Results: 448 patients responded, reporting "good to excellent" general health (316/447; 71%); "somewhat to much better" quality of life (201/448; 45%); and "somewhat to much better" emotional well-being (202/448; 45%) following ICD implantation. A small sample reported "fair-poor" general health (131/447; 29%), with fewer patients experiencing decrements in quality of life (42/447; 9%) and emotional well being (66/448; 15%) following ICD implantation. Younger recipients (<50 yrs. of age) reported significantly better general health ($X2 = 8.796$, $p < 0.05$) but poorer quality of life health ($X2 = 10.799$, $p < 0.05$) as compared to all older recipient age groups. The youngest recipient groups had significantly more difficulty with a range of psychosocial concerns. For example, worry was significantly higher for younger recipients compared to the older age groups (46% (<50 yrs. of age) & 39% (51–60) vs. 21% (61–70) & 18% (71–98)) ($p < 0.05$). Increased ICD shock experiences were associated with greater difficulty with generalized fear ($X2 = 29.273$, $p < 0.001$), fear of physical exertion ($X2 = 25.927$, $p < 0.001$), worry ($X2 = 21.594$, $p < 0.001$), and stress management ($X2 = 12.872$, $p < 0.001$).

Conclusion: These results suggest that most ICD recipients experience desirable quality of life outcomes but that young ICD patients and those who experience ICD shocks are at greater risk for psychosocial adjustment difficulties.

1261 Fast non-sustained ventricular tachycardias predict sudden cardiac death in patients following myocardial infarction

D. Andresen, G. Steinbeck[1], T. Brüggemann, E. Hoffmann[1], C. Ehlers, R. Haberl[1]. *Dept of Cardiology, Urban Hospital Berlin; [1]Klinikum Großhadern, University of Munich, Germany*

The MADIT study has shown that electrophysiologic study (EPS) can be successfully applied to identify high-risk pts. following myocardial infarction (MI) that benefit from prophylactic implantation of a cardioverter/defibrillator (ICD). However, EPS is an invasive and non-standardized method that was applied to highly selected pts. late after MI. The purpose of the present study was to assess if a similar high-risk group could be defined prior to hospital discharge after an acute MI by using standard Holter ECG only.

Method: In a prospective study we analyzed arrhythmias on 24-h Holter ECG in 1202 post-MI pts. prior to hospital discharge (13 ± 4 days after acute MI). Pts.' mean age was 64 yrs., 69% were male, and 29% had an ejection fraction < 40%. During a median follow up of 25 months 20% (235) of pts. died: 4% (51) sudden cardiac death (SCD), 9% (102) non SCD, 3% (40) non cardiac death, and 3% (42) from unknown cause.

Results: Non-sustained ventricular tachycardias (nsVT) were observed in 11% (136/1202) of pts and fast nsVT (rate ≥ 150/min) in 3.7% (45/1202). The SCD rate was 14% for pts. with nsVT and 2.4% for pts. without ($p < 0.001$). Pts. with fast nsVT showed an even higher SCD rate of 22% ($p < 0.0001$). Fast nsVT was more predictive for SCD compared to all cause mortality (relative risk 6.3 vs. 3.0).

Conclusion: Pts. with fast nsVT in the first weeks following acute MI are at high risk of SCD. Whether these pts. will benefit from prophylactic implantation of a cardioverter/defibrillator is currently investigated in the IRIS (Immediate Risk-stratification Improves Survival) study.

1262 Efficacy of antitachycardia pacing in 160 patients with a history of ventricular fibrillation

A. Schaumann, O. Fabian[1], A. Poppinga[1], G. Hasenfuss[1], B.-D. Gonska[1]. *Cardiology Dept., St. George Hospital, Hamburg; [1]Cardiology Dept., University of Goettingen, Göttingen, Germany*

The efficacy of antitachycardia pacing (ATP) for the termination of ventricular tachycardias (VT's) was prospectively evaluated in 160 patients with implanted cardioverter defibrillators after survived sudden cardiac death due to ventricular fibrillation (VF). In all patients with a history of VF and no known VT's new tiered therapy ICD's were implanted and ATP was programmed on. Most of the patients had coronary artery disease (n = 90) or idiopathic cardiomyopathy (n = 48). The left ventricular function was reduced (EF = 38%). In only 37 of the 160 patients a VT was inducible at the baseline ventricular stimulation. Spontaneous ventricular arrhythmias were analyzed with the stored ECG and therapy history recorded by the ICD.

Results: During the follow-up of 31 (3–80) months 1857 spontaneous ventricular arrhythmias occurred in 97 (61%) patients. VF was seen 185 times and treated with primary shock delivery. ATP attempts were successful in terminating 1496 (90%) of 1672 spontaneous VT's. An acceleration of the arrhythmia due to ATP was seen in 5.7% of ATP attempts. VF was the only recurrent arrhythmia in 36 patients. Spontaneous VT's were seen in 27 patients and 34 patients had both, VT and VF recurrences. In 35 of 97 patients ATP was able to terminate 90–100% of all spontaneous VT's although the known history of arrhythmia was VF.

Conclusion: Patients with a history of ventricular fibrillation alone have more often recurrences of spontaneous VT's than VF (90% vs 10%). The efficacy of ATP (90%) for terminating VT's is high even in patients with a history of VF alone. Therefore we recommend that ATP be programmed for these patients, too.

1263 Higher incidence of inappropriate, but also appropriate implantable cardioverter-defibrillator therapy in survivors of cardiac arrest with atrial fibrillation

G. Grönefeld, O. Mauss, S.H. Hohnloser. *J. W. Goethe-University, Div. of Cardiology, Frankfurt, Germany*

Background and methods: Atrial fibrillation (AF) is a frequent arrhythmia, associated with increased morbidity and mortality in large population based studies. The effect of this arrhyhtmia on device-therapy in survivors of cardiac arrest with an implanted cardioverter/defibrillator (ICD) has not been studied systematically. In a prospective study all consecutive patients (pts) undergoing transvenous ICD-implantation at our institution between 1/1994 and 12/1998 were stratified for presence of AF at ICD-implantation, and incidence and adequacy of ICD-therapy was analyzed during follow-up.

Results: 205 patients (79% male; mean age 60 ± 11 years, ejection fraction 36 ± 13%; coronary artery disease 67%) were analyzed. At baseline, 46 pts (22%) presented with AF. During a mean follow-up of 20 ± 12 months 89 pts had adquate and 30 pts inadequate ICD-therapy as assessed by analysis of recorded electrograms. 10/46 pts (22%) with AF had at least one episode of inadequate ICD-therapy delivery compared to 20/159 (13%) in pts in sinus rhythm (SR) ($p < 0.05$). Adequate device therapy, however, was also significantly more frequently observed in pts presenting with AF (27/46 pts, 59%) compared to SR (62/159 pts, 39%; $p < 0.05$). Important clinical characteristics such as age, gender, and ejection fraction (EF) were similar in pts presenting with AF or SR. Multivariate analysis showed EF to be an independent predictor of adequate Tx in pts of both groups. Antiarrhythmic drug use with amiodarone and sotalol was also more frequent in AF-patients with 19/46 pts (46%) compared to 36/159 (23%) in SR-patients ($p < 0.02$).

Conclusion: ICD recipients with AF have a significantly higher incidence of inadequate, but also adequate device therapy despite higher use of antiarrhythmic agents in this subgroup of patients. These data are in agreement with the notion, that the presence of AF may identify a group of pts at particular high mortality risk.

1264 Value of programmed electrical stimulation to predict clinical outcome in survivors of cardiac arrest: subgroup analysis from the Cardiac Arrest Study Hamburg (CASH)

R. Cappato, R. Rüppel, J. Siebels, K.-H. Kuck. *On behalf of the CASH Investigators; St. Georg Hospital, Hamburg, Germany*

CASH was designed to assess the 2-yr mortality of ICD therapy compared to treatment with either propafenone (PROP), amiodarone (AMIO) or metoprolol (METO) in survivors of cardiac arrest. Due to an excessive mortality in pts randomized to PROP, assignement to this group was prematurely terminated. Final analysis showed an improved 2-yr survival in 99 pts randomized to ICD (12.6%) as compared to that in 189 pts randomized to AMIO/METO (19.6%, 1-sided p = 0.047). Baseline programmed electrical stimulation (PES 1) was performed in all pts during hospitalization after the index event; pts randomized to drug treatment also underwent PES under the drug assigned (PES 2). The value of PES to predict clinical outcome was retrospectively assessed.

Results. PES 1 was performed in 97 ICD pts, in 92 AMIO pts and in 97 METO pts; inducibility of sustained VT or VF using a 3 extra-beats, 2-site PES protocol was observed in 47%, 49% and 44% of pts, respectively. 2-yr survival was at 89% higher in 135 noninducible (nonI) than it was at 75% ($p < 0.001$) in 152 inducible (I) pts. Of 82 AMIO and 84 METO pts undergoing PES 2, lower 2-yr survival rates (70% in 20 pts and 68% in 19 pts) were observed among those who still were I, compared to those suppressed (83% in 18 pts and 76% in 17 pts). Conversely, a 2-yr survival rate as high as 94% in 33 AMIO pts and 92% in in 39 METO pts was observed were nonI at both PES 1 and PES 2. Inducibility only at PES 2 (11 AMIO and 9 METO pts) was associated with a 91% and 100% 2-yr survival.

Conclusions. The present data suggest that PES is a valuable tool to select pts who most likely benefit of an ICD treatment among survivors of cardiac arrest. Prospective investigation is required to confirm this observation

1265 Baroreflex sensitivity contributes to the risk stratification of patients considered for a prophylactic implantable cardioverter defibrillator

M.T. La Rovere, A. Mortara, J.T. Bigger Jr, F.I. Marcus, M. Malik, S.H. Hohnloser, P.J. Schwartz. *For the ATRAMI Investigators; Division of Cardiology, Fondazione "S. Maugeri", IRCCS, Montescano (PV), Italy*

The growing use for primary prevention of the ICD, together with its high cost and invasive procedure, calls for accuracy in the identification of the patients (pts) who really need it. In the MADIT-II and SCD-HeFT studies risk stratification is based only on depressed ejection fraction (EF). The ATRAMI study has provided definitive evidence that alterations in the autonomic balance play an important role in cardiac mortality, and are of prognostic value independently of EF and ventricular arrhythmias. We have evaluated whether the presence of an autonomic imbalance defined by a depressed Baroreflex Sensitivity (BRS < 3 ms/mmHg) could improve the management strategy for the prophylactic use of ICD. In the ATRAMI population (1284 patients, age 57 ± 10 yrs, EF 49 ± 12%) the 2-year cardiac mortality of pts with EF < 35% (n = 180) differed significantly according to the presence (n = 33) or absence (n = 147) of nonsustained ventricular tachycardia (NSVT) at Holter recording (21.2 vs 8.2%, p = 0.027). In the presence of NSVT the mortality rates for BRS < or ≥3 ms/mmHg were 31% and 17% respectively (ns). By contrast, among patients without NSVT the 2-year mortality was markedly lower, only 4.6% vs 18% (χ^2 6.02, p = 0.014) according to a BRS ≥ 3 or <3 ms/mmHg. As patients with BRS ≥ 3 ms/mmHg account for 70% of patients without NSVT, the analysis of BRS (which has a Negative Predictive Accuracy of 95.4%) would allow to reduce by about 50% the number of implanted devices without any loss for the high risk pts.

In conclusion, among pts with EF < 35%, those without NSVT but depressed BRS have the same mortality (18 vs 21%) of those with NSVT; this enhances the identification of pts at high risk. Conversely, and perhaps more important, those without NSVT and BRS ≥ 3 ms/mmHg are at very low risk and may not need an ICD. Thus, the use of BRS can markedly improve the risk stratification strategy for the primary prevention of sudden cardiac death.

CATHETER ABLATION OF ATRIAL FIBRILLATION

1266 Electrophysiologic findings after open chest endocardial radiofrequency catheter ablation of atrial fibrillation during mitral valve surgery

G. Inama, A. Graffigna[1], L. Gramegna, M. Del Greco, L. Martinelli[1], M. Disertori. *Cardiology Department of S. Chiara Hospital, Trento; [1]Cardiac Surgery Department of S. Chiara Hospital, Trento, Italy*

Open chest endocardial radiofrequency catheter ablation (RFA) of atrial fibrillation (AF) during mitral valve surgery (MVS) is a novel technique that combines catheter ablation with surgery to treat atrial AF. We used radiofrequency energy (RF) applied under direct vision through an ablation catheter during MVS to perform the long continuous lesions in the left atrium in patients (pts) with AF and mitral valve disease (MVD). The focus of this paper is to describe the electrophysiologic findings in the following days after the procedure and during the follow-up.

Methods: from February to November 1998 twelve pts (7 female and 5 male) underwent MVS and left atrial endocardial RF ablation in our Department. All had chronic AF (mean 13 months, range 4 to 18) and MVD needing surgery. Using a standard approach, under cardiopulmonary by-pass with bi-caval cannulation, warm cardioplegia was administered. Through left superior atriotomy (roof of the left atrium) RF was now applied encircling the two right and the two left PV, using an ablation catheter Medtronic or Cordis Webster 7F 2-5-2 with distal tip of 4 mm modified and fluid irrigated to provide a pen-like device. The energy was continually delivered at 30 Watts from a power generator (Medtronic Atacr) with a median procedure time of 10 mins. All the pts were studied through the epicardic wires in the following days after the operation and with electrophysiologic endocavitary study (EPS) after 3 months.

Results: the postoperative course was smooth in all pts. The extra corporal circulation and the aortic cross clamp time were minimally increased. At the echo check before discharging from the hospital and after 3 months all the pts with sinus rhythm (SR) showed recovery of atrial contractility. At the end of the operation all the pts had restoration of SR. At discharge all pts were in SR and without AA. All 5 pts with AF recurrence underwent DC shock with acute recovery of SR. Amiodarone therapy (A) was administered in all AF recurrences. 83% of the pts now continue to remain in SR after a medium follow-up of 6 months and 17% are in chronic AF. In the EPS immediatly after the procedure in all the pts we documented a delayed left atrial activity at SR and during right ventricular pacing. In 3 pts with recurrence of AF we performed EPS during AF and during SR after DC shock. In the right atrium we recorded the AF waves while through the coronary sinus catheter we observed a regular left atrial rhythm dissociated from the right atrium.

Conclusion: the combination of the open chest RF ablation during MVS, is an attractive option associated with excellent early procedure outcome at low risk and with stable electrophysiologic findings during the follow-up. Pts with MVD and AF, who require concomitant MVS, seem to be good candidates for this combined approach.

1267 Linear radiofrequency ablation in the right atrium for drug refractory paroxysmal atrial fibrillation: clinical results from a prospective multicenter study

Claudio Tondo, Roberto De Ponti, Paolo Della Bella, Jorge U. Salerno, Zoltan Csanadi, George Theodorakis, Ernst G. Vester, Michelle Adam, Annibale S. Montenero. *For the REVELATION European Atrial Fibrillation Ablation Group; Milan, Italy*

In order to test the use of a catheter (REVELATION, Cardima, Fremont, CA, USA) specifically designed for creating linear lesions, 43 patients (12 female, mean age 54 ± 10) with highly symptomatic (16 ± 23 episodes/month), paroxysmal, lone atrial fibrillation (AF) underwent radiofrequency (RF) ablation in 6 European centers. Patients were refractory to 2–6 antiarrhythmic medications before ablation, and had paroxysms for 4 months to 40 years with a frequency of 2–150 episodes/month. Symptoms were documented to be due to AF with Holter and/or an Event Recorder. Three lines of lesions were created in the right atrium using the 3.3 Fr REVELATION microcatheter which contains 8 coiled electrodes, each 3 mm long with 2 mm interelectrode spacing. RF lesions were placed between: 1. Inferior Vena Cava (IVC) and Superior Vena Cava (SVC) posterolaterally, 2. SVC and Tricuspid Annulus (TA) anteriorly, and, 3. SVC and TA posteriorly. Ablation along the IVC-TA isthmus was also performed with conventional catheter and technique. Patients were anticoagulated with heparin during the procedure and with antivitamin K post-ablation. After the procedure, patients were kept on the arrtiarrhythmic drug regimen previously ineffective, and monitored with Holter ECG and/or Event Recorder.

Results: In the 34 patients with 1 month follow up data available, the number of symptomatic AF episodes decreased from 16 ± 23/month to 4 ± 6/month post-ablation, and from 17 ± 15 to 3 ± 4 in the 25 patients with 3 month follow up. At least 50% reduction in AF episodes was demonstrated in 23 patients (68%), 80% reduction in 19 patients (56%), including 12 patients (35%) without any recurrence. No procedure related death or major complications occurred in any of the patients.

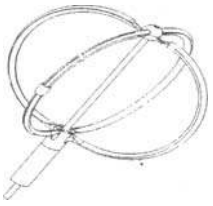
Conclusions: Linear ablation in the right atrium is safe using the REVELATION microcatheter. Short and medium term clinical benefit was confirmed in most patients with drug refractory, paroxysmal AF.

1268 In vitro and vivo results with the new ATLAS basket catheter for linear radiofrequency ablation of atrial fibrillation

S. Osswald, D. Baumgartner[1], D. Follett[2], C. Bonnerup[2], A. Eberhart[1], Th. Cron, V. Barbosa, Larry Stotts[2]. *Cardiac Unit, Univ. Hosp. Basel, Switzerland; [1]Sulzer Osypka Grenzach, Germany; [2]BTF Sulzer Intermedics, Angleton, USA*

Purpose: To assess the efficacy of the ATLAS catheter for transvenous linear radiofrequency ablation (RFA) of atrial fibrillation (AF).

Methods/Results: The ATLAS basket catheter for linear RFA of AF was designed with 4 expandable struts and a movable electrode for temperature-controlled RFA. In vitro studies were carried out on muscle tissue in saline solution. Additionally, linear transvenous RFA of AF was attempted in a dog model of chronic AF. Size, morphology and location of the lesion in the right and left atrium (RA, LA) were analyzed. In dogs with discontinuous endocardial lesions, epicardial RFA along the endocardial lesion line was added in order to assess the biological effect of each distinct lesion line. In vitro, continuous lesions of 20 mm in length, 6 mm in width and, depending on temperature and settings, up to 4 mm in depth were achieved at low energy setting (4 ± 2 watts, 65 ± 5 C). In 3 dogs (24–31 kg) with chronic AF (≥ 2 months), 2 RA and 2 LA lesions via left upper pulmonary or transseptal approach were created, which terminated chronic AF in all 3 animals. EP-studies in sinus rhythm demonstrated continuous electric wave propagation throughout both atria, attempts to re-induce AF were not successful in 2 dogs, whereas atrial flutter was sustained in 1 dog. Postmortem examination of the hearts revealed, that the majority of lesions were discontinuous and non-transmural, in particular, in the trabecular parts of the atria.



Conclusion: Our study demonstrates that creation of transvenous linear lesions with the ATLAS catheter is both feasible and successful in abolishing chronic AF despite the fact, that the majority of lesions are non-transmural and discontinuous.

1269 Efficacy to perform atrial linear radiofrequency lesions: an experimental histologic comparison

M.A.E. Schneider, G. Ndrepepa, T. Richter[1], A. Vallant, U. Gayk, J. Henke[2], B. Zrenner, M.R. Karch, W. Erhardt[2], A. Schömig, C. Schmitt. *1. Med. Klinik and German Heart Center; [1]Dept. of Pathology; [2]Dept. of Experimental Surgery, TU Munich, Germany*

Catheter ablation of atrial flutter and atrial fibrillation requires the radiofrequency (RF) application of linear lesions. In the sheep model we investigated the efficacy of three different multipolar ablation catheters.

Methods: In 22 sheep a multipolar ablation catheter was inserted via the internal jugular vein into the right atrium and placed in the posteroseptal, posterior and lateral region. In 11 sheep a sheath guided 3.3-F catheter with 8 electrodes of 3-mm length with 2 mm interelectrode spacing was used (Cardima). For linear bipolar radiofrequency (RF) energy application the electrodes were connected consecutively in pairs (10–20 watts, 60 seconds). In 7 sheep a steerable 7-F catheter with four 6-mm electrodes (EPT) and in 4 sheep a steerable 7-F catheter with four 5-mm electrodes (Bard) was placed to perform temperature controlled unipolar RF applications (target T 70° C, 60 seconds). All sheep were heparinised (5000 IE bolus i.v.). The histology was achieved 6–10 days later.

Results:

	7-F	3.3-F	p
Depth [mm]	3.3 ± 1.8	0.8 ± 0.9	<0.001
Width [mm]	6.1 ± 3.4	2.9 ± 2.6	<0.001
Length [mm]	16.1 ± 10.0	10.8 ± 9.4	0.03

There were no differences in the lesion extension related to the ablation site.

Conclusion: In order to achieve transmural linear lesions by catheter ablation in the right atrium, the usage of a 7-F steerable catheter working in unipolar temperature control mode is more promising compared to a sheath guided 3.3-F catheter without T° control ability.

1270 A novel microcatheter approach to the ablation of atrial fibrillation: safety and feasibility in 43 patients

M. Adam, Z. Casnadi, C. Tondo, P. Della Bella, R. De Ponti, J.A. Salerno, G. Theodorakis, E.G. Vester, M. Villani[1], A.S. Montenero. *REVELATION TM, European Atrial Fibrillation Group, Rome, Milan; [1]Arrhythmia Control Unit, La Sapienza University, Rome, Italy*

The placement of linear lesions is considered an effective treatment strategy for the Ablation of atrial fibrillation (AF). The purpose of this multi-center prospective study was to assess the performance of a new multi-electrode radiofrequency (RF) ablation catheter designed to achieve continuous linear lesions. Feasibility and safety of this novel procedure was evaluated in 43 patients with highly symptomatic paroxysmal lone AF. A 3.3 Fr microcatheter (REVELATIONTM, Cardima) which contains 8 coiled electrodes, each 3 mm long with 2 mm interelectrode spacing, was used in the right atrium to deliver multiple 60 second impedance-controlled RF pulses under constant power of 10–25 Watts. The energy was delivered in sinus rhythm sequentially from two adjacent electrodes as anode and a large back plate as cathode. One to two withdrawals of the catheter were required to complete the following four lines: A) IVC to SVC posterolaterally, B) SVC to TA anteriorly, C) SVC to TA posteriorly, and D) IVC to TA along the isthmus. The isthmus line was created with a conventional catheter and technique. The presence of sinoatrial and AV nodal conduction disturbances were evaluated. Assessment of linear lesions was based upon changes of electrograms (egm) amplitude and stimulation threshold.

Results: Impedance rises (>200 W) were only observed at power settings >15 W. There was no thrombus formation or any damage to the catheter. Mean procedure and fluoroscopy times (± sd) required to complete the procedure were 206 ± 65 and 40 ± 20 minutes, respectively. Three ablation EGM amplitude decreased significantly from 1.6 ± 0.20 to 0.6 ± 0.06 mA post ablation, from 1.4 ± 0.08 to 0.8 ± 0.06 mA, to 2.1 ± 3.6 to 1.6 ± 0.51 mA ($p < 0.001$ for paired values comparing pre-vs-post ablation). Pacing threshold values rose significantly when comparing pre-vs-post ablation values from 2.4 ± 0.22 to 6.6 ± 0.41 mV, from 3.7 ± 0.47 to 5.9 ± 0.54, from 2.4 ± 3.8 to 7.8 ± 0.70, for lines A, B and C respectively ($p < 0.001$ for pair values comparing pre-vs-post ablation).

Conclusions: These results indicate linear RF ablation in the right atrium is technically feasible and safe using the REVELATION Microcatheter.

1271 Clinical follow-up after linear left atrial radiofrequency lesions to treat atrial fibrillation

S. Ernst, F. Ouyang, M. Schlüter, M. Volkmer, J. Hebe, M. Antz, R. Cappato, K.-H. Kuck. *St. Georg Hospital, Hamburg, Germany*

Using the CARTO (Biosense Ltd.) electroanatomical mapping technique, we performed a right atrial (RA) ablation procedure in 14 pts (11 m, 3 f) with idiopathic atrial fibrillation (AF). Postablation, AF recurred daily in all pts and a left atrial (LA) ablation procedure was subsequently performed. Three linear lesions were created: between the ostia of superior lateral and septal pulmonary veins ("roof line"); from the anterior aspect of the mitral annulus (MA) to the center of the roof line ("anterior line"); and from the center of the roof line to the posterior aspect of the MA, with an intentional gap of 1–2 cm left in its inferior part. The anterior line was omitted in the first 4 pts. Creation of the pattern of ablation lines required 47 ± 18 radiofrequency current applications. LA sessions lasted for 8.7 ± 1.9 hours, median fluoroscopy time was 25.5 minutes. During a median follow-up of 112 days and continued antiarrhythmic medication, 7 pts (50%) were predominantly in sinus rhythm, interrupted occasionally by atrial ectopy. All but one of these pts developed incessant atrial tachycardia (AT) at least once during follow-up, suggestive of an unintended conduction gap in a lesion; termination of AT was achieved by overdrive pacing from the coronary sinus. Four other pts had a marked decrease in number and/or duration of AF episodes, accompanied by symptomatic improvement. The final 3 pts exhibited an unchanged number and duration of AF episodes. Of the 4 pts without an anterior line, none reverted to sinus rhythm.

Conclusions: LA linear lesions including an anterior line supplementing previously created RA ablation lines leads to predominant sinus rhythm in 50% of pts. The occurrence of AT may be attributed to conduction gaps in the applied lesions. This underlines the necessity to validate ablation lines for completeness.

SMOKING: RISKS, MECHANISMS AND STOPPING

1294 Smoking habits and cardiovascular risk in middle-aged inhabitants of Tartu and Stockholm in the SWESTONIA study

M. Viigimaa, A. Kask, V. Tiganik, J. Johansson[1]. *Tartu University Hospital, Estonia; [1]Karolinska Hospital Tartu, Sweden*

Coronary heart disease mortality per 100 000 inhabitants among 50–54 year old Estonian males and females is about 500 and 100, respectively, which exceeds corresponding Swedish mortality rates approximately 5 times. Smoking is generally recognised as the major cardiovascular risk factor. The aim of the present study was to compare smoking habits and other cardiovascular risk factors in 35 year old and 55 year old population of the city of Tartu (Estonia) and Stockholm (Sweden).

Methods: From the population registers four random groups of the 35 year old and 55 year old subjects were invited both from Tartu and Stockholm. Altogether, 545 subjects (274 from Estonia and 271 from Sweden) filled in a questionnaire (including questions concerning smoking habits), had a physical examination (including blood pressure measurement) and donated blood for analysis. The list laboratory parameters studied consisted of serum total cholesterol, triglycerides, HDL-cholesterol, LDL-cholesterol, lipoprotein (a), apolipoproteins and glucose.

Results: In Tartu, 45% of 35-year old females and 51% of 35-year old males are regular smokers in comparison with 26% in Swedish females and 15% in males. This huge difference is stastistically highly significant ($P < 0.05$ for females and $P < 0.001$ for males). The smoking rate did not differ between 55-year old Estonian (16%) and Swedish (18%) females. However, Estonian 55-year old men were smoking much more frequently (58%; $P < 0.001$) when compared to Swedes (20%). Clearly higher systolic blood pressure was found in Estonian 35-year old men (133 vs. 126 mmHg; $P < 0.01$). No major difference was found in laboratory cardiovascular risk factors studied. Less Estonians believe that lifestyle matters for the risk of cardiovascular disease.

Conclusion: Much higher mortality rates from coronary heart disease in Estonian inhabitants are likely to be ascribed to 3-fold higher rate of smoking, higher blood pressure and less believe that lifestyle matters for the risk of cardiovascular disease.

1295 Antioxidant ascorbic acid attenuates the endothelial dysfunction after acute cigarette smoking

K. Stamatelopoulos, C. Papamichael, J. Lekakis, A. Cimponeriu, A. Voutsas, T. Papaioannou, S. Stamatelopoulos. *Alexandra University Hospital, Athens, Greece*

Endothelial dysfunction has been reported in systemic arteries after acute smoking and it is a persisting phenomenon lasting 60–90 min. In chronic smokers endothelial dysfunction is mediated by increased oxidative stress and is reversed by antioxidants; it is not known whether oxidative stress has a potential role in mediating endothelial dysfunction after acute smoking.

Methods. In a randomized, crossover, double blind study endothelial dependent dilatation of the brachial artery (flow-mediated dilatation, FMD) was assessed in 12 healthy volunteers 30.7 ± 7.8 years) before and immediately, 30, 60, 90 and 120 min after smoking. All subjects were examined on 2 occasions; on Day 1 all subjects received 2 g of ascorbic acid per os 2 hours before smoking and Day 2 all participants received placebo.

Results. Heart rate, blood pressure were not different in two treatment groups in all stages of the study. FMD was similar in two groups before smoking. In the group of ascorbic acid FMD was reduced immediately after smoking, remained depressed 30 min after smoking ($p < 0.05$) and returned to baseline 60 min after smoking (ns). In the group of placebo FMD was reduced immediately after smoking, remained depressed 30, 60 and 90 min after smoking ($p < 0.05$) and returned to baseline values 120 min after smoking (ns); thus the time of impaired endothelial function after smoking was reduced from 90 to 30 min by the use of ascorbic acid.

Conclusions. The administration of ascorbic acid ameliorates the deleterious effect of acute smoking on endothelial function, indicating that increased oxidative stress may be an important mechanism for the endothelial dysfunction after short term smoking.

1296 Short-term mortality of habitual cigarette smokers after acute myocardial infarction: the "smoker's paradox" in a statewide study

G. Andrikopoulos, D. Richter, P. Dilaveris, A. Zaharoulis, J. Gialafos, P. Toutouzas, E. Chimonas. *From the investigators of the Greek Multicenter Study for Acute Myocardial Infarction; 251 Airforce General Hospital, Athens, Greece*

Cigarette smokers paradoxically present improved outcome after acute myocardial infarction (MI). We evaluated the relation between cigarette smoking and in-hospital mortality of MI in the Greek population, which is a low coronary risk population with exceptionally increased use of tobacco products.

Methods: The study population was obtained from the Greek multicenter study for MI and consisted of 7433 consecutive pts with MI (5755 men and 1678 women, mean age 60 ± 14 and 69 ± 13 years respectively) who were hospitalized in 76 hospitals throughout Greece, from May 1993 to May 1994.

Results: Smokers had lower mean age (59 ± 12 vs 70 ± 11 years) and decreased unadjusted in-hospital mortality rates (7.4% vs 14.5%, $p < 0.001$) compared to non-smokers. However, in a logistic regression model with age and gender included as covariates, smoking was not significantly related to prognosis ($p = 0.671$) and the smoker to non-smoker relative risk was 1.053 (0.828–1.339). When diabetes, hypertension, fibrinolytic therapy and the existence of previous MI were added in the model, smoking was still not significantly associated with in-hospital mortality ($p = 0.627$, relative risk 1.065, limits 0.828 to 1.369). The univariate analysis of smokers' clinical characteristics is presented below:

Proportion of cigarette smokers in the subgroups of the studied patients

				p value
Males	80.7%	Females	23.2%	<0.001
Diabetics	56.0%	Non-diabetics	73.8%	<0.001
Hypercholesterolemics	68.6%	Normocholesterolemics	70.1%	0.243
Hypertensives	60.8%	Normotensives	76.6%	<0.001
Positive heredity	75.1%	Negative heredity	67.6%	<0.001
Previous MI	68.3%	No previous MI	69.8%	0.367
Thrombolyzed pts	77.0%	Non-thrombolized pts	63.1%	<0.001

Conclusion: Unadjusted mortality rates are significantly lower in smokers but age accounted for much of their improved outcome. When a number of additional clinical variables were taken into consideration, no significant influence of habitual smoking on early outcome after acute MI was observed.

1297 Related factors with a lower mortality in smokers after an acute myocardial infarction: a subanalysis of the TIM study

J.M. Cruz-Fernández, V. López, L. López-Bescós, A. Cabadés, L. Martín-Jadraque, J. Velasco, D. García-Dorado, A. Castro, C. Navas, F. Torres. *TIM investigators Group; Unidad Coronaria, Hospital Virgen Macarena, Avda. República Argentina, 15, 5° A, 41011 Seville, Spain*

Objectives: Smokers that develop an acute myocardial infarction (AMI) have a lower mortality during the acute phase of the infarction than non-smokers. Recently, it has been suggested that this fact can be attributable to a higher thrombosis incidence on small plaques in smokers that develop an AMI, due to the systemic thrombogenic action of smoking. Therefore, fibrinolysis would be more efficient to reduce mortality in smokers than in non smokers.

Material and methods: The TIM study (Triflusal in Acute myocardial infarction) is an international, multicenter, double-blind, randomized, sequential clinical trial that compares Triflusal versus Aspirin in the prevention of vascular complications (death, non-fatal reinfarction and non-fatal cerebrovascular event) in patients (P) with AMI. The total of 2124 P that were included in the study constitute the basis for this analysis.

Results: On day 35th after the infarction, 148 P had died (7.0%). Mortality was significantly lower in smokers than in non-smokers (3.6% vs 11.0%, $P < 0.001$). Fibrinolysis, given to 70.8% of patients, was associated with a significant mortality reduction both in overall population (5.3% vs 11.0%, $p < 0.001$) and in non-smokers (8.1% vs 16.6%, $p < 0.001$). However, reduction of mortality by fibrinolysis in smokers was not significant (3.3 vs 4.5%, NS). Smoker population was significantly younger, with less females, lower incidence of hypertension, diabetes, obesity, previous angina, MI, heart failure and stroke. A multivariant analysis adjusting by age, sex, and prior MI showed that these risk factors influence mortality and reduces the apparent association between smoking status and mortality.

Conclusion: Although our study shows a lower mortality in smoker patients that suffer an AMI, the reduction in mortality does not seem due to a higher efficacy of thrombolysis in this population. In fact, after performing a multivariant analysis, we can infer that smoking causes the first AMI in younger patients who have less associated risk factors. In consequence, their mortality in acute phase is lower.

1298 Demographical, clinical and psychological characteristics related to long-term smoking cessation in post-myocardial infarction patients

T.F.M. van Berkel, M. van der Vlugt, E. Boersma. *Department of Cardiology and, Heartcentre, Rotterdam, Netherlands*

Aim: To evaluate which characteristics are related to long-term smoking cessation in 1472 post myocardial infarction (MI) patients.

Methods: Smoking habits of 520 (35%) patients, who were smoking during the year before admission for a myocardial, were related to baseline demographical or clinical characteristics. Furthermore, survivors were asked to fill in a set of questionnaires with items on smoking and psychological questions.

Results: At averagely 3.8% years follow-up, 405 (80%) of the 520 smokers were still alive, while of the non-smokers 573 (60%) had survived. This so-called 'Smoker's Paradox' is primarily explained by the difference in mean age: smokers had their MI 10 years earlier (59 vs. 69 years). In 319 (79%) of the smokers, smoking habits were followed: 167 (52%) patients were persistent smokers. No differences in baseline demographical or clinical characteristics could be found between quitters and persistent smokers. 247 (77%) baseline smokers completed a set of questionnaires: 33% patients had stopped smoking within 30 days of the AMI. Persistent smokers had a higher number of smokers in the environment, especially children, family and friends. Quitters were significantly more encouraged, particularly by partner and colleagues, but also their cardiologist. Furthermore, smokers had higher levels of depression, anxiety; fatigue and somatisation at follow-up.

Conclusion: The better survival of the smokers could largely be explained by their younger age. About 50% of the patients continued smoking 4 years after their myocardial infarction. Persistent smokers had more smokers in their environment and received less encouragement to stop. Furthermore, they had a less favourable psychological profile. In order to offer support for smoking cessation, patients' symptoms as depression and anxiety should be taken into account. Furthermore, it is preferred to involve partner and other close family members to encourage smoking cessation.

1299 Effects of cigarette smoking on proinflammatory cytokines and platelet activation in patients with stable angina

I. Ikonomidis, F. Andreotti[1], C. Stefanadis, C. Pitsavos, E. Economou, P. Toutouzas, P. Nihoyannopoulos[1]. *Cardiology Ippocration Hospital, Athens, Greece; [1]Hammersmith Hospital London, UK*

Cigarette smoking is associated with significant endothelial dysfunction. Injured endothelium releases macrophage colony stimulating factor (MCSF) which induces macrophage activation and consequently, causes the release of vasoactive substances, interleukin 6 (IL6), platelet chemoattractants and tissue factor. We investigated the effects of smoking on cytokines, platelet activation and thrombin generation in patients with stable angina (SA) We also examined whether these effects are reversed by aspirin treatment.

Methods: We measured prothrombin fragments (PF1 + 2, nmole/l) MCSF, IL6 (pg/ml) plasma levels and 24 h urine excretion of 11-dehydrothromboxane B2 (DTXB2, ng/mg creatinine) in 60 patients with SA and in 24 matched controls. Thirty four patients (56%) and 13 controls (54%) were smokers (p = NS). Patients had angiographically documented disease and were given ASA 300 mg, o.d. or placebo for 3 weeks in a double blind, cross-over trial.

Results: PF1 + 2, MCSF and IL6 were increased in patients with SA compared to controls (table, $p < 0.05$). Smoker patients had higher MCSF, platelet (PLT) count ($\times 10^3$) and DTXB2 compared to non-smokers ($p < 0.01$). Aspirin reduced MCSF, IL6, DTXB2 and PF1 + 2 ($p < 0.05$). MCSF levels remained higher in smokers than non-smokers after aspirin administration ($p < 0.05$). Conversely, DTXB2 levels became similar between smokers, non-smokers and controls High MCSF was related to high DHTXB2 before and after aspirin administration ($r = 0.40$ and $r = 0.50$, $p < 0.01$)

	All	Smokers	Non-smokers	ASA	Controls
MCSF	1076 ± 613	1095 ± 716	610 ± 390	950 ± 567	479 ± 287
DTXB2	4.4 ± 2.8	4.7. ± 3.4	2.6 ± 2.0	2.2 ± 2.1	3 ± 3.3
IL6	4.2 ± 1.3	4.7 ± 3.0	4.6 ± 2.4	3.5 ± 0.8	2.0 ± 0.9
PF1 + 2	2.26 ± 1.8	1.9 ± 1.5	2.0 ± 1.4	1.73 ± 1.2	0.93 ± 0.5
PLT	230 ± 59	245 ± 55	194 ± 51		190 ± 50

Conclusion: Smoking is related to increased MCSF production and platelet activation in SA but not to thrombin generation. Aspirin reduces cytokine production, thrombin generation and eliminates smoking-induced but not cytokine-induced platelet activation.

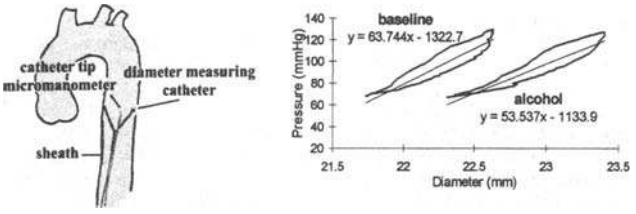
EPIDEMIOLOGY AND PREVENTION: FATS, ALCOHOL AND MAGNESIUM

1300 Beneficial effect of alcohol on the elastic properties of the aorta

C. Vlachopoulos, C. Stefanadis, N. Giatrakos, E. Economou, E. Tsiamis, C. Spiliopoulou, A. Koutselinis, P. Toutouzas. *Hippokration Hospital, Athens Medical School, Athens, Greece*

Moderate alcohol consumption has a cardioprotective effect. However, the underlying mechanisms have not been fully elucidated and its direct vascular effects are not well understood. To assess the effect of alcohol on the elastic properties of the aorta (Ao), serial pressure-diameter loops (right fig.) were obtained from the simultaneous recordings of Ao diameter and pressure in 10 patients before and after i.v. administration of ethanol (0.5 gr/kg). Ao diameters were measured by an ultrasonic dimension intravascular catheter developed in our institution (*Ann Intern Med 1998; 128: 426–34*) and Ao pressures by a Millar micromanometer (left fig.).

Results: Ao distensibility (= 2 [pulsatile change in Ao diameter]/[diastolic Ao diameter] × [pulse presssure]) was significantly increased after ethanol administration (2.1 ± 1.0 vs. 2.6 ± 1.1 10^{-6} cm^2 dyn^{-1}, P < 0.001) denoting improvement of aortic elastic properties. Moreover, the shifting of the loop to a new hypothetical line of elasticity (right fig.) indicated an active (direct) effect of ethanol on the intrinsic elastic properties of the Ao.



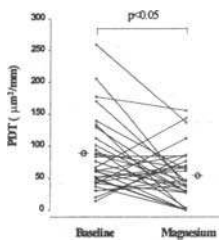
This improvement of Ao elastic properties may contribute to the protective effects of moderate alcohol consumption on the cardiovascular system.

1301 Oral magnesium treatment inhibits platelet-dependent thrombosis in patients with coronary artery disease

M. Shechter, C.N. Bairey Merz, M. Paul-Labrador, S.R. Meisel, M.D. Molloy, R.K. Rude, P.K. Shah, S. Kaul. *Cedars-Sinai Medical Center, Los Angeles CA, USA*

The role of magnesium (Mg) treatment in CAD is controversial. To determine whether oral Mg treatment inhibits platelet-dependent thrombosis (PDT), we conducted a randomized prospective, double-blind, cross-over, placebo controlled study in 36 stable CAD patients (32 men, 4 women, mean age 68 ± 9 years) on aspirin. Patients received either Mg oxide tablets 1,200 mg/day or placebo for 3 months followed by a 4-week washout period, and the crossover treatment for 3 months. PDT was evaluated by exposing porcine aortic media to the flowing non-anticoagulated venous blood for 5 minutes at a shear rate of 800 sec^{-1} using ex-vivo chamber model. PDT was measured by computerized morphometry and expressed as 2 m^2/mm of the aortic surface.

Results: Median PDT (θ) was significantly reduced by 35% (Figure) in patients who received Mg versus placebo. There were no significant differences in platelet aggregation, serum lipids, fibrinogen, platelet count or serum Mg levels between the two treatment groups.



Conclusion: PDT is significantly reduced by Mg treatment in stable CAD patients. This effect is additive to that of aspirin, suggesting a potential mechanism whereby Mg may beneficially alter outcomes in CAD patients.

1302 Combined effects of plasma lipids on 10-year risk of ischaemic heart disease: the Caerphilly collaborative studies

J. Yarnell, C. Patterson, P. Sweetnam[1], H. Thomas[1], N. Miller[2]. *Department of Epidemiology, Queen's University of Belfast, Belfast; [1]MRC Epidemiology Unit, Cardiff; [2]Department of Cardiovascular Biochemistry, St Bartholomew's and the Royal London College of Medicine and Dentistry, London, UK*

We have previously shown triglyceride levels to be an important predictor of subsequent risk of ischaemic heart disease (IHD) in men by 5 years of follow-up. Few studies have examined the combined effects of HDL cholesterol (HDL-C), triglyceride (T-G) and total cholesterol (T-C) on subsequent risk of IHD. We examine the combined effect of plasma lipids on risk of IHD by 10 years of follow-up of 4362 British men aged from 45 to 63 years at baseline in two study populations; 533 major IHD events occurred in this population. By 10 years T-C and HDL-C were each contributing independently to risk of IHD but the association with T-G was no longer statistically significant. High, intermediate and low levels of each lipid were defined using the tertiles of the distributions. Men were then grouped into the 27 (= 33^3) possible combinations.

Incidence of IHD by 10 years follow-up was 5% among men in the risk factor combination with lowest expected risk 23% among men in the highest. The number of IHD events observed in each combination was compared with the number predicted from a logistic regression model which included terms for the three lipid variables each in three categories. Additional potential confounding variables (age, study area, pre-existing IHD, smoking, diastolic blood pressure and body mass index) were included in the model. There was no evidence of significant deviation between the observed and predicted numbers of IHD events when the three lipid levels were included in the model; in particular there was no need to include interaction terms between the lipid variables in the model to attain a satisfactory fit.

We conclude that groups of men with a high risk combination of lipid factors exist within this population, but that the joint effect of adverse levels of all three lipids is no greater than the effect predicted by the logistic model from the separate contributions of the three individual lipids.

1303 The role of triglyceride-rich lipoproteins in predicting coronary artery disease

J. Ferrières[1,2], B. Perret[3], J.B. Ruidavets[2], D. Taraszkiewicz[1], H. Chap[3], J. Puel[1]. *[1]Department of Cardiology; [2]Department of Epidemiology (INSERM 518); [3]Department of Biochemistry (INSERM 326), Purpan Hospital, Toulouse, France*

Accumulating evidence indicates that triglyceride (TG)-rich lipoproteins, such as VLDL, IDL or chylomicron remnants, are more related to the progression of coronary artery disease (CAD) than TG. Levels of lipoprotein lipids, apolipoproteins [apolipoprotein (apo) A-I, apo B, apo E, apo C-III] and of lipoprotein particles [Lp(a), LpA-I, LpB:E, LpB:C-III] were measured in 672 men enrolled in a case-control study. All patients were referred for coronary angiography and the control group consisted of randomly selected men from the general population [360 men with CAD (55 ± 7 years) and 312 controls (53 ± 7 years, p < 0.01)]. The patients with CAD had a higher proportion of CAD risk factors than controls. There were no significant differences in LDL-cholesterol (3.75 ± 1.06 vs 3.82 ± 0.96 mmol/L), apo B (130 ± 30 vs 130 ± 27 mg/dL) or LpA-I (43 ± 23 vs 41 ± 17 mg/dL) levels between cases and controls. CAD cases had lower (p < 0.001) HDL-cholesterol (1.19 ± 0.34 vs 1.55 ± 0.47 mmol/L) and apo A-I (138 ± 23 vs 156 ± 24 mg/dL) levels than controls. CAD cases had higher (p < 0.001) TG (1.74 ± 1.25 vs 1.48 ± 1.02 mmol/L), Lp(a) (55 ± 61 vs 25 ± 31 mg/dL), apo E (7.22 ± 5.42 vs 5.13 ± 1.90 mg/dL), apo C-III (3.46 ± 1.55 vs 2.77 ± 1.10 mg/dL), Lp B:E (3.16 ± 5.05 vs 0.77 ± 0.90 mg/dL), Lp B:C-III (1.80 ± 1.43 vs 1.35 ± 0.71 mg/dL) levels than controls. Logistic regression analyses were carried out after adjustment for confounding factors. Models of equivalent predictive power were achieved by the combination of HDL cholesterol [Odds ratio (OR): 0.08, p < 0.001], Lp(a) [OR: 1.76, p < 0.001] and apo E [OR: 6.46, p < 0.001] or apo C-III [OR: 5.20, p < 0.001] or LpB:E [OR: 4.24, p < 0.001] or LpB:C-III [OR: 1.36, p = 0.07]. TG were not an independent risk factor. In conclusion, both HDL-cholesterol, Lp(a) and TG-rich lipoprotein particles contributed independently to the discrimination between cases and controls. Furthermore, our study suggests that TG metabolism related apolipoproteins or lipoprotein particles may be more specific parameters of CAD than lipids currently measured.

1304 Air force/Texas Coronary Atherosclerosis Prevention Study: invasive procedures and extent of disease

W.B. Kruyer, V. Zagrebelsky, J. Farmer, Q. Yu, J.R. Downs, M. Clearfield, S. Weis, E. Whitney, D. Shapiro, P.A. Beere, A.M. Gotto, Jr.. *DPhil. Wilford Hall Medical Center, San Antonio TX; University of North Texas Health Science Center, Fort Worth TX, USA*

Background: In AFCAPS/TexCAPS, a randomized, double-blind placebo-controlled primary prevention trial of 6605 men and women without clinical evidence of atherosclerotic disease, treatment with lovastatin 20–40 mg daily reduced first acute major coronary events: fatal or nonfatal MI, unstable angina or sudden cardiac death, by 37% ($p < 0.001$).

Methods: Time to first surgical (CABG) or catheter-based (PTCA) revascularization was a pre-specified secondary endpoint. Exploratory analyses included all with diagnostic coronary angiography regardless of endpoint status. Coronary lesions were categorized by percent stenosis, number and distribution. LV dysfunction was assessed by ejection fraction, presence of mitral insufficiency and wall motion abnormalities.

Results: Treatment with lovastatin reduced the risk of revascularization by 33% (106 vs. 157) [p = 0.001, RR 0.67, 95% CI 0.52, 0.85] and reduced CABG [58 (1.8%) vs. 74 (2.2%)], PTCA [48 (1.5%) vs. 83 (2.5%)] and first diagnostic coronary angiography [188 (5.7%) vs. 238 (7.2%)]. There were fewer patients with significant CHD (worst lesion > 50%) treated with lovastatin [139 (4.2%) vs. 200 (6.1%)]. The extent of LV dysfunction was independent of treatment group.

Conclusion: Treatment with lovastatin reduced total, surgical and catheter based revascularizations, diagnostic angiography and presence of significant CHD. Among those with significant lesions, there was a similar degree of LV dysfunction in both groups.

1305 The acute coronary syndrome and cholesterol dynamics: an association with peak cardiac troponin I levels

B.L. Croal, W.G. Simpson, P. Duff, S. Walton[1], I.S. Ross. *Clinical Biochemistry, Aberdeen Royal Infirmary, Aberdeen; [1]Cardiology Dept, Aberdeen Royal Infirmary, Aberdeen, UK*

A fall in serum cholesterol immediately following myocardial infarction has been previously reported, although controversy exists over the timing and magnitude of such events. To assess the variability, we looked at changes in total cholesterol immediately following admission with chest pain.

Method: Lipid profiles were measured on admission and on the second morning after admission, in non-selected consecutive patients presenting to the chest pain triage unit of a large general hospital. In addition, troponin I (Bayer Diagnostics) levels were measured daily for three days following admission.

Results: Patients (n = 212) were grouped by primary clinical diagnosis and the changes in serum cholesterol (mmol/l) calculated (n, mean change in cholesterol, maximum drop, maximum rise, p [paired t-test]): Myocardial infarction (59, −0.49, −2.6, +0.9, <0.0001): Unstable angina (67, −0.01, −1.5, +2.5, 0.897): Other cardiac (49, −0.17, −1.6, +1.2, 0.057): Non-cardiac (37, −0.17, −2.0, +1.3, 0.096). A statistically significant change in cholesterol was shown only for the myocardial infarction group. In patients who demonstrated a net rise in cholesterol, the mean peak troponin I level was 6.65 ng/ml compared to 23.4 ng/ml in those with a net fall in cholesterol ($p < 0.05$; t-test).

In conclusion: The data shows that there are potentially clinically significant variations of serum cholesterol within the first 48 hours following admission in all patient groups. Important therapeutic decisions with regards to the introduction of lipid lowering drugs (and assessment of the effectiveness of such interventions) are often based on the results of serum cholesterol levels measured during admission. To minimise the potential error, we recommend that all patients should only have lipid profiles performed on an admission sample. Use of results from subsequent samples, even within the first 48 hours, can lead to clinically significant misclassification, or misinterpretation of an apparent lack of response to subsequent hypolipidaemic therapy. Peak cardiac troponin I levels have been previously shown to be correlated with infarct size. Patients exhibiting a fall in cholesterol in this study statistically had higher peak troponin I levels. The interpretation of cholesterol values in patients with more extensive infarction may require even more caution.

NEUROHUMORAL ASPECTS OF CARDIOVASCULAR REMODELLING

1314 Adrenergic and reflex abnormalities in obesity-related hypertension

G. Seravalle, C. Turri, R. Dell'Oro, M. Colombo, G. Grassi, G. Mancia. *Clinica Medica, University of Milan, Ospedale S. Gerardo, Monza; Centro Fisiologia Clinica e Ipertensione, IRCCS, Ospedale Maggiore, Milan; Istituto Auxologico Italiano, IRCCS, Milan, Italy*

Hypertension (H) is characterized by sympathetic hyperactivity and we have previously shown that this is the case also in obesity (O), even in absence of H. It is unsettled, however, whether the concomitant presence of H and O further enhances the abnormalities characterizing the above mentioned diseases.

Methods: In 13 normotensive lean control subjects (C, age: 33.1 ± 2.3 yrs, body mass index, BMI: 22.6 ± 0.7 kg/m^2, mean ± SEM), 10 untreated essential lean H (BMI: 24.2 ± 0.8 kg/m^2,), 10 normotensive O (BMI: 36.1 ± 1.1 kg/m^2) and 11 untreated HO (BMI: 37.2 ± 1.6 kg/m^2), all age-matched with C, we measured beat-to-beat mean arterial pressure (MAP, Finapres), heart rate (HR, EKG) and postganglionic muscle sympathetic nerve traffic (microneurography at a peroneal nerve) at rest and during baroreflex stimulation and deactivation via stepwise i.v. infusions of phenylephrine (PHE) and nitroprusside (NTP).

Results: MAP was higher in H and in HO (112.9 ± 1.9 and 109.4 ± 2.3 mmHg respectively, $p < 0.01$ for both) than in C and in O (89.3 ± 1.8 and 91.6 ± 1.6 mmHg), while HR was significantly increased only in OH. MSNA values were significantly higher in H and in O than in C (44.9 ± 3.7 and 50.0 ± 3.1 vs. 31.6 ± 2.6 bs/100 hb respectively, $p < 0.01$ for both), a further increase being detected in OH (57.4 ± 4.8 bs/100 hb, $p < 0.05$). In C the mean BP increase induced by PHE caused a reflex reduction in HR (−18.7 ± 1.6 b/min) and in MSNA (−78.5 ± 12% i.a.), while the mean BP fall induced by NTP caused opposite effects (HR: +20.9 ± 2.2 b/min; MSNA: +103.4 ± 19% i.a.). While in H only baroreflex modulation of HR was impaired (−48.4 ± 8%, $p < 0.01$ vs. C), in O both HR and MSNA changes were attenuated (−37.1 ± 5 and −42.9 ± 7% respectively, $p < 0.01$ for both), a further attenuation being observed in OH (−59.4 ± 9 and −61.3 ± 7% for HR and MSNA, $p < 0.05$ vs. O).

Conclusions: These data provide the first evidence that the concomitant presence of O and H triggers a sympathetic activation greater for magnitude than that found in these pathological conditions. This is accompanied by a marked impairment in baroreflex control of both vagal and sympathetic components, which is greater for magnitude than that observed in O and H.

1315 Depressed baroreflex sensitivity is associated with angiotensin II type 1 receptor gene polymorphism C1166 in adults free of clinical heart disease

E. Reissell, M. Perola[1], J. Virolainen, K.J. Airaksinen[2], A. Ylitalo[2], H. Huikuri[2], M. Kupari. *Division of Cardiology, Helsinki University Central Hospital, Helsinki; [1]National Institute of Public Health, Helsinki; [2]Division of Cardiology, Oulu University Hospital, Oulu, Finland*

Aging, hypertension and genetic variation have been associated with decreased baroreflex sensitivity (BRS). Angiotensin II (ATII) can modify BRS through direct central and humoral effects which are mediated mostly by type 1 receptor (AT1R) at the cellular level. The cytosine (C) allele of A1166C (A = adenosine) polymorphism in the untranslated region of the AT1R gene has been associated with hypertension and left ventricular hypertrophy.

A random sample of population (n = 83, 39 men) born in 1954 was studied. All subjects were free of heart disease and hypertension. A prospective 2-month collection of life-style data included recording of daily ethanol and cigarette consumption, leisure-time physical activity and 1-week salt intake. The means of 3 blood pressure (BP) measurements during this period were used in the analysis. BRS was evaluated from the overshoot phase of the Valsalva maneuver, and AT1R polymorphism by restriction enzyme digestion of PCR products. Multiple regression analysis was used to assess the effect of genotype with other variables on BRS. Variables with skewed data distribution were logarithmically transformed prior to analyses.

AC + CC genotypes were compared together (n = 23) with AA homozygotes (n = 60). The groups did not differ regarding BP and heart rate: the mean systolic BP was 122(12) vs 126(15) mmHg; diastolic BP, 70(11) vs 71(15) mmHg; and heart rate, 66(9) vs 67(10) bpm. However, BRS was significantly smaller in the presence of C allele with a median of 11.4 (5.4–16.9) in the AC + CC group vs 13.5 (2.7–47.3) ms/mmHg in the AA group (P = 0.030). This association was independent of sex, body mass index and all life-style traits.

We conclude that the A1166C polymorphism of the AT1R gene predicts interindividual variation in BRS in healthy individuals. As low BRS is an established risk factor for cardiovascular morbidity and mortality this observation merits further study.

1316 Sympathetic nerve traffic and baroreflex control of circulation in systodiastolic and isolated systolic hypertension of the elderly

G. Grassi, C. Turri, G. Seravalle, R. Dell'Oro, G. Bertinieri, M.L. Stella, G. Mancia. *Clinica Medica, University of Milan, Ospedale S. Gerardo, Monza; Centro Fisiologia Clinica e Ipertensione, IRCCS, Ospedale Maggiore, Milan, Italy*

Previous studies have shown that young and middle-age essential hypertensives are characterized by a sympathetic overactivity coupled with an impaired baroreflex heart rate control. It is unkown, however, whether this is also the case for systodiastolic (SDH) and isolated systolic hypertension (ISH) of the elderly.

Methods: In 9 healthy normotensive subjects (age: 67.8 ± 2.0 yrs, mean ± SEM), in 8 SDH and 8 ISH, both untreated and age-matched with C, we measured beat-to-beat arterial blood pressure (BP, Finapres), heart rate (HR, EKG) and efferent postganglionic muscle sympathetic nerve activity (MSNA microneurography at a peroneal nerve) at rest and during baroreflex stimulation and deactivation induced by stepwise i.v. infusions of phenylephrine (PHE) and nitroprusside (NTP) respectively.

Results: Resting systolic and diastolic BP values were 127.8 ± 5.8/78.9 ± 2.9 mmHg in C, 163.9 ± 4.1/98.4 ± 1.3 mmHg in SDH and 174.8 ± 3.3/85.9 ± 2.3 in ISH. While HR was similar in the 3 groups, MSNA values were significantly greater in SH than in C (66.4 ± 6.5 vs 50.6 ± 4.4 bs/100 heart beats respectively, $p < 0.05$), a further increase characterizing SDH (78.7 ± 6.3 bs/100 heart beats, $p < 0.01$ vs C). In C the mean BP increase induced by PHE caused a reflex reduction in HR (−6.3 ± 0.7 b/min) and in MSNA (−64.2 ± 6.6.% i.a.), while the mean BP fall induced by NTP caused opposite effects (HR: +6.9 ± 1.2 b/min; SNA: +89.6 ± 17.0% i.a.). For similar BP changes, in SDH and ISH reflex changes in HR were markedly and significantly ($p < 0.01$) attenuated as compared to C (−43.2 ± 7.0 and −34.3 ± 8.0% respectively). In contrast reflex modulation of MSNA was superimposable.

Conclusions: These data provide evidence that sympathetic activation is a phenomenon which 1) characterizes not only the hypertensive state of young and middle-age patients but also hypertension of the elderly, 2) is not peculiar to SDH but can be detected also in ISH and 3) is accompanied by an impairment in baroreflex cardiovascular control, which, however, is limited to its vagal component.

1317 Baroreflex sensitivity predicts unexpected death in chronic heart failure

A. Morley-Davies, H.J. Dargie[1], S.M. Cobbe. *Cardiology Dept., GRI, Glasgow; [1]CRI, Glasgow University, Glasgow, UK*

Accurate identification of patients at greatest risk of sudden death remains elusive. We hypothesised that abnormalities of autonomic dysfunction would predict sudden death in CHF.

Established clinical variables were determined in 199 patients with stable CHF remote from myocardial infarction: age (59 ± 9 years), aetiology of CHF (ischaemic n = 163, nonischaemic n = 36), NYHA status (2.7 ± 0.8), maximal oxygen consumption (VO_2max 16.9 ± 4.9 ml/kg/min). Investigational variables included: heart rate variability from 24 hour tapes (HRV, median SDNN 118 msec), baroreflex sensitivity by phenylephrine bolus injection (BRS median 5.4 msec/mmHg), signal averaged ECG (25 positive) and QT dispersion (median 94 msec).

Events were categorised by established standards using information from death certificates, autopsy findings and hospital and GP case records. Patients who died of a documented ventricular arrhythmia, or who did not survive a community resuscitation attempt were classed as sudden cardiac death. Patients who died at home with no recent (>4 weeks) documented change in cardiac status were also classed as sudden cardiac death, unless an obvious alternative aetiology was documented. Mean duration of follow-up was 971 ± 378 days. There were 54 all cause deaths, 47 cardiac deaths and 24 unexpected deaths.

A Cox-proportional hazards analysis was performed with age, NYHA class, aetiology of CHF and LVEF as forced variables and multivariate analysis of VO_2max, HRV measures and BRS.Variables were dichotomised above and below median values.

Cox hazards ratios

	Hazard Ratio	95% CI	p value
Age	0.95	± 0.05	0.09
NYHA	1.75	± 0.97	0.25
Cause	7.13	± 2.10	0.09
LVEF	2.04	± 1.05	0.17
IVCD	2.60	± 0.89	0.03
BRS	5.71	± 1.24	0.005

Cox hazards ratios (above/below median)

BRS was the only additional co-variate which predicted both cardiac and sudden death (see table). In patients with severe LV dysfunction (EF < 20%), BRS retained this prognostic power. BRS testing identifies patients most likely to die sudden, unexpected deaths in CHF.

1318 Hypertrophic remodelling in subcutaneous small arteries of normotensive and hypertensive patients with non-insulin-dependent diabetes mellitus

D. Rizzoni, E. Porteri, A. Piccoli, M.L. Muiesan, M. Castellano, U. Valentini[1], A. Cimino[1], D. Guelfi, G. Pasini, E. Agabiti Rosei. *Chair of Internal Medicine, Dept. of Medical and Surgical Sciences, University of Brescia; [1]Diabetologic Unit, Spedali Civili di Brescia, Italy*

Objective Vascular structure is influenced by several neurohumoral growth factors, including insulin levels. It is not known whether patients with non insulin dependent diabetes mellitus (NIDDM), who are characterised by high levels of circulating insulin, present structural alterations in small resistance arteries. Therefore, we have investigated structural characteristics of subcutaneous small arteries in 12 normotensive subjects (NT), in 18 patients with essential hypertension (EH), in 15 patients with NIDDM, and in 15 patients with NIDDM and essential hypertension (NIDDM + EH).

Design and Methods All subjects were submitted to a biopsy of subcutaneous fat. A blood sample was taken in order to evaluate the circulating levels of intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) (ELISA)

Small resistance arteries were dissected and mounted on a micromyograph (Mulvany's technique). The normalized internal diameter (ID), the media/lumen ratio (M/L) as well as the remodeling index (RI) and the growth index (GI) were calculated (Heagerty and coll, Hypertension 1993).

Results The results are summarised in the table:

	NT (n = 12)	EH (n = 18)	NIDDM (n = 15)	NIDDM + EH (n = 15)
SAP (mm Hg)	128 ± 8	161 ± 7***	130 ± 10	157 ± 15***
DAP (mm Hg)	79 ± 7	98 ± 7***	80 ± 3	96 ± 9***
M/L (%)	5 ± 1	9.3 ± 2.3***	10.0 ± 2.4***	11.2 ± 1.5$^{***\#}$
ID (μm)	299 ± 53	226 ± 67*	245 ± 56*	2220 ± 47***
RI e GI	–	92%, 6%	75%, 46%	86%, 40%
ICAM-1 (ng/ml)	205 ± 26.4	271 ± 26.0***	333 ± 87.6$^{***\#}$	318 ± 71.2$^{***\#}$
VCAM-1 (ng/ml)	520 ± 105	670 ± 194*	892 ± 114$^{***\#}$	852 ± 177$^{***\#}$

($^{*}p < 0.05$, $^{***}p < 0.001$ vs. NT, $^{\#}p < 0.05$ vs.

NIDDM and EH; SAP and DAP: systolic and diastolic arterial pressure). M/L and ID were significantly different in EH, NIDDM and NIDDM + EH compared with NT. Moreover, NIDDM + EH had a significantly higher M/L compared with EH and NIDDM. EH showed the presence of eutrophic remodelling, while NIDDM and NIDDM-EH presented a 40–46% cell growth (hypertrophic remodelling). Plasma ICAM-1 and VCAM-1 concentratons were higher in EH, NIDDM and NIDDM + EH than in NT. Moreover, NIDDM and NIDDM + EH showed higher levels of adhesion molecules than EH.

Conclusions Our data suggest that diabetes mellitus and essential hypertension have a synergistic effect on vascular structure. This may represent an important mechanism underlying the increase of cardiovascular events observed in the presence of the two risk factors.

1319 Agonist-induced downregulation of the β_2-adrenoceptor is modulated by the amino-acid at position 16 but not by the amino-acid at position 27 in essential hypertension

S.G. Megarry, A. Maqbool, A.S. Hall, S.G. Ball, A.J. Balmforth. *Institute for Cardiovascular Research, University of Leeds, Leeds, UK*

Two common polymorphisms resulting in the amino-acid substitutions Arginine 16→Glycine and Glutamine 27→Glutamate, occur in the N-terminus of the β_2-adrenoceptor. *In-vitro* functional studies revealed that the Arginine 16→Glycine variant underwent increased agonist-promoted downregulation but that the Glutamine27→Glutamate variant was resistant to downregulation. Importantly, the combination of both mutants resulted in downregulation equal to that for the Arginine 16→Glycine variant alone. Changes in agonist-promoted regulation may alter vascular reactivity affecting blood pressure and recently the Arginine 16→Glycine variant has been associated with essential hypertension in an African Caribbean population. Previous studies have examined these functionally opposing variants individually, with conflicting results. We wished to assess the relationship between them in essential hypertension.

Methods: We genotyped 211 patients with essential hypertension for both variants using a fluorogenic 5′ nuclease assay. This assay utilises PCR and the 5′ exonuclease activity of Taq polymerase to cleave a fluorescent dye from an allele specific probe. For each variant two probes were used, one specific for each allele and labelled with a different fluorescent dye facilitating allelic discrimination. The accuracy of this technique was assessed by fluorescent sequencing of DNA from a random sample of 50 patients.

Results: The sequencing data confirmed the results of the fluorogenic assay in all 50 patients. The genotype frequency for the first variant was; Arg16/Arg16: 10%, Arg16/Gly16: 55%, Gly16/Gly16: 35% and the second was Gln27/Gln27: 34%, Gln27/Glu27: 50%, Glu27/Glu27: 16%. Although all genotypes were common, the Glu27/Glu27 variant only occurred in association with the Gly16/Gly16. Furthermore in no cases that were Arg16/Arg16 was the Glu27 allele found. Therefore the Glu27 allele appears to occur only in the presence of the Gly16 allele in this population.

Conclusions: Two groups have previously suggested that the Glu27 allele results in resistance to downregulation of the β_2-adrenoceptor in man. Our results demonstrate that the Glu27 allele only occurs with Gly16, which functionally dominates it. We therefore conclude that, at least in subjects with essential hypertension, the Glu27 allele does not determine the degree of downregulation of the β_2-adrenoceptor.

PHARMACOLOGIC ALTERATIONS OF ENDOTHELIAL FUNCTION

1320 Effects of estrogen and simvastatin on markers of inflammation in hypercholesterolemic postmenopausal women

K. Koh, C. Cardillo[1], B. Minh[1], L. Hathaway[1], R. Mincemoyer[1], J. Panza[1], R. Cannon III[1]. *Division of Cardiology, Gachon Medical College, Inchon, South Korea; [1]Cardiology Branch, NHLBI, NIH, Bethesda, USA*

Background: Atherosclerosis in humans associated with inflammation. Therapies that increase nitric oxide (NO) bioactivity may reduce synthesis if proinflammatory proteins within the vessel wall by inhibiting transcriptional activation of target genes.

