max. ST-segment shift during stress (1.56 ± 1.05 vs 0.57 ± 0.9 mm, P < 0.0001) and the mean peak dipyridamole WMSI (1.86 ± 0.27 vs 1.69 ± 0.30, P < 0.005). Shortening of QTc interval occurred in 52/53 (98%) pts of group I, and in 5/56 (9%) pts of group II; mean ΔQTc group I = –20.6 ± 10% vs mean ΔQTc group II = +0.03 ± 5.7% (P < 0.0001).

Conclusion: Early after an acute myocardial infarction a significant ΔQTc shortening, measured in the infarct related leads, showing ST-segment shift during DET, is a noninvasive ECG parameter, useful in predicting a residual severe (occlusive or subocclusive) stenosis in the infarct related artery.

P3636 Low-dose adenosine stress echocardiography in detection of viable myocardium

A.D. Djordjevic, M. Ostojic, B. Beleslin, I. Nedeljkovic, J. Saponjski, J. Stepanovic, R. Babic, S. Stojkovic, M. Nedeljkovic, G.S. Stankovic. *Cath lab, Institute for Cardiovascular diseases, Belgrade, Yugoslavia*

Background: Low-dose adenosine may recruit inotropic reserve by increasing coronary blood flow or by increasing extracellular level of adenosine.

Objective: The aim of this study was to compare evaluate the potential of low-dose adenosine (Ado) echocardiography (echo) to identify myocardial viability.

Methods: Thirty patients with resting dyssynergy, due to previous myocardial infarction, and angiographically proven coronary artery disease (diameter stenosis ≫50% of at least one major coronary artery), scheduled for coronary revascularization, underwent low-dose Ado (80, 100, 110 mcg/kg/min in 3 minutes intervals) echo test. A criterion for myocardial viability was improvement in systolic thickening of ≫1 dyssinergic segments of ≫ 1 grade. In all patients, echo follow-up was obtained after 3 months.

Results: Systolic blood pressure (rest: 142 ± 20 mmHg) decreased slightly, but nonsignificantly after low-dose Ado (134 ± 25 mmHg, p = ns vs rest), whereas diastolic blood pressure was unchanged (81 ± 8 mmHg to 82 ± 11 mmHg, p = ns). Heart rate (rest: 65 ± 7 bpm) increased significantly to 83 ± 4 bpm ($p < 0.01$) during low-dose Ado. No patient developed echo or ECG signs of ischemia during low-dose Ado. Wall motion score index (WMSI) improved significantly from rest 1.49 ± 0.33 to low-dose Ado (1.24 ± 0.28, $p < 0.01$). Of the 174 segments with baseline dyssinergy, 72 were responders, and 102 were non-responders. An improvement of one grade or more was shown in 68 segments (viable), while 106 segments showed no improvement (necrotic). Follow-up WMSI was 1.23 ± 0.30 ($p < 0.05$ vs. rest). The sensitivity of adenosine for predicting recovery was 89%, while specificity was 89%. Positive and negative predictive values were 85% and 93%, respectively.

Conclusion: Low-dose adenosine echo test is physiologic, hemodynamically neutral test, with high diagnostic value for predicting functional recovery following successful revascularization – thus providing adequate alternative to low-dose dobutamine test for evaluation of myocardial viability.

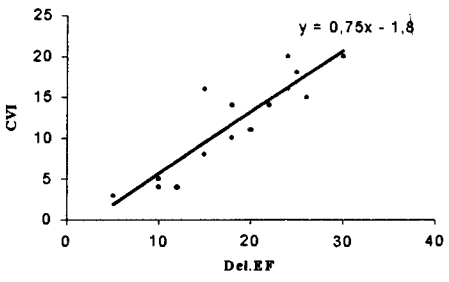
P3637 Usefulness of quantitative ultrasonic myocardial texture analysis for the prediction of myocardial contractile reserve in patients with idiopathic dilated cardiomyopathy

B. Dagdeviren, O. Bolca, O. Bolca, M. Eren, S.S. TerziAltinmakas[1], T. Tezel. *Cardiology Dept, Siyami Ersek Cardiac Surgery Center, Istanbul; [1]Cardiology, Maltepe Un. of Medical faculty, Istanbul, Turkey*

The aim of this study was to investigate the relation between videodensitometric parameters of patients with idiopathic dilated cardiomyopathy (IDC) and contractile reserve determined by low-dose dobutamine stress echocardiography (DSE). For this purpose 15 patients (mean age 42 ± 20) with IDC were enrolled in to the study. Baseline echocardiographic variables and left ventricular ejection fraction (EF) before and after 5 min. infusion of 10 mμg/kg/min dobutamine were collected. Quantitative analysis of echocardiographic digitized imaging was performed through a calibrated 256 grey level digitization system to calculate mid-septum and mid-posterior textural analysis. Systolic and diastolic Mean Grey Level (MGL) distribution of septum and posterior wall was observed and Cyclic Variation Index (CVI) was calculated according to formula: $(MGL_{diast} - MGL_{syst})/MGL_{diast} \times 100$. Baseline means of CVI obtained from septum and posterior wall were correlated to ejection fraction changes by DSE (ΔEF%) by using linear regresion analysis. The results are listed in the table and correlation between ΔEF% and CVI presented in the figure below.

	Pre-DSE values	Correlation with ΔEF%	p values
EF%	27 ± 5	0.41	NS
ESVI (ml)	124 ± 21	–0.47	NS
CVI	12 ± 6	0.89	<0.0001

NS: Not Significant



In conclusion, ultrasonic myocardial texture analysis of patients with IDC may help to predict the contractile reserve.

P3638 Value of harmonic imaging during dobutamine-atropin stress echocardiography

H. Lehmkuhl, E. Nagel, J. Lokies, R. Bartels, M. Gräfe, W. Boçksch, M. Schartl, E. Fleck. *Department of Internal Medicine & Cardiology, Charité; Campus-Virchow, Humboldt University Berlin; German Heart Institute Berlin, Germany*

Image quality exerts a major influence on the accuracy of dobutamine stress echocardiograms. This study examines the impact and value of harmonic imaging on segmental analysis of echocardiograms during dobutamine stress.

Methods: 50 consecutive DSEs according to standard protocols were performed in patients referred for the evaluation of chest pain. Digital images in cine-loop were acquired in 4-, 2-chamber views and LAX at rest and during maximal stress in fundamental (FUN; 2.0–3.5 MHz) and harmonic imaging mode (HI; 1.5–1.7/3.0–3.4 MHz). 800 segments were evaluated for left ventricular endocardial delineation and tracing (ENDO score 1–5, 5 = best imaging quality) and wall motion (WMSI score 1–4 according to ASE criteria).

Results: HI was superior to FUN in 76%, equal in 16% and inferior in 8%. The number of diagnostic segments increased from 62% (FUN) to 92% (HI). 12% of patients with non-interpretable echocardiograms during FUN became diagnostic with HI. Image quality for both FUN and HI decreased non-significantly during stress. HI increased imkage quality of especially lateral, anterior and basal-inferior segments. WMSI changed in 14% of patients.

Mean score	ENDO FUN	ENDO HI	WMSI FUN	WMSI HI
Rest	2.6 ± 0.3	3.7 ± 0.4	1.14 ± 0.09	1.11 ± 0.17
Peak stress	2.3 ± 0.2	3.3 ± 0.3	1.28 ± 0.16	1.32 ± 0.24

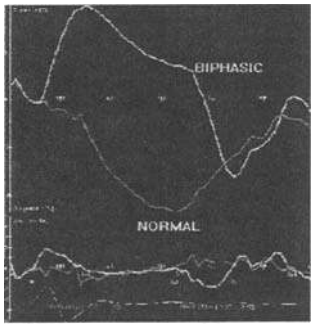
Conclusions: Harmonic Imaging significantly enhances image quality during DSE and increases the number of diagnostic LV segments.

P3639 Biphasic strain compression wave morphology during dobutamine stress echo relates to segment location and not ischaemia

P. Cain, G. Armstrong, T. Baglin, L. Short, T. Marwick. *University of Queensland, Brisbane QLD, Australia*

Myocardial strain is developing as an objective tool to assess regional LV function during dobutamine echo (DbE). Biphasic strain compression wave morphology (BSC) has been considered a characteristic of ischaemia, reflecting tardokinesis. We sought to examine the frequency of BSC morphology in normal vs diseased segts and address whether the phenomenon is site specific.

Methods: Digital images during DbE from 41 patients were acquired in tissue velocity image format from 3 apical views (Vingmed System FiVe) at rest, low dose dobutamine, prepeak, and peak stages. Wave morphology was examined post acquisition in 1264 base and middle myocardial segments for occurrence of BSC morphology. Comparison with wall motion scoring by an expert reader was analyzed.



Results: Biphasic morphology was identified *only* in normal basal segts (mainly anteroseptal). No abnormal basal or septal segts showed BSC;

Morphology	Abn mid LV	Norm mid LV	Abn basal LV	Norm Basal LV
Biphasic (12)	0	0	0	12
Normal (1252)	416	202	451	195

BSC expansion occurred between mitral closure and aortic opening.

Conclusion: Biphasic strain compression pattern appears unrelated to ischaemia. Possible explanations include detection of late atrial systole or generation of tension in the aortic root during isovolumic contraction.

P3640 Can off-line tissue Doppler echocardiography make dobutamine stress echocardiography objective?

R. Grocott-Mason, N. Payne, U. Wilkenshoff[1], M. Wutte[2], A. Ionescu, B. Lind[3], B. Janerot-Sjoberg[4], A. Fraser. *Cardiology Dept., Univ. of Wales College of Medicine, Cardiff, UK; [1]Cardiology Dept., Univ. Hosp. Benjamin Franklin, Berlin, Germany; [2]Cardiology Dept., Vienna Univ. Medical School, Vienna, Austria; [3]Cardiology Dept., Huddinge Univ. Hospital, Huddinge; [4]Fac. of Health Sciences, Linköpings Univ., Linköping, Sweden*

Dobutamine stress echocardiography (DSE) is now commonly used to establish the presence or severity of myocardial ischaemia, yet it relies on subjective interpretation of grey-scale images and has sub-optimal inter-observer and inter-centre reproducibility. Tissue Doppler echocardiography (TDE) may overcome these problems, since it can accurately quantify regional myocardial function.

The utility of real-time digital acquisition of TDE data with subsequent off-line quantification of spectral tissue Doppler profiles, to diagnose coronary artery disease, is being assessed prospectively in the MYDISE study (Myocardial Doppler in Stress Echocardiography). All patients undergo maximal DSE with data acquisition using the Vingmed System Five. To test the reproducibility of off-line measurements, 7 observers from 5 participating centres analysed studies from 8 patients. From apical 4- and 2-chamber (A4C, A2C) and parasternal long-axis(PLAX) loops, each observer measured peak systolic velocity V and other parameters, in two beats from all 16 segments (ASE model), at baseline, 20 ug/kg/min, and peak dose, using newly-developed software.

In A4C and A2C, V at rest was highest in basal segments and declined towards the apex; mean V was 6.7(sd 1.2), 4.6(0.9) and 3.1(1.2) cm/s in basal, mid and apical septum respectively ($p < 0.001$). The coefficient of variability for V showed a similar but opposite gradient, being 8–13% for basal segments (Table), 11–21% for mid-ventricular segments, and 15–47% for apical segments ($p < 0.05$). The reproducibility of anteroseptal segments in PLAX was very poor (104%).The reproducibility of V in basal and mid segments in patients with optimal images was <5%. At peak stress, reproducibility of V in basal segments remained good (coefficients of variability 10–18%).

Basal segment TDE data

	Septal	Lateral	Anterior	Inferior	Posterior
Peak velocity (cm/sec)	6.7	7.5	6.7	7.2	5.6
Pooled standard deviation (cm/sec)	0.6	1.0	0.9	0.6	0.6
Coefficient of variability (%)	9	13	13	8	11

We conclude that stress echocardiography with off-line quantification of regional myocardial function by tissue Doppler echocardiography is feasible, and that the best reproducibility and clinical value will be obtained by analysing basal myocardial segments on apical images.