Methods: As estrogen and statin lipid-lowering therapies improve vascular NO bioactivity, we administered conjugated equine estrogen (CEE) 0.625 mg, simvastatin 10 mg, or the combination daily for 6 weeks to 28 hypercholestrolemic (low-density lipoprotein 165 ± 36 mg/dL; mean ± SD) postmenopausal women in a randomized, double-blind, double-crossover study. We measured brachial artery flow-mediated dilation (FMD) following forearm ischemia as a bioassay of endothelial NO, and serum levels of E-selectin, intercellular adhesion molecule (ICAM-1), and vascular cell adhesion molecule (VCAM-1).

Results: Equivalent improvement in FMD (P = 0.600 by ANOVA) was seen with each therapy: CEE 4.0 ± 2.6 to 10.2 ± 3.9%, simvastatin 4.3 ± 0.4 to 10.0 ± 3.9%, CEE/simvastatin 4.6 ± 2.0 to 9.8 ± 2.6% (all P < 0.001 vs respective baselines). However, only therapies including CEE significantly reduced levels of cell adhesion molecules. CEE reduced levels of E-selectin, ICAM-1, and VCAM-1 by −17 ± 14%**, −3 ± 22%, and −14 ± 21%*, respectively. Simvastatin reduced levels of E-selectin, ICAM-1, and VCAM-1 by 6 ± 3%, 5 ± 27%, and −3 ± 26%, respectively. CEE/simvastatin reduced levels of E-selectin, ICAM-1, and VCAM-1 by −18 ± 16%**, −8 ± 15%*, and −11 ± 19%*, respectively. Data (mean ± SD) = %change from respective pretreatment values; *P < 0.01; **P < 0.001.

Conclusion: Thus, therapies that improve NO bioactivity in postmenopausal women may not have comparable effects on markers of inflammation, and suggest a primary mechanism of estrogen.

1321 A six-month statin therapy reduces endothelial ICAM-1 levels in 30 patients with very early stages of coronary atherosclerosis

D. Baller, T. Brinkmann[1], G. Notohamiprodjo, U. Gleichmann, D. Horstkotte, K. Kleesiek[1]. *Clinic of Cardiology; [1]Institute of Laboratory and Transfusion Medicine, Heart Center NRW, University of Bochum, Bad Oeynhausen, Germany*

Background: Increased expression and endothelial release of adhesion molecules such as intercellular adhesion molecule-1 (ICAM-1) play a key role in initiation and progression of atherosclerosis under the impact of risk factors. Aim of our study was to measure ICAM-1 levels in patients with mild-to-moderate LDL-hypercholesterolemia, angina pectoris, reduced coronary flow reserve (CFR) and minimally affected coronary vessels before and after 6 months of intensive lipid lowering with statins (20–40 mg simvastatin n = 28, others n = 2), previously not receiving lipid lowering drugs.

Methods: In 30 patients CFR was determined from dipyridamole (0.56 mg/kg) flow/basal flow ratio with dynamic positron emission tomography (PET) and N-13-ammonia as flow tracer. Coronary angiogram was performed due to exertional or atypical angina revealing minimal changes in terms of wall irregularities or minimal stenosis (≤30%). Baseline data: 20 males, 10 females; mean age: 58 ± 8 years. After 6 months lipid lowering therapy with statins, supported by fat- and cholesterol-reduced diet, soluble ICAM-1 levels were measured by solid phase sandwich enzyme linked immuno sorbent assay (ELISA) in venous blood.

Results: (mean ± SD) CFR: 2.3 ± 0.7, LDL: 176 ± 47 mg/dl at baseline. After 6-month follow-up LDL decreased to 103 38 mg/dl ($p < 0.01$), ICAM-1 levels decreased from 95 ± 65 to 66 ± 44 ng/ml ($p < 0.05$). The clinical course showed a regression of anginal symptoms in the majority of patients ($p < 0.01$).

Conclusions: An intensive lipid lowering therapy induces a significant reduction of ICAM-1 levels after ≈6 months in patients with hypercholesterolemia and early stages of coronary atherosclerosis, possibly demonstrated for the first time. Measurement of ICAM-1 could serve as a new atherosclerosis response marker in the control of coronary risk factors.

1322 Influence of oestrogen replacement therapy on endothelial function

I. Guevara, J. Krzysiek[1], A. Zdzienicka, T. Milewicz[1], A. Dembińska-Kieć. *Department of Clinical Biochemistry; [1]Chair and Clinic of Endocrinology and Fertility, CM Jagiellonian University, Kraków, Poland*

Several studies have suggested that estrogen supplementation may improve the vascular dysfunction by promoting endotelium-dependent vasodilatation exerting a cardioprotective effect in postmenopausal women. Three groups of menopausal women (basal estradiol level below 50 pg/ml) were included into the study:

(a) the first group (n = 22: n = 18 after natural menopause and n = 4 after total hysterectomy with bilateral salpingoophorectomy) received transdermal 17 β-estradiol therapy (Estraderm MX 50, Novartis)
(b) the second group (n = 6 after natural menopause) received simvastatin (Zocor, MSD, 20 mg/day)
(c) the third group (n = 12 after natural menopause) remained without pharmacotherapy

At the beginning, after 3 and 6 months of the study the nitric oxide (NOx), and endothelin-1 (ET-1) plasma levels were measured before, during and after standard exercise test (according the Bruce's protocol) whereas $VEGF_{165}$ was measured only before exercise test at the some time points. NOx concentration was analysed in serum by modified Griess method, ET-1 was determined with RIA kit (Amersham) and $VEGF_{165}$ with ELISA Kit (R & D Systems).

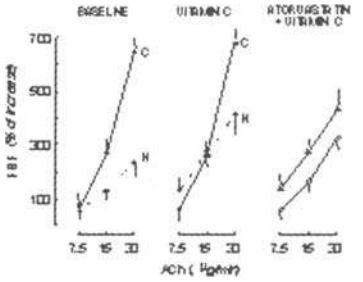
The simvastatin as well as 17β-estradiol therapy resulted in an increase of NOx release during maximal exercise (by above 50%) and in decrease of basal ET-1 level after 6 month therapy. Thus the NOx/ET-1 ratio was significantly increased at maximal exercise and after exercise by 71% and 85% respectively. The improved blood perfusion was also documented by the decrease of plasma $VEGF_{165}$ level after 6 months of both kind of therapy but not in control group, since ischemia is the main activator of VEGF gene induction.

In summary transdermal therapy with estrogen as well as oral one with simvastatin equipotentially modulate the endothelium-dependent regulation of blood redistribution during effort and protect tissue against ischemia.

1323 Effects of atorvastatin and vitamin C on endothelial function of hypercholesterolemic patients

F. Perticone, R. Ceravolo, R. Maio, S. Iacopino, G. Ventura, M. Candigliota, A. Sciacqua, P.L. Mattioli. *Med. Sper. e Clin. "G. Salvatore", Università di Catanzaro, Catanzaro, Italy*

Endothelial dysfunction has been reported in presence of different risk factors such as hypertension, smoking, diabetes and hypercholesterolemia. We tested in 18 hypercholesterolemics (H) (10 M/8 W, age = 40 ± 6 yrs), the effects of 1-month of atorvastatin alone (10 mg/day) on impaired endothelium-dependent vasodilation and during coadministration of vitamin C (24 mg/min). Twelve normal volunteers (7 M/5 F, age = 39 ± 5 yrs) were also enrolled as control group (C). The responses of the forearm blood flow (FBF) to acetylcholine (ACh) (7.5, 15 and 30 mcg/ min), sodium nitroprusside (SNP) (0.8, 1.6, 3.2 mcg/min) and L-NMMA (2, 4, 8 mmol/ min) were evaluated at baseline and after 1 month of atorvastatin treatment by strain-gauge plethysmography. At baseline, the response to ACh was significantly attenuated in H vs C: at the highest dose (30 mcg/min), FBF was 27.0 ± 3.4 vs 11.5 ± 1.9 mL. 100 mL tissue^{-1} min^{-1} respectively ($p < 0.0001$). No significant differences were found between groups during SNP infusion. The atorvastatin significantly improved ACh-stimulated FBF: at highest dose the FBF increased to 14.9 ± 1.5 mL. 100 mL tissue^{-1} min^{-1} ($p < 0.0001$). Similarly, the L-NMMA endothelial effects were significantly potentiated by atorvastatin treatment. Vitamin C increased ACh-vasodilation in the same way before and after atorvastatin treatment.



In conclusions, the endothelial dysfunction in H is due to oxidative stress, and atorvastatin rapidly improves impaired endothelial vasodilation by lipid-lowering action and, probably, by pleiotropic effects.

1324 Endothelin selectively induces functional and morphological coronary alterations in cardiac transplant recipients

M. Weis, S.M. Wildhirt[1], C. Schulze[1], S. Pehlivanli, W.P. Wolf, U. Wilbert-Lampen, G. Rieder[2], B.M. Meiser[1], G. Enders[2], W. von Scheidt. *Medical Unit I, University Hospital Grosshadern, Munich; [1]Cardiac Surgery Dept., University Hospital Grosshadern, Munich; [2]Surgical Research, University Hospital Grosshadern, Munich, Germany*

Endothelin (ET) opposes the effects of NO and plays a significant role as a modulator of coronary vascular reactivity in the early stages of arteriosclerosis. We have previously detected that coronary endothelial dysfunction after HTx is associated with increased myocardial ET mRNA expression. However, the impact of early ET and eNOS-activation on development of functional and morphological coronary alterations during follow-up is unknown.

Methods: We investigated the impact of myocardial ET and eNOS-gene (RT-PCR) expression as well as ET and nitrite/nitrate-plasma levels (aorta and coronary sinus; RIA, Griess) on development of morphological and functional coronary changes in 42 cardiac transplant recipients (CTr) early (1 month) and 12 months after HTx. Epicardial (QCA) and microvascular (ic Doppler) endothelium-dependent (acetylcholine) and endothelium-independent (adenosine) vasomotor-function was studied sequentially. IVUS was performed to determine intimal hyperplasia.

Results: Significant ET uptake by the heart (aortic-coronary sinus plasma level > 1 fmol/ml) was noticed early and during follow-up in the majority of CTr ($p < 0.001$). Endothelium-dependent flow increase during follow-up was inversely correlated to early aortic ET-levels ($r = -0.38$; $p < 0.05$). CTr with newly developed intimal thickening and epicardial endothelial dysfunction during follow-up had an increased ET mRNA expression score at baseline compared to patients with no functional and morphological changes over time (2.8 ± 1.0 versus 1.7 ± 0.8; $p < 0.03$). Importantly, eNOS-mRNA expression and nitrate/nitrite levels at baseline were comparable in CTr with and without development of intimal thickening and/or endothelial dysfunction during follow-up.

Conclusion: Coronary endothelial vasomotor dysfunction as well as morphological coronary alterations during follow-up after HTx are at least in part induced by early myocardial activation of the ET-pathway.

1325 L-arginine administration improves insulin-mediated endothelial dysfunction in patients with syndrome X

G. Fragasso, P.M. Piatti, L.D. Monti, A. Caumo, G. Valsecchi, A.E. Pontiroli, S.L. Chierchia. *IRCCS H San Raffaele, Milan, Italy*

Patients (pts) with angina pectoris, positive exercise test and smooth coronary arteries (syndrome X-SX) have been shown to be insulin (I) resistant. We assessed whether I sensitivity could be improved by the administration of L-arginine, the natural precursor of nitric oxide (NO). Nine SX pts and 13 matched controls (C) were recruited. All SX pts underwent 120 min L-arginine (A) (0.125 g/min) and saline (S) infusions in random order, while C underwent only S infusion. In all cases, after the first 60 min of infusion, a 0.1 U/kg i.v. insulin bolus was administered and blood glucose (G) levels were maintained at basal values by means of a variable G (20%) infusion rate (GIR). At baseline, I, G, NO_2/NO_3, triglycerides, free fatty acid blood levels, systolic-diastolic blood pressure (SBP-DBP) and forearm blood flow (FBF) were similar in SX and C. In SX pts, A induced a reduction in SBP ($p < 0.01$) and DBP ($p < 0.01$) and an increase of FBF (3.11 ± 0.23 vs 2.34 ± 0.16 ml/100 ml/min, $p < 0.05$) reaching values similar to those observed in C (3.2 ± 0.31 ml/100 ml/min). while I and G levels were unchanged. Conversely, no changes were observed during S in both groups. After I, there was an increase in ΔAUC (0–30) of NO_2/NO_3 during A compared to S (60.8 ± 19.2 vs 14.8 ± 31.8 μmol/L, $p < 0.05$) in SX, even though levels remained well below those found in C during S (168.8 ± 52.5 μmol/L, $p < 0.01$). In SX during A, GIR was 32% higher than during S (282 ± 27 vs 213 ± 23 mg/kg, $p < 0.05$), but these levels were inferior to those observed in C (390 ± 32, $p < 0.01$ vs A and S of SX).

In conclusion, L-arginine mediated increase of NO production improves I sensitivity in SX pts. Endothelial dysfunction may concur in the pathogenesis of I resistance in these pts.

LEFT VENTRICULAR REMODELLING AND HUMORAL REGULATION IN ACUTE MYOCARDIAL INFARCTION

1326 Influence on left ventricular remodelling after a first myocardial infarction of a randomly allocated ACE-inhibition, β-blocker or ACE-inhibition + β-blocker therapy

R. Ricci, C. Coletta, A. Sestili, F. Rulli, A. Porzio, G. Pajes, R.L. Putini, A. Salustri, G. Bottero, M. Pasquale, V. Ceci. *On behalf of R.I.M.A. Investigators; Coronary Care Unit, S. Spirito Hospital, Rome, Italy*

The R.I.M.A. (Rimodellamento Infarto Miocardico Acuto) study was designed to assess the relative effect of ACE-inhibition (ACE), β-blocker (BB) therapy or their combination on left ventricular (LV) remodeling process in patients (pts) with a first, uncomplicated myocardial infarction (MI). Two hundred-fifty consecutive pts were randomly allocated to receive for >3 months captopril (up to 75 mg/day, Group A), metoprolol (up to 200 mg/day, Group B) or both (Group C) within 24 hours from the onset of symptoms. Of these, 130 pts (Group A = 46, Group B = 47, Group C = 37) were free of cardiac events or revascularization procedures at 6 months from MI: all underwent 2D echo at the admission, 3 and 6 months from MI. LV diastolic areas and volumes (modified Simpson rule) were blindly calculated and averaged by the same operator in the core laboratory from the apical 2- and 4-chambers views. The wall motion score index (WMSI) was calculated on a 16 segments model (score 1 to 4).

Results: Baseline LV areas, volumes, ejection fraction and WMSI were comparable in the three groups. The relative increase of diastolic LV areas at 3 months (Group A: 2.1 ± 11.6%, Group B: 5.5 ± 10.6%, Group C: 9.0 ± 15.5%, $p = 0.047$; Bonferroni: $p < 0.05$ Group A vs C) and at 6 months (Group A: 2.2 ± 15.1%, Group B: 7.3 ± 11.8%, Group C: 12.8 ± 18.1%, $p = 0.02$; Bonferroni: $p < 0.05$ Group A vs C) was comparable in Groups A and B; a significantly major increase of LV areas was observed in Group C in comparison with Group A. In the subgroups of pts with anterior MI similar differences were observed, but the statistical significance was not achieved being the sample inadequate.

Conclusions: The early BB treatment was as effective as ACE in preventing LV dilatation after uncomplicated MI, but their combination resulted in a more pronounced LV remodeling process in comparison with ACE alone.

1327 Effects of β-blocker compared to angiotensin converting inhibitor on left ventricular remodelling in acute myocardial infarction: a randomized study

Y. Yoshitomi, S. Kojima, M. Yano, T. Sugi, Y. Matsumoto, M. Kuramochi. *Cardiology, Tohsei National Hospital, Shizuoka, Japan*

Background: Angiotensin converting enzyme (ACE) inhibitor attenuates left ventricular (LV) remodeling after acute myocardial infarction (AMI), but it is still unclear whether beta blocker therapy affects LV remodeling. We assessed the effects of beta blocker therapy compared with ACE inhibitor therapy on LV remodeling after AMI.

Methods: Sixty patients with AMI who underwent reperfusion therapy within 4 hours were randomly assigned to 2 treatment groups: imidapril (ACE inhibitor: group I, 20 patients) or bisoprolol (beta blocker: group B, 20 patients), or to a control group (group C, 20 patients). Each treatment was started within 24 hours. Cardiac catheterizations were performed on admission and after 1 and 3 months after admission. LV function and regional LV function were determined by the area-length method and the center-line method.

Results: Baseline clinical, procedural, and hemodynamic characteristics on admission were similar in the 3 groups. All patients had documented patency of infarct-related artery during 3 months. Mean pulmonary wedge pressure (PCWP), right atrial pressure (RA), and LV end-diastolic pressure (LVEDP) after 1 month were higher in group B than group I and group C (PCWP: 11 ± 6 vs 7 ± 3 vs 8 ± 3 mmHg, RA: 6 ± 2 vs 4 ± 2 vs 4 ± 2 mmHg, LVEDP: 16 ± 7 vs 12 ± 6 vs 13 ± 7 mmHg, $p < 0.01$). LV end-diastolic volume index (EDVI) increased in group B throughout the 3-month period ($p < 0.05$), whereas EDVI in group I decreased ($p < 0.05$). The changes in EDVI in group B were greater than those of group I and group C (group B: 6 ± 2, group I: −6 ± 2, group C: −3 ± 2 mL/m^2, $p < 0.05$). The changes in regional wall motion of the infarct zone in group B were smaller than those in group I and group C (group B: 0.38 ± 0.12, group I: 0.78 ± 0.15, group C: 0.67 ± 0.13, $p < 0.05$).

Conclusion: It is suggested that treatment of AMI with beta blocker further increase the preload and cannot prevent LV remodeling. Conversely, early treatment with ACE inhibitor attenuated LV remodeling.

1328 Left ventricular shape distortion after first myocardial infarction is related to the extent of initial ischaemic damage and to the recovery of viable myocardium but not to infarct site

L. Badano, F. Macor, F. Gentile, P. Giannuzzi, D. Lucci, G. Levantesi, R. Piazza, J. Stoian, P.L. Temporelli, G.L. Nicolosi. *On behalf of the GISSI-3 Echo Investigators, Centro Studi ANMCO, Florence, Italy*

Ventricular cavity geometry is an important determinant of LV function and patients' exercise capacity. Distortion of LV geometry and progressive deterioration in LV function are known sequelae after acute myocardial infarction (AMI). The aim of our study was to characterize the time course and determinants of LV geometry changes after a first, uncomplicated AMI. Therefore, 2D echoes were obtained in 567 pts at 36 ± 8 hrs (S1), 12 ± 5 days (S2), at 6 weeks (S3), and at 6 months (S4) after AMI to assess LV size (Simpson's biplane volumes), shape (Lama's sphericity index) and function (ejection fraction), and percentage of LV that was akinetic or dyskinetic (%WMA, 16-segment model)

	S1 (n = 587)	S2 (n = 587)	S3 (n = 577)	S4 (n = 567)	F Value	p
ED volume (ml)	144 ± 38	150 ± 42	152 ± 45	155 ± 47	21.2	<0.0001
ES volume (ml)	76 ± 27	80 ± 31	82 ± 35	83 ± 37	14.0	<0.0001
ED sphericity	0.42 ± 0.09	0.43 ± 0.09	0.45 ± 0.10	0.45 ± 0.10	26.6	<0.0001
ES sphericity	0.33 ± 0.10	0.34 ± 0.10	0.36 ± 0.10	0.37 ± 0.10	29.3	<0.0001
EF (%)	48 ± 7	48 ± 8	47 ± 9	48 ± 8	1.0	NS
%WMA	26 ± 43	23 ± 15	21 ± 15	19 ± 1	62.6	<0.0001

ED = end diastolic; ES = end systolic; p values = repeated measures ANOVA.

Multivariate stepwise regression analysis of clinical, including AMI location, and echo data showed that %WMA at S1, change in %WMA from S1 to S4, and change in LV volume from S1 to S4 were the only independent determinants of LV shape at S4 ($p < 0.0001$).

Thus, after AMI, progressive LV dilation is associated to increasing LV shape distortion. Six-month LV shape changes are directly related to extent of initial ischemic damage and changes in LV volumes, and inversely related to extent of recovery of viable myocardium, but it is not related to site of AMI.

1329 Increased plasma cardiotrophin-1 following an acute myocardial infarction and its relationship to left ventricular systolic dysfunction

S. Talwar, P.F. Downie, I.B. Squire, J.E. Davies, D.B. Barnett, L.L. Ng. *Dept of Medicine & Therapeutics, Leicester University, Leicester, UK*

Augmented ventricular gene expression of Cardiotrophin-1 (CT-1), a member of the interleukin-6 related cytokines that act via the gp130 signalling pathway, following myocardial infarction (MI) in rats is thought to be involved in the process of ventricular remodelling.

Method: To clarify the role of CT-1 following MI we compared plasma CT-1 in 40 patients(30 males and 19 anterior infarcts) and 30 controls (17 males). A competitive immunoluminometric assay using a methyl acridinium ester to label the peptide and an in-house polyclonal antibody to amino acids 105–120 of the CT-1 sequence was developed. Serial blood samples were obtained at 4 time points following admission between day 0–2, 3–5, 6–8 and at the 6 week outpatient appointment. Echocardiogram was performed before discharge (WMI1) and at the outpatient visit (WMI2).

Results: Patient CT-1 levels were significantly elevated at all time points compared to controls ($p < 0.0001$). Median values of CT-1 (in fmol/ml) of the patients at the 4 time points were 53.35 [range 17–428.5], 47.2 [19–2228.5], 52 [19.9–780.5] and 70.30 [16.9–223.6] Vs. 27.7 [7.6–42.1] for the controls. In the high risk patient group with anterior infarcts WMI1 and WMI2 correlated with log CT-1 levels in the first 48 hours ($r = -0.48$ & -0.57 respectively, for both $p < 0.05$).

Conclusion: This is the first quantitative assessment of CT-1 in humans. Furthermore this is the first demonstration of significant elevation of CT-1 levels following an MI. The study suggests the intriguing possibility that CT-1 may discriminate patients who will be at risk of an adverse outcome.

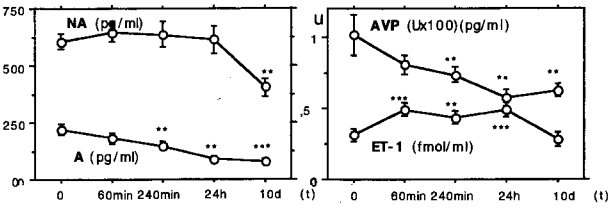
1330 Differential effects of reperfusion on vasoactive neurohormone levels in patients with acute myocardial infarction treated with direct angioplasty

F. Hartmann, T. Kurz, R. Tölg, H. Bonnemeier, A. Maghsoudi, U. Schäfer, H.A. Katus, G. Richardt. *Medizinische Klinik II, Medizinische Universität zu Lübeck, Lübeck, Germany*

Activation of neurohumoral systems plays an important role in the extension of myocardial infarct size in myocardial injury during acute myocardial infarction (AMI). Although neurohumoral activation is known to persist in complicated AMI, no data are available on changes of hormone levels in AMI pts undergoing reperfusion therapy.

Methods: We analysed 63 consecutive pts with AMI, who had successful reperfusion (TIMI 2 and 3) by direct angioplasty. Arterial plasma levels of adrenaline (A), noradrenaline (NA), endothelin-1 (ET-1), arginine vasopressin (AVP) were determined before, 60, 240 min, 24 h and 10 days after reperfusion.

Results: Two different patterns of hormonal changes were found: A, Na and AVP levels (mean ± SEM) slowly decreased from high initial values, whereas, ET-1 levels initially rised after reperfusion, followed by a subsequent decrease at 10 d.



Neurohormone patterns. *,**,***$p < 0.05, < 0.01, < 0.001$ compared to 0 min levels.

Conclusion: Primary angioplasty in the acute phase of AMI is associated with rapid normalization of most vasoactive neurohormone levels. A different pattern of ET-1 may reflect reperfusion-dependent activation mechanisms and rise the opportunity for therapeutic interventions. Early normalization of neurohumoral activation should be considered as a marker for effective treatment of AMI.

1331 The clinical implication of circulating levels of angiogenin in acute myocardial infarction patients

K.I. Kapetanios, E.V. Economou, C.I. Stefanadis, C.E. Pitsavos, D.M. Farmakis, K. Vassiliadou, M.G. Toutouza, P.K. Toutouzas. *Cardiology Dept. University of Athens, Athens, Greece*

Angiogenesis, the formation of new blood vessels, plays a central role in a variety of physiological and pathological processes. Angiogenin (ANG), a potent modulator of Angiogenesis, has been found to be activated in peripheral occlusive arteriopathy. The aim of our study was to clarify the importance of ANG activation in acute myocardial infarction (AMI) patients.

Methods: 29 patients with first attack of AMI, and no previous history of any other disease, were examined for plasma levels of ANG, measured by ELISA, and compared to corresponding levels of 20 Normal controls (NC) with mean values: 207.31 ± 14.8 ng/ml. All pts were divided in 2 sex and age-matched groups. Group A: pts with limited AMI, EF > 45% and normal LV function. Group B: pts with extensive AMI, EF < 45% and subsequent heart failure. Plasma samples were collected at the time of hospital admission (0 hours) and 6 h, 12 h, 18 h, 24 h, 48 h, 3 days, 4 d, 5 d, 7 d, 15 d, 30 d thereafter. All pts received thrombolysis.

Results are expressed as mean values ± SEM in ng/ml as follows:

Pts	0 h	6 h	12 h	18 h	24 h	48 h	3 d	4 d	5 d	7 d	15 d	30 d
A (14)	346 ± 47.4 *	278 ± 19.7 *	262 ± 2.04	260 ± 14.3	261 ± 19.5	299 ± 17.3 *	333 ± 21.8 *	329 ± 24.4 *	330 ± 23.6 *	343 ± 28.3 *	349 ± 29.2 *	355 ± 30.1 *
B (15)	293 ± 21.2 *	292 ± 14.2 *	273 ± 15.4	248 ± 16.8	232 ± 16.2	309 ± 25.7	301 ± 17.1	292 ± 15.3	287 ± 14.1	272 ± 21.5	243 ± 15.3	229 ± 14.8

p < 0.05 compared to corresponding values of: a) NC (*) (Wilcoxon test).

Conclusions: Both groups exhibit initial high ANG plasma levels statistically compared to NC. This increase is followed by a gradual decrease, probably as a result of thrombolysis, that is reversed in both groups. However this late rebound of ANG 48 h after AMI is significant and remains only in group B and may imply that the process of angiogenesis is enhanced, thus preserving LV function and exerting a cardioprotective potential. On the other side angiogenesis seems to be in a much lesser extent in pts with large infarct size, thus resulting in LV decompensation. These data support the rationale for using specific pharmacologic interventions that could modify the progression of ventricular remodeling following AMI particularly in pts whose disease is not amenable to direct revascularisation.

ACUTE CORONARY SYNDROMES: PROGNOSIS

1332 Long-term outcome in patients with unstable angina pectoris compared to patients with non-Q-wave myocardial infarctions: results from a 10-year follow up

P. Abrahamsson, M. Dellborg, A. Rosengren, K. Swedberg. *Department of Medicine, Sahlgrenska University Hospital Östra, Gothenburg, Sweden*

Purpose.The aim of the present study was to asses the long term outcome in patients with unstable angina pectoris (UAP) compared to patients with non-Q wave myocardial infarctions (NQAMI).

Methods: 3941 patients (2627 men and 1314 women) with UAP or NQAMI admitted to the coronary care unit at Östra hospital, Gothenburg between 1988 and 1997 were followed until the end of 1997. Infarct and unstable angina diagnoses were based on clinical presentation, ECG and CK-MB mass concentration (= 15 μkat/l for infarct).

Results: The average age was 66.0 years for UAP patients vs 70.7 years for NQAMI patients (p < 0.001). By multivariate analysis including prior myocardial infarction, age, sex, diabetes mellitus, prior revascularization, smoking and hypertension, the development of a NQAMI compared to UAP was independently associated with higher mortality (RR = 1.7 p < 0.0001). However most part of the difference in outcome was accounted for by a higher mortality in the early phase among the infarct patients, in particular the first 30 days. After 2 years the mortality rate was similar in booth groups (see Table).

Table: Cumulative survival

Follow up time	Unstable angina pat	Non-Q infarct patients
30 days	98.3 (97.6–98.9)%	86.8 (85.4–88.1)%
1 year	92.7 (91.3–94.0)%	76.7 (75.0–78.4)%
2 years	88.2 (86.5–89.9)%	70.2 (68.3–72.1)%
4 years	79.8 (77.4–82.0)%	59.4 (57.3–61.5)%
6 years	71.7 (68.8–74.6)%	50.1 (47.8–52.5)%
10 years	52.6 (44.9–60.4)%	35.5 (31.4–39.5)%

Conclusion: Patients with unstable coronary syndromes suffer a poor long term outcome. Mortality is higher for those with non-Q myocardial infarction during the first 2–3 years after which the yearly risk for death is similar to that of unstable angina patients.

1333 The risk of adverse outcome in patients with acute coronary syndromes without ST-segment elevation is mainly determined by baseline clinical factors

Eric Boersma, Karen Pieper, Robert G. Wilcox, Ewout Steyerberg, Wei-Ching Chang, Kerry L. Lee, Martijn Akkerhuis, Robert A. Harrington, Paul W. Armstrong, Robert M. Califf, Maarten L. Simoons. *For the PURSUIT Investigators; Erasmus University, Rotterdam, Netherlands; Duke University, Durham NC, USA; University of Alberta, Edmonton AB, Canada*

Background Appropriate treatment policies should include a satisfactory estimation of the patient's baseline clinical risk. So far, however, risk-modelling in acute chest pain patients without ST-segment elevation is underexposed.

Methods To evaluate the relationship between baseline characteristics and the 30-day occurrence of mortality or non-fatal myocardial infarction, we analysed data collected on the 10,948 ischemic chest pain patients without persistent ST-elevation, which enrolled the PURSUIT trial. Risk modelling was performed by multivariable logistic regression and validation by bootstrapping techniques. Variables examined included demographics, history, hemodynamic condition, symptom duration and treatment assignment.

Results There were 3.6% deaths and 11.4% non-fatal myocardial (re)infarctions in PURSUIT. Over 20 significant contributors were determined, both to mortality alone and the combined outcome. The most important predictors of mortality are presented in the table, together with the relative contribution to the mortality model. Variables that were predictive for mortality alone generally were so for the combined outcome. However, the strength of the relation between predictors and combined outcome was less than for mortality alone (c-index 0.67 vs. 0.80). Furthermore, differences were observed in the ranking order by the degree of risk stratification. Still, in both models, age, heart rate and enrollment diagnosis contained about 45% of the total prognostic information available in the examined variables.

Characteristic	Contribution	Characteristic	Contribution
Age	24%	ST-depression	4%
Heart rate	10%	Heart failure	3%
MI at enrollment	8%	Weight	3%
Blood pressure	5%	Angina class	3%

Conclusions The occurrence of adverse cardiac events after an episode of ischemic chest pain is affected by multiple factors, which are often not treatment related. These determinants should be considered in the clinical decision process.

1334 New Q-wave development following acute myocardial infarction does not predict increased short or long-term mortality

Wayne L. Miller, R. Scott Wright, Samuel Asirvatham, Fabio Sgura, Joseph P. Grill, Stephen L. Kopecky. *Mayo Clinic and Foundation, Rochester MN, USA*

Background: ECG changes in acute myocardial infarction (MI) have been used to assess relative risk of future complications. New Q-wave development has been associated with greater myocardial damage than non-Q-wave MI but it is not clear if long-term mortality is affected.

Hypothesis: New Q-wave development is associated with increased short and long-term mortality following acute MI.

Methods: We analyzed 815 patients from Rochester, MN admitted to the Mayo Clinic CCU. 389 (47.7%) developed Q-waves following the MI and 426 (52.3%) did not develop Q-waves.

Results:

Survival by New vs. No New Development of Q-Waves

Survival Summary	New Q-Wave Development (N = 389)	No New Q-Wave Development (N = 426)	Log-Rank Statistic	P value
Est. % Surv & 95% CI at:				
• 30 days	95.8% (93.9, 97.9)	97.6% (96.2, 99.1)	1.13	0.29
• 6 months	92.3% (89.7, 95.0)	93.5% (91.1, 95.9)		
• 1 year	90.6% (87.7, 93.6)	90.8% (88.1, 93.7)		
• 2 years	86.6% (83.0, 90.3)	85.1% (81.6, 88.8)		
• 5 years	75.5% (70.5, 80.5)	70.1% (64.8, 75.7)		
Adjusting for ECG classification, age & gender	Adjusting for ECG classification, age & gender	Adjusting for ECG classification, age & gender	0.06[a]	0.81

[a]Chi-square statistic resulting from the likelihood ratio test

Conclusions: No significant differences in short and long-term mortality were observed, even after adjustment for ST segment pattern at presentation, age and gender. The development of a Q-wave MI ECG pattern does not suggest a high risk subset of patients who require different risk stratification efforts consistent with non-Q-wave MI patients.

1335 Improving prognosis amongst 178,000 patients hospitalised with acute myocardial infarction between 1981 and 1995

K. MacIntyre, S. Capewell, M. Livingston, J. Chalmers[1], J. Boyd, A. Finlayson[1], A. Redpath[1], J. Pell[3], C. Evans, J.J.V. McMurray[4]. *Department of Public Health, University of Glasgow; [1]Information and Statistics Division Edinburgh; [3]Greater Glasgow Health Board; [4]Department of Cardiology, Western Infirmary, Glasgow, UK*

Background: Though many new therapies have been shown to improve prognosis after myocardial infarction (MI), in clinical trials, the *population* impact of these treatments is unknown. We report trends in survival for all patients hospitalised with acute MI in Scotland over a 15 year period.

Methods: Scotland (population 5.1 million) has a national Morbidity Record Database holding comprehensive, high quality data, which links all hospitalisations and deaths. A Scottish wide, retrospective, cohort study of all 178,077 individual MI patients admitted between 1981–1995 was carried out. Mortality up to 10 years was calculated with Cox-modelling for the effects of age, sex, socioeconomic deprivation, co-morbidity and year of treatment.

Results: Over the whole period of study, one months, one year, 5 year and 10 year case fatality rates were 24, 33, 50 and 65 years. The principal factors independently influencing prognosis were age and prior morbidity. Both short (1 month) and longer term (1–5 years) *adjusted* case fatality rates fell by about half between 1981 and 1995.

Conclusions: Modern treatment appears to have dramatically improved the short and long-term survival of patients hospitalised with acute MI.

1336 History of angina and early prognosis of myocardial infarction

M. Fiol, J. Marrugat[1], C. Rubert, J.I. Ayestaran, A. Cabadés[2], M.J. Tormo[3], A. Segura[4], J. Muniz[5], E. Aldasoro[6]. *Unitat Coronaria, Hospital Son Dureta, Palma de Mallorca; [1]Unitat Lipids & Epidemiol. Cardiovasc., Institut Municipal Investigacio Medica, Barcelona; [2]Unidad Coronaria, Hospital La Fe, Valencia; [3]Servicio de Epidemiologia, Consejeria de Sanidad, Murcia; [4]Centro Regional de Salud Publica, Consejeria de Sanidad, Talavera de la Reina; [5]Asociacion de Estudios Biomedicos, La Coruna; [6]Departamento de Sanidad, Gobierno Vasco, Bilbao, Spain*

Background: It has been suggested that previous angina may result in a lower number of complications after acute myocardial infarction (MI).

Objective: To assess whether first-MI patients with prior angina develop less complications than those without such a history.

Methods: All first-MI patients aged less than 75, consecutively admitted to the hospitals participating in the pilot phase of the IBERICA study. Twenty-eight-day survival and complications were assessed. Patients were divided in two groups according to the presence of history of angina before 48 hours of the index event.

Results: Among the 1996 patients recruited, 841 had had previous angina. Mean age was 60.6 (59.9 in non-angina patients and 61.4 in the rest), and 20.0% were women (19.4 and 20.1, respectively). Previous-angina patients had similar mortality (10.0% and 11.5%, respectively) and proportion of life-threatening arrhythmias (14.2% and 13.3%), atrio-ventricular block (5.6% and 5.0%), stroke (1.1% and 1.2%), mecanical complications (2.1% and 1.5%) but higher incidence of acute pulmonary oedema or cardiogenic shock (13.8% and 17.5%, $p = 0.03$), reinfarction (2.0% and 4.0%, $p = 0.007$) and angina post-MI (11.5% and 22.7%, $p < 0.0005$).

Conclusions: Although 28-day mortality rate was similar, first-MI patients with previous angina had worse prognosis than the rest, particularly, they show higher angina post-MI, severe left ventricular dysfunction and reinfarction rates.

1337 Comparison of PTCA to medical therapy in patients with silent ischaemia after myocardial infarction: results of the Swiss Interventional Study on Silent Ischaemia (SWISSI II)

P. Erne, D. Burckhardt[1], M. Pfisterer[1], P. Dubach[2], M. Zuber, D. Evequoz, W. Kiowski[3]. *Div of Cardiology, Kantonsspital, Lucerne; [1]Div of Cardiology, University Hospital, Basel; [2]Div of Cardiology, Kantonsspital, Chur; [3]Internal Medicine Dept, University Hospital, Zurich, Switzerland*

Background: Silent ischemia (SI) post myocardial infarction (MI) adversely affects outcome. We studied the influence of PTCA or antiischemic drug therapy (Rx) on survival free of death, MI, or unstable angina (UA)and exercise capacity and left ventricular ejection fraction.

Methods: 201 patients (pts; 1 or 2 vessel disease) with SI (stress echo, MIBI or radionuclide ventriculography) were randomized after angiography (<3 months from MI) to PTCA of MI and ischemia related vessel(s) (n = 96) or aggressive drug therapy (Rx (n = 105): bisoprolol, amlodipine, molsidomine alone or in combination; acetylsalicylic acid was used in all pts)aiming at elimination of exercise induced ischemia.

Results: Both groups did not differ at baseline. Event free survival (median follow up (FU) 4.1 years) was not different in both groups (probability of survival 0.52 vs 0.752 Rx vs PTCA) at 7 years). Endpoints (Rx/PTCA) were: death 3/2, MI 15/8, UA 18/13). During FU, ejection fraction decreased more in Rx pts (from 59.7 ± 11.8 to 49.2 ± 9.4%) than PTCA pts (from 53.8 ± 9.9 to 53.7 ± 8.9%) suggesting less ventricular impairment in the PTCA group despite similar event rates. Also, PTCA pts increased their exercise capacity (from 140 ± 31 to 169 ± 40 watts, $p < 0.001$) while it remained unchanged in Rx pts (146 ± 33 vs 148 ± 38 watts, n.s.), had less ST-segment depression (0.033 ± 0.054 vs 0.064 ± 0.065 mV, $p < 0.001$) and received less frequently antiischemic therapy (bisoprolol: 13 vs 95; amlodipine: 6 vs 56; molsidomine:1 vs 61; $p < 0.001$).

Conclusions: PTCA of SI post MI did not significantly influence the rate of ischemic events as compared to drug therapy. However, revascularization by PTCA preserved left ventricular ejection fraction, improved exercise capacity and reduced the need for antiischemic drug therapy during long-term follow up.

NEW DEVELOPMENTS IN THE MANAGEMENT OF PROSTHETIC VALVE THROMBOSIS

1338 Incidence and predictors of prosthetic thrombosis on mitral bileaflet prosthesis during the postoperative period

B. Iung, T. Haghigat, E. Garbarz, P. Michaud, P. Berdah, B. Farah, E. Dadez, P.L. Michel, B. Cormier, A. Vahanian. *Cardiology Department, Tenon Hospital, Paris, France*

The post-operative period after mitral valve replacement (MVR) is at particularly high risk for prosthetic thrombosis (PT). Besides occlusive thrombosis, transoesophageal echocardiography (TEE) after MVR may reveal non-occlusive PT. The aim of this study was to assess the incidence and predictive factors of PT after MVR with a bileaflet prosthesis.

Between 1988 and 1996, 331 consecutive patients (pts) underwent MVR with a bileaflet prosthesis (Saint-Jude 192, Sorin 74, Carbomedics 30, Duromedics 9, ATS 26). Mean age was 56 ± 13 yrs; 58 pts had previous embolism (18%) and 180 (54%) were in atrial fibrillation. Anticoagulant therapy used heparin and vit. K blockers without systematic use of anti-agregant therapy. TEE was performed 15 ± 6 days after surgery in 319 pts (96%).

Occlusive and non-occlusive thrombi were differentiated according to the motion of the leaflets on TEE and fluoroscopy. TEE revealed PT in 57 pts (18%): occlusive thrombi in 6 pts (2%) and non-occlusive thrombi in 51 (16%).

Multivariate logistic regression identified 5 independent predictors of PT: previous myocardial infarction ($p = 0.03$), the type of prosthesis (Sorin vs. others $p < 0.001$), post-operative atrial fibrillation ($p = 0.007$), spontaneous left atrial echo contrast ($p = 0.002$), and the presence of fibrin strands ($p = 0.008$).

In conclusion 1) PT frequently occurs early after MVR with bileaflet prosthesis. 2) Predictors are mainly related to blood stasis. 3) Identification of patients at high risk for thromboembolism may be useful to offer them a more aggressive post-operative anticoagulant therapy.

1339 Diagnostic work-up in patients with suspected prosthetic heart valve thrombosis: is echocardiography always justified?

P. Montorsi, F. De Bernardi, M. Muratori, D. Cavoretto, M. Matturri, M. Pepi, M.D. Guazzi. *Institute of Cardiology University of Milan, Centro Cardiologico Fondazione Monzino, IRCCS, Milan, Italy*

The aim of the study was to evaluate and compare the diagnostic efficacy of cine-fluoroscopy (CF), transthoracic (TTE) and transesophageal echocardiography (TTE) in pts with clinically suspected prosthetic heart valve thrombosis (PVT).

Methods: Eighty-two consecutive pts with single mechanical prostheses were submitted to CF, TTE and TEE. Criteria for PVT were: leaflet(s) motion restriction at CF, increased Doppler gradients at TTE and evidence of thrombi at TEE.

Results: Patients were divided in 4 groups according to CF and TTE results. Group 1 (n = 24) had +CF and TTE; TEE showed prosthetic thrombosis in all, suggesting that CF and TTE, when both +, always identify PVT so as to defer TEE. Group 2 (n = 12) had +CF and −TTE. TEE showed PVT in 4/12 (33%): all were pts with bileaflet mitral valves and slight restriction of leaflet motion at CF. This suggest that in pts with hemodynamically non critical PVT a correct diagnosis may be missed by TTE alone: CF should be always carried out in these cases. The remaining 8 pts of this group were carriyng monocuspid prostheses and had −TEE for thrombus and pannus; the abnormal leaflet motion at CF was therefore thought to be functional (valve adaptive changes). Group 3 (n = 18) had −CF and +TTE. All had small size aortic prostheses, very high Doppler gradients and no symptoms. TEE ruled out PVT in all cases outlining the diagnostic role of CF in this subset of pts. TEE should be programmed if symptoms are present and they are not due to other cardiac or extracardiac sources. Group 4 (n = 28) had −CF and TTE. TEE confirmed these results by showing no thrombi in 24/28 (86%), suggesting that, when both −, CF/TTE confidently rule out PVT in most pts. However, in 4/28 (all with mitral prostheses, chronic atrial fibrillation and embolism in 3/4) TEE showed "non-obstructive" PVT. Thus, TEE should be performed in selected cases despite −CF and TTE results. Sensitivity and specificty were 87%, and 84% for CF and 75% and 64% for TTE. Both tests correctly identified PVT in 70/82 (85%) of pts. TEE was actually required in 15% of the cases.

Conclusions: PVT has a multiform clinical and non-invasive presentation. CF and TTE are quick, effective and complementary diagnostic tools to diagnose PVT in most pts. Transesophageal echocardiography remains the goldstandard technique in selected cases.

1340 Thrombolysis in stuck bileaflet heart valves: experience in 25 episodes

Y. Shapira, I. Herz, M. Vaturi, Y. Birnbaum, B. Strasberg, A. Sagie. *Cardiology Dept., Rabin Medical Center, Tel Aviv, Israel*

Thrombosis is a serious complication of prosthetic heart valves. A re-do operation carries a substantial risk. Current therapeutic recommendations are partially based on older valve models and inclusion of patients with high-risk thrombi. We present our experience with thrombolysis in bileaflet heart valves.

Thirteen patients (M/F = 3/10, age 54.0 ± 16.1, range 32–75) experienced 25 episodes of valve thrombosis over a 28-month period. The valves involved were mitral (13 episodes), tricuspid (11 episodes), and both valves (1 episode). In only 7 episodes (28%) admission INR was >2.5. The diagnosis was raised in all cases clinically and by TTE, and confirmed in all by fluoroscopy (n = 24) and/or TEE (n = 17). One leaflet was involved in 11 episodes, and both leaflets were affected in the others. There was no evidence of a mobile or large (>5 mm) thrombus.

A total of 36 courses of thrombolysis were administered, with streptokinase, urokinase or tPA (11, 8 and 17 courses, respectively). In 11/13 patients (84.6%) a re-do operation was avoided. A full resolution was achieved in 21/25 episodes (84%). Treatment failed in 2 cases [5 courses (13.9%)]. Five courses (13.9%) were interrupted due to adverse reactions. Minor bleeding occurred in 5 courses (13.9%), allergic reaction in 4 (11.1%), and in 5 courses (14.7%) there were transient, vague neurologic complaints, without subjective findings. TPA was more effective than the other agents. A completely occluded leaflet was associated with the lowest success rate [only 6/16 (37.5%) completely successful courses in 10 patients]. Two patients with thrombosed mitral valve, who failed to respond to thrombolysis, were referred to a re-do operation. One died due to pump failure, and the other had a complicated course. Six patients had one or more relapses within 5.2+3.7 months (1–12) from the previous episode, and were given thrombolysis successfully.

In patients with stuck bileaflet valves without large visible clots, thrombolysis offers a valid alternative to surgery, with high success rate and minimal complications. Despite a high recurrence rate, repeated thrombolysis is highly successful.

1341 The utility of transoesophageal echocardiography guidance of thrombolytic therapy in prosthetic mitral valve thrombus

Vedat Koca[1], Tahsin Bozat[1], Cetin Sarikamis[1], Vakur Akkaya[2], Senol Yavuz[1], Ayhan Ozdemir[1]. [1]*Bursa Postgraduate Hospital, Bursa;* [2]*Cardiovascular Research Center, Istanbul, Turkey*

Purpose: The aim of the study is to assess the utility of transesophageal echocardiography (TEE) for guiding thrombolytic therapy in prosthetic mitral valve thrombus.

Method: The study cohort consists of 29 consecutive cases of prosthetic mitral valve thrombus diagnosed from January 1995 to May 1998 and managed according to data obtained from TEE. Three patients with pedunculated thrombus and 5 patients in NYHA functional class (FC) I–II were triaged to surgical treatment. The patients who refused surgery or in NYHA FC III–IV and had unpedunculated thrombus were selected for thrombolytic therapy.

Results: Twenty-one cases (7 male, mean age 47 ± 8 years) were given streptokinase as thrombolytic therapy. The mean duration from surgery was 36 ± 23 months, and the mean duration from onset of symptoms was 9.2 ± 14.3 months. Anticoagulant use was inadequate in 16 (76.2%) patients and adequate in 5 (23.8%) cases. Fourteen cases (66%) were NYHA FC IV, 4 (19%) in FC III and 3 (15%) in FC II. The cardiac rhythm of 10 (47.6%) patients were atrial fibrillation. In the first 24 hours of thrombolytic therapy mitral valve peak and mean gradient decreased from 25.6 ± 4 and 13.8 ± 2.5 mmHg to 11.7 ± 5.3 and 7.1 ± 3.1 mmHg respectively ($p < 0.0001$). Four cases with inadequate response to thrombolysis were treated for an additional 24 hours. The second, third day and 1 month peak and mean transmitral gradients were 10.4 ± 5.8 and 5.9 ± 3.1, 10.3 ± 5.4 and 5.3 ± 3.0, and 9.3 ± 3.2 and 4.4 ± 1.7 mmHg respectively ($p > 0.05$). The mitral valve area increased from 1.0 ± 0.1 cm2 to 2.3 ± 0.7 cm2 at the end of the first month ($p < 0.0001$). Early full success in thrombolysis was achieved in 17 (81%) cases. Three cases (14.3%) had partial success and one case (4.7%) was referred to surgical therapy on the third day because of failure of thrombolysis. Two minor skin bleeds (9.4%) not requiring transfusion was attributed to thrombolytic therapy. One case of successful thrombolysis had a non-fatal stroke after therapy and one case was referred to surgery for recurrent prosthetic mitral valve thrombus at the sixth month of follow-up. Mortality was nil in the surgically treated patients.

Conclusion: It was concluded that TEE guidance for choosing patients for thrombolytic therapy in prosthetic mitral valve thrombus is safe and effective.

1342 Effects of picotamide on thrombus formation and clinical outcomes in patients with mechanical heart valves: a double-blind, randomized, placebo-controlled trial

G. Melandri, B. Descovich, S. Nanni, P. Tricoci, F. Semprini, V. Cervi, O. Leone[1], P. Chieco[1], A. Branzi. *Istituto di Cardiologia, Ospedale S. Orsola-Malpighi, Bologna;* [1]*Anatomia Patologica, Ospedale S. Orsola-Malpighi, Bologna, Italy*

Adding aspirin to warfarin may benefit patients with mechanical heart valves, but the risk of bleeding is increased. In this study we investigated the effects of the dual thromboxane synthase inhibitor/thromboxane A2 receptor antagonist picotamide on thrombus formation and clinical events in patients with mechanical heart valves.

Methods: 39 patients aged 18–75 years were randomly treated with picotamide or placebo over 4 months according to a double-blind protocol. Thrombus formation was investigated ex-vivo in a perfusion chamber (Badimon) allowing native blood to flow at low (212 sec^{-1}) and high (1690 sec^{-1}) shear rate. Thrombotic burden was measured by computerized morphometry of the deposition on porcine arterial segments (mild or deep vascular injury). Clinical events, INR values (target INR 2.5–3.5), bleeding time, β-thromboglobulin, platelet factor 4 and prothrombin fragment 1+2 were also obtained.

Results: Picotamide was extremely well tolerated over 4 months (no excess of major or minor bleeding compared with placebo, no interference with INR values, no changes in haematocrit values, no prolongation of the bleeding time). Duplicate measurements of thrombus deposition yielded a good correlation ($r = 0.688$, $p < 0.0001$). Picotamide decreased the ex-vivo thrombus formation on deep vascular injury at high shear rate (picotamide: 2834 ± 1247 vs 1552 ± 879 micron^2/mm, $p < 0.0001$; placebo 1492 ± 731 vs 1655 ± 890 micron^2/mm, p = NS) but not at low shear or in presence of mild injury. Systemic markers of thrombosis were not affected by the treatment.

In conclusion, thromboxane A2 blockade by picotamide may decrease thrombus formation at high shear rate (typically occurring near hinges or pivots of mechanical heart valves), apparently without side-effects. A large-scale trial may be warranted.

1343 Oral anticoagulant therapy (OAT)following heart valve replacement (HVR): comparison of a daily fixed 2.5 mg with a 5 mg, INR-adjusted, dose

W. Ageno, A.G.G. Turpie[1], L. Steidl, F. Ambrosini, R. Cattaneo, B. Nardo, R.L. Codari, N. Castelli, G. Tarelli, A. Venco. *Dept of Clin and Biol Sciences, University of Insubria, Varese, Italy; [1]McMaster University, Hamilton ON, Canada*

We have previously observed that patients starting OAT following HVR are more sensitive to warfarin (W) than non surgical patients. They also require an initially lower target INR (2.0, range 1.5–2.6) because of a higher risk of bleeding until pericardial wires are removed. In a randomized trial, we compared a fixed, lower dose of W (2.5 mg) with the standard treatment during the first 5 days of OAT in HVR patients.

Methods: The study was carried out at the Hamilton Civic Hospitals, Canada and at the University Hospital of Varese, Italy. Patients were randomized to receive a loading 5 mg dose of W then adjusted to a target INR of 2.0 (range 1.5–2.6) or a fixed 2.5 mg dose. INRs were measured daily, but fixed dose was only modified on day (D) 3 if the INR was <1.5 or >3.0.

Results: Of the 245 patients enrolled (123 in the 5 mg group and 122 in the 2.5 mg), 197 were eligible (113 and 84 respectively) and 48 excluded (10 and 38 respectively) because the protocol was not respected without an evident clinical reason. Daily management of the study was left to the same physicians or registered nurses usually in charge of the patients in order to not interefere with the routinary activity in the wards. The 2 groups were well matched according to age, gender, height, weight, body mass index, concomitant treatments, and type of valves implanted. The proportion of INRs > 2.6 during the study period was reduced from 42.5% in the 5 mg group to 26.2% ($p < 0.05$) in the 2.5 mg group, and the proportion of INRs > 3.0 on D3 from 23.9% to 9.5% ($p < 0.05$) respectively. In the 2.5 mg group, 35.7% of patients had a D3 INR < 1.5 and had the dose increased (vs 3.5%, $p < 0.001$), but in the 5 mg group 95.6% had the initial dose reduced, 49.6% had the dose withheld for at least 1 day, and the mean dose during the 5 days of study was 3.08 mg. Average time to achieve therapeutic range was higher in the 2.5 mg group (2.72 vs 1.98, $p < 0.0001$), but the approach to the targeted INR was more regular (D2: 1.66 vs 2.27, D3: 1.91 vs 2.46, D5: 1.99 vs 2.21, $p < 0.0001$). There were no bleeding nor thromboembolic complications in both groups.

Discussion: Starting OAT with a lower dose of W in HVR patients reduces the rates of excessive anticoagulation, and gives a more stable achievement of the therapeutic target by reducing the number of dose adjustments. In the fixed dose group, 44% of the patients never required a dose adjustment, and 42% had 1 adjustment on D3. Nevertheless, because of the large individual variability in W response, a daily monitoring of the INR is still recommended.

NEW ASPECTS OF AORTIC DISSECTION

1344 Accuracy of transthoracic echocardiography imaging for the diagnosis of acute aorta dissection

M. Zairis, S. Argirakis, S. Manousakis, A. Stefanidis, D. Vitalis, C. Ramos, G. Vitsas, K. Perdikouris, S. Handanis, S. Foussas. *Cardiology, Tzanio Hospital, Piraeus, Greece*

Objectives: We sought to determine the diagnostic accuracy of transthoracic echocardiography (TTE) in patients (pts) survived an acute aortic dissection (AD).

Methods: We studied 36 consecutive pts (mean age 54 ± 10 years old) with the diagnosis of acute (AD) confirmed by transesophageal echocardiography (TEE) performed just on their admission. Out of 36 pts 18 (50%) had a De Bakey type I, 10 a type II and 8 type III. Subsequently a TTE performed from investigator unaware of the results of TEE(during patient's preparation for surgery).

Results: We found the following abnormalities with either method.

– Pericardial effusion (TTE: n = 6/17% – TEE: n = 6/17%).
– Aortic regurgitation (TTE: n = 17/47% – TEE: n = 17/47%).
– Aortic dilatation (TTE: n = 30/83% – TEE: n = 33/92%).
– False lumen and intimal flap (TTE: n = 21/58% – TEE: n = 36/100%).
– Thrombus and echocontrast in the false lumen (TTE: n = 0/0% – TEE: n = 11/31%).

Conclusions: Our results show that the TTE has 100% diagnostic agreement with TEE for pericardial effusion and aortic regurgitation and ninety per cent for aortic dilatation. The TTE can manifest the false lumen and intimal flap for 58% of the cases. Therefore the diagnosis of acute AD become suspected approximately for 90% of the cases (aortic dilatation, pericardial effusion, aortic regurgitation). The diagnosis becomes odds-on for 58% with the manifestation of false lumen-intimal flap. Farther experience with the TTE for the diagnosis of AD will increase the diagnostic accuracy of this method.

1345 Aortic root replacement with preservation of the aortic valve – five years experience

W. Harringer, K. Pethig, C. Hagl, K. Kallenbach, A. Haverich. *Thoracic and Cardiovascular Surgery, Hannover Medical School, Hannover, Germany*

Background:

Reimplantation of the native, structurally intact aortic valve within a Dacron tube graft in patients with aortic root aneurysm corrects annular ectasia as well as dilatation of sinotubular junction. Durability of this valve repair with respect to increased mechanical stress on valve cusps is discussed controversially and yet unknown.

Methods and Results: From 7/93 to 1/99 replacement of the ascending aorta with repair of the aortic valve was performed in 81 patients (56 male, 25 female; 50 ± 19 years). Twenty-two patients (27%) had a Marfan syndrome and 12 patients (15%) had an aortic dissection type Stanford A (6 acute, 6 chronic). In 20 patients (25%), concomitant replacement of the aortic arch was necessary. In 6 patients (7%) an additional Trusler valvuloplasty was performed to achieve perfect cusp coaptation. Clinical and echocardiographic follow-up was performed in 6–12 months intervals for a cumulative study period of 140 patient years.

There were no operative deaths. Two patient (3%) died 5 and 20 months postoperatively. One additional patient experienced a TIA within the first post-operative week. Three patients (4%) with progressive aortic insufficiency (AI) required aortic valve replacement after 9, 11, and 14 months. All other patients have no or mild aortic insufficiency. The repair now remains stable for up to 70 months (mean: 22 ± 20 months). Other valve related complications did not occur.

Conclusions: Our results demonstrate that this type of aortic valve repair achieves excellent results in selected patients. Perfect coaptation of valve cusps during the repair with no or only trace AI at initial echocardiography seems to be essential for durability.

1346 Predictive factors of thoracic aorta enlargement in type B aortic dissection follow-up

A. Evangelista, M. Mateos, A. Salas, M.T. González Alujas, A. Salas, M.C. Sebastia, R. Dominguez, J. Soler-Soler. *Cardiology. Vall d'Hebron Hospital: Barcelona, Spain*

Progressive enlargement of descending aorta is one of the complications in the type B aortic dissection follow-up. This study aimed to determine which factors could by related to this enlargement. 74 type B aortic dissection were prospectively studied. Those with Marfan's syndrome or difficult hypertension control were excluded. The remaining 43 patients were followed for more than 3 years (4.7 ± 1.4; range 3–9 y.). Prior to hospital discharge, a TEE was performed in each patient. All had at least a yearly a TEE, MRI or CT.

Results: Descending aorta diameter (DAD) prior to hospital discharge was 42.4 ± 6.5 mm (range: 32–61 mm). 7 patients (16%) had diameter >55 mm. 15 patients had a proximal entry tear, 24 a non-proximal tear and in 4 tear was not detected. Entry-tear was >7 mm in 19 patients and <7 mm in 20. Entry site flow was unidirectional in 7, bidirectional with similar velocities (SD) in 13 and bidirectional with a false-to-true flow predominantly (Sd) in 29. False lumen thrombosis was partial in 12 and total in 4.

On follow-up DAD increased 2.4 ± 2.6 mm per year, range 0–10 mm/y. In 16 patients (37%) DAD did not increase in 16 (37%), it increased mild to moderately (1–4 mm/y) 18 (42%) and increased importantly (> 4 mm/y) 9 (21%). 7 of the 9 cases (78%) with significant enlargement had an entry tear >7 mm with SD flow. In contrast, in patients who did not suffer aortic enlargement, entry tear was >7 mm in only 6 (37%); none had SD flow, 7 had Sd flow and 5 unidirectional flow. No significant differences related to initial DAD (43 ± 7.4 vs 43 ± 5.1 mm) or to partial or total thrombosis (33% vs 50%) were observed.

Conclusions: Some type B aortic dissections (20%) have significant progressive diameter enlargement during follow-up. A wide entry tear with inflow and outflow of similar velocities is related to significant increase DAD. Small size entry tear or a unidirectional entry tear flowlare signs of good prognosis.

1347 Endovascular treatment of complicated aortic dissection

M. Delomez, J.P. Bérégi[1], E.P. Mac Fadden[2], P. Asseman, A. Prat[3], J. Marécaux[1], S. Willoteaux[1], C. Janne d'Othee[1], J.J. Bauchart, C. Thery. *Dept des Soins Intensifs, Institut Cardiologique, Lille; [1]Department of Radiology, Hopital Cardiologique, Lille; [2]CHRU, Hopital Cardiologique, Lille; [3]Department of Surgery, CHRU, Lille, France*

Purpose: To evaluate the acute results and midterm follow-up of percutaneous treatment of visceral and lower limb ischaemia resulting from aortic dissection.

Materials and Methods: Between March 1997 and December 1998, we treated 9 patients (6 men, 3 women) with visceral or lower limb ischaemia secondary to acute aortic dissection (4 Type A, 5 Type B) using direct stenting (n = 4) alone, or in combination with a novel fenestration technique (n = 5)that requires neither endovascular echo guidance nor the use of needle perforation. Fenestration was performed through a single introducer sheath using 2 guidewires to create a longitudinal tear between the true and false lulen. Presenting symptoms and signs included anuria (3), severe hypertension (4), mesenteric ischaemia (3), acute lower limb ischaemia (2), and severe abdominal pain (4). Echodoppler and or helical CT showed stenosis or compression of the renal arteries (10), superior mesenteric artery (4), coeliac axis (3), inferior mesenteric artery (2), or the supra-aortic vessels (1).

Results: After arteriography, 4 patients (2 with mesenteric ischaemia, 1 with renal ischaemia, 1 with lower limb ischaemia) underwent direct stenting of the involved vessels with a good initial result. The other 5 patients, with extensive compression of the true lumen by the dissection had ischaemia involving multiple vessels; they were all successfully treated by fenestration with subsequent renal stent implantation in 2 patients. At follow-up (range 3–16 months), 3 patients were dead (2 deaths were due to extension of the dissection, 1 of undetermined aetiology); the remainder were well with no signs or symptoms of residual ischaemia.

Conclusions: Endovascular treatment has an important role in the management of complications resulting from aortic dissection. While localised compression or ischaemia can be treated by stenting the vessel involved, fenestration with spot stenting is an effective alternative when multiple vascular territories are compromised by the dissection.

1348 Follow-up of aortic aneurysms treated by stent graft implantation using magnetic resonance imaging

E.P. McFadden, X. Hurtevent[1], B. Janne d'Othee[1], H. Warembourg[1], J.P. Beregi[1]. *Service de Cardiologie B, Hôpital Cardiologique, Lille[1] Vascular Radiology Dept., Hôpital Cardiologique, Lille, France*

Purpose: To report our preliminary experience with magnetic resonance imaging in the follow-up of aortic aneurysms treated by stent graft implantation.

Materials and Methods: Between November 1997 and December 1998, 27 patients underwent stent graft implantation (Vanguard, Boston Scientific) as treatment for abdominal aortic aneuryms. Follow-up MRI studies (Vision 1.5T, Siemens) were performed at 1-month (n = 24), 6-month (n = 12), and 12-month (n = 3). The examination included T1-and T2-weighted TSE sequences, a turbo-MRA sequence, and an axial T1-weighted TSE sequence after injection of gadolinium. Helical CTA (Somaton Plus 4) was perfomed at 6 months (n = 12) and 12 months (n = 3), and where a leak was suspected on MRI. Imaging was perfomed in the arterial and late phase.

Results: MRI was performed in all but 3 patients (1 allergic to gadolinium, 1 technical problem, 1 patient lost to follow-up). On the 1-month examinisation (n = 24), thrombuys was observed as a heterogeneous signal on T1- and T2-weighted TSE sequences in 23/24 patients. Gadolinium uptake was observed in 8 of these 23 patients; no uyptake was seen in the patient in whom the signal was homogeneous. A significant leak was also seen on CT in 5 of these 8 patients. Arteriography showed leakage in all 8 patients; all were treated by embolisation. MRI at 6 months found a heterogeneous T2 signal and gadolinium uptake in 4/12 patients, suggestive of a lead that was confirmed on arteriography. Abnormal CT findings were present in 2 of these 4 patients. Overall, 12/24 patients had MRI findings suggestive of leakage, evidenced by abnormal uptake of gadolinium on the early (1 month) scans or by persistence of a heterogeneous T2 signal on the 6 month scan. No leaks were seen at 12-month follow-up.

Conclusions: MRI appears to be mre sensitive than helical CT angiography in the detection of leaks after stent graft implantation for abdominal aortic aneurysms.

1349 Coronary reimplantation by the Cabrol technique: medium-term clinical follow-up

J. Pereira, I. Maté, M. Mateos, L.J. Jiménez-Borreguero, J.L. Merino, J.M. Mesa, A. Garrido, N. Sobrino, A. Sánchez-Recalde, J.A. Sobrino. *UMQ de Cardiologia, Hospital La Paz, Madrid, Spain*

The Cabrol technique for the coronary reimplantation is employed in the replacement of the ascending aorta. The mid-term evolution of these patients is controversial. Our objective was to revise the mid-term clinical evolution and coronary permeability in patients submitted to the Cabrol technique in our centre.

Methods: The study included 14 patients, 13 male and 1 female, mean age 51 ± 12 years. Surgery was indicated for aortic insufficiency associated with annulo-aortic ectasia in 12 patients, and ascending aorta aneurysm in 2 patients None of the patients demonstrated coronary lesions in preoperative coronary arteriography. Chronic oral anticoagulation treatment was initiated in all patients following surgery. Follow-up included clinical examinations and echocardiograph, magnetic resonance (MR) in the 8 surviving patients, and coronary angiography in 4 patients where occlusion of one of the two coronary anastomosis was suspected.

Results: One patient died postoperatively from cardiogenic shock. At follow-up, of the 13 remaining patients, 5 had died (38% mortality at follow-up, 43% global mortality), two of them from inferior myocardial infarct. The single patient submitted to autopsy showed obstruction of the right coronary anastomosis. Of the 8 surviving patients, 3 developed obstruction of the right coronary anastomosis, and one of the left, which were demonstrated through both MR and angiography. In the 4 remaining patients, MR revealed permeability of the coronary systems. Survival free of coronary occlusion was 28% at 4.3 ± 2.9 years, and 26.4% at 7.5 years when applying the Kaplan-Meier survival analysis.

Conclusions: These results suggest that obstruction of the right coronary anastomosis is a frequent complication at follow-up after the coronary reimplantation by the Cabrol technique.