P3641 Color kinesis-dobutamine stress echocardiography in the detection of involved coronary arteries

Z. Dogan, B. Ilerigelen, E. Alkan[1], S. Tavsanoglu, I. Uslu[1], D. Ucak. *Cardiology Dept., Cerrahpasa Medical Faculty, Istanbul; [1]Nuclear Medicine Dept, Cerrahpasa Medical Faculty, Istanbul, Turkey*

To facilitate a more objective evaluation of regional left ventricular performance, Color Kinesis (CK) can be used instead of conventional methods during stress echocardiography. The present study aimed to compare the accuracy of CK-dobutamine stress echocardiography (CK-DbSE) with that of Tc-99m-MIBI SPECT scintigraphy (Db-MIBI) for the identification and localization of coronary artery disease (CAD). Twenty patients (16 males,mean age 57 ± 10) were studied at the time of coronary arteriography (CA). All completed a dobutamine (Db) stress test (5 to 40 mcg/kg/min dose increments) with the addition of atropine in 5. MIBI was injected at peak stress and images were obtained 1 to 2 hours later and compared with a resting scan. CAD was identified by worsening,unchanged or new wall motion abnormality during stress at CK-DbSE and by either fixed or reversible defects at Db-MIBI. Images were interpreted in respective departments by experienced observers blinded to all clinical data and presence of CAD which was defined as > 50% stenosis in CA. For both tests,left anterior descending (LAD), circumflex (Cx) and right coronary artery (RCA) territories were determined and findings were compared with that of CA.

Results are summarized in the table.

		Sensitivity	Specifity	Accuracy
LAD	CK-DbSE	8/9 (89%)	9/11 (82%)	85%
	Db-MIBI	8/9 (89%)	10/11 (91%)	90%
Cx	CK-DbSE	7/11 (64%)	9/9 (100%)	80%
	Db-MIBI	9/11 (82%)	7/9 (78%)	80%
RCA	CK-DbSE	9/11 (82%)	8/9 (89%)	85%
	Db-MIBI	10/11 (91%)	7/9 (78%)	85%
Total	CK-DbSE	24/31 (77%)	26/29 (90%)	83%
	Db-MIBI	27/31 (87%)	24/29 (83%)	85%

In conclusion,despite a lower sensitivity in Cx territory,CK-DbSE is as accurate as Db-MIBI for the identification and localization of CAD.

P3642 Evaluation of left ventricular regional function in stress echocardiography improves by combining anatomic M-mode with tissue second harmonic imaging. Preliminary results

D. Mele, I. Pedini, K. Bettiol, P. Alboni, R.A. Levine[1]. *Division of Cardiology, Ospedale Civile, Cento, Italy; [1]Noninvasive Cardiac Laboratory, Massachusetts General Hospital, Boston, USA*

Background: Improved image quality by noncontrast harmonic imaging (HI) has been shown to reduce observer variability and increase the number of diagnostic two-dimensional (2D) examinations in dobutamine stress-echocardiography (DobSE) but interpretation of wall motion can still be difficult expecially at peak stress and in presence of subtle abnormalities. The aim of this study was to apply Anatomic M-mode (AnatMm), a new technique allowing motion and thickening of any myocardial segment to be evaluated in M-mode format, to assess segments where wall motion evaluation remains difficult or equivocal with tissue HI, particularly in the setting of DobSE.

Methods: Nine consecutive DobSE studies performed for myocardial ischemia were recorded in both fundamental (FUND) and HI modality (Octave Tissue Imaging, OTI). Four patients (pts) had a left bundle branch block. All pts underwent a nuclear stress-echo study. Two experienced observers were asked to evaluate independently all examinations, with FUND and OTI studies provided in a random sequence. After analysis of results, observers were asked to reevaluate by AnatMm the disagreement segments. Regional myocardial function was scored visually at rest and peak stress using a 1–5 scale according to the ASE 16-segments model for a total of 288 segments by each technique.

Results: The overall number of segments (rest+peak stress) considered uninterpretable (score 1) by one or both observers decreased from 5.5% (16/288) by FUND to 2.1% (6/288) by OTI ($p < 0.05$). Among the interpretable segments, interobserver disagreement decreased from 18.0% (49/272) by FUND to 11.3% (32/282) by OTI ($p < 0.01$). By applying AnatMm to this latter group (32 segments), overall observer disagreement became 4.6% (13/282) ($p < 0.01$ vs FUND). Evaluation based on AnatMm was in agreement with the nuclear examination results.

Conclusions: AnatMm reduces observer variability of DobSE particularly in segments where wall motion evaluation is difficult or equivocal even by HI. This is due to better appreciation of mild abnormalities and preserved myocardial thickening and may improve accuracy of DobSE.

P3643 In vitro validation of a new PISA method for assessing the effective regurgitant orifice area

A. Delouche, M.P. Augusseau[1], A. Decesare, P.H. Delouche[1], B. Diebold[1]. *U 494, INSERM, Paris; [1]Dept. de Cardiologie, Hôpital Broussais, Paris, France*

The present work has been designed to validate the calculation of the effective regurgitant orifice area (ERO) with the use of a new formula insensitive to any fixed error in the determination of the position of the regurgitant orifice Dr and that takes into account the velocity profile (Vr versus r) along different radius (r) of the flow convergence and the velocity at the orifice (Vo). Assuming an hemispheric model, ERO = 2p (r+Dr)2.Vr/Vo and the slope of a linear regression between Ö (Vo/Vr) and r is inversely proportional to the orifice diameter. Thus, ERO = 6.25/slope^2.This approach was tested in vitro in pulsatile conditions on circular, conical and slit-like orifices. The calculated ERO was compared with the actual jet cross sectional area derived from the transverse velocity profile at the jet origin. For the purpose of comparison the "classical" ERO was calculated for all the configurations, angulations and threshold velocities. The relationship between D(Vo/Vr) was linear (correlation > 0.98) over a wide range of velocities. The non hemispheric components were found to modify the constant and not the slope. The mean variation of the calculated ERO was 6.5%. The correlation between the calculated and the actual ERO was very close (>0.97) with slope equal to. 96. By comparison with the new method, the classical formula gave an underestimation of the ERO which dramatically increased when studying the flow closer to the orifice or in the case of error on the measurement of r.

In conclusion, a method using velocity profiles instead of isolated values improves the accuracy of the PISA method for measuring the ERO.

PROGNOSIS BY STRESS ECHOCARDIOGRAPHY

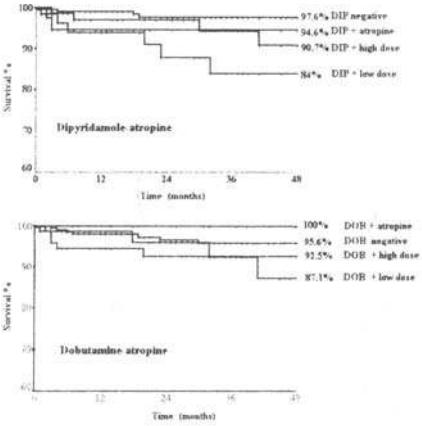
P3644 The elusive prognostic meaning of atropine addition to pharmacological stress echocardiography

Alessandro Pingitore, Albert Varga, Massimo Quarta Colosso, Wilson Mathias, Jorge Lowenstein, Eugenio Picano. *On behalf of the EPIC-EDIC Study Group; Pisa, Italy*

Background: Atropine coadministration increases the diagnostic accuracy both of dobutamine (DOB) and dipyridamole (DIP) stress echocardiography

Aim: To evaluate whether the addition of atropine increases the prognostic value of DIP and DOB stress echocardiography in patients with known or suspected coronary artery disease in a large scale, multicenter, observational and prospective study design.

Methods and Results: DIP (up to 0.84 mg/kg over 10′)-atropine (up to 1 mg over 4′) and DOB (up to 40 μg/kg/min)-atropine (1 mg over 4′) stress testing were performed on different days, in random order and within 15 days in 460 patients. During the follow-up (38 ± 21 months), there were 18 cardiac deaths. Survival was similar in patients with negativity and atropine-positivity



DIP + low dose vs DIP negative, $p < 0.0001$.

Conclusion: In patients at low-to-moderate risk of cardiac events, atropine addition to pharmacological stress echocardiography does not improve its prognostic value when cardiac death is considered.

P3645 Dipyridamole echocardiography test performed between third-fifth day in the uncomplicated acute myocardial infarction for early risk stratification

C. Astarita. *Sorrento (Naples), Italy*

Purposes: to evaluate if the dipyridamole echocardiography test(DET) performed between the 3th-5th day in the uncomplicated acute myocardial infarction(AMI) allows an early discharge in some cases or the indication of a faster coronarography in others.

Methods: in the period between febr. '97 and sept. '98 were admitted 190 patients with AMI, 138 males (72.6%), age = 59 ± 10.3 years. The DET was performed between the 3th-5th day with a dipyridamole(DIP) infusion of 0.84 mg/kg over 10′ followed by atropine 1 mg from the 12th to the 15th minute. The DET was considered positive in the presence of a new or worsening dyssynergy. Patients with heart failure, angina, mayor arrhythmias, poor acoustic window were excluded. In the follow-up events were defined as cardiac death, non-fatal myocardial reinfarction, unstable angina and revascularization procedures.

Results: 92 patients (48.4%) performed the DET, all without complications. 29 patients (31.5%) had a negative DET result; 63 patients (68.5%) a positive DET. The mean stay in hospital of the patients with a negative test was significantly lower in comparison with that of the patients with a positive test (7.55 + 1.32 days vs 9.29 + 1.61, $p < 0.0001$). Events occurred in 55 patients (59.8%), 6/29 patients with a negative DET (20.7%), 49/63 patients with a positive DET (77.8%). At the multivariate Cox analysis the DET positivity was the only independent predictor of events, with relative risk = 11.48 for heterozonal positivity ($p = 0.00001$), 2.98 for homozonal positivity after atropine ($p = 0.03$).

Conclusions: the DET between third-fifth day in the uncomplicated AMI is feasible, tolerable and safe. A negative DET allows an earlier hospital discharge with lower costs; the heterozonal positivity as well as the homozonal positivity after low and high doses of DIP, indicates a quick performance of the coronarography for the high risk of events in the follow-up.

P3646 Prognostic value of pharmacologic stress echocardiography in outpatients

L. Cortigiani, E. Picano[1], P. Landi[1], W. Mathias[1], A. Varga[1], G. Gigli[2], C. Dodi[3], C. Coletta[4], A. Pingitore[1], R. Sicari[1]. *Cardiovascular Unit, Hospital of Lucca, Lucca; [1]Institute of Clinical Physiology, Pisa; [2]Cardiovascular Unit, Hospital of Rapallo, Rapallo; [3]Cardiologia, Ospedale civile, Guastalla (Reggio Emilia); [4]Cardiovascular Unit, Hospital of Roma, Rome, Italy*

To investigate the prognostic importance of pharmacologic stress echocardiography (SE) performed in an outpatient setting, data of 1482 patients (pts) evaluated with either dipyridamole (n = 846) (up to 0.84 mg over 10′ + atropine up to 1 mg) or dobutamine (n = 636) (up to 40 mgr/kg/min+atropine up to 1 mg) SE were analyzed. A positive echocardiographic result (new or worsening of preexisting wall motion abnormality) was identified in 459 (31%) pts. During the follow-up (28 ± 24 months), there were 25 cardiac deaths, 34 infarctions and 228 coronary revascularizations. Adopting an interactive stepwise procedure, age > 70 years (OR = 2.7; 95% CI = 1.3–6.6; p = 0.0199), resting WMSI (OR = 3.0; 95% CI = 1.1–8.0; p = 0.0252) and male gender (OR = 3.2; 95% CI = 1.0–9.6; p = 0.0432) were independent predictors of cardiac death among clinical covariates; this clinical model had a global chi-square of 20.7. After the addition of SE data, SE positive result (OR = 6.2; 95% CI = 2.6–14.8; p = 0.0000) and resting WMSI (OR = 3.1; 95% CI = 1.2–7.9; p = 0.0252) were associated with cardiac death; the global chi-square at this second step increased to 46.1. The 4-year survival rate was 99% for pts with negative and 91% for pts with positive result of SE (log rank = 33.2; p = 0.0000). Considering hard cardiac events (death and infarction) as end-points, the clinical independent prognostic predictors were resting WMSI (OR = 2.2; 95% CI = 1.1–4.4; p = 0.0252), male gender (OR = 2.0; 95% CI = 1.0–3.9; p = 0.0427) and previous infarction (OR = 1.7; 95% CI = 1.0–2.9; p = 0.0650); the global chi-square of the clinical model was 22.5. In the second step, with the addition of SE findings, SE positive result (OR = 3.6; 95% CI = 2.1–6.2; p = 0.0000) and resting WMSI (OR = 2.3; 95% CI = 1.1–4.5; p = 0.0184) were independently correlated with prognosis; the global chi-square increased to 49.5. The 4-year infarction-free survival rate was 97% for pts with negative and 85% for pts with positive result of SE (log rank = 36.6; p = 0.0000).

In conclusion, pharmacologic SE has shown a strong prognostic power in pts evaluated in an ambulatory setting, incremental to that provided by clinical data.

P3647 Does the presence of multiple markers of myocardial ischaemia during dobutamine stress echocardiography identify patients at a higher risk of cardiac events during follow-up?

M. Previtali, M. Ceresa, R. Fetiveau, C. Cavalotti, L. Lanzarini, C. Klersy[1]. *Cardiology Dept., IRCCS Policlinico S.Matteo, Pavia; [1]Biometry Unit, IRCCS Policlinico S.Matteo, Pavia, Italy*

Aim: To assess whether the presence of multiple markers of myocardial ischemia (I) (ECG, echo and chest pain) during dobutamine stress echocardiography (DSE) identifies pts at higher risk of cardiac events.

Methods: 265 pts with suspected or proven coronary artery disease (CAD), 91% men, aged 56 ± 9 yrs, 70% with angina, 57% with previous myocardial infarction (MI), 46% with previous PTCA or bypass, 37% with multivessel CAD, with a mean ejection fraction of 57 ± 14%, underwent DSE (5–40 mcg/kg/min + atropine) and were followed for 16 ± 15 months for major (cardiac death and MI), minor (unstable angina, PTCA or bypass at least 2 months after DSE) and total events. Criteria for a positive test were a >1 mm ST-segment shift for ECG and a new or worsening asynergy for echo.

Results: On the basis of DSE results pts were divided in 4 groups: Group (Gr) 1 (79 pts, 30%): Negative DSE; Gr 2 (71, 27%) positive DSE with 1 marker only (ECG or echo); Gr 3 (57, 21.5%): positive DSE with 2 markers (ECG and echo); Gr 4 (57, 21.5%): positive DSE with all 3 markers of I. During follow-up 17 major events (7 cardiac death and 10 re-MI) and 129 minor events (113 unstable angina, 16 PTCA or bypass) occurred. By Cox multivariate analysis ejection fraction (EF) (Hazard ratio (HR) = 0.96), diabetes mellitus (HR = 1.95), multiregional asynergy (HR = 1.22) and use of atropine during DSE (HR = 0.36) were found to be independent predictors of major events, while the presence of multiple markers of I did not increase the risk of major events. On the other hand, the presence of multiple markers of I during DSE was an independent predictors of minor and total events, together with EF (HR = 0.98), multivessel CAD (HR = 1.78) and diabetes (HR = 1.58); risk for events was higher in Gr 4 compared to Gr 2 (HR = 1.63, p < 0.04) and Gr 3 (HR = 1.50, p = 0.10), but not in Gr 3 compared to Gr 2 (HR = 1.09, p = 0.7).

Conclusions: The presence of multiple markers of I during DSE does not identify pts at a higher risk of major events, but is a significant independent predictor of minor and total events, with a risk increasing with the increasing number of markers of I detected during DSE.

P3648 T-wave positivization as a marker of higher cardiac risk in a prospective study of dobutamine stress echocardiography after acute myocardial infarction

R. Rambaldi, R. Bigi, G. Curti, G. Occhi. *Cardiology Dept., Sondalo Hospital (So), Baura (Fe), Italy*

Aim: An increasing evidence is supporting T-wave positivization (TWP) during dobutamine stress echocardiography (DSE) after uncomplicated acute myocardial infarction (AMI) as a potential marker of myocardial viability. We focused on TWP in this setting as a predictor of cardiac events in a long-term prospective study.

Methods: Two-hundred twenty-nine patients (pts), mean (± SD) age 56 ± 9 years, 199 males, who underwent a standard DSE within 10 days after uncomplicated AMI, were selected for exhibiting negative T waves in the infarct area in at least 2 adjacent leads of resting ECG. A follow-up of 735 days (1 month-6 years) for hard: cardiac death, reinfarction, and soft cardiac events: unstable angina and coronary revascularization was completed. Cox multivariate analysis and Kaplan-Meier survival curves with log-rank test were applied.

Results: TWP appeared during DSE in 76 (33%) pts (at low dose in 69 pts). TWP agreement with DSE-elicited myocardial viability was 64%. At follow-up TWP discriminated 62% cardiac events (47 events/76 pts) in TWP pts vs 46% (70/153) in the remaining pts (p < 0.05), with a median event-free survival period: 490 days of TWP pts vs 1740 days of the remaining pts: ratio: 3.5 (95% CI 2.9–4.2). At univariate analysis basal wall motion score index (WMSI) (p < 0.01), low dose DSE WMSI: 10 μg/kg/min (p < 0.01), peak WMSI (p < 0.01), peak heart rate (HR) (p < 0.01), myocardial viability (p < 0.01) and TWP (p < 0.05) were predictors of cardiac events. Age, thrombolysis, ST shifting, dobutamine time, rest HR, rest or peak systolic or diastolic blood pressure did not reach significance. At Cox multivariate analysis TWP was no independent predictor. Rest WMSI (p < 0.05), peak WMSI (p < 0.01) and peak HR (p < 0.01) were independent predictors.

Conclusions: In case of doubtful or nondiagnostic DSE for myocardial viability, TWP can be helpful to sort pts at higher risk. TWP onset at low dose DSE and its agreement with myocardial viability may be clues to relate it to a viable substrate.

P3649 Stress echocardiography for prognostic stratification in patients with unability to exercise or uninterpretable electrocardiogram

L. Cortigiani, P.R. Mariani, A. Boni, E.A. Paolini, A. Azzarelli, M. Masini, E. Nannini. *Cardiology Dept, Hospital of Lucca, Lucca, Italy*

In aim to determine the prognostic value of stress echocardiography (SE) in patients (pts) with unability to exercise or uninterpretable electrocardiogram, data by 394 pts (149 men; age 69 ± 10 years) who underwent dipyridamole (n = 194) (up to 0.84 mg/kg over 10′ + atropine up to 1 mg) or dobutamine (n = 200) (up to 40 mgr/kg/min+atropine up to 1 mg) SE were analyzed. Of them, 318 were unable to exercise because of systemic disorders and 76 had left bundle branch block at baseline electrocardiogram or paced rhythm. SE was positive for echo criteria (new or worsening of preexisting wall motion abnormality) in 98 pts. During follow-up (34 ± 24 months), there were 14 cardiac deaths, 19 infarctions and 36 revascularizations. By using an interactive stepwise procedure, among the 9 clinical variables analyzed, resting WMSI (OR = 7.8; 95% CI = 2.4–25.8; p = 0.0008) and previous infarction (OR = 4.9; 95% CI = 1.5–16.5; p = 0.0096) were independently correlated with cardiac death; the global chi-square of this clinical model was 37.2. After the addition of SE findings, resting WMSI (OR = 14.5; 95% CI = 4.6–46.2; p = 0.0000) and SE positive result (OR = 24.6; 95% CI = 5.2–116.2; p = 0.0001) were predictive of cardiac death; at this second step the global chi-square was 68.0. The 4-year survival rate was 99% for the negative and 80% for the positive population (log rank = 39.0; p = 0.0000). When hard cardiac events (death and infarction) were taken as end-points, the clinical predictors of prognosis were resting WMSI (OR = 4.4; 95% CI = 2.0–9.8; p = 0.0002), previous infarction (OR = 3.5; 95% CI = 1.6–7.4; p = 0.0012) and age ³70 years (OR = 2.0; 95% CI = 1.0–4.3; p = 0.0557); the global chi-square was 53.6. After the addition of SE data, SE positive result (OR = 14.1; 95% CI = 6.0–32.9; p = 0.0000), resting WMSI (OR = 10.4; 95% CI = 4.5–24.1; p = 0.0000) and age ³70 years (OR = 2.2; 95% CI = 1.1–4.6; p = 0.0319) showed independent prognostic power; the global chi-square increased to 49.5. The 4-year infarction-free survival rate was 97% for the negative and 59% for the positive population (log rank = 67.8; p = 0.0000).

In conclusion, SE was effective for prognostic assessment of coronary artery disease in patients unable to exercise or with uninterpretable electrocardiogram.

EXERCISE STRESS ECHO

P3650 Harmonic imaging improves interobserver agreement and sensitivity of bicycle stress echocardiography in patients with impaired image quality

Harald Lethen, Hans P. Tries, Okan Ekinci, Heinz Lambertz. *Fachbereich Kardiologie, Deutsche Klinik für Diagnostik, Wiesbaden, Germany*

Harmonic imaging (HI) has shown to improve image quality in patients (pts) with impaired image quality. Especially in bicycle exercise stress echocardiography (BESE) image acquisition is frequently reduced at peak stress due to hyperpnea.

Methods: To evaluate the impact of HI on sensitivity, specificity and interobserver agreement of BESE 90 pts with reduced image quality at rest (≥3 segments not visible, 16 segment model, ASE) were investigated. In all pts image acquisition was performed in fundamental imaging modality (FI) and HI during the same diagnostic procedure (Acuson, Sequoia, FI 3.5 MHz, HI 1.75 → 3.5 MHz). Images were acquired at rest and at peak stress. Examinations were separately stored on Quad-screen cine loop format BESE was performed until 85% of maximal age predicted heart rate was achieved. Interpretation of stress echos was performed independently by three stress echo experienced physicians. In all pts quantitative coronary angiography was performed.

Results: Interobserver agreement (concordant interpretation of three physicians), sensitivity and specificity were analyzed as follows:

	FI	HI	
Concordant Interpretation	65%	81%	$p < 0.02$
Kappa value	0.38	0.67	$p < 0.01$
Sensitivity	68%	87%	$p < 0.05$
Specificity	78%	80%	p = n.s.

Conclusion: HI significantly improves interobserver agreement of BESE in pts with impaired image quality at rest as well as diagnostic sensitivity. HI should therefore routinely be applicated in BESE in pts with impaired quality.

P3651 Exercise echocardiography : its accuracy and value in the prognosis of patients with known or suspected coronary artery disease

J.F.T. Baltasar, O.P. Saniel[1], E.B. Baello Jr[2]. *Internal Medicine, National Kidney & Transplant Institute, Quezon; [1]Epidemiology & Biostatistics, University of the Philippines, Manila; [2]Cardiovascular Section, National Kidney & Transplant Institute, Quezon, Philippines*

Objectives: To determine the validity and prognostic value of exercise echocardiography in predicting the occurrence of coronary events among a cohort of patients with known or suspected coronary artery disease (CAD) followed-up within a span of 3–5 years.

Background: Exercise echocardiography had been added to the diagnostic tests used to detect CAD. While many studies have been published showing its superior capability in detecting CAD, only few show its potential in predicting coronary events.

Methods: Patients >44 years with known or suspected CAD seen at the National Kidney and Transplant Institute underwent exercise echocardiography and were followed-up regularly on an outpatient basis. Coronary events were recorded. Validity of the test in relation to coronary events was determined. Cox regression analysis was used to assess variables for prognostic significance.

Results: Of the 356 patients, 18 were lost to follow-up. There were 52 (15%) patients who developed coronary events. Forty three had spontaneous coronary event and 9 underwent revascularization. When patients without ischemia on exercise echocardiography but with submaximal exercise were excluded, sensitivity was 95% and specificity was 94%. Of the clinical and exercise test variables, male sex (relative risk [RR] = 3.2446; 95% confidence interval [CI] = 1.6506–6.3780), METs < 6 (RR = 2.1839; 95% CI = 1.1668–4.0874), age-predicted maximal heart rate < 85% (RR = 2.8893; 95% CI = 1.4304–5.8361), a decrease of one unit peak double product (RR = 1.0001; 95% CI = 1.00004–1.0002), and ST depression (RR = 1.8825; 95% CI = 1.0002–3.5431) were shown to be associated with increased risk for coronary event. However, the presence of ischemia on exercise echocardiography (RR = 14.7730; 95% CI = 7.0421–30.9912) was shown to be highly significant for the prediction of coronary event, and its presence made all other previously significant variables irrelevant.