APOPTOSIS

1359 Involvement of apoptosis, Bcl-2 family and P53 in the morphogenesis of the trabecular and compact regions of ventricular wall during cardiogenesis

E. Abdelwahid, L.J. Pelliniemi[1], E. Jokinen[2]. *Pediatrics, Turku University Central Hospital, Turku; [1]Electro microscopy Dept., University of Turku, Turku; [2]Department of Pediatrics, University of Helsinki, Helsinki, Finland*

Although apoptosis is an important feature of normal development and organogenesis, little is known about apoptosis in the developing heart. The molecular regulation of apoptosis via several factors is an area of intensive investigation. We evaluated the role and localisation of apoptosis and apoptosis related genes in the developing ventricular wall of fetal mice hearts by using apoptosis specific labeling (ISEL), Immunocytochemistry and both light and electron microscopy. Fetal mice hearts of 11, 12, 13, 14 and 16 days of gestation were used. Three embryos of each day were fixed in 4% paraformaldehyde, dehydrated and embedded in paraffin. Ten sections (4–5 m) of each embryo were in situ labeled for detection of apoptosis using proteinase-K method, in which digoxigenin attaches to the N-terminal of fragmented DNA and anti-digoxigenin antibody reacts with attached digoxigenin. Fragmented DNA is stained with NBT/BCIP. Ultrastructural identification of apoptotic cells was done by using Jeol JEM-100SX transmission electron microscope. Bcl-2, Bax and P53 were detected immunocytochemically in the corresponding sections of the ventricular wall. The proportions of apoptotic cells of all cells in the ventricular wall differed between the trabeculted and compact regions and between days of gestation (p = 0.0001, 0.0033) respectively, ANOVA for repeated measures). In the looped heart on days 11, 12, 13 of gestation, the proportions of apoptotic cells in the trabeculated (non-trabeculated) regions were 3.2 ± 1.3% (4.4 ± 2%), 2.1 ± 1.1% (2.9 ± 1.8%), 3.6 ± 1.7% (2.8 ± 1.4%) (mean ± SD) respectively. After formation of the four chambers, on days 14 and 16 of gestation, the proportions of apoptotic cells were 2.8 ± 1% (3.3 ± 1.2%), 0.4 ± 0.2% (0.6 ± 0.3%) (mean ± SD) respectively. Electron microscopy confirmed the typical features of apoptotic cells. Bl-2, Bax and P53 expression was observed during early and late embryonic development at the same period when apoptosis took place in different cell types. We conclude that apoptosis is active phenomenon both the trabeculated and non-trabeculated parts of the ventricular wall in the developing mouse heart of days 11, 12, 13, 14 and 16 of gestation. The expression of bcl-2, Bax and P53 may indicate additional role in the differentiation process. This is a very active period of ventricular growth. Thus, apoptosis and its regulation are tightly integrated components in the morphogenesis of the ventricular wall of the mammalian heart.

1360 17β-Oestradiol reduces caspase-3 activity: a mechanism for the anti-apoptotic effect of oestrogen in cardiac myocytes

T. Pelzer, T. De Jager, M. Schumann, J. Muck, L. Neyses. *Department of Medicine, University of Wuerzburg, Wuerzburg, Germany*

Introduction: Cardiac myocyte apoptosis as a mechanism leading to heart failure is currently under discussion. One of the key events in apoptosis is the activation of caspase-3 which finally leads to death of the cell. We have previously shown that cardiac myocytes contain functional estrogen receptors and thereby identified the heart as a target for estrogen. It is known that estrogen has an anti-apoptotic effect in breast carcinoma and therefore we have asked the question whether estrogen can reduce cardiac myocyte apoptosis.

Methods and Results: Isolated rat cardiac myocytes were treated with physiological concentrations of 17β-estradiol (E2, 10 nM) for 24 hours followed by induction of apoptosis by 100nM staurosporine. Morphological assessment, TUNEL assay and cell nuclei fragmentation analysis by Hoechst dye staining showed a reduction of the number of apoptotic cells by E2. To investigate the underlying mechanism involved, we have observed a 45 ± 6% reduction of caspase-3 activation by E2. Western blot analyses of the anti-apoptotic proteins Bcl-2 and Bcl-XL and the pro-apoptotic BAX protein revealed no change in the amount of these proteins.

Discussion: The prevention of cardiac myocyte apoptosis may be one of the cardioprotective effects of estrogen.Identification of the exact underlying mechanism may therefore be an important starting point for developing new treatment strategies for heart disease.

1361 Occurrence of apoptosis in specific cell types in isolated perfused rat hearts exposed to ischaemia and reperfusion

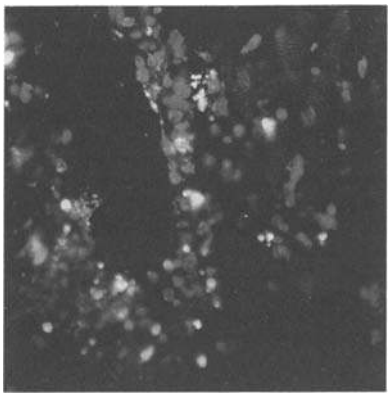
T.M. Scarabelli, N.B. Rayment[1], R.A. Knight[2], T.J. Cooper[2], A. Stephanou[3], B. Brar[3], D.S. Latchman[3], G.F. Baxter, D.M. Yellon. *UCL Hospitals and Medical School, The Hatter Institute, London; [1]Department of Immunology, Royal Free and UCL Medical School, London; [2]Department of Cystis Fibrosis, Imperial College, London; [3]Department of Molecular Pathology, Windeyer Institute of Medical Sciences, London, UK*

Apoptosis is a particular type of cell death implicated in the aetiology of ischaemia/reperfusion injury.

The apoptotic process has been seen to affect cardiac myocytes of ischaemic/reperfused hearts, occurring primarily during reperfusion. Nonetheless, the occurrence of apoptosis in specific cell types, with particular reference to the earliest stages of reperfusion, has still to be clarified.

Materials and Methods: Isolated Langendorff perfused rat hearts were randomly divided into three groups: control group (n = 6), subjected to 60′ of perfusion; ischaemic group (n = 6) exposed to 35′ of regional ischaemia and ischaemic/reperfused group (n = 6), exposed to 35′ of regional ischaemia followed by 5′ of reperfusion. Hearts were cross-sectioned into slices which were fixed in 4% formaldehyde and embedded in paraffin. Serial 5 microns sections were cut, dewaxed and incubated with trypsin. After the employment of TUNEL assay, sections were labelled with anti-desmin antibody, in order to accurately address apoptosis in specific cell types and counterstained with propidium iodide (PI).

Results: Apoptosis was seen only in sections from hearts subjected to ischaemia and reperfusion. In ischaemic/reperfused hearts the number of TUNEL positive cells was significantly higher in endothelial cells (24 ± 3%) than in cardiac myocytes (4 ± 1%). In the same sections the most common pattern of TUNEL staining was represented by rings of positive cells within the wall of vessels of different sizes. Amongst these, the largest may be surrounded by a few positive cardiac myocytes easily recognisable by the red desmin-banding of the cellular body (figure).



Conclusions: The data show that cells within vessel walls are the predominant cell type affected by apoptosis in the very early stage of reperfusion.

1362 Chronic hypoxia induces apoptosis in cardiac myocytes: a possible role for the apoptotic markers Bcl-2 and Bax

F. Jung, U. Weiland, A.M. Zeiher, S. Dimmeler. *Dept. of Internal Medicine IV, Molecular Cardiology, University of Frankfurt, Germany*

Although ischemia and myocardial infarction can trigger apoptosis in cardiac myocytes, the effect of prolonged hypoxia/ischemia as well as the molecular mechanisms are not well established. Studies in different cell types have proposed a possible anti-apoptotic role of the Bcl-2 protein in hypoxia-induced apoptosis. Here we demonstrate the effect of chronic hypoxia on the expression of the anti-apoptotic Bcl-2 and the proapoptotic Bax protein in hearts from rats exposed to chronic hypoxia.

Methods: Adult rats were exposed to hypoxia (n = 4) or normoxia (n = 4) for 3 weeks. Hearts from hypoxic rats showed an increased rate of apoptosis as demonstrated by increased DNA fragmentation compared to hearts from normoxic animals. Bcl-2 protein expression was significantly decreased ($p < 0.05$), whereas Bax expression was increased, up to 3 fold, ($p < 0.05$) in myocardium from animals exposed to chronic hypoxia (n = 4) compared to normoxia (n = 4). As previously demonstrated, overexpression of p53 can induce apoptosis in cardiac myocytes possibly via modulation of Bcl-2 and Bax expression. Our results demonstrate an increased p53 expression, about 2-fold, in hearts from hypoxic rats compared to normoxic rats.

Conclusion: These results demonstrate for the first time in vivo an increased apoptosis rate in hearts from rats exposed to *chronic* hypoxia compared to normoxia, accompanied by a significant decrease of Bcl-2 and an increase of Bax protein expression in hypoxic hearts. These results suggest a possible role of these markers in hypoxia induced cell death, most likely dependent of p53. Additional studies are needed in vivo and in vitro to further elucidate the role and regulatory mechanisms of Bcl-2 and Bax protein expression in hypoxia induced apoptosis in cardiac myocytes.

1363 Prolonged effect of cardiomyocyte apoptosis on ventricular remodelling after myocardial infarction in rats

E. Palojoki, A. Saraste[1], A. Eriksson[2], L.M. Voipio-Pulkki[3], I. Tikkanen. *Department of Medicine, Helsinki University Central Hospital, Helsinki; [1]Department of Anatomy, University of Turku, Turku; [2]Minerva Institute for Medical Research, Helsinki; [3]Medicine Dept., University of Turku, Turku, Finland*

Apoptotic cardiomyocyte death (CA) occurs in acute myocardial infarction (AMI) and in heart failure both in experimental animals and in man. To clarify the role of CA in the post-AMI remodelling process, we studied the amount and site of CA during 12 weeks after experimental AMI in rats.

Methods: AMI was produced by ligating the proximal LAD coronary artery in adult male Wistar rats. Sham-operated animals were used as controls. Rats were sacrificed and myocardial samples obtained at 24 hrs and at 1, 4 and 12 weeks post AMI. In histological sections, the infarcted area was demarcated and apoptotic cardiomyocytes quantified (TUNEL assay) in the areas adjacent to infarction and in the remote non-infarcted tissue. To measure left ventricular (LV) end-diastolic dimension (LVDD) and ejection fraction (EF), echocardiography was performed at baseline, at 24 hrs and at 1 and 4 weeks after LAD ligation.

Results: Sham-operated animals showed no statistically significant change in LVDD or EF during the study. Also CA was low (0.04 ± 0.02%, mean ± SD) and remained stable during the study. At 24 hrs, TUNEL positivity was observed in up to 8.5% of total cardiomyocytes in the infarcted areas. In the remote non-infarcted areas, CA was already elevated at 24 hrs (0.09 ± 0.04%, $p < 0.05$ vs. sham) and remained increased at 1 week (0.11 ± 0.09%, $p < 0.05$). However, at 4 and 12 weeks CA in the remote myocardium did not differ from control samples. In contrast, CA was more frequent in the peri-infarct zone: 0.34 ± 0.18% at 1 week, decreasing thereafter gradually but remaining at 0.13 ± 0.04% ($p < 0.05$) even after 12 weeks. By echocardiography, mean LVDD increased gradually from 24 hrs to 1 week (+3.8% vs. baseline) and to 4 weeks (+11.1% vs. baseline) whereas mean EF showed no significant change during the study.

Conclusions: Post-AMI LV remodelling, assessed as progressive increase of LVDD, parallelled the occurrence of cardiomyocyte apoptosis in both the remote and peri-infarct areas up to 1 week after experimental AMI in rats. In contrast, prolonged and remarkable increase of CA was observed only in viable areas adjacent to the infarct scar as long as 12 weeks post AMI. This probably contributed significantly to the extended LV dilatation and remodelling after coronary artery occlusion.

1364 Simvastatin modulates nitric oxide synthase expression and myocytic apoptosis induction after acute ischaemia in isolated rat hearts

P. Di Napoli, R. Spina[1], A.A. Taccardi[1], A. Maggi[1], A. Di Crecchio[1], G. Ranalli[1], G. Vianale[1], L. Stuppia[2], G. Palka[2], A. Barsotti[1]. *Cardiology Dept, Casa Di Cura Villa Pini, Chieti; [1]Cardiology Dept, University of Chieti, Chieti; [2]Med. Genetic, Inst. of Cytomorphology, University of Chieti, Chieti, Italy*

Previous studies have suggested that Simvastatin (S), an inhibitor of B-hydroxy-B-methylglutaryl-coenzyme A (HMG-CoA), may exert an endothelial-protective and anti-ischemic effects via nitric oxide (NO) mediated mechanism. The aim of this study was to evaluate the effects of acute S administration on endothelial and inducible NO-synthase (e-NOS and i-NOS) mRNA expression and myocytic apoptosis after ischemia-reperfusion (I/R).

Isolated working rat hearts were used (Neely's technique) and submitted to 15 min. global ischemia and 190 min. reperfusion. To detect myocytic apoptosis we used DNA agarose gel electrophoresis and TUNEL technique; e-NOS and i-NOS expression were evaluated by multiplex RT-PCR; glyceraldheyde-3-phosphate deydrogenase (G-3PDH) was used as internal standard. The e-NOS and i-NOS mRNA were expressed as G-3PDH/e-NOS and G-3PDH/i-NOS densiometric ratio.

Hearts were divided into four groups: A) hearts excised and used as histological controls; B) hearts submitted to I/R; C) hearts treated with actinomycin D, an inhibitor of genic transcription (1.5 mg/kg); perfused with 25 μM S, subjected to I/R; D) hearts perfused with S 25 μM and submitted to I/R.

In group B we evidenced a significant myocytic apoptotic damage, reduced in C and D groups. In B group an increase in G-3PDH/e-NOS ratio vs A group was detected; in D group a reduction in G-3PDH/e-NOS ratio vs B group occurred; no significant changes were observed between C and D groups. G-3PDH/i-NOS ratio was significantly increased in D group respect to A and B groups.

Our data point out that S acutely modulates NO-synthase mRNA expression (induction of e-NOS mRNA expression and inhibition of i-NOS post-ischemic over-expression) by a post-transcriptional mechanism and reduces myocytic apoptosis.

TRANSGENIC MODELS

1365 Kinetics, toxicities, and efficacies of new transfection reagents: increased cellular uptake of antisense-oligonucleotides encapsulated into GS 2888 Cytofectin®

D.I. Axel[1], R. Riessen[1], H. Runge[1], R. Viebahn[2], K.R. Karsch[1]. *[1]Medical Clinic III, Dept. of Cardiology; [2]Dept. of Surgery, University of Tübingen, Germany*

Transfection of cells with viral vectors or antisense oligonucleotides (ASO) is of major interest for both experimental studies, as well as therapeutical options. In restenosis, growth of human arterial smooth muscle cells (haSMC) is stimulated by the paracrine PDGF release of human arterial endothelial cells (haEC) and the autocrine secretion of TGF-β1. Transfection with ASO against the mRNA of PDGF and TGF-β1 might be an interesting therapeutical concept but requires sufficient transfection efficacy.

Methods: Viability of haSMC and haEC 24, 48, or 72 h after transfection with the liposomes Lipofectin® (LF), GS 2888 Cytofectin® (CF), and DAC-30® and the dendrimer Superfect® (SF) for 1, 2, 3, 4, 5 h was examined in MTT-tests. Uptake studies were performed with FITC-labeled mismatch control-oligos and specific ASO with or without incorporation into transfection reagents. Effects of ASO on PDGF-AB and TGF-β1 protein production was studied in conditioned media by ELISA and Western blotting, effects on mRNA-expression were examined by non-radioactive Northern blotting.

Results: In contrast to SF > 3 μg/ml, DAC-30 and CF showed no significant toxic effects on haSMC. Addition of LF to serum-containing medium caused cell detachment. At haEC, SF and CF showed the less toxic effects. Fluorescence microscopy of FITC-labeled ASO demonstrated no remarkable intracellular incorporation of naked ASO. In contrast, transfection with CF- or SF-encapsulated ASO showed a strong cytoplasmic labeling after 1–2 h and a nuclear labeling after 4–6 h. With DAC-30, just a slight cytoplasmic labeling after 6 h was found. Interestingly, SF caused a 10-fold stimulation of PDGF-AB secretion by haEC independently of the ASO-effects. Thus, CF-encapsulated ASO (0.05–2.0 μg/ml) were used in order to inhibit PDGF-AB secretion of haEC and TGF-β1 release by haSMC. ELISA, Western and Northern blots showed a significant inhibition of PDGF-AB and TGF-β1 expression with a 50% inhibition at 0.5 μg/ml after 3–5 h transfection. High ASO-doses > 2 μg/ml and transfection periods > 5 h caused toxic effects. Mismatch control-oligos did not influence PDGF-AB and TGF-β1 expression.

Conclusions: New transfection reagents, such as SF or CF showed an improved transfection efficacy and less toxicity than the 'classical' liposom LF. Depending on the structure and cell type, an unspecific activation of cells may occur. CF was found to be superior to other transfection reagents at haSMC *and* haEC and thus offers a promising therapeutic concept with encapsulated antisense oligonucleotides e.g. against growth factors.

1366 Delivering adenoviral vectors to rabbit myocardium: effect of dose and method of delivery on efficiency and micro-infarction

A. Docherty, M.N. Hicks, G.L. Smith[1], S.M. Cobbe, H.M. Prentice[1]. *Department of Medical Cardiology, Royal Infirmary, Glasgow; [1]IBLS, University of Glasgow, Glasgow, UK*

In vivo adenoviral mediated gene transfer through the coronary circulation may prove valuable in models of gene therapy and for functional experiments on cardiac tissue following infection.

In adult New Zealand white rabbits we have compared a minimally invasive selective right coronary injection technique with an aortic cross-clamp technique at open thoracotomy. We used replication deficient adenoviral vectors encoding a beta-galactosidase reporter gene. Animals were sacrificed 5 days after viral introduction for tissue histochemistry and the proportion of positively staining cardiomyocytes calculated by point counting.

Right coronary injections were performed using 1 ml of vector at a concentration of 5×10^9 plaque forming units (pfu)/ml (n = 6) and in a separate group, 1 ml of 1×10^{10} pfu/ml (n = 8). In the low dose group beta-galactosidase reporter gene expression was localised morphologically to perivascular cardiac myocytes and non-myocytes in the right ventricles of 5 animals. In these animals 2.6% (range 1.2%–4.3%) of right ventricular (RV) cardiomyocytes stained positively for the reporter gene product. The heart of one animal displayed areas of lymphocyte infiltration with associated cardiomyocyte cell death (micro-infarction). In the high dose group, reporter gene expression was found in the hearts of 7 animals. In these animals 4.3% (range 0.2%–11%) of RV free wall cardiomyocytes and 10% (range 0.2%–31%) of RV trabecular cardiomyocytes stained positively for the reporter gene product. However, all of these animals displayed areas of micro-infarction. In each animal the left ventricular free wall served as a non-infused control. Animals infused with an adenoviral vector encoding a skeletal troponin c mutant under the control of a human cardiac actin promoter served as infused controls. None of the control tissues stained positively for the reporter gene product beta-galactosidase.

In an aortic cross-clamp group (n = 8) each animal received 1 ml of vector at a concentration of 1×10^{10} pfu/ml. Only occasional positively staining cardiomyocytes were found in the epicardial region of both ventricles, amounting to less than 1% of ventricular cardiomyocytes. None of the right ventricular trabeculae from this group stained positively for the reporter gene product.

We conclude that adenoviral mediated gene transfer to rabbit myocardium is more efficiently achieved by selective coronary injection than by the aortic cross-clamp technique. However, high dose coronary infusion is commonly associated with areas of micro-infarction.

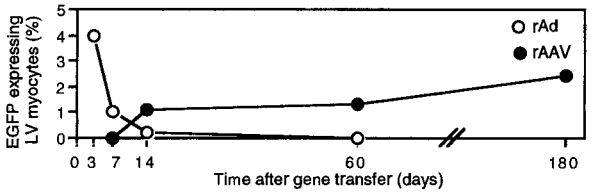
1367 In vivo gene transfer into mouse myocardium and arteries: a comparison of recombinant adenovirus and adeno-associated virus vectors

Giuseppe Vassalli[1,2], Hansruedi Büeler[3], Christel Sadeghi[2], Lukas Kappenberger[1], Patrick Aebischer[2]. *[1]Division of Cardiology; [2]Division of Surgical Research and Gene Therapy Center, CHUV, Lausanne; [3]Institute of Molecular Biology, University, Zurich, Switzerland*

The aim of the present study was to compare recombinant adenovirus (rAd) and adeno-associated virus (rAAV) for myocardial and arterial gene transfer.

Methods: rAd (titer: 5 × 10E9 PFU/mL) and rAAV (titer: 2 × 10E7 TU/mL) expressing a green fluorescent protein (EGFP) marker gene from a CMV promoter were used in the present study. Vectors with no EGFP gene were used as controls (C). Myocardial gene transfer was carried out by virus injection (2 μl) into the anterior LV wall in open-chest CD1 mice (n = 22). Hearts were explanted at various time points after gene transfer and EGFP expressing myocytes were counted on heart slices (n = 5 per heart) by fluorescence microscopy. Arterial gene transfer was carried out by infusion of either virus into mouse carotids (n = 3 each). EGFP expressing endothelial cells were counted on arterial sections (n = 30 per vessel).

Results: Myocardial gene transfer: EGFP expressing myocytes (in % of LV myocytes on heart slices) peaked at 3 days with rAd (median value: 4%; range: 3–14%) and at 180 days with rAAV (2.5%; 1–4%; C = neg.). Gene transfer was focal with up to approximately 30% transduced cells with rAd and 20% with rAAV at the injection site. The time course of gene expression (median values) was as follows:



Arterial gene transfer: EGFP expressing endothelial cells in mouse carotids were 13% (8–30%) after gene transfer with rAd vs. 2% (0–3%) with rAAV.

Conclusions: Under the study conditions (virus titers), rAAV was nearly as efficient as rAd at transducing mouse myocardium but less efficient than rAd at transducing arteries. Gene expression is rapid but short-lived with rAd, slow but stable with rAAV. These data show that rAAV is a good candidate vector for gene therapy of chronic cardiac diseases, where longterm gene expression is required.

1368 Reduction of G-protein β-subunits in atrial cardiomyocytes leads to abnormal sinus node automaticity in mice

J. Gehrmann, M. Meister[1], C.T. Maguire, U. Mende[1], E.J. Neer[1], C.I. Berul. *[1]Boston Children's Hospital, Brigham MA; Women's Hospital, Harvard Medical School, Boston MA, USA*

Background: Acetylcholine, acting through M_2-muscarinic receptors coupled to a G-protein system, slows heart rate by opening the atrial muscarinic I_{KACh} channel. This channel is directly activated by $\beta\gamma$-subunits released from G-proteins. In sinus node cells, activation of this channel decreases spontaneous depolarization (pacemaker activity) and slows conduction velocity in the atrioventricular node.

Objective: To determine, whether the reduction of G-protein β-subunits in the membrane of atrial myocytes in transgenic mice (TG) affects sinus node pacemaking function and atrioventricular conduction at baseline (BL) and after pharmacologic stimulation with the M_2-muscarinic receptor agonist carbachol (CCH).

Methods: Surface electrocardiograms (ECG) and intracardiac electrophysiology (EP) studies were performed in TG with a 50–60% reduction of β-subunits in atrial cardiomyocytes, and wild-type (WT) controls. The RR, PR, QRS and QT intervals were measured on surface ECG. Sinus node recovery times (SNRT, CSNRT), AV refractory periods (AVERP), paced AV and VA Wenckebach cycle lengths (AV/VA-W), paced AV 2:1 cycle lengths, and ventricular effective refractory periods (VERP) were assessed by EP study.

		SNRT	CSNRT	AvERP	AV-W	vA-W
WT	BL	360 ± 49	155 ± 49	75 ± 5	89 ± 7	103 ± 10
	CCH	348 ± 53	125 ± 49	80 ± 6	90 ± 8	107 ± 14
TG	BL	213 ± 51*	60 ± 33*	84 ± 11	96 ± 8	120 ± 10
	CCH	181 ± 72*	51 ± 39*	74 ± 15	84 ± 8	100 ± 17

(* = p < 0.01, TG vs WT; values in ms)

Results (see table): SNRT and corrected SNRT (CSNRT) were significantly decreased in TG compared to WT mice at baseline, as well as after parasympathetic stimulation. There were no significant differences in ECG or other EP parameters between groups.

Conclusions: Sinus node automaticity (spontaneous depolarization) is increased as a result of G-protein β-subunit reduction in atrial cardiomyocytes. Reduction of G-protein $\beta\gamma$-subunits constitutes the molecular mechanism responsible for I_{KACh} channel malfunction and abnormal parasympathetic heart rate regulation.

1369 A targeted disruption of connexin40 leads to abnormal heart rate regulation in mice

J. Gehrmann, C.T. Maguire, P.E. Hammer, L.M. Bevilacqua, A.M. Simon, J.K. Triedman, D. Paul, C.I. Berul. *Boston Children's Hospital, Harvard Medical School, Boston MA, USA*

Background: Electrical coupling of pacemaker cells at gap junctions, formed by connexins, appears to play an important role in sinus node function. Connexin40 (Cx40) is widely distributed in the sinus node region. Electrical cell-to-cell uncoupling by Cx40 disruption may result in action potential generation delay and loss of shielding the primary pacemaker from the atrial hyperpolarizing influence.

Objective: The purpose of this study was to determine, whether a homozygous deletion of Cx40 ($Cx40^{-/-}$) in mice affects action potential generation and sinus node pacemaker synchronization.

Methods: We developed a method to compute heart rate variability (HRV) analysis in mice. Implantable telemetry devices were used to record conscious heart rate (HR) in 6 transgenic ($Cx40^{-/-}$) and 7 control mice ($Cx40^{+/+}$). Autonomous influences on HR were quantified by standard frequency domain techniques of HRV analysis. Low (LF) and high (HF) frequency bands were defined as 0.4–1.5 and 1.5–4 Hz respectively. LF and HF were also measured in normalized units (LFn, HFn), and LF/HF ratio, reflecting sympathetic/parasympathetic balance, was calculated.

Results: Mean and median RR intervals were significantly increased in $Cx40^{-/-}$ mice. LF and HF bands were increased in $Cx40^{-/-}$ compared to control mice. The LF/HF ratio was also increased in Cx40-deficient mice.

	$Cx\ 40^{+/+}$	$Cx\ 40^{-/-}$	P
RR mean (ms)	88 ± 4	110 ± 19	0.01
RR median (ms)	88 ± 5	110 ± 20	0.01
LF (ms^2)	2.7 ± 2.3	23.9 ± 24.8	0.04
HF (ms^2)	7.2 ± 5.5	19.2 ± 12.8	0.04
LFn	0.25 ± 0.1	0.52 ± 0.19	0.01
HFn	0.75 ± 0.1	0.48 ± 0.19	0.01
Ratio (LFn/HFn)	0.38 ± 0.3	1.34 ± 0.82	0.01

Conclusions: Cell-to-cell communication within the murine sinus node is mediated through gap junction channels formed by connexin40. Electric impulse propagation is impaired in Cx40-deficient mice reflected by decreased basal heart rate and pacemaker desynchronization (increased heart rate variability).

1370 Increased velocity of shortening and relengthening in adult rat cardiomyocytes after S100A1 adenoviral gene transfer

P. Most[1], S.T. Pleger[1], A.D. Eckhart[2], C.W. Heizmann[3], W.J. Koch[2], H.A. Katus[1], A. Remppis[1]. *[1]Medizinische Klinik II, Medizinische Universität zu Lübeck, Germany; [2]Department of Surgery, Duke University, Durham NC, USA; [3]Klinische Chemie und Biochemie, Kinderspital Zürich, Universität Zurich, Switzerland*

A compromised contractility in human end stage heart failure is correlated with a decrease in Ca^{2+} release from the sarcoplasmatic reticulum (SR) during systoly. Since S100A1 has been shown to enhance the caffeine induced Ca^{2+} release from SR we hypothesized that S100A1 overexpression might improve contractility and thus would be an attractive candidate for gene therapy of heart failure.

Isolated adult rat cardiomyocytes were transfected with an adenoviral construct containing S100A1 cDNA under the control of a CMV promotor. Green fluorescent protein (GFP) served as reporter protein. Efficacy of transfection was controlled by GFP detection, S100A1 overexpression was documented by Northern and Western blotting. Non-transfected (NT) and empty virus transfected (EV) served as controls. Myocytes were stimulated with 5 ms pulses at 1 Hz. Shortening and relengthening of myocytes were measured by a video edge detection system. There was no significant difference between NT and EV cells concerning contractility thus excluding effects by the empty virus. S100A1 overexpression lead to an increased velocity of shortening (−dL/dt; +19%; p = 0.02) and of relenghtening (+dL/dt; +19%; p = 0.03) as well as an increase of cell shortening (CS; +22%; p = 0.01). These data demonstrate for the first time that adenoviral S100A1 overexpression improves contractility of cultured adult rat cardiomyocytes.

1392 Can coronary flow velocity patterns predict the improvement of left ventricular function after successful reperfusion for acute myocardial infarction?

T. Takahashi, Y. Hiasa, T. Harada, J. Yamashita, N. Suzuki, H. Miyamoto, S. Hosokawa, K. Kishi, M. Tanimoto, R. Otani. *Komatsushima Red Cross Hospital, Komatsushima, Japan*

The aim of this study was to assess coronary flow velocity (CFV) patterns after successful reperfusion for acute myocardial infarction (AMI) as a predictor of left ventricular function improvement.

Methods: Using a Doppler guidewire, we measured CFV and coronary flow reserve (CFR; ATP i.c.) in 50 AMI patients (pts) immediately after successful primary balloon angioplasty or stenting. The measurements were repeated at 1 month and at 3–6 months follow up. Left ventricular ejection fraction (LVEF) and regional wall motion (RWM; 1 = normal, 4 = aneurysmal) were evaluated by left ventriculography at 1 month and at late follow up.

Results: In 38 pts without restenosis (LAD = 20, LCX = 5, RCA = 13), 16 pts showed low systolic peak velocity (SPV; <10 cm/see) and high diastolic systolic velocity ratio (DSVR; ≥3) (G1) and 22 pts showed normal pattern (G2). Among G1, increase of SPV and normalization of DSVR were observed in 6 pts (G1B). Other 10 pts in G1 showed no significant change of CFV patten (G1A).

	G1A (n = 10)	G1B (n = 6)	G2 (n = 22)	p value
CFR				
Immediate	1.2 ± 0.2	1.4 ± 0.3	1.5 ± 0.3	N.S
1 month	1.8 ± 0.3	2.2 ± 0.3	2.2 ± 0.5	N.S
3–6 months	1.8 ± 0.3	2.4 ± 0.2	2.5 ± 0.4	<0.001
ΔLVEF	−3.4 ± 6.8	4.8 ± 5.1	6.2 ± 4.4	<0.01
ΔRWM	0.8 ± 0.7	−1.0 ± 0.8	−0.3 ± 0.6	<0.01

In conclusion, CFV pattern characterized with low SPV and high DSVR at 1 month may be due to irreversible severe microvascular dysfunction. CFV patterns at 1 month could be available as a predictor of left ventricular function improvement after successful reperfusion for AMI.

1393 Monitoring of coronary blood flow velocity using intracoronary doppler in patients with acute myocardial infarction before, during, and after coronary angioplasty

A. Furber, M. Merheb, S. Boulet, F. Prunier, P. L'Hoste, A. Tadéi, P. Geslin. *The University Hospital, Angers, France*

Using intracoronary Doppler, we have studied the variations in coronary blood flow observed before, during, and after reperfusion of the infarct coronary artery through angioplasty in 40 patients of 60.2 ± 15.4 years of age admitted to hospital because of a primary myocardial infarction either inferior (n = 22) or anterior (n = 18).

Methods: Average peak velocity (APV) was continuously measured, using a 0.014 doppler guidewire, to quantify collateral flow, and flow velocities during reperfusion and after PTCA.

Results: Before removing obstructions, the collateral flow peak velocity distal to the occlusion is 14.8 ± 8.1 cm/s. Collateral flow, which is bi-directional, is predominantly retrograde (n = 32), negative (n = 1) or positive (n = 5). There is a slight difference between the five Rentrop 0 patients and Rentrop 1, 2 or 3 patients (Rentrop 0: 14.9 ± 6.4 cm/s; Rentrop 1: 12.3 ± 9.9 cm/s; Rentrop 2: 15.2 ± 8.2 cm/s; Rentrop 3: 17.5 ± 6.3 cm/s). The patients with TIMI 3 reperfusion flow display the highest distal APV Doppler velocities ($APV_{TIMI\ 3}$ 20.2 cm/s versus $APV_{TIMI\ 1\ and\ 2}$ 10.9 cm/s; p = 0.05). After angioplasty, distal APV is 18.7 ± 10.4 cm/s (p = 0.001). Diastolic flow is predominant. Seventeen patients showed a retrograde systolic flow, 12 had a small systolic flow and 17 displayed a steep slope of diastolic deceleration.

Conclusion: Thus, intracoronary Doppler reveals that coronary flow in the patients with TIMI 3 flow is highly varied morphologically speaking as well as quantitatively speaking. This disparity might help us to isolate a subset of risk patients, candidates for a complementary therapy.

1394 Flow variation during direct acute myocardial infarction angioplasty with coronary stent implantation

B. Chevalier, B. Glatt, P. Guyon, T. Royer, V. Stratiev. *Centre Cardiologique du Nord, Saint-Denis, France*

In order to assess flow variations during direct acute myocardial infarction angioplasty (DAMIA), we retrospectively studied 180 pts (57 +– 17 y.) consecutively treated on native arteries, excluding rescue PTCA and cardiogenic shock. Thrombus (T) was scored; TIMI flow grade and TIMI frame count (TFC, sec.) were assessed at different steps. Baseline TIMI flow was: 0 62%, I 13%, II 16%, III 9%. A T length > 1 cm. was noted in 22%. DAMIA was successful in 162 pts (90%). Stent(s) was used in 76% of the pts. We noted one procedural death. Reference diameter was 3.1 +– 0.5 mm and MLD went from 0.2 +– 0.4 mm up to 2.9 +– 0.6 mm.

TFC decreased from 3.1 +– 1.4 sec. to 1.1 +– 1.1 sec at the end of the procedure (p < 0.001). After stenting, flow was increased in 10%, and decrased in 22%. In 40 pts with post-stenting flow decrease, final flow was III in 33 pts (82%), using i.c. verapamil in 14 pts and IIb/IIIa antagonist in 5 pts. In the global cohort, final flow was I in 6%, II in 9% and III in 85%. Initial T length > 1 cm was associated with a transient slow-flow after stenting (57% vs 17%, p < 0.005) and with a final non-TIMI III flow (50% vs 17%, p < 0.01).

Thus, coronary stenting during DAMIA may be associated with a slow-flow. This flow decrease is usually transient. A large T is a predictive factor of non-TIMI III flow result and adjunctive techniques may be assessed in this subgroup.

1395 The slope of the instantaneous hyperemic diastolic coronary flow velocity-pressure relation can predict myocardial salvage in acute myocardial infarction patients underwent primary angioplasty

T. Takagi, M. Nakamura, M. Yamamoto, T. Suzuki, K. Matsuda, H. Hara, T. Nishida, K. Mitsuo, T. Yamaguchi. *Third Department of Internal Medicine, Toho University, Ohashi Hospital, Tokyo, Japan*

Background: The status of the coronary microcirculation in the infarcted area has been proposed to determine the effects of reperfusion therapy on myocardial salvage in patients with acute myocardial infarction (AMI). Thus, we hypothesized the slope of the instantaneous hyperemic diastolic flow velocity-pressure relation (IHDVPS), reflects the coronary microcirculation status independently from the hemodynamic parameters, can predict LV function in reperfused AMI patients.

Methods: A total of 25 AMI patients (LAD 20, RCA 5) underwent primary stenting was studied, coronary flow velocity and pressure were monitored in the infarcted artery simultaneously. Coronary flow reserve (CFR) was measured by administration of intracoronary ATP and IHDVPS during hyperemia was calculated from coronary flow velocity-pressure loop. Left ventriculogram (LVG) was obtained on admission and follow up (mean 5.7 months) and regional wall motion (RWM: SD/chord) and ejection fraction (EF:%) were assessed. The correlation between IHDVPS and the recovery of left ventricular function (recovery of RWM and EF)were evaluated.

Results: There was no difference in EF between on admission and at follow-up. However, RWM were significantly improved (p = 0.0003). Correlation between flow parameters and recobery of left ventricular function was as in Table.

Correlations

	r	p value
CFR vs recovery of EF	0.28	0.33
CFR vs recovery of RWM	0.10	0.70
IHDVPS vs recovery of EF	0.82	0.0005
IHDVPS vs recovery of RWM	0.84	<0.0001

CFR, Coronary flow reserve; IHDVPS, Instantaneous hyperemic diastolic coronary flow velocity-pressure slope; EF, Ejection fraction; RWM, Regional wall motion

In conclusion: There was good correlatin between IHDVPS and the recovery of left ventricular function. These results indicate that IHDVPS after successful primary stenting is the useful index to predict the improvement of left ventricular function in reperfused AMI patients. Low IHDVPS would possibly reflect severe injury of microvascular bed after primary PTCA.

1396 Time course of recovery of impaired coronary flow reserve in remote vascular areas in acute anterior myocardial infarction

M. Bax, R.J. de Winter, K.T. Koch, C.E. Schotborgh, J.J. Piek. *Department of Cardiology, Academic Medical Center, Amsterdam, Netherlands*

Coronary flow reserve (CFR) is reduced in the infarct related artery (IRA) directly after primary PTCA in acute myocardial infarction (MI). The CFR may also be impaired in non-obstructed remote vascular beds, (non-infarct related artery, n-IRA). The time course of recovery of CFR in the n-IRA is unknown. We prospectively evaluated the alterations in CFR and average peak flow velocity (APV) in both the IRA and the n-IRA in patients with a first anterior MI.

Methods: Primary PTCA was performed within 6 hours in 41 patients with an anterior MI. CFR and APV were measured directly after successful PTCA at baseline and after adenosine induced hyperaemia in the IRA and the n-IRA, by means of a Doppler guide wire. This was repeated and at 1 week (n = 23) and 6 months follow up(n = 17).

Results: After primary PTCA, the CFR was reduced in both the IRA and the n-IRA and improved in both vessels at 1 week and 6 months. The difference between the CFR in both vessels remained significant during follow up. At 1 week, the increase of CFR in the IRA and n-IRA was due to an enhanced hyperaemic APV (from 34 ± 15 to 42 ± 15, p = 0.18 and from 40 ± 13 to 50 ± 16 cm/s, p = 0.11 respectively) whereas subsequent the increase of CFR at 6 months was due to a decrease in baseline APV (see table).

CFR and baseline APv

	PTCA (A)	1 week (A)	6 months (A)	PTCA (B)	1 week (B)	6 months (B)
IRA	1.7 ± 0.4	2.0 ± 0.4[1]	2.7 ± 0.9[1]	20.0 ± 9.6	21.1 ± 6.7	14.6 ± 7.7[1]
n-IRA	2.4 ± 0.5	2.9 ± 0.5[1]	3.5 ± 0.5[2]	17.0 ± 6.3	17.8 ± 6.6	13.9 ± 6.3

(A): CFR (hyperaemic/baseline APV); (B): baseline APV (cm/s); All figures as mean (± SD): [1]p < 0.05 vs PTCA; [2]p < 0.0001 vs PTCA.

Conclusions: The time course of recovery of baseline and hyperaemic average peak flow velocity determining coronary flow reserve is similar in both the infarct and non-infarct related artery, suggesting disturbed autoregulation in remote normal perfusion territories following acute anterior myocardial infarction.

1397 Coronary and myocardial perfusion mismatch in patients with acute coronary syndromes

J. Ge, J. Qian, M. Haude, D. Baumgart, R. Bhate, D. Welge, O. Oldengurg, R. Erbel. *Department of Cardiology, University-GH Essen, Germany*

After coronary interventions, coronary flow improves but is usually normalized only after stenting. However, myocardial perfusion may be impaired despite an optimal interventional result. In order to detect a possible mechanism of the disturbed myocardial perfusion after intervention, we investigate whether plaque characteristics may be related to the effect the improvement of coronary flow velocity reserve (CFVR) after stenting.

A total of 54 patients (pts) who had significant coronary luminal narrowing were examined with intracoronary Doppler: stable angina pectoris (SAP) in 31 pts, unstable angina pectoris (UAP) in 11 pts, and in 12 pts with 1 to 3 months after myocardial infarction (MI). Intracoronary flow measurements were performed before, after PTCA and after stent implantation using a 0.014 inch FloWire® (Cardiometrics). CFVR was calculated by the ratio of the hyperemic average peak velocity to the baseline average peak velocity after intracoronary injection of adenosine (18 μg for the left coronary arteries, 12 μg for the right coronary artery).

CFVR	before PTCA	after PTCA	after stent
SAP	1.53 ± 0.90	2.38 ± 0.82*	3.21 ± 0.79*
UAP	1.86 ± 0.79	1.97 ± 0.85#	2.34 ± 1.03*
MI	1.31 ± 0.36	2.17 ± 0.52*	2.44 ± 0.37*

*p < 0.01 versus before PTCA; #p = 0.08

Impairment of CFVR in patients with UAP and MI may still be present immediately after successful stenting despite optimal coronary stenting. As this impairment of CFVR was found in UAP and MI but not in SAP patients, it indicates a preexisting or intervention-induced coronary-myocardial perfusion mismatch.

ADJUNCTIVE PLATELET INHIBITION WITH STENTING

1398 Accelerated inhibition of platelet activity by clopidogrel loading dose in patients following coronary stent implantation

H. Darius, H.-J. Rupprecht, P. Kreß, C. Bauer, W. Jungmair, C. Bickel, J. Meyer. *Dept. of Medicine II, Johannes Gutenberg-University Mainz, Germany*

The incidences of subacute thrombosis following stent implantation into human coronary arteries within the first days after the procedure has decreased substantially. Clopidogrel, a newly introduced ADP-antagonist, was studied as an alternative to ticlopidine. Patients undergoing successful stent implantation were randomized to receive either ticlopidine (500 mg/d) plus aspirin 300 mg/d for 4 weeks (TA; n = 13), clopidogrel 75 mg/d plus aspirin 300 mg/d (CA, n = 13) or a clopidogrel loading dose of 300 mg on day 1 followed by 75 mg/d for the following 27 days plus aspirin 300 mg/d (CALD, n = 14). Platelet aggregation and adhesion molecule expression (CD62p) was determined immediately after stent implantation and after 1, 2, 3, 6 and 13 days. No subacute stent thrombosis was observed in any of the patients. ADP (20 μM)-induced platelet aggregation decreased in the TA group from 80.3 ± 4.9% after stenting to 69.3 ± 7.8% on day 1 and to 36.8 ± 10.8% on day 13. Platelet inhibition was comparable in the CA group with aggregation response to 69.0 ± 8.8% on day 0, 65.1 ± 8.8% on day 1 and 35.9 ± 9.9% on day 13 (p = 0.2 vs TA). In contrast, platelet aggregation was inhibited much earlier in the CALD group with 74.3 ± 13.5 on day 0 before drug administation, decreasing already on day 1 to 48.4 ± 6.7% (p ≤ 0.01 vs TA or CA) and to 30.9 ± 9.9% on day 13. The ADP-induced expression of p-selectin (CD62p) on the platelet surface was influenced to a comparable degree. While initial values for CD62p were not different for the 3 groups, significant differences were seen on day 1 with 63.8 ± 7.5% for TA, 58.5 ± 4.7% for CA and 40.4 ± 5.4% for CALD (p ≤ 0.01).

Thus, administration of clopidogrel instead of ticlopidine following stent implantation results in a comparable degree of platelet inhibition. Administration of a clopidogrel the loading dose (300 mg) on the day of stent implantation markedly accelerates platelet inhibition being statistically significantly different already 1 day following the first drug administration.

1399 A randomized comparison of clopidogrel and aspirin versus ticlopidine and aspirin after the placement of coronary-artery stents

Ch. Müller, H.J. Büttner, J. Petersen, P. Betz, H. Roskamm. *Herz-Zentrum Bad Krozingen, Germany*

The introduction of an effective antiplatelet therapy with aspirin (A) plus ticlopidine (T) after the placement of coronary-artery stents has dramatically decreased the risk of subacute thrombosis (SAT) as well as hemorrhagic complications. However, the use of T is limited by hematologic and gastrointestinal adverse effects. Clopidogrel (C), a new thienopyridine derivate, has an excellent overall safety profile. Its efficacy after stenting remains to be established.

Methods: After successful coronary stenting during elective or emergency PTCA, 1000 patients (P) will randomly be assigned to a four week course of either 500 mg T or 75 mg C in addition to their regular medication with 100 mg A. The primary endpoint is a combination of major cardiac (death, myocardial infarction, angiographically documented SAT, revascularisation of the target vessel or hospitalization for unstable angina) and noncardiac (peripheral or hemorrhagic, or discontinuation of study medication due to side effects) events in the first 30 days.

Results: Follow up has been completed for 159 P with C and 178 P with T. Major cardiac events occurred in 13 P (8.2%) and 11 P (6.2%, p = ns) respectively, noncardiac events in 7 P (4.4%) and 16 P (9.1%, p < 0.05).

Conclusion: After the successful placement of coronary-artery stents, antiplatelet therapy with A and C is as effective as A and T. Noncardiac events are significantly reduced by C. Final results will be available at presentation.

1400 Two- or four-week ticlopidine therapy after coronary stent placement?

Helmut Schühlen, Adnan Kastrati, Jörg Hausleiter, Martin Hadamitzky, Jürgen Pache, Anne Wehinger, Josef Dirschinger, Albert Schömig. *Deutsches Herzzentrum; 1. Medizinische Klinik rechts der Isar, Technische Universität Munich, Germany*

Three large randomized studies (ISAR, STARS, FANTASTIC) demonstrated the superiority of combined antiplatelet therapy after stenting. Although they used a 4-week or longer ticlopidine regimen, increasing numbers of patients are only treated for 2 weeks to minimize potential side effects of ticlopidine. To test this rationale, we retrospectively compared the major adverse cardiac event rates (MACE: death, myocardial infarction, repeat target lesion revascularization) in the early (first 2 weeks) with the late period (week 3 and 4) of 2259 patients with and 574 without ticlopidine. Patients were stratified into 2 risk groups according to the incidence of recently published risk factors for MACE (age, diabetes, acute myocardial infarction, unstable angina, impaired LV function, residual dissection, stented segment length, stent overlap). The population quartile with the highest risk constituted the high risk group (HIGH; n = 708), the low risk group comprised the other 3 quartiles (LOW; n = 2128). In the first 2 weeks, MACE rates were significantly lower with ticlopidine in HIGH (7.3% with ticlopidine vs 12.2% without ticlopidine; $p = 0.04$) and LOW (0.9 vs 2.1%; $p < 0.04$). In the late period, MACE rates were higher without ticlopidine. However, this was only of borderline significance in HIGH (1.2 vs 3.2%; $p = 0.06$) and not significant in LOW (0.2 vs 0.5%; $p = 0.44$).

Conclusions: These data provide no support for a general reduction of the ticlopidine regimen from 4 to 2 weeks after stent placement. In a high risk population, this may lead to significantly higher MACE rates in the 3rd and 4th week. In a low risk population however, the minimal benefit of a 4-week therapy has to weighted against potential (ie, hematologic) side effects of ticlopidine. Prospective studies are needed to specifically address this topic prior to any general recommendations.

1401 Does preprocedural ticlopidine treatment modify the short-term outcome after coronary angioplasty?

B. Chevalier, B. Glatt, P. Guyon, T. Royer, A. Luycx-Bore. *Cardiologie Interventionnelle, Centre Cardiologique du Nord, Saint-Denis, France*

In order to improve the antiplatelet treatment during coronary angioplasty, we decided to use in selected pts, since april 1997, a preprocedural treatment with ticlopidine (PPTT). The aim of this single center study is to retrospectively study the effect of PPTT on acute outcome. From april 97 to january 99, we treated 4183 pts with PTCA, among whom 677 pts with acute MI PTCA were excluded from the study. Thus, we compared: group A – 2075 pts treated with ticlopidine after the procedure, group B – 643 pts with PPTT. Baseline data of these two cohorts were not statistically different (including stent use) except a higher rate of type C lesion in group B (37% versus 32%, $p < 0.05$) and a higher rate of multilesion angioplasty in group B (1.46 ± 0.6) versus group A (1.28 ± 0.5) ($p < 0.01$). In both groups, pts have a similar rate of minor thrombotic events during the angioplasty procedure (composite endpoint associating distal embolization, no- flow, new onset of thrombus and rescue use of abciximab) 7% vs 7.1%. However, we noted during the in-hospital stay a lower rate of acute and subacute stent thrombosis in group B (0.5% versus 1.9%, $p < 0.05$) despite a similar rate of MACE (including death, emergency CABG, Q and nonQ MI, need for re-angioplasty during hospital stay) in group B (2.9%) versus group A (4.2%), p = NS. Furthermore, PPTT was not associated with a higher rate of local complications (3.6% versus 3.2%, p = NS).

Thus, PPTT benefit is limited to stent thrombosis reduction but is not effective on thrombotic events during angioplasty or MACE rate during inhospital outcome. Further randomized study is necessary to clarify PPTT effect in comparable cohorts.

1402 Abciximab in coronary stenting: routine use cannot be justified

D.J. Price, P.G. Campbell, E.D. Grech, M.J. Stewart, A. Davies, J.A. Hall, M.A. de Belder. *Cardiothoracic Division, South Cleveland Hospital, Middlesbrough, UK*

The EPISTENT trial reported improved outcomes of coronary stenting procedures after pre-treatment with abciximab in patients at all levels of risk. The cost of using abciximab in all cases where stents are deployed would be enormous. We report results of a protocol encouraging restriction of abciximab therapy to patients at particularly high risk, and calculate consequent cost savings.

Methods and results. During a 34 month period we studied outcomes of all patients who underwent a coronary stenting procedure and who also fulfilled criteria for inclusion in the EPISTENT trial (808 cases). Major adverse clinical events (MACE) for this group are given below;

	Stable angina (367)		Unstable/postMI (234)		Acute MI (207)	
	No abcix (349)	abcix (18)	No abcix (207)	abcix (27)	No abcix (164)	abcix (43)
Ac Occ	–	–	1	–	2	–
Non–QMI	5	1	4	4	–	–
QMI	–	–	–	–	N/A	N/A
CABG	3	1	1	–	2	1
Death	–	–	–	1	7	3
Rpt PCI	2	–	–	1	–	–
SAT	–	–	–	–	–	–

(abcix = abciximab; Ac Occ = acute occlusion; Rpt PCI = urgent repeat percutaneous coronary intervention; SAT = subacute thrombosis)

Overall MACE rate was 4.8%, compared with 10.8% and 5.3% for the placebo and stent-plus-treatment groups respectively in the EPISTENT trial.

Conclusion. For patients undergoing coronary stenting, it is unnecessary to administer abciximab to all those fulfilling EPISTENT criteria in order to achieve similarly low MACE rates. The additional cost of treating all those eligible for the EPISTENT protocol would have been $1,152,000 in order to try to prevent only 27 outcome events ($ 42,667 per event).

1403 The impact of abciximab therapy as bail out procedure in 1903 patients undergoing PTCA

H. Mahrholdt, A. Baumbach, E. Dirr, S. Schroeder, K.K. Haase, M. Oberhoff, K.R. Karsch. *Medical Clinic, Division of Cardiology, University of Tübingen, Germany*

The clinical efficacy of GP IIb/III antagonists is documented and approved for preinterventional prophylactic application. Aim of this study was to assess the efficacy of postinterventional Abciximab usage as bail out procedure to manage threatened or acute vessel closure without stent implantation.

Methods: Overall acute vessel closure was observed in 105 (5.5%) of the 1903 patients. In this population abciximab was administered in bail out situations in a dosage of 9 mg given as a bolus which was followed by an intravenous infusion of 4.5 mg over 12 hours. Repeat PTCA was performed shortly after the administration of the abciximab bolus.

Results: In 99 of the 105 patients TIMI Flow III could be restored by this procedure only. In 6 patients an additional stent implatation was necessary. One day post PTCA, early follow up angiography was performed and all 105 vessels were patent. In hospital events occurred in 2 patients. Both had to undergo emergency CABG due to subacute vessel closure. One patient died during surgery. Follow-up after one year included clinical status and control angiography of the target vessel. During long term follow up MACE occurred in 18 patients (2 MI's, 12 CABG und 5 RePTCA's).

Conclusion: The results of this prospective trial demonstrate the high efficacy of Abciximab in bail out situations occurring during or early after PTCA. This effect is due to the dethrombotic property of Abciximab in the presence of fresh thrombus. The use of Abciximab as a bail out rather than a prophylactic therapy appears clinically beneficial and economic sound.

NEWER APPROACHES TO CONGENITAL HEART DISEASE

1423 Quantification of stenosis in patients with coarctation by magnetic resonance imaging using haemodynamic and morphologic changes: comparison of phase shift velocity mapping with multiplanar reformation

M. Gutberlet, N. Hosten, J. Beier, H. Abdul-Khaliq[1], L. Luo[2], M. Vogel[1], R. Felix. *Diagnostische Radiologie, Charite Campus Virchow-Klinikum, Berlin; [1]Department of Congenital Heart Disease, German Heart Institute, Berlin, Germany; [2]Department of Radiology, University of Jinan, Jinan, China*

Aim: The quantitative, non-invasive assessment of the degree of a stenosis in patients with coarctation can be performed morphologically using the vessel diameters or hemodynamically using the changes in peak velocity. The geometry of restenosis in patients after repair of coarctation is often very complex. Therefore the usually performed 2-dimensional assessment might be not sufficient. In this study we compared the calculation of the cross-sectional areas from a 3-dimensional data set using MPR of a 2-D MR-angiography and MR flow measurements.

Materials and Methods: We examined 25 patients within the age of 5 to 35 years (mean age 19 ± 9 years). The MR examinations were performed with a 1.5 T Gyroscan ACS-NT (Philips, Best, Netherlands) using a standard body coil. Flow measurements were performed using phase shift velocity mapping to calculate peak velocity at the site of a stenosis. The maximum pressure gradient at the stenosis was estimated using the Bernoulli-equation and compared with cardiac catheter and/ or Doppler-echocardiography data. In the first step simple threshold segmentation of data from an two-dimensional in-flow MR-angiography to three-dimensional (3D) was used to reconstruct the aortic lumen. Within this 3D space, a flight path was defined, following the vessel course. The cross sectional area of the vessel lumen was calculated using reformatted image planes perpendicular to the vessel course. Thus, the percentual stenosis of the aorta was derived.

Results: The estimated pressure gradients at the site of a stenosis using PCA correlated very well with pressure gradients estimated by Doppler echocardiography, with a slight tendency to underestimate even as compared with invasively measured pressure gradients, which was extremely high in two patients with high grade stenosis (pressure gradient > 80 mmHg) and a lot of collaterals. With MPR a quantification of the stenosis was possible in all patients and showed advantages as compared to simple quantification from 2 dimensional images, especially to evaluate pseudocoarctation and complex geometry of the stenosis.

Conclusions: The quantification of low- or midgrade stenosis/ restenosis in patients with coarctation with the estimation of pressure gradients at the site of a stenosis by PCA is sufficient for the clinical routine. In patients with high-grade stenosis or complex geometry of the aortic arch and a lot of collateral vessels flow measurements are not reliable. MPR of an MR-angiography supplies additional information in this cases to improve the diagnostic value of the non-invasive MR examination.

1424 Right ventricular geometry in postoperative tetralogy of Fallot as determined by echocardiographic acoustic quantification: correlation with two-dimensional echocardiography

M.A. Seliem, M.R. Palileo. *Speciality Pediatrics Dept., ARAMCO Dhahran Health Center, Dhahran, Saudi Arabia*

Background: The right ventricular (RV) geometric changes (from hypertrophy to dilatation) becomes evident in many patients after repair of the Tetralogy of Fallot (TOF) due to a variable degree of pulmonary insufficiency (PI). Echocardiography remains the main modality for monitoring such changes and their hemodynamic consequences.

Objective: To investigate the utility of Acoustic Quantification (AQ) to quantify RV geometric changes (dilatation) in repaired TOF and to compare this new technique with 2D-echocardiography.

Methods: Echocardiographic examination was performed on 24 patients, who underwent total repair of TOF, and 11 controls. Two subcostal orthogonal planes [the subcostal frontal (F) and sagittal (L)] were used to measure the RV geometric parameters, during the (AQ) application and 2D imaging. All measurements were made at end diastole from 10 cardiac cycles and averaged. During the AQ application, the RV area was obtained in both views (F&L). During 2D imaging, the RV areas (F&L) and long axis (A) [from the level of the pulmonic valve to the endocardial surface of the inferior wall) were obtained. The RV volume (V) was then calculated in both techniques from the equation V = FxL/A and corrected for the BSA (M2).

Results: There were good correlations between the RV areas (F&L) and volume during AQ and 2D imaging (r = 0.85, 0.87 and 0.85 respectively). The RV was dilated significantly in TOF when compared with controls by either AQ or 2D (P = 0.02 and 0.01 respectively). The areas and volumes obtained by AQ were significantly less than that obtained by 2D imaging.

Conclusions: The RV becomes significantly dilated in TOF patients after total repair due to a variable degree of PI. AQ is an excellent technique to measure these geometric changes instantly on line and serially. AQ correlates well with 2D, but tends to underestimate the measured areas and volumes.

1425 Thrombembolic complications after Fontan procedure: diagnosis, risk factors and comparison of different therapeutic approaches

A. Franke, E.G. Mühler[1], R. Seipelt[2], S. Däbritz[2], W. Lepper, B.J. Messmer[2], G. von Bernuth[1], P. Hanrath. *[1]Medical Clinic I, Paediatric Cardiology; [2]Cardiothoracic Surgery, University Hospital; Aachen, Germany*

Patients (pts) after Fontan procedure represent a growing subgroup among complex congenital heart disease with special postoperative problems. Even though thrombembolic complications (TEC) cause a high mortality, anticoagulant therapy is not yet recommended uniformly. Aim of this study was to analyse the frequency and clinical relevance of TEC after Fontan using different therapeutic/prophylactic approaches and the value of diagnostic procedures.

Patients: 87 consecutive pts were included in the study (46 male, 8 ± 9 years [y], range 3–45 y). Early postoperative mortality was 16% (14 pts) and not due to TEC. 71 of the 73 residual pts were examined 0.6–12 y (4.2 ± 3.0 y) after Fontan.

Results: 10/71 pts (14%) developed TEC, 5 became symptomatic (2 cerebral strokes, 2 thrombi in the caval vein, 1 pulmonary embolism), the other 5 remained asymptomatic (3 thrombi in the occluded pulmonary artery (PA) trunk, 2 thrombi in caval vein/right atrium). 63% of all TEC occurred within the first year after Fontan. Using prophylactic medication, there was a tendency towards lower cumulative TEC rate: 16.7% in pts without medication (n = 51), 8.3% in pts with antiplatelet therapy (n = 12) and 4.2% in pts with anticoagulant therapy (n = 24, n.s. using log-rank-test).

Invasive controls (45 pts) and transesophageal echocardiography (TEE, 24 pts) revealed the following otherwise not detectable findings: stenoses of the PA (4), the coronary sinus (1) or the atrial tunnel (2) and abnormal veno-venous (4) or veno-left atrial connections (4). Potential risk factors for TEC were persistent connections to an occluded PA trunk in 25 pts or to a rudimentary subpulmonary ventricle in 14 pts and – mostly small-atrial right to left shunts in 17 pts.

Conclusions: TEC are a frequent clinical problem in the first year after Fontan which can be reduced using anticoagulant therapy. Some risk factors and relevant postoperative sequels can only be detected with invasive follow-up examinations or TEE. Routine early postoperative anticoagulant therapy may be a therapeutic consequence.

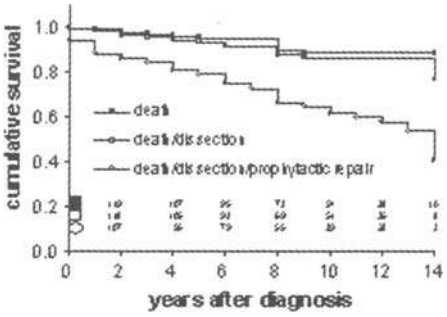
1426 Survival and complication-free survival in Marfan's syndrome: implications of current guidelines

T. Lohuis, M. Groenink[1], J.G.P. Tijssen[2], M.S.J. Naeff[3], R.C.M. Hennekam[4], E.E. van der Wall[5], B.J.M. Mulder[1]. *Cardiology B2-240, [1]Cardiology Dept, [2]Epidemiology and Biostatistics Dept, [3]Paediatric Cardiology Dept, [4]Paediatrics and Human Genetics, Academic Medical Centre, Amsterdam; [5]Cardiology Dept, Leiden University Medical Centre, Leiden, Netherlands*

Objective: To evaluate survival in 130 Marfan patients, attending our institution in the past 14 years, and to assess the possible influence of recently revised guidelines for prophylactic aortic root repair in these patients.

Methods: Kaplan-Meier analysis was performed with the endpoints: death, aortic root dissection and prophylactic repair after diagnosis. In the patients developing aortic root dissection, current guidelines for aortic root repair were retrospectively applied to investigate the number of dissections which could theoretically have been prevented. Current guidelines were considered to be: (1) aortic root diameter > 55 mm,(2) positive family history of aortic dissections and aortic root diameter > 50 mm, and (3) aortic root growth > 2 mm/year. Furthermore, survival following emergency surgery (15 patients) and prophylactive surgery (30 patients) of the aortic root were compared.

Results: 5 Patients presented with aortic root dissection before diagnosis was established and were excluded from survival analysis. Of the remaining 125 patients, 13 developed dissection, 30 underwent prophylactive repair and 82 had an uncomplicated course. Results from Kaplan-Meier analysis with defined endpoints are shown in the figure. In the patients developing dissection, 11 out of 13 (85%) could theoretically have been prevented by application of the current guidelines. 5-Year survival following emergency and prophylactic repair of the aortic root was 51% and 97%, respectively.



Conclusions: Survival in the Marfan syndrome in the past 14 years seems satisfactory. By application of current guidelines, survival is probably even improved. This is, however, at the cost of even more surgical intervention, which seems already extensive at 36% in 10 years (figure).

1427 Cardiorespiratory exercise function after arterial switch operation for transposition of the great arteries

T. Reybrouck, M. Weymans, B. Eyskens, W. Daenen, M. Gewillig. *Dep Pediatric Cardiology, University Hospital Gasthuisberg, 3000 Leuven, Belgium*

In patients (pts) with Senning repair for transposition of the great arteries [TGA (Senning)] systemic (right) ventricular dysfunction has been documented. This has stimulated the development of arterial switch operation [TGA (switch)]. Only limited information is available about exercise function in pts with TGA (switch) since they only reach now the age at which formal exercise testing is feasible. The purpose of the present study was to compare cardiorespiratory exercise function in pts with TGA (switch) to pts with TGA (Senning) and normal controls (nl). 13 pts with TGA (switch) underwent exercise testing (age at testing: 8.4 ± 3.1 yrs). The pts were compared to a group of 29 pts with TGA (Senning) (age at testing: 10.3 ± 2.5 yrs) and to a group op 13 nl of comparable age (8.8 ± 4.3). Exercise testing was perfomed on a treadmill and gas exchange was measured on a breath-by-breath basis with a mass spectrometer. Cardiorespiratory exercise function was assessed by determination of the steepness of the slope of VO_2 vs exercise intensity (SVO_2) and determination of the ventilatory anaerobic threshold (VAT, V-slope method).

Results:

Patients	N	VAT (ml O_2/min/kg$^{-2/3}$)	VAT (%NL)	SVO_2
TGA (Senning)	29	74.9 ± 12.7*	70.9 ± 12.0*	1.50 ± 0.64*
TGA (switch)	13	94.7 ± 9.8	90.0 ± 9.4	1.96 ± 0.49*
NL	13	105.5 ± 17.3		2.45 ± 0.40

*$p < 0.05$ compared with normals

In conclusion, from a functional point of view, cardiorespiratory exercise function in TGA (switch) is at or only slightly below the lower limit of normal, as compared to pts with TGA (Senning) where the lowest values for cardiorespiratory exercise function were observed.

1428 Acute effect of pulmonary artery banding on right ventricular pressure-volume relationship: relevance to the arterial switch operation

J.K.F. Hon, P. Steendijk[1], K. Wong, A.K. Hasnat, M. Yacoub. *Academic Dept. of Cardiac Surgery, Royal Brompton Hospital, London, UK; [1]Department of Cardiology, Leiden University Medical Center, Leiden, Netherlands*

Background: Preparation of the low pressure, thin-wall morphological left ventricle in transposition of great arteries is achieved by imposing acute pressure overload with pulmonary artery banding (first stage of the two-stage arterial switch operation). Changes in the pressure-volume relations of low-pressure ventricles to such a load have not been documented. We report the functional response of the right ventricles of young sheep to acute pressure overload, using the combined micromanometer-conductance technique.

Methods: 6 Dorset Down sheep (Wt.18.08 ± 1.02 kg, age 3 months) were studied. Surgical access was achieved via a left thoracotomy and the pericardium was opened. Right ventricular function measurements before and half an hour after pulmonary artery banding were obtained using a combined micromanometer-conductance catheter inserted into the right ventricle just below the pulmonary valve. Band tightness was adjusted so as not to allow the left ventricular systolic pressure to fall below 55 mmHg. Further tightening of the band resulted in severe bradycardia and rapid decrease in arterial pressure, which regressed when the band was released. End-systolic (ESPVR) pressure-volume relationships were obtained employing inferior vena cava occlusion. The ESPVR was fitted to a linear function to obtain the slope (Ees) and the volume intercept at 16 mmHg (V16).

Results: Pulmonary artery banding increased the mean ratio between the right ventricular and left ventricular systolic pressure from 0.35 ± 0.02 to 0.63 ± 0.04, $p < 0.05$ (Mean ± SEM). Acute pressure overload to the right ventricle produced no significant changes in heart rate, end-systolic volume and the ejection fraction of the right ventricle. However, there was a significant increase in the end diastolic volume (11.25 ± 1.07 to 13.54 ± 1.44, $p < 0.05$), stroke volume (4.25 ± 0.45 to 6.19 ± 0.78, $p < 0.05$), cardiac output (533.32 ± 72.82 to 771.14 ± 112.11, $p < 0.05$) and Ees (4.19 ± 0.95 to 10.24 ± 4.48,$p < 0.05$). Post banding V16 was significantly reduced (7.34 ± 0.66 to 5.11 ± 0.64, $p < 0.05$).

Conclusion: This first documentation of the pressure-volume relations of the thin-wall, low-pressure right ventricle of young sheep to acute pressure loading showed evidence of an intact Frank-Starling mechanism and an apparent improvement in the contractile state of the right ventricle half an hour after pulmonary artery banding. The reason for this "improved contractility" is unclear and requires further evaluation. Possible mechanisms include neuro-humoral activation and ventricular-interdependence via the interventricular septum.

EMERGING CONCEPTS IN NEUROHORMONAL MODULATION

1437 Blunted cGMP production in adult ventricular cardiomyocytes in heart failure

K. Hoehnel, A. Feldheiser, M. Scheuermann, S. Philipp, R. Dietz, R. Willenbrock. *Labor für exp. und klin. Herzinsuffiz., Franz-Volhard-Clinic, Berlin, Germany*

Blunted cGMP production in adult ventricular cardiomyocytes in heart failure

Background: The existence of specific cardiac receptors for natriuretic peptides (NPR) has been reported. The specific ligands of the NPR-A and NPR-B subtypes are atrial natriuretic peptide (ANP) or C-type natriuretic peptide (CNP), respectively. Both NPR-A and -B possess an intrinsic guanylate cyclase moiety. The function and regulation of cardiac NPR in heart failure is unknown.

Methods: Heart failure was induced in Wistar rats by an aortocaval shunt, which was created by 1.8 mm needle. Sham- operated animals were used as controls. After 28 days ventricular cardiomyocytes were prepared by collagenase digestion. To decrease the number of non-cardiomyocytes, cells were pre-plated and only the cells which adhered to the cell culture wells were studied. cGMP production was stimulated by ANP and CNP and cGMP was determined by RIA.

Results: cGMP in adult ventricular cardiomyocytes from controls increased, after stimulation with ANP and CNP (10^{-9} to 10^{-6} M peptide) in a dose-dependent fashion. The CNP induced cGMP production increased to the same extent in cells isolated from heart failure rats, compared to controls. In contrast, cGMP production in response to ANP (10^{-9} to 10^{-6} M) was blunted in heart failure rats (at 10^{-9} M ANP from 25 ± 6 fmol/300000 cells to 8.6 ± 2 fmol/300000 cells, $p < 0.05$; 10^{-8} M: 18 ± 5 to 7 ± 1, $p < 0.05$; 10^{-7} M: 25 ± 5 to 14 ± 2 $p < 0.05$; 10^{-6} M: 42 ± 9 to 17 ± 3 $p < 0.01$ control vs heart failure).

In conclusion: Based on the specifity of ANP and CNP to their specific natriuretic peptide receptors these data indicate that functional NPR-A and NPR-B receptors are present on ventricular cardiac myocytes. The blunted cGMP response of cardiomyocytes of rats with heart failure to ANP suggests a selective desensitization of the NPR-A receptor subtype in heart failure.

1438 N-terminal proBNP as a marker of left ventricular dysfunction: the influence of heart failure treatment

S. Talwar, I.B. Squire, J.E. Davies, D.B. Barnett, L.L. Ng. *Dept of Medicine & Therapeutics, Leicester University, Leicester, UK*

N-Terminal proBNP(NT) may provide a more sensitive index of the presence of LVD than BNP in CHF. It has been suggested that the value of the assay may be reduced in treated populations. The aim of this study was to compare the relationship between plasma NT and LV function in treated and untreated patients within a population undergoing echo-cardiography.

Methods: We studied 243 patients (129 Male, mean age 70 yrs, range 20–94). Echocardiographic LV function was assessed using a 9-segment wall motion index (WMI). NT levels were established by immunoluminometric assay with in-house antibody to the human N-terminal proBNP and blind to WMI. The relationship between WMI and a variety of clinical and laboratory variables was examined, comparing patients treated (ACE inhibitor, diuretic or both) or untreated for heart failure.

Results: 132 (54%) patients were treated with ACEI or diuretic (48 both, 69 diuretic alone, 15 ACEI alone). Those treated were older (74 ± 10 yrs) than those untreated (66 ± 17)($p < 0.0005$). There was a strong correlation between NT (NR < 200 pmol/L) and WMI in treated ($r = -0.661, p < 0.005$) and untreated ($r = -0.587, p < 0.005$) patients. NT levels (pmol/L; Median, IQ Range) were similar in untreated (368, 225–536) compared to treated patients (355, 225–509), those receiving ACEI alone (382, 190–664), diuretic alone (398, 229–498) or both (332, 225–513)($p = 0.981$, Kruskal-Wallis). WMI did not differ among groups ($p = 0.10$). On multiple regression analysis, independent predictors of WMI in treated patients were NT ($p < 0.005$), Age ($p < 0.005$), ACEI use ($p = 0.017$), diuretic use ($p = 0.039$). In untreated patients only NT ($p < 0.005$) and mitral regurgitation ($p = 0.01$) independently predicted WMI.

Conclusions: Plasma NT remains elevated in patients treated with ACEI and/or diuretics. NT is a strong predictor of reduced WMI in treated and untreated patients. Further studies are required to explore the effect of initiation of treatment on plasma NT levels.

1439 Elevated plasma cardiotrophin-1 in patients with left ventricular systolic dysfunction

S. Talwar, P.F. Downie, L.L. Ng. *Dept of Medicine & Therapeutics, Leicester University, Leicester, UK*

Cardiotrophin-1 (CT-1), a member of the interleukin-6 related cytokines that act via the gp130 signalling pathway, may be involved in the process of ventricular remodelling and has been shown to stimulate the assembly of sarcomeric units in series in cardiomyocytes. We hypothesized that CT-1 is increased in left ventricular systolic dysfunction (LSVD).

Method: A competitive immunoluminometric assay using a methyl acridinium ester to label the peptide and an in-house polyclonal antibody to amino acids 105–120 of the CT-1 sequence was developed. We measured CT-1 in 100 patients who were referred for an echocardiogram. All patients with creatinine > 130 mmol/l or a significant valvular lesion were excluded. Sixty two patients (28 male, median age 64 yrs [20–85]) had a WMI of 2 = Group 1. Fifteen patients (11 male, median age 71 yrs [56–85]) had a WMI between 1.9–1.3 = Group 2. Twenty three patients (15 male, median age 67 yrs [43–87]) had a WMI of or = 1.2 = Group 3. Results are expressed as medians (ranges) fmol/ml.

Results: CT-1 levels were 53.9 [18.2–120.8], 48.8 [21.7–99.6] and 75.5 [31.4–130.6] in groups 1, 2, and 3. [Normal range for CT-1 is <40]. Mean log CT-1 differed amongst groups 1–3 ($p = 0.01$) and between groups 1&3($p < 0.005$) and groups 2&3($p = 0.01$) only.

Conclusion: This is the first demonstration of significant elevation of plasma CT-1 in patients with LVSD. The exact role of CT-1 in LVSD and ventricular remodelling remains to be determined.

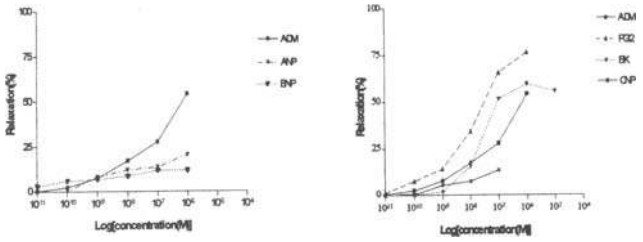
1440 Powerful vasodilator effect of adrenomedullin in human resistance arteries is preserved in chronic heart failure

M.C. Petrie[1], C. Hillier[2], F. Johnstone[2], J.J.V. McMurray[1]. *[1]MRC CRI in Heart Failure, University of Glasgow; [2]Caledonian University, Glasgow, UK*

Background: Adrenomedullin (ADM) may be an important endogenous vasodilator though its potency compared to other vasoactive substances is unknown in human vessels. ADM is of particular interest in chronic heart failure (CHF) where plasma blood concentrations are elevated. We have compared the potency of ADM with circulating and locally acting vasodilators in systemic resistance arteries from patients with CHF and controls without CHF.

Methods: Arteries were obtained from gluteal biopsies from 13 patients with CHF and 10 patients with coronary heart disease but preserved left ventricular systolic function and studied using wire myography.

Results: ADM is a more potent vasodilator than the circulating atrial (ANP; $p = 0.03$) and brain natriuretic peptides (BNP; $p = 0.008$).



ADM was similar in potency to the locally acting agents prostacyclin (PGI_2) and bradykinin (BK). There was a trend towards greater potency than C type natriuretic peptide (CNP; $p = 0.06$). ADM was similar in potency when compared to the acetylcholine (ACh) and SNP. Quantitatively and qualitatively similar results were found in the control patients.

Conclusion: ADM is a powerful vasodilator in human resistance arteries and its action is preserved in CHF despite chronically elevated plasma concentrations.

1441 Omapatrilat, a vasopeptidase inhibitor, produces long-term beneficial haemodynamic and neurohormonal effects in heart failure

H. Ikram[1], D.R. McClean[1], M.F. Rousseau[2], E. Fleck[3], Y. Juilliere[4], E. Gronda[5], C. Bryson[6], J. Hanyok[6]. *For the Omapatrilat Study Group; [1]Christchurch Hospital, Christchurch, New Zealand; [2]Clinique Universitaire Saint-Luc, Brussels, Belgium; [3]Virchow Klinikum, Berlin, Germany; [4]Centre Hospitalier Universitaire Nancy-Brabois, Nancy, France; [5]Ospedale Niguarda, Milan, Italy; [6]Bristol-Myers Squibb, Princeton NJ, USA*

Omapatrilat, a novel vasopeptidase inhibitor, is a single molecule that simultaneously inhibits neutral endopeptidase (NEP) and ACE. This study assessed dose-related effects of omapatrilat added to background therapy in patients (pts) with heart failure (HF).

Methods: This randomized, double-blind, multicenter study included 369 pts with HF: NYHA Class II–IV, EF ≤ 40%, PCWP ≥ 15 mm Hg, and cardiac index (CI) ≤ 3.0 L/min/m^2. Serial hemodynamic measurements were made at baseline, on day 1, and after 12 wk of once-daily omapatrilat therapy with 2.5, 5, or 10 mg (first 190 pts, Panel 1) or 2.5, 20, or 40 mg (last 179 pts, Panel 2).

Results: The table shows mean changes from baseline in PCWP, SBP, HR (bpm), CI, and systemic vascular resistance (SVR; dynes·sec/cm^5) measured 4 hr after dosing at wk 12.

	Panel I			Panel 2		
	2.5 mg	5 mg	10 mg	2.5 mg	20 mg	40 mg
PCWP	−6.0	−7.2	−8.4	−4.4	−7.8*	−8.0*
SBP	−12.2	−7.8	−14.7	−5.1	−13.3*	−11.7*
HR	−1.5	−3.1	−2.6	−1.1	−3.7	−6.2
CI	−0.04	+0.02	+0.13	+0.12	+0.20	+0.13
SVR	−84	−34	−253	−118	−190	−232

(*$p < 0.05$ vs 2.5 mg, a dose primarily inhibiting ACE)

In Panel 2 patients, EF increased 2.3% (2.5 mg), 2.5% (20 mg), and 4.9% (40 mg), and the incidence of death, hospitalization for HF, or cointervention for HF was 34% (2.5 mg) and 19% (40 mg). In a substudy, NEP inhibition was evident at wk 12 by dose-related increases (vs trough) of 1% (2.5 mg), 38% (20 mg), and 91% (40 mg) in mean plasma levels of atrial natriuretic peptide 3 hr after dosing.

In conclusion, omapatrilat produces dose-related beneficial hemodynamic effects in HF. Neurohormonal effects consistent with NEP inhibition are observed at higher doses of omapatrilat.

PROGNOSTIC EVALUATION IN HEART FAILURE

1442 Mortality trends in 86,000 patients admitted with heart failure, 1981–1995

K. MacIntyre, S. Capewell, M. Livingston, J. Chalmers[1], J. Boyd, A. Finlayson[1], A. Redpath, J. Pell[3], C. Evans, J.J.V. McMurray[4]. *Department of Public Health, University of Glasgow; [1]Information and Statistics Division Edinburgh; [3]Greater Glasgow Health Board; [4]Department of Cardiology, Western Infirmary, Glasgow, UK*

Background: Heart failure is associated with a high morbidity and mortality that result in a significant clinical burden. Prognosis is related to the severity of left ventricular dysfunction and New York Heart Association criteria. Large clinical trials have shown significant benefits from ACE inhibitor therapy. It is however unclear whether these benefits extend to the general population and whether they have contributed to a reduction in case-fatality.

Methods: The Scottish Morbidity Record Database holds comprehensive high quality data linking all 86,336 heart failure patients admitted in Scotland (population 5.1 million) since 1981, and all 71,017 subsequent heart failure deaths. This Scottish-wide-based retrospective cohort study calculated case-fatality to 10 years, with logistic regression and Cox modelling for the effects of age, sex, socio-economic deprivation, prior morbidity and year of treatment.

Results: Overall case-fatality following hospital admission with heart failure was 21%, 46% and 78% at one month, one year and five years respectively. Cox modelling and logistic regression identified statistically significant independent prognostic factors. Thirty day mortality increased with a) each decade of age, and b) with any prior morbidity.

After adjustment for age, sex, deprivation and prior morbidity, short-term (1 month) case-fatality rates fell significantly between 1981 and 1995, by 36% in men and by 20% in women. Adjusted case fatality rates at 1–5 years fell by approximately 30% in men and 10–15% in women.

Conclusions: There was a striking increase in survival amongst patients hospitalised with heart failure in Scotland between 1981–1995. This improvement in prognosis may be due to the wider use of ACE inhibitors in patients with heart failure during the period of study.

1443 Long-term prognostic value of FDG SPECT in patients with ischaemic left ventricular dysfunction

J.J. Bax, F.C. Visser, D. Poldermans, A. Elhendy, E. Boersma, J.H. Cornel, P.M. Fioretti, C.A. Visser. *Leiden; Amsterdam; Alkmaar, Netherlands; Udine, Italy*

FDG SPECT has been used to predict improvement of function post-revascularization (REV) in patients with ischemic LV dysfunction. The current study evaluated its long-term prognostic value.

Methods: 135 patients with advanced coronary artery disease and depressed LV function (LVEF 37 ± 11%) were studied with FDG SPECT and early thallium-201 SPECT (to assess perfusion). Data were analyzed using polar maps (13-segment model). Resting function was assessed by 2D-echo. Dysfunctional segments showing normal perfusion or mismatch pattern were considered viable. Patients were classified viable when ≥ 3 dysfunctional segments were viable (this cutoff criterium was derived by previous ROC curve analysis). Fifty-eight patients underwent successful REV, while 77 patients were treated medically (MED). Follow-up was performed by chart review or telephone contact. Only hard events were considered (cardiac death or non-fatal myocardial infarction).

Results: The mean duration of follow-up was 28 ± 11 months. A total of 28 events occurred in 28 patients. The highest event-rate was observed in viable patients (n = 30) who were treated MED: 60% ($P < 0.05$ vs other groups). Viable patients (n = 26) undergoing REV had the lowest event-rate (4%). An intermediate event-rate was observed in nonviable patients treated MED or undergoing REV (9% and 16% respectively).

Conclusions: The results indicate that FDG SPECT (similar to FDG PET) identifies patients with a high risk for future events; patients with substantial viability who are treated conservatively had a significantly higher event-rate as compared to the other groups.

1444 Ventilatory response to exercise but not peak oxygen consumption predicts death in chronic heart failure patients with preserved exercise tolerance

P. Ponikowski[1,2], M. Piepoli[1], T.P. Chua[1], W. Banasiak[2], A.J.S. Coats[1], S.D. Anker[1,3]. *[1]Clinical Cardiology, NHLI, London, UK; [2]Cardiology Department, Military Hospital, Wroclaw, Poland; [3]Franz-Volhard-Klinik at MDC, Charité Berlin-Buch, Germany*

In chronic heart failure (CHF) the assessment of exercise capacity remains a gold standard in risk stratification. Peak oxygen consumption (peak VO_2) and ventilatory response to exercise (measured as the regression slope relating minute ventilation to carbon dioxide [VE/VCO_2-slope]) are both independent indices used for prognostic purposes in pts with symptomatic CHF. Whether these two exercise testing derived measures would provide a relevant prognostic information in less symptomatic CHF pts with only mild exercise intolerance has never been investigated. This study sought to assess the short (6-month) and long-term (2-year) prognostic power of peak VO_2 and VE/VCO_2-slope in this group. Among consecutive 324 CHF pts who underwent exercise testing in our laboratory between January 1993 and December 1997 we identified 132 pts (41%) with preserved exercise capacity, as evidenced by peak $VO_2 \geq 18$ ml/kg/min (mean age: 56 y, LVEF: 30%; peak VO_2: 23.5 ml/kg/min, NYHA: 1.9). Using 2SD above the mean $VE\text{-}VCO_2$ slope of age-matched controls as cut-off we defined an abnormally high ventilatory response to exercise as a $VE\text{-}VCO_2$ slope of >34.

Results: During the mean follow-up of 40 months, 24 pts (18%) died. In Cox-univariate analysis peak VO_2 was neither a significant predictor of short-term (p = 0.9) nor long-term survival (p = 0.8). On the contrary, VE/VCO_2-slope predicted short-term (p = 0.0009) and long-term mortality (p = 0.002) in pts with preserved exercise capacity. Forty-three (33%) pts who demonstrated a high ventilatory response to exercise had a worse outcome compared to pts with normal ventilatory response (table).

	High VE/VCO_2 (n = 43)	Normal VE/VCO_2 (n = 89)	p
6-month survival	88% (CI: 79–98%)	98% (CI: 95–100%)	0.025
2-year survival	72% (CI: 56–87%)	93% (CI: 87–99%)	0.002

p – log-rank test; CI – 95% confidence interval;

Conclusions: In CHF pts with preserved exercise tolerance, peak VO_2 provides no clinical information in risk stratification. In these pts, augmented ventilatory response to exercise allows to identify those at risk of a poorer outcome.

1445 Prognostic value of neurohormonal changes over time in chronic heart failure

F. Pousset, R. Isnard, J.N. Trochu[1], O. Chavirovskaia, A. Carayon[2], J.L. Golmard[3], D. Thomas, P. Lechat[4], J.B. Bouhour[1], M. Komajda. *Service de Cardiologie, Hôpital Pitié Salpétrière, Paris[1]Cardiology Dept., Hopital Laennec, Nantes[2]Biochemistry Dept., Hopital Pitié Salpétrière, PARIS[3]Biostatistics Dept., Hôpital Pitié Salpétrière, Paris[4]Pharmacology Dept., Hopital Pitié Salpétrière, Paris, France*

Neurohormones provide important prognostic information in chronic heart failure, but less is known about the rate of change of theses hormones over time and whether any changes of these hormones correlate with prognosis.

We studied 110 ambulatory heart failure patients still alive without cardiac transplantation at one year (54 ± 11 years, mean ejection fraction (EF) 28 ± 9%, NYHA functional class I to IV). Blood pressure, cardiothoracic ratio, echocardiographic left ventricular end diastolic diameter (EDD) and EF, plasma norepinephrine (NE), plasma atrial natriuretic peptide (ANP) and plasma endothelin-1 (ET1) were obtained from all patients at baseline (V0) and at one year (V1).

After a further follow-up of 474 days, 13 cardiovascular deaths occurred and 3 patients underwent an urgent cardiac transplantation (combined end point). In multivariate stepwise Cox analysis including the following parameters at one year (V1) and their changes from baseline (V1-V0): NYHA class, blood pressure, cardiothoracic ratio, echocardiographic EDD and EF, and neurohormonal parameters, only V1ANP (p = 0.0003), V1EDD (p = 0.007), V1ET1 (p = 0.004) and ANP changes (p = 0.007) were related to prognosis.

In patients with chronic heart failure, change of plasma ANP levels over time appeared to provide additional important prognostic information. Therefore it would be useful to repeat neurohormonal measurements in the management of chronic heart failure patients.

1446 Increased QT dispersion as a predictor of sudden death in postinfarction patients with severe congestive heart failure

A. Nargizyan. *Department of Heart Failure, Institute of Cardiology, Yerevan, Armenia*

QT dispersion (d) from the 12-lead ECG has been introduced as a non-invasive index of d of ventricular repolarization and increased QTd has been associated with an adverse prognosis in various patient populations. Prognostic value of this parameter in postinfarction patients (pts) is discussed. We examined significance of QTd on intrahospital mortality prognosis in postinfarction pts (infarct age > 1 year) with severe (III–IV NYHA grade) congestive heart failure (CHF).

Methods: We retrospectively evaluated resting 12 lead ECGs from 86 survivors and 39 pts who died in hospital (19 sudden death, 20 death of CHF progression). Exclusion criteria were atrial fibrillation, bundle branch block, low amplitude of T-wave, age > 65 years, ejection fraction (EF) > 30%. All pts clinical investigation has included 12-lead standard ECG at paper speed 50 mm/s and amplifier gain of 10 mm/mv, chest radiography, two-dimensional echocardiography. These groups of pts were not significantly different for age, gender, NYHA grades, cardio-thoracic ratio, EF, left ventricular enddiastolic dimension. Measurements of QT and RR intervals were performed manually in a blinded fashion in respect of outcome data. Heart rate corrected QT (QTc) were calculated by Bazett's formula. Repolarization d was determined by the difference between maximum and minimum QT intervals in each ECG (QT-d, QTc-d). All data were expressed as M ± m.

Results:

	Survivors (n = 86)	Progressive CHF deaths (n = 20)	Sudden deaths (n = 19)
QT max (ms)	376 ± 7.4	367 ± 12.4	393 ± 10.4
QTc max (ms)	467 ± 7.7	480 ± 13.2	508 ± 8.5*
QT-d max (ms)	45 ± 3.2	50 ± 5.0	87 ± 5.2**
QTc-d max (ms)	57 ± 3.8	65 ± 5.3	105 ± 4.3**

* = $p < 0.01$; ** = $p < 0.001$ vs. survivors

QT-d and QTc-d did not depend on infarct localization (anterior or inferior). The prognosis was significantly worse in pts with QTc-d > 85 ms, with sensitivity 91.6% and specificity 94%. The four week treatment 64 pts with captopril (50 mg t.i.d.) resulted in decrease of QT-d and QTc-d (from 46 ± 4.1 to 36 ± 2.7 ms, $p < 0.05$, and from 60 ± 6.1 to 49 ± 3.2 ms, $p > 0.05$, respectively), but individual analysis showed that in 1/3 of pts repolarization d was slightly increased.

In conclusion, increased repolarization d is strongly associated with the occurrence of sudden cardiac death in postinfarction pts with CHF and may be useful for risk stratification of these pts.

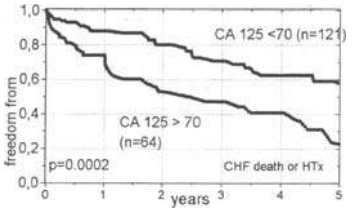
1447 CA 12-5: a prognostic marker in heart failure?

H. Nägele, M. Bahlo, M. Bohlmann, F. Dapper, R. Klapdor, W. Rödiger. *Herzchirurgie, Universitäts-Krankenhaus Hamburg-Eppendorf, Germany*

Background: We recently showed that blood levels of CA 12-5 correlate with clinical and hemodynamic parameters of heart failure (CHF) pts. This study should clarify the prognostic power of the oncofetal protein.

Methode: Prospective determination of serum levels of CA 12-5 (ELISA) in 185 CHF pts in the years 1993–1998 (40% NYHA II, 42% NYHA III, 18% NYHA IV, 49% iDCM, mean age 49 ± 9 years, mean EF 24 ± 8%). We compared survival (Kaplan-Meier) in two groups separated by a cut-off level of 70 U/ml = twofold normal (mean observation time 2.4 ± 1.9 years).

Results: CHF pts presenting with a CA 12-5 > 70 U/ml experienced significantly more pump failure death or heart transplants ($p = 0.0002$, CHI-Quadrat 13.9). Sudden death was not associated with elevated CA 12-5 serum levels.



Conclusions: Elevated CA 12-5 serum levels (possibly due to oncofetal gene activation) give prognostic informations in CHF pts.

ARTERIAL THROMBOSIS: UNDERLYING MECHANISMS

1457 Expression of platelet activation markers and monocyte Mac1 is increased in patients with chest pain but angiographically unobstructed coronary arteries

C. Altmann, D. Welge, M. Haude, B. Schwippert[1], R. Erbel, D. Tschöpe[1]. *Dept of Cardiology, University Hospital Essen, Essen; [1]Diabetes Research Institute, University of Düsseldorf, Düsseldorf, Germany*

Background: Activated circulating platelets and interactions of platelets with leukocytes play a central role in acute thrombotic events, but are also suspected to be involved in the development of microvascular disturbance as underlying coronary small vessel disease.

Methods: We investigated the extent of platelet (plt) activation and platelet-leukocyte aggregation (PLA) as well as expression of activation dependent adhesion receptor Mac1 on monocytes in 43 patients (20 female/23 male; age 56.0 ± 9.8) with chest pain and pathological stress test but angiographically unobstructed coronary arteries (microCAD) and 21 patients (5 female/16 male; age 61.5 ± 8.4) with angiographically documented coronary artery disease (macroCAD). Whole blood analysis of platelet degranulation markers P-selectin (CD62) and GP-53 (CD63), extent of platelet-bound fibrinogen (anti fibrinogen), of PLA, and expression of Mac1 (CD11b) was performed by 4-parameter flow cytometry. Results are expressed as an index of percent positive cells times mean fluorescence for surface markers and percentage leukocytes bound in aggregates for PLA.

Results:

	MicroCAD	MacroCAD	p
CD 62 (plt)	38.7 ± 17.2	27.9 ± 8.5	0.02
CD 63 (plt)	61.6 ± 30.8	41.7 ± 12.5	< 0.01
anti fibrinogen (plt)	1037 ± 267	947 ± 212	0.12
PLA (%)	2.8 ± 0.6	2.6 ± 0.9	0.10
Mac1 (monocytes)	2066 ± 981	1527 ± 822	0.04

Conclusion: The significantly higher expression of activation dependent platelet adhesion molecules (CD62/CD63) and activation dependent Mac1 on monocytes in patients with chest pain and pathological stress test despite absence of significant coronary stenoses may reflect underlying disturbances in coronary microcirculation (small vessel disease).

1458 Platelet glycoprotein IIb/IIIa inhibition with or without additional vitronectin receptor antagonism reduces thrombus accumulation and subsequent neointimal formation in a porcine angioplasty model

T.J.A. Chico, J. Gunn, N.D. Arnold, S.L. Bullens[1], S. Bunting[1], D.C. Cumberland, D.C. Crossman. *Cardiovascular Medicine, University of Sheffield, UK; [1]Genentech inc., San Francisco CA, USA*

Abciximab, an antibody to both IIb/IIIa and the vitronectin receptor (VNR) reduces thrombotic complications associated with PTCA and may reduce restenosis. We investigated the effect of lamifiban (a selective IIb/IIIa inhibitor) and G3580 (which inhibits both IIb/IIIa and VNR) on thrombus accumulation and neointima formation following PTCA.

Methods: Yorkshire White swine were given an iv bolus of lamifiban (0.2 mg/kg) G3580 (0.875–1.5 mg/kg) or saline, followed by a continuous infusion (lamifiban 0.12–0.21 mg/kg/hr, G3580 0.875–1.125 mg/kg/hr or saline). 15 min following the bolus, coronary angiography and oversized PTCA (1.3:1) to RCA and LAD were performed. The infusions adjusted aiming for 80% inhibition of platelet aggregation to 20 μM ADP and were continued for 6 hours (thrombus experiments) or 14 days (28 day neointima experiments). Thrombus formation and neointima were assessed using computerised morphometry at 6 hours and 28 days respectively

Results: 6 animals were used for the thrombus experiments (2 control, 2 lamifiban and 2 G3580). Mean (SEM) platelet aggregation (% baseline) during the infusions; Control 135 (11.5), lamifiban 1.6 (1.0) G3580 0.6 (0.4). 12 arteries were examined; 4 in each group. Mean % lumen obstruction by thrombus; Control 18.7 (4.7), lamifiban 6.4 (2.0) $p < 0.05$, G3580 7.9 (1.9) $p < 0.05$

22 animals were used for the neointima experiments (8 control, 7 lamifiban, 7 G3580). Mean (SEM) platelet aggregation (% baseline) during the infusions; Control 113.9 (2.6), lamifiban 15.9 (1.8) G3580 15.2 (1.7). 37 arteries were analysed (12 control, 13 lamifiban, 12 G3580). The mean (SEM) intimal area/medial area/injury scores were; Control 0.095 (0.027), lamifiban 0.038 (0.003) $p < 0.001$, G3580 0.048 (0.005) $p < 0.05$.

Conclusions: GP IIb/IIIa inhibition reduces thrombus accumulation following PTCA and this reduction is associated with a similar reduction in neointima. Additional effect against VNR does not appear to give additional benefit in either thrombus reduction or neointimal formation.

1459 Monocyte L-selectin down-regulation triggered by platelet-monocyte adhesion: a novel target to improve outcome following coronary intervention?

H. El Gendi, A.G. Violaris, T.F. Ismail, R.A. Foale, D.J. Sheridan. *Division of NHLI, St Mary's Hospital, Academic Cardiology Unit, London, UK*

Background: Monocyte activation induces pro-coagulant and pro-adhesive inflammatory responses and may play an important role in the thrombotic complications associated with coronary intervention. Platelet-Monocyte Adhesion (PMA) may trigger this. The aim of our study was to determine the level of local PMA during coronary intervention and to characterise its effects on monocyte activation status.

Method: PMA and monocyte activation status was prospectively examined in 30 patients undergoing left coronary system intervention (19 males, mean age 62). Coronary sinus and peripheral samples were obtained at baseline, post-first-inflation, immediately after intervention, and 24 hours later. For PMA, a novel technique was used. Blood samples were labelled with fluorochrome-conjugated monoclonal antibodies directed against CD14 (a monocyte specific marker) and GP1b (a platelet-specific marker). CD14-GP1b positive particles with the correct side scatter (granularity) profile were considered to be platelet-monocyte aggregates and were measured by flow cytometry. Monocyte activation status was assessed by determining the extent of L-selectin down-regulation.

Results: PMA increased significantly in coronary sinus samples immediately after the first balloon inflation (56.4 ± 7.6 vs 36.5 ± 3.3 at baseline, P = 0.014), but this was transient and levels returned to baseline immediately after angioplasty (33.2 ± 3.0 vs 36.5 ± 3.3 at baseline, P = NS). No increase was seen in peripheral samples (36.5 ± 3.3 (baseline) vs 36.2 ± 2.8 (after first inflation) vs 31.7 ± 3.0 (post procedure)). Monocyte activation (assessed by quantifying the degree of L-selectin mean channel fluorescence down-regulation)increased from a baseline level of 30.2 ± 2.5 to 29.3 ± 3 (P = NS) immediately after angioplasty to 20.9 ± 2.5 (P = 0.016 vs baseline) 24 hours later.

Conclusion: Our data suggest that PMA is transiently increased at the balloon injury site during angioplasty. This heterotypic platelet-monocyte interaction results in prolonged monocyte activation and may play an important role in the development of complications following coronary intervention.

1460 Thrombin generation and tissue factor activity of human coronary atherosclerotic plaques

P.A. Merlini, D. Ardissino, E. Bramucci, R. Fetiveau, L. Angoli, E. Colombi, R. Coppola, R. Ariens, R.D. Rosenberg, P.M. Mannucci. *Division of Cardiology, IRCCS, Policlinico San Matteo, Pavia; Ospedale Niguarda, Hemophilia and Thrombosis Center, Milan, Italy; Beth Israel Deaconess Medical Center, Boston MA, USA*

Tissue factor (TF) is the primary initiator of blood coagulation and its activity is higher in coronary plaques extracted from patients with unstable angina or myocardial infarction than in patients with stable angina. It is not known whether higher contents of TF are associated with higher procoagulant activity in vivo.

Methods: We measured intracoronary thrombin generation (prothrombin fragment 1 + 2; F1 + 2, nM/L) in 40 patients (22 stable angina, 18 unstable angina) undergoing directional coronary atherectomy (DCA). Intracoronary blood samples were collected proximally (Ao) and distally (Co) to the lesion, prior (pre) and after (post) DCA, a model for plaque disruption. TF activity of the extracted plaques was measured by means of factor Xa generation assay (mU/mg plaque weight).

Results: (median, interquartile range)

	Stable (N = 22)	Unstable (N = 18)	P
TF mU/mg	0.15 (0.08–0.25)	0.25 (0.18–0.42)	0.011
F1 + 2 preAo	0.95 (0.78–1.28)	1.16 (0.86–1.49)	NS
F1 + 2 preCo	1.0 (0.7–.17)	1.5 (1.15–2.07)	0.004
ΔF1 + 2 preCo-preAo	−0.06 (−0.22–0.15)	0.13 (−0.04–0.37)	0.002

There was a correlation between TF activity of the extracted plaques and thrombin generation measured after DCA (rho = 0.38; p = 0.018).

Conclusion: Tissue factor activity is increased in unstable coronary plaques and is associated with an increased local thrombin generation in vivo. During DCA-induced plaque disruption the intracoronary prothrombotic response is correlated with TF activity.

1461 Effects of recurrent thrombus formation on tissue factor expression in the arterial wall

D. D'Andrea, P. Golino, F. Vigorito, P. Tommasini, M. Ravera, M. Chiariello. *Division of Cardiology, University of Naples Federico II, Naples, Italy*

Tissue factor (TF), a membrane glycoprotein that activates the extrinsic coagulation pathway, is normally expressed at low levels in the media of blood vessels. We have previously demonstrated that recurrent thrombus formation upregulates TF in the media of stenotic rabbit carotid arteries with endothelial injury. The aim of the present study was to investigate whether this upregulation of TF is related to thrombus formation, vessel damage, or both. Cyclic flow variations (CFVs), due to recurrent thrombus formation, were induced in stenotic rabbit carotid arteries with endothelial injury. CFVs were observed for either 30, 120, 240, or 480 min in different groups of animals (n = 6 in each group). An additional group of animals (n = 6) was treated with hirudin (1 mg/kg) before inducing the damage to inhibit thrombus formation and observed for 480 min. At the end of the experiment, the carotid arteries were isolated, rinsed with saline, embedded in methyl methacrylate and quick-frozen in liquid nitrogen. Arterial sections (4 μm) were mounted on microscope slides and immunohistochemical staining for TF was performed using AP-1, a monoclonal antibody against rabbit TF, as primary antibody, and rabbit anti-mouse IgG conjugated with peroxidase, as secondary antibody. A semiquantitative score (from 0 to 3) was given to sections as follows: 0 = no positivity in the media; 1 = slight positivity in the media, but less than that observed in the adventitia; 2 = positivity in the media comparable to that of the adventitia; and, 3 = positivity in the media more pronounced than that of the adventitia. Scores were assigned by two different investigators who were blind as per group assignement. At least 15 arterial sections were evaluated per animal. Contralateral, undamaged carotid arteries without CFVs served as controls. An increase in TF expression was observed over time from 0 ± 0 in control vessels, to 0.8 ± 0.3, 1.3 ± 0.4, 1.8 ± 0.6*, and 2.2 ± 0.6*, at 30, 120, 240, and 480 min, respectively (* = $p < 0.05$). In contrast, in hirudin-pretreated animals, a very low level of TF expression was detected at 480 min after the damage (O.5 ± 0.3, p = ns). We conclude that: 1) A progressive increase in TF expression was observed in the media as CFVs progressed; 2) This increase in TF expression seems to be related only to recurrent thrombus formation, as TF was not upregulated in hirudin-pretreated animals, in which arterial damage was not accompanied by CFVs. These data demonstrate that thrombus-induced TF upregulation may contribute to sustain intravascular thrombus formation after the initial thrombogenic stimulus.

1462 Risk of myocardial infarction in association with the platelet collagen receptor GPIa C807T dimorphism

S.A. Croft, R. Steeds[1], K.A. Hampton, J.A. Sorrell, N. Samani[2], M. Daly, K.S. Channer[1]. *Molecular Medicine Dept, Royal Hallamshire Hospital, Sheffield; [1]Cardiology Dept, Royal Hallamshire Hospital, Sheffield; [2]Cardiology Dept, Leicester Royal Infirmary, Leicester, UK*

Aim: The formation of platelet rich thrombi following rupture of atherosclerotic plaque is the primary adhesive event leading to the formation of occlusive thrombus and subsequently to acute myocardial infarction (MI). The platelet collagen receptor, GPIa/IIa, is an important mediator of platelet adhesion. Variation in GPIa/IIa receptor density correlates with functional differences in platelet adhesiveness to fibrillar collagens and is associated with a silent dimorphism at nucleotide C807T of the GPIa cDNA. The aim of this study was to investigate the relationship of the GPIa C807T dimorphism to the risk of MI.

Methods: 1053 subjects were studied (546 patients with acute MI recruited consecutively from the hospital coronary care units and 507 population-based controls). The TaqMan allelic discrimination system was used to determine the GPIa C807T genotypes. All subjects were white Caucasians aged under 75 years

Results: In the overall cohort, the frequency of the 807T allele (which was associated with increased receptor density) was 0.4 (95% C.I. 0.37–0.43) in the case group compared to 0.43 (95% CI 0.40–0.46) in the control group. This gave an odds ratio for MI of 0.88 (95% CI 0.74–1.05, p = 0.17). There was no difference in the genotype distributions between cases (TT 17%, CT 46%, and CC 37%) and controls (TT 19%, CT 48%, and CC 33%, p = 0.22 for TT; p = 0.24 for CT). There was no increase in prevalence of the 807TT or 807CT genotype after stratification for age or sex. Similarly, restriction of the analysis to low risk subgroups comprised of women only, normotensive subjects or subjects with a cholesterol or BMI below the group medians failed to show an increased risk of MI

Conclusion: This case-control study did not demonstrate an association between the GPIaC807T dimorphism and risk of MI. This would suggest that the variation in the GPIa/IIa receptor density and the differences in adhesiveness of platelets to fibrillar collagens associated with the C807T dimorphism do not contribute to an increased coronary arterial thrombotic risk.

CORONARY INTERVENTION FOR UNSTABLE ANGINA

1463 Role of enoxaparin in patients undergoing percutaneous revascularization in the setting of unstable angina. A TIMI 11B substudy

L.A. Guzman, R. Henquin, E. Gurfinkel[1], G. Bozovich[1], D. Radley[2], E. Antman[3]. *Interventional Cardiology Dept, Instituto Cardiovascular Buenos Aires, Buenos Aires; [1]Cardiology Dept, Fundacion Favaloro, Buenos Aires, Argentina; [2]Biostatistics Dept, Rhone Poulenc Rorer, Collegeville; [3]Cardiology Dept, Brigham and Women's Hospital, Boston MA, USA*

Percutaneous revascularization (PTCI) in patients (Pts) with unstable angina (UA) is associated with ischemic complications. Recently, enoxaparin (ENOX) has been approved and adopted in many centers as the treatment for Pts with UA. The TIMI 11B trial randomized 3910 Pts with UA/NonQwMI to test the hypothesis that ENOX is superior to unfractionated heparin (UFH). A subset of 784 Pts (20%), after being pre-treated with either UFH or ENOX, underwent PTCI, and represent the subject of this substudy (403 randomized to UFH and 381 to ENOX); 2600 patients received only medical therapy (No PTCI or CABG). The aim of this substudy was to compare the efficacy and safety of a strategy of ENOX prior to and after PTCI versus UFH prior to PTCI. All Pts were treated with open label UFH during the PTCI. Clinical baseline characteristics were similar in the two treatment groups. Approximately 80% of Pts in each group had ECG changes and 45% had elevated serum cardiac markers. The admitting diagnosis was similar in the two groups (56% UA, 40% NonQwMI, 4% QwMI).

Outcome at 43 days

	UFH	ENOX	OR	CI
PTCI Pts	N = 403	N = 381		
Successful	359 (89%)	351 (92%)	1.43	(0.88–2.4)
Death (D)	11 (2.7%)	8 (2.1%)	0.76	(0.30–1.9)
MI	21 (5.2%)	15 (3.9%)	0.75	(0.38–1.47)
Urgent Revasc (UR)	14 (3.5%)	7 (1.9%)	0.52	(0.21–1.30)
Combined (D,MI,UR)	38 (9.4%)	27 (7.1%)	0.73	(0.44–1.23)
Major Bleeding	19 (4.7%)	18 (4.7%)	1	(0.52–1.94)
Medical Rx Only	N = 1286	N = 1314		
D, MI	86(6.7%)	77 (5.9%)	0.87	(0.63–1.19)
All Pts	N = 1957	N = 1953		
D,MI,UR	385 (20%)	337 (17%)	0.85	(0.72–1.00)

Conclusions: The benefit of ENOX was similar in patients who underwent PTCI and those who received only medical therapy. Pre-treatment with ENOX prior to PTCI is safe, appears to increase the success of the procedure, and tends to decrease the rate of ischemic complications. These results suggest a beneficial role for ENOX regardless of whether UA/NonQwMI Pts are managed with an early invasive or early conservative strategy.

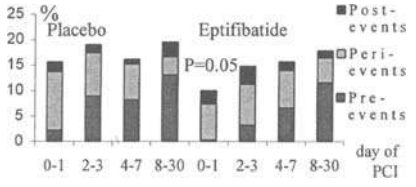
1464 Optimal timing of percutaneous intervention in unstable angina

E. Ronner[1], E. Boersma[2], R.A. Harrington[3], A.M. Lincoff[4], M.L. Simoons[2]. *[1]Cardialysis, Rotterdam; Heartcenter, Rotterdam, Netherlands; [3]Duke University, Durham NC; Cleveland Clinic Foundation, Cleveland OH, USA*

Background. Early PCI prevents recurrent and refractory ischemia and pre-procedural infarction in unstable angina and myocardial infarction without persistent ST-segment elevation (UAP). Both pre-and peri- (<48 hours after PCI) procedural death and myocardial infarction ("Pre" and "peri-events") rates change over time, the sum of both at different moments in time is unknown. In the PURSUIT database the effect of timing of PCI on pre-and peri-procedural (peri) events was documented for eptifibatide and placebo.

Methods. 9.461 patients with UAP were randomized to eptifibatide or placebo, given during 72 hours. Further treatment was left entirely to the investigators.

Results. 30 day pre, peri and post-procedural events in percentages, see graph: Deferring PCI in placebo patients lead to a decline in peri-events (10.8 to 3.6%, P = 0.006), while pre-events increased (2.2 to 13%, P = 0.001). Eptifibatide reduced high peri-events on day one (10.8 to 7.1% P < 0.05), with low pre-events. Over time, peri-events with eptifibatide remained nearly constant, but pre-events cumulated.



Events till day 30, without events after bypass surgery:

Amounts:	Placebo#P = 0.001				Eptifibatide			
Day PCI	0–1	2–3	4–7	8–30	0–1	2–3	4–7	8–30
Patients:	308	311	287	288	308	311	287	288
Pre-	7	28	27	40#	1	10	19	33#
Peri-	34	26	22	11#	22	25	21	14
Post	6	5	3	9	8	11	5	4

Conclusions. More peri- than pre-procedural events were reduced with eptifibatide, therefore PCI on day one demonstrated highest treatment benefit, as peri-procedural risk was reduced markedly and pre-events were still low.

1465 Long-term results of early coronary angioplasty in unstable angina compared with delayed coronary angioplasty

R. Sabatier, S. Dargham, G. Grollier, E. Lecluse, E. Saloux, M. Hamon, J.-C. Potier. *Cardiology Dept., CHU Caen Côte de Nacre, Caen, France*

In unstable angina, the time when angioplasty must be carried out is still discussed. In some cases, a conservative approach to achieve stabilization by medical treatment seems preferable to early invasive strategy. The aim of this study is to assess the immediate and long-term results after early and delayed coronary angioplasty in patients with unstable angina.

Methods: Between January and December 1996, 499 patients were admitted for unstable angina. 170 consecutive patients were eligible for coronary angioplasty of the culprit lesion. They were separated in two groups depending on the duration of conventional medical treatment before the invasive procedure: less than 48 hrs (91 patients, group A) and more than 48 hrs (79 patients, group B).

Results: Group B included more women (35% vs 15%; $p < 0.002$) and the patients were older (67.6 ± 9.5 yrs vs 62.5 ± 11.2 yrs; $p < 0.005$). Other clinical data, angiographic and procedural characteristics were similar in the two groups. Stenting was performed in 82% of the patients in group A and 86% in group B (NS). The immediate success rate was identical (93% in group A vs 95% in group B; NS). In-hospital stay was shorter in group A (2.9 ± 1.1 days vs 8.5 ± 3.6 days; $p < 0.00001$). The clinical outcome at 10.9 ± 6 months in group A and 10.2 ± 6.5 months in group B (NS) was available for all patients. Long-term clinical success rate (asymptomatic patients or with stable angina) was not different between the two groups (91% in group A vs 86% in group B; NS). Recurrent unstable angina during follow-up occurs more frequently in group B ($p = 0.02$).

Conclusion: These results suggest that early coronary angioplasty in unstable angina is a safe and effective strategy with a shorter hospital stay. The excellent long-term outcome after early coronary angioplasty has to be confirmed in a randomized study.

1466 Comparison of early invasive versus early medical management of acute coronary syndromes: a meta-analysis

L. Melilli, R. Arora. *Interventional Cardiology Dept., Columbia University, Katonah NY, USA*

Background: One critical controversy in cardiology today is the use of early invasive versus medical management of acute coronary syndromes (ACS). While aggressive management may provide long-term clinical benefits over pharmacologic therapy in some patients, it is unclear whether the risks outweigh the benefits. This meta-analysis was conducted to asses the appropriateness of early invasive versus early medical management of ACS.

Methods: A meta-analysis was conducted of all randomized, placebo-controlled, double-blind clinical trials published from January 1988 to June 1998 of aspirin and/or heparin, glycoprotein IIb/IIIa blockers, and invasive procedures (thrombolysis, coronary angioplasty, coronary bypass surgery) administered within 24 hours to patients presenting with unstable angina or non-Q-wave infarction.

Results: Early invasive management resulted in significantly greater reduction in mortality (−8.5, 95% CI −2.25, −14.75 versus −3.5, 95% CI 2.61, −4.39). Early medical intervention resulted in significantly reduced need for subsequent revascularization (−6.8, 95% CI −2.61, −10.99 versus −0.51, 95% CI −6.02, 5.00) and the combined endpoint of reduced mortality and infarction (−14.62, 95% CI −8.36, −20.87 versus −11.08, 95% CI −22.35, 0.20).

Conclusion: Early invasive procedures for ACS should be reserved for patients at high-risk of mortality and subsequent cardiovascular events. In patients without evidence of high risk, early medical management appears to be sufficient in reducing the need for subsequent revascularization, and reducing the combined endpoint of mortality and infarction when compared to early invasive management.

1467 Early invasive versus early non-invasive strategy in the setting of long-term versus a short-term treatment with s.c. low-molecular-weight heparin in unstable coronary artery disease: a randomised trial with one year follow-up

Lars Wallentin, Fredrik Kontny, Bo Lagerqvist, Sten Husted, Elisabeth Ståhle, Eva Swahn. *For the FRISC II study group; Deparments of Cardiology, University Hospital in Uppsala; Oslo; Aarhus and Linköping, Sweden*

There is little evidence from randomised studies to support a policy of early invasive procedures in UCAD without incapacitating symptoms or severe ischemia. Both invasive procedures and antithrombotic treatment have been considerably improved. Thus, there is an urgent need for randomised studies of an early invasive versus an early noninvasive strategy in the settings of different modern antithrombotic treatment alternatives in unstable CAD.

Design: 2456 patients with chest pain and signs of ischemia (ST-depression, T-wave inversion or elevation of cardiac markers) were randomised to a direct invasive strategy (n = 1220) with coronary angiograms and, if appropriate, early revascularisation within the first 7 days or to a noninvasive approach (n = 1236) with invasive procedures only at incapacitating symptoms or severe ischemia at exercise testing. All received aspirin and s.c. lmw heparin (dalteparin) 120 IU/kg b.d for 5 – 7 days and thereafter randomisation to 3 months of s.c. dalteparin or placebo twice daily. Endpoints were death or MI, new revascularisation, symptoms and readmission at 6 and 12 months.

Results There were only minor differences in base-line characteristics. In the invasive group 78% had a revascularisation procedure which in 91% was performed within the first 10 days. In the non-invasive group 38% had a coronary procedure and only 24% of these were performed within the first 10 days. At 6 months the mortality was 2.4% and death + MI 10.6%. The 6 and 12 months end-points in the randomised groups and in subgroups based on short- or long term dalteparin, gender, ECG changes and biochemical cardiac markers obtained in all patients at admission will be presented.

Conclusion: The present study is the first large scale trial randomising patients with UCAD to an early invasive versus an early conservative approach on a background of two alternatives of modern antithrombotic treatment, i.e. short-versus long-term s.c.lmw heparin. The one year results of these alternative strategies will have a large impact on short and long-term management and tailoring of treatment for patients with unstable coronary syndromes.

1468 Invasive versus conservative Treatment of Refractory Unstable Coronary Syndromes (TRUCS study) in geographically isolated areas without cardiac surgery: in-hospital, 30-day events and preliminary follow-up

C.S. Stroumbis, L.K. Michalis, K. Pappas[1], J.A. Goudevenos, K. Siogas[1], D.A. Sideris. *University Hospital; [1]General Hospital of Ioannina, Ioannina, Greece*

The Treament of Refractory Unstable Coronary Syndromes (TRUCS) study is a randomized clinical trial to compare invasive vs medical management of unstable angina (UA) in patients with refractory symptoms in isolated areas without surgical backup.

Methods: Patients with refractory UA (recurrent angina ± ECG changes) were randomised according to the date of admission to Group A (invasive approach-odd dates) and Group B (conservative approach-even dates). Group A patients underwent urgent coronary angiography (CA) followed by revascularization if appropriate (PTCA in-house, CABG in a cardiac surgery center after emergency air ambulance transfer). Group B patients remained on medication and were dealt with invasively only if symptomatic for 5 days. Stabilization, duration of hospitalization, new non-fatal MI, mortality, combined outcome and readmission for UA and revascularization were compared on an intention to treat basis in hospital, at 30-days and 12 month median (8 ± 5 month, mean ± SD) follow-up.

Results: From Mar 1997–Oct 1998, 148/719 (21%) consecutive patients with UA had refractory symptoms (Group A: 76, Group B: 72, similar baseline characteristics). 40 (53%) Group A patients underwent PTCA, 19 (25%) were transferred for CABG and 17 (22%) continued medical treatment. 38 (53%) patients in Group B were managed invasively (CA) due to refractory UA [PTCA: 23 (60%), CABG: 4 (10%), left on medical treatment: 11 (30%)]. Outcomes (Group A vs Group B): a) In hospital: stabilization (96% vs 43%, $p < 0.001$), new non fatal MI (1.3% vs 4.1%, p = NS), mortality (1.3% vs 8.1%, p = NS) and combined outcome (mortality and new non fatal MI: 3.9% vs 12.1%, $p < 0.1$) and hospitalization (11.8 ± 6.3 vs 12.7 ± 8.0 days, p = NS). b) 30-days: new non-fatal MI (2.6% vs 4.1%, p = NS), mortality (2.6% vs 10.8%, $p < 0.1$) and combined outcome (5.3% vs 14.8%, $p < 0.1$). c) 12 month follow-up (median): non-fatal MI (5.2% vs 4.1%, p = NS), mortality (3.9% vs 10.8%, p = NS), combined outcome (9.2% vs 14.8%, p = NS) and readmission's for a) UA: (6.6% vs 9.7%, p = NS), b) PTCA: (11% vs 3%, p = NS) and c) CABG: (4% vs 13%, p = NS).

Conclusion: Invasive treatment of patients with refractory angina in remote areas without surgical backup results in significant stabilization and a reduction of major events in hospital, at 30 days and at 12 months (median) follow-up with fewer re-admissions for UA and CABG, at the cost of increased subsequent PTCA. Initial data suggest that immediate CA and on the spot PTCA or air transfer for urgent CABG should be the treatment of choice for patients with refractory UA under these circumstances.

REGIONAL FUNCTION BY DOPPLER TIME IMAGING

1469 Assessment of non-uniformity of transmural myocardial velocities by colour-coded Doppler tissue imaging: characterization of normal, ischaemic and stunned myocardium

G. Derumeaux, M. Ovize[1], J. Loufoua[1], R. Douillet, F. Jamal[1], A. Cribier. *Rouen; [1]Lyon, France University*

Transmural contractile performance is nonuniform across the different layers of myocardial walls. We evaluated the accuracy of color M-mode Doppler tissue imaging (DTI) to assess the transmural distribution of myocardial velocities and to quantify the severity of dysfunction induced by ischemia and reperfusion in the inner and outer myocardial layers.

Total brief occlusion of LAD was followed by reperfusion in 13 open-chest dogs. M-Mode DTI was performed from an epicardial short-axis view. We calculated mean systolic velocities (S, cm/sec) within endocardium (endo) and epicardium (epi) of the anterior wall (AW) and the subsequent velocity gradient between endo and epi (Gr). Myocardial blood flow (MBF, ml/min/g) was measured by the radioactive microsphere technique.

S were highly correlated with systolic shortening assessed by sonomicrometry provided by 2 pairs of microcrystals positionned in endo and epi of the AW ($p < 0.0001$). Sendo, Sepi and Gr significantly decreased during LAD occlusion. After 30 minutes of reperfusion, Sendo showed a greater improvement when compared to Sepi and Gr resumed although to a limited extent, indicative of stunning.

	Baseline	Occlusion	Reperfusion	p
S endo	4.9 ± 0.7	0.4 ± 0.1	2.6 ± 0.4	<0.0001
S epi	1.7 ± 0.4	0.2 ± 0.2	0.5 ± 0.2	<0.0001
Gr	3.2 ± 0.5	0.3 ± 0.1	2.1 ± 0.3	<0.0001
MBF	0.88 ± 0.05	0.12 ± 0.04	3.81 ± 0.93	<0.0001

DTI is an accurate method to assess the nonuniformity of transmural velocities. It is promising to quantify ischemia-induced myocardial alterations and to differentiate ischemic from stunned myocardium.

1470 Pulsed Doppler tissue imaging for assessment of myocardial viability

D. Yuan[1], R. Hoffmann[1], E. Kleinhans[2], M. Ploch[1], H. Kühl[1], A. Franke[1], U. Buell[2], P. Hanrath[1]. *[1]Medical Clinic I; [2]Department Nuclear Cardiology, University RWTH Aachen, Germany*

Objective: To evaluate the value of pulsed Doppler Tissue Imaging (DTI) for quantitative assessment of myocardial viability.

Method: In 30 patients (58 ± 9 years) with prior myocardial infarction positron emission tomography (PET) and dobutamine echocardiography (DE) with additional pulsed DTI were performed to evaluate myocardial viability. Peak systolic myocardial velocities (PSMV) were measured for each segment at baseline and low-dose dobutamine stress (5–10 μg/kg/min.) by pulsed DTI. 364 segments with adequate pulsed DTI tracing were divided according to 2-D DE and according to PET findings into normal, viable and non-viable segments. Pulsed DTI results were correlated with 2-D DE and PET.

Results: Based on 2-D DE there were significant differences between normal, viable and non-viable segments in pulsed DTI findings.

	Normal (N = 241)	Viable (N = 55)	Non-viable (N = 68)	P
Low-dose PSMV (cm/s)	8.16 ± 2.53	6.86 ± 3.11	6.48 ± 2.51	<0.001
PSMV difference (cm/s)	2.72 ± 1.90	1.86 ± 2.15	0.99 ± 1.16	<0.001
% increase in PSMV	54 ± 39	38 ± 39	18 ± 20	<0.001

Based on PET findings % increase in PSMV was 54 ± 40, 24 ± 21 and 18 ± 23 (p ANOVA < 0.001) for normal, viable and non-viable segments, respectively.

Conclusion: Measurement of PSMV by pulsed DTI with low-dose DE is feasible and effective for the identification of regional myocardial function and is likely to complement the standard interpretation of low-dose stress echocardiography in myocardial viability from qualitative to quantitative analysis.

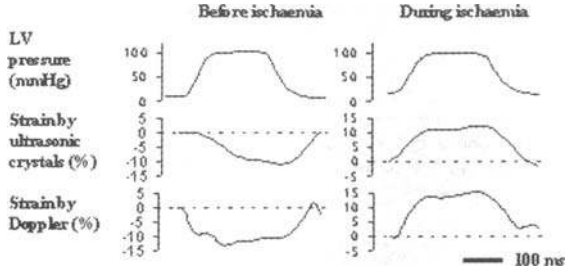
1471 Myocardial strain by Doppler echocardiography: a new method to measure regional myocardial function

S. Urheim, H. Torp[1], T. Edvardsen[2], B. Olstad[1], B. Angelsen[1], O.A. Smiseth[3]. *Inst. for Surgical Research, The National Hospital, Oslo; [1]NTNU, Trondheim; [2]Department of Cardiology, The National Hospital, Oslo; [3]Institute for Surgical Research, The National Hospital, Oslo, Norway*

Myocardial strain derived from tissue Doppler velocities has been proposed as a new method to quantify regional LV function. We investigated whether this method reflects changes in myocardial function induced by myocardial ischaemia.

Methods: In 8 anesthetized dogs myocardial ultrasonic crystals were placed longitudinally in the LAD and the Cx regions and micromanometer in the LV. Measurements were done before and during LAD occlusion. Strain rate was calculated in real-time on apical images as differences in tissue velocity per unit length (1/sec). Strain was obtained by integrating strain rate over time. The strain estimates express percentage variations in longitudinal shortening.

Results: LV pressure-strain loops constructed from Doppler strain rate approximated loops constructed from sonomicrometry. Before ischaemia both loops moved counterclockwise and during ischaemia there was a clockwise rotation of the loops. Before ischaemia percentage systolic strain was -16 ± 1 ($\pm$ SEM) by sonomicrometry and -12 ± 1 (%) (ns) by the Doppler method, and during ischaemia 13 ± 2 and 11 ± 2 (%) (ns), respectively. Peak Doppler derived strain correlated with peak strain measured by sonomicrometry ($y = 0.80x - 1.75$, $r = 0.91$, $p < 0.01$). the figure shows a representative experiment and displays myocardial strain by Doppler along with myocardial segment lengths.



In conclusion, Doppler derived strain reflects myocardial ischaemia and may represent a new powerful tool for quantifying left ventricular function.

1472 Strain rate imaging can facilitate evaluation of left ventricular regional wall motion in patients with myocardial infarction: preliminary results

D. Mele, B. Olstad, K. Bettiol, I. Pedini, P. Alboni, R.A. Levine[1]. *Division of Cardiology, Ospedale Civile, Cento, Italy; [1]Noninvasive Cardiac Laboratory, Massachusetts General Hospital, Boston, USA*

Background: Color Doppler Tissue Imaging (CDTI) can evaluate regional systolic function of the left ventricle (LV) in ischemic heart disease but it is limited in discriminating passive from active movements of the ventricular walls. Strain Rate Imaging (SRI) is a new method of analysis of myocardial velocities designed to measure regional velocity gradients. Applied to apical views, SRI allows evaluation of in-plane longitudinal myocardial strain rate that can be used as an indirect and inverse estimate of local wall thickening, virtually unaffected by motion of adjacent segments and heart translation. In this study we applied SRI to the study of LV regional systolic function in comparison with conventional CDTI.

Methods: Five normal subjects (mean age 40 ± 8 years, 3 males) and 7 patients (mean age 58 ± 9 years, 5 males) with myocardial infarction and wall motion abnormalities who underwent a clinically indicated nuclear examination were studied. For each patient, the 3 standard apical views were acquired by using a Vingmed System 5 echo scanner in a high frame rate cineloop format and transferred to a computer. According to ASE 16-segments model, a total of 192 segments were available for analysis by SRI and CDTI. The pattern of LV wall motion over time by each technique was displayed as color coded images using a curved anatomic M-mode line passing through the LV walls from base to apex in each apical view. Regional systolic function was visually evaluated on the colored M-mode SRI and DTI images.

Results: In 169 normally perfused segments, SRI showed a normal pattern of motion in 96% (162/169) and CDTI in 94% (159/169). In 23 abnormally perfused segments, SRI showed an abnormal pattern of motion in 91% (21/23) and CDTI in only 69% (16/23) reflecting passive motion of tethered myocardial segments, including 5 infarct segments.

Conclusions: SRI improves evaluation of LV segmental wall motion compared with CDTI because it can identify segments that are moving passively but not thickening normally and therefore can assist evaluation of regional systolic function in ischemic heart disease.

1473 A tissue-Doppler based analysis of the longitudinal left ventricular shortening in patients with different forms of ECG bundle-branch blocks

L. Brodin, B. Lind, M. Gaballa, M. Jensen-Urstad[1], J. van der Linden[2]. *Dept of Clinical Physiology, Huddinge University Hospital, Huddinge; [1]Dept of Cardiology, Karolinska Hospital, Stockholm; [2]Cardiac Surgery and Anesthesiology, Huddinge University Hospital, Huddinge, Sweden*

The importance of the longitudinal shortening with the systolic movement of the atrioventricular ring (AV plane) towards the apex and the largest movement in the lateral wall is well established as a nominator of cardiac function. Apart from M-mode measurements, the amplitudes of movements can today also be calculated from tissue Doppler based velocity measurements. This means that both velocities, the timing and the movement of the tissue can be measured. The present study was performed to establish reference values during different forms of ventricular electrical activation disturbances.

Methods: 10 normals, 10 patients with left bundle branch block (LBBB), 8 with right bundle branch block (RBBB) and 6 with left anterior hemiblock (LAH), all without known earlier myocardial infarction, were studied. The myocardial velocities during two consecutive beats were acquired on a GE-Vingmed System 5, and transferred to a computer for offline analysis including velocity profiles, integrated velocity and curved M-mode (C-Mode) analysis.

Results: The patients with LBBB had a significantly reduced average amplitude of AV plane movement (7.2 ± 2.2 mm), as compared to RBBB (10.4 ± 2.6 mm), LAH (10.9 ± 2.6 mm), and normals (11.3 ± 2.1 mm). Patients with LAH and normals had the highest amplitude in the lateral wall; RBBB and LBBB in the septal wall. In normals the highest systolic velocity was measured in the posterior wall, in LAH and RBBB in the lateral wall, and in LBBB in the anterior wall. The time delay between maximal velocities in the four locations was longer in LBBB (>110 ms) than in the other.

Conclusion: Electrical activation disturbances induce significant changes in both timing and amplitude of the AV-plane movement. The effect is most pronounced in patients with LBBB.

1474 The systolic descent of the mitral annulus in a large unselected population

G. Berna, P. Barbier, A. Grimaldi, M. Alimento, M.D. Guazzi. *Echocardiography Dept, Centro Cardiologico, Fondaz. Monzino, Milan, Italy*

We have identified in a preliminary study left ventricular (LV) long axis shortening (LAS) and stroke volume as the main determinants of the systolic descent of the mitral annulus (DMA). We report the influence of underlying myocardial disease on DMA in a large (500 pts) unselected population, examined by a single operator, subdivided in: normal subjects (Norm, 114), ischemic heart disease (IHD, 146), hypertension with LV hypertrophy (Hyp, 70), dilated cardiomyopathy (DCM, 33), mitral prosthesis (MP, 32), aortic or mitral regurgitation (35), mixed (70). We measured DMA, indexed by BSA, at the 4- (DMA4m) and 2-chamber (DMA2m) mid- and 4-chamber lateral anulus (DMA4l). The independent determinants common to the three DMA indices in both the total population and normal subgroup were: LAS (positive coeff., $p < 0.001$), age (negative coeff., $p < 0.001$), indexed LV diastolic long axis (pos. coeff., $p < 0.001$), LV outflow tract integral (pos. coeff., $p < 0.01$), and presence of atrial fibrillation (neg. coeff., $p < 0.05$). All DAM indices correlated moderately with LV EF ($r = 0.37$ to 0.54, $p < 0.001$) but only in IHD and DCM. Compared to Norm, all DMA indices were similarly reduced, as LV EF, in the IHD, DCM and MP groups (see table). All DMA indices were reduced in MP with normal wall kinesis (MPn, 25), compared to age-matched Norm, and in IHD with (IHDa, 73) compared to without (IHDn, 73) wall diskynesis.

	LV EF	DMA4m	DMA4l	DMA2m	
Norm	66 ± 6	0.66 ± 1.7	0.74 ± 0.18	0.64 ± 0.18	
IHD	58 ± 13**	0.53 ± 0.15**	0.63 ± 0.18**	0.47 ± 0.15**	vs Norm
DCM	34 ± 12**	0.40 ± 0.13**	0.49 ± 0.15**	0.34 ± 0.17**	vs Norm
MP	58 ± 11*	0.50 ± 0.15*	0.61 ± 0.18*	0.52 ± 0.15*	vs Norm
MPn	62 ± 8*	0.55 ± 0.14*	0.64 ± 0.17*	0.57 ± 0.11*	vs Norm
IHDn	65 ± 8	0.57 ± 0.15	0.67 ± 0.17	0.53 ± 0.14	
IHDa	51 ± 12**	0.48 ± 0.15**	0.59 ± 0.18*	0.41 ± 0.14**	vs IHDn

In conclusion, the DMA is multifactorially determined by LAS, age, LV preload (diastolic long axis), and stroke volume. It is an index of LV systolic function distinct from EF, and easier to obtain. The DMA is independently reduced by atrial fibrillation, segmental wall abnormalities and presence of mitral valvular prosthesis, secondary to impairment of LV longitudinal fiber function.

MAGNETIC RESONANCE IMAGING AND ELECTRON-BEAM COMPUTED TOMOGRAPHY IN CORONARY ARTERY DISEASE

1475 Contrast-enhanced three-dimensional breath-hold magnetic resonance coronary angiography for detection of coronary artery stenosis

M. Regenfus[1], D. Ropers[1], S. Achenbach[1], W. Kessler[1], W. Moshage[1], G. Laub[2], W.G. Daniel[1]. *[1]Department of Internal Medicine II, University Erlangen-Nuernberg; [2]Siemens Medical Engineering Group, Erlangen, Germany*

Recently, magnetic resonance (MR) coronary angiography made feasible the visualization of coronary arteries by means of the application of T1-shortening contrast-agents and ultrashort gradient-echo sequences. Aim of this study was to evaluate a new, ultrafast Gadolinium-enhanced 3D breath-hold MR technique for detection of coronary artery stenoses in oblique projection angiograms.

Methods: MR investigation was performed in 35 patients with suspected or known coronary artery disease on a 1.5T scanner (VISION, Siemens AG). After visualization of the course of the main coronary arteries using contiguous cross-axial spin-echo images, MR coronary angiography was performed within one single breath-hold using an ultrafast contrast-enhanced 3D gradient-echo sequence (TR/TE 4.2/1.6, spatial resolution 1.25 × 1.25 × 1.5 mm^3). In sucessive studies, the imaging volume which consisted of 32 contiguous parallel sections was positioned along the course of right (RCA) and left circumflex (LCX) and along left main (LM) and left anterior descending (LAD) coronary arteries, respectively. During each measurement, 20 ml Gadolinium-DPTA (0.5 mol/l, MAGNEVIST, Schering AG) were applied intravenously according to the individually determined contrast transit time. Image data were evaluated by two independent observers. The results were compared with conventional contrast angiography in a blinded manner.

Results: 179 of 245 coronary segments (LM, proximal and mid segments of LAD, LCX and RCA) could be visualized (73.1%). In these, 35 of 43 significantly stenotic (>/= 50%) and 123 of 136 non-stenotic coronary segments could be exactly classified. Thus, the overall sensitivity and specifity for stenosis detection resulted in 81.4% and 90.4%, respectively.

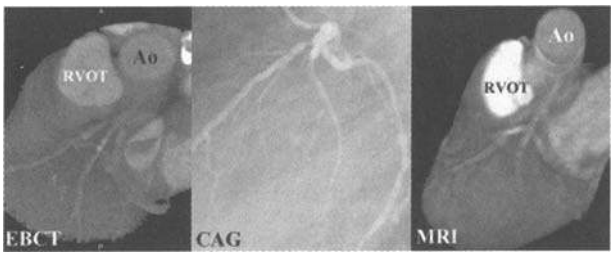
In conclusion, using ultrafast Gadolinium-enhanced 3D breath-hold imaging, oblique projection MR coronary angiograms can be successfully performed in the majority of cases. However, sensitivity for detecting coronary stenoses is not yet sufficient and further techniqual improvements are mandatory to introduce this technique as a reliable diagnostic tool in clinical practice.