Conclusion: The presence of ischemia on exercise echocardiography is sensitive and specific for subsequent coronary event. This study shows that exercise echocardiography has a prognostic value in patients with known or suspected CAD.

P3652 Labil subaortic obstruction during exercise stress echocardiography

L. Montserrat, J. Peteiro, A. Castro-Beiras. *Echocardiography Unit and Cardiology Department, Juan Canalejo Hospital, A Coruña, Spain*

Although the development of subaortic obstruction (SO) has beeen extensively reported during dobutamine stress testing, it's appearance during physical dynamic exercise has not been equally studied. Since Exercise Echocardiography (EE) is an increasingly used method to evaluate patients with chest pain we hypothesized that non-suspected labil SO may be present in patients referred for this test.

To determine the frecuency of newly developed subaortic obstruction during exercise, and the clinical characteristics of these patients, we prospectively studied 2280 patients by color and pulsed Doppler before and immediately after treadmill EE (Bruce protocol). Exercise-induced SO was seen in 38, exercise-induced mitral valve systolic anterior motion (SAM) causing mitral regurgitation (MR) in 2, and exercise-induced SO together with MR was seen in 3. The LVOT Doppler-derived gradient increased from 10 ± 3 to 69 ± 29 mmHg (34–130) in the 41 patients with SO. In 8, SAM without septal contact was seen at rest and could again be demonstrated during exercise (n = 2) or postexercise (n = 8). New mitral valve SAM was recorded in 18 at both exercise and postexercise (n = 9), or only at postexercise (n = 9). The Doppler increased gradient was thought to be due to midventricular SO in another 8 patients, whereas no cause of SO could be demonstrated in 9. Concentric left ventricular hypertrophy (LVH) was seen in 23, asimetric LVH in 10 and normal baseline echo in 10. LVH was associated to high blood pressure (HBP) in 16 (37%), whereas was idiophatic in 17 (40%). LVH patients achieved lower exercise time than non-LVH (9 ± 3 min vs 11 ± 1 min), in spite of similar Doppler gradients, although age and% of females were higher in the former group (58 ± 10 vs 49 ± 7 years, $p < 0.05$; 24% vs 10%, p = NS).

In conclusion, exercise-induced subaortic obstruction and mitral regurgitation due to exercise-induced mitral valve SAM are relatively infrequent in patients submitted to Exercise Echocardiography. These findings are associated to LVH due to HBB or idiophatic. Doppler postexercise study may unmask this condition.

P3653 Is the exercise stress echocardiography able to identify patients with three-vessel disease?

C. Auguadro, F. Buzzetti, M. De Salvo, M. Grillo, S. De Feo, L. Angoli, C. Falcone. *Cardiology Dept, Policlinico San Matteo, Pavia, Italy*

Objective: The aim of this study was to assess in a large population of CAD patients (pts) whether the echo-monitoring during exercise stress test could provide additional and independent diagnostic information for the detection of the three-vessel disease.

Methods: The study population included 281 pts (260 M and 21 F, mean age 58.1 ± 8.5 yrs) with CAD documented by angiography who underwent exercise stress echocardiography (EST-Echo). The left ventricular end-diastolic volume (LV-EDV), the end-systolic volume (LV-ESV), the ejection fraction (LV-EF) and the wall motion score index (WMSI) were calculated both in basal condition and at peak exercise. The development during exercise of a new wall motion abnormality or the worsening of baseline wall motion abnormalities was considered to be an ischemic response. The pts were divided into two groups: Group1 (G1) included 219 pts (204 M and 15 F, mean age 57.3 ± 8.3* yrs) with one and two vessel disease, Group 2 (G2) 62 pts (56 M and 6 F, mean age 60.8 ± 8.7* yrs) with three-vessel disease (*p = 0.003).

Results: On the rest echocardiogram the LV-EDV, the LV-ESV, the LV-EF and the WMSI were similar between the two groups (G1:146.3 ± 47.9, 68.4 ± 37.2, 54.1 ± 9.3 and 1.2 ± 0.3 respectively; G2: 152.3 ± 49.6, 74.9 ± 40.4, 53.2 ± 10.4 and 1.4 ± 0.4 respectively). At peak exercise pts of G2 showed lower LV-EF (50.5 ± 11.2 vs 56.1 ± 10.5, p = 0.02), larger LV-EDV and LV-ESV (165.5 ± 48.9 vs 147.3 ± 50.2, p = 0.02 and 82.1 ± 42.9 vs 66.5 ± 37, p = 0.03, respectively) and higher WMSI (1.7 ± 0.4 vs 1.4 ± 0.3, p = 0.001) than G1 pts. The multivariate logistic regression analysis identified as independent predictors of the presence of three vessel disease the WMSI at peak of EST-Echo (p = 0.0004), the occurrence of ventricular arrhythmias during exercise stress test (p = 0.001) and a low exercise tolerance (min of exercise) (p = 0.001).

Conclusion: In our experience it was demonstrated that the information coming from EST-Echo might be useful in the identification of pts with 3-vessel disease.

P3654 Accuracy of exercise echocardiography to detect coronary artery disease in non-infarcted left bundle-branch block patients

L. Montserrat, J. Peteiro, D. Martinez, J. Cordo, J.M. Vazquez, A. Castro-Beiras. *Echocardiography Unit and Cardiology Department, Juan Canalejo Hospital, A Coruña, Spain*

Exercise ECG is not useful for the diagnosis of coronary artery diasease (CAD) in patients with left bundle branch block (LBBB), while thallium scintigraphy has limited specificity and accuracy. Exercise echocardiography (EE) has been proposed as an alternative test to detect coronary artery disease in these patients, but the diagnostic value in this context has not been extensively studied.

We studied 39 patients (25 male, 14 female; mean (±SD) age 63 ± 8 years; rest LVEF 55 ± 9) with complete LBBB and chest pain suspicious of CAD. All of them underwent treadmill EE and coronary angiography within 16 weeks. Patients with a clinical history of acute myocardial infarction, revascularization procedures or severe LV dysfunction (rest LVEF < 35%) were not included. The development of new or worsening regional dysfunction was considered as an ischemic response. Significant CAD on angiography was defined as a ≥50% luminal narrowing in ≥1 epicardial coronary artery.

Multivessel disease (MVD) was found in 12, one-vessel disease in 8, and non significant CAD in 19. EE sensitivity, specificity and global accuracy were 80% (CI: 69–91), 84% (CI: 74–94) and 82% (CI: 74–90), respectively; left anterior descending CAD 100%, 80%, and 87%; left circunflex CAD 50%, 78% and 67%; and right CAD 45%, 79% and 69%. Sensitivity was very high for MVD (100%), lower for one-vessel disease (50%).

In conclusion, treadmill Exercise Echocardiography is highly accurate in detecting coronary artery disease in non-infarcted patients with left bundle branch block and clinical suspicion of coronary artery disease. Sensitivity is very high for left anterior descending artery and multivessel CAD detection, lower for one-vessel CAD.

P3655 Relationship between exercise and dobutamine stress echocardiography wall motion abnormalities and stenosis severity and location

P. Cokkinos, D. Tousoulis, L. Rallidis, I. Moissakis, G.J. Davies, P. Nihoyannopoulos. *Cardiology Unit, Hammersmith Hospital Imperial College Medical School, London, UK*

Quantitative coronary angiography has been shown to allow the functional assessment of coronary stenosis, while exercise (ESE) and dobutamine (DSE) stress echocardiography are both widely accepted methods for assessing the functional significance of coronary stenosis. The relationship between ESE or DSE induced wall motion abnormalities and stenosis severity and location however remains controversial. 30 patients (mean age 58 ± 9 years, 23 male) with single vessel coronary artery disease with ≥50% minimal luminal reduction) and stable angina were studied. All patients had normal resting left ventricular function and no previous history of myocardial infarction. Coronary stenosis severity was assessed by computerized angiography. All patients underwent ESE and DSE on random order. Positive result was defined as occurrence of a new or worsening wall motion abnormality.

Results. At peak ESE 23 patients developed wall motion abnormalities (group 1) and 7 did not (group 2). A positive ESE was associated with stenosis severity ≥80% in 65% and with a proximal location in 94% of stenoses ($p < 0.01$). A significant correlation was found between stenosis area and wall motion abnormality difference score from baseline during peak exercise ($r = 0.53$, $p < 0.01$). During DSE 18 patients developed wall motion abnormalities (group 1) and 12 patients did not (group 2). A positive DSE was assosiated with stenosis severity ≥80% in 72% and with a proximal location in 81% of stenoses. A weak correlation was found between stenosis area and wall motion abnormality difference score from resting during peak dobutamine ($r = 0.37$, $p < 0.05$). There were fewer positive results with DSE than with ESE (60% vs 78%, $p < 0.01$). The proportion of positive ESE results was greater (62% vs 46%, $p < 0.01$) in stenoses with severity <80% and in middle and distal senoses (57% vs. 36%, $p < 0.01$) than in DSE

Conclusions. In patients with single vessel coronary artery disease, positive stress echocardiography tests are usually associated with a proximally located ≥80% stenosis. Patients with stenoses of <80% have a greater chance to have a positive exercise than dobutamine stress.

P3656 Silent and symptomatic myocardial ischaemia during exercise stress echocardiography

C. Falcone, C. Auguadro, F. Buzzetti, M. De Salvo, A. Serio, M. Grillo, E. Nai, L. Angoli. *Cardiology Dept, Policlinico San Matteo, Pavia, Italy*

Background: The results of the various studies, which attempted to verify if the magnitude of myocardial ischemia could influence the appearance of anginal pain, are contradictory.

Objective: This study aim was to evaluate the clinical, angiographic and echocardiographic features of CAD patients (pts) with and without anginal pain during exercise stress echocardiography-induced myocardial ischemia.

Methods and patients: Exercise stress echocardiography (EST-Echo) was performed in 339 pts (300 M, 39 F, mean age 59.5 ± 8.6 yrs) with angiographically documented coronary artery disease (CAD).The patients were classified into two groups: Group1 (G1) included 204 pts with silent ischemia during EST-Echo and Group 2 (G2) 135 pts who experienced moderate to severe chest pain during the test.

Results: Angina pectoris in history was present in 128 (62.7%) pts of G1 and in 120 (88.8%) of G2 ($p = 0.001$). The distribution of CAD was similar between the two groups. During EST-Echo pts of G1 showed higher rate-pressure products and greater work loads, both at the ischemia threshold (20555 ± 5600 vs 18200 ± 3917, $p = 0.001$ and 80.7 ± 28.9 vs 71.4 ± 23.6, $p = 0.005$, respectively) and at peak exercise (22870 ± 5733 vs 20654 ± 4715, $p = 0.003$ and 94.3 ± 26.9 vs 84 ± 25.6, $p = 0.01$, respectively) than G2 pts. A similar entity of ST segment depression at peak of EST-Echo was documented in G1 and G2 pts (1.7 ± 0.4 vs 1.5 ± 0.8, respectively). The left ventricular end-diastolic volume, the end-systolic volume, the ejection fraction and the wall motion score index were similar between the two groups both in basal conditions (G1: 146.2 ± 47.7, 70.1 ± 37.8, 54 ± 10.5 and 1.3 ± 0.3 respectively; G2: 145.8 ± 45.2, 67.3 ± 32.9, 54.8 ± 8.8 and 1.2 ± 0.4 respectively) and at peak of EST-Echo (G1: 151.2 ± 50.2, 68.9 ± 39.4, 54.7 ± 11.6 and 1.8 ± 0.3 respectively; G2: 151.7 ± 47.2, 72.4 ± 33.9, 53.5 ± 10.3 and 1.7 ± 0.4 respectively). At the multivariate analysis no echocardiographic parameter was predictive of silent myocardial ischemia during EST-Echo. The absence of anginal symptoms during daily life resulted the only variable predictive of silent ischemia during exercise ($p = 0.000$).

Conclusion: In our population the occurrence of anginal pain during EST-Echo was not related to the extension of the ischemic myocardium. Also the left ventricular function, both on baseline and in response to effort, was similar between the symptomatic and asymptomatic pts. These results confirmed that the pain sensitivity follows individual patterns.

EXERCISE TESTING OF HEART FAILURE IN NORMAL PEOPLE AND ATHLETES

P3657 Contributions of left ventricular systolic and diastolic functions on increase in cardiac output during constant work rate exercise in patients with chronic heart failure

K. Maehara, N. Komatsu, A. Hirosaka, M. Mitsugi, Y. Maruyama. *First Department of Internal Medicine, Fukushima Medical University, Fukushima, Japan*

Left ventricular (LV) systolic function indicated by ejection fraction (EF) does not correlate with exercise capacity in patients with chronic heart failure, however, cardiac function would participate the increase in cardiac output during exercise, at least partially, even if it is not the main determinant. We investigated how LV systolic or diastolic function participates the increase in cardiac output during constant work rate exercise.

[Methods] Fifteen cardiac patients (resting LVEF: 25–77%, average 43 ± 17%) performed a constant work rate exercise testing using a supine bicycle ergometer for 6 min with a respiratory gas analysis under catheterizations to pulmonary and brachial arteries and left ventricle. Work rate was previously determined as an equivalent to 10 ml/kg/min of VO_2 by incremental exercise test. Cardiac output and pressures were measured, and left ventriculogram and blood sampling were performed before and at 6 min of exercise.

[Results] VO_2 at 6 min of exercise was 57 ± 12% of peak VO_2 obtained from incremental exercise test. Blood lactate was 2.8 ± 1.2 mmol/L and norepinephrine was 4.3 ± 2.4 pmol/mL at 6 min. Cardiac index at 6 min was 3.9 to 8.8 L/min/m^2, which did not correlate with LVEF both at rest and at 6 min. The rate of increase in cardiac output from the resting state correlated with the rate of decrease in systemic vascular resistance ($r = 0.84$, $p < 0.01$) and the rate of changes in LVEF ($r = 0.72$, $p < 0.05$), and inversely correlated with the rate of changes in LV end-diastolic pressure/volume ($r = -0.68$, $p < 0.05$) as an index of LV diastolic compliance, however, did not correlate with either the rate of changes in LV end-systolic pressure/volume as an index of LV contractility or the changes in heart rate. Moreover, the rate of changes in LVEF did not correlate with the rate of changes in LV end-systolic pressure/volume, but correlated with the rate of decrease in systemic vascular resistance ($r = 0.81$, $p < 0.01$). In conclusion, the increase in cardiac output during constant work rate exercise would be mainly dependent on the decrease in systemic vascular resistance reflecting vasodilation in the working skeletal muscle, and on LV diastolic function, but not systolic function in chronic heart failure. In addition, change in LVEF might be dependent on the change in peripheral vascular resistance.

P3658 Undetermined anaerobic threshold in chronic heart failure: incidence and clinical implications

U. Corrà, E. Bosimini, P. Giannuzzi. *Division of Cardiology, "S. Maugeri" Foundation, IRCCS, Veruno (NO), Italy*

Peak oxygen consumption (pVO_2) is an indipendent predictor of prognosis in chronic heart failure (CHF) and is a useful guide for timing heart transplantation. The detection of the anaerobic threshold (AT) is mandatory to validate pVO_2, but it's undetermined in a substanstial percentage of patients.

Methods: To investigate the incidence and the clinical features of patients (pts) with undetermined (noAT), 520 CHF pts (89% male, 57 ± 8 yrs), in NYHA class I–IV, who performed an incremental bicycle exercise test limited by fatigue or dyspnea were reviewed: mean EF and peak VO_2 were 24 ± 8%, 14.5 ± 3 ml/kg/m′, respectively. AT was detected using the V-slope method. 134 pts (26%) had noAT: noAT pts compared to AT pts were in more advanced NYHA class (2.5 ± 0.5 vs 2.0 ± 0.6, $p < 0.001$), treated with higher Furosemide dose (126 ± 112 vs 82 ± 68 mgr, $p < 0.05$), were studied at a shorter time from last acute episode (206 ± 236 vs 365 ± 128 days, $p < 01$), had a higher end-diastolic volume index (141 ± 54 vs 127 ± 47 ml/m2 $p < 0.01$), a lower EF (22 ± 7 vs 26 ± 9%, $p < 0.001$) a shorter mitral flow deceleration time (153 ± 49 vs 168 ± 51 msec, $p < 0.01$), and more impaired resting spirometric data (FVC% 84 ± 16 vs 92 ± 17, $p < 0.001$, FEV −1% 82 ± 17 vs 89 ± 19, $p < 0.01$). At peak exercise, gas exchange ratio and Borg scale score (0–10) were not different in the two groups (1.1 ± 0.1 vs 1.1 ± 0.09, 7.5 ± 1.1 vs 7.5 ± 1.0. NS), but noAT pts showed a significant reduced peak VO_2 and a steeper VE/VCO_2 slope (12.1 ± 3 vs 15.3 ± 3 ml/kg/m′, 37 ± 10 vs 30 ± 5, $p < 0.001$). Moreover, noAT was observed in 50% (58/116) of pts with atrial fibrillation (AF), in 52% (18/35) of pts with AF and advanced NYHA class III–IV, and in 56% (14/25) of those pts with AF, NYHA class III–IV evaluated within 30 days of last acute episode.

In conclusion, noAT is frequent in CHF, particularly in pts with AF, advanced NYHA class, recent clinical instability and severe functional impairment. In these subsets of pts, incremental symptom-limited test should be postponed till better clinical conditions are achieved, or replaced with a submaximal trial.

P3659 Long term clinical outcome with low and high dose captopril in heart failure

D.L. Clement, M. De Buyzere, M. Tomas[1]. *Cardiology Dept., University Hospital, Gent; [1]Medical Dept., Bristol-Myers Squibb Belgium, Waterloo, Belgium*

Background: Although angiotensin converting enzyme inhibitors (ACE-I)are recommended as first line therapy in patients with chronic heart failure, the target doses proven to be effective in major morbidity and mortality trials are not much used in daily practice in Belgium. This study was undertaken to assess the long-term effects of a low dose (25 mg b.i.d.) and a high dose (50 mg b.i.d.) of captopril in mild to moderate heart failure.

Methods: After a titration period, patients who tolerated 50 mg b.i.d. were randomized and followed up to 2 years.

Results: 298 patients were included and were followed up for a mean of 12 months. Progression in heart failure were respectively 31.5% and 22.4% for low and high dosage ($p = 0.088$). Treatment with high dose showed a reduction in the number of hospitalisations for all causes from 18.5 to 11.8% ($p = 0.1$) and for congestive heart failure from 14.7 to 7.2% ($p = 0.06$); moreover, the incidence of fatal and nonfatal cardiac events showed a trend in favour of the high dose of 21% ($p = 0.142$). The total number of adverse events was the same for both dosages and no difference in renal function was observed.

Conclusion: Although the statistical significance has not been reached, this study supports the trend seen in ATLAS study, that the use of higher dose of ACE-I such as 50 mg captopril b.i.d. improves clinical outcome. Therefore, clinicians should be encouraged to achieve target dose studied in large randomised trial.

P3660 The six-minute walking test in advanced chronic heart failure: an accurate procedure to assess clinical severity, functional capacity and daily physical activity

U. Corrà, E. Bosimini, P. Giannuzzi. *Division of Cardiology, "S. Maugeri" Foundation, IRCCS, Veruno (NO), Italy*

The six-minute walking test (WT) is a simple, noninvasive, inexpensive and safe method to assess functional capacity in chronic heart failure (CHF) patients (pts).

Methods: The potential role of WT to detail clinical severity, functional capacity and daily physical activity was invastigated in 130 pts (59 ± 9 yrs, 81% male), with advanced CHF, in NYHA class II–IV, who performed an incremental bicycle symptom-limited exercise test and two WT (repeated within 1 week): mean EF, end-diastolic volume index (EDVi), and peak oxygen consumption (pVO_2) were 22 ± 7%, 131 ± 44 ml/m2, 11.1 ± 2 ml/kg/m′, respectively. Mean walking distance (Wd) was 365 ± 50 mt. Habitual daily physical activity level was evaluated by an interviewer-determined scoring (Activity score, AcS: range 0–9) considering leisure-time, occupational activities and hospital admissions. Wd correlated significantly with pVO_2 ($r = 0.40$, $p < 0.0001$) and AcS ($r = 0.37$, $p < 0.0001$). Pts were divided according to the Wd: pts with Wd > 365 mt (group A, 59 pts) and Wd > 365 mt (group A, 71 pts): group A pts were older (62 ± 8 vs 57 ± 9 yrs, $p < 0.01$), had a reduced peak VO_2 (10.5 ± 2 vs 11.7 ± 2 ml/kg/m′, $p < 0.01$), a steeper VE/VCO_2 slope (39 ± 11 vs 34 ± 8, $p < 0.01$), a more impaired spirometric data (FVC% 79 ± 12 vs 86 ± 13, $p < 0.01$, FEV 1% 78 ± 14 vs 83 ± 13, $p < 0.05$) and were studied at a shorter time from last acute episode (146 ± 81 vs 314 ± 144 days, $p < 01$). Moreover group A pts had a significantly lower AcS in (3.1 ± 1.5 vs 4.1 ± 2.9, $p < 0.01$) and shorter mitral flow deceleration time (DecT: 132 ± 45 vs 144 ± 37 msec, $p < 0.05$) and a higher daily Furosemide dose (125 ± 95 vs 90 ± 75 days, $p = 0.06$), whereas NYHA class, EDVi, EF were similar in two groups.

In conclusion: WT is reliable functional test in advanced CHF pts and allows an appropiate definition of clinical severity, exercise tolerance and daily physical activity. WT may substitute incremental symptom-limited exercise test in advanced CHF pts.

P3661 Atrial fibrillation in chronic heart failure: influence on exercise capacity and therapeutic implications

E. Bosimini, U. Corrà, F. De Vito, P. Giannuzzi. *Division of Cardiology, "S. Maugeri" Foundation, IRCCS, Veruno (NO), Italy*

Atrial fibrillation (AF) complicates chronic heart failure (CHF) and may promote its progression due to uncontrolled heart rate (HR), loss of atrial contribution and irregularity of ventricular rhythm. Few data are available on the influence of AF on exercise tolerance in CHF.

Methods: We studied 104 CHF pts (89% male, 54 ± 8 yrs), in NYHA class II–III, who performed an incremental bicycle exercise test with invasive haemodynamic evaluation limited by fatigue or dyspnea: mean EF and peak oxygen consumption (VO_2) were 22 ± 7%, 14.9 ± 4 ml/kg/m′, respectively. 17 pts (16%) were in AF: etiology of CHF, age, sex, NYHA class, daily diuretic dose, end diastolic volume index, and EF were similar in AF pts compared to pts in sinus rhytm (SR), Resting heamodynamic variables were similar in the two groups, but AF pts had a significant lower stroke volume (SV: 56 ± 11 vs 69 ± 20 ml, $p < 0.05$) and cardiac index (CI: 2.1 ± 0.2 vs 2.6 ± 0.6 5 ml/min/m2, $p < 0.05$). At peak exercise, gas exchange ratio, Borg scale score, peak VO_2 (13.9 ± 5 vs 14.8 ± 4 ml/kg/m′, NS) and CI (4.1 ± 1.1 vs 4.9 ± 1.5 ml/min/m2, NS) were not different in AF and SR pts, whereas AF pts had a significant higher peak HR (149 ± 22 vs 122 ± 21 beat/min $p < 0.01$), greater chronotropic response (difference between peak exercise and rest: 62 ± 22 vs 49 ± 20 beat/min, $p < 0.05$) and lower SV (59 ± 13 vs 75 ± 10 ml, $p < 0.05$). After adjusting for chronotropic response, a 24% decrease in peak VO_2 was observed in AF pts (9.5 ± 3 vs 12..6 ± 3 ml/kg/m′, $p < 0.05$).

In conclusion: CHF pts with AF show similar functional capacity compared to pts in SR and chronotropic response is crucial to maintain cardiac index and exercise tolerance. Medications that inhibit exertional chronotropic compensatory response may modify the ability to work in these pts.

P3662 Is the chronotropic response in dilated cardiomyopathy dependent on left ventricular function and gives implications for rate adaptive pacing?

S. Geil, B. Nowak, S. Genth-Zotz, T. Lewalter[1], N. Heider, D. MacCarter[2], E. Himmrich, B. Lüderitz[1], J. Meyer. *II. Medical Clinic, University Mainz; [1]Dept. of Cardiology, University of Bonn, Germany [2]ELA Medical, Minneapolis MN, USA*

The heart rate (HR) to work rate (WR) relationship has been reported in normals, but not in pts with dilated cardiomyopathy (DCM). We studied the influence of LV dysfunction on the HR/WR-slope below and above the anaerobic threshold (AT) in such pts, which may potentially impact pacemaker sensor programming.