1476 Non-invasive coronary imaging: a comparison between magnetic resonance imaging and electron beam computed tomography

R.J.M. van Geuns, P.A. Wielopolski[1], B.J.W.M. Rensing, H.G. de Bruin[1], P.M.A. van Ooijen, M. Oudkerk[1]. *Cardiology, Thoraxcentrum, Bd 377, University Hospital Rotterdam, Rotterdam; [1]Radiology Dept., Dr Daniel den Hoedkliniek, Rotterdam, Netherlands*

Background: Non-invasive coronary imaging with magnetic resonance imaging (MRI) and electron beam computed tomography (EBCT) are promising new techniques for the detection of coronary artery stenoses. A direct comparison in the detection of significant coronary artery stenosis between both techniques has not yet been performed.

Methods: 27 Patients were examined on the same day with a respiratory gated 3D-gradient echo MRI technique and an intravenous contrast enhanced EBCT technique. Conventional coronary angiography (CAG) was performed within 2 weeks of the non-invasive coronary angiograms. Proximal and mid segments of the RCA, LAD and CX were evaluated by a radiologist and cardiologist unaware of the results of the CAG.



Comparison between EBCT, CAG and MRI

Results: MRI visualized 139 (74%) of the coronary artery segments, EBCT visualized more, 155 (82%), segments with a diagnostic image quality. The parameters of diagnostic accuracy of both techniques for the detection of stenoses of >50% are listed in the table.

	Sensitivity	Specificity	PV+	PV−
MRI	54%	91%	58%	82%
EBCT	77%	95%	74%	96%

Respiratory motion artifacts occurred to the same extent in all three vessels during MR imaging, while in EBCT artifacts originated from non-breathholding, arrhythmias or movement of the RCA during the heart cycle.

Conclusion: MRI and EBCT enable non-invasive coronary angiography. With presently clinical available techniques EBCT is closer to clinical implementation.

1477 Magnetic resonance flow measurements after stent implantation allow the assessment of in-stent restenosis

E. Nagel, T. Thouet, S. Bünger, J. Hug, C. Klein, S. Schalla, E. Wellnhofer, E. Fleck. *Internal Medicine/Cardiology, Charité, Campus Virchow, HU Berlin; German Heart Institute, Berlin, Germany*

We have recently shown a close correlation between noninvasive coronary artery flow measurements with magnetic resonance and invasive flow measurements with Doppler flow wire using a new navigator corrected technique with high temporal resolution. This technique was used to assess flow velocities proximal and distal to coronary stents. In stented segments the coronary arteries cannot be non invasively visualised with magnetic resonance imaging.

Methods: In 64 patients the peak coronary blood flow velocity was determined non invasively within 24 hours and 3 months after stent implantation using a 1.5 Tesla MR tomograph (Philips Gyroscan NT). After localization of the coronary arteries and the stented segments flow measurements were performed proximal and distal of the stent using a flow sensitive gradient echo technique. Spatial resolution was 1 × 0.9 × 4 mm, temporal resolution 45 ms. Adaptive navigator motion correction was used to minimize breathing artifacts. Maximal flow velocity was measured and corrected for cardiac motion perpendicular to the imaging plane.

Results: In 43 patients it was possible to obtain an antegrade pulsatile flow signal distal to the stent. In 4 additional patients no proximal signal could be obtained, as the stent artifact overlapped the origin of the vessel. Non invasive determination of the maximal flow velocity yielded 19 ± 3 cm/s for the RCA, 23 ± 6 cm/s for the LAD and 21 ± 9 cm/s in the RCX proximal of the stent (distal: 18 ± 8 cm/s, 21 ± 7 cm/s, 18 ± 9 cm/s). After 3 months a significant decrease of maximal flow velocity was observed distal to the stent ($p < 0.05$) which correlated with in-stent luminal diameter reduction.

Conclusions: Magnetic resonance techniques allow the determination of coronary blood flow velocities after intracoronary stent implantation. An in-stent restenosis can be detected by a reduction of maximal diastolic flow velocity distal to the stent.

1478 Prospective diagnosis of coronary artery disease with magnetic resonance perfusion imaging

N. Al-Saadi, E. Nagel, M. Gross, B. Schnackenburg[1], A. Bornstedt, C. Klein, H. Oswald, E. Fleck. *Internal Medicine/Cardiology, Charité, Campus Virchow, HU Berlin; German Heart Institute, Berlin; [1]Philips Medical Systems, Hamburg, Germany*

Magnetic resonance (MR) perfusion measurements allow the determination of myocardial perfusion reserve (MPR). We evaluated prospectively the diagnostic accuracy of MPR by MR for the detection of significant coronary artery stenosis ≥ 75% (CAD) after the definition of a cut off value.

In 40 patients with coronary artery disease referred for angiography one short axis image per heart beat was acquired at the base of the papillary muscle with a turbo gradient echo technique (spatial resolution 1.7 × 1.9 × 8 mm, acquisition time 360 ms) using a 1.5 Tesla MR tomograph (Philips ACS NT). A central venous gadolinium DPTA bolus (0.025 mmol/kg body weight) was injected before and after dipyridamole injection (0.56 mg/kg body weight). The signal intensity (SI) curves of the left ventricle and 6 radial segments of the myocardium were obtained and linear fitting of the upslope was performed and corrected for the upslope of the left ventricular SI curve. MPR was calculated as the relative change of the steepness after dipyridamole in comparison to rest and was compared to angiographic results. If the increase of steepness was below 1.5 MPR was regarded as pathologic. This cut off value was previously defined in a different group of 15 patients with angiographically single CAD and 5 patients without CAD.

MPR showed a highly significant difference between ischemic and non ischemic segments (1.08 ± 0.23 and 2.33 ± 0.41, $p < 0.001$). The sensitivity, specificity and diagnostic accuracy for the detection of CAD were 93%, 89% and 91%, respectively. The linear fit of the upslope showed minimal intra- and interobserver variability ($r = 0.99$ and 0.96).

The determination of myocardial perfusion reserve from magnetic resonance first pass measurements is feasible and reproducible. This technique yields a high diagnostic accuracy for the detection of coronary artery disease in a prospective patient population.

1479 Magnetic resonance real time imaging of left ventricular function: comparison with conventional magnetic resonance techniques and echocardiography

S. Schalla, E. Nagel, C. Klein, H. Lehmkuhl, A. Bornstedt, B. Schnackenburg[1], E. Fleck. *Internal Medicine/Cardiology, Charite Campus Virchow, Humboldt University; German Heart Institute, Berlin; [1]Philips Medical Systems, Hamburg, Germany*

The development of new ultrafast gradient systems and improvements in software-applications make the aquisition of a complete image in 65 msec possible. Thus, functional cardiac images can be obtained in real time without breath holding or ECG-triggering.

In 21 patients left ventricular ejection fraction (EF), enddiastolic (EDV), endsystolic (ESV) volume and left ventricular muscle mass (LVM) were determined by magnetic resonance (MR) (ACS NT, 1.5T, Philips) from continuous short axis views covering the entire left ventricle with a standard turbo-gradient-echo (TFE), echo-planar-imaging (EPI) and a new real-time technique (RT). EF was additionally obtained by digital echocardiography (Echo) from longitudinal 4- and 2-chamber views using a modified Simpson's formula.

The results of RT technique correlated well with those of ECG-triggered TFE- and EPI-techniques. Differences between RT and TFE were 1.3 ml for EDV, 5.0 ml for ESV and 23.8 g for LVM. Differences between EPI and TFE were 3.9 ml for EDV, 0.9 ml for ESV and 2.6 g for LVM. The correlation and mean error for EF acquired with different techniques are listed in the table:

	Correlation	Mean error
Echo vs. TFE	0.84	25%
RT vs. TFE	0.93	12%
Echo vs. RT	0.86	7%

Using the new real time technique, scan time can be reduced considerably. A close correlation with echocardiography and conventional MR-techniques can be demonstrated. The mean error of 25% for Echo vs TFE can be explained by different approaches (complete cardiac volume with MR vs. geometric assumptions with Echo). MR real time imaging allows to acquire a 3d data set covering the entire heart in minimal measuring time without ECG-triggering. Thus it is feasible to examine patients with atrial fibrillation or frequent extrasystoles.

1480 Predictors of hard cardiac events in patients screened with electron-beam computed tomography

P. Raggi, T.Q. Callister, N.J. Lippolis, B.Q. Reynolds, D.J. Russo. *Clinical Research, EBT Research Foundation, Hendersonville TN, USA*

The prognostic significance of coronary artery calcification (CAC) discovered on a screening Electron Beam-CT (EBCT) scan is the focus of much debate. Investigators have criticized the frequent pattern of patients self-referral for EBCT screening which carries inherent pre and post-test biases, damaging the epidemiological validity of the information collected. We investigated the occurrence of hard cardiac events (HE's = myocardial infarction and cardiac death) in asymptomatic patients referred by primary care physicians (PCP's) for a screening EBCT because of the presence of risk factors for coronary artery disease (CAD), to identify the best predictors of events.

Methods: Prospective follow-up (average of 32 ± 7 months) of 632 patients referred by PCP's for a screening EBCT. Traditional risk factors for CAD and severity of CAC, measured as a calcium score (CS), were employed in a multivariate logistic regression analysis to identify predictors of HE's. Absolute as well as age and gender adjusted percentiles of CS were used.

Results: The mean age of the 632 patients was 52 ± 9 years (range 35–70) and 340 patients (54%) had CAC on the screening EBCT scan. 27 patients suffered a HE and – of these – 26 patients (96%) had CAC. Strong predictors of HE's were smoking (OR = 2.99; CI 1.2–7.3) and CS > 75th percentile (OR = 2.5; CI 1.0–6.2). In contrast, a CS percentile in the lowest quartile (<25th%) portended a very low risk for HE (OR = 0.08; CI 0.01–0.66) independent of the presence of other risk factors for CAD. All other variables were not predictive of HE's.

Conclusions: CAC discovered on a screening EBCT in referred high-risk asymptomatic patients, offers important prognostic information for the occurrence of HE's even after a short follow-up time. Both smoking and high CS percentiles portend a high risk of HE; low CS percentiles identify patients at very low risk of events.

COMPUTER DEMONSTRATIONS

D1493 An integrated multi-centre angiography database and reporting system

A. Harkness, L. Moretti[1], A.D. Cunningham, P.D. MacIntyre[1], I.N. Findlay[1], H.J. Dargie. *Clinical Research Initiative in Heart Failure, Western Infirmary, Glasgow; [1]Royal Alexandra Hospital, Paisley, UK*

Current database systems for cathlabs often focus on the collection of data for audit purposes and rarely generate reports with enough detail and flexibility to replace the dictated or hand-written report. Furthermore, they are either stand-alone or tightly integrated with commercial solutions.

We developed a database system primarily to assist in the thorough and complete reporting of cathlab procedures, while still collecting data required for local and national auditing (i.e., demographics, risk factors, indications, presenting symptoms and outcome).

An object-orientated model of the coronary anatomy was written in Delphi 4. This model 'understands' the significance of coronary lesions in relation to the underlying anatomy. It scores disease severity by a traditional vessel count and using the Duke Coronary Artery Disease Index. The model allows considerable flexibility in the modification of the coronary anatomy by the user and visualisation of lesions and grafts through a highly graphical user interface. The full ACC/AHA classification of lesion morphology can be indicated, eliminating the need for free text.

The central database is stored at the referring hospital and data-entry performed at the tertiary referral centre. The system is integrated into each hospital's patient information system and the electronic patient record of the referring hospital. Data is transferred by e-mail via NHSnet after encryption with a secure Blowfish algorithm.

A complete report is generated for the case-notes as well as a letter to the general practitioner and any referral letter to the surgeon or interventional cardiologist. These reports and letters are written in natural English and stored as Word 97 documents, allowing the secretary to file them with all other letters and edit them if necessary.

This system eliminates the need to write or dictate cathlab reports. It provides immediate, detailed and flexible reports while gathering data required for audit and research purposes.

D1494 Software for documentation, automated result and report generation, medical and economical statistics, and quality control in the cardiac catheterisation laboratory

M. Claus, J. Tröster, K. Kronberg, G.-H. Reil, P. Jensch[1]. *Klinik für Innere Medizin I, Kardiologie, Städtische Kliniken Oldenburg; [1]Fachbereich 10-Informatik, Carl v. Ossietzky Universität Oldenburg, Germany*

In cooperation with the University of Oldenburg Software was created for Interventional Cardiology. Over the last decade further development of the existing product led to a stable and powerful program which is easy to use. Its main features are:

- Documentation of Left- and Right-Heart-Catheterisation, Coronary Interventions (PTCA, Stent, Atherectomy, Rotablation, etc.), Peripheral Angiography, and Angioplasty
- Automatic generation of results and reports based on standardized expressions without the need for dictation
- Storage and retrieval of up to eight still images per procedure
- Documentation of used materials and serial numbers of products with barcode scanners
- Calculation of all data for the national health system including ICD and ICPM
- Dataexport and statistics for quality control, as well as for medical and economical purposes
- Planning of operating dates for patients and generating letters of appointments for patients automatically
- Partially automated stock-management
- Integration into the documentation system for heart surgery and echocardiography and interfaces with other programs.

The version in operation is based on a client server architecture using ORACLE® 8 as database system. The frontend runs under Windows NT 4.0 and Windows 9x and has been developed with ORACLE®'s Developer 2000. The database contains more than 25,000 records of patients.

Conclusion: Over than 10 years of experience in the development of an information system have resulted in a stable and practical program which makes the task of documentation easier, faster and more reliable and allows doctors and nurses to concentrate on medical treatment. In a further development storage and retrieval of DICOM films are tested.

STENTING: TECHNICAL ASPECTS

P1495 A prospective randomised study of Angio-Seal versus FemoStop for femoral haemostasis after transcathater coronary intervention

F.R. Amin, M. Yousufuddin, W. Shamim, R.H. Stables, J. Clague, A.S. Kurban, U. Sigwart. *Division of Interventional Cardiology, National Heart and Lung Institute, Royal Brompton Hospital, London, UK*

The regional complications related to femoral access site for various cardiovascular interventional procedures cause significant in-hospital morbidity and some times prolonged hospital stay. A number of haemostatic devices are used for closure of the access site and to achieve early ambulation after interventional procedures. We have prospectively compared 150 patients randomly assigned to external compression using the FemoStop or sealing with the Angio-Seal device. The Angio-Seal was immediately deployed in the catheter laboratory. Patients randomised to FemoStop, had their sheath removed when the activated clotting time (ACT) was less than 150 sec. The primary endpoint was the composite of the incidence of bleeding, haematoma, requirement for blood transfusion, and clinical indication for ultrasound examination at 2-hours and 24-hours after the procedure. There was no difference in age, gender, height, weight, and cardiovascular risk factor profile between two groups. 95% of the Angio-Seal and 96% of FemoStop patients were discharged the following day. A higher number of patients in the Angio-Seal group reached a clinical end-point within the first 2 hours (42.6% vs 4%; p = <0.0001). This difference became insignificant at 24-hours (12% vs 9.3%; p = 0.79). FemoStop patients noticed more often moderate to severe groin discomfort compared to Angio-Seal patients (33.3% vs 6.8%; p = 0.0005). 14.6% of Angio-Seal patients crossed over to FemoStop because of persistence bleeding (p = 0.004) and 5.1% required additional manual compression.

	FemoStop (n = 75)	Anglo-Seal (n = 75)	p value
Procedure success	74 (98.6%)	73 (96%)	0.61
Primary end-point at 2 hr	3 (4%)	32 (42.5%)	<0.0001
Primary end-point at 24 hr	8 (10.4%)	9 (11.97)	0.79
Crossover	0	11 (14.63%)	0.004

Although less comfortable, the overall efficacy of the FemoStop appears higher than that of Angio-Seal.

P1496 First report of the European multi-center registry of the Duett vascular sealing device

S. Silber for Duett Investigators, G. Gershony[1]. *Department of Cardiology, Müller Hospital, Munich, Germany[1] Vascular Solutions Dept, Alamo CA, USA*

Purpose: Conventional management of the arterial access site following diagnostic angiography (DA) and percutaneous vascular interventions (PVI) is associated with patient discomfort, prolonged bedrest and local complications. We report the preliminary experience of the European multi-center registry of a new vascular sealing device, Duett, which is comprised of a balloon delivery catheter (~3F) and a procoagulant consisting of thrombin and collagen in a flowable suspension.

Methods: Immediately following DA and PVI, patients at 23 European centers were treated with the Duett sealing device. Patients were included in the study if the arterial sheath used during their DA or PVI procedure was 5-9F and if the ACT was <400 seconds ± an approved GPIIb/IIIa platelet receptor blocker.

Results: A total of 1202 patients were enrolled in the study. Hemostasis was achieved in 2–5 minutes following deployment of the Duett sealing device. Patients were ambulated at 1–6 hours following their invasive procedure depending on sheath size and level of anti-coagulation. Patients treated with a GPIIb/IIIa platelet receptor blocker were not fully ambulated until completion of the drug infusion. A total of 5 patients (0.4%) required vascular surgical repair (pseudoaneurysm 4, large hematoma 1). Limb ischemia after Duett deployment occurred in 2 patients (0.2%) and was successfully treated in both cases by intra-arterial infusion of urokinase. A blood transfusion was given in 3 cases (0.2%). Pseudoaneurysms were detected in 34 patients (2.8%), the majority of these were small (30/34) and successfully treated with ultrasound-guided compression or resolved spontaneously.

Conclusions: This large multi-center European experience with the Duett sealing device demonstrates that it is highly effective in achieving rapid and reliable hemostasis following DA and PVI with a very low incidence of major complications.

P1497 Non-invasive treatment of pseudoaneurysms of the femoral artery by ultrasound-guided aspiration-reinjection repair

M. Petzsch, K. Pulya, T. Körber. *University Hospital, Department of Cardiology, University of Rostock, Rostock, Germany*

Both large or compartmentalised postcatheterization pseudoaneurysms (PSA) with great, painful haematomas and anticoagulation therapy are the reasons for unsuccessful ultrasound-guided (UG) compression repair.

The aim of our investigation was to apply another method of UG vessel repair: To achieve thrombosis of the PSA and closure of the communicating channel by aspiration of blood from the PSA and reinjection into the PSA (AR).

In 1998 we applied this method in eight patients (PT) with a mean age of 65.0 ± 8.6 years. All PT were treated with Flucloxacillin or Cefotiam intravenously prior to the procedure and antibiotic therapy was continued orally for the next three days. After skin disinfection and adequate local anaesthesia UG puncture of the PSA followed. Blood was aspirated from the PSA and reinjected after 15 to 30 seconds. The continuous ultrasound control revealed the thrombosis of the PSA and the closure of the communicating tract. In the same period in 58 PT (mean age 62.7 ± 8.9 years) conventional UG compression repair was performed in case of PSA ($p < 0.0001$).

The eight PT presented with a large PSA, mostly complex forms with two to five compartments, severe pain in the groin, massive haematoma, two PT were receiving anticoagulants. In three cases spontaneous reopening had developed up to three times after successful UG compression repair. The mean volume of the PSA was 14.6 ± 2.9 cm^3, in conventional UG compression repair 3.7 ± 2.2 cm^3 ($p < 0.02$). Thrombosis of the PSA was achieved with 4.8 ± 2.6 AR-procedures and 6.2 ± 3.1 ml of blood. In two cases (PT on anticoagulant therapy) further mild UG compression for three minutes became necessary to achieve closure of the communicating channel. No PT suffered from infectious or inflammatory complications following this procedure, no change in ankle-arm index was observed (1.20 ± 0.07 before and 1.24 ± 0.12 after AR, p = 0.42).

The AR-technique offers an effective alternative as a non-surgical method in the treatment of complicated postcatherization PSA. AR is easy to perform, as a non-invasive technique it is safe, efficient and cost-effective. This technique might help to avoid local and hemodynamic complications of PSA.

P1498 Does arterial sealing device decrease the rate of local complication: interim analysis of the haemostase trial?

B. Chevalier, B. Lancelin, J. Puel, R. Koning, M. Henry, A. Gommeaux, R. Pillière, M.C. Morice, J.L. Guermonprez, J. Marco. *On behalf of HEMOSTASE investigators. Centre Cardiologique du Nord, Saint-Denis, France*

In order to evaluate the potential benefit of Angioseal* to decrease the rate of local complications after coronary stenting, a randomized study was organized in 11 centers to enroll high local risk pts (= age > 70, hypertension, previous puncture, aggressive antiplatelet therapy, continuous heparin infusion, lytics, 8 F sheath use). Pts were randomized at the end of PTCA between delayed sheath removal + manual pressure (MP) with delayed ambulation or immediate sheath removal + Angioseal (AS) with early ambulation (4 h.).

From 01/98 to 09/98, 450 pts were randomized. All pts had systematic duplexscan examination at 24 h. and 7 d. follow-up. Baseline data were similar in both groups:

	MP	AS	p
Immediate hemostasis (%)	0	90.6	<0.001
Compression time (min.)	54 ± 75	4 ± 24	<0.001
4 h bedrest cessation (%)	3	68.3	<0.001
Major endpoint (%)	18.6	6.2	<0.001

(= composite of surgery, transfusion, false-aneurysm, AV fistula, infection, vein thrombosis, hematoma > 6 cm., bleeding requiring prolonged compression). After this interim analysis, study was stopped and final results in the global cohort of 612 pts will be available.

AS dramatically reduces need for compression, bedrest duration and complications after coronary stenting in high local risk patients.

P1499 Incomplete expansion and apposition of stents on the focal balloon at nominal versus high inflation pressures: an intravascular-ultrasound-controlled study

A.B. Buchwald, J. Stevens, K.H. Scholz, C. Unterberg. *Dept. of Cardiology, University Clinic Göttingen, Germany*

The concept of a focal balloon as a stent delivery system aims at optimal stent expansion with low risk of peri-stent dissection. The optimal pressure to implant stents using this system is not known.

Methods: We randomly implanted this stent-system in de-novo lesions at the rated burst-pressure of 10 atm (inflation pressure IFP 10, n = 10 patients-PTS), at 12 atm (IFP 12, n = 10 PTS) and at 15 atm (IFP 15, n = 10). System size was chosen to exceed reference diameter by 0.1 to 0.4 mm and was 3.0 mm (focal balloon segment) in 8 of 10 PTS in each of the three groups. Complete apposition (CA) was defined as no strut found within the lumen as assessed by intravascular ultrasound (IVUS, Endosonics system), and complete expansion was defined as the minimal cross sectional area (CSAmin) within the stent exceeding 80% of the distal reference cross sectional area (CSAref).

Results: In the IFP 10-group, passage of the IVUS-catheter was impossible in 8 of 10 PTS. In the remaining two, incomplete stent apposition was apparent. High pressure dilatation (HPD) at 20 atm using an additional balloon was neccessary in all 10 PTS to achieve CA and expansion to >80% of CSAref. In the IFP 12-group, IVUS passage after stent was successful in 9 of 10 PTS. However, subsequent high pressure dilatation was neccessary in 5 PTS to achieve >80% of CSAref. In the IFP 15-group, IVUS after stent showed CA in all 10 PTS, and CSAmin averaged 91 ± 4% of CSAref ($p < 0.002$ vs. IFP 12). Peri-stent dissection (1 PT per group) after HPD resulted in an additional stent in one PT (IFP 10).

Conclusion: The focal stent-system requires a primary IFP significantly exceeding the rated burst pressure of 10 atm to achieve complete apposition and expansion of the stent. Post dilatation using high-pressure balloons carries the risk of peri-stent dissection due to the very weak radioopacity of this stent, thus loosing the advantage of "focal" stenting.

P1500 Stent implantation with different pressure: evidence of superior results in experimental studies?

P. Gonschior, G. Valassis, C. Vogel-Wiens, S. Milz[1], P. Boekstegers[2]. *I. Medizinische Klinik, Klinikum rechts der Isar und Deutsches Herzzentrum, Technische Universität München, Munich; [1]Dept. of Anatomy, LMU München, Munich; [2]Med. Dept. I, Klinikum Grosshadern, LMU-München, Munich, Germany*

In an experimental porcine coronary model, different stent implantation-pressures were examined. The vessel reaction and the deployment homogenity of the implants were analyzed.

Methods: Palmaz-Schatz Stents were implanted with a 3 mm balloon in with 3D IVUS selected porcine coronary arteries (diameter 3 mm) using either 12 atm or 18atm (group 1: 12 atm, n = 9; group 2: 18 atm, n = 9). The arteries were explanted after 14 days, embedded in methylmetacrylate, serially cut (120–200 μm), stained histologically (mod. Laczko-Levai) and digital morphometry was performed (Image, 4th Dimension). Inhomogenity of the implant was enhanced at the stent edges (+22% versus mean stent lumen) leading to trumpet-like structures. Inhomogenous circumferential tissue hyperplasia is the predominant feature 14 days after stenting. Initial and luminal areas varied remarkably within the stent. Stenosis at the stent edges might be induced by trumpet-like deployment behavior at the edges of slotted tube stents.

	Group 1	Group 2
Total stent lumen	5.2 mm^2	5.6 mm^2
Lumen range	±17%	±16%
Total intimal area	0.4 mm^2	0.6 mm^2
Intimal area range	±60%	±57%

In conclusion: Uniform circumferential homogenous tissue hyperplasia is an unique feature after stent implantation and offers a clear and defined target for prophylactic approaches. High pressure implantation did not result in enhanced intimal hyperplasia.

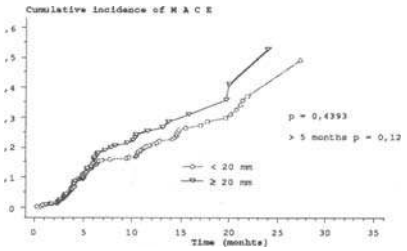
P1501 Does stent length affect long-term outcome following coronary stent implantation?

D. Carrié, M. Elbaz, G. Mayoux, S. Mourali, J. Fourcade, M. Andrieu, J. Puel. *Department of Cardiology, Purpan Hospital, Toulouse, France*

The reported results of stenting for long lesions are unfavorable and the effect of stent length on the rate of major adverse cardiac events (MACE) is not well known.

We analyzed clinical and angiographie data of a consecutive series of 732 pts, with 843 lesions treated with stent implantation. To evaluate the effect of different stent length we used 20 mm as a threshold to separate short (n = 530 pts) and long stenting (n = 202 pts). In comparison with short lesions, coronary stenting on long lesions was safe and associated with a remarkably low reocclusion rate (1.94% vs 1.79%: ns). Clinical follow-up (FU) was performed in 616 patients of 688 eligible patients (89.5%).

At the beginning of FU the outcome is similar in the two groups but after the fifth month, the group longer stent length is associated with a higher rate of MACE. However, after multivariate analysis, type B3-C lesion, Jeopardy score > 6 (importance of proximal lesions), but not stent length, were identified as independent predictors of cumulative events.



Conclusions: In long lesions, unfavorable prognosis of clinical follow-up after five months is explained more by severity of proximal coronary artery disease at baseline, than the implanted stent length.

P1502 Coronary artery side-branch jailing after stent deployment: acute and long-term results

E. Grenadier, A. Roguin, S. Cohen, I. Lashevsky, B. Peled, L. Gruberg, M. Boulos, R. Beyar. *Division of Invasive Cardiology, Rambam Medical Center and Technion, Haifa, Israel*

We aimed to assess side-branch (SB) jailing with various stent designs and relate it to clinical results.

Methods: Stents (n = 185) were deployed over small to moderate (<2.5 mm) SB in 121 patients (pts), with a mean age of 66 ± 14 years.

Results: Jailing occurred in 89 pts (Group A) and non-significant (<50%) SB stenosis occurred in 32 pts (Group B). The percentage of stents used in Groups A and B is given below:

	NIR	GFX	beStent	Cross-flex	Sea-quence	JRII
Group A	74/121	24/121	19/121	8/121	2/121	3/121
SB jail	61%	19%	16%	7%	2%	2.5%
Group B	11/48	19/48	11/48	7/48	4/48	3/48
No SB jail	23%	40%	23%	15%	8%	6%

The incidence of SB jailing according to stent type is 87% (74/85) for NIR, 68% (19/30) for the beStent, 53% (8/15) for the Crossflex, 59% (24/43) for the GFX, 33% (2/6) for the Seaquence and 50% (3/6) for the GRII. Twenty-two pts in Group A (25%) had attempted revascularization of the jailed SB. Of these, 13.6% had major complications (2 MI, 1 CABG), whereas in the group with no attempt to treat the SB (n = 67), only 1 (1.5%) had non-Q MI. Follow-up for 17 ± 6 months is available for 71/89 pts (80%), of which 53 pts (87%) are asymptomatic. Repeated revascularization was required in 8/71 pts (11%) where all events occurred in the group with attempted SB revascularization.

Conclusion: SB jailing occurs more frequently with tubular stents than with coil stents, among those used in this study. Peri-procedural complications are uncommon if jailed SBs are left untreated. Long-term follow-up of these pts shows an excellent event-free survival comparable to non-bifurcation lesions.

P1503 Is the short coronary stent too short and the long too long?

E. García[1], A. Iñiguez[2], R. Seabra-Gomes[3], A. Bethencourt[4], P. Bordés[5], J. Rigla[6]. *For the ESPORT-NIR Registry Investigators; [1]H. Gregorio Marañon, Madrid; [2]Fundación Jiménez Díaz, Madrid; [4]H. Son Dureta, Mallorca; [5]H. General de Alicante; [6]Clinical BSC, Barcelona, Spain; [3]H. Santa Cruz, Lisbon, Portugal*

Introduction: Long stents have been associated with an increased rate of clinical and angiographic restenosis. For this reason, it has been proposed the use of short stents in the treatment of all lesions including long ones. The ESPORT-NIR Registry (ESpaña and PORTugal NIR stent registry) is a multicentre prospective observational study, conducted in 50 centres from Spain and Portugal. To assess the influence of the length of the implanted stent on the angiographic restenosis rate and clinical outcome, we have analysed the results of 1004 patients (1146 lesions) included in the 50 participating centres. Angiographic restenosis rate was evaluated from 300 randomly selected patients.

Methods: We define four groups according to the length of the stent used. Group A (9 mm), Group B (16 mm), Group C (25 mm), Group D (32 mm). From Aug 97 to Oct 98, 1004 pts (1136 lesions) were recruited by 50 centres. Primary end-points were major adverse cardiac events (MACE) at 7 months. Angiographic restenosis rate was evaluated from 213 randomly selected patients (237 lesions).

Results: Clinical, angiographic and procedural data usually correlated with an increased rate of restenosis and worse clinical outcome were similar in all groups. The angiographic restenosis rate and clinical events for each group are summarised below:

	Group A (9 mm)	Group B (16 mm)	Group C (25 mm)	Group D (32 mm)
#Lesions	191	692	133	116
#MACE/#Patients	8/142 (6.3%)	55/622 (8.8%)	11/126 (8.7%)	12/112 (10.7%)
#Restenosis/#QCA	9/37 (24%)	16/147 (11%)	7/27 (26%)	9/26 (35%)
Group[(1)]				

[(1)]Between Group A and B p = 0.033; Between Group B and C p = 0.034; Between Group B and D p = 0.0015. All Groups p = 0.0063.

Conclusion: Short (9 mm) and long (25 and 32 mm) stents were associated with an increased rate of angiographic restenosis in our study. Technical difficulties surrounding the procedure of short stent implantation and longer lesions when using long stents could be the explanation for these findings.

P1504 QCA results of nominal-pressure stent deployment vs high-pressure stent expansion in the same patient

S. Eltobgi, M. Abdel Ghany, S. Salama. *Cardiology Department, Cairo, Egypt*

Background: High-pressure (HP) balloon inflation was shown to achieve larger and more symmetrical stent expansion than nominal-pressure (NP) stent deployment in comparative patient populations. Since HP inflation is also associated with larger balloon diameter using semicompliant balloons, it is not clear whether the salutary effects on stent expansion are secondary to the higher inflation pressure or the larger balloon diameter. **Objectives:** We measured and compared the immediate quantitative coronary angiographic (QCA) parameters of stent expansion initially at NP $\leq$ 12 atmospheres (8–12) and subsequently at HP > 14 atm (14–20) in the same patient. This design avoided the confounding effects of comparing different patients with different atherosclerotic plaque characteristics.

Methods: The study included 30 pts (3 females) with mean age 52 (±4). On-line QCA measurements were recorded using Philips computerized edge detection system. Measurements were performed at large magnification (5 inch) on diastolic frames with the arteries homogeneously filled with contrast, in the same angiographic view (RAO 25, Caudal 20) after the administration of intracoronary NTG 200 μg bolus.

Results: see table.

Post-Stent Data (n = 30)

	NP	HP	p =
Pressure (atm)	10.5 ± 1	17 ± 2	0.001
B/A Ratio*	1.15 ± 1	1.26 ± 0.1	0.002
Stent MLD** (nm)	2.4 ± 0.3	2.9 ± 0.4	0.0001
Acute gain*** (nm)	1.6 ± 0.4	2.2 ± 0.4	0.0001
Largest stent diameter (nm)	3.0 ± 0.3	3.4 ± 0.3	0.0001
Stent expansion index**** (%)	+5 ± 10	+19 ± 14	0.001

*Balloon diameter/reference vessel diameter. **Minimal lumen diameter within the stent. ***Absolute increase in MLD compared to predilatation values. ****Largest stent diameter/reference vessel diameter%.

The mean reference vessel diameter was 2.8 ± 0.6 mm. Acute gain correlated more strongly with the inflation pressure ($r = 0.5$, $p < 0.002$) than with the B/A ratio ($r = 0.37$, $p < 0.02$).

Conclusion: Compared to NP stenting; HP stent expansion was associated with larger stent lumen diameter and greater acute gain. HP appears to be more important than balloon diameter in achieving the increase in stented vessel diameter.

P1505 Effects of pressure and sizing of balloon on immediate lumen gain after coronary stent implantation depend upon stent type and vessel size

P. Yang, M. Gyöngyösi, K. Felsenstein[1], D. Glogar. *On behalf of the Wiktor and Paragon Stent Investigators; Dept. of Cardiology, University of Vienna; [1]Institute of Statistics, Technical University of Vienna, Austria*

Background: Current strategies of coronary stenting include the use of high balloon pressures (BP) or oversized balloons in order to maximize lumen gain. The aim of the present study was 1) to determine whether operator-dependent procedural factors such as BP and balloon: artery ratio (BA) are predictors of immediate lumen gain, and 2) to evaluate whether effects of BP and BA on lumen gain depend upon differences in stent type and size of the treated vessel.

Methods: Quantitative angiographic analysis was performed in 348 coronary lesions from 265 pts with successful implantation of a single stent per lesion. Chronic total occlusions, bypass grafts, and bailout procedures were excluded. AVE Micro (9%), AVE Gfx (12%), Palmaz-Schatz (14%), Paragon (30%), and Wiktor (35%) stents were implanted. To determine the independent influence of BP and BA on post-intervention minimal lumen diameter (MLD) and relative gain (= {MLD pre − MLD post}/reference diameter [RD]), a multiple regression analysis was performed in a linear fashion and after logarithmic transformation, taking into account MLDpre, RD, lesion location, and stent type.

Results: Multiple linear regression ($p < 0.0001$, $R^2 = 0.39$) revealed BA as a significant predictor of both MLDpost (coeff. = 0.39, $p < 0.001$) and relative gain (coeff. = 0.35, $p < 0.01$), in addition to MLDpre (coeff. = 0.16, $p < 0.01$) and RD (coeff. = 0.53, $p < 0.001$). Significant response to BA was found only for Wiktor (coeff. = 0.47, $p < 0.001$) and Paragon (coeff. = 0.61, $p < 0.001$) stents, and in vessels < 2.5 mm (coeff. = 0.56, $p < 0.01$). BP revealed no relevant influence on MLDpost or relative gain. Using regression analysis after logarithmic transformation of variables ($p < 0.0001$, $R^2 = 0.93$), a mathematical model of immediate angiographic outcome was elaborated: MLDpost = 0.89 * RD * $\sqrt{BA}$.

Conclusions: 1) Stent type and balloon to artery ratio, but not balloon pressure were found to be independent predictors of immediate angiographic result. 2) Response to balloon pressure or sizing was different among stent types and vessel sizes.

P1506 Is high-pressure stent implantation still required with the new less rigid second-generation stents mounted on non-compliant balloons?

R. Hoffmann, P. Haager, H. Klues, U. Janssens, A. Franke, J. vom Dahl, P. Hanrath. *University RWTH Aachen, Aachen, Germany*

Background: First generation stents were limited by excessive rigidity and non-uniform expansion patterns.

Methods: To analyze whether the new ACS HP MultiLink stent (15 mm length) mounted on a non-compliant high-pressure balloon still requires high pressure implantation quantitative angiography and intravascular ultrasound was performed for 70 native lesions randomly assigned to low pressure stent implantation (10 atm) or high pressure implantation (16–18 atm). Minimal lumen diameter and reference diameter were determined by angiography. Intravascular ultrasound was used to determine stent cross-sectional area (CSA) and minimal lumen diameter at 1 mm increments as well as reference CSA.

Results: Stent apposition was complete in all 70 lesions. A lumen/reference CSA ratio $\geq$ 70% was obtained in 61 vs 75% of stents using low vs. high pressure stent implantation techniques.

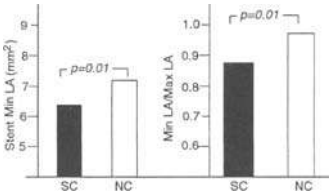
	Low pressure (n = 35)	High pressure (n = 35)	P
QCA reference (mm)	3.01 ± 0.50	3.13 ± 0.40	0.104
QCA MLD final (mm)	2.60 ± 0.47	2.81 ± 0.46	0.051
IVUS lumen CSA final (mm^2)	6.03 ± 1.41	7.50 ± 1.22	0.001
IVUS MLD final (mm^2)	2.33 ± 0.35	2.65 ± 0.28	0.002
Lumen CSA/Ref. CSA	0.80 ± 0.21	0.88 ± 0.19	0.255

Conclusion: Implantation of the less rigid MultiLink stent with a non-compliant balloon results in good stent apposition already at low implantation pressure. However, to obtain good stent expansion throughout the whole lesion length high balloon pressures are still required.

P1507 Do second generation stents require high-pressure inflation with non-compliant balloons?

B.F. Uretsky, S. Rosanio, M. Tocchi. *Division of Cardiology, The University of Texas Medical Branch, Galveston TX, USA*

Second generation stents may allow for high pressure (HP) implantation with the semicompliant (SC) balloon on which the stent (ST) is mounted rather than requiring a HP noncompliant (NC) balloon post-stent deployment. We tested the hypothesis that post-dilation with a NC balloon results in better ST expansion at the same inflation pressure for second generation (MultiLink, NIR) as well as first generation (Palmaz-Schatz) ST at sites with post-implantation angiographic stenosis < 10%. We compared by intravascular ultrasound the ST minimal lumen area (Min LA) and the ratio of Min LA to maximum (Max) LA as a measure of ST expansion in 29 lesions in 25 patients using moderate to HP (8–14 atm) after SC inflation followed by NC inflation at the same atm in stented lesions (PS = 9; ML = 18; NIR = 2) (graph).



Despite moderate to HP inflation with the SC balloon, the ST was more fully expanded at the same pressure with the NC balloon. This occurred for the PS, ML and NIR ST. The present practice of HP SC inflation may limit ST expansion with the potential for worse late outcomes.

P1508 Are premounted stents safer than manually crimped bare stents?

B. Chevalier, B. Glatt, P. Guyon, T. Royer. *Centre Cardiologique du Nord, Saint-Denis, France*

In order to evaluate the influence of the delivery system (premounted stent (PMS) on balloon versus manually crimped bare stent (CBS)) on coronary stenting results, we retrospectively studied 5433 pts who underwent PTCA in our center (4 operators) from 05/95 to 08/98. Eighty-two% of pts who received at least one stent (a total of 6314 stents) were selected. Indication was predominantly acute syndromes: unstable angina 32%, recent MI 26%, acute MI 15%. Type C lesion was noted in 42%. Clinical success rate was 96.7% (emergent CABG 0.1%, MI 1.4%, death 0.8%). Results in PMS group (38%) versus CBS group (62%) were:

	PMS	CBS	p
type C lesion (%)	42	43	NS
Artery diameter < 3 mm (%)	53	60	<0.001
Heavy calcification (%)	31	26	<0.001
stent failure + retrieval (%)	9.5	8.6	NS
Inapropriate deployment (%)	0.8	0.4	NS
Stent loss (%)	2.1	0.6	<0.01
Any kind of stent failure (%)	12.4	9.6	<0.01
Technical success (%)	92	95.8	<0.001
MACE (%)	3.9	1.4	<0.001

(Technical success: successful placement of, at least, one stent on the target lesion).

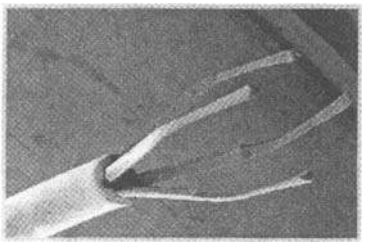
Thus, in routine practice, the choice of a PMS instead of a CBS is more frequent in calcified artery but this delivery device does not reduce stent failure, stent loss, or MACE.

P1509 A new microforceps device for retrieval of embolized coronary stents

M. Haude, H. Eggebrecht, A.E. Guber[1], M. Fritz[1], R. Erbel. *Cardiology Department, University GHS Essen; [1]Institute for Microstructure Technology, Karlsruhe Research Center Karlsruhe, Germany*

Today, the embolization of premounted or manually crimped coronary stents is a major complication of this widely applied coronary intervention. The incidence in a large registry is reported to be 2.2%. The retrieval of embolized stents is primarily intended but causes technical problems and is time consuming. Especially, the pull-back of the embolized stent into the guiding catheter frequently is troubleshooting.

We present a new retrieval device, which consists of a micro-forceps made of nitinol. The microforceps is closed via a hand-grip by means of a teflon hose which is moved forwards over the distal end. The open forceps has a diameter of 2.0 mm and of 0.82 mm when it is closed. The inner surface of the bits is zigzag shaped to allow better fixation of the stent. The outer diameter of the teflon tube is 1.8 mm with an additional sideport for wire guidance, which



permits access even to small vessel dimensions. The advantage of this device is that it bites the embolized stent at the proximal end and therefore permits a more protected and easier retrieval into the guiding catheter compared to e. g. lasso devices. Furthermore, this device can be provide cost-benefit since it provides reapplication of the retrieved stent because damage is minimized.

P1510 Efficacy and safety of transradial coronary angioplasty: a report of 5354 consecutive cases

A.J. Black, R. Cortina, A. Aoun, G. Lucas, J. Fajadet, J. Marco. *Unité de Cardiologie Interventionnelle, Clinique Pasteur, Toulouse, France*

Background: Vascular complications can increase the morbidity and cost of percutaneous coronary intervention procedures (PTCA). Transradial arterial access (TRA) may reduce this risk, especially in patients (pts) receiving anti-coagulant or anti-platelet therapy.

Methods: Between Feb. 1994 and Dec. 1998 TRA was attempted in 5354 of 9070 (59%) PTCA procedures. Only pts with an ischemic Allen test or undergoing PTCA at the time of diagnostic catheterization were systematically excluded. TRA pts were allowed to ambulate 1 hour after completion of the PTCA procedure.

Results: Compared to pts undergoing transfemoral PTCA, TRA Pts were more likely to be male Successful coronary instrumentation was possible in 5244 (97.9%) procedures of which 5224 (99.6%) were successful. Stent implantation was performed in 3350, rotational atherectomy in 96 and excimer laser angioplasty in 38.

Adverse cardiac events occurred in 80 Pts (1.5%) (see table):

Adverse cardiac events

Death	Emergency CABG	Q-wave MI	Non-Q MI	Occlusion > reopened no sequelae
0.3%	0.1%	0.4%	0.5%	0.2%

Vascular complications were as follows: 0.5% hematoma, 0.06% surgical repair, and 4% asymptomatic loss of radial pulse.

Conclusions: We conclude that TRA for PTCA is effective and safe, and is compatible with the use of new devices. It has the potential to reduce complications, hospital stay and cost compared with transfemoral angioplasty.

P1511 Arteriography of the left internal thoracic artery from the right brachial artery using the Yumiko Lita catheter

Y. Miyake, M. Shimizu, H. Andou, T. Inoue[1], S. Morooka[1]. *Cardiology Dept., Kasukabe Central General Hospital, Saitama; [1]Cardiology, Koshigaya Hospital, Dokkyo university School of Medicine, Saitama, Japan*

Recently, an approach from the right brachial artery for coronary angiography has been increasingly used for patients' benefits. Coronary bypass surgeries using the left internal thoracic artery (LITA) are widely performed and the technique of the arteriography of LITA is therefor critical. However, no satisfactory approach through the right brachial artery has been established for the arteriography of LITA. We accordingly designed our own catheter, named YUMIKO LITA catheter, for this particular purpose. In this study, we investigated the efficacy of the catheter.

Method: The subject included 61 patients with significant stenotic lesion in the left anterior descending artery, or with a past history of the artero-coronary bypass surgery using LITA. To investigate the efficacy of the catheter, we evaluated the total period of fluoroscopy for the catheter engagement, the quality of angiographic image, and the complications.

Results: The average total period of fluoroscopy was 7 minutes 18 seconds.Good images were obtained in 58 of the total 61 patients. No patients were complicated with both cerebro-vascular accidents and damages of the aortic wall.

Conclusion: The use of the YUMIKO LITA catheter makes the arteriography of LITA easy and shorten the time of catheterization procedure. We consider the YUMIKO LITA catheter to be useful in the arteriography of LITA before and after bypass surgery.

ATHERECTOMY

P1512 The X-SIZER catheter system: initial multicenter clinical experience of a novel device for removal of occlusive tissue material from coronary arteries

T.A. Ischinger, N. Reifart, D. Mathey, J. Schofer, A. Escobar. *Hospital Bogenhausen, Munich, Cardiac Institutes Bad Soden; Hamburg, Germany; Clinica Medellin, Colombia*

The X-SIZER catheter system is a novel device designed to remove obstructive material from coronary arteries and saphenous vein grafts using standard catheterization procedures. The X-SIZER (6 Fr) single use device consists of of a battery driven hand held motor unit, helical cutter and conventional vacuum system and is compatible with conventional 8 Fr guiding catheters and 0.014 angioplasty wires. Preclinical data show successful thrombus removal from PTFE grafts, and from native iliac, femoral and carotid arteries.

The initial multicenter clinical study included 25 pts (LCA 8, RCA 13, SVG 4) at four centers. All pts had unstable angina syndromes, 6 of them evolving MI, 4 stent occlusions. TIMI 0-1 flow was present in 16 pts prior to X-SIZER tx, TIMI 2 in 5 pts. All pts received standard antiplatelet regimen including Ticlopidine & ASS and in selected cases ReoPro. The X-SIZER was successful in 15 pts including two occluded stents (success = TIMI flow increase, stenosis reduction, no MACE), with X-SIZER stand alone success in 2 and routine adjunct procedures in 13 pts. Mean post X-SIZER diameter stenosis was 61%, final stenosis 19%. Lack of success was due to inability to reach/pass lesion (n = 7) and to remove material (n = 3) due to catheter rigidity, profile and technical deficits. In 10 pts tissue particles up to lemon seed size were retrieved and histologically identified (7 pts) as fresh and partially organized thrombus, hyalin and fibroblast containing particles. No coronary vascular, access site or other complication occurred acutely or during FU (3 to 12 mos) to date.

In conclusion, the X-SIZER represents an intriguing simple to use coronary recanalization concept for selected pts, which seems to be safe and effective in removing obstructive atherothrombotic materials from native coronary arteries, SVGs and stents. Further investigation with improved lower profile devices is warranted and under way.

P1513 Long-term efficacy of debulking strategy by rotational atherectomy for complex lesion in small coronary artery

J. Azuma, E. Tsuchikane, M. Kirino, K. Izumi, S. Otsuji, H. Tateyama, N. Awata. *Cardiology Dept, Osaka Medical Center, Osaka, Japan*

Restenosis rate following percutaneous coronary balloon angioplasty (PTCA) for complex lesions in small coronary artery still remains high even if stents are implanted. Rotational atherectomy (RA) is effective for plaque debuking in a broad spectrum of lesion types included complex lesions. We examined the efficacy of plaque debulking by RA on reduction restenosis after PTCA for complex lesions in small coronary artery and determined predictors of angiographic restenosis. We analyzed consective 148 complex (AHA/ACC classification type B2 or C) lesions in small vessels (<3.0 mm) which were treated by RA and were eligible for 6 month follow-up angiography. Pre-procedural lesion morphology was as follows; calcified 81%, total occlusion 18%, reference diameter 2.32 ± 0.4 mm, lesion length 18.37 ± 0.93 mm. Adjunctive stent implantation was performed in 55% of lesions. Follow-up angiography was performed 179 ± 53 days after the procedure. Serial quantitative coronary angiography was conducted using Cardiovascular Measurement System. Angiographic restenosis was defined as diameter stenosis (DS) >50% at follow-up. Overall angiographic restenosis rate was 52.3%. Univariate analysis including 56 variables (11 clinical, 25 angiographic, and 20 procedural) showed that post-procedural minimal lumen diameter (no restenosis group (NR) 1.96 ± 0.49 vs. restenosis group (R) 1.79 ± 0.48 mm, p = 0.024), post-procedural DS (NR 23.26 ± 15.01vs. R 29.38 ± 12.50%, p = 0.006), and the presence of post-procedural dissection (NR 18% vs. R 31%, p = 0.067) were predictive of restenosis. Of those variables, post-procedural DS was the independent predictor detected by multiple logistic regression analysis(p = 0.074, Odds ratio = 1.033).

Conclusion: Long-term efficacy of plaque debulking by RA for complex lesions in small coronary artery is not satisfying. Other revascularization strategy should be considered if an optimal result can not be expected in those lesions.

P1514 Long-term clinical outcome of patients undergoing directional coronary atherectomy followed by stent implantation

E. Bramucci, L. Angoli, A. Poli, S. Lucreziotti, A. Repetto, P.A. Merlini, C. Auguadro, C. Cavallotti, M. Gnecchi, D. Ardissino. *Division of Cardiology, IRCCS, Policlinico San Matteo, Pavia., Ospedale Niguarda, Milan, Italy*

Debulking the atherosclerotic plaque by means of directional coronary atherectomy (DCA) prior to stent implantation is a safe procedure which is associated with excellent acute results and a low rate of 6-month angiographic restenosis. The effect of the combined techniques on long-term clinical outcome remains to be determined.

Methods: We prospectively evaluated 197 consecutive patients (171 male, 26 female, mean age 56 yrs) who underwent successful (residual stenosis < 50%) DCA followed by stent implantation of a native vessel for stable (73 pts) or unstable (124 pts) angina. Specific angiographic criteria for enrollment included >75% and <100% stenosis of a proximal non-tortuous coronary artery with a reference diameter of >2.5 mm and a lesion length < 15 mm. All patients were followed-up for a median period of 25.5 months (range 7–61 months). The follow-up evaluation included cardiovascular death, non-fatal myocardial infarction, severe angina requiring re-hospitalization and the need for repeat target lesion revascularization (TLR)

Results: The incidence and average period of onset of the events are:

	Pts.	%	Mean time (months)
Death	3	1.5	5
Myocardial infarction	2	1	0.2
Severe angina requiring re-H	17	8.6	4.8
TLR	19	9.6	5.8

Conclusion: In suitable lesions of native coronary arteries, DCA followed by stent implantation is associated with low incidence of clinical adverse events and with a limited need for repeat target lesion revascularization.

P1515 Rotational atherectomy in small vessels (<2.5 mm): immediate results and six-month follow-up

E. Pérez-David, E. García, R. López-Palop, M.E. Fuentes, J.R. Rey, J.F. Portales, R. Moreno, J. Soriano, J. Botas, J. Elízaga, M. Abeytua, J.L. Delcán. *H G U Gregorio Marañon, Madrid, Spain*

Background: Percutaneous revascularization in lesions located in small vessels (<2.5 mm) shows poorer results than procedures performed in larger vessels. Small angiographic lumen diameter is frequently an expression of diffuse arteriosclerotic disease. The aim of this study is to analyze immediate and 6-month results of rotational atherectomy in small vessels.

Methods and results: All rotational atherectomy procedures performed in small vessels (diameter < 2.5 mm) in our institution for two years were assessed retrospectively. 104 procedures in 93 patients (pts) were included, with a mean age of 67 ± 10 years; 43% were women, 27% were diabetic and 73% presented multivessel disease. All of them presented complex lesions (12% B1, 63% B2, 25% C), which were located more frequently in the LDA (80%) and LCX (13%). Procedural success (residual stenosis < 50% and TIMI flow 2–3 with no major complications) was obtained in 97 cases (93%). Minimum lumen diameter changed from 0.69 ± 0.24 mm to 1.76 ± 0.44 mm (67 ± 10% to 25 ± 11%) with a reference diameter corresponding to 2.15 ± 0.2 mm and 2.3 ± 0.4 mm. No deaths during in-hospital stay nor emergency CABG were recorded. 3 pts presented Q-wave AMI and 4 pts non-Q-wave AMI.

6-month angiographic reevaluation was performed in 62.5% of the patients; 29% of the patients reevaluated required re-PTCA because of restenosis; another 11% presented asymptomatic restenosis. No statistically significant differences were demonstrated between rotablator + stent and rotablator + balloon PTCA in restenosis rate (p = 0.3). Clinical follow-up was obtained in 90% of the patients, with a mean follow-up of 18 months. 71.9% of the patients remained free of cardiac events (cardiac death + AMI + re-PTCA) after 12-month follow-up

Conclusions: Rotational atherectomy in patients with small vessels is followed by good immediate results and an acceptable rate of cardiac events at six-month follow-up in spite of unfavorable clinical characteristics.

P1516 Clinical and angiographic follow-up results of the German atherolink registry

B. Scheller, W. Höpp[1], P. Braun[2], J. Waigand[3], B. Hennen, K.H. Kuck[4], O. Ickrath[5], K.E. Hauptmann[6], E. Vester[7], C. Özbek[8]. *Innere Medizin III, Universität des Saarlandes, Homburg/Saar[1] Universitätskliniken, Cologne[2] Kaiser Wilhelm Krankenhaus, Duisburg[3] Franz Volhard Klinik, Berlin[4] AK St. Georg, Hamburg[5] Katharinenhospital, Stuttgart[6] Barmherzige Brüder Krankenhaus, Trier[7] Universitätskliniken, Düsseldorf[8] Cardiology II Dept., Heart Center, Völklingen, Germany*

Background: Debulking prior to coronary stenting may result in a lower restenosis rate by theoretical considerations, which are supported by intravascular ultrasound. To test this hypothesis in regard of feasibility and safety a prospective, multihospital registry was established. Directional coronary atherectomy (DCA) was performed prior to stent deployment (S; ACS MultiLink) in patients (pts) with a suitable coronary anatomy for both.

Patients and methods: By protocol, it was aimed to achieve a residual stenosis of <20% after DCA and of <15% after S. The registry included 175 pts (79% males, age 56 ± 19 years; 33% unstable angina, 81% type B2 or C lesions, ejection fraction 64 ± 14%).

Results: DCA was successful by means of the protocol in 58% of pts and S further improved this result to 91%. 3 pts died within 6 months. 6 month angiographic follow-up was completed in 124 pts with the following event rates: unstable angina 6.5%, Q-wave MI 0.8%, non-Q-wave MI 4.8%, CABG 2.4%. 4 pts had acute or subacute stent thrombosis. The binary restenosis rate by means of angiography was 10.5%.

Conclusion: The combined approach of debulking prior to stenting is feasible and safe. The low restenosis rate with regards to the high prevalence of complex lesions justifies a prospective, randomized study to test the hypothesis of reduced restenosis by debulking prior to stenting.

P1517 Is there an appropriate strategy for treatment of non-aorto ostial lesions in large vessels? acute and long-term results

A. Kini, S.K. Sharma, E. Shalouh, T. King, T. Bertea, J.D. Marmur. *Division of Cardiology, Box 1030, Mount Sinai Hospital, New York NY, USA*

Background: Ostial lesions have been shown to have higher restenosis compared to non ostial lesions. Non-aorto ostial lesions (ostial LAD diagonal or circumflex) in large vessels (>2.75 mm) pose problems with stent alone, due to plaque shift, resulting in the pinching of the adjacent vessel. Therefore, debulking may be advantageous in this setting. In order to evaluate the acute and long-term results of three different interventional strategies, rotational atherectomy alone (R), stent alone (S), and both we analyzed the results of 212 non-aorto ostial lesions for acute outcome and the need for target lesion revascularization (TLR).

Results: Baseline characteristics revealed high incidence of diabetes in S (34%), and R + S (36%), compared to R (19%) ($p < 0.01$) and higher rest angina and post MI in S.

Characteristics	R alone (n = 114)	S alone (n = 39)	R + S (n = 59)
Reference vessel (mm)	2.82 ± 0.42*	3.31 ± 0.41	3.28 ± 0.42
Final MLD (mm)	2.31 ± 0.21*	3.27 ± 0.21	3.25 ± 0.18
Diameter stenosis post (%)	18 ± 7*	4 ± 3	1 ± 2
Procedural success (%)	98.2	94.8	98.3
Sidebranch narrowing (%)	3.5	12.8	6.8
Major complications (%)	0.9	2.4	0
CK-MB elevations (%)	13.1*	23.1	20.3
TLR (%)	29*	15	12

Conclusions: Three different strategies for non-aorto ostial lesion intervention are associated with high procedural success rate and low complications. S alone is associated with higher incidence of side branch narrowing compared to R or R + S and higher CK-MB release. R alone is associated with higher restenosis. Therefore debulking with rotational atherectomy followed by stent implantation should be the preferred approach in treatment of non-aorto ostial lesions.

P1518 Efficacy of pre-stent plaque debulking for chronic coronary total occlusions

E. Tsuchikane, S. Otsuji, M. Kirino, T. Kobayashi, H. Tateyama, M. Sakurai, N. Awata, T. Kobayashi. *Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan*

Background: Stenting improves the patency of successfully recanalized chronic coronary total occlusions (CTO) by percutaneous coronary balloon angioplasty, however restenosis rate still remains high. Massive plaque burden in CTO is considered to interfere with full stent expansion and be a cause of restenosis.

Methods: We examined the pre-stent plaque debulking strategy with rotational atherectomy (RA) for CTO (TIMI flow grade = 0, occlusive duration ≥ 3 months). We performed RA for 34 CTO before stenting. Follow-up results were compared to those of consecutive 127 CTO recanalized with stenting in which RA could be indicated retrospectively. Results: RA was performed with max. burr size was 1.86 ± 0.21 mm. RA procedural success (TIMI flow grade = 3) was obtained in all lesions without perforation, flow disturbance, or any major complications. Adjunctive stenting pressure was 8.0 ± 1.4 atm. No major complications were observed during the hospital stay. Follow-up angiography was performed in 33 lesions 154 ± 53 days after the procedure to date. There were no significant difference in baseline characteristics between the two groups. Quantitative coronary angiography data are shown in the table.

	Stenting after RA	Stenting alone	P value
Reference diameter (mm)	2.61 ± 0.46	2.73 ± 0.46	NS
Post RA MLD (mm)	1.04 ± 0.38		
Post balloon MLD (mm)	2.05 ± 0.41	1.09 ± 0.53	<0.0001
Post procedural MLD (mm)	2.82 ± 0.45	2.42 ± 0.43	<0.0001
Follow-up MLD (mm)	1.90 ± 0.62	1.24 ± 0.86	0.0001
Restenosis rate (%)	18.2	55.1	0.0002

Conclusion: RA is a safe procedure for plaque debulking of CTO in selected cases. Plaque debulking of CTO facilitates Sub-sequent stent dilatation and reduce the restenosis rate.

P1519 Excimer laser for total coronary occlusions: results of the EXACTO trial

R. Simon, E. Fleck, R. Seabra-Gomez, B. Lauer, A. Sanati, S. Oeztuerk, K. Wegscheider. *Cardiology Dept., University Hospital Kiel, Kiel, Germany*

The impact of debulking for recanalization of totally occluded coronary arteries (TOC)is controversial. In the multicenter randomized EXACTO trial a strategy of excimer laser and ancillary balloon angioplasty (ELCA) is compared to standard balloon angioplasty alone for treatment of TOC. In 15 centers in Europe, Asia and US, 314 patients with angina and/or ischemia and TOC were randomized to ELCA (157) or balloon (157) after a coronary guidewire had passed the occlusion and its position within the free distal lumen of the treated artery had been proven by angiography. Additional stenting was not restricted by the study protocol.

Acute results and 30 days events

Acute	ELCA	Balloon	30 days	ELCA	Balloon
Proc success	94%	90%	MI	2.5%	4.5%
TIMI > 2	97%	96%	CABG	1.9%	1.3%
Add. stent	68%	80%*	RePTCA	1.3%	1.9%
Tamponade	1.9%	0	Death	0.6%	1.3%

*$p < 0.05$

Acute results and cumulative events within the first 30 days after treatment are given in the table. Although ELCA was performed "aggressively" (1.7 or 2.0 mm laser catheters in 63% of procedures), there was no increase in major adverse events or necessary surgery as compared to standard balloon angioplasty. In the ELCA group significantly fewer additional stents were used due to a more satisfying primary result with less prominent dissection or threatening reocclusion when compared to balloon alone. In contrast to previous studies, therefore, laser angioplasty with subsequent balloon dilatation in the EXACTO trial compared favorably to standard balloon angioplasty concerning immediate results and early follow-up. Since enrollment was completed at the end of June, 1998, final clinical results as well as 6 months angiographic follow-up data will be available at the time of the presentation.

COATED AND BIODEGRADABLE STENTS

P1520 Evaluation of the biocompatibility of two new diamond-like stent coatings (Dylyn™) in a porcine coronary stent model

I. De Scheerder, H. Yanming, Q. Bei Ping, L. Xiao Shun, M. Szilard, E. Verbeken, D. Neerinck, E. Demeyere, W. Coppens, F. Van de Werf. *University Hospitals Leuven, Belgium*

Hydrogenated Diamond-like Carbon films (DLC, a-C:H) and Diamond-like nanocomposite coatings (DLN or Dylyn™), offer a promising solution for many industrial applications. In this study the biocompatibility of two diamond-like stent coatings are evaluated in a porcine coronary stent model.

Methods: Either coated or non-coated stents were randomly implanted in two coronary arteries of 20 pigs so that each group contained 13 stented arteries. Quantitative coronary analysis, before, immediately after stent implantation, and at 6 weeks, was performed using the semi-automated Polytron 1000® system. Morphometry was performed using a computerized morphometric program.

Results: Histopathology revealed a similar injury score in the 3 groups. Inflammation was significantly increased in the DLN-DLC coating group. Thrombus formation was significantly decreased in both coated stent groups. Neointimal hyperplasia was decreased in both coated stent groups, however, the difference with the non-coated stents was not statistically significant. Area stenosis was lower in the DLN coated stent group than in the control group (41 ± 17 vs. 54 ± 15%, p = 0.06).

Conclusion: The results indicate that the Diamond-like Nanocomposite stent coatings (DLN) behave as biocompatible stent coatings, resulting in a decreased thrombogenicity and a decreased neointimal hyperplasia. Covering this coating with another Diamond-like Carbon film (DLC) resulted in an increased inflammatory reaction and no additional advantage compared to the single layer Diamond-like Nanocomposite coating.

P1521 Clinical evaluation of a biocompatible phosphorylcholine-coated coronary stent

T. Corcos, P. Barragan[1], H. Zheng, J.B. Siméoni[1], X. Favereau, M. Zimarino[2], P.O. Roquebert[1], Y. Guerin. *Centre Médico-Chirurgical, Parly II, Le Chesnay[1] Polyclinique "Les Alpilles", Marseilles, France[2] Cardiology and Cardiac Surgery, San Camillo Hp, Chieti, Italy*

Background: The ByodivYsio™ stent is a new coated with phosphorylcholine, a cell membrane molecule, which was designed to reduce the formation of thrombus and potentially the risk of restenosis.

Methods: We prospectively studied 224 consecutive patients (pts) who underwent elective (67%) or bail-out implantation of 303 BiodivYsio™ stents in 286 lesions. Most lesions (62%) had unfavorable characteristics (type B2 or C) and 50% had thrombus and/or chronic occlusion. Clinical follow-up was obtained in all pts at one month and in the first 132 pts (147 lesions) at six months. Repeat angiography was undertaken in all pts with recurrent ischemia.

Results: Successful stent deployment was achieved in 284 lesions (99.3%). Angiographic success rate (post-intervention stenosis < 30%) was 98.3% (281/286 lesions). There was 1 (0.4%) subacute stent thrombosis (with Q-wave myocardial infarction) and 2 (0.9%) non-stent related in-hospital deaths. No emergency CABG was required. Reference diameter was 2.82 ± 0.32 mm. Minimal luminal diameter increased from 0.38 ± 0.25 to 2.97 ± 0.35 mm and diameter stenosis decreased from 83.8 ± 12.1% to 5.8 ± 9.7%. No cardiac event occurred during the first month after intervention. At 6 months follow-up, repeat target lesion revascularization was required in only 8 lesions (5.4%).

Conclusions: The implantation of phosforylcholine-coated stents appears to be safe and efficacious in the treatment of complex coronary lesions and is associated with an extremely low target vessel revascularization rate. Randomized studies are warranted to compare this coated stent with currently available non-coated stents.

P1522 Immobilized hyaluronic acid: a potential thromboresistant coating for endovascular devices

S. Verheye, M.Y. Salame, K.A. Robinson, K. Skinner[1], C. Nickerson[1], S.B. King III, S.R. Hanson[2], N.A.F. Chronos. *Interventional Cardiology, Emory University Hospital, Atlanta GA; [1]Genzyme Coroporation, Boston MA; [2]Dept of Hematology, Yerkes Primate Research Institute, Atlanta, GA, USA*

Background: Stainless steel stents are highly thrombogenic and may therefore lead to an increased acute or subacute closure rate after coronary stenting. Coating of stents with a biocompatible and non-thrombogenic material may solve the problem. Hyaluronic acid (HA) has been shown to inhibit platelet aggregation when administered systemically. However, the effect on platelet deposition of coating stents with immobilized HA is unknown. We therefore assessed the thrombogenicity of stainless steel tubes and stents coated with immobilized HA and compared these results with uncoated control stainless steel tubes and stents.

Methods: Thrombosis was assessed by continuous Indium^{111}-platelet imaging using a gamma camera over 2 hours after exposing coated and uncoated stainless steel tubes and stents (4.0 mm diameter, n = 16) to non-anticoagulated blood (100 ml/min) in exteriorized baboon arteriovenous (AV) shunts.

Results: Time course of platelet deposition is presented as mean (SD). A 2-way ANOVA test to compare the effect of coating or time found that coating tubes and stents with HA resulted in a significant decrease in platelet deposition ($p < 0.001$ and $p = 0.003$ respectively).

Time course of platelet deposition

	Platelets × 10^{-9}			
	30 min	60 min	90 min	120 min
HA Tubes	0.02 (0.02)	0.001 (0.002)	0.04 (0.07)	0.24 (0.29)
Control Tubes	0.5 (0.29)	3.44 (0.83)	5.49 (0.89)	6.12 (0.97)
HA Stents	0.03 (0.05)	0.09 (0.06)	0.30 (0.19)	0.65 (0.52)
Control Stents	0.13 (0.12)	0.98 (0.77)	1.73 (1.19)	1.90 (1.03)

Conclusions: In this primate AV shunt model, coating stainless steel tubes and stents with immobilized hyaluronic acid significantly reduced platelet deposition. Immobilized HA may therefore provide a thromboresistant coating material for endovascular use.