Methods: We included 31 male pts (age 51 ± 13 y) with DCM and an ejection fraction (EF) < 0.40, all on stable therapy with diuretics, digitalis and ACE-inhibitors, but not on beta-blockers. Based on LV dysfunction, two groups were defined: A: EF ≤ 0.25 (n = 19) and B: EF > 0.25 (n = 12). Symptom limited cardiopulmonary peak exercise testing was performed starting at 20 W with an increase of 10 W/min. The HR/WR slope was determined using linear regression analysis.

Results: The mean EF was A: 0.22 ± 0.02 vs. B: 0.34 ± 0.06 ($p < 0.05$). There was no difference for NYHA class (A: 2.6 ± 0.5 vs. B: 2.0 ± 0.5), HR at rest (A: 89 ± 16; B: 82 ± 17 bpm), or HR at AT (A: 122 ± 23; B: 122 ± 29 bpm) and HR at peak exercise (PE) (A: 143 ± 20; B: 125 ± 22 bpm), but a trend towards a steeper HR/WR slope from rest to PE in group B (0.74 ± 0.24 bpm/W), as compared to group A (0.52 ± 0.29 bpm/W) (n.s.). The HR/WR slope from rest to AT was significantly steeper (+38%) in group B (0.64 ± 0.28 bpm/W) with less severe LV dysfunction, as compared to group A (0.46 ± 0.25 bpm/W) ($p = 0.02$). In both groups a further increase in the HR/WR slope was measured above the AT (A: +26% to 0.62 ± 0.41 bpm/W; B: +20% to 0.80 ± 0.36 bpm/W) (n.s.).

Conclusion: Pts with DCM and moderate LV dysfunction show a steeper HR/WR response below the AT, as compared to those with severe dysfunction. The HR/WR slope in both groups does not down regulate above the AT, as observed in healthy subjects. To mimic this rate response with pacemaker sensors, other rate response slopes may be required, as compared to patients with normal LV function.

P3663 Left ventricular function in dilated cardiomyopathy – acoustic quantification assessment

E. Michalak, J. Grzybowski[1], M. Skwarek[1], Z. Bilinska[1], W. Ruzyllo[1], W. Rydlewska-Sadowska[2]. *Department of Noninvasive Cardiology, National Institute of Cardiology, Warsaw; [1]Department of General Cardiology, National Institute of Cardiology, Warsaw; [2]Department of Noninvasive Cardiology, National Institute of Cardiology, Warsaw, Poland*

Left ventricular(LV) function was assessed in 41 pts with dilated cardiomyopathy (DCM) aged 37.0 ± 10.7 yrs and 33 controls aged 38.6 ± 9.0 yrs with good quality echocardiograms. Automated boundary detection (ABD) with modified Simpson's rule was used for LV volume estimation from apical 2-chamber view. We evaluated: LV enddiastolic volume (LVEDV), ejection fraction (EF%),% volume change during rapid filling (RF%) and filling due to atrial contraction (AF%)in relation to total filling volume, peak volume changing during rapid filling (dV/dtRF) and filling due to atrial contraction (dV/dtAF), normalized peak filling rate (PFR), time to PRF (tPFR) and normalized peak ejection rate (PER). Mean pulmonary wedge pressure (mPWP) and ejection fraction were determined invasively after echocardiographic study in DCM pts. Results are shown below.

We found negative correlation between mPWP and PFR (r = −0.49)as well as PER (r = −0.54). The DCM pts we divided into 2 groups: A – with mPWP ≥20 mmHg, B – with mPWP < 20 mmHg. We noticed significantly reduced PFR (2.0 ± 0.65 vs 2.6 ± 0.77EDV/s, $p < 0.03$) and PER (1.4 ± 0.5 vs 2.2 ± 0.93EDV/s, $p < 0.02$) in group A compared to group B. The correlation between LVEF obtained invasively and from ABD was strong (r = 0.84).

LV function in DCM and control group

		DCM	Control	p
LVEDV	(ml)	183.0 ± 83.3	71.7 ± 20.7	<0.0001
LVEF	(%)	25.2 ± 10.0	58.2 ± 7.1	<0.0001
RF	(%)	61.7 ± 15.6	70.7 ± 9.2	<0.05
RF	(%)	40.0 ± 11.2	29.6 ± 12.9	<0.04
dV/dtRF	(ml/s)	355.5 ± 150.2	276.4 ± 95.6	<0.02
dV/dtAF	(ml/s)	243.4 ± 110.2	168.4 ± 67.8	<0.0004
PFR	(EDV/s)	2.4 ± 0.71	4.2 ± 0.83	<0.001
tPRF	(ms)	77.2 ± 35.8	114.0 ± 63.4	<0.01
PER	(EDV/s)	1.8 ± 0.79	3.5 ± 0.47	<0.0001

Conclusions: Acoustic quantification is an effective noninvasive method to assess LV function in pts with DCM in which reduced peak filling rate, time to peak filling rate and peak emptying rate are observed. Markedly reduced PFR, tPFR and PER suggest significantly increased filling pressure with increased chamber stiffness of enlarged LV and can be a marker of poor prognosis.

P3664 Usefulness of VO_2 half-time after exercise as an indicator of functional status

Y. Takeda, H. Takaki, N. Tahara, Y. Gotou, K. Sunagawa. *Division of Cardiology, National Cardiovascular Center, Osaka, Japan*

Delayed VO_2 kinetics after exercise have been characterized in patients with cardiocirculatory disorders such as seen in heart failure patients, its clinical significance, however, is not fully established. Since VO_2 following exercise does not necessarily decay in an exponential fashion, simple half-time (1/2T) of the VO_2 recovery might be a convenient, proper parameter. To further clarify its significance as an index of functional status, we first determined possible age-related changes in 1/2T in healthy controls and then examined its diagnostic significance as an index for therapeutic effects (exercise training).

Methods: We measured 1/2T in 229 control subjects at various ages (40 ± 17 yo.) with normal exercise tolerance (%peak VO_2 > 80%) and no structural cardiac disease. Then we evaluated the changes in 1/2T after 3-month exercise training in patients with recent myocardial infarction (MI, n = 119) and coronary artery bypass graft (CABG, n = 36). 1/2T was defined as the elapsed time (s) required for a 50% fall in the peak value.

Results: In controls, age-related increases in 1/2T were observed as evidenced by a significant correlation (y = 0.33×age ± 42, r = 0.48). 1/2T before training were much greater in CABG patients (109 ± 41 s) than in MI patients (78 ± 20 s, $p < 0.001$). After exercse training, 1/2T was shortened in all but 6 (unchanged in 4)in CABG patients (87 ± 30 s, $p < 0.001$), but remained unchanged in MI patients. The changes in peak VO_2 after training correlated with those in 1/2T in neither MI nor CABG patients.

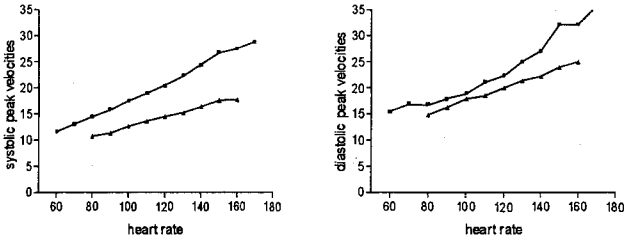
Conclusions: VO_2 kinetics after exercise is delayed with aging in normal subjects. 1/2T seemed to reflect the deconditioning of the skeletal muscle rather than the cardiac dysfunction.

P3665 Doppler tissue echocardiography during exercise stress test in normals and athletes

G. Pelà, G. Bruschi, M. Calzolari, G. Orlandini, A. Cabassi, A. Cattabiani, T. Mazzella, A. Borghetti. *Dipartimento di Clinica Medica, Nefrologia e Scienze della Prevenzione University of Parma, Italy*

DTE is a new ultrasound technique allowing myocardial velocity measurements during cardiac cycle. Aim of the present study was the assessment of the heart function during all phases of exercise stress test measured by DTE in Normals (N) and in trained Athletes (AT).

Methods: 15 sedentary subjects and 12 Athletes underwent a DTE from the apical 4-Ch view during supine exercise test; the sample volume was positioned at the lateral mitral annulus within the color Doppler image and systolic (S) and diastolic (D, including both early and late ventricular filling) tissue waves were recorded from rest to the peak of exercise (90% of the maximal age-predicted heart rate) The peak velocity, mean velocity, time-velocity integral and duration of S and D waves were calculated and referred to the heart rate. As the figures show, in both groups (AT, solid square, N solid triangle) we observed during the test an increase of systolic and diastolic peak velocities, which was more relevant in AT. In both groups the percent increase of D wave was higher than that of S wave. Similar results were obtained with integrals and mean velocities.



Conclusions: Systolic and diastolic tissue velocities can be monitored during all steps of exercise test, DTE appears to be a new tool to quantify the ventricular response of different groups to exercise, for which clinical applications are foreseeable.

P3666 Long-term modification of cardiopulmonary performance after mitral valvuloplasty

I. Šimková, V. Fridrich, M. Grožajová, I. Riečanský. *Dept. Cardiology, Slovak Institute of Cardiovascular Diseases and Postgraduate Medical School, Bratislava, Slovakia*

Percutaneous transvenous mitral valvuloplasty (PTMV) has been proved as an effective method in the treatment of patients (pts) with mitral stenosis (MS). In order to evaluate the evolution of cardiopulmonary performance in the long-term follow-up (5 yrs) after successful PTMV we performed a prospective study of 108 pts with pure or dominant MS. PrePTMV, early and late postPTMV echocardiography, exercise ECG and pulmonary function (PF) were compared in the whole group and in the subgroups created according to the valve echo score.

Results: The analysis revealed:

(1) Substantial increase of mitral valve area, fell of mitral gradient and pulmonary hypertension (PH) in the whole group, with higher significance in the subgroup with lower echo score ($p < 0.01$ vs 0.001)

(2) Significant improvement ($p < 0.05$) of some PF parameters (FVC, FEV_1) in all pts early post PTMV, in the late period significant only in the subgroup with mild to moderate PH and lower echo score (8 vs 11) (3) In pts with high echo score, severe PH prePTMV and/or persisting moderate to severe PH postPTMV: a) no improvement of DICO b) worse ($p < 0.01$) PF in comparison to the pts with mild PH

(4) Improvement of exercise capacity ($p < 0.01$) and functional status

Conclusion: PTMV is safe and effective method in the treatment of MS in pts with pliable valves and reversibility of pulmonary hemodynamics abnormalities. But PTMV seems to provide also in pts with less suitable valves acceptable results with improvement of cardiopulmonary performance persisting in the follow-up period. The long-term modifications of PF are determined probably by the degree of organic changes of pulmonary interstitium, what implies also no improvement of diffusing capacity and irrelevant changes of PF in the subgroup with severe PH.

DIAGNOSIS RISK STRATIFICATION IN CORONARY HEART DISEASE

P3667 Exercise tolerance is depending directly on coronary reserve and inversely on rate-pressure product response to exercise in hypertensive patients without myocardial ischaemia

G. Bigalli, M. Kozàkovà, M. Emdin, C. Morizzo, A. Magagna[1], G. Nassi, S. Buralli[1], C. Palombo, A. Salvetti[1], A. L'Abbate. *Cardiology Dept., Institute of Clinical Physiology, Pisa; [1]Department of Internal Medicine, Pisa, Italy*

A reduced coronary flow reserve (CFR) is reported in patients with essential hypertension (HT) even in absence of angiographically significant coronary stenosis. Whether or not such an impairment in coronary vasodilator capacity may affect exercise tolerance (ET) even in absence of myocardial ischemia is not yet established.

Aim of this study was to evaluate the relationship between ET and CFR in patients with HT, angiographically normal coronary arteries and ECG on effort negative for myocardial ischemia.

Methods: in 30 lean patients with mild to moderate untreated HT (office BP > 150/90 mmHg and <180/110 mmHg; mean age 53 ± 10; 25 males), angiographically normal coronary arteries and ECG on effort negative for myocardial ischemia, blood flow velocity in left anterior descending coronary artery was monitored by transesophageal Echo-Doppler in basal condition and during i.v. adenosine infusion (140 μg/kg/min in 5 min): the adenosine/basal flow velocity ratio was computed as an index of CFR. All patients underwent a maximal exercise test by cycloergometer, with stepwise increments of 25 W every 2 minutes, until exhaustion: blood pressure (BP), heart rate (HR) and rate-pressure product (RPP) were measured every minute, while 12-lead ECG was continuously recorded during exercise and 5-min recovery.

Results: CFR was significantly lower in HT patients, as compared to a group of normotensive controls of similar age (2.63 ± 0.61 vs 3.32 ± 0.64; $p < 0.001$). Exercise test, negative for chest pain and electrocardiographic ischemia, was interrupted due to exhaustion at the 88.1 ± 11.3% of age-adjusted maximal HR. Exercise time was 10.2 ± 3.6 min in average, and correlated directly with CFR ($r = 0.56$, $p < 0.01$), and inversely with the slopes of the linear regression lines of HR, systolic BP and RPP vs. increasing workload ($r = 0.55$, 0.68 and 0.61, respectively).

Conclusions: in patients with mild to moderate essential HT and angiographically normal coronary arteries, ET seems to be limited by a reduced CFR and a steeper rate of increment of HR and systolic BP during exercise even in absence of detectable myocardial ischemia.

P3668 Prediction of culprit lesion localization by using a new index on predischarge exercise stress test in patients with acute inferior myocardial infarction

O. Bolca, B. Dagdeviren, M. Eren, T. Norgaz, M. Polat, T. Tezel. *Cardiology Dept, Siyami Ersek Cardio Thoracic Center, Istanbul, Turkey*

In patienst with acute inferior myocardial infarction localization of culprit lesion is directly related with prognosis. Aim of this study is to test ST segment index that is calculated by dividing ST segment elevation in limbs lead D2 with D3, as a new marker for prediction of culprit lesion localisation if it is in right coronary artery (RCA) or left circumflex coronary artery (LCX). For this purpose 82 patients with acute inferior myocardial infarction who have ST segment elevation on predischarge symptom limited and/or submaximal treadmill exercise test by using modified Bruce protocol were included in the study. ST segment index was calculated from the ratio of ST segment elevation in limbs lead D2 and D3 on the peak exercise level.Patients were classified according to ST segment index in two groups. Group 1 consisted of the patients with ST segment index > 1 (n = 24) and group 2 the patients with ST segment index < 1 (n = 58). All patients were underwent coronary angiography.

Results: Both group 1 and 2 patients were similar in age gender, peak exercise level and double products they were achieved. Group 1 patients had LCX lesion (specificity% 87, sensitivity 87%, positive predictive value 75%, negative predictive value 94%, accuracy 88%) and group 2 patients had RCA lesion more frequent (sensitivity 87%, specificity 87%, poditive predictive value 94%, negative predictive value 75%, accuracy 88%) ($p < 0.001$).

Relation between culprit coronary artery and ST segment index

	Cx (n = 28)	RCA (n = 54)	p
Group 1 (n = 24)	21	3	<0.001
Group 2 (n = 58)	7	51	<0.001

In conclusion ST segment index can be used to predict culprit lesion localisation on predischarge exercise tests in patients with inferior myocardial infarction.

P3669 Pronounced post-exercise HRV in inferior ischaemia – determinants of its appearance and revascularization effects

N. Tahara, H. Takaki, T. Kawada, M. Sugimachi, K. Sunagawa. *Division of Cardiology, National Cardiovascular Center, Osaka, Japan*

Exercise-induced inferior ischemia, possibly experienced in daily activities, might result in vagal activation as well as acute inferior myocardial infarction. Our recent data indicating more pronounced HRV and shorter decay of HR after exercise in patients with inferior ischemia compared in those with anterior ischemia supports this possibility, however, these indexes could not completely differentiate two lesions. To further establish our notion, we examined various factors possibly affecting this phenomenon in patients with inferior ischemia, and then evaluated the effects of revascularization (RV) on these parameters in patients with inferior and anterior ischemia.

Methods: In 52 patients with exerise-induced significant ST depression and documented inferior ischemia, we measured post-exercise HRV (6 min) with use of A/D converted ECG. They were divided into 2 group with (G-P, n = 26) and without (G-N, n = 26) pronounced post-exercise HRV accoring to Delta-RR (successive RR differences averaged at 60–90 sec, cut-off = 15 ms/beat), HR decay was also measured as a time constant (TC). Clinical characteristics including sex, risk factors, medications, exercise test results, angiographic findings, and ventricular function, were compared between the 2 groups. Furthermore, by repeating the test in patients with inferior (n = 11) and anterior (n = 10) ischemia after successful RV, pre-RV and post-RV data were compared.

Results: Except for age and resting HR (both, $p < 0.05$), all other factors were comparable between the 2 groups, suggesting prerequisite of preserved vagal activity in the appearance of this phenomenon. After RV, Delta-RR in patients with inferior ischemia attenuated in all but one (22 ± 13 to 8 ± 5 ms, $p < 0.05$). TC concordantly prolonged in all but 3 (73 ± 20 to 98 ± 29 s, $p < 0.05$). Both parameters changed toward the same level as those in patients with anterior ischemia, in whom both remained unchanged. This indicated a direct role of ischemia localized in inferior wall on this phenomenon.

Conclusion: The data supports our previous notion that inferior ischemia, even provoked by physiological stress such as exercise, activates vagal nerve resulting in cardioinhibitory reflex. Preserved basal vagal function seems to a prerequisite for the appearance of this phenomenon.

P3670 Post-exercise VO_2 "hump" phenomenon as an indicator for myocardial ischaemia in patients with anterior myocardial infarction

S. Sakuragi, H. Takaki, M. Sugimachi, T. Kawada, K. Sunagawa, Y. Goto.
Cardiology Dept., National Cardiovascular Center, Suita, Japan

In patients with exercise-induced myocardial ischemia, we occassionally observe abnormal post-exercise blood pressure responses (i.e. delayed recovery or paradoxical increase), presumably caused by transiently enhanced stroke volume following ischemia. Similar mechanisms may be operative in the genesis of abnormal transient VO_2 kinetics early after exercise, which may possibly serve as an indicator for inducible myocardial ischemia. Since the diagnostic accuracy of ischemia by exercise ECG is limited in patients with prior q-wave anterior infarction, we examined this hypothesis in those patients with (G-I) and without (G-N)inducible residual ischemia.

Methods: We examined 50 patients with recent anterior infarction who underwent cardiopulmonary exercise testing within 3 weeks after MI onset. The presence of residual ischemia was clinically defined as the necessity of revascularization within subsequent 3 months (n = 14). To quantify abnormal manifestation in early post-exercise VO_2 kinetics, we standardized the time-series of instantaneous post-exercise VO_2 up to 4 min for peak VO_2, and then exponentially fitted the curve with use of peak VO_2 and continuous data for a period of 90–240 sec. D curve obtained by subtraction of measured VO_2 curve by fitted VO_2 curve was compared between the 2 groups.

Results: Standardized VO_2 was greater in G-I than in G-N for a period of 36–198 sec ($p < 0.05$). In a further limited period of 48–72 sec, D curve in G-I was greater than that in G-N ($p < 0.05$). When "Hump" defined as (1) D curve peaked between 40–60 sec after exercise and (2) absolute peak value of D curve $\geq$ 100 ml/min, it was found only in G-I (n = 6/14, 38%), but not observed in G-N (n = 0/36.0%).

Conclusions: Although not highly sensitive, post-exercise VO_2 "Hump" phenomenon, with its peak occurring around 50 sec after exercise, seems to be a specific marker for inducible myocardial ischemia. The identification of this phenomenon may be useful, particular in patients with limited diagnostic accuracy of exercise ECG such as those with anterior myocardial infarction.

P3671 Use of myocardial perfusion imaging (MPI) with exercise testing (ET) in patients with low likelihood of coronary disease: physician adherence to published guidelines

J.R. Kizer, L. Araujo, J.S. Schwartz[1]. *Cardiology Dept, University of Pennsylvania, Philadelphia PA; [1]Health Economics Dept, University of Pennsylvania, Philadelphia PA, USA*

MPI is not recommended in patients with low CAD likelihood because of its low positive predictive value (AHA/ACC '95). Our objectives were to assess physician use of MPI as an adjunct to ET in low-risk patients; differences between cardiologists and noncardiologists in ET-MPI use; and incremental value and economic impact of concurrent ET-MPI. We conducted a longitudinal review of ET with or without Tc-99 sestamibi SPECT in patients with normal rest ECGs performed at the Hospital of the University of Pennsylvania (1/96–4/98) and identified a subset with low (<10%) likelihood of CAD (based on Diamond and Forrester data). 122/5170 ETs (2.4%) were done in low-risk patients. 77/122 (63%) had adjunctive MPI. MPI use among cardiologists and noncardiologists was similar, 19/31 (59%) vs 59/91 (65%)[p = 0.29] 71/77 (92%) patients who underwent ET-MPI had negative ETs and normal MPI. 4/77 patients had negative maximal ETs with abnormal MPI (all small isolated defects), while 2/77 patients had positive maximal ETs with normal MPI. Only the latter would merit MPI retesting had they been originally referred for routine ET. All 45 routine ETs were negative and none required MPI retesting. No patient was referred for catheterization. Using 1996 medicare fees, a sequential strategy with MPI retesting of positive ETs cost $15,600, while the observed approach favoring ET-MPI by 1.7:1 cost 3.5-fold or $53,830. Although results from this referral center underestimate the proportion of low-risk patients nationwide, extrapolation to the estimated >1,000,000 annual ET-MPI in the US yields substantial savings. We conclude that despite national guidelines, MPI continues to be used frequently – and in similar proportions among cardiologists and noncardiologists – for low-risk patients; MPI adds little information in this patient subset; significant cost savings could occur by restricitng MPI use in these patients; additional interventions are necessary to improve adherence to national guidelines.

P3672 Evaluation of exercise-induced changes in Q, R and S-waves during exercise stress testing in patients with ischaemic heart disease

G. Kesmarky, Z. Marton, A. Toth, L. Czopf, R. Halmosi, I. Juricskay, T. Habon, K. Toth. *1st Dept. of Medicine, Univ. Medical School of Pecs, Pecs, Hungary*

Exercise-induced ST-segment displacement is the most frequently used parameter in detecting ischemic heart disease, however, the value of this marker was proven to be limited with varying sensitivity and specificity. Therefore, several new parameters emerged to improve the efficacy of exercise testing. Our study aimed at evaluating the recently described QRS score based on the exercise induced changes in Q, R and S waves in the diagnosis of ischemic heart disease.

Methods: Data of 212 subjects performing treadmill exercise test were analyzed. 197 of them underwent stress myocardial perfusion SPECT and 54 of them were examined by coronary angiography. The extent of perfusion defect and the severity of coronary artery disease were characterized by simple scores. QRS score and cumulative ST depression were calculated at each subject and the values were correlated to the results of the myocardial SPECT and coronary angiography. Sensitivity, specificity and validity of QRS score and cumulative ST depression were also calculated.

Results: A significant, inverse correlation was found between the QRS score and the results of stress myocardial perfusion SPECT and coronary angiography in the whole population, especially in males, while females did not show significant relationship. The sensitivity, specificity and validity of the QRS score at the cut-off point of 3.5 mm were 73.5, 71.3 and 72.6%, respectively. These values surpassed those of the cumulative ST depression at the cut-off point of 6 mm. QRS score in patients with conclusive tests (achieving 85% of the maximal predicted heart rate) correlated significantly with stress myocardial perfusion SPECT and coronary angiography; nevertheless, in cases of inconclusive tests this issue could not be proven. The specificity of the QRS score in the group of inconclusive tests was lower than that of patients with conclusive tests and of the whole population in relation with stress SPECT; otherwise the diagnostic values of the QRS score concerning the coronary angiography in patients with inconclusive exercise were not markedly different from those of patients with conclusive tests. Similar correlation values between the QRS score and the severity of myocardial ischemia were obtained in subjects with and without antiischemic medication.

Conclusions: QRS score was significantly related to the extent of myocardial ischemia and the severity of coronary heart disease, thus along with the analysis of ST-segment displacement may contribute to the more precise evaluation of exercise stress testing.