P1523 Comparison of the heparin-coated and the uncoated version of the JOMED stent with regard to stent thrombosis and restenosis rates

J. Wöhrle, U. Grötzinger, I. Al-Kayer, C. Schindler, M. Kochs, M. Höher. *Dept. of Cardiology, University of Ulm, Ulm, Germany*

Heparin coating has been proposed to reduce stent thrombosis and proliferative vascular response. We compared the uncoated (U) and the heparin-coated (C) version of the recently available Jomed stent. In the coated version heparin molecules are covalently bound to an inert polyamine chain layer covering the stent surface (Corline Corp).

A total of 368 stents were implanted in 303 lesions from 278 patients. Stents were successfully delivered in 99%. After stent implantation patients received ASS and ticlopidin (96%). Clinical and angiographical 6-months follow-up was done in 95% and 79% of the lesions, respectively. The treatment groups (U/C) did not differ in terms of: de-novo stenoses 125/124, restenosis 26/32, LAD 65/79, CX 23/30, RCA 55/40, CABG 8/7, AHA B2 or C lesion 56/43, occlusion 25/27, unstable angina 66/65, stable angina 44/42, acute infarction 23/24, and risk factors. Heparin coating (U/C) had no impact on the incidence of stent thrombosis (2/4) or myocardial infarction (3/3), restenosis rate (29.2% versus 30.5%) or reintervention rate (25.0% versus 24.4%).

	Uncoated (U)	Heparin Coated (C)	
MLD [mm] pre PTCA	0.53 ± 0.40	0.54 ± 0.40	n.s.
MLD after stenting	2.48 ± 0.52	2.48 ± 0.44	n.s.
MLD at follow-up	1.77 ± 0.89	1.69 ± 0.87	n.s.
RD [mm] pre PTCA	2.65 ± 0.64	2.58 ± 0.91	n.s.
RD after stenting	2.66 ± 0.53	2.66 ± 0.52	n.s.
RD at follow-up	2.63 ± 0.66	2.75 ± 0.62	n.s.
Late loss index	0.37 ± 0.45	0.41 ± 0.42	n.s.

The design of the Jomed stent provides a high success rate. Heparin coating has no impact on in-hospital complications such as stent thrombosis or the angiographic long-term results.

P1524 Tantalum coating reduces surface corrosion of stents

A.W. Frey, S. Schwarzacher[1], M.C.H. Tataru[2], B. Stark, H. Roskamm, A. Yeung[3]. *Kardiologie Abteilung, Herz-Zentrum, Bad Krozingen, Germany; [1]Kardiologie Abteilung, Universität Innsbruck, Innsbruck, Austria[2]Kardiologie Abteilung, Herz- und Gefässklinik, Bad Neustadt, Germany[3]Cardiology Dept, Stanford University, Palo Alto, USA*

After deployment, stents may suffer from corrosion which could provoke inflammatory processes of the coronary wall tissue. In the present study we therefore investigated the corrosion behavior of different actually used stent materials.

Methods: Commercially available stents (316L stainless steel, deployed and non-deployed state) with different treatments and coatings were tested for their corrosion behavior in vitro after exposure to a mildly acid solution (aqueous Machu solution = 5% NaCl, 1% H_2O_2 buffered by acetic acid to pH 6), well simulating physiological conditions due to its oxygen potential similar to the one in circulating blood. After a 30, 60, 180 and 300 minute exposure to this solution the morphology of stent surface corrosion was investigated by scanning electron microscopy (SEM).

Results: Stainless steel stents without additional treatment or coating exhibited a high degree of surface corrosion with severe damage of single stent struts. Coating with 5 mm thick gold layer led to even greater surface damage due to the formation of pores > 200 mm and partly loss of the gold layer. Best results were achieved by high vacuum annealed stents with additional tantalum coating. Surfaces of this type of stents showed very little or no damage at all, even after the longest exposure to the acidic solution.

Table 1

Stent Material (316L)	SEM Results of Corrosion Test
No HV annealing	Major surface defects pore size > 100 μm
+ HV annealing, + Tantalum implantation	Minor surface defects pore size < 5 μm
+ 5 μm Au coating	Major surface defects pore size > 200 μm
+ Tantalum HV annealing + Ta coating	No surface damage no pores visible

SEM = Surface electron microscope, HV = high vacuum, 316L = stainless steel

Conclusion: Most actual stent models exhibit severe surface corrosion in chemical environments similar to blood. However, annealing and additional coatings highly reduce surface damages and therefore might improve performance of stents deployed in vivo.

P1525 Quantitative angiographic results of the phosphorylcholine coated bio-divYsio stent in the SOPHOS study

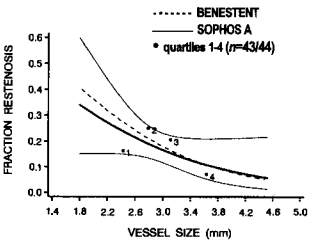
P.W. Serruys[1], C. Buller[2], J.J.R.M. Bonnier[3], A. Colombo[4], R. Erbel[5], M. Pieper[6], J.A. Mangioni[7], H.F. Londero[8], C. Disco[9], D.C. Cumberland[10]. *[1]Thorax Center, Rotterdam; [3]Catharina Hospital, Eindhoven; Cardialysis, Rotterdam, Netherlands; [2]Vancouver Hospital & Health Sciences Centre, Vancouver BC, Canada; [4]Centro Cuore Columbus, Milan, Italy; [5]Universitäts-klinikum für Innere Medizin, Essen, Germany; [6]Herzzentrum Bodensee, Kreuzlingen, Switzerland; [7]Hospital Sao Joaquim, Sao Paulo, Brazil; [8]Institute Favaloro, Buenos Aires, Argentina; [10]Northern General Hospital, Sheffield, UK*

In the SOPHOS Study (Study Of PHosphorylcholine coating On Stents) 426 patients with (un)stable angina and a target vessel of 2.75 mm (QCA)/3.0 mm (visually) – 4.0 mm diameter were selected for implantation of the 15 mm phosphorylcholine coated biodivYsio stent. Angiographic follow-up at 6 months was performed in the 200 first patients (SOPHOS A).

Aim: We investigated the relationship between the vessel size (reference diameter pre-procedure; RD_{pre}) and the restenosis rate (RR; >50% diameter stenosis at 6-month follow-up).

Methods: With 177 6-month angiograms available, 174 matching lesions could be assessed. Mean vessel size was 2.99 mm and the overall restenosis rate was 17%. To investigate the relationship between vessel size and restenosis rate, logistic regression was performed on SOPHOS A data (log $RR/[1 - RR] = 0.75 - 0.97 \cdot RD_{pre}$) and compared to the same analyses of the BENESTENT I/II^{rand} trial data. In addition, quartile means are given for SOPHOS A.

Results:



Conclusion: The overall 17% restenosis rate in SOPHOS is comparable with the outcome of the BENESTENT trials. Both logistic regression analysis and quartile data (1st quartile = 1.80–2.66 mm) indicate a specific beneficial effect of the biodivYsio stent in small vessels, suggesting that the phosphorylcholine coating is especially beneficial under these stringent conditions. However, this promising feature needs confirmation in a prospective study.

P1526 Reduction of platelet adherence by different coatings of coronary stents

C. Bickel, H.-J. Rupprecht, H. Darius, C. Binz, F. Krummenauer[2], B. Hauröder[3], J. Meyer. *II. Medical Clinic, University Mainz; [2]Department of Medical Statistics and Documentation, University Mainz; [3]Central Institute of the Federal Armed Forces Medical Services, Division for Electron Microscopy, Koblenz, Germany*

Although antiplatelet therapy has improved the results after coronary stenting, restenosis and vessel occlusion still play an important problem. We tested the role of different stent coatings in reducing platelet adherence.

Methods: We investigated the in vitro platelet adherence on different stents in an uncoated, electropolished stainless steal and a coated version (carbon, carbon and additional heparin, silicon carbide, heparin). 100 μm thick stainless steal plates (uncoated, electropolished, carbon and carbon with additional heparin) were examined too. Stents and stainless steal plates were incubated in heparinized whole blood with radiolabeled ^{14}C-arachidonic acid platelets in the presence of 30 μM ADP. After washing the stents and plates four times, radioactivity, caused by the adhesion of radiolabeled platelets, was measured. Also electron microscopy studies of platelet adherence on different stent coatings were performed.

Results: Platelet adhesion measured on the uncoated, electropolished stent was defined as 100% and was compared with the same stent model with coating. For carbon coating the adherence of radiolabeled platelets was measured with 108.7%, for silicon carbide with 58.6%, for carbon and additional heparin coating 32.9% and for heparin coating 7.7.% (median). Heparin coating was statistically different from all other tested stent coatings ($p = 0.043$). The platelet adhesion measured on the uncoated stainless steal plate was also defined as 100%. For the stainless steal plates we measured an adhesion of 95.6% for the electropolished plate and 88.8% for the carbon plate. Additional heparin coating of the carbon coated stent reduced platelet adhesion to 39.0% compared with the uncoated plate. The results for additional heparin coating were statistically different from all other tested plate coatings ($p = 0.043$).

Conclusion: Heparin coating of coronary stents is very effective in reducing platelet adherence on stent surface.

P1527 Multicentre open evaluation of the phosphorylcholine coated biodivYsio stent in native *de novo* coronary lesions: the SOPHOS study

J.L. Boland[1], H.A.M. Corbeij[2], R. Seabra Gomes[3], W. Wijns[4], H. Suryapranata[5], C. Hanet[6], M.J. Suttorp[7], C. Oosterwijk[8], P.W. Serruys[9], D.C. Cumberland[10]. *For the SOPHOS Study Investigators; [1]CHR Citadelle, Liè; [4]Onze Lieve Vrouwe Hospital, Aalst; [6]UCL Saint-Luc, Brussels, Belgium; [2]Ignatius Hospital, Breda; [5]Isala Clinics, Zwolle; [7]Antonius Hospital, Nieuwegein;; [8]Cardialysis, Rotterdam; [9]Thorax Center, Rotterdam, Netherlands; [3]Hospital de la Santa Cruz, Linda a Velha, Portugal; [10]Northern General Hospital, Sheffield, UK*

The biodivYsio stent is a stainless steel, balloon expandable, 15 mm mesh stent, with a unique phosphorylcholine copolymer coating to limit thrombus formation. The **SOPHOS** Study (**S**tudy **O**f **PH**osphorylcholine coating **O**n **S**tents) is an efficacy and safety evaluation of the biodivYsio stent for treatment of patients with (un)stable angina and de novo coronary lesions.

Aim: The aim of the study is to assess the major adverse cardiac events (MACE) at 6 months, testing a null-hypothesis of 15% MACE (taken from historical control data).

Methods: 426 patients (74% male, mean age 59.5 y) were included from July 97 to July 98 in 24 European, Canadian and South-American centers. All patients were treated with ticlopidine 250 mg/day for 1 month (M) and with aspirin $\geq$ 100 mg/day and had or will have a clinical follow-up at 1, 6 and 9 months. The first 200 patients (SOPHOS A) had also an angiographic follow-up at 6 months, contrary to the last 226 patients (SOPHOS B).

Baseline Results: Preprocedure ischemic status was unstable (41%), stable (53%) or silent (6%). The target vessel were LAD: 52%, LCX: 17% and RCA: 31%. All patients but 1 were effectively stented (3 with another brand, 47 required multiple stenting). 97.4% patients were MACE-free at discharge.

Follow-up Results (*to be updated for 6 and 9 months*): Significantly (*) lower Target Vessel Revascularization (TVR) and % MACE-free occurred in SOPHOS B versus A:

MACE (%)	1 M	6 M			9 M
		A + B	A	B	
Death	0	0.9	0.5	1.3	1.2
MI Q/NON Q	1.2/1.6	1.6/2.3	5.0	3.1	1.6/2.3
CABG	0.2	1.4	2.5	0.4	1.4
CABG	0.2	1.4	2.5	0.4	1.4
TVR	0	5.6	10.5	4.0*6.3	
MACE-free	96.9	88.0	84.0	91.6*87.1	

Conclusion: The impact of 6-month angiography on revascularization rates cleary appears comparing SOPHOS A and B. The overall result indicates that the phosphorylcholine coated bidivYsio stent is at least as safe and effective as "classical" stents.

P1528 Impact of surface electrochemical polishing on stent performance: insights from a porcine coronary model

I. De Scheerder, L. Xiaoshun, Q. Bei Ping, H. Yanming, M. Szilard, E. Verbeken, F. Van de Werf. *University Hospitals Leuven, Belgium*

The interface between the outer layer of the metallic surface of a stainless steel stent and blood on the one hand and the vascular wall on the other hand, are considered to be important players in the induction of the neointimal hyperplastic response.

Methods: Non-polished (n = 10) and polished MultiLink 16 mm coronary stents (Guidant, Santa Clara, CA, USA) were randomly implanted in 2 of the coronary arteries of 10 pigs. All pigs underwent a control angiogram at 6 weeks and were then sacrificed. Quantitative coronary analysis, before, immediately after stent implantation and at 6 weeks was performed using the semi-automated Polytron 1000® system (Siemens, Erlangen, Germany). Morphometry was performed using a computerized morphometric program.

Results: Selected vessels, stent oversizing and final post stent diameter were similar in both groups. At 6 weeks follow-up, the minimal luminal stent diameter was smaller in the non-polished MultiLink group (2.70 $\pm$ 0.93 vs. 2.80 $\pm$ 0.18 mm, p: NS). Histopathology revealed an increased injury in the non-polished group (1.05 $\pm$ 0.44 vs. 0.74 $\pm$ 0.28, p = 0.052). Inflammation and perivasculitis were significantly more pronounced in the non-polished stent group. Morphometric analysis showed a significantly more pronounced neointimal hyperplasia (2.31 $\pm$ 1.13 vs. 1.25 $\pm$ 0.34, p < 0.005), and a more severe area stenosis in the non-polished MultiLink group compared to the polished stent group (46 $\pm$ 23 vs. 24 $\pm$ 8%, p = 0.004).

In conclusion: This study demonstrates again the importance of surface electrochemical polishing of stainless steel coronary stents to decrease the foreign body response and subsequent neointimal hyperplasia.

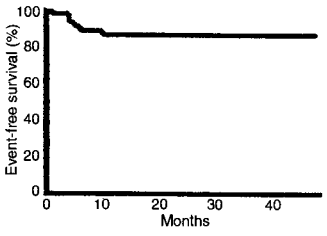
P1529 Long-term outcome after the implantation of the autologous venom graft-covered stent

K. Toutouzas, C. Stefanadis, E. Tsiamis, I. Kallikazaros, C. Stratos, M. Vavuranakis, K. Tentolouris, P. Toulouzas. *Hippakration Hospital, University of Athens, Greece*

The autologous venous graft-covered stent (AVGCS) was implanted in patients (pts) with coronary artery disease. The immediate and mid-term results were favourable. This study demonstrates the long-term clinical outcome of 51 pts.

Methods: Conventional stents were covered by autologous venous grafts that were removed from the right cephalic vein. The stabilization of the venous grafts on the stents was accomplished by the application of sutures. A stent was either covered completely both externally and internally or only externally by the graft. Non-premounted (Palmaz™, a Palmaz-Schatz™) and premounted stents (Multilink™) were used. Fifty-three AVGCSs were implanted in 51 pts for several indications (elective lesions, ostial lesions, totally occluded vessels, thrombus containing-lesions, by-pass vein grafts, and bail-out cases). Follow-up was obtained in all pts until 3.5 $\pm$ 12.3 years.

Results: The procedure of AVGCS preparation and delivery to the target vessels was feasible and uncomplicated. The duration of AVGCS preparation was not prolonged (<20 min). Acute thrombosis was not observed. One patient suffered from subacute thrombosis. The angiographic restenosis rate was 13.95%. The target lesion revascularization (TVR) at 2 years was 9.43% and remained unchanged until 3.5 $\pm$ 12.3 years. However, one patient required by-pass surgery due to the progression of the disease in another vessel. The event-free survival rate was 86% at 42 months (figure).



Conclusions: Long-term follow-up did not reveal late restenosis after AVGCS implantation. The clinical outcome of these pts is favourable and no late stent-related complications were mentioned.

P1530 Angiographic and histomorphometric outcome of ePTFE-covered stent grafts in pig coronary arteries

S. Verheye, M.Y. Salame, K.A. Robinson, W.D. Wingard, S.P. Mulkey, S.B. King III, N.A.F. Chronos. *Andreas Gruentzig Cardiovascular Center, Dept. Medicine (Cardiology), Emory Univ. Sch. of Medicine, Atlanta, GA, Georgia*

Background: ePTFE-covered stent grafts (SG) are being used in the treatment of perforations and aneurysms in coronary arteries. However, information on histologic and angiographic appearances at 1 month is sparse. We therefore evaluated the histologic, histomorphometric and angiographic effects in pig coronary arteries.

Methods: A SG was implanted in the LCX or RCA, and an ungrafted control stent in the LAD of 8 farm pigs. All pigs were pretreated with aspirin and ticlopidine. QCA was done at implantation and prior to harvest at 28 days. Plastic embedded sections were prepared by saw-and-grinding and measured by computer-assisted histomorphometry.

Results: Baseline QCA showed no differences between the two groups. 1 pig died within 24 h due to acute SG thrombosis. At follow up angiography, 2 other SG were found to be occluded and there was a trend to increased late loss (p = 0.08). Neointimal area was significantly increased without a loss in luminal area.

QCA	Control stents	Stent Grafts	p-value
MLD at 28 days	1.89 $\pm$ 0.5 mm	1.18 $\pm$ 0.86 mm	0.08
Late loss	1.15 $\pm$ 0.65 mm	1.79 $\pm$ 0.63 mm	0.08

The excessive neointima internal and external to the graft consisted of a prominent foreign-body reaction with numerous multinucleated giant cells, organized thrombus and prominent neovascularizaton channels.

Histomorphometry	Lumen area (mm^2)	Vessel area (mm^2)	Intimal area (mm^2)
Control stents	3.07 $\pm$ 1.4	8.95 $\pm$ 1.9	3.37 $\pm$ 1.78
Graft stents	2.49 $\pm$ 1.8	11.37 $\pm$ 1.9	5.39 $\pm$ 1.27
p-value	0.52	0.03	0.03

Conclusions: In coronary arteries of pigs treated with antiplatelet therapy, ePTFE-covered stent grafts were associated with marked thrombus formation, severe inflammatory reaction, and excessive neointima formation at 28 days compared to ungrafted control stents.

P1531 Does a newly developed covered stent with PTFE-membrane prevent restenosis after stent implantation?

P. Sick, O. Brosteanu[1], C. Hehrlein[2], G. Schuler. *University of Leipzig, Heart Center; [1]Insititute for Medical Informatics, Statistics and Epidemiology, Leipzig; [2]Dept. of Cardiology, University of Heidelberg, Heidelberg, Germany*

Background: Restenosis after stent implantation is due to neointimaproliferation (NP) through the spaces between stent struts into the vessel lumen. A newly developed stent with a membrane of polytetrafluoroethylene (PTFE) sandwiched between two stents was investigated for capability of prevention of NP.

Methods: In 19 rabbits NP was analyzed by histomorphometry 5 weeks after implantation of 15 PTFE-covered and 14 uncovered stents with identical design in iliac arteries.

Results:

#Areas [mm²]	Center part of stents		End of stents	
	Covered	Uncovered	Covered	Uncovered
#Strut area*	1.58 ± 0.13	0.37 ± 0.05	1.24 ± 0.25	0.47 ± 0.08
#Neointimal area	0.68 ± 0.65	0.7 ± 0.22	1.52 ± 0.54	1.34 ± 0.29
#Lumen area	3.18 ± 0.67	3.35 ± 0.34	2.55 ± 0.37	2.7 ± 0.41
#Vessel area*	5.44 ± 0.43	4.42 ± 0.31	5.31 ± 0.49	4.51 ± 0.44
#Stenosis [%]*	41.4 ± 11.8	24.2 ± 4.9	51.8 ± 8.1	39.9 ± 6.2
Stenosis [%]** max	covered: 76.0 ± 13.7		control: 62.9 ± 12.9	

*, **covered versus uncovered (*$p < 0.001$, **$p < 0.05$). #mean values

Conclusions: Mean neointimal area and free lumen area are not different between covered and uncovered stents. Due to thicker strut area in covered stents, there is an overdilatation of the vessel wall leading to a significantly higher relative lumen stenosis despite comparable free lumen area. Locally, especially at the end of the membrane there was a higher degree of NP in covered stents compared with control stents. Therefore, covered stents have no advantage with respect to NP as the barrier function of the membrane cannot compensate for local proliferation processes at the end of the membrane.

P1532 PTFE-covered stent in percutaneous coronary interventional procedures: results and outcome

C. Briguori, M. Sangiorgi[1], M. Sallam, M. Adamian, J. De Gregorio, L. Di Francesco, R. Albiero, C. Di Mario, L. Inglese[1], A. Colombo. *Centro Cuore Columbus; [1]San Donato Hospital, Milan, Italy*

We evaluated the outcome of patients who had PTFE (polytetrafluroethylene) covered coronary stent implantation.

Methods: 55 consecutive patients with 58 lesions where treated with 62 covered stents in: 43 denovo lesions (35 in saphenous vein grafts [SVG]); 8 coronary aneurysms; 4 vessel rupture; 3 restenosis Clinical follow-up was assessed in all patients (8 ± 4 months). Angiographic follow-up (8 ± 4 months) is in progress and at present performed in 26 patients.

Results:

Mean age (years)	67 ± 10	Lesion length (mm)	14 ± 12
Diabetes, n (%)	10 (18)	Ref vessel diam (mm)	3.5 ± 8
Unstable angina, n (%)	20 (36)	MLD pre (mm)	1.1 ± 9
LVEF%	55 ± 16	MLD post (mm)	3.8 ± 9
Previous CABG, n (%)	35 (63)	Residual Stenosis, %	3.6 ± 9
Time to CABG (yrs)	9 ± 4	Procedure Success, %	96
3 vessel disease, n (%)	39 (71)	Acute thromb, n (%)	0
Type C lesion, n (%)	35 (60)	Subacute thromb, n (%)	0
Ostial & prox site n (%)	39 (67)	30-day MACE, n (%)	3 (5)
Balloon/artery ratio	1.1 ± 1	6-month MACE, n (%)	7 (13)
Max Inf Press (atm)	17 ± 3	TLR, n (%)	9 (18)
Stent length (mm	21 ± 6	Restenosis rate, n (%)	8 (31)

MLD = minimal lumen diameter. MACE = major adverse cardiac event. TLR = target lesion revascularization.

Conclusions: Short and long-term clinical outcome with this device show it to be a safe and effective tool especially for the treatment of SVG disease and vessel rupture, while its role to reduce restenosis still needs to be defined.

P1533 The influence of external stent porosity on early neointima formation and medial wall thickening in a pig model of saphenous vein bypass grafting

J.Y. Jeremy, S.J. George, P. Gadsdon, W. Atassi, A.P.C. Yim, S. Wan, A.C. Newby, G.D. Angelini, M.B. Izzat. *Bristol Heart Institute, Bristol, UK; Department of Surgery, Prince of Wales Hospital, Hongkong, China*

External, non-restrictive, macro-porous, stents around pig vein grafts prevent neointima formation and medial thickening. Whether porosity determines this effect, however, has not been determined. The effect of external micro-porous stents (polytetrafluorethylene [PTFE]) of equal diameter on neointimal and medial thickening, microvessel formation and platelet derived growth factor (PDGF) content and receptors was therefore investigated in pig vein grafts.

Methods: Bilateral saphenous vein-carotid artery interposition grafting was performed in Landrace pigs with external placement of 8 mm diameter stents made of: 1) macro-porous Polyester velour and 2) micro-porous PTFE. One month later, grafts were excised and morphometry and histology carried out. PDGF protein content and receptor expression was assessed using immunochemical methods.

Results: In grafts with miro-porous stents there was marked neointima formation and medial thickening, which was dramatically less in grafts with macro-porous stents (table 1). Micro-porous stents significantly increased PDGF content and PDGF receptor expression in all regions of the grafts compared to macro-porous stents. Microvessel formation was also suppressed by micro-porous compared to macro-porous stents.

Table 1. Morphometry of stented vein grafts

Parameter	Dacron stent	PTFE stent	p value
Wall thickness (mm)	0.2 ± 0.04	0.42 ± 0.03	0.0005
Medial thickness (mm)	0.1 ± 0.02	0.17 ± 0.02	0.0007
Intimal thickness (mm)	0.1 ± 0.02	0.25 ± 0.03	0.001

In conclusion, porosity is crucial to the efficacy of external stents in preventing neointima formation in porcine vein grafts. Changes in PDGF protein and receptor expression mediates, at least in part, the difference. In addition, macro-porous stents allow adventitial microvessels to connect with the vasculature outside the stent, thus improving oxygenation of the graft.

P1534 Treatment of degenerated saphenous vein conduits with coronary polytetrafluorethylene stent grafts

Mathias Elsner[1], Stephan Baldus[2], Wolfgang Auch-Schwelk[1], Andreas M. Zeiher[1], Christian W. Hamm[2]. *[1]Med. Klinik IV, J.W. Goethe-University, Frankfurt a.M.; [2]University Hospital Eppendorf, Hamburg, Germany*

Background: Interventional therapy of degenerated saphenous vein grafts is associated with high rates of procedural complications and of restenosis. Coronary stent grafts [SG] containig a microporous [PTFE]- membrane provide a hermetic sealing of the vessel wall, which may prove beneficial for 1) reducing distal embolization of debris during deployment; 2) eliminating protrusion of residual plaque; 3) providing a barrier to the transmigration of inflammatory cells and diffusion of macromolecules, thus potentially reducing restenosis.

Methods: In a prospective multicenter observational study, 59 patients [pts] aged 66 ± 7 years (10% female) were treated with PTFE-SG, a median of 123 months after bypass surgery. A total of 67 SG were implanted (mean 1.1 ± 0.3 SG; total length 18.5 ± 8.2 mm) with a pressure of 16.3 ± 3.1 atm on balloons sized 3.6 ± 0.5 mm.

Results: (6 mo)

	Death	MI	Occlusion	Re-PTCA
In-hospital	0	2 (3.4%)	0	0
Follow-up	5 (8.5%)*	1 (1.7%)	2 (3.4%)	5 (8.5%)

*: 4 cardiac, 1 non-cardiac; MI = myocardial infarction

Quantitative angiography data are available for 42 pts. Dichotomous restenosis rate was 9.5%. Diameter stenosis pre-, post-procedure and at follow-up were 70% ± 16, 13% ± 12 and 27% ± 25, respectively.

Conclusions: Implantation of coronary PTFE stent-grafts allows for a safe and effective acute therapy of degenerated saphenous vein grafts and is associated with an extremely low restenosis rate. However, delayed vessel occlusion may occur and clinical outcome needs to be evaluated in a randomised, prospective trial.

P1535 Distribution of neointimal proliferation inside polytetrafluorethylene stent grafts in human coronary arteries

Mathias Elsner, Martina Britten, Wolfgang Auch-Schwelk, Dirk H. Walter, Volker Schächinger, Andreas M. Zeiher. *Medizinische Klinik IV, Dep. of Cardiology, J.W. Goethe-University, Frankfurt a.M., Germany*

Background: Stent-grafts [SG] containing a polytetrafluorethylene [PTFE-] membrane have recently become available for implantation into human coronary arteries. The microporous PTFE-layer in the body of the SG may inhibit restenosis by eliminating plaque protrusion, attenuating diffusion of cytokines and hindering transmigration of inflammatory cells. There are no data available on the pattern of neointima [NI] formation in these novel devices.

Methods: We performed intravascular ultrasound [IVUS] in 21 patients aged 64 ± 7 years at 3–6 months follow-up after coronary implantation of 1.1 ± 0.3 SG with a total length of 18.1 ± 7.8 mm. SG were deployed into 12 native coronary arteries and 9 saphenous vein grafts at 19 ± 1 atm.

Results: Angiographic minimal lumen diameter before and after intervention and at follow-up was 0.72 ± 0.57, 3.03 ± 0.38 and 2.01 ± 0.89 mm respectively. At follow-up, there was complete SG-apposition in all cases and no indication of PTFE-membrane disruption.

IVUS:	Prox. edge	SG-body	distal edge	P
SG-area [mm^2]	7.40 ± 2.05	7.01 ± 1.80	7.47 ± 2.34	n.s.
NI-area [mm^2]	1.55 ± 1.05	0.74 ± 1.37*	1.59 ± 1.27	<0.01
Max. NI [mm]	0.34 ± 0.24	0.14 ± 0.19*	0.31 ± 0.25	<0.01

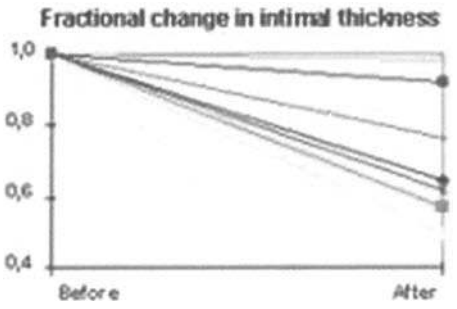
Conclusions: Neointimal proliferation in coronary PTFE stent-grafts occurs predominantly at the edges not covered by the PTFE-membrane. There is only minimal proliferation in the body of PTFE stent-grafts, indicating an antiproliferative effect of hermetically sealing the vessel wall.

P1536 PhVEGF coated stent reduces restenosis intimal hyperplasia

H. Mir-Akbari, C. Sylven, B. Lindvall, V. Drvota, R. Pieper[1], J. Charles[2]. *Department of Cardiology, Huddinge Hospital, Huddinge; [1]Vascular Surgery Dept., Huddinge Hospital, Huddinge; [2]Radiology Dept., Huddinge Hospital, Huddinge, Sweden*

Background: Restenosis after PTCA is characterized by endothelial injury and proliferation of arterial smooth muscle. The restenosis process can be counteracted by reendothelialization that can be stimulated by Vascular Endothelial Growth Factor (VEGF). The aim of our study was to evaluate the effect of phVEGF coated stent on intimal hyperplasia.

Methods and Results: The study was performed on seven rabbits. Endothelial injury was created by balloon angioplasty over-dilation (20%) of the iliac artery, 3 × 30 sec. Cook stent, active or control were, respectively, dipped into a saline solution with phVEGF or with placebo plasmid (control). Thereafter the phVEGF stent was implanted into the left and the control stent into the right iliac artery. To avoid thrombosis all rabbits received dalteparin 200 IE/kg/day from a subcutaneous osmotic pump during the study period of three weeks. Morpho-metric analysis of the tissue sections after three weeks showed that all arteries with phVEGF coated stent had a decreased intimal thickness (figure) with a mean of 29 ± 18%, $p < 0.016$ compared to arterial segments treated with placebo plasmid.



Conclusion: The phVEGF coated stent reduced intimal hyper-plasia. Suggesting a new mode of treatment against restenosis.

P1537 Acute recoil of biodegradable poly-l-lactic acid coronary stents in humans

H. Komori, H. Tamai, K. Igaki[1], E. Kyo, K. Kosuga, A. Kawashima, S. Matsui, T. Tsuji, S. Motohara, H. Uehata. *Cardiology Dept, Shiga Medical Center for Adults, Moriyama Shiga; [1]Igaki Medical Planning Co., Ltd., Kyoto, Japan*

Background: Although, metallic stents are thought to be effective to prevent acute reocclusion and to reduce late restenosis following coronary angioplasty, the long-term safety still remains to be studied. A biodegradable stent is thought to solve the problems of metallic stents. This is the first report of recoil of PLLA stents in human with intravascular ultrasound (IVUS).

Methods and Results: The Igaki-Tamai stent is made of PLLA monopolymer with 0.17 mm thickness, and has a zigzag helical coil design with self expanding ability. Fifteen patients electively underwent PLLA Igaki-Tamai stent implantation for coronary artery stenosis. There were 14 males and 1 female in this study, and 25 stents were implanted through 17 procedures in 19 lesions (8 in left anterior descending artery, 4 in right coronary artery and 7 in left circumflex coronary artery). PLLA stents were successfully implanted in all patients. To evaluate recoil of the PLLA stent IVUS studies were performed immediately after, and at 1-day using 40 MHz IVUS system (Discovery SCIMED) with motorized pullback system. The mean stent cross-sectional area (ST-CSA) was analyzed with computerized measurement system (Manual Measure: Goodman Co.,Ltd.) in all stents. There was no significant difference in ST-CSA between immediately after and at 1-day (7.42 ± 1.52 mm^2 vs 7.37 ± 1.44 mm^2, n.s.). Thus far three patients underwent 3 months angiographic and IVUS follow-up, and no restenosis were detected. IVUS showed that the mean ST-CSA was significantly bigger at 3 months than at 1 day (11.68 ± 0.74 mm^2 vs 8.91 ± 0.65 mm^2, $p = 0.026$) with minimal neointimal hyperplasia.

Conclusions: IVUS showed no significant stent recoil between immediately after implantation and at 1 day and self expanding ability at 3 months. Long-term IVUS follow-up will determine the efficacy of PLLA stents.

P1538 Sustained intramural retention and regional redistribution of locally delivered nanoparticulate probucol

B.K. Klugherz, N.F. Meneveau, W. Chen[1], F. Wade-Whittaker, G. Papandreou, R. Levy[1], R.L. Wilensky. *Cardiovascular Dept., University of Pennsylvania Health Sys., Philadelphia PA; [1]Cardiology Dept., Children's Hospital of Philadelphia, Philadelphia PA, USA*

Background: Probucol (Pr) reduces restenosis following angioplasty, provided oral administration is begun 1 month prior to the procedure. The urgency of many angioplasties, however, hampers its therapeutic utility. Local vascular delivery of a nanoparticulate formulation of Pr may obviate the need for drug loading by acutely raising arterial intramural concentration and providing sustained intramural retention. We characterized the retention and redistribution of 35S-Pr encapsulated in liposomal (Lip)and polylactic-coglycolic acid (PLGA) nanoparticles following local delivery.

Methods: Nanoparticles were delivered using a Crescendo microporous infusion catheter (Cordis, Warren, NJ) following balloon angioplasty of rabbit iliac arteries (n = 12–18 arteries/formulation/time point). Animals were euthanized on day 0, 3, or 7 following delivery. Iliac arteries, perivascular fat, and downstream tissues were harvested and the radioactivity (dpm) measured. Autoradiographic and confocal microscopic analyses of tissue sections were performed to evaluate intramural distribution of Pr.

Results: Immediately following delivery, radioactivity in the iliac arteries (log[dpm/mg], mean ± S.E.M.), was greater with PLGA (2.72 ± 0.08) than with liposomal encapsulation (2.10 ± 0.08), $p = 0.001$. Intramural retention of Pr was 23% at 7 days using liposomes and 10% using PLGA, corresponding to a Pr concentration of 0.1 ng/mg tissue for both formulations. At day 3 following iliac delivery, radioactivity in peri-iliac fat, femoral arteries, and hindlimb muscle increased by 88%, 29%, and 154%, respectively. Thereafter, radioactivity fell to 56%, 43%, and 134% of initial dpm respectively, by day 7. Autoradiography demonstrated a homogeneous distribution of radiolabeled Pr in the arterial wall at day 7. Confocal microscopy confirmed retention of nanoparticles through day 7.

Conclusions: 1) Nanoparticulate formulation of probucol resulted in sustained intramural retention; 2) Although delivery efficiency was superior with PLGA encapsulation, intramural concentrations of probucol were similar on day 7 using both formulations; 3) Radial and axial redistribution of probucol was observed, manifest as an early increase in adjacent tissue concentrations followed by delayed washout.

P1539 A comparison of a biodegradable poly-l-lactic acid coronary stent and a metallic stent in porcine coronary artery

T. Tsuji, H. Tamai[1], K. Igaki[2], E. Kyo[1], K. Kosuga[1], A. Kawashima[1], H. Komori[1], S. Motohara[1], H. Uehata[1], K. Takeuchi[1]. *Cardiology Dept., Shiga Medical Center for Adults, Moriyama Shiga; [1]Cardiology Dept., Shiga Medical Center for Adults, Moriyama, Shiga; [2]Igaki Medical Planning Co., Ltd., Kyoto, Japan*

Background: Although biocompatibility of biodegradable stents is controversial, stents made of high molecular weight Poly-l-Lactic Acid(PLLA) are thought to be the most promising among biodegradable polymers. The aim of this study was to assess the biocompatibility of PLLA stents histologically and angiographically in porcine coronary arteries.

Methods: Igaki-Tamai stent is made of PLLA monofilament (molecular mass 183 kD) with a zigzag helical coil design. Fourteen PLLA stents in 6 pigs and 9 Palmaz-Schatz(P-S) half stents in 9 pigs were implanted in 15 normocholesterolemic juvenile domestic farm pigs, weighing 25 to 35 kg. Stents were mounted on the delivery catheter 3.0 mm in diameter, and were implanted percutaneously into coronary arteries. Coronary angiography was performed before and immediately after stenting, at 2 and 6 weeks in 5 PLLA pigs and 9 P-S pigs. Histologic studies were performed in PLLA pigs; 2 pigs at 2 weeks, at 3 pigs at 6 weeks and 1 pig at 16 weeks with hematoxylin-eosin and van Gieson's methods.

Results: No acute or subacute thrombotic occlusion was detected in PLLA and P-S groups. There were no differences in percent stenosis angiographically between the PLLA and P-S groups immediately after (4.2 ± 4.6%; n = 14 vs 8.4 ± 5.5%; n = 9), at 2 weeks (23.8 ± 14.4%; n = 12 vs 13.7 ± 6.3%; n = 9) and at 6 weeks (24.2 ± 19.8%; n = 7 vs 15.9 ± 15.6%; n = 4). Histological findings at 2, 6 and 16 weeks revealed no inflammation with minimal neointimal coverage on the stent struts of PLLA stents and showed that the PLLA stent maintained scaffolding force at 16 weeks in porcine coronary arteries.

Conclusions: The results in the study suggest biocompatibility and sufficient scaffolding force of PLLA biodegradable stents in porcine coronary arteries. Clinical trial will be required to validate the efficacy of PLLA stent in humans.

P1540 Polyhydroxybutyriate (PHB) biodegradable stent – experience in the rabbit

M. Unverdorben, M. Schywalsky[1], D. Labahn[1], S. Hartwig[1], F. Laenger[2], D. Lootz[3], D. Behrend[3], M. Schaldach[1], J. Schuettler[1], C. Vallbracht. *Interventional Cardiology, Center for Cardiovascular Diseases, Rotenburg a.d. Fulda; [1]University, Erlangen; [2]University, Frankfurt/M.; [3]University, Rostock, Germany*

Stents are established devices in interventional cardiology but their long-term vascular trauma might be reduced when being manufactured of biodegradable material.

Methods: After implantation into the iliac arteries of 19 New Zealand White Rabbits 19 biodegradable PHB stents and 18 tantalum stents were compared. The animals were kept on aspirin 6 mg/kg/day. Animals were sacrificed at various intervals. Specimens were fixed in paraformaldehyde (2%), cut to slices of 5 mm each, the tantalum struts were removed, the PHB struts were left in place, and the specimens were paraffin embedded and stained by H&E and Goldner.

Results:

	4 wks	11 wks	16 wks	26 wks
– Tantalum stents	5	4	2	7
Stent stenosis	<20%	30–40%	<20%	<20%
– PHB stents	5	5	4	5
Stent stenosis	>90%	>90%	<20%	<80%
Stent biodegraded	None	incomplete	nearly completely	

In conclusion, the prototype PHB-stent is nearly completely dissolved after 16 to 26 weeks but the marked transient proliferation makes it inferior to ordinary tantalum stents.

P1541 Acute result of biodegradable poly-l-lactic acid coronary stents in humans: an alternative to metallic stents?

H. Tamai, K. Igaki[1], E. Kyo, T. Tsuji, K. Kosuga, A. Kawashima, S. Matsui, H. Komori, S. Motohara, H. Uehata. *Cardiology Dept., Shiga Medical Center for Adults, Moriyama Shiga; [1]Igaki Medical Planning Co., Ltd., Kyoto, Japan*

Background: Although, metallic stents are thought to be effective to prevent acute reocclusion and to reduce late restenosis following coronary angioplasty, the long-term safety still remains to be solved. Poly-l-lactic acid (PLLA) biodegradable stents are expected to solve the problem. This is the first experience with PLLA stents in humans.

Methods and Results: Fifteen patients electively underwent PLLA Igaki-Tamai stent implantation for coronary artery stenosis. The Igaki-Tamai stent is made of PLLA monopolymer with 0.17 mm thickness, and has a zigzag helical coil design with self expanding ability. There were 14 males and 1 female in this study, and 25 stents were implanted through 17 procedures in 19 lesions (8 in left anterior descending artery, 4 in right coronary artery and 7 in left circumflex coronary artery). Coronary angiography was performed before, immediately after, and 1-day after the procedure and assessed by quantitative coronary angiography method. PLLA stents were successfully implanted in all patients with mean inflation pressure of 10.8 ± 1.5 atm. The reference vessel diameter was 2.85 ± 0.34 mm, and the lesion length was 13.4 ± 5.9 mm. The percent stenosis before, immediately after, and 1-day after stent implantation were 64 ± 11%, 12 ± 8%, and 13 ± 11%. The acute recoil ratio of the stent defined as (1-minimal lumen diameter immediately after implantation/maximal balloon diameter) × 100(%) was 22 ± 7%. After stent implantation there was no further recoil at 1-day. No stent thrombosis and no major cardiac events developed within 30 days. Three patients underwent 3 months follow-up angiography, and no restenosis were detected.

Conclusions: Our preliminary experience suggest feasibility, safety, and efficacy of PLLA biodegradable stents in humans. Long-term follow-up with larger numbers of patients will be required to validate the long-term efficacy of PLLA stents.

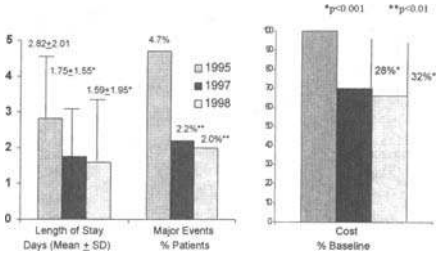
MANAGEMENT OF UNSTABLE ANGINA

P1542 Abciximab provides cost efficient, safely expedited care for unstable angina

D. Kereiakes[1], M. McDonald[2], T. Broderick[3], E. Roth[3], D. Whang[3], L. Martin[1], W. Howard[1], J. Schneider[3], T. Shimshak[3], C. Abbottsmith[3]. *[1]The Lindner Research Center, Cincinnati OH; [2]The Christ Hospital, Cincinnati OH; [3]Ohio Heart Health Center, Cincinnati OH, USA*

To determine influence of abciximab (AB) on cost and outcomes of treatment following percutaneous coronary intervention (PCI) in patients with unstable angina (UA), we analyzed three cohorts of consecutive patients with UA having PCI by Ohio Heart Health Center operators at The Christ Hospital: 1995 (April–June; n = 94), 1997 (Jan–June; n = 321), 1998 (Jan–June; n = 352).

Results: No demographic differences between cohorts were noted. Procedural use of AB and coronary stents were 16 and 19% (1995); 70 and 60% (1997); 75 and 81% (1998) respectively. AB use during PCI for UA was guideline driven in 1997 and 1998. Hospital length of stay, major events (death, Q-wave infarction, urgent revascularization) and total hospital cost (percent baseline 1995) are shown. Urgent revascularization to 30 days post PCI was significantly reduced in both 1997 and 1998.



In conclusion, practice guideline driven AB for PCI allows safely expedited care for patients with UA. Cost of AB can be counterbalanced by shorter length of stay and low incidence of costly major complications.

P1543 Long-term outcome of a prospective randomized, multicentre, placebo-controlled trial of 3 months treatment with low-molecular-weight heparin (dalteparin) in unstable coronary disease: the FRISCII trial

Lars Wallentin, Fredrik Kontny, Bo Lagerqvist, Sten Husted, Elisabeth Ståhle, Eva Swahn. *For the FRISC II study group; Deparments of Cardiology, University Hospital in Uppsala; Oslo; Aarhus and Linköping, Sweden*

Despite the salutary effects of early antithrombotic treatment in UCAD there still is a disappointingly 10 – 15% rate of myocardial infarction (MI) during the subsequent 3 – 6 months. Several trials have demonstrated a reactivation of the underlying disease early after termination of the intense antithrombotic treatment. This is the first presentation of the late follow-up after three months twice daily subcutaneous lmw heparin versus placebo treatment.

Design: 2266 patients, 68% men, median age 68 years, with chest pain and signs of ischemia (ST-depression, T-wave inversion or elevation of cardiac markers) were randomised to 3 months s.c. dalteparin or placebo b.d. All patients had aspirin, 5 days s.c dalteparin. beta-blockade and a primarily non-invasive approach concerning revascularisation. Endpoints are death or myocardial infarction, revascularisation, readmissions, and symptoms at 3 and 6 months. Subgroup analyses are based on baseline characteristics, ECG and biochemical markers in blood samples obtained at admission from all patients

Results: At entry 33% had hypertension, 26% ere smokers, 60% cholesterol > 5.5 mmol/l and 29% history of previous MI and 81% of chest pain at rest. In 50% ECG showed ST-depression and 59% had troponin-T > 0.1 ug/l. After the acute phase 92% entered the three months randomised treatment which was concluded by 81% and prematurely terminated in 7% because of patient request, 7% adverse events and 4% other reasons. The 3 months rate of death or myocardial infarction was 10.5% and revascularisation 20%.

Conclusion: The long-term outcome of these vastly different durations of antithrombotic treatment will have a large impact on the future treatment strategy and tailoring of treatment for these patients and on the design of future trials on similar issues.

P1544 Early angiography in the evaluation of patients presenting with unstable angina

V. Mathew, M.E. Farkouh, G.S. Reeder, C.S. Rihal, S.L. Kopecky, D.E. Grill, J.H. Chesebro, B.J. Gersh, D.R. Holmes, Jr. *Mayo Clinic, Rochester MN, USA*

Background: The role of early angiography in the evaluation of patients with unstable angina or suspected non-Q-wave myocardial infarction remains controversial.

Methods: We reviewed data from the Olmsted County Acute Chest Pain Study, a population-based dataset which includes all patients residing within Olmsted County presenting for emergency department evaluation of acute chest pain from 1985–1992. Patients presenting with symptoms consistent with myocardial ischemia qualifying as unstable angina by conventional definitions were classified as undergoing early (≤7 days of index presentation) angiography or not.

Results: 2282 consecutive patients with unstable angina were identified, of which 892 underwent early angiography. Mean duration of follow-up was 5.9 years. For the entire cohort, early angiography was associated with an adjusted relative risk reduction in all-cause mortality (RR 0.66, 95% CI 0.55–0.78). When patients were risk stratified according to Agency for Health Care Policy and Research guidelines, early angiography in intermediate risk patients (n = 1562) was associated with a reduction in all-cause mortality (RR 0.64, 95% CI 0.52–0.79) as well as the composite endpoint of death, myocardial infarction, congestive heart failure, stroke, or cardiac arrest (RR 0.65, 95% CI 0.52–0.80). Early angiography was weakly associated with mortality reduction in high risk patients (n = 442) (RR 0.75, 95% CI 0.55–1.02), but not in low risk patients (n = 278) (RR 0.34, 95% CI 0.08–1.51).

In conclusion, in this population-based retrospective study, early angiography was associated with a reduction in all-cause mortality during the course of long-term follow-up, which was most evident in the intermediate risk cohort. Further analysis of various subgroups will also be presented.

P1545 Perhexiline normalizes platelet responsiveness to nitric oxide in patients with stable and unstable angina pectoris

S.R. Willoughby, S. Stewart, Y.Y. Chirkov, J.D. Horowitz. *Cardiology Unit, The Queen Elizabeth Hospital, Adelaide, Australia*

Perhexiline is a prophylactic anti-anginal agent which inhibits the enzyme carnitine palmitoyltransferase-1 (CPT-1), thus inhibiting metabolism of long-chain fatty acids and increasing responsiveness to insulin and glucose utilization. We examined the effect of short-term perhexiline therapy on platelet responsiveness to nitric oxide (NO).

Methods: Inhibition of ADP-induced platelet aggregation by the NO donor sodium nitroprusside (SNP) was examined in patients with stable angina (SAP, n = 30) and unstable angina pectoris (UAP, n = 40) who had refractory angina despite conventional therapy, before and after initiation of adjunctive treatment with perhexiline. SNP responsiveness was compared to normal volunteers (n = 24). Correlations were sought with symptomatic responses and plasma perhexiline concentrations.

Results: After initiation of perhexiline therapy, SNP response was significantly increased (towards normal) from baseline (see Table). In patients with SAP, anginal frequency reduced from 7 ± 1 to 1 ± 0.3 episodes per day, while 73% of those patients with UAP became asymptomatic. These UAP patients demonstrated a larger increase in SNP response than those who remained symptomatic. The increase in SNP response was correlated ($p < 0.01$) with resolution of symptoms in both groups of patients. Perhexiline plasma concentration was not correlated with either SNP responsiveness or resolution of symptoms. A cohort of UAP (n = 11) not receiving perhexiline demonstrated no change in responsiveness to SNP. Platelet response to perhexiline did not vary between diabetic (n = 20) and non-diabetic (n = 50) patients.

Table: Inhibition of aggregation

Group	Baseline	Perhexiline	P-value
Normals	51 ± 4		
SAP	35 ± 5	52 ± 4	<0.001
UAP	28 ± 3	39 ± 4	<0.01

%; mean ± SEM.

Conclusion: Perhexiline markedly improves platelet responsiveness to NO, both in SAP and UAP. While this may contribute to resolution of symptoms, the mechanism of benefit remains to be elucidated.

P1546 Bed-side predictors of the degree of platelets activation in patient with unstable angina

L.A. Guzman, A. Alves de Lima, M. Casey, F. Botto, L. Padilla, M. Trivi, J.A. Belardi. *Interventional Cardiology Dept, Instituto Cardiovascular Buenos Aires, Buenos Aires, Argentina*

Platelets play an important role in the pathophysiology of unstable angina (UA). However, which patients (Pt) may benefit from or may need a stronger antiplatelet therapy is not established. The purpose of this study was to determine predictors of the degree of platelets activation (PA) in pt with UA. PA was determined by flow cytometry measuring the expression of P-Selectin (P-S), CD-63 and Anti-Fibrinogen (AF) at admission and 48–72 hs after antithrombotic treatment (aspirin and iv Heparin) in 32 pt admitted with UA. Several clinical (prior history, prior meds, clinical presentation, etc), laboratory (CK, CK-MB, Troponin T, fibrinogen, and PCR) and EKG (ST vs T changes) variables were studied in order to find predictors of PA. None of the variables evaluated predicted the degree of PA at admission but the timing of the last episode of pain to admission, with higher PA in pt with > 6 hs compared with <6 hs (P-S, 1.3 ± 2.3% vs 0.67 ± 1.2%, p:0.3; CD-63, 7.1 ± 10% vs 1.6 ± 2%, p:0.02; AF, 61 ± 26% vs 40 ± 22, p:0.04). Two variables predicted the response to treatment, the Troponin T and the type of EKG changes. Pt with Troponin T(+) and ST changes had a significant lesser response or even higher levels of PA after treatment. The table shows the change in PA markers between admission and treatment.

	Troponin T (+)	Troponin T (–)	EKG (ST)	EKG (T)
P-S (%)	(In) 1.1 ± 2.3	(Dec) 0.4 ± 2.3	(In) 0.4 ± 1.2 *	(Dec) 0.23 ± 1.2
CD-63 (%)	(In) 6.4 ± 11 *	(In) 1.1 ± 4.7	(In) 2.6 ± 4.4 *	(In) 2.1 ± 9.1
AF (%)	(Dec) 5.5 ± 22	(Dec) 15 ± 32 *	(Dec) 7.0 ± 27	(Dec) 20 ± 37 *

Increase (In); Decrease (Dec); *p < 0.05

Conclusions: Bed-side variables like the timing of the last episode of pain, the admission Troponin T and the type of EKG changes were associated with different degree platelets activation at admission and response to antithrombotic treatment. These findings may have important clinical implication in the treatment of patients with unstable angina.

UNSTABLE CORONARY DISEASE: MECHANISMS AND STRATIFICATION

P1547 Infection with cytomegalovirus and risks of coronary heart disease

A. Kaftan, B. Küçükkaya, S. Alpsoy. *Cardiology Dept, University of Pamukkale,Faculty of Med, Denizli, Turkey*

The human cytomegalovirus plays a causal role in atherosclerosis etiology,but it is discussed as controversial.We conducted a case control study to investigate whether previous infection with cytomegalovirus is associated with coronary heart disease and markers of systemic inflammation,because systemic inflammation may play a role in atherosclerosis too.

We enrolled 100 cases aged 38–70 years (mean age 59.8 years) with a coronary stenosis greater than 50% in the study and 150 controls(blood donors without angina pectoris)who were matched for sex and age. Cytomegalovirus serology was performed to determine presence of specific IgG-antibodies.In addition C-reactive protein(CRP),leucocytes and neutrophils were determined.The prevalance of specific antibodies to cytomegalovirus was 55% in cases and 52% in controls ($p > 0.05$ for difference among groups). Mean value of CRP was 1.68 mg/l in IgG-positive cases, 1.49 mg/l in IgG-negative cases, 1.30 mg/l in IgG-positive controls.The odds ratio for coronary heart disease was 1.05 (95% confidence interval 1.00–1.08) given a positive serostatus of IgG-antibodies to cytomegalovirus after adjustment for covariates.

In conclusion,although cases had higher mean CRP-values than cytomegalovirus-negative subjects,serological evidence of previous infection with cytomegalovirus is no independent risk factor for coronary heart disease in this population.

P1548 Hepatocyte growth factor as a novel marker for unstable angina in patients with chest pain at rest

A. Tanaka, T. Kawarabayashi, H. Taguchi, T. Sakamoto, Y. Nishida. *Cardiology Dept., Baba Memorial Hospital, Sakai, Japan*

Background: We previously reported that serum hepatocyte growth factor (HGF), a novel endothelial growth factor, were elevated in patients with unstable angina pectoris. We hypothesized that elevated serum HGF levels might have a diagnostic value for unstable angina. To verify our hypothesis, we measured serum HGF in patients with chest pain at rest.

Methods: The subjects were 44 consecutive patients who complained chest pain at rest without any abnormalities of ST-T segments in ECG. Serum HGF levels were measured by the ELISA method before administration of heparin. +2 S.D. value of serum HGF levels in 20 normal subjects was used as a cut off value (normal 0.21 ± 0.03 ng/mL, cut off value >0.28 ng/mL). Patients with acute myocardial infarction, renal failure, and liver disease were excluded.

Results: 27 patients were confirmed having significant stenosis in coronary angiography (Plaque group). 16 patients were finally diagnosed as a variant angina and 1 patient was a chest pain syndrome (non-plaque group). The non-plaque group did not have a significant stenosis in coronary angiography. The plaque group had significantly higher serum HGF levels than the non-plaque group (0.34 ± 0.07 vs 0.23 ± 0.03 ng/mL, $p < 0.01$). A cut off value of >0.28 ng/mL had 85% of sensitivity and 88% of specificity for diagnosis of having stenosis on CAG in patients with chest pain at rest.

Conclusions: High serum HGF levels have favorable sensitivity and specificity for diagnosing an unstable angina. Measurements of serum HGF may influence a diagnosis of unstable angina pectoris.

P1549 The activity of antioxidant enzymes in red blood cells of patients with unstable angina

P. Burduk, P. Guzik[1], M. Piechocka, G. Drewa, M. Bronisz, M. Jazdon, A. Rozek, P.K. Burduk, T. Drewa. *Cardiology Dept, MSWIA Hospital, Bydgoszcz; [1]Div. of Cardiology – Intens. Therapy, University School of Medical Sciences, Poznan, Poland*

It is thought that the activity of enzymes with antioxidant properties is changed by toxic oxygen metabolites released during oxidative stress. The oxidative stress takes place in ischemia and reperfusion and therefore should be observed in patients with myocardial ischemia. The study aim was to evaluate whether the activity of endogenous antioxidants in patients with unstable angina (UA) differs from noticed in healthy subjects. The activity of superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) were measured in red blood cells of 125 UA patients (59.1 ± 10.7 years old; 42 female) and 35 healthy people (57.3 ± 8.7 years old; 12 female). Results presented in U/ml are shown in table 1. The obtained results indicate that there is an increase in erythrocyte SOD activity in patients with UA compared with healthy subjects. On the contrary, the activity of CAT and GPx in red blood cells of UA subjects are significantly lower than observed in healthy people.

Table 1

All in U/ml	Healthy subjects	UA patients	p value
SOD	1251 ± 378	1971 ± 908	<0.0001
CAT	34.0 ± 4.8	27.1 ± 10.9	=0.0007
GPx	31.1 ± 2.9	22.0 ± 11.6	<0.0001

The noticed changes in the activity of enzymes playing a crucial role in antioxidant systems support the concept of the oxidative stress appearance in the course of myocardial ischemia.

P1550 The role of intensive metabolic control by insulin infusion on fibrinolytic profile during an acute coronary event

A. Stefanidis, A. Melidonis[1], S. Tournis[1], S. Manoussakis[2], M. Zairis[2], S. Hantanis[2], D. Psomali[2], N. Spyropoulou[3], L. Dadiotis[3], S. Foussas[2]. *Athens; [1]Diabetic Unit, Tzanio Hospital, Piraeus; [2]Cardiology Clinic, Tzanio Hospital, Piraeus; [3]Blood Banking Department, Tzanio Hospital, Piraeus, Greece*

We investigate the impact of intensive insulin therapy on fibrinolytic parameters during an acute coronary event (unstable angina or myocardial infarction) in patients with type 2 diabetes mellitus.

Methods: The study group consisted of 48 type 2 diabetic patients. 24 randomized to conventional treatment plus intensive insulin therapy (Group A) and 24 to conventional therapy only (Group B). Group A patients received insulin by infusion for at least 48 hours according to a predefined protocol. Multiple dose subcutaneous insulin treatment was started immediately after insulin infusion cessation until the end of hospitalization aiming to maintain normoglycaemia. The two groups were comparable according to sex, age, bmi, whr, duration of diabetes, antidiabetic treatment, type of ischaemic events and the classic risk factors for coronary artery disease. Insulin treated patients were excluded from the study. Plasma levels of Fibrinogen, t-PA, PAI-1 were measured on admission and discharge. Differences between groups were tested by Student's unpaired t-test and Wilcoxon test for two samples for continuous data and Fisher's exact test for nominal data. Differences within groups were tested by students paired t-test. A two tailed p value less than 0.05 was considered statistically significant.

Results: t-PA increased in both Groups during hospitalization (Group A: $p < 0.000037$, Group B: $p < 0.001$ respectively) (see table). On the contrary, fibrinogen and PAI-1 levels increased remarkably in controls (Group B: $p < 0.002$ and $p < 0.003$ respectively) finding that was not observed in intensive insulin therapy group (Group A:p = NS and p = NS respectively).

Fibrinolytic parameters values

	Group A	Group B
Fibrinogen on admission	2.87 ± 0.73 gr/lt	2.98 ± 1.04 gr/lt
Fibrinogen on discharge	2.67 ± 0.72 gr/lt	3.59 ± 1.01 gr/lt
t-PA on admission	15.42 ± 4.4 ng/ml	14.47 ± 6.31 ng/ml
t-PA on discharge	21.2 ± 5.74 ng/ml	19.18 ± 6.88 ng/ml
PAI-1 on admission	30.75 ± 15.81 ng/ml	30.6 ± 17.34 ng/ml
PAI-1 on discharge	27.75 ± 6.43 ng/ml	40.62 ± 23.48 ng/ml

In conclusion: Intensive insulin therapy during an acute coronary event improves fibrinolytic profile in patients with diabetes mellitus.

P1551 Nutcracker oesophagus – a common finding in unexplained chest pain patients

M. Borjesson, M. Pilhall[1], P. Rolny, M. Dellborg, T. Eliasson, C. Mannheimer. *Medicine Dept, Sahlgrens Univ Hospital/ Östra, Gothenburg[1] Clinical Physiology Dept, Sahlgrens Univ hospital/ Östra, Gothenburg, Sweden*

Non-cardiac chest pain remains an important clinical problem. The most common etiology is esophageal dysfunction; gastroesophageal reflux, esophageal dysmotility and visceral hypersensitivity. Nutcracker esophagus is the principal dysmotility associated with chest pain. The aim of this study was to explore the prevalence of esophageal dysmotility in patients referred for esophageal evaluation because of chest pain.

Methods: 597 consecutive esophageal investigations 1993–98 were studied retrospectively. Esophageal motor function (by esophageal manometry) and acid related disorders (by 24-h pH), were compared to symptoms of referral. Nutcracker esophagus was defined as mean amplitude of >180 mmHg at any level of the esophagus; Hypertensive lower esopageal sphincter was defined as amplitudes >45 mmHg in the sphincter region and Diffuse esophageal spasm as >30% simultaneous contractions. A pH < 4 in >4% of recorded time was considered as a sign of gastro esophageal reflux disease.

Results: 244 patients (41%) were referred for evaluation because of chest pain; 203 had chest pain as only symptom. 60 investigations in chest pain patients (25%) showed esophageal dysmotility; most commonly nutcracker esophagus in 14.3% (compared to 4.5% in the patients without chest pain, $p < 0.0001$, and 2.6% in 234 patients with reflux dyspepsia). 55% of patients with esophageal dysmotility also had an increased acid exposure time >4%.

Conclusions: Esophageal dysmotility is a common finding in patients referred for esophageal evaluation because of chest pain, and was found in 25% in this study. Nutcracker esophagus is 3 times more common in patients with chest pain, compared to patients referred for other symptoms. If only 24-h pH measurements were carried out, 45% of patients with possible esophageal etiology of chest pain may have been missed. Esophageal manometry should be part of the esophageal investigation of chest pain patients, in addition to 24-h pH.

P1552 Clinical relevance of apoptosis mediator-soluble forms in acute myocardial infarction

J. Parissis, S. Adamopoulos, K. Venetsanou, D. Mentzikof, M. Kalantzi, S. Karas, D. Kremastinos. *Amalia Fleming Hospital and Onassis Cardiac Surgery Center, Athens, Greece*

Background: Fas and tumor necrosis factor receptor I (TNFRI) are cell-surface proteins and apoptosis-signaling molecules. Furthermore, Fas ligand (FasL), a member of the TNF family, induces apoptosis in Fas (the receptor of FasL) bearing cells. This study investigates the kinetics of soluble forms of these apoptosis mediators (sFasL, sFas and sTNFRI) in relation to the severity of acute myocardial infarction (AMI).

Methods: Serum concentrations of sFasL, sFas and sTNFRI were determined in 31 AMI patients (20 men and 11 women; aged: 59 ± 8 yrs) without present history of infection or malignancy by high sensitive Elisa assays serially during the first week of hospitalization. Patients of group A (n = 16) had uncomplicated AMI (Killip class I), while patients of group B (n = 15) had severe AMI (Killip class ≥ II). Finally, 10 age-matched volunteers were used as healthy controls.

Results: Peaks of sFasL levels were not significantly different between the two groups of AMI patients (102 ± 29.1 vs 109.5 ± 31.2 pg/ml, p = NS) but were significantly higher than the respective levels of healthy controls (79.1 ± 21.3 pg/ml, $p < 0.03$). Peaks of sFas and sTNFRI levels were significantly higher in group B, compared with group A (sFas: 5.7 ± 1.5 vs 3.4 ± 0.7 ng/ml, $p < 0.01$ and sTNFRI: 4.1 ± 1.1 vs 2.9 ± 0.6 ng/ml, $p < 0.01$) and healthy controls (sFas: 2.6 ± 0.9 ng/ml and sTNFRI: 1.9 ± 0.1 ng/ml, $p < 0.001$). In group B, regression analysis showed that the peak of sTNFRI levels was significantly correlated with peak of sFas levels ($r = 0.55$, $p < 0.05$), white blood cell counts ($r = 0.60$, $p < 0.01$), peak of serum CK MB isoenzyme ($r = 0.63$, $p < 0.01$) and ejection fraction ($r = -0.65$, $p < 0.01$). In the same group, the peak of sFas levels was also significantly correlated with white blood cell counts ($r = 0.49$, $p < 0.05$), peak of serum CK-MB ($r = 0.57$, $p < 0.05$) and ejection fraction ($r = -0.60$, $p < 0.01$). Finally, in group B non survivors (n = 4) had significantly higher peaks of sTNFRI and sFas levels (both $p < 0.05$) than those of survivors (n = 11).

Conclusions: Serum activity of apoptosis mediator soluble forms increases substantially in AMI. Furthermore, we observed a significant relation of sFas and sTNFRI levels with the severity of AMI. Thus, these molecules closely correlated with worse prognosis of severe AMI patients, may be used as alternative prognostic indicators of severe AMI.

P1553 Increased cell adhesion molecules levels in patients with chest pain and normal coronary arteriograms

E. Zouridakis, D. Tousoulis[1], G. Asimakopoulos[1], H. Homeyra[1], N. Ahmed[1], G.J. Davies[1], J.C. Kaski. *Cardiological Sciences, St George's Hospital Medical School, London; [1]Cardiology Unit, Hammersmith Hospital, London, UK*

Background: The pathogenesis of anginal chest pain in patients with angiographically normal coronary arteries (CPNA) remains unclear, however, endothelial microvascular dysfunction appears to play a role. A chronic inflammatory process with leukocyte activation and adhesion to vascular endothelium may lead to vascular dysfunction. The aim of this study was to test whether markers of endothelial activation i.e. intracellular and vascular cell adhesion molecules (ICAM-1 and VCAM-1) are increased in CPNA patients.

Methods: We studied 21 patients (6 men; mean age: 56 ± 9 ys) with exertional anginal chest pain, positive response to exercise stress testing and completely normal coronary angiograms (CPNA), 36 patients (34 men; mean age 62 ± 9 ys) with chronic stable angina and documented coronary artery disease (CAD) and 11 healthy volunteers (8 men; mean age 49 ± 14 ys) (Control). Circulating ICAM-1 and VCAM-1 plasma levels were measured in all subjects, using commercially available ELISA methods.

Results: Plasma ICAM-1 levels were significantly higher in CPNA patients compared to controls and similar to those of patients with CAD. VCAM-1 levels were also higher in CPNA and CAD patients than in controls. Results are summarized in the table:

	CPNA (n = 21)	CAD (n = 36)	Control (n = 11)
ICAM-1 (ng/ml)	362 (22)*	328 (26)#	225 (29)*#
vCAM-1 (ng/ml)	656 (43)	626 (42)	551 (60)

*CPNA vs Control: $p < 0.05$, #CAD vs Control: $p < 0.05$

Conclusions: Our findings indicate that chronic inflammation with endothelial involvement, as suggested by increased cell adhesion molecules levels, is present in patients with chest pain and normal coronary angiograms. The precise role of these findings in the pathophysiology of this condition deserves further investigation.

P1554 Elevated plasma homocysteine is associated with increased myocardial injury in the acute coronary syndromes

M. Al-Obaidi, P. Collinson[1], R. Conroy[2], I. Graham[2], M. Noble[3], P. Stubbs[3]. *Cardiac Surgery, Royal Brompton Hospital, London; [1]Chemical Pathology, Mayday University Hospital, London, UK; [2]Epidemiology Dept, Royal College of Surgeons, Dublin, Ireland[3]Cardiology Dept, Charing Cross Campus, Imperial College School of Medicine, London, UK*

Moderately raised plasma homocysteine levels are an independent risk factor for coronary artery disease and predict mortality in this patient group. The relationship between elevated plasma homocysteine levels and the degree of myocardial injury during acute coronary events is not known.

Methods: Plasma samples were collected on admission and prior to clinical intervention in patients presenting with acute myocardial infarction (MI)(n = 205), and unstable angina pectoris (UAP)(n = 185). Homocysteine assay was performed by high performance liquid chromatography. Troponin T (TnT), a highly specific marker of myocardial injury was measured on admission (admission TnT) and 12 hours after admission (Peak TnT).

Results: There was a significant correlation between homocysteine and peak TnT in MI ($r = 0.2$, $p < 0.003$), and UAP ($r = 0.3$, $P < 0.0001$). There was no correlation between homocysteine and admission TnT in both MI and UAP. Categorizing the patients by quintiles of admission homocysteine revealed a significant rise in peak TnT levels with increasing homocysteine quintiles in MI (ANOVA, $p < 0.02$) and UAP (ANOVA, $p < 0.0001$). A threshold effect was observed in MI with TnT levels (11.33 ± 1.29 ng/ml) in the 4th and 5th quintiles being significantly higher than TnT levels (6.82 ± 0.75 ng/ml) in the 1st, 2nd and 3rd quintiles ($p = 0.002$). Similarly in UAP, peak TnT levels were significantly higher in the 4th and 5th quintiles Vs the lower three quintiles (0.43 ± 0.09, 0.14 ± 0.03 ng/ml respectively, $p < 0.001$).

Peak TnT by Homocysteine Quintiles

Unstable Angina	(1)	(2)	(3)	(4)	(5)
Homocysteine Quintiles (umol/l)	<8.5	8.5–10.3	10.3–12.1	12.1–15.6	>15.6
Peak TnT (ng/ml)	0.14 ±0.06	0.18 ±0.07	0.10 ±0.05	0.30* ±0.13*	0.57* ±0.13*
Myocardial Infarction	(1)	(2)	(3)	(4)	(5)
Homocysteine Quintiles (umol/l)	<8.5	8.5–10.1	10.1–12.6	12.6–16.9	>16.9
Peak TnT (ng/ml)	7.42 ±1.66	5.66 ±0.78	7.32 ±1.26	10.131** ±1.81	12.54** ±1.86

TnT = Troponin T, TnT valus are expressed as mean ± SEM, *$p < 0.001$ Vs lower three quintiles,**$p = 0.009$ Vs lower three quintiles.

Conclusion: Elevated admission plasma homocysteine levels are associated with increased myocardial injury in the acute coronary syndromes.

P1555 Prevalence of the mutation of the gene for factor V is significantly increased in myocardial infarction

S. Nikol, K. Middendorf, P. Goehring[1], D. Seidel[1], G. Steinbeck. *Medical Clinic I, Klinikum Grosshadern, Munich; [1]Inst. Clinical Chemistry, Klinikum Grosshadern, Munich, Germany*

Mutation of Factor V has been identified as the underlying cause of resistance against activated protein C (APC). APC has been shown to be responsible for 50% of congenital defects causing thrombophilia in the venous system. While early publications in 1995 and 1996 did not find an association between APC resistance and myocardial infarction, there is increasing evidence of a possible correlation in more recent publications, probably due to the availability of improved functional tests. Also, patient numbers in published studies were too low to reach significance due to high regional differences of the prevalence of the underlying genetic defect (1–15%). Therefore, we investigated a more homogeneous group of patients with myocardial infarction using a test with higher sensitivity.

The patient population analyzed comprised 237 patients with documented myocardial infarctions, 25.5% women and 74.5% men, age 23–86 (mean 52.5) years, 82.7% single and 17.3% multiple myocardial infarctions. Prevalence of the gene in the normal population in southern Germany is 5.5% (control group). A sensitive functional test was used, with all patients with pathological test results also genotyped.

Prevalence of factor V mutation in those patients with myocardial infarctions was 10.1% (24/237), with 2 homozygote and 22 heterozygote patients, which is a nearly two-fold increase of prevalence of resistance against APC compared with the normal population (10.1% versus 5.5%, $p < 0.05$). Of those 24 patients 33.3% of patients were women and 66.7% men. Age ranged between 35–80 (mean 52.0) years at the time of the first myocardial infarction and 13 patients were 50 years or younger.

Conclusion: A nearly two-fold incidence of resistance against APC in patients with myocardial infarctions may indicate a role in the etiology (dysmobility) of this disease, and perhaps even more in arterial thromboembolism.

P1556 "Low-risk" patients with chest pain have a high prevalence of significant coronary artery disease

Graham S. Hillis, Craig Oliner, Ning Zhao, Pamela Taggart, William C. Dalsey, Antoinette Mangione. *Albert Einstein Medical Center, Philadelphia PA, USA*

Patients with chest pain who have low risk clinical features and negative cardiac troponins may be suitable for direct discharge from the Emergency Department. Little is known about the prevalence and severity of coronary artery disease (CAD) in such patients, though this has implications for follow-up.

Methods: Subjects included all patients who entered the Cardiac Ischaemia Rule Out study at our institution, who were at <7% risk of acute myocardial infarction (MI) at presentation, had cardiac troponin I levels $<2\ \mu g ml^{-1}$ and remained clinically stable (using predefined criteria) at 0, 3, 6 & 12 h (n = 432). Those undergoing stress tests (STs) during this admission had these scored (high risk positive, positive or negative for reversible ischaemia and positive or negative for prior MI) by 2 independent blinded observers using predefined criteria. Coronary angiograms (CAs) were graded using AHA/ACC criteria: high risk if CABG would be recommended on prognostic grounds, positive for other patterns of CAD and normal or insignificant CAD (ie no stenosis >50%).

Results: Twenty five percent of patients had a history of MI, 11% of PTCA and 8% CABG. Fifty five percent had a history of hypertension, 22% were diabetic and 20% were current smokers. Ten percent had pathological Q waves on their presenting ECG, 13% had ≥1 mm ST segment +/or T wave deviation in ≥2 contiguous leads and 30% had more minor changes. Of the 165 STs performed, 7% were high risk positive for ischaemia, 20% positive and 73% negative. Of the 82 CAs, 10% were high risk positive, 61% positive and 29% normal/insignificant. Overall, 34% (149/432) of 'low risk' patients had objective evidence (a ST showing ischaemia or infarction +/or a positive CA +/or a history of revascularisation +/or pathological Q-waves) of significant CAD.

Conclusion: Many 'low risk' patients with chest pain have significant CAD and/or risk factors. This does not preclude early discharge from the Emergency Department but makes adequate follow up mandatory.

P1557 Early risk stratification of patients with unstable coronary artery disease based on cardiac troponin T, admission ECG and ST-segment monitoring. Proposal of a risk score system

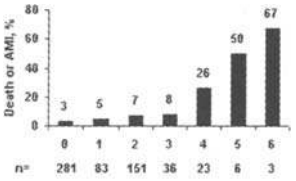
K. Andersen, L. Holmvang[1], P. Grande[1], B.L. Norgaard[2], K. Thygesen[2], M. Dellborg[3]. *Dept of Medicine, Sjukrahus Reykjavikur, Reykjavik, Iceland; [1]The Heart Center, Rigshospitalet, Copenhagen; [2]Dept of Medicine and Cardiology, Aarhus University Hospital, Aarhus, Denmark; [3]Dept of Medicine, Sahlgren's University Hospital/Östra, Gothenburg, Sweden*

Patients admitted to hospital for unstable angina or non-Q wave infarction have a 15–20% risk of death or re-infarction during the first year after discharge from hospital. The majority of these events occur during the first 30 days. Cardiac troponin T, the admission ECG and continuous ST segment monitoring have been proven useful to risk stratify these patients. We constructed a comprehensive risk score based on each of these markers.

Methods and Results: Among 1209 patients participating in the multicentre TRIM study, 583 patients had at least 2 of the three markers prospectively recorded. Each of the three risk markers contributed 0, 1 or 2 points in a total risk score for each patient (table). The total risk score of 0–6 points was related to the event rate of death or myocadial (re-) infarction within 30 days of follow-up (figure).

Contibution of each marker to risk score

Points	Troponin T	ECG	ST monitoring
0	less than 0.1	0–1 mm ST depr	0 episodes
1	0.1–0.19	2–3 mm ST depr	1–4 episodes
2	0.2+	4+ mm ST depr	5+ episodes



Event rate according to risk score.

Conclusion: Risk stratification of patients with unstable coronary disease is improved by a simple risk score based on 3 major markers of risk.

P1558 Peripheral arterial tonometry – a novel sensitive noninvasive method for the detection of silent myocardial ischaemia in unstable angina

Y. Birnbaum, K. Sheffy[1], S. Sclarovsky, D. Goor[2]. *Cardiology Dept, Rabin Medical Center, Petah Tiqva; [1]Itamar Medical, Caesarea; [2]Sheba Medical Center, Ramat Gan, Israel*

Unstable angina (UA) is a heterogeneous clinical entity. In some patients, ischemia resolves after hospitalization and initiation of therapy, whereas in others repeated ischemia occurs despite therapy. In these patients there are by fluctuations in coronary blood flow due to constant change in size of the intraluminal thrombus and release of vasoactive substances, resulting in diastolic and then systolic dysfunction, electrocardiographic (ECG) changes and pain. Not all ischemic episodes cause ECG changes or pain. Hence, ECG is relatively insensitive for detection of ischemia. Currently, the troponin tests give us retrospective information whether the recent ischemic episodes were severe enough to cause myocardial damage. Ability to enhance online detection of ischemia noninvasively may help in diagnosis and monitor therapy.

Methods: 17 patients (pts)(15 men) with UA underwent overnight monitoring in ICCU with continuous 12-lead ECG and a peripheral arterial tonometry (PAT). The PAT is basically a pneumatic volume finger plethysmograph which monitors a peripheral arterial pulse wave amplitude (PWA) with however, improved performance in eliminating false signals. A reduction in the PWA signals an underlying peripheral arterial vasoconstriction (PAVC).

Results: 38 episodes of PAVC were detected in 14 pts (1–6 episodes per pt). In 3 pts no PAVC episodes were detected. Episodes lasted 2.5- 77 min. ECG changes (ST– or ST^-) were noted in 21 (55%) of the PWA episodes. In episodes with ECG changes, PAVC preceded (n = 18, 86%) or occurred simultaneously (n = 3, 14%) with ECG changes and PAC continued to be attenuated for several min after ECG changes resolved. There was only 1 episode of ECG changes without PAC. Chest pain was noted in 10 PAC episodes, in 9 of them ECG changes were noted.

In conclusion, PAT is a simple and noninvasive method that can be used for online detection and monitoring of spontaneous silent ischemia.

P1559 Myocardial gated spect using Tc-99m tetrofosmin can detect high risk patients whose symptoms had been resolved before arrival

M. Ohsawa, N. Ogiu, T. Suzuki, K. Ohira, Y. Taniguchi, T. Itoh, K. Fukami, K. Nakai, K. Hiramori. *Second Department of Internal Medicine, Iwate Medical University, Morioka, Japan*

Accurate and immediate diagnosis is need for a therapy in patients with unstable angina. Previous reports have demonstrated the diagnostic usefulness of initial myocardial perfusion imaging in the evaluation of patients with chest pain. However, it was not confirmed whether this strategy could be useful among patients whose symptoms had been resolved prior to examination. Subjects consisted of 76 patients (45 males, 31 females; 66 ± 10 years) with history of recent chest pain, who were admitted to coronary care unit (CCU) and demonstrated no evidence of acute myocardial infarction. Electrocardiogram (ECG) and echocardiography (ECHO) were performed on admission, and myocardial gated SPECT using Tc-99m tetrofosmin (gated TF) were subsequently performed. We defined positive ischemia as residual ischemic ST-T change on ECG, focal asynergy of left ventricular wall on ECHO, and focal decrease of myocvardial perfusion on gated TF. Coronary artery disease (CAD) was defined as exceeding 50% narrowing in diameter on coronary angiography (CAG). We estimated the sensitivity, specificity, and accuracy of each diagnostic method based on CAG findings. An event-free ratio was determined by Kaplan-Meier estimation for an average of 199 days.

Results: Sensitivity, specificity, and accuracy of each diagnostic method and the average time duration from the time of most recent chest pain to each diagnostic evaluation were as follows (table).

	ECG	ECHO	Gated TF
Sensitivity	0.57	0.50	0.79
Specificity	0.36	0.80	0.56
Accuracy	0.52	0.54	0.74
Duration (by hour)	15.6	15.6	23.9

Further, Kaplan-Meiere estimation revealed that the significant increase of needs of revascularization (RE) was noted in positive gated TF as compared to that in negative gated TF (total RE: 24/53 vs 3/23 $p < 0.01$, urgent RE: 9/53 vs 0/23 $p = 0.06$). In conclusion, gated TF allowed for reasonably accurate evaluation of high risk group of CAD under emergency circumstances even in the case that the episode of chest pain had been resolved prior to examination.

THE ECG IN UNSTABLE CORONARY DISEASE

P1560 The incremental prognostic value of continuous ST-segment monitoring to baseline clinical descriptors in acute myocardial infarction

A. Maas, C.M. Wyatt[1], C.L. Green[1], K.M. Trollinger[1], M.W. Krucoff[1]. *Cardiology Dept, VA Medical Center, Durham NC; [1]Cardiology Dept, Duke University Medical Center, Durham NC, USA*

We sought to define the incremental prognostic value of ST recovery parameters from continuous 12-lead ECG monitoring when added to the main adverse prognostic risk factors from the GUSTO-I mortality model.

825 patients were analyzed from substudies of 6 major thrombolytic trials. ST recovery parameters were: time to stable ST-recovery (>50% resolution of ST-segment elevation > 4 hours) and late ST elevation after stable ST recovery. High-risk patients had at least 1 of the following GUSTO-I predictors: age > 70, systolic BP < 110 mmHg, heart rate > 90, anterior MI, or previous MI. High, moderate, and low risk ST-groups were defined by the presence of both slow ST recovery (>2 hr) and late ST elevation, one or the other, or neither, respectively. Clinical endpoints were death, re-infarction, and congestive heart failure.

Results are shown in the table below.

Combined Outcome (%)

	Low ST	Medium ST	High ST	Overall
Low clin.risk*	21/143 (15)	14/99 (14)	7/19 (37)	42/261 (16)
High clin risk**	64/274 (23)	70/219 (32)	33/71 (49)	167/564 (30)
Overall**	85/417 (20)	84/318 (26)	40/90 (44)	209/825 (25)

*$p = 0.038$, **$p < 0.001$

Multivariable analysis revealed age, heart rate and late ST elevation as independent predictors of mortality, with model c-indices of 0.81 for clinical descriptors alone and 0.84 when combined with ST recovery variables.

In combination with baseline clinical descriptors, continuous 12-lead ST-segment monitoring significantly enhances the ability to predict clinical outcome.

P1561 Markers of risk in patients with unstable angina and MI without ST elevation: UK Prospective Registry of Acute Ischaemic Syndromes (PRAIS-UK)

J. Collinson, M. Flather, A. Wright, P. Dooley, I. Findlay[1], E. Rodrigues[2], K.A.A. Fox[3]. *Clinical Trials and Evaluation Unit, Royal Brompton & Harefield NHS Trust, London; [1]Royal Alexandra Hospital, Paisley; [2]Aintree Hospitals NHS Trust, Liverpool; [3]Royal Infirmary of Edinburgh, Edinburgh, UK*

Background: The acute coronary syndromes (ACS) of unstable angina (UA) or myocardial infarction (MI) without ST elevation on the admitting ECG are important and frequent causes of admission in UK hospitals. Little is known about their outcomes or risk factors.

Methods: A prospective cohort registry of patients with UA or MI without ST elevation on the admitting ECG was carried out in 56 UK hospitals. Twenty consecutive eligible patients were enrolled in each centre.

Results: Data are available on 950 patients (target sample 1000). Mean age (standard deviation) was 66 (12) years, 40% female, 47% prior MI, 23% previous PTCA/CABG, 16% diabetes, 36% hypertensive. Admission diagnosis was 95% UA and 5% MI without ST elevation. On admission 15% had a normal ECG, 66% had other abnormalities (T wave changes, Q waves etc.) and 19% had ST segment depression. Median length of hospital stay was 4.5 days (inter-quartile range 2–7). The in-hospital rate of death or new non-fatal MI was 5.0%, and the rate of death, MI and severe recurrent ischaemia with documented ECG changes was 13.7%. Rate of death or new MI in those with normal ECG, other abnormality, and ST depression was 1.4%, 4.4%, and 9.9% respectively (odds ratio [OR] for other abnormality compared to normal ECG was 3.3 [$p = 0.11$] and, for ST depression compared to normal was 7.9 [$p = 0.006$]). Risk of death or new MI was greater with advancing age. In an analysis of age as a continuous variable, the proportional excess risk was 3% (95% confidence interval 0–6%) for each year ($p = 0.02$). The rate of death or new MI for those <60, 60–70 and >70 years was 2.0%, 5.6% and 6.9% respectively (OR for 60–70 compared to <60 was 2.9 [$p = 0.03$] and, for >70 compared to <60 was 3.7 [$p = 0.005$]).

Conclusion: These data confirm that age and ST depression on the ECG are important markers of risk in patients with unstable angina or MI without ST elevation. A multi variable model evaluating these and other risk factors will be presented using complete in-hospital and 6 month follow-up data.

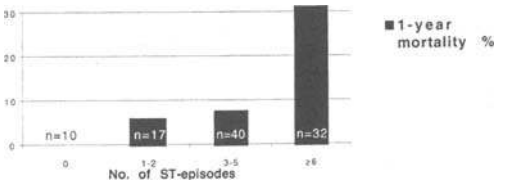
P1562 One-year mortality predicted non-invasively during the first four hours of acute myocardial infarction

P. Johanson, H. Svensson, K. Swedberg, M. Dellborg. *Dept. of Internal Medicine, Sahlgrenska University Hospital/Östra, Gothenburg, Sweden*

Introduction: ST-recovery has been used to predict patency and outcome in acute myocardial infarction (AMI). Continuous ST-monitoring provides real-time presentation of the dynamics in ECG-changes. ST-variability has been shown to predict outcome in patients with acute coronary syndromes. We have re-analysed ST-vector-monitoring in a unique material of 178 patients with suspected AMI, treated with either t-PA or placebo.

Methods: 178 patients with suspected AMI were monitored for 24 hours after admission using vectorcardiography. Changes in ST-Vectormagnitude (ST-VM) were calculated and presented as a trend-curve. Patients were included within 2.75 hours from onset of symptoms, randomised to 100 mg of rt-Pa or placebo. Heparin, aspirin and betablockade were given unless contraindicated. ST-segment variability was defined as an increase in ST-VM exceeding 25 μV, for at least 2 min. In the final analysis only patients with diagnosis of AMI were included (n = 102). 1 patient was excluded due to lack of 1-year-information, 2 due to lack of sufficient VCG-data.

Results: Patients alive at one year (86%) had significantly less ST-variability, 4.3 vs. 7.1 episodes ($p = 0.007$) and lower maximal ST-VM, 255 vs. 424 μV ($p = 0.002$). In a multivariate analysis, only ST-variability contributed to information about prognosis. The patients receiving t-PA had fewer ST-episodes 3.9 vs. 5.7 ($p = 0.015$) and a trend towards lower 1-year-mortality. 12 vs. 17% (p = ns).



Conclusion: ST-variability observed in the acute phase of AMI significantly is associated with adverse long-term outcome.

P1563 QT interval prolongation and mortality in type 1 diabetic patients: a 5-year cohort prospective study

A. Chinaglia, M. Veglio[1], R. Sivieri[2], L. Scaglione[2], P. Cavallo Perin[2].
Cardiology Dept, Ospedale Maria Vittoria, Torino; [1]Endocrinology Dept, Ospedale Mauriziano, Torino; [2]Internal Medicine Dept, University of Torino, Torino, Italy

The association between QT interval prolongation on resting ECG and excess mortality in diabetic populations has been suggested in non diabetic populations and, recently, in newly diagnosed type 2 diabetic patients. **Aim:** To assess the relationship between QTc and mortality in type 1 diabetic patients.

Methods: We assessed neuropathy and corrected QT in a random sample of 379 out of all 766 type 1 diabetic patients attending 22 outpatients clinic in Piemonte, Italy and 118 healthy subjects matched for sex and age. This sample was representative of the type 1 diabetic population in the area of the study. Data on survival after 5 years were obtained in 316/379 patients (83.3%) and 106/118 control subjects (90.5%). The patients lost at follow up were not significantly different in age, duration of disease, body mass index, blood pressure and prevalence of autonomic neuropathy.

Results: Mortality at 5 years was 6.32% and 0.9% in the control group ($p < 0.001$). Patients who survived had a significantly different age (31.4 ± 11.1 vs 36.7 ± 10.7 years, $p = 0.04$), duration of diabetes (13.6 ± 8.7 vs 18.7 ± 10.9 years $p = 0.01$), systolic (123.9 ± 20.0 vs 138.0 ± 35.6 mmHg, $p = 0.004$) and diastolic blood pressure (80.5 ± 13.6 vs 83.6 ± 11.2 mmHg, $p = 0.03$) and QTc (0.41 ± 0.03 vs 0.45 ± 0.02 sec, $p = 0.000005$) compared to those who died. At univariate analysis patients had a higher risk of dying (OR, 95% CI) if they had a prolonged QTc (20.14, 5.7–70.8) or were affected by autonomic neuropathy (3.55, 1.4–8.9). QTc prolongation was the only variable which showed a highly significant mortality OR at multivariate analysis ($p = 0.000004$).

Conclusion: This is the first cohort-based prospective study indicating that QTc prolongation is predicitve of increased mortality also in type 1 diabetic patients. Even though the mechanism linking QTc prolongation and the excess mortality remains to be elucidated, QTc interval analysis is a simple non-invasive test that could be used to stratify the death risk in diabetic patients, particularly those who are candidates to surgery or kidney and/or pancreas transplantation.

P1564 Does bundle-branch block at hospital admission predict mortality in patients with acute myocardial infarction? A study in the thrombolytic era

Monika Rameken, Karlheinz Seidl, Rudolf Schiele, Ulf Gieseler[1], Jocher Senges. *For the MITRA Study Group; Herzzentrum Ludwigshafen; [1]Diakonissenanstalt Speyer, Germany*

Aim of the study: A poor prognosis has been reported for patients with bundle branch block (BBB) on admission ECG in the setting of acute myocardial infarction (AMI). We investigated incidence and outcome of unselected, consecutive patients (pts) with AMI and BBB in the thrombolytic era.

Methods and results: Between 6/94 and 12/96, 6068 patients with acute AMI were admitted to one of 54 hospitals in southwest Germany and consecutively enrolled in the MITRA-registry (Maximally Individually Optimized Therapy after Acute Myocardial Infarction). Out of these, 593 pts (7%) presented with right- or left-BBB. Recanalisation therapy (including thrombolysis, primary PTCA, or both) was performed in 57.8% of pts without and 41.8% of pts with BBB ($p < 0.0001$). Pts with BBB had cardiogenic shock or heart failure in 10.8% and 14.0% of cases at admission, resp., compared to 4.0% and 8.3% in pts without BBB ($p < 0.0001$). 2-fold higher in-hospital mortality rates were found in pts with BBB and AMI compared to patients with AMI without BBB (31.4% vs. 15.2%, $p < 0.0001$), and analysis of long-term mortality of survivors revealed an even 2.5-fold higher mortality rate of pts with BBB and AMI compared to those without BBB (27.5% vs. 11.7%, $p < 0.0001$). After adjustment for other prognostic factors, BBB remained an independent predictor of in-hospital and long-term mortality (OR 1.7 and 1.6, resp.), with an higher prognostic impact of LBBB.

Conclusions: 1. BBB in pts with AMI is an independent predictor of in-hospital and long-term mortality. 2. Despite poor outcome of these pts, they receive recanalisation therapy less often than pts with AMI without BBB. 3. A careful monitoring of this high-risk subgroup of AMI pts is indicated, and 4. Reperfusion therapies need to be initiated more often to ameliorate the poor prognosis of pts with AMI and BBB.

P1565 QT dispersion in patients after acute myocardial infarction and unstable angina is dependent on the time from ischaemic event

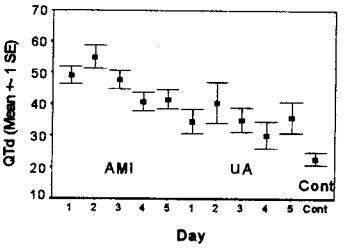
Yee Guan Yap, Kudret Aytemir, Xiao-Hua Goa, Mark Gallagher, A. John Camm, Marek Malik. *St. George's Hospital Medical School, London, UK*

Background: The optimal timing for QT dispersion (QTd) measurement is important in ischaemic patients but there is a lack of information on the time course of QTd after an ischaemic event.

Aim: We hypothesised that QTd after acute myocardial infarction (AMI) and Unstable Angina (UA) are not static and may have an impact on the QTd measurement.

Method: 81 AMI patients (61 M, age 63 ± 12) and 22 UA patients (17 M, age 63 ± 13) were prospectively examined using Marquette MAC VU electrocardiograph equipped with QT Guard software which automatically analysed QTd on digitally stored ECGs. 10 consecutive ECGs were recorded and the mean QTd calculated each day from day 1 to 5 after AMI or UA. 68 controls (33 M, age 38 ± 9.3) each had 10 ECGs recorded and their mean QTd calculated.

Results: Compared with controls using student's t-test, AMI patients had higher QTd from day 1–5 after the index infarct (day 1, 2, 3, 4, 5: $P < 0.0001$) (fig.) UA patients had higher QTd from day 1–3 only and normalised on day 4 and 5 (day 1, 2, 3: $P < 0.05$, day 4, 5: P = NS). AMI patients had higher QTd than UA on day 1 ($P = 0.004$), 3 ($P = 0.012$) and 4 ($P = 0.046$) and a trend on day 2 ($P = 0.058$) but insignificant on day 5 (P = NS).



Conclusions: 1) QTd is increased on day 1–5 after AMI but on day 1–3 only in UA patients. 2) AMI patients had higher QTd on day 1, 3, 4 and a trend on day 2 than UA patients. 3) AMI and UA patients have different pattern and degree of dynamic changes of QTd. 4) The timing of QTd measurement is crucial in ischaemic patients and must take into account the time from ischaemic event as well as the degree of ischaemia

P1566 ST-segment depression patterns in transmural acute myocardial infarction: an analysis of significance using echocardiography

P. Andriono. *Adult Cardiology, Philippine Heart Center, Quezon City, Philippines*

Concomittant ST segment depression in leads other than infarct-related areas in acute transmural MI can be "reciprocal phenomena" or "ischemia at a distance". In order to investigate the significance of the presence of concomittant ST segment depressions, we restrospectively studied all ECG patterns together with the echocardiographic wall motion findings of patients with acute transmural MI.

Methods: 138 patients with acute transmural MI were randomly chosen and their records reviewed. 62 patients met the inclusion criteria. ECG on admission and 24 hours after admission were evaluated. Echocardiographic and demographic data were reviewed.

Results: Among the patients with inferior wall MI, 45% died and were found to have significantly larger infarct areas based on the peak CK-MB value. Forty-two percent precented with maximal ST segment depression in leads V4-V6(group III); these same patients were also found to have larger infarct sizes ($p = 0.005$), experienced more severe heart failure ($p = 0.04$) and cardiogenic shock ($p = 0.04$), experienced higher incidence of ventricular tachycardia ($p = 0.03$) and had significantly higher in-hospital mortality rates ($p = 0.045$) than among patients who did not have ST segment depressions (group I) or had ST segment depression sums in leads V1 to V3 equal to or more than the sum of ST segment depression in V4 to V6 (group II). Inferior, Posterolateral and Anteroseptal regional wall motion abnormality differences were statistically significant in the groups II patients with inferior wall MI. Among patients with anterior wall MI, 50% died. The patients who had maximal ST segment depression in both lateral and inferior leads (group A3) had statistically significant larger infarct sizes ($p = 0.01$), more severe heart failure upon admission ($p = 0.04$); cardiogenic shock ($p = 0.03$) and higher in-hospital mortality rates ($p = 0.02$). Posterolateral region wall abnormality score was also found to be significantly higher in these patients.

Conclusion: Certain ST segment depression patterns in patients with acute transmural MI in areas other than the infarct-related leads do not simply point to a "reciprocal phenomena", but rather an "ischemia at a distance". This ECG finding during admission of patients with acute transmural myocardial infarction might be an important and inexpensive tool for risk stratification and management in the era of therapeutic revascularization.

ACUTE MYOCARDIAL INFARCTION — MANAGEMENT STRATEGIES

P1567 How management strategy for acute myocardial infarction is influenced by established guidelines in an academic centre: comparison between 2 populations at 5 years interval

B. Delaire, M.-F. Seronde, F. Schiele, N. Meneveau, J.-P. Bassand. *Service de Cardiologie, Hôpital Univ. Saint-Jacques, Besançon, France*

Aim: To examine the evolution of the management strategy of acute myocardial infarction (AMI) according to established guidelines at a 5 year interval in an academic centre.

Methods: A retrospective study comparing 2 pts cohorts referred for AMI in 1991 and 1996.

Results: 156 pts in 1991 (average age 68 ± 13 years) and 144 pts in 1996 (average age 66 ± 13 years) were referred for AMI. Clinical characteristics were similar. Between 1991 and 1996, median time to hospitalisation decreased from 6 ± 2 hours to 5 ± 2 hours, and length of hospital stay from 7 ± 2 days to 6 ± 2 days. In-hospital mortality decreased from 10.2% in 1991 to 8.3% (NS). Reperfusion therapy was undertaken more frequently in 1996, due to increased use of primary angioplasty. Medications prescribed during hospital stay and at discharge varied significantly during the observational period. Use of nitrates and of Ca blockers dececeased, whilst use of beta-blockers, Ace inhibitors and statins increased. Coronary angiography and PTCA were carried out before hospital discharge in 47.4% and 30% of pts respectively in 1991 versus 72.2% and 48.6% in 1996 ($p < 0.0001$).

Treatments undertaken during hospital stay

	1991 (n = 156)	1996 (n = 144)	p value
Reperfusion%	43.6	53.5	0.08
Thrombolysis%	43	41.6	0.86
Primary PTCA%	0.6	11.8	0.0001
Rescue PTCA%	4.5	4.9	0.87
Aspirin%	73	82.6	0.03
Nitrates%	37	5.5	0.0001
Beta-blockers%	45	50	0.0001
Ca blockers%	39.7	3.5	0.0001
ACE inhibitors%	34	40.9	0.21
Statins%	1.2	58	0.0001

Conclusion: Reperfusion therapy is more frequently applied to AMI thanks to more frequent primary PTCA. Medical therapy is more frequently in keeping with established guidelines, but complementary invasive and revascularization procedures after the initial period are increasingly used, despite the lack of established guidelines. This may be related to the short length of hospital stay, and the need for early discharge of patients.

P1568 How many patients with acute myocardial infarction are at risk of being erroneously released from the emergency room?

R. Bassan, L. Pimenta, M. Scofano, H.F. Dohmann, R. Gamarski, M. Araujo, C. Clare, K. Mohallem. *On behalf of Chest Pain Project investigators; Pró-Cardíaco Hospital/PROCEP, Rio de Janeiro, Brazil*

Patients with chest pain and no ST segment elevation on admission may be inappropriately discharged from the emergency room without the knowledge that they are having an acute myocardial infarction (AMI). It has been estimated that this occurs in 5% of patients, with an out of hospital mortality rate over 20%.

Methods: In order to increase diagnostic accuracy we have developed an algorithm to systematically evaluate patients with chest pain in the emergency room. From a series of 1003 consecutive patients 635 had neither ST segment elevation or left bundle branch block (LBBB) in their first ECG nor a definitely not angina-type chest pain associated with a normal/non-specific (N/NS) ECG. These patients underwent serial ECG and plasma CKMB measurements and 79 of them had an AMI by typical CKMB curve.

Results: Table depicts the observed incidence of AMI in these patients:

1st ECG	AMI	Plus 1st CKMB	AMI
↓ST/↓T (n = 159)	28%	Normal (n = 120)	18%
N/NS (n = 476)	6%	Normal (n = 395)	4%

Irrespective of ECG, patients with atypical angina had a very low rate of AMI, specially when first CKMB was normal.

Conclusions: Patients with chest pain and no ST elevation or LBBB on admission had an 11% chance of having AMI. Neither N/NS ECG nor normal first CKMB ruled out AMI, even when both were associated. Chest pain type was a good discriminator for non-AMI in these patients, specially when first CKMB was normal. If systematic and careful screening is not done atypical AMI patients will continue to be missed in the emergency room.

P1569 Clinical impact of local implementation of agreed guidelines for the management of patients with acute myocardial infarction

L.P. Badano, M. Cassin[1], L. Solinas[1], F. Macor[1], C. Burelli[1], G.L. Nicolosi[1]. *Cardiology Dept, A.O. S. Maria della Misericordia, Udine; [1]U.O. Cardiology, A.O.S. Maria degli Angeli, Pordenone, Italy*

Development of clinical practice guidelines is one of the most popular methods intended to promote translation of results from clinical trials into routine care. However, very little is known about the actual impact on pt. routine care of clinical guidelines for the management of pts. with AMI. To address this issue, we reviewed a prospectively collected cohort of consecutive pts. discharged with diagnosis of AMI from a 870-bed community based hospital in North-East Italy. Eighty-six consecutive pts. treated in 1996 (before guideline implementation) were compared with 70 consecutive pts. treated in 1997 (after guideline implementation) with respect to patterns of use of guideline directed pharmacotherapies for AMI, diagnostic testing, length of CCU stay, and clinical outcome.

The 2 groups were similar in male gender, age, AMI location and severity. Pts. managed before guideline implementation were less likely to receive thrombolysis (36% vs. 50%, $p = 0.05$), i.v. B-blockers at admission (13% vs. 31%, $p = 0.002$), oral B-blockers at CCU discharge (45% vs. 74%, $p = 0.0003$). When given, pts. managed before guideline implementation received lower dosage of i.v. heparin as manifested by a lower proportion of pts. reaching adequate aPTT levels at 24 hrs. (14% vs. 62%, $p < 0.0001$), of oral B-blockers (−50%, $p < 0.0001$) and higher dosage of aspirin (+100%, $p < 0.0001$). The time to mobilization (+1 day) and the length of CCU stay (+0.5 day) were longer in pts. managed before guideline implementation ($p < 0.0001$). Incidence of major complication were similar between the two groups (19% vs. 13%, respectively, $p = NS$).

Pts. with AMI managed after local implementation of clinical practice guidelines were more likely to receive evidence-based effective pharmacotherapies, had an earlier mobilization and an earlier discharge from CCU. This study strongly supports the role of clinical practice guideline local implementation to optimize management of pts. with AMI.

P1570 Clinical characteristics and in-hospital mortality of patients receiving ACE-inhibitor therapy for acute myocardial infarction

G. Andrikopoulos[1], D. Richter[1], M. Zairis[4], E. Karambinos[2], N. Katinioti[1], K. Paravolidakis[3], D. Manolatos[2], C. Stefanadis[1], J. Gialafos[1], P. Toutouzas[1]. *From the investigators of the GEMIG study; [1]Departments of Hippokration; [2]Euaggelismos; [3]Agios Panteleimon; Laikon Hospital, Athens; [4]Tzanion, Hospital, Piraeus; Hippokration Hospital, Salonica, Greece*

The aim of this study was to evaluate the effects of ACE-Dinhibitor therapy (ACE-I) for acute myocardial infarction (MI) in the Greek population. We also examined the clinical characteristics of the studied patients (pts) with regard to ACE-inhibitor therapy.

Methods: The GEMIG study is an ongoing, multicenter, prospective study focused on Genetics and Epidemiology of acute MI in the Greek population. A total of 1217 concecutive pts (954 men and 263 women, mean age 62 ± 13 years) with the diagnosis of MI have been enrolled in this study from April 1997 to December 1998. Out of the 1217 pts, 625 (51.4%) received ACE-I (group I pts) while 592 (48.6%) did not (group II pts). The unadjusted in-hospital mortality was 9.1 and 6.3% for women and men, respectively.

Results: The characteristics of patients' subgroups are shown in the table:

	Group I	Group II	P value
Age (years)	64 ± 12	61 ± 13	<0.001
Females/Males (%)	47/52	53/48	0.131
Diabetics/Non diabetics (%)	60/48	40/52	0.001
Smokers/Non smokers (%)	51/52	49/48	0.629
Hypercholesterolemics/Non (%)	53/50	47/50	0.219
Positive heredity/Negative heredity (%)	55/50	45/50	0.083
Hypertensives/Normotensives (%)	61/43	39/57	<0.001

Group I pts had significantly lower in-hospital mortality rate (3.2% vs 10.8%, $p < 0.001$). In univariate analysis, most likely to receive ACE-I were pts with an anterior MI (66 vs 34%, $p < 0.001$), pts admitted in the CCU (56% vs 44%, $p < 0.001$), those with echocardiographic left ventricular ejection fraction < 40% (63 vs 37%, $p = 0.013$), thrombolyzed pts (55 vs 45%, $p = 0.002$) and those who also received b-blockers (55 vs 45%, $p = 0.019$) and nitrates (56 vs 44%, $p < 0.001$). In multivariate analysis, left ventricular dysfunction, previous MI, transient conduction abnormalities and lethal arrhythmias, although strongly related to prognosis, were not significantly related to the administration of ACE-I. When all of these factors were included as covariates in a logistic regression model, ACE-I therapy was still significantly associated with lower in-hospital mortality.

Conclusion: ACE-I therapy was strongly related to improved early outcome after acute MI. Although this is not a specifically designed randomized trial and consequently we could not control for all characteristics of the studied pts that might have influenced the physician's decisions, our results are in favor of the beneficial effects of ACE-I therapy for MI in this low coronary risk population.

P1571 Prehospital thrombolysis may abort myocardial infarction

E.J.P. Lamfers[1], T.E.H. Hooghoudt[1], A. Uppelschoten[1], P.W.J. Stolwijk[2], F.W.A. Verheugt[3]. *Departments of Cardiology of [1]Canisius-Wilhelmina Hospital, Nijmegen; [2]Hospital Rijnstate, Arnhem; [3]University Hospital, Nijmegen, Netherlands*

Following initiation of a prehospital treatment program at two Nijmegen hospitals, we found the delay between symptom onset and thrombolytic treatment (TT) shortened by 63 minutes. In large trials it has been difficult to prove that early treated patients have a reduced mortality, so we hypothesized that the incidence of abortion of myocardial infarction (MI) can be used to evaluate a prehospital thrombolysis program.

Methods: Abortion of MI was diagnosed when chest pain disappeared, together with a decrease of the cumulative ST-segment elevation and depression to less than 50% within two hours after thrombolysis and with a less than a twofold increase of the normal value of cardiac enzymes (CK and CK-MB). Data from prehospital treated patients in the Nijmegen region were compared with those from Arnhem, where MI patients were all treated in-hospital.

Results: In total 227 prehospital patients were treated and compared to 269 in-hospital treated patients. We found significantly ($p < 0.05$) more abortion of MI using prehospital TT (30/227, 13%), compared to in-hospital TT (12/269, 4%).

Aborted MI after...	Prehospital TT	In-hospital TT	p
Age (range)	62 (36–68)	55 (42–81)	ns
Minutes to treatment (median)	85	165	<0.05
Anterior MI	13 (43%)	9 (75%)	ns
Total ST-segment shift (mean)	1.2 mV	0.9 mV	ns
12 months reinfarction	5 (17%)	3 (25%)	ns
12 months revascularisation	13 (43%)	9 (75%)	ns
• PTCA	9	6	
• CABG	4	3	
12 months mortality	0	0	ns

Conclusion: Prehospital thrombolysis results in a threefold increase of abortion of MI, due to earlier treatment. Assessment of aborted MI might be a better criterion for the efficacy of early thrombolysis than mortality data.

P1572 The prognosis of patients with a first non-Q-wave acute myocardial infarction in the pre and thrombolytic eras

M. Haim, S. Gottlieb, H. Hod, S. Behar. *Neufeld Cardiac Research Institute, Sheba Medical Center, Tel Hashomer, Israel*

Previous studies have shown that patients (pts) with non-Q wave AMI have better in-hospital and similar long-term prognosis compared to pts with Q wave infarction. The aim of the study was to compare the management and outcome of pts with a first non-Q wave MI in the pre and thrombolytic eras. Among 5839 consecutive AMI pts hospitalized in 13 CCUs during 1981–83, 610 (10%) had a first non-Q wave infarction. In a national 5 month survey conducted in the same CCUs during 1996, 437/2377 (18%) had a first non-Q wave MI. Characteristics, management and prognosis in the two groups were as follows:

	1981–83 (n = 610)	1996 (n = 437)	p Value
Men	397 (65%)	299 (68%)	NS
Age (mean)	63 ± 11 yrs	62 ± 13 yrs	NS
Diabetes	134 (22%)	108 (25%)	NS
Hypertension	255 (42%)	180 (41%)	NS
Smoking	185 (30%)	157 (36%)	NS
ASA	537 (4%)	400 (91%)	<0.001
β-Blockers	143 (27%)	262 (60%)	<0.001
Thrombolysis	-	116 (26%)	<0.001
Coronary Angiography	12 (2%)	185 (42%)	<0.001
PTCA/CABG	-	118 (27%)	<0.001
Mortality: 30 day	77 (12.6%)	26 (6.0%)	<0.001
1 year	117 (19.2%)	42 (10.4%)	<0.001

Conclusion: The frequency of non Q-wave infarction increased significantly in the thrombolytic era. Baseline characteristics were fairly similar, and early and late mortality declined by nearly 50% between the two periods. It is possible that changes in management were responsible for the significant mortality reduction in the '90's.

ACUTE CORONARY SYNDROMES — PHARMACOTHERAPY

P1573 Prognostic influence of pre-treatment platelet counts on coronary angioplasty with abciximab

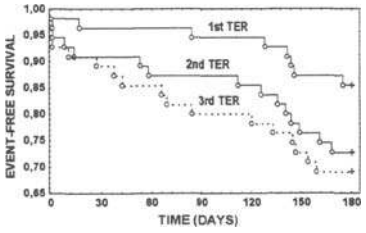
J. Ferreira, C. Aguiar, M. Almeida, R. Teles, J. Baptista, J. Palos, F. Machado, A. Silva, R. Seabra-Gomes. *Cardiology Department, Santa Cruz Hospital, Carnaxide, Portugal*

Background: Pre-treatment platelet counts may influence the magnitude of platelet IIb/IIIa receptor blocking achieved with the standard weight-adjusted regimen of Abciximab.

Objective: We sought to examine the prognostic influence of pre-treatment platelet counts on coronary angioplasty (PTCA) with Abciximab.

Methods: We studied 165 consecutive patients who underwent PTCA with Abciximab. Patients were divided in 3 groups according to pre-treatment platelet counts: 1st tercile (114 to 179 × 10^9/L), 2nd tercile (180 to 234 × 10^9/L) and 3rd tercile (235 to 446 × 10^9/L). There were no significant differences among all groups in baseline demographic and clinical characteristics, unplanned use of Abciximab ("rescue") and implantation of stents.

Results: Rate of hemorrhagic complications requiring blood transfusional therapy was 1.8% in each group. Thrombocytopenia (<50 × 10^9/L) occurred in 3.6% in 1st tercile group and 1.8% in the 3rd tercile. In-hospital rate of death or myocardial infarction was 1.8% in the 1st tercile group, 3.6% in the 2nd tercile and 5.4% in the 3rd tercile. Composite 6-month event rate of death, myocardial infarction or target vessel revascularization was 14.5% in the 1st tercile group, 27.3% in the 2nd tercile and 30.9% in the 3rd tercile ($p < 0.02$ between 1st tercile and 2nd plus 3rd terciles).



Conclusion: In the present population of patients undergoing PTCA with Abciximab, lower pre-treatment platelet counts were associated with a more favourable 6-month outcome.

P1574 Left ventricular thrombus after acute anterior myocardial infarction: a prospective study of streptokinase, tissue plasminogen activator and heparin

A.A. Gehani, A. Ammar, F. Mahrous, M. Desouky, H.A. Hajar. *Cardiology/Cardiac Surgery, Hamad Medical Corporation, Doha, Qatar*

Left Ventricular Thrombus (LVT) is a relatively common and potentially serious complication of Acute Anterior Myocardial Infarction (AAMI). The value of heparin in preventing LVT is controversial. This is the first prospective randomised study to examine the effect of LV heparin on LVT after AAMI.

Patients with documented first AAMI (N = 609) had echocardiography prior to discharge for evidence of LVT. 438 patients received Thrombolysis (Tx) and 171 did not (NoTx). Tx was Streptokinase (SK) in 279 and r-tPA in 159. The SK group was randomised to 4 days of I.V Heparin (n = 147) or Placebo (n = 132). NoTx group was also randomised to Heparin (n = 88) or No Heparin (n = 83). However as recommended, all r-tPA group had I.V Heparin. APTT was maintained at 3–4 normal. All patients received 325 mg oral Aspirin daily.

Overall, LVT was detected in 21.4% in Tx Vs 26.4% in NoTx groups (P = N.S). In SK group, LVT incidence was 20.7% with Heparin Vs 20.1% without Heparin (p = N.S). In r-tPA group, LVT incidence was 22.5%. In NoTx group, LVT incidence was 22.5% with Heparin Vs 33.3% without ($p < 0.05$). When the r-tPA group was compared with the SK sub-group on heparin, there was a tendency towards more frequent LVT in the former (22.5% Vs 20.7%, but this was not statistically significant). When the entire group was analysed using multiple regression analysis, disregarding the therapy received, it was evident that those with LVT had larger infarction as shown by higher peak CPK (3662 ± 2237 U/ml) than those without LVT (2954 ± 2050 U/ml).

Conclusion: Thrombolytic therapy reduces the incidence of LVT following AAMI. However, I.V Heparin *after* thrombolysis does not enhance this effect. LVT seems to be related to the size of infarction. Heparin seems important only in patients who did not receive thrombolysis. A different anticoagulant may have to be tried.

P1575 Systematic review of trials evaluating abciximab as a pre-treatment of patients undergoing PTCA

R. Lorenzoni, G. Mazzotta, G.F. Gensini, R. De Caterina. *Lucca, Italy*

Abciximab (Ab) has been demonstrated to prevent thrombotic events if used as a pre-treatment before PTCA. We performed a systematic review of three large trials (EPIC, EPILOG, CAPTURE) which evaluated Ab in specific, different subgroups of patients (pts) undergoing PTCA. Methods. Analysis was performed upon 5461 pts enrolled in the three trials and allocated to receive placebo (P, n = 2270) or Ab (n = 3191; 0.25 mg/kg bolus + 10 μg/min 12-hour infusion). Six-month major end-points were considered death, myocardial infarction, repeated PTCA and bypass surgery; six-month major complications were considered intracranial haemorrhages and non-intracranial haemorrhages requiring transfusions. Number-needed-to-treat (NNT) was calculated for composite and single end-points and number-needed-to-harm (NNH) was calculated for complications as: 100 divided by the difference of percentage incidence of composite and single end-points and complications in P and Ab groups. Results. At six months, 70.13% of P pts versus 74.96 of Ab pts were free of end-point events (RR 0.84, IC 95% 0.77–0.91; NNT for composite end-point 21). NNT was 227 for death, 24 for myocardial infarction, 37 for repeated PTCA and 75 for bypass surgery. NNH was 1667 for intracranial haemorrhages and 63 for non-intracranial haemorrhages requiring transfusions. Conclusion. Ab is effective in preventing six-month thrombotic events across the spectrum of pts undergoing PTCA.

P1576 Safety of enoxaparin in the geriatric population

L. Arcavi, A. Maier[1], A. Caspi[1]. *Rehovot; [1]Kaplan Hospital, Rehovot, Israel*

Background: Administration of intravenous heparin and aspirin has become an integral part of the therapeutic regimen in patients with unstable angina. However, the use of heparin may lead to excessive bleedings and there is a need of close laboratory supervision especially in the elderly patients. Low molecular weight heparin,is easier to administer and its efficacy in treatment of unstable coronary disease has been demonstrated. However, no study included elderly patients, therefore its safety was not demonstrated in this population.

Objectives: The major objective of this study was to examine whether treatment with a low- molecular weight heparin (enoxaparin), is safe in very old patients with unstable angina. In addition, we examined whether enoxaparin is protective against new cardiac events during the first week of therapy, and after 14 days.

Methods: Ninety-eight patients over the age of 80 (average: 84 years) with unstable coronary artery disease, were randomly assigned to receive either treatment with enoxaparin (1 mg/kg subcutaneously twice daily) or continuous intravenous standard heparin (1000 IU/hr) for 7 days. Event rates were tested by chi-square analysis.

Results: During the first week the risk of bleeding (measured by decrease of the hemoglobin and the need of blood transfusions) was similar in both groups. The incidence of thrombocytopenia (platelet count < 100,000/ml) was lower in the clexane group than in the standard heparin group (0% vs 2.7%); increase in liver transaminases occurred in 4 patients (7.8%) in the clexane group and none in the standard heparin group. There were no significant differences in the rate of cardiac death, angina pectoris or EKG changes in neither one of the groups.

Conclusions: This preliminary study shows that enoxaparin, a low molecular weight heparin, can be used safely in the very elderly population. However, the safety of long-term enoxaparin treatment, in this population, warrants further assessment.

P1577 Amlodipine in post-angioplasty ischaemia: results from the Coronary Angioplasty Amlodipine Restenosis Study (CAPARES)

B. Jørgensen, S. Simonsen, K. Forfang, K. Endresen, E. Thaulow. *Rikshospitalet, University of Oslo, Oslo, Norway*

Despite successful coronary angioplasty (PTCA), many patients (pts) still have ischemia early after the procedure. Ischemia may increase later on due to the luminal narrowing process occurring in most of the dilated lesions. Aims of the present study was to examine the effect of the calcium channel blocker amlodipine in reducing of post-PTCA ischemia.

Methods: 635 patients were randomly assigned to either amlodipine or placebo in a double blind prospective study. 450 pts were scheduled to perform exercise testing (ET) and 48 hours ambulatory holter monitoring (AHM) 2 weeks before, 2 (early) and 20 weeks (late) after PTCA. Of these 410 pts underwent successful PTCA, 67 had stents implanted. After PTCA 405 pts underwent ET, and 332 AHM (of whom 274 had technically readable recordings). Ischemia was defined as 1 mm ST depression at ET-ECG, and 1 mm ST depression lasting $\geq$1 min at the AHM.

Results: There were no significant differences in clinical and angiographic baseline characteristics between the groups, or the percentage of pts who had restenosis at follow-up (amlodipine: 24.0% vs. placebo: 23.8%). There were no difference in the incidence ischemia between the groups assessed by ET and AHM before PTCA. Ischemia occurred in both groups after PTCA, but was significantly reduced in the amlodipine group.

	Ischemia 2 weeks after PTCA		Ischemia 20 weeks after PTCA	
	Amlodipine	Placebo	Amlodipine	Placebo
ET	17.5%	27.7%*	46.9%	56.5%
AHM	30.6%	40.5%	28.3%	43.2%**

*p = 0.02, **p = 0.01

Multivariate logistic regression analysis revealed that amlodipine treatment exerted a positive and independent influence on freedom from ischemia on ET both 2 (p = 0.01) and 20 weeks (p = 0.03) after PTCA, when adjustment were made for age, sex, smoking, previous infarction, diabetes, restenosis, dilatation of left anterior descending, β-blockade and gain in luminal diameter.

Conclusion: Ischemia occurred after successful PTCA, and was significantly reduced by amlodipine.

P1578 Primary stenting in acute myocardial infarction: acute and short-term angiographic and clinical outcomes with a comparison of antiplatelet agents between cilostazol and ticlopidine: single center experience – Fujigaoka Antiplatelet Stent Trial (FAST study)

B. Ebato, F. Asano, M. Shibata, T. Sato, N. Zenda, H. Ide, M. Sato, T. Suzuki, Y. Shimizu, M. Kasama, M. Ebato, Y. Higashi, T. Hashimoto, T. Tsutsumi, Y. Takeyama. *Depatment of Cardiology, Showa University Fujigaoka Hospital, Yokohama, Japan*

Aspirin and Ticlopidine have been commonly utilized following elective coronary stenting since many studies showed the superiority of the combined antiplatelet therapy. However, the regimen of antiplatelet agents following primary stenting in acute myocardial infarction (aMI) has not yet been established. Cilostazol is an antiplatelet agent that is suggested to inhibit cyclic AMP phosphodiesterase in platelets and vascular smooth muscle and attributed to antiplatelet, vasodilation and inhibitory effect of intimal proliferation. We prospectively compared the efficacy of the combined antiplatelet therapies such as aspirin and cilostazol verses aspirin and ticlopidine after primary stenting in aMI.

Method: To elucidate the efficacy of cilostazol, patients (pts) who underwent primary stenting in aMI were randomized to receive cilostazol (200 mg/day) and aspirin (162 mg/day): (Group C), or ticlopidine (200 mg/day) and aspirin (162 mg/day): (Group T), then the angiographical and clinical outcomes were compared.

Results: Forty nine patients were randomized to Group C (n = 23) and Group T (n = 26). Angiographical f/u was performed at 4.1 $\pm$ 2.9 months and Clinical f/u was completed at 13 months after primary stenting. Primary success was achieved in all the patient and there was no major adverse cardiac event including death and CABG. Although subacute thrombpsis (SAT) did not occurre in both groups, active bleeding requiring blood trandfusion was seen in 2 pts in Group T. Quantitative coronary angiography (QCA) analysis showed as follows. Post procedural minimum lumen diameter (MLD) in both groups were similar (Group C: 2.70 $\pm$ 0.38 mm vs. Group T: 2.53 $\pm$ 0.43 mm p = ns) but f/u MLD was significantly bigger in Group C (2.38 $\pm$ 0.38 vs 1.89 $\pm$ 0.57: p < 0.05) resulting in the significant difference of the late loss between the two groups. Restenosis occurred in 4 pts in Group T while there was no restenosis in Group C, and the difference is statistically significant (p < 0.03)

Conclusion: Combined antiplatelet therapy was effective after primary stenting in aMI, however cilostazol was suggested to have better clinical and angiographical outcomes compared with ticlopidine.

P1579 Hemodynamic effect of trimetazidine during exercise in patients with coronary artery disease

T. Mandecki, J. Kastelik[1], A. Szulc, K. Mizia-Stec, L. Szymanski, J. Haratyk[1].
IInd Clinic of Cardiology, Katowice; [1]Cardiological Dept, General Hospital, Bielsko-Biala, Poland

It is accepted that the beneficial effect of trimetazidine (TMZ) in patients (pts) with coronary heart disease (CHD) is due to cytoprotective action and that this drug does not alter the hemodynamic parameters.The aim of the study was to evaluate the effect of TMZ on the ECG exercise test (ET) in pts with CHD.The study group consisted of 85 pts with coronarographically confirmed two-or three vessels CHD.ET was performed twice in all pts:after single oral dose (60 mg) TMZ and without this drug.Both test were done according to Bruce protocol in identical conditions,and the sequence of them was randomly chosen.In 76.5% (65 pts) ST segment depressions were smaller after TMZ and their duration time was shorter in 54.2% (46 pts).The anginal pain during ET after TMZ occurred in 16.5% (14 pts) and in 54.2% (46 pts) during ET without TMZ.

TMZ increased the workload during ET ($p < 0.001$). TMZ also lowered asystolic ($p < 0.001$), diastolic ($p < 0.001$) and mean ($p < 0.001$) blood pressure as well as the double product (DP, $p < 0.001$) during ET.These changes were more pronounced in pts with three-vessels disease.These results suggest that in some pts TMZ may improve the exercise tolerance and attenuate the ECG signs of cardiac ischemia during ET.The lower afterload due to the decrease of DP may be one of the factors responsible for it.Thus in some CHD pts TMZ may have favourable hemodynamic effect apart from its cytoprotective action.

P1580 Effect of age on use of treatments for acute myocardial infarction

A. Owen. *Kent and Canterbury Hospital, Canterbury, Kent, UK*

Introduction Reports published in the literature suggest that elderly patients with acute myocardial infarction (MI) have inappropriately had thrombolytic treatment (TT) and beta blockers (BB) withheld. This is despite clear recommendations in the literature that these treatments are beneficial in the elderly. This abstract describes the current practice in a general hospital where the majority of patients are cared for by physicians without specialist training in cardiology.

Methods The records of all patients admitted with MI over 2 three month periods were examined. Patients were identified prospectively by visiting wards, examining the admissions register and discharge diagnosis system and reviewing all records of patients with a raised CK for patients with MI.

Results There were 166 patients of whom 113 were <75 years and 53 ≥75 years. The inpatient mortality was respectively: 8%, 31%. Elderly patients were less likely to fulfil the ECG criteria for TT 43% Vs 60%, $P < 0.05$. Thrombolytic treatment was received by 94% of all eligible patients with no discrimination against the elderly. Aspirin was received by 84% of all patients with no discrimination against the elderly. The elderly were less likely to be prescribed BB at discharge 33% Vs 63%, $P < 0.001$, or ace inhibitors at discharge 45% Vs 66%, $P < 0.05$.

Conclusions The historical reluctance to use TT in the elderly appears to have been overcome, but has been replaced by a reluctance to use ace inhibitors. The reluctance to use BB in the elderly patients persists. This is especially disappointing in view of the very high mortality that elderly patients with MI have.

P1581 Administration of β-adrenergic blockers at hospital discharge after acute myocardial infarction in the Greek population

G. Andrikopoulos[1], D. Richter[1], M. Zairis[3], D. Kostakis[4], P. Vogiatzi[2], E. Gialafos[1], A. Michaelides[1], C. Stefanadis[1], J. Gialafos[1], P. Toutouzas[1].
From the investigators of the GEMIG study; [1]Cardiac Departments of Hippokration; Euaggelismos; Agios Panteleimon; [2]Laikon Hospital Athens; [3]Tzanion, Hospital, Piraeus; [4]Hippokration Hospital, Salonica, Greece

The administration of beta-adrenergic blockers (BB) has been related to improved survival after acute myocardial infarction (MI). Although the beneficial effects of BB have been recently expanded to patients (pts) with heart failure (HF), diabetes mellitus (DM) and older age, beta-blockade therapy is frequently underused.

Methods: The GEMIG study (Genetics and Epidemiology of acute Myocardial Infarction in the Greek population) is an ongoing, multicenter, prospective study which has recruited 954 men and 263 women with a mean age of 60 ± 12 and 69 ± 12 years respectively ($p < 0.001$), from May 97 to December 1998.

Results: BB were administered to 63% of the studied pts at hospital discharge. Pts receiving BB were significantly younger (59 ± 12 vs 66 ± 12 years, $P < 0.001$).

Proportion of patients under beta-blockade therapy at discharge (%)

		P
Females/Males	54/65	0.003
Age ≥ 70 years/Age < 70 years	46/70	<0.001
Diabetics/Non diabetics	22/78	<0.001
Hypertensives/Normotensives	63/63	0.998
Non Q wave MI/Q wave MI	51/65	0.003
Non thrombolysed pts/Thrombolysed pts	56/68	<0.001
LVEF ≤ 40%/Echocardiographic LVEF > 40%	49/70	<0.001

In a multivariate analysis with all the aforementioned clinical characteristics included as covariates, age ≥ 70 years, Non-Q wave MI and LVEF < 40% were significantly related to decreased administration of b-blockade therapy. Relative risks were 0.468 (0.328–667, $p < 0.001$), 0.424 (0.261–0.668, $p = 0.001$) and 0.440 (0.318–609, $p < 0.001$) respectively.

Conclusion: In this MI cohort a relatively high proportion of pts after MI received BB at hospital discharge. However, b-blockade therapy still seems to be underused in pts with older age, nontransmural MI and dysfunction of the left ventricle, despite the fact that pts with these conditions may also benefit from b-blockade therapy.

P1582 Importance of antithrombin therapy in combination with abciximab and low-dose fibrinolytic therapy: preliminary results of the GUSTO-4 pilot study

C. Bode, W.J. Cantor[1], E.M. Ohman[1], A. Betriu[2], F. Forycki[3], G. Morocutti[4], D. Ardissino[5], P.E. Aylward[6], R.M. Califf[1], E.J. Topol[7]. *Univ. of Heidelberg, Heidelberg, Germany; [1]Duke Clinical Research Institute, Durham NC, USA; [2]Hospital Clinic I Provincial, Barcelona, Spain; [3]Krankenhaus Neukoelln, Berlin, Germany; [4]Ospedale S. Maria, Udine; [5]Policlinico San Matteo, Pavia, Italy; [6]Flinders Med Ctr, Bedford Park, Australia; [7]Cleveland Clinic Foundation, Cleveland OH, USA*

In the GUSTO-4 Pilot trial, low-dose reteplase (5+5 U) combined with standard-dose abciximab and heparin (Hep, 60 U/kg) resulted in TIMI grade 3 flow in 63% of cases (TIMI grade 2 or 3 flow in 82%). In the dose-confirmation phase of the study, this reteplase-abciximab regimen (Combo) was compared with reteplase alone (10+10 U) with 70 U/kg heparin. During this phase, the initial heparin dose used in the Combo arm was reduced from a 60-U/kg bolus (max 6000 U) to a 40-U/kg bolus (max 4000 U). We assessed bleeding and patency before and after this reduction, to determine effects on efficacy and safety. An independent core laboratory assessed angiographic patency, and core laboratory data were available for 89% of cases.

Patency and Bleeding by Heparin Dose

	Combo, 60 U/kg Hep (n = 34)	Combo, 40 U/kg Hep (n = 75)	r-PA 10 + 10 U (n = 107)
Minutes to angiography	61 (57, 72)	65 (60, 71)	62 (60, 68)
TIMI grade 3 flow	18 (62%)	34 (51%)	47 (48%)
TIMI grade 2 or 3 flow	23 (79%)	51 (77%)	76 (78%)
Transfusion	5 (15%)	9 (13%)	12 (12%)
Max Hgb drop, adjusted	3 (1.9, 4.4)	2.8 (1.9, 4)	2.6 (2.0, 3.4)

Only one intracranial hemorrhage occurred, in the reteplase 10+10-U group. These findings suggest the need for antithrombin therapy with low-dose reteplase and standard-dose abciximab, to maximize its effect.

P1583 Brief use of ticlopidin after coronary stent implantation : a comparative study

F. Aboujaoudé, J.P. Rinaldi, J.M. Coutelour, H. Belhakem, R. Caputo, S. Alsagheer, F. Ben Ahmed, M. Boursier, K. Khalifé. *Cardiology Dept., Hôpital Bon Secours, Metz, France*

Many studies have demonstrated the efficiency of combined use of platelet inhibitors, as aspirin plus ticlopidin, after stent implantation, in reducing the incidence of acute thrombosis.Nevertheless, the duration of the use of ticlopidin is not well established.

The aim of our study is to compare two regimens of treatments, using long term administration of aspirin (100 mg/day), in association with ticlopidin (500 mg/day), for 15 days (201 patients) or 30 days (152 patients) after 353 consecutive Wiktor® stent-Medtronic deployement.

The principal clinical criterias at 30 days follow-up were: acute thrombosis of the stent (TH); acute myocardial infarction (AMI), unstable angina (UA), bypass surgery (BP), repeated angioplasty (RA), mortality (M), all cardiac events (ACE) and non cardiac events as cutaneous rash (CR), gastro intestinal (GI) and leucopenia (L).

	TH (%)	M (%)	AMI (%)	UA (%)	BP (%)	RA (%)	ACE CR (%)	GI (%)	L (%)	(%)
Ticlo 30 d.	1.9	0.6	1.9	1.9	0	2.6	2.6	1.9	1.9	0.65
Ticlo 15 d.	3.4	0.4	0.9	3.9	0	4.4	6.4	0	0	0
p	NS	NS	NS	NS	NS	NS	NS	NS	NS	NS

At 30 days follow-up, there is no difference between the two groups in term of incidence of thrombosis or cardiac events.

A briefer use of ticlopidin after stent implantation is possible without increasing the thrombotic risk, and is helpfull to avoid side effects of ticlopidine.

P1584 Are different angiotensin converting enzyme inhibitors identical for treatment of acute myocardial infarction? results from the Hong-Kong post-myocardial infarction trial

C. Lau, H.F. Tse, W. Ng, S.K. Li[1], K.K. Chan[1], Y.K. Lau[2], K.H. Kwok[2], S.K. Leung[3], Y.W. Tang[3], S. Turton. *Medicine Dept, University of Hong Kong, Hong Kong; [1]Medicine Dept, Pamela Youde Nethersole East. Hospital, Hong Kong; [2]Medicine Dept, Ruttonjee Hospital, Hong Kong; [3]Medicine Dept, Kwong Wah Hospital, Hong Kong, Hong Kong*

Hypotension with angiotension converting enzyme inhibitors (ACEIs) during acute myocardial infarction (AMI) not only limits adequate dosing but is associated with increased mortality. ACEIs have different degrees of first dose hypotension.

Methods: We studied 212 patients with first AMI randomly assigned to receive captopril (CAP, initial 6.25 mg, upto 50 mg/day or perindopril (PER, initial 2 mg, upto 8 mg/day). Automatic blood pressure monitoring was performed every 15 minutes for 14 h, then hourly for 10 h. Echocardiography and mortality were monitored for 6 months.

Results: At baseline, there was no difference between CAP (102 pts) and PER (110 pts) in age (65 ± 1 vs 64 ± 1 yrs), sex (% male: 81.4 vs 72.7%), AMI location, peak CK and baseline mean blood pressure (MBP, 83.0 ± 1.1 vs 84.4 ± 1.1 mmHg), but PER pts tended to have a higher Killip score (1.4 ± 0.1 vs 1.2 ± 0.1, p = 0.06). Compared to PER, CAP resulted in more severe hypotension following initiation of treatment (% MBP reduction: 20.3 ± 0.9 vs 16.6 ± 1.0%, p < 0.01), a lower minimum MBP (66.0 ± 1.1 vs 70.1 ± 1.1 mmHg, P < 0.01), and a more rapid fall in MBP (time to minimum: 2.6 ± 0.1 vs 4.3 ± 0.5 h, p < 0.005). At 6 months there was no significant difference between CAP and PER in left ventricular function, need for revascularisation, and NYHA heart failure class. Significantly more patients, however, withdrew from CAP than from PER (44.1 ± 4.9 vs 28.2 ± 4.3, P = 0.016). This was also a strong tendency in favour of a mortality reduction with PER (8.1% vs 19.7% in CAP, P = 0.06).

Conclusion: In pts with AMI, PER is better tolerated and has lower hypotensive complications than conventional treatment with CAP, which may be translated into improved patient survival.