P3673 Ergonovine and serotonin-induced coronary microvascular responses in subjects with false positive exercise ST-segment depression and normal coronary artery

K. Kurosawa, T. Ishihata, A. Hirosaka, M. Igarashi, N. Komatsu, K. Maehara, Y. Maruyama. *Fukushima Medical University, Fukushima, Japan*

The mechanism of exercise ECG ST depression in subjects with normal coronary artery still remains unclear. We have reported that ergonovine (EM)-induced coronary microvascular dilatation was significantly greater in these subjects, suggesting enhanced serotonin (5HT) receptor mediated vasodilation.

Methods: In 52 subjects with atypical chest pain and normal coronary artery, we studied coronary flow responses using a Doppler-tipped guide wire (FloWire) and quantitative coronary angiography. 24 subjects had exercise-induced ST-depression (ExP group) and 28 subjects did not (Control group). After an administration of nitroglycerin (0.2 mg) to eliminate vasomotion of coronary conduit arteries, acetylcholine (ACh, 50 μg), papaverine (PAP, 10 mg), ergonovine (EM, 20 μg) and serotonin (5HT, 10 μg) were separately injected into the left main coronary artery in this order. Coronary blood flow (CBF) was estimated from average peak velocity and coronary arterial cross-sectional area.

Results: Baseline CBFs were not different in two groups. ACh, PAP and 5HT increased CBF similarly in both groups. EM did not change CBF in normal group (154 ± 9%, mean ± SEM), however, significantly increased CBF in ExP group (287 ± 34%, $P < 0.001$). The calculated maximum CBF (ml/min) in each intervention was as follows ($^*p < 0.01$ vs control),

	Baseline	ACh	PAP	EM	5HT
ExP (N = 24)	50 ± 5	153 ± 20	185 ± 15	121 ± 10*	116 ± 18
Control (N = 28)	52 ± 4	155 ± 12	194 ± 19	80 ± 8	101 ± 30

In conclusion, there was not abnormal vasoconstrictive response but vasodilatory response induced by EM in microvascular beds in ExP subjects, presumably leading to steal phenomenon. This vasodilatory response would not be caused by enhanced 5HT receptor pathway but might be related to attenuated alpha adrenergic vasoconstrictor pathway.

P3674 Comparison of multichannel magnetocardiography and body surface potential mapping in detection of exercise induced myocardial ischaemia

H. Hänninen, P. Takala[1], M. Mäkijärvi, K. Simelius[1], J. Montonen[1], J. Nenonen[1], T. Katila[1], L. Toivonen. *Division of Cardiology/BioMag, Helsinki University Central Hospital, Helsinki; [1]Laboratory of Biomedical Engineering, Helsinki University of Technology, Helsinki, Finland*

Introduction: The aim of the study was to compare multichannel magnetocardiography (MCG) and 128-lead body surface potential mapping (BSPM) in detection of myocardial ischemia.

Methods: We studied coronary artery disease patients; 10 with left anterior descending (LAD) and 7 with right coronary artery (RCA) stenosis, and 12 age matched healthy controls during supine bicycle exercise testing. MCG and BSPM were registered in two separate similar stress tests in random order. Magnetic isofield and electrical isopotential maps were formed using averaged QRST signals in the ST-segment at rest and at cessation of exercise and at the T-wave apex at rest and 4 minutes postexercise. Changes from the rest state in the isofield and isopotential maps were quantified as rotations of the line connecting magnetic field and electric field maximum and minimum over the torso model.

Results: The rotation of the MCG isofield maps during ST-segment at cessation of exercise separated LAD patients from controls ($97 \pm 44°$ vs $37 \pm 35°$, $p < 0.005$), but not RCA patients from controls. On the contrary, the rotation of the BSPM isopotential maps during ST-segment did not differ between LAD and RCA patients and controls. At T-wave apex 4 minutes postexercise the rotation of the MCG isofield maps ($49 \pm 34°$ vs $10 \pm 16°$, $p < 0.005$) and BSPM isopotential maps ($71 \pm 43°$ vs $18 \pm 21°$, $p < 0.005$) separated RCA patients from controls. Same parameters separated RCA patients also from LAD patients (both $p < 0.05$). Only 6/17 patients fulfilled the standard ischemia criterion of >0.1 mV ST-segment depression in BSPM. Better performance of MCG may be due to its higher sensitivity to tangential injury currents produced by subendocardial myocardial ischemia.

Conclusion: Magnetocardiographic isofield maps seem superior to BSPM isopotential maps in detecting myocardial ischemia. Both isofield and isopotential maps during repolarization phase, at the T-wave apex, may have application in identifying the stenosed coronary vessel.

P3675 Echocardiography in systemic lupus erythematosus

Ahcene Chibane, Salim Benkhedda, Kheireddine Merad-Boudia. *Servife de Cardiologie CHU Mustapha Alger, Algeria*

Aims: use of trans-thoracic-echocardiography (TTE) to study the frequency and the type of heart 1 lesions in a cohorte of 125 SLE Algerian patients

Methods: during a 6 years periode we have prosprectively studied 125 SLA patients diagnosed according to at least 4 ARA criterias. All patients were screened according to the ASE recommandations with the 1500 HP or with the ULTRAMARK 9 echocardiograph.

Results: 72 patients (57.6%) presented cardiac abdominalities. 50 patients (40%) had pericardial involvement. In 28 cases there xas pericardial effusion, 21 cases had a thikneed pericardium and 8 of them showed a moderate pericardial effusion. In one case there was a constrictive pericarditis., 43 patients (34.4%) had valcular abnormalities. There was a valcular thikning in 36 patients. The mitral valve was the most frequently involved (29 cases). In 2 cases there was also a mitral stnosis and mitral regurgitation grade 2 or 3 was found in 7 other cases. In 3 patients there was vegetations involving the mitral valve in 2 cases and the aorta in one case, 33 patients (26.4%) had myocardial abdnormalities. 3 patients had left atrial (LA) dilatation with normal sinus rrhythm. In 4 other patients the left ventricular (LV) was dilated and in 19 patients there was left cventicular hypertrophy (LVH). The LV revealed meanly a distolic relaxation abnormality in 14 cases and systolic contraction abdnormality in 6 cases. There was aloso a dysfunction regarding the segmental contractility in 5 cases including 2 patients with myocardial infarction. In 16 cases the SPAP was higher than 30 mmHg.

Conclusion: The heart involvelment in SLE Algerian population ins very high (56%). TTE appeared to be the best non agressive and the cheapest investigation tool in SLE patients.

P3676 Right ventricular ejection fraction in patients with left ventricular dysfunction

M. Alami, R. Bennani, R. Ghannam, M. Sadeli, H. Benjelloun, M. Benomar. *Department of Cardiology, Ibn Sina Hospital, Rabat, Morocco*

Several studies are proposing normal range for right ventricle ejection fraction (RVEF) with radionuclide angiography (RA). But can we apply this values to the patients with left ventricle (LV) dysfunction?

Inter-relation between right and left ventricle (Berheim effect) may lead to a significant dependence of RVEF on left ventricle ejection fraction (LVEF).

In order to assess RVEF in pts with LV dysfunction, we studied 245 cases of RA.

Methods: 245 patients underwent equilibrium RA with measures of RVEF, right ventricle end diastolic volume (RVEDV), LVEF, and left ventricle end diastolic volume (LVEDV). We divided this population into 2 groups: group A with LVEF $\geq$ 40% (n = 119) and group B with LVEF < 40% (n = 126).

Results: in the entire group of 245 patients, RVEF was 33%, LVEF 39%. There was a significant difference between RVEF in group A (36%) and RVEF in group B (30%), $p < 0.001$. In both groups there was no correlation between RVEF and LVEF (group A: r = 0.14 and group B: r = 0.28).

In conclusion, RVEF decreases significantly in presence of left ventricle dysfunction. The absence of correlation between RVEF and LVEF is probably due to the numerous causes affecting RVEF.

P3677 Evaluation of T-wave pseudonormalisation on surface electrocardiogram as a marker of reversible myocardial ischaemia due to epicardial coronary artery disease

A.K. Agarwal[1], P. Venugopalan[2], J. Sobitharaj[3], L. Aligante[3], S. Estoya[3]. *Departments of [1]Medicine; [2]Child Health; [3]Clinical Physiology, Sultan Qaboos University Hospital, Muscat, Oman*

Pseudonormalisation of T wave on surface electrocardiogram (ECG) during cardiac exercise testing is suggested to be one of the criteria for the positivity of the test. We performed stress thallium isotope scan and coronary angiography in patients exhibiting exercise induced T wave pseudonormalisation to assess its strength as an independent marker of reversible myocardial ischaemia.

Methods: 22 patients showing treadmill exercise induced pseudonormalisation in the surface ECG underwent coronary angiography. Presence of ST segment depression on ECG during exercise test associated with pseudonormalisation was also recorded.

Results: Of the 22 patients, 12 had angiographically demonstrated coronary artery disease. These 12 patients also had ST segment depression on exercise ECG. Remaining 10 patients neither had demonstrable coronary obstruction nor did they exhibit exercise induced ST segment depression. Thus in about one half of the patients with T wave pseudonormalisation, there was no demonstrable coronary artery obstruction on angiography.

In conclusion, exercise induced T wave pseudonormalisation, without ST segment depression does not appear to be an independent marker of reversible myocardial ischaemia due to disease in epicardial coronary arteries or its large branches. Its significance in identifying small vessel disease would need further evaluation.

P3678 Implantation of permanent pacemakers guided by transthoracic echocardiography

Gonzalo Díaz, Primo Pacheco, Hércules Acuña, Alex Díaz. *Northen Institute of Cardiology, Las Mercedes Teaching Hospital Chiclayo, Peru*

The objective of this study is to demonstrate the usefulness, efficiency and safeness of transthoracic echocardiography (TTE) as a guide in the implantation of permanent pacemakers (PM).

Methods: We implanted PM (type VVI) in 42 patients, 28 (67%) male; the age was 22 to 91 years. 30 (74%) were diagnosed with complete AV block, 8 (19%) with second degree AV block and 4 (10%) with others. 32 (76%) presented Stoke Adams crisis. Pacemakers of different brand names were used; we also used 2.25 and 3 MHz transducers. The initial TTE, subcostal and apical views, evaluated the proximal cava veins and the right chambers. Special attention were given to measurements morphology, moderator band, apex and tricuspid valve. Vascular access was gained through the right subclavian vein in 32 (76%), right internal yugular vein in 4 (10%) and left subclavian vein in 6 (14%) cases. X-ray, ECG and TTE follow ups were done at 3 and 10 days.

Results: TTE showed an appropiate or optimal visibility of the cardiac chambers, the advancing catheter and the implant zone. The technique proved successful and had no complications in any case. Follow up evaluations verified proper PM catheter position and PM impulse capture.

Conclusions: TTE is efficient, safe and very useful in guiding the implantation of permanent pacemakers; fluoroscopy would not be needed. TTE makes the procedure easier and cheaper. As oppossed to fluoroscopy, TTE implies no ionizing radiation to the patient. This new technique is simple, lowers costs and could be performed in more medical facilities without fluoroscopy. Fluoroscopy is needed in cases of deficient echocardiographic windows.

P3679 Comparison of myocardial contrast echocardiography with Tc-99m SPECT in the assessment of segmental myocardial perfusion in patients with Chagas cardiomyopathy

N. Beer, M. Pinedo[1], V. Taisma[1]. *Dept. of Medicine, Hospital de Clinicas Caracas, Caracas; [1]Cardiology Dept, Fundacion Del Congreso de la Republica, Caracas, Venezuela*

Nuclear agents proved to be useful for the evaluation of tissue perfusion in patients with Chagas disease. It has been reported that second generation contrast agents (Levovist, Shering,AG) leads to improve endocardial visualization and to the possible use of these agents for the determination of tissue perfusion.

Methods: We studied 50 myocardial segments in ten patients at rest after the injection of Levovist followed 24 hour latter by the injection of Tc sestamibi. All the patients had normal coronary arteries.

Results: 100% of the patients demonstrated abnormalities in tissue perfusion. All the patients demonstrated apical defects by both techniques. Contrast echocardiography was not able to identify two patients with lateral wall defects. Septal abnormalities were present in 80% of the patients. Inferior wall abnormalities were present in four patients. The anterior wall was spared in all the ten patients.

Conclusion: These findings coincide very well with the pathology in this disease entity. Myocardial contrast echocardiography provides a reliable tool for the diagnosis of wall motion and tissue perfusion in Chagas disease.