P1585 Worse short-term prognosis of myocardial infarction patients with hyperglycaemia on and during admission

J. Marrugat, F.J. Gonzalez de Molina[1], J. Sala[1], R. Masia[1], W. Ricart[2], M. Gil, M. Senti. *Unitat Lipids & Epidemiol. Cardiovasc., Institut Municipal Investigacio Medica, Barcelona; [1]Cardiologia, Hospital Universitari Dr. Josep Trueta, Girona; [2]Endocrinologia, Hospital Universitari Dr. Josep Trueta, Girona, Spain*

Background: Worse mortality after acute myocardial infarction (AMI) has been reported among diabetics, but patients with hyperglycaemia after myocardial infarction have received less attention.

Objective: To assess the role of hyperglycaemia in survival after AMI.

Methods: An inception cohort obtained in a population-based prospective registry of AMI patients held in the reference hospital in Girona, Spain. All consecutive AMI patients aged < 75 years registered between 1993 and 1996 were included. Patients and clinical characteristics, including history of diabetes, and glycaemia on admission, were recorded. The adjusted effect (odds ratio [OR]) of hyperglycaemia over 126 mg/dL (7 mmol/L) on survival at 28 days was analyzed with logistic regression.

Results: A total of 631 patients with AMI were included. Hyperglycaemic (n = 345) were significantly older (62.9 Vs 57.7 years) and more often diabetic (39.9% Vs 11.0%), and developed more severe AMIs than normoglycaemic: i.e. severe ventricular arrhythmias (26.3% Vs 17.5%) and acute pulmonary edema or cardiogenic shock (24.8% and 10.5%), all p < 0.02. Revascularization procedures within 28 days were performed in and thrombolysis and aspirin given to a similar proportion of both type of patients. Twenty-eight-day mortality rate was 11.0% in hyperglycemic and 1.9% in normoglycaemic patients. After adjustment, the risk of 28-day death in Hyperglycaemic patients was 3.71 (95% confidence interval 1.05–13.13) times that of normoglycaemic.

Conclusions: AMI patients with hyperglycaemia on admission develop more lethal and severe AMIs than men regardless of comorbidity, age and clinical characteristics.

P1586 Effects of oral pirenzepine on heart rate variability after acute myocardial infarction: a randomized trial

Anna Klinaki, John Chiladakis, Christos Stathopoulos, Antonis S. Manolis. *Patras University, Patras, Greece*

Augmenting cardiac vagal outflow in post-myocardial infarction (MI) patients may have a favorable effect on clinical outcome. The aim of the present study was to investigate in an open-labelled randomized manner the vagotonic effects of oral pirenzepine on heart rate variability (HRV) in patients (pts) who sustained an acute MI. Pts who survived an acute MI were randomized to receive along with their standard therapy either placebo (**n** = 23, 19 men/4 women, aged 58 ± 11 yrs) or pirenzepine 25 mg bid (n = 22, 20 men/2 women, aged 59 ± 12 yrs) at the time of their discharge from the hospital. A baseline 24-h Holter recording assessing HRV was obtained prior to randomization. Baseline demographics and clinical characteristics did not differ in the two groups. MI location was anterior in 52% and 45% respectively; mean left ventricular ejection fraction was 45 ± 8% and 49 ± 6% respectively. HRV was reevaluated at 1-month and 3-month intervals while on treatment. Pts tolerated their treatment well with no reported side-effects. Baseline HRV parameters were similar in the two groups. Pirenzepine increased SDNN from 115 ± 30 to 130 ± 29 at 1 month (p = 0.045) and to 132 ± 33 at 3 months (p = 0.001); SDANN index also increased from 95 ± 24 to 106 ± 30 at 1 month (p = 0.05) and to 114 ± 32 at 3 months (p = 0.001), while no significant difference was noted in the placebo group (SDNN: 101 ± 23 vs 105 ± 30 at 1 month, vs 114 ± 31 at 3 months; SDANN index: 85 ± 19 vs 88 ± 28 at 1 month, vs 102 ± 36 at 1 month; p = NS). At 3 months there were no sudden or other cardiac deaths or arrhythmic events; there was only one cardiac death at 2 months in the placebo group.

In **conclusion,** short-term therapy with oral pirenzepine favorably affects HRV indices at 1-month and 3-month follow-up in post-MI pts. Whether this effect is further sustained or whether it influences survival remains to be seen at 6- and 12-month follow-up.

P1587 Comparative efficacy of losartan and carvedilol in patients with postinfarction left ventricular remodelling and heart failure

K.G. Adamian, A.L. Chilingarian, A.V. Astvatsatrian, A.Z. Garibgeanian, T.R. Astvatsatrian, S.I. Vardanian. *Institute of Cardiology, Yerevan, Armenia*

Aim of the study was compare the efficacy of losartan (L) and carvedilol (C) in patients (pts) with postinfarction left ventricular remodeling (LVR) and heart failure (NYHA III) who are already on standard therapy (ST) by enalapril 10–20 mg/day, digoxin 0.25 mg/day, furosemide 20–40 mg/day at least 2 months.

Methods: After 1 week of drug (L and C) toleration determination 93 pts (age 63 ± 9 yrs, 14% female) on ST with EchoCG proved LVR and NYHA III were randomized to 2 groups in order to receive 1) L 50 mg/day (n = 47) or 2) C 12.5 BID (n = 46). 30 pts on ST served as control. 16 segment model score index contractility (SIC) on peak dobutamin-stress test, total ischemic burden (TIB) by 24 hour Holter monitoring, EF, indexes of SV and anterior and posterior segment lengths (AS; PS) on papillary muscles level in parasternal short axis view were measured in all pts by investigators without knowledge of study aims in 30, 60, 180 days after study initiation.

Results: In 30 day there were no statistically significant differences between all groups in all parameters. In 60 day TIB, SVI, SIC were significantly better in group C (TIB: C 28 ± 9 min* vs 33 ± 11 min L vs 32 ± 11 min; SVI: C 29 ± 8* vs L 24 ± 5 vs 25 ± 6; SIC: C 1.1 ± 0.2* vs L 1.3 ± 0.3 vs 1.4 ± 0.3; * – $p < 0.05$). EF was greater in the group L vs C and control (32 ± 5%** vs 28 ± 3%** vs 30 ± 4%; ** – $p < 0.01$). However in 90 day all parameters were better in L group, including LV size (SIC: L 1.2 ± 0.2* vs 1.3 ± 02 vs 1.4 ± 0.2; SVI: L 32 ± 8** vs C 25 ± 4 vs 24 ± 4; EF: L 31 ± 6%* vs 29 ± 4% vs 28 ± 4%; AS: L 6.3 ± 0.6* cm vs C 6.0 ± 0.7 cm vs 5.9 ± 0.6 cm; PS: L 3.4 ± 0.15* cm vs C 3.5 ± 0.15 cm vs 3.4 ± 0.13). TIB was significantly less in L and C groups compare to control ($p < 0.01$) and did not significantly differ between groups L and C (C: 27 ± 8 min. 24^{-1} vs L 26 ± 7 min. 24^{-1}; p = NS). In 180 day TIB also did not differ between L and C, however other better results in L group observed in 90 day became more prominent compare to C and control (SIC: L 1.1 ± 0.1*** vs C 1.2 ± 0.3 vs 1.3 ± 0.3; SVI: L 34 ± 8*** vs C 24 ± 4 vs 25 ± 4; EF: L 33 ± 6%*** vs C 28 ± 4% vs 29 ± 4%; AS: L 5.9 ± 0.6 cm*** vs C 6.1 ± 0.5 vs 6.0 ± 0.4; PS: L 3.3 ± 0.15*** vs C 3.9 ± 0.2 vs 3.8 ± 0.2; *** – $p < 0.001$).

Thus, adding C to ST in pts with LVR and HF is beneficial in first 60 days of therapy than L + ST. However in pts on L + ST effects are better after 90 day and increase up to 180 day.

P1588 Oral administration of a novel, selective and potent endothelin-A receptor antagonist (TA-0201) improves left ventricular remodelling after myocardial infarction without haemodynamic changes

G. Ui, S. Imai, Y. Sugito, Y. Ito, K. Imai, H. Kamiyama, F. Naganuma, H. Aihara[1], H. Yabana[1], S. Murata[1], R. Nagai. *The Second Department of Internal Medicine, Gunma University, Gunma; [1]Discovery research laboratory (Tanabe Seiyaku Co. Ltd.), Gunma, Japan*

Objective: We investigated whether oral administration of endothelin-A receptor antagonist protects the LV against remodeling after myocardial infarction.

Methods: A novel, selective and potent endothelin-A receptor antagonist (TA-0201, 0.3 mg/kg) was given orally from the second day to the 6 weeks in 7 dogs subjected to the left anterior descending coronary artery ligation (TA group). Other 7 dogs served as Controls. Based on serial two-dimensional echocardiogram, the effects of TA-0201 during healing after myocardial infarction on alterations in ventricular size, shape, mass, and function were estimated. Postmortem measurements of scar size and geometry were assessed. Moreover, immunohistochemical evaluation of ET expression was performed.

Results: TA-0201 showed no significant effect on either blood pressure or heart rate. After 6 weeks of treatment with TA-0201, increases in the LV mass, end-diastolic volume, expansion index and wall motion score index were significantly reduced in the TA group as compared with those in the control group ($p < 0.05$). A thinning ratio and EF was significantly greater in the TA group than in the control group ($p < 0.05$). By immunohistochemical study, ET was detected in extracellular matrix in border zone of controls. We observed interstitial hyperplasia and myocardial cell hypertrophy in the border zone of controls. In TA group, these changes were less.

Conclusion: Endothelin-A receptor antagonist may offer a promising therapeutic approach for the protection against not only LV remodeling but also functional deterioration after myocardial infarction independently of hemodynamic changes.

ATRIA BY TRANSOESOPHAGEAL ECHOCARDIOGRAPHY

P1589 Pulmonary venous flow patterns in a large normal population: comparison between transthoracic and transoesophageal echocardiography

S.F. de Marchi, M. Bodenmüller, C. Seiler. *Cardiology, University Hospital, Berne, Switzerland*

Background: Recently, increasing importance has been attributed to the pulmonary venous flow velocity (PVF) pattern for the assessment of left ventricular diastolic function or mitral regurgitation. However, normal PVF patterns have not been determined in a large population. Furthermore, it remains unclear how the normal values differ between TTE and TEE in various age groups.

Methods: A total number of 400 patients (pts) with normal Doppler echocardiography and without a history of cardiovascular disease was investigated. The flow velocity pattern of the right upper pulmonary vein was recorded in 307 pts using TTE and in 93 pts using TEE. Peak systolic (Peak S, m/s), peak diastolic (peak D, m/s) and peak reversed flow velocity at atrial contraction (peak A, m/s), systolic to diastolic peak flow velocity ratio (S/D) and duration of reversed flow (Adur, ms) were measured. Patients were divided into six age groups (table). The values were compared between TTE and TEE within the age groups.

Results:

	Age groups (years)					
	10–19	20–29	30–39	40–49	50–59	≥60
PeakS TTE	0.48±0.14 (14)	0.49±0.12 (75)	0.54±0.14 (92)	0.57±0.11 (52)	0.57±0.14* (39)	0.58±0.12 (35)
PeakS TEE	0.35 (1)	0.49±0.13 (16)	0.55±0.17 (34)	0.59±0.15 (16)	0.70±0.15* (12)	0.64±0.20 (15)
PeakD TTE	0.66±0.16 (14)	0.64±0.13 (75)	0.59±0.12 (92)	0.56±0.13 (52)	0.48±0.12 (39)	0.49±0.13 (35)
PeakD TEE	0.81 (1)	0.61±0.10 (16)	0.54±0.16 (34)	0.54±0.11 (16)	0.51±0.11 (12)	0.45±0.12 (16)
PeakA TTE	0.25±0.05 (11)	0.22±0.08 (59)	0.24±0.06* (76)	0.27±0.06 (44)	0.27±0.09 (35)	0.29±0.06* (29)
PeakA TEE	0.18 (1)	0.22±0.08 (15)	0.20±0.09* (27)	0.25±0.09 (11)	0.25±10 (11)	0.23±0.09* (10)
Adur TTE	108±10 (11)	116±32* (59)	121±27* (76)	114±31 (44)	117±33 (35)	127±42 (29)
Adur TEE	87 (1)	96±17* (15)	90±18* (27)	94±29 (11)	99±19 (11)	111±24 (10)
S/D TTE	0.75±0.23 (14)	0.81±0.30 (75)	0.92±0.22* (92)	1.05±0.31 (52)	1.24±0.30 (39)	1.24±0.32 (35)
S/D TEE	0.43 (1)	0.82±0.19 (16)	1.06±0.26* (34)	1.15±0.40 (16)	1.41±0.29 (12)	1.48±0.53 (15)

*indicates $p < 0.05$, number of patients are given in parentheses.

Conclusions: There is a considerable tendency to overestimate the duration of flow reversal at atrial contraction using TTE. This is of importance for the assessment of LV diastolic function using the PVF pattern. The S/D ratio increases later with advancing age in TTE compared to TEE. This must be accounted for in the assessment of mitral regurgitation.

P1590 Comparison of different provocation manoeuvers for echocardiographic detection of persistent foramen ovale

S. Pfleger, S. Stark, W. Voelker[1], A. Latsch, K.K. Haase, P. Gaudron. *II. Dep. of Medicine, University Clinic Mannheim; [1]Dep. of Cardiology University Würzburg, Germany*

Persistent foramen ovale (PFO) is found in 9.2% to 32% of echocardiographic examinations. Gold standard for the detection of a PFO is transesophageal echocardiography (TEE) and the mostly used provocation test is Valsalva maneuver. The aim of our study was to evaluate the effectiveness of Valsalva maneuver compared to other provocation tests by hemodynamic measurements of the right and left atrial pressure simultaneously.

Methods: 37 patients underwent Swan-Ganz catheterization. Right atrial pressure and pulmonal capillary wedge pressure, which nearly corresponds to the left atrial pressure, were measured simultaneously. The following maneuvers to compare were: Valsalva maneuver, coughing, deep inspiration and expiration pressure (exp.) of 20, 40 and 60 mmHg. Our interest was to compare the incidence of of appearance of pressure gradients (right atrial pressure > left atrial pressure).

Results:

Incidence of pressure gradient

Valsalva	Cough	inspiration	exp 20	exp 40	exp 60
92%	86%	86%	59%	78%	73%

Mean gradients over the time of one heart cycle (mmHg)

Valsalva	Cough	Inspiration	exp 20	exp 40	exp 60
5.6	4.0	5.1	3.7	3.8	4.1

During Valsalva maneuver the frequency of pressure gradients and the mean gradients were higher than during alternative maneuvers.

Conclusions: Valsalva maneuver is the most effective test to provoke a right to left atrial shunt for the detection of a PFO during echocardiographic examinations.

P1591 Clinical importance of a patent foramen ovale for unexpected decompression illness in divers

Markus Schwerzmann, Aija Kinnunen, Christian Seiler. *Department of Cardiology, University Hospital, Berne, Switzerland*

Background: The presence of endogenous nitro-bubbles during dives with compressed air can lead to decompression illness (DCI) with potentially severe consequences. Symptoms and clinical presentation of decompression sickness (DCS) or arterial gas embolism (AGE) may occur even in divers adhering strictly to the recommended decompression tables. Intracardiac right to left shunting of venous bubbles through a patent foramen ovale (PFO) offers a plausible pathophysiological explanation for this kind of unexpected DCI. However, the clinical importance of a PFO in divers has not been clearly assessed.

Methods: In 48 divers with at least 200 dives, we performed a transesophageal echocardiography for detecting intracardiac shunts. By using contrast material and the Valsalva manoeuvre during echocardiography, its sensitivity was optimised. Before the exam, all divers answered to a detailed questionnaire about their diving habits and diving accidents.

Results: In 12 divers we detected a PFO. No differences were present in diving habits between divers with a PFO [PFO] and the control group [PFO/]. However, divers with a PFO reported more often major decompression illness with cerebral (blurred vision, dysarthria, loss of consciousness, hemiplegia) and spinal (impaired bowel and bladder control, limb weakness) involvement. Similarly, divers with a PFO reported more often minor decompression symptoms (headache, paresthesias, dizziness, bends) according to a score from 0 to 24.

	PFO (n = 12)	PFO/ (n = 36)	p
Number or dives (mean)	772	812	0.89
Number of dives > 40 m (mean)	57	84	0.43
Prevalence of major cerebral DCI	0.43/1000 dives	0.10/1000 dives	0.03
Prevalence of major spinal DCI	0.32/1000 dives	0.03/1000 dives	0.02
Minor decompression symptoms	4.3 ± 0.7 (SE)	2.4 ± 0.3 (SE)	0.01

Conclusions: A causal relation between PFO and unexpected DCI must be considered. Divers with major unexpected DCI should undergo transesophageal echocardiography to exclude a PFO. For divers with a PFO and episodes of major DCI, it is advisable to refrain from deep dives with high risk of bubble formation. Prospective trials are needed for further evaluation of this concept.

P1592 Transcatheter closure of atrial septal perforations under echocardiographic guidance without need for fluoroscopy

P. Ewert, F. Berger, I. Dähnert, G. Krings, P.E. Lange. *Department of Congenital Heart Diseases, German Heart Institute, Berlin, Germany*

Transcatheter closure of atrial septal perforations is presently performed under fluoroscopic guidance, but echocardiography is playing an increasingly important role in the procedure. We have now developed a technique using transesophageal echocardiography alone, without resort to fluoroscopy.

Methods: We selected 5 patients (3 to 16 years of age, bodyweight 14 to 60 kg) with atrial septal defects centrally located in the oval fossa and 5 patients (21 to 61 years of age, bodyweight 55 to 118 kg) with persistent foramen ovale after presumed paradoxical embolism for transcatheter closure. After sedation with midazolam and propofol, a diagnostic and interventional catheterization was performed in all cases under echo-cardiographic guidance without fluoroscopy. Oximetric shunt estimation and pressure recordings were taken, the defects were sized over the wire with a balloon catheter, and finally an Amplatzer Septal Occluder was placed into the defects. In 8 patients a 5 MHz monoplane transducer, and in 2 patients a 5 MHz multiplane probe was used.

Results: The patients with an atrial septal defect had a ratio of pulmonary to systemic flow of 1.6 (1.5 to 2.1). The stretched diameters of all 10 perforations ranged from 6 to 14 mm (mean 9 mm). The implantation of Amplatzer Septal Occluders led to complete closure of the defects in all patients. Mean procedure time was 92 min (45 to 130 min), no complications were encountered.

Conclusion: In selected cases with an atrial septal defect located centrally in the oval fossa and clear-cut echocardiographic findings, an Amplatzer Septal Occluder can be safely deployed under echocardiographic guidance alone.

P1593 Segmental evaluation of the left atrial appendage by anatomic M-mode: initial observations in patients with sinus rhythm and atrial fibrillation

D. Mele, I. Pedini, P. Alboni, R.A. Levine[1]. *Division of Cardiology, Ospedale Civile, Cento, Italy; [1]Noninvasive Cardiac Laboratory, Massachusetts General Hospital, Boston MA, USA*

Background: Two-dimensional (2D) and pulsed wave (PW) Doppler echocardiography can evaluate left atrial appendage (LAA) global function but assessment of regional function is limited. The aim of this study was to test the capability of M-mode to evaluate the LAA function on a segmental basis.

Methods: An initial group of 10 patients (pts), mean age 56 9 years, 4 with sinus rhythm (SR) and 6 with atrial fibrillation (AF), was studied by transesophageal echocardiography viewing the LAA from the basal short axis and acquiring digital 2D cineloops containing 3 consecutive cardiac cycles. The Anatomic M-mode line was positioned at the base, midportion and apex of the LAA. At each level, LAA internal diameter, wall motion and thickening were related to the electrocardiogram and the PW Doppler pattern of flow.

Results: In all pts the LAA could be studied by Anatomic M-mode. In pts with SR, the basal portion of the LAA obliterated at the time of atrial systole and the lateral wall showed a clear thickening (Fig. 1, arrow) that coincided with the highest Doppler emptying flow wave. The LAA midportion and apex obliterated longer. In pts with AF, basal obliteration and thickening of the lateral wall were not observed (Fig. 2).

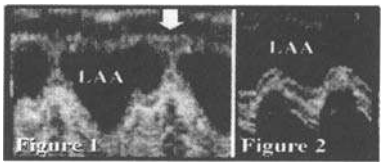


Figure 1 Figure 2

Conclusions: This initial study shows that the LAA function can be easily evaluated in M-mode format at segmental level. It also documents in pts with SR pre-systolic active contraction of the LAA, recognized for the first time by M-mode thickening of the lateral wall.

P1594 Morphologic characteristics of left atrial thrombi in patients with rheumatic mitral valve disease in relation to embolic events

N. Özdemir, C. Kaymaz, C. Kirma, M. Balkanay, C. Yakut, F. Turan, M. Özkan. *Cardiology Dept, Kosuyolu Heart & Research Hosp., Istanbul, Turkey*

In patients with rheumatic mitral valve disease (RMVD) presence of thrombus (THR) and spontaneous echo contrast (SEC) in left atrium (LA) have been considered to be predictors for embolic events (EE). However impact of morphologic characteristics (MC) of LATHR in relation to EE has not been investigated. This study aims to evaluate whether MC of LATHR is associated with EE, and to assess the grade of LASEC in relation to MC of LATHR in pts with RMVD. Study population comprised 474 pts of RMVD (F 320, M 154, mean age 40+14.6) whom transesophageal echocardiography (TEE) was performed prior to mitral valve surgery (MVS). Pure or predominant mitral stenosis (MS) and mitral regurgitation (MR) were detected in 333 and 141 of pts, respectively. Rhythm was atrial fibrillation in 267 pts. Embolic event (n = 26) was defined as presence of emboli in last 30 days prior to TEE. Thrombus was detected in 101 (LA 13, LAA 62 and LA+LAA 26) and SEC in 128 of pts. Morphology of THR was defined as their age (organised vs nonorganised; 54 vs 47), as their surface appearence (smooth vs irregular; 69 vs 32), and largest diameter (cm) (D) and thickness (T) of THR were measured by TEE. Frequency of EE was 27%, 19.5%, 16.6% and 8.5% in pts with THR+SEC, SEC, THR and without SEC and THR, respectively. In pts with THR history of EE was found to be associated with surface characteristics (irregular vs smooth) of THR (40.6 and 18.8%, $p = 0.0001$), but not with intraatrial location and the age (24 vs 26%, $p > 0.05$), D (2.8+1.6 vs 2.8+1.8, $p > 0.05$) and T (1.6+1.0 vs 1.4+0.9, $p > 0.05$) of THR. None of the MC of THR was found to be associated with SEC grade. Multivariate analysis confirmed that surface characteristics of THR was independently associated with EE in pts with THR, and presence of THR with irregular surface, SEC and absence of MR (>2) were independent variables in overall study group.

We conclude that surface characteristics of LATHR seems to be associated with history of recent EE in pts with RMVD irrespective of intraatrial location, age, diameter or thickness of THR detected by TEE.

P1595 Cost analysis model of low-molecular-weight heparin versus unfractionated heparin for antithrombotic therapy in patients undergoing TEE-guided cardioversion from atrial fibrillation

R.D. Murray, S.E. Jasper, A. Goodman, E.R. Becker, S.D. Culler, W.S. Weintraub, J.F. Malouf, A.L. Klein. *Cleveland Clinic, Cleveland OH; Emory University, Atlanta GA; Mayo Clinic, Rochester MN, USA*

Patients with atrial fibrillation (AF) of >2 day's duration requiring early cardioversion (CV) are often hospitalized for antithrombotic therapy (AT) for 2 to 5 days with IV unfractionated heparin (UFH) plus initiated oral warfarin Cardioversion follows a therapeutic PTT and a negative TEE for thrombus. Self-administered low molecular weight heparin (LMWH) and warfarin will obviate the need for hospitalization and PTT monitoring, and thus potentially lower costs for these patients.

Methods: We present a cost analysis model in US$ to show the potential savings with LMWH vs. UFH for patients in AF undergoing TEE guided CV. We used ESSENCE Trial costs of LMWH at $69/day, and UFH with equipment/monitors was estimated at $35/day. Estimated total pharmaceutical costs were $276 for LMWH and $140 for UFH. Assuming a 4-day period to achieve therapeutic INR on warfarin, hospitalization costs were estimated at $800 for LMWH including instructional time and materials for home care, and $3200 for UFH. Sensitivity analyses for differences in stroke and bleeding rates were also evaluated.

Results: Assuming equivalency in stroke and bleeding rates, LMWH may lower costs from $3340/patient to $1076/patient; a 68% savings.

Conclusions: Because of the relatively low costs associated with home treatment, low molecular weight heparin may markedly lower treatment costs over unfractionated heparin for AF patients requiring early TEE guided CV. Utility analysis may show even greater advantages of LMWH for these same reasons.

P1596 Relationship between left atrial appendage flow and the outcome of cardioversion

A. Palinkas, B. Nyuzo, G.Y. Marosi, I. Papp, A. Nemes, R. Sepp, T. Forster, M. Csanady. *2nd Department of Medicine, A Szent-Györgyi Medical University, Szeged, Hungary*

The aim was to search for a relationship between the mean left atrial appendage flow, measured by transoesophageal echocardiography (TEE) in patients with atrial fibrillation lasting continuously for more than 48 hours, and the success of cardioversion. A study was made of the relationships between the mean left atrial appendage anterograde peak flow (LAAPFL) and some transthoracic echocardiographic parameters (left atrial diameter and left ventricular ejection fraction). TEE was performed in 79 patients (25 females, 54 males) with atrial fibrillation before cardioversion to exclude left atrial thrombus. The mean age of the patients was 63.5 years. Following TEE, the patients underwent either electrical (36 patients) or pharmacological (43 patients) cardioversion. In 61 patients (77%) the cardioversion was successful (group 1). In 18 patients (23%), a sinus rhythm did not return (group 2). In group 1, the mean LAAPFL was 37 cm/sec; in group 2, it was 26.9 cm/sec. The two groups were compared by means of the Mann-Whitney U test and a significant difference was found ($p < 0.01$). The sensitivity, specificity, and positive and negative predictive values of LAAPFL over 35 cm/sec were considered with regard to the outcome of cardioversion. The sensitivity was 56%, the specificity 89%, the negative predictive value 37%, and the positive predictive value 94%.

Conclusion: The mean value of anterograde left atrial appendage peak flow over 35 cm/sec, measured before cardioversion by TEE, demonstrates high specificity and a positive predictive value with regard to the outcome of cardioversion.

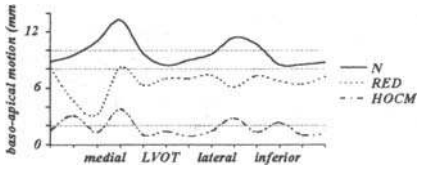
THREE-DIMENSIONAL ECHOCARDIOGRAPHY

P1597 Quantitative analysis of shape, area and cyclic changes of the mitral annulus in reduced left ventricular function, hypertrophic cardiomyopathy and normal controls using dynamic three-dimensional echo

A. Franke, F. Mohammed, H.P. Kühl, C. Jansen, P. Hanrath. *Med. Clinic I, University Hospital, Aachen, Germany*

To evaluate the spatial and temporal changes of the mitral annulus (MA) during the heart cycle, transesophageal three-dimensional (3D) echo was used in 30 patients with sinus rhythm (pts, 58 ± 12 years, 14 female): 10 normal controls (N), 10 pts with hypertrophic obstructive cardiomyopathy (HOCM), 10 pts with reduced left ventricular function (RED; EF < 40%). The following parameters were measured in the 3D data set every 40 ms during one complete heart cycle: maximal baso-apical distance of highest to lowest MA points at each time-point (H_{max}), baso-apical BAM of the MA from end-systole to end-diastole (BAM) and MA area (calculated using a summation of slices technique).

Results: Non-planarity of the MA in all groups was most apparent in the portion adjacent to the left ventricular outflow tract, consistently showing displacement towards the left atrium. H_{max} averaged for the pts of every group ranged between 2 mm at systole to 7 mm at diastole for N (2–4 mm for RED and 2–3 mm for HOCM; both $p < 0.05$ vs. N).



The graph shows the averaged BAM of all circumferential points of the MA (x-axis) which was largest in N and smaller in RED and HOCM ($p < 0.01$ for every MA point). There was no significant difference between the MA areas of all groups with a minimum at end-diastole (9.8 ± 2.5 cm^2) and a maximum between end-systole and early diastole (11.8 ± 3.2 cm^2) during opening of the mitral valve.

Conclusions: Dynamic 3D echo allows a precise quantitative analysis of MA morphology and its temporal changes. Systolic left ventricular dysfunction and HOCM reduce H_{max} as well as BAM. This approach may yield further insight into mitral valve pathophysiology in a variety of left ventricular diseases and also after reconstructive surgery.

P1598 Estimation of atrial septal defect stretched diameter by 2D and 3D transoesophageal echocardiography

O.W. Franzen, C. Hamm, J. Weil, T. Hofmann. *Cardiology Dept, Universitäts-Krankenhaus Eppendorf, Hamburg, Germany*

In 15 patient with atrial septal defect (ASD) type II, who underwent transvenous defect closure, measurements from echocardiographical three dimensional (3D) reconstruction of the defect were compared to measurements from two dimensional transesophageal echocardiography (2D-TEE) and to the ballon stretched diameter of the defect. The data acquisition for 3D-recontruction was performed with a Hewlett Packard Sonos 5500 ultrasound and a 5 MHz multiplane transesophageal probe. Using 2D-TEE the maximum diameter of the defect was obtained by rotating the imaging plane to the appropriate position. In the 3D reconstruction the longest diameter and a diameter perpendicular to that, als well as the defect area were each measured in the phase were maximum or minimum defect cross sectional areas were visualized. The maximum diameter of the defect was 15.3 ± 6.6 mm using 2D-TEE as compared to 17.7 mm ± 6.6 mm using 3D-TEE ($p < 0.001$). The difference between 2D-TEE and the stretched diameter was 4.8 ± 3.4 mm as compared to 2.4 ± 3.4 mm when 3D reconstruction was used ($p < 0.005$).

The mean fractional change of the defect area (3D reconstruction) was 30 ± 20% (1–60%). In patients with a high fractional area change (>40%) the difference between the maximum diameter from 2D-TEE and the maximum streched diameter was significant larger than in patients with a fractional area change less than 40% (7.6 mm vs. 3.0 mm, $p < 0.01$).

Conclusions: The stretched diameter of the ASD can be more accurately estimated by 3D-TEE as compared to 2D-TEE. The difference of 2D-TEE maximum diameters and strechted diameter is larger in patients with a higher fractional change of defect area.

P1599 Real-time three-dimensional echocardiographic evaluation of mitral annular characteristics in myocardial hypertrophy

F. Yalcin, H. Tsujino, N. Greenberg, F. Bauer, C. Farias, T. Shiota, H. Lever, J.D. Thomas. *Department of Cardiology, The Cleveland Clinic, Cleveland OH, USA*

It has been shown that systolic excursion of mitral annulus (MA) has good correlation with left ventricular (LV) systolic function. Evaluation of complicated shape and dynamics of mitral annulus, however, may require rigorous methodology, such as 3 dimensional echocardiography (3DE) and reconstruction. We previously reported that hypertrophic cardiomyopathy (HCM) has large basal LV cavity with small volume in midcavity while secondary LV hypertrophy (LVH) has basal LV cavity narrowing by 3DE. The aim of this study was to investigate differences in mitral annular motion between HCM and LVH using real-time 3DE.

Methods: We studied 12 HCM and 12 secondary LVH patients to observe 3 dimensional structure and motion of mitral annulus. Real-time 3DE images were acquired from apical views and stored on optical disks. After the 3DE datasets were transferred into a computer, each 3D volume data was segmented in 9 consecutive rotational apical planes (20° between each plane). Subsequently, the coordinates of the two mitral leaflet insertion points were identified in each plane. MA geometry was reconstructed from these coordinates (x, y, z) and mitral area change, circumference (CF) change and long axis motion between end-diastolic and end-systolic frames were calculated.

Results: The motion and area change of MA from ED to ES were smaller in HCM comparing with other groups.

	% CF	% Area	Excursion (mm)
HCM	10 ± 4.3	10.1 ± 4.3***	6.6 ± 4.9*
SEC LVH	14.4 ± 8.2	28.1 ± 14.8	11.9 ± 4.5

*$p < 0.05$, ***$p < 0.001$

In conclusion, real-time 3D imaging and digital reconstruction accurately display complicated MA geometry and dynamics during cardiac cycle. Annular excursion and sphincter action is reduced in HCM, while LVH had remarkably smaller end-systolic mitral annular area. This may be a consequence of altered myocardial function in HCM and dominant LV basal hypertrophy in LVH.

P1600 Real-time 3-D dobutamine stress echocardiography in quantitative assessment of ischaemia

T. Xie, G. Abreo, M. Ahmad. *Cardiology Dept, University of Texas Medical Branch, Galveston TX, USA*

Preliminary observations during Real-time 3-D Dobutamine stress echocardiography (RT-3D DSE) revealed the extent of the stress induced LV wall motion abnormality (WMA) was greater in extent in parallel or C-scans compared to the orthogonal 2-D images. We prospectively examined a set of 30 pts (mean age 58.2 ± 10.6 yrs) with both RT-3D and conventional 2-D images obtained during DSE. Nineteen pts had cineangiographic evidence of CAD and 1 pt. was post heart transplant. All 30 pts had evidence of new WMA by RT-3D DSE compared to only 19 pts by 2-D DSE. LV wall motion score at peak DSE was 1.56 ± 0.41 for RT-3D and 1.23 ± 0.25 for 2-D ($p < 0.0005$).

Orthogonal apical 4 and 2 chamber views along with C-scans were assessed for segmental LV wall motion by RT-3D. The length of the induced WMA at peak DSE was measured in orthogonal apical 4 or 2 chamber views by defining the outer edges of the abnormal LV segment and then measuring its length in cm. WMA was then visualized in the corresponding C-scans and longitudinally measured by identifying the upper and lower slices of the abnormal segment. Mean ± SD length of the WMA was 2.57 ± 1.27 cm in orthogonal apical views compared to 3.33 ± 1.23 cm in C-scans ($p < 0.0001$).

Conclusions: C-scan mode in RT-3D identifies a larger area of LV WMA when compared to the same segments in orthogonal images. These findings may in part explain the higher sensitivity of RT-3D in detection of ischemia and provide the basis for quantifying the extent of ischemia by RT-3D.

P1601 Left ventricular and left atrial volumes during the heart cycle assessed by three-dimensional echocardiography

T. Poutanen[1], A. Ikonen[2], P. Vainio[2], E. Jokinen[3], T. Tikanoja[1]. *[1]Dept. of Pediatrics; [2]Clinical Radiology, Kuopio University Hospital and Kuopio University, Kuopio; [3]Hospital for Children and Adolescents, Helsinki University Hospital, Helsinki, Finland*

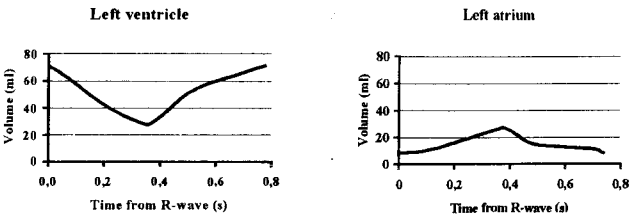
We assessed the dynamic changes in left ventricular (LV) and left atrial (LA) volumes by three-dimensional echocardiography (3DE). The maximal and minimal volumes and the LV mass were compared with the results obtained by magnetic resonance imaging (MRI).

Methods: Thirty healthy children (aged 8 to 13 years, 15 boys and 15 girls) underwent examination by 3DE and MRI. Three-dimensional echocardiography of LV was performed using rotational acquisition of planes at 18-degree intervals from the transthoracic apical view with ECG gating. Imaging of LA was performed from the parasternal window. LV and LA volumes were measured at every frame (median 54, range 33–72 frames) during one heart cycle. Left ventricular mass was assessed in end diastole. Ejection fraction was calculated

Results: The average values obtained by 3DE and MRI were equal for LVmax, LVmin, and LVmass. However, the two methods produced slightly diverging results for LA size.

	LVmax (ml)	LVmin (ml)	EF (%)	LVmass (g)	LAmax (ml)	LAmin (ml)
MRI	65.2 ± 15.6	26.6 ± 7.0	59.2 ± 3.9	74.1 ± 16.3	26.7 ± 7.4	14.5 ± 4.4
3DE	69.3 ± 14.9	27.1 ± 6.3	60.9 ± 1.9	75.4 ± 17.3	29.1 ± 6.7	9.0 ± 2.0
r	0.80	0.88		0.82	0.48	0.72

As 3DE imaging is performed with high frame rates, curves reflecting changes in LV and LA volumes during the heart cycle can be calculated (figure).



Conclusions: Three-dimensional echocardiography detects the different phases of left ventricular and left atrial emptying and filling during the heart cycle.

P1602 Quantitative assessment of prosthetic valve area with three-dimensional transoesophageal echocardiography

H. Mannaerts, Y. Li, O. Kamp, S. Rippa, J. Hrudova, C. Visser. *University Hospital VU, Amsterdam, Netherlands*

Aims: The currently used methods for prosthetic effective orifice area (EOA) assessment based on transthoracic Doppler pressure half time and continuity equation (EOA-Doppler) have their own known limitations. A new method of direct 3 D planimetry for EOA (EOA-3 D) is compared with EOA-Doppler and with the EOA's provided by Doppler literature (EOA-L) and with the manufacturer's values (EOA-M) for the corresponding valve types and sizes.

Methods: With HP 2500 transesophageal multiplane TEE 3 D acquisition was performed and processed off-line with Tom-Tec 4.0 EchoView. From the long axis of the mechanical valve, short axis anyplane images with the EOA at maximal valve opening were generated. Three D TEE with Doppler measurements was performed in 14 consecutive patients: 9 patients after mitral valve replacement (MVR); (6 St Jude and 3 Medtronic Hall, sizes 27–33) and 5 after aortic valve replacement (AVR); (4 St Jude, 1 Carbomedics, sizes 21–27).

Results: 3 D planimetry was possible in all 14 patients. The means (± SD) of EOA's after MVR, AVR and the total group for EOA-3 D, EOA-Doppler, EOA-L and EOA-M are shown in the table. There were no statistical differences between these 4 methods, only EOA-M in the MVR and total group was larger ($P < 0.001$; ANOVA). Correlations for all 4 methods ranged between 0.76–0.82.

EOA (cm^2)	3D	Doppler	Literature	Manufact.
MVR	3.06 ± 0.65	2.61 ± 0.74	2.98 ± 0.35	4.46 ± 0.72
AVR	1.95 ± 0.45	1.65 ± 0.77	1.72 ± 0.47	2.76 ± 0.85
Total group	2.66 ± 0.79	2.50 ± 0.71	2.53 ± 0.73	3.85 ± 1.12

Conclusion: 3 D effective orifice area (EOA-3D) is comparable with Doppler-and literature derived EOA assessment in normal functioning mitral and aortic mechanical prosthetic valves with good correlations between all EOA's. The manufacturer's EOA's were consistently larger than the Doppler-and 3 D planimetry EOA's, possibly due to pannus/thrombus formation in vivo.

P1603 Real-time three-dimensional echocardiographic assessment of acute haemodynamic changes during ventricular and atrioventricular sequential pacing

T. Helmy, R. Sheahan, M. Trough, T. Xie, S. Utley, A. Jones, M. Ahmad. *Cardiology, University of Texas Medical Branch, Galveston TX, USA*

Previous studies have reported variable hemodynamic changes during different pacing modes. Real-time 3-D echocardiography (RT-3D, VOLUMETRICS) measures LV volumes accurately and rapidly during pacing; 21 pts (age 64.7 ± 14.5 yrs) with permanent pacemakers had sequential RT-3D measurements of LV volumes (ml), cardiac output (CO, l/min), LV ejection fraction (EF, %) and systolic blood pressure (SBP, mmHg) at baseline and at paced rates of 80, 100 and 120/min in AV sequential (DDD) and ventricular paced (VVI) modes. AV interval was fixed at 150 ms in DDD mode. Mean ± SD hemodynamic parameters were:

	EDV	ESV	CO	EF	SBP
Baseline	108.2 ± 46.9	63.7 ± 36.7	2.8 ± 1.5	42.6 ± 12.7	130.9 ± 30.8
DDD 80	100.7 ± 40.5*	60.2 ± 33.5	3.3 ± 1.8	42.1 ± 14.2	122.3 ± 21
DDD 100	94.4 ± 45.8*	59.8 ± 38.6	3.5 ± 1.9*	39.2 ± 14.7	124.2 ± 22.4
DDD 120	89 ± 45.3*	60.5 ± 41.1	3.4 ± 1*	36.2 ± 12**	122.1 ± 26.3*
VVI 80	96.2 ± 41.8*	57.4 ± 36*	3.2 ± 1.4	43.2 ± 13.5	114.2 ± 22.5*
VVI 100	93.7 ± 44.6*	57.3 ± 37.7*	3.7 ± 2.1*	41.3 ± 14.5	118 ± 21.6*
VVI 120	88.2 ± 42.8*	62.6 ± 42.1	3.1 ± 1.6	32.7 ± 14.8**	111.1 ± 27.9*

(*$p < 0.05$, **$p < 0.001$, comparisons of VVI and DDD to baseline) EDV decreased with increasing rate in both pacing modes; ESV decreased VVI 80, 100; CO increased DDD 100, 120, VVI 100, 120 due to increased heart rate; EF decreased DDD 120, VVI 120; SBP decreased DDD 120, VVI 80, 100, 120.

Comparisons between VVI and DDD modes showed no significant differences in the parameters except for a higher SBP in DDD mode ($p < 0.05$). In 6 pts with baseline LV dysfunction (EF < 40%) the results of comparisons between the two modes were similar.

Conclusions: 1) RT-3D is useful in accurate measurement of volumetric changes during pacing. 2) DDD pacing does not offer significant hemodynamic advantage over VVI in pts with either preserved or depressed LV function.

DIASTOLIC FUNCTION

P1604 Influence of alteration in preload on the pattern of left ventricular diastolic filling as assessed by Doppler tissue imaging.

A. Abaci, A. Oguzhan, B. Kiranatli, S. Unal, N.K. Eryol, A. Ergin. *Department of Cardiology, Erciyes University School of Medicine, Kayseri, Turkey*

Pulsed Doppler indexes of diastolic filling have been used as measures of diastolic function. However, various hemodynamic factors and loading conditions independent of the intrinsic properties of the hart also influence the pattern of LV filling. Doppler Tissue Imaging (DTI) is a new technique currently under investigation for assessment of regional systolic and diastolic left ventricular function. The aim of the present study has been to evaluate whether the diastolic mitral annular velocities by Doppler tissue imaging is affected by changes in preload conditions.

Methods: Doppler transmitral inflow velocities (E, A), diastolic mitral annular velocities at the lateral (LatE, LatA) and septal (SepE, SepA) side of the mitral annulus by pulsed DTI, and the ratio of peak early to peak atrial filling velocities (E/A, LatE/A, SepE/A) were assessed in 42 subjects (age 56 ± 9 years) with coronary artery disease at the baseline and after nitroglycerine administration. All the measures were performed at end expiration and averaged over three cardiac cycles.

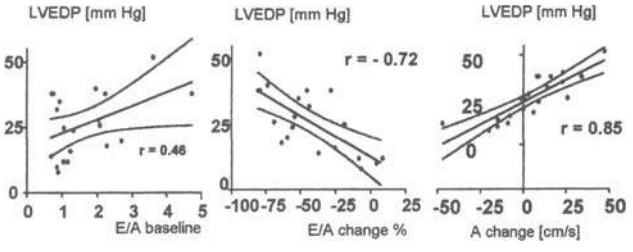
Results: Heart rate slightly increased from 68 ± 10 to 77 ± 12 beats/min ($p < 0.001$). The E, LatE, and Sep E velocities (cm/sec) decreased from 68.7 ± 25.6 to 54.2 ± 18.7 ($p < 0.0001$), from 9.2 ± 3.2 to 8.1 ± 2.6 ($p < 0.001$), and from 7.4 ± 2.8 to 6.6 ± 2.6 ($p = 0.001$), respectively. The A, LatA, and SepA velocities were not significantly changed (68.6 ± 21.2 vs. 71.3 ± 21.4; $p = 0.518$, 9.4 ± 2.4 vs. 9.5 ± 2.5; $p = 0.721$, 8.8 ± 2.0 vs. 8.7 ± 2.0; $P = 0.521$, respectively). The E/A, LatE/A, and SepE/A were decreased from 0.98 ± 0.33 to 0.87 ± 0.36 ($p = 0.0001$), from 1.07 ± 0.59 to 0.92 ± 0.44 ($p = 0.0002$), and from 0.87 ± 4.2 to 0.78 ± 3.2 ($p = 0.0049$), respectively.

Conclusions: In the present study, alterations in preload significantly altered the pattern of diastolic filling as assessed by DTI of mitral annular velocities in a similar manner to the Doppler transmitral flow velocity profile. These results suggest that DTI of mitral annular velocities must also be interpreted cautiously when used as indexes of diastolic function.

P1605 Unmasking significantly elevated filling pressure in patients with an impaired left ventricular with relaxation pattern using the Valsalva manoeuvre

B.A. Popescu, A.C. Popescu, E. DiSegni, E. Kaplinsky, B. Rabinowitz, V. Guetta, S. Rath, M. S. Feinberg, E. Schwammenthal. *Heart Institute, Chaim Sheba Medical Center, Tel Hashomer; Sackler School of Medicine, Tel Aviv, Israel University*

Impaired relaxation is frequently masked by elevated filling pressures resulting in a pseudonormal flow pattern (E/A > 1.0) which can be unmasked using the Valsalva maneuver. Because the E/A wave ratio increases as filling pressures rises it is generally assumed that patients with an E/A ratio < 1.0 (impaired relaxation pattern) have lower or even normal filling pressures when compared with patients who have a pseudonormal or restrictive filling pattern. However, based on individual observations, we hypothesized that patients with an E/A ratio < 1.0 can nonetheless have severely elevated filling pressures. Since left ventricular enddiastolic pressure (LVEDP) essentially determines atrial afterload, the response of the A-wave velocity to a reduction of aftrial afterload by a standardized Valsalva maneuver should be best suited to estimate LVEDP. This was tested in 20 patients at the time of diagnostic cardiac catherization:



Conclusion: Just as elevated filling pressures can mask impaired relaxation, the impaired relaxation pattern can mask the presence of elevated filling pressures. This can be revealed by testing the response of the A-wave to the Valsalva maneuver allowing estimation of LVEDP independent of the baseline E/A ratio.

P1606 Validation of five non-invasive Doppler methods for the assessment of left ventricular filling pressure

Markus Schwerzmann, Bernhard Meier, Christian Seiler. *Gardiology, University Hospital, Berne, Switzerland*

Background: There are several non-invasive Doppler methods to estimate left ventricular end-diastolic pressure [LVEDP]. So far, it has not been evaluated which one most accurately predicts LVEDP in an unselected patient population.

Methods: In 50 consecutive patients with sinus rhythm, undergoing elective coronary angiography, transthoracic Doppler echocardiography was performed during or at least within 10 hours before/after cardiac catheterization. LVEDP was estimated by Doppler measurements of – if present – the mitral regurgitant peak gradient [A], the mitral regurgitant gradient at aortic valve opening [B] or the end-diastolic gradient of aortic regurgitation [C] in combination with blood pressure measurement with an oscillometric cuff. LVEDP was additionally estimated using regression equations of transmitral inflow parameters [D] and of mitral A-wave and pulmonary vein A-wave duration [E]. All estimates were compared with invasive LVEDP.

Results: Echocardiography was performed 4 ± 7 hours after the invasive exam with mean systolic and diastolic blood pressure unchanged. Angiographic mean LVEDP was 17 mmHg (range 4–36 mmHg). For each method a regression equation was calculated (see table). A dependence of the method from ejection fraction [EF] was postulated, if its unexplained variation in a multivariate regression model using EF as predictor variable, was significantly reduced.

	Valve regurgitant methods			Regression equations	
Method:	A	B	C	D	E
n patients (total 50)	18	16	7	42	40
Intercept	5.7	0.61	5.4	3.6	16
Slope	0.6	1.0	0.63	0.78	0.1
Regression coefficient	0.58	0.71	0.53	0.21	0.01
EF dependent	no	no	no	yes	yes

Conclusions: The estimation of LVEDP using valve regurgitant jets is EF independent. For clinical use, regression equations of mitral inflow or pulmonary vein flow are not reliable. In half the patients, estimation of LVEDP can be done using regurgitation gradients (A–C). Under these circumstances, the mitral regurgitation gradient at aortic valve opening (B), allows the most reliable estimate.

P1607 Diastolic pulmonary artery pressure evaluation by continous wave Doppler in patients with tricuspid regurgitation: proposal of a new method

M. Bertella, F. Scalise, L. Melchiorre, M. Lazzarotti, S. Suraci, M. Catalano, R. Valentini. *Vimercate, Italy*

Background: In patients (pts) with tricuspid regurgitation (TR) the diastolic pulmonary artery pressure (dPAP) can be estimated using the right ventricular-right atrial pressure gradient (RV-RA_{grad}), measured on the continuos wave doppler (CWD) TR velocity curve at the opening of the pulmonary valve and adding it to the value of the right atrial pressure (RAP) at that moment. In order to locate, beat by beat, the TR velocity just before the onset of the right ventricular ejection into the pulmonary artery (RVE_{PA}), when the right ventricular and the pulmonary artery pressure are alike, we often observed two different areas of echo gray level distribution into the CWD spectrum of TR, with increased echoreflectivity in the proximal one. As the intensity of the spectral recording is influenced by the number of red cells passing through the regurgitant orifice, the onset of RVE_{PA} may produce a reduction of the spectral echo-density. The initial point of the boundary line between the two areas could coincide with the onset of RVE. Purpose: to locate the onset of RVE_{PA} on the CWD-TR velocity curve and calculate dPAP.

Methods: we studied 12 consecutive pts (8 men, age 50–73 years), presenting TR and submitted to right heart catheterization, using a balloon flotation (Swan-Ganz) catheter, for heart failure, in recent myocardial infarction. The echocardiografic (RV-RA_{grad} at the onset of RVE_{PA}) and hemodynamic measurements (mean RAP_{hemo} and RAP_{hemo} at the onset of RVE_{PA}) were performed by two independent observers. The PAP at the onset of RVE_{PA} was calculated adding the RV-RA_{grad} to the RAP_{hemo} (both measured at the onset of RVEPA). The values of PAP at the onset of RVE_{PA} vs $dPAP_{hemo}$ and the values of the mean RAP_{hemo} vs RAP_{hemo} at the onset of RVE where compared.

Results: The initial point of the boundary line between the two areas of different echodensity into the CWD-spectrum of TR was detected in 10/12 pts (83.3%). In these pts we observed a good correlation between the values of dPAP estimated by CWD-echo and hemodinamic data ($R = 0.98$, $P < 0.0001$). There was also a good correlation between the mean value of the RAP at the onset of RVE_{PA} and the mean RAP (9.63 ± 4.33 mmHg versus 9.5 ± 4.65 mmHg) ($R = 0.98$, $P < 0.0001$).

Conclusions: diastolic PAP can be calculated adding the value of the right ventricular-right atrial pressure gradient, measured on the CWD-TR velocity curve at the opening of pulmonary valve, to mean RAP.

P1608 Opposite to standard Doppler parameters, the difference of duration of pulmonary and mitral A-wave is independent of mitral regurgitation and may reliably estimate left ventricular filling pressure

A. Rossi, M. Cicoira, G. Golia, M. Anselmi, P. Marino, P. Zardini. *Divisione Clinicizzata di Cardiologia, Ospedale Civile Maggiore, Verona, Italy*

Mitral (MV) and pulmonary vein (PV) parameters have extensively been used to predict left ventricular (LV) filling pressure (LVfp). Elevated LVfp causes increased MV early diastolic and decreased systolic PV flow. However, mitral regurgitant volume (RVol) modifies MV and PV pattern exactly in the same direction. Therefore, measurements independent of RVol have to be identified in order to reliably predict LVfp.

Methods: 69 pts (age: 56 ± 23), who underwent left heart catheterization with end-diastolic pressure recording (pTD), had a complete echocardiographic evaluation. Patients had a broad range of pTD (12–36 mmHg), LV EF (19–72%) and mitral regurgitant volume (RVol) (0–65 ml). The only esclusion criteria were presence of mitral stenosis or unsatisfactory PV flow recordings (9.5%). E (Emax), A wave velocity, E/A, E (Dte) and A (Dta) deceleration time, PV systolic (S), diastolic (D), S/D were measured. MV A wave and PV A wave duration were measured and their difference (A-A′) calculated. A quantitative assessment of RVol was also obtained.

Results: Doppler parameters more strongly associated with pTD were: Emax (0.52; $p < 0.0001$), Dte ($r = 0.53$; $p < 0.0001$), E/A ($r = 0.56$; $p < 0.0001$), S/D ($r = 0.55$; $p < 0.0001$), LV EF ($r = 0.47$; $p = 0.0002$), and A-A′ (0.58; $p < 0.0001$). RVol was not significantly associated with pTD. Among Doppler parameters only A-A′ and DTa were not correlated with RVol. Multivariate analysis showed that A-A ($p < 0.0001$) and DTe ($p = 0.04$) were independent predictors of pTD. A A-A′ cut-off > 30 msec predicted a pTD > 20 mmHg with a positive predictive value of 91% and negative predictive value of 78%.

Conclusion: A-A′ is an accurate parameter to estimate LVfp independently of Rvol. This method could be enhenced by contrast technology, which can markedly improve PV flow recording.

P1609 Comparative accuracy of pulmonary venous flow velocity variables and mitral flow velocity variables in predicting pulmonary wedge pressure in the presence of atrial fibrillation

F. Chirillo, M.C. Brunazzi[1], M. Pasqualini[1], C. Longhini[2], A. Bruni, A. Cavarzerani, O. Totis, P. Stritoni. *Department of Cardiology, Regional Hospital, Treviso; [2]Medical Clinics-University of Ferara, Italy; [1]Civic Hospital Pieve di Coriano, Mongolia*

We have previously demonstrated that pulmonary wedge pressure (PWP) could be estimated in patients with either sinus rhythm and atrial fibrillation (AF) from transthoracic Doppler analysis of pulmonary venous flow (PVF) velocities. Other investigators have found excellent correlation between PWP and mitral velocity variables in patients with sinus rhythm. Because sampling PVF velocities by transthoracic Doppler is technically more difficult in presence of dilated atria, such as those found in presence of chronic AF, we sought to compare the accuracy of PVF and mitral Doppler in predicting PWP in patients with AF. In 48 consecutive patients (32 M/16F aged 46 to 82 years) with chronic AF, suffering mainly from dilated cardiomyopathy, PWP was compared with PVF and mitral velocity parameters. For both PVF and mitral flow the best correlation was found for deceleration time (DT). In patients with normal (≤12 mmHg) PWP mitral DT (295 ± 54 ms) was longer than in patients with elevated PWP (215 ± 53 ms), but this difference was not statistically significant. PVF DT was significantly longer in patients with normal PWP (264 ± 45 ms) as compared with patients with elevated PWP (145 ± 20 ms $p < 0.0001$). The correlation between PVF DT with PWP was significantly stronger ($r = -0.91$, SEE 0.03, F ratio 158.2) than the correlation between mitral DT and PWP ($r = -0.54$, SEE 22.17, F ratio 13.25). The equations derived from mitral and PVF variables were prospectively tested in 32 additional patients. When estimating PWP using the PVF-derived equation the measured and predicted PWP agreed with a mean difference of −0.88 mmHg. When using the mitral-derived equation the mean difference was significantly larger (−3.11 mmHg; $p < 0.01$).

Possible explanations are: the presence and continual variations in the degree of mitral regurgitation following changes in the R-R interval; the stronger dependence of mitral variables on the position of the Doppler sample volume, and finally the fact that the theoretical simplification that left atrial stiffness is very low (assumed when considering the relation bewteen mitral flow velocity pattern and left ventricular filling pressures) may be not true in presence of chronic AF.

In conclusion PVF DT is more accurate than mitral DT in predicting PWP in presence of chronic AF.

P1610 Left ventricular relaxation patterns and their relation with P-wave duration in ankylosing spondylitis

Aylin Yıldırır, Serdak Aksöyek, Meral Çalgüneri[1], Kudret Aytemir, Mustafa Kemal Batur, Giray Kabakcı, Güner Gürsel, Ferhan Özmen, Ali Oto, Sırrı Kes. *[1]Hacettepe University, Faculty of Medicine, Dept. of Cardiology and Rheumatology, Ankara, Turkey*

Valvular involvement with aortic insufficiency, increased myocardial fibrosis and conduction system disturbances are known complications of ankylosing spondylitis (AS). In this study P wave analysis and echocardiographic measurements of systolic and diastolic functions were studied in patients with AS and compared with healthy controls.

Methods and Results: The study included 88 AS patients with no cardiac symptom (44 M, 44 F; age 19–64, mean 32.9 ± 11.1) and 31 healthy subjects (16 M, 15 F; age 19–60, mean 32.7 ± 8.5). Recordings for P wave analysis were obtained with Kardiosis ars-LP high resolution ECG analysis system and filtered P wave duration (PWD) was calculated. Left ventricular systolic and diastolic diameters and ejection fraction were used as systolic parameters whereas A peak, E peak, E/A ratio, E deceleration time (Edec) and isovolumic relaxation time (IVRT) were used as diatolic parameters. AS patients and controls were similar according to age and sex characteristics ($p > 0.05$). Systolic functions and left atrial (LA) diameters of both groups were similar ($p > 0.05$) but diastolic functions were found to be impaired in AS group (Table). Mean PWD in AS was 102.4 ± 13.4 ms which is higher but not significantly different than controls (100.1 ± 6.2 ms) ($p > 0.05$). PWD in AS patients was positively correlated with LA diameter ($p < 0.05$, $r = 0.27$) and negatively correlated with E peak ($p < 0.05$, $r = -0.24$) and E/A ratio ($p < 0.05$, $r = -0.23$). LA diameter of AS patients was also found to be correlated with IVRT ($p < 0.05$, $r = 0.25$).

	Anklosing Spondylitis	Control	P Value
E Peak (m/s)	0.73 ± 0.17	0.81 ± 0.15	$p < 0.05$
A Peak (m/s)	0.61 ± 0.14	0.53 ± 0.12	$p < 0.05$
E/A Ratio	1.27 ± 0.38	1.57 ± 0.54	$p = 0.001$
DT (ms)	217.91 ± 38.26	193.39 ± 23.54	$p < 0.001$
IVRT (ms)	94.38 ± 16.73	79.35 ± 13.95	$p < 0.001$

In conclusion myocardial involvement may be seen in asymptomatic AS patients and parameters of left ventricular diastolic functions can be used in this period. Further studies are needed to clarify the value of P wave analysis in cardiac evaluation of patients with AS.

P1611 Pulsed Doppler tissue imaging in assessing regional myocardial function changes associated with ACE inhibitor decreased left ventricular mass

M. Deljanin Ilić, S. Ilić, B. Lović, I. Tasić, D. Djordjević. *Institute of Cardiology, Niška Banja, University of Niš, Yugoslavia*

The aim of the study was to evaluate the regional systolic and diastolic myocardial velocities (mv) changes associated with pharmacologically reduced left ventricular mass (LVM).

Methods: Thirty-two hypertensive patients (pts, 22 male, 10 female; mean age 56.7 ± 10.1 years) with increased LVM index (LVMI > 110 g/m^2 in F, >134 g/m^2 in M), free of coronary artery disease were treated with ACE inhibitor (enalapril or ramipril) for a period of 24 weeks. Before and after treatment in all pts LVMI was calculated and in the pulsed wave Doppler tissue imaging (PW DTI, Acuson-Sequoia) examination of LV interventricular septum (IVS) and posterior wall (PW) in the short axis view we calculated peak velocities of systolic (S), early (E) and late (A) diastolic waves and their ratio E/A.

Results: At the end of the treatment period in 19 (59.4%) pts LVMI significantly decreased (from 161.7 ± 22.5 to 137.7 ± 24.1 g/m^2; $P < 0.005$), while in 13 (40.6%) pts LVMI was not changed significantly (from 158.2 ± 21.7 to 150.5 ± 22.1 g/m^2; NS). In pts with regression of LVM, mv of IVS and PW showed: increased E by 13% and 10.5%, decreased A by 8.2% and 4.2%, increased ratio E/A by 22.8% and 16%, and slightly increased S by 2.5% and 1.2% compared with baseline values. In pts without significant LVM reduction, evaluation of mv of IVS and PW showed slightly changes: increased E by 6.2% and 5.4% and ratio E/A by 7.2% and 6%, while A and S were unchanged compared with baseline values.

Conclusion: Our data showed that PW DTI allows quantification of regional myocardial function changes associated with LVM regression. Increased regional E/A ratio and E wave are the most prominent changes in pts with ACE inhibitor decreased LVM.

P1612 Diastolic function in hypertrophic cardiomyopathy: pulmonary venous flow assessment as an adjunct to mitral valve inflow patterns

T. Kinnaird, P.M. Elliott[1], P. Sorrajja[1], G. Smith[1], W.J. McKenna[1]. *Department of Cardiology, St Bartholomew's Hospital, London; [1]Department of Cardiology, St Georges Hospital, London, UK*

Background: Abnormalities of diastolic function are common in hypertrophic cardiomyopathy (HCM). Although Doppler patterns of mitral valve inflow (MVI) can be used to assess diastolic function, pulmonary venous flow (PVF) analysis has been shown to supplement this assessment, and several PVF parameters correlate with left ventricular end-diastolic pressure.

Methods: We studied 69 patients (pts) with HCM (37 men, mean age 41 (19–70)). Transthoracic pulse-wave Doppler tracings of MVI and PVF were taken and the following parameters measured: early (E), late (A), E/A ratio and A duration (Ad) of MVI; systolic (S), diastolic (D), atrial systolic wave (PA) and duration of PA (PAd) of PVF. The pts were divided into 4 groups (Gp): Gp 1 (normal) with an E/A 1–2.1, a PA < 35 cm/s and a negative PAd-Ad, Gp2 (impaired relaxation) with E/A < 1, Gp 3 ("pseudonormal") with an E/A 1–2.1 but a PA > 35 cm/s or a positive PAd-Ad, and Gp 4 (restrictive) with an E/A > 2.2.

Results: See table

Pulmonary venous flow parameters by group

Group	No.	S	D	S/D	PA	PAd-Ad
1	10	74	40	1.7	27	−20
2	21	64	34	1.7	34	53
3	25	60	50	1.3	41	45
4	13	38	72	0.7	27	24

Gp 4 when compared with the combined other groups has larger left atria(47 vs 41 mm, $p < 0.1$), a higher mean end diastolic diameter (46 vs 42 mm, NS), and a higher mean end-systolic diameter (28 vs 22 mm, $p < 0.1$). The maximal LV wall thickness, pattern of hypertrophy and outflow tract gradient were similar in all groups. Patients in gp 3 were more likely to be in NYHA class II or III than those in gp 1 (40 vs 10%, $p < 0.05$). Chest pain was also more common in gp 3 than in gp 1 (40 vs 30%, NS).

Conclusions: 1) PVF identifies HCM patients with a "pseudonormal" pattern of diastolic dysfunction. 2) Abnormal PVF correlates with diastolic function and clinical parameters.

P1613 Regional left ventricular myocardial function in hypertrophic cardiomyopathy: assessment by tissue Doppler imaging and ^{123}I-β-methyliodophenyl pentadecanoic acid scintigraphy

H. Yamada, T. Oki, Y. Mishiro, M. Abe, Y. Onose, T. Tabata, M. Nomura, S. Ito. *Second Department of Internal Medicine, The University of Tokushima, Tokushima, Japan*

Background: Myocardial velocity gradient (MVG) obtained by tissue Doppler imaging (TDI) is a new noninvasive index in evaluating regional myocardial thickening or thinning. On the other hand, ^{123}I-β-methyliodophenyl pentadecanoic acid (123I-BMIPP) myocardial scintigraphy has been established as a technique for evaluating the myocardial fatty acid metabolism. We assessed the relationship between diastolic MVG and 123I-BMIPP scintigram findings in patients with asymmetric septal hypertrophic cardiomyopathy (HCM).

Methods: We recorded the left ventricular (LV) M-mode color-coded TDI in 20 patients with HCM and age-matched 15 normal controls (NC), and calculated maximal MVGs in the ventricular septum (VS) and posterior wall (PW) during early diastole and atrial systole by off-line analysis. We also performed 123I-BMIPP myocardial scintigraphy in all patients, and calculated the washout ratio (WR) of SPECT imaging in the VS and PW.

Results: 1) Early diastolic MVGs in the PW and VS, particularly VS, were significantly lower in the HCM group than in the NC group. 2)Atrial systolic MVG in the PW was significantly greater, whereas that in the VS was significantly lower in the HCM group than in the NC group. 3) WR in the PW and VS, particularly VS, were significantly greater in the HCM group than in the NC group. 4)There were negative correlations between early diastolic MVG and WR in both PW and VS.

Conclusions: There was a close relationship between early diastolic MVG and WR of the hypertrophied VS in patients with HCM. The regional myocardial wall motion abnormality detected by MVG may reflect the regional metabolic abnormality in this disease.

P1614 Reversibility of ischaemic diastolic left ventricular disfunction by successful coronary angioplasty: follow-up of 70 patients 3 months after percutaneous transluminal coronary angioplasty

E. Apetrei, M. Rugină, C. Ginghină, C. Macarie, D. Deleanu, L. Zarma, A. Mereuţă, R. Ciobanu, D. Qeshta. *National Institute of Cardiology, Bucharest, Romania*

The aim of the study was to assess the relation between the left ventricular diastolic function and myocardial viability 3 months after percutaneous transluminal coronary angioplasty (PTCA).

Material: 70 patients (pts), 61 men (87.1%), mean age 52.6 ± 9.06 years, with coronary artery disease: unstable angina (91.4%) and stable angina (8.6%), who underwent PTCA. Most of our pts had one-vessel disease (58.5%), the others having two-vessel (21.5%) and three-vessel disease (20%). None had evidence of mitral stenosis, severe mitral regurgitation, atrial fibrillation or conduction disturbances such as second- or third-degree heart block.

Methods: All patients underwent successful PTCA, and were prospectively followed over a 3-month period by Doppler echocardiography. Diastolic transmitral flow variables were recorded 1 day before PTCA and 1 week, 1 and 3 months after the procedure. We measured the following variables of diastolic function: peak E and A velocities (cm/s), E wave deceleration time (Edt, ms), A wave deceleration time (Adt, ms), E/A ratio, isovolumetric relaxation time (IVRT) (ms), and the ejection fraction (EF). The measurement of left ventricular end-diastolic pressure (LVEDP) was done by left heart catheterization.

Results: According to the Doppler transmitral flow velocity profile, as expressed by the E/A ratio, the study pts were assigned to the following 3 groups: group 1 with E/A $\leq$ 1, with impaired relaxation filling pattern (35 pts, 50%),; group 2 with 1 $\leq$ E/A < 2 which may signify a normal or "pseudonormal" filling pattern (30 pts, 42.8%); group 3 with E/A $\geq$ 2 representing "restrictive" filling pattern (5 pts, 7.1%). LVEDP was 10 to 35 mmHg. In all three groups, we found a very good correlation between Adt and LVEDP (r = 0.95) and between Edt and LVEDP (r = 0.89) before PTCA. In all study pts, Adt showed a significant increase at 1 week as well as at 1 and 3 months. In both group 1 and 2, the E/A ratio showed significant improvement after PTCA (0.76 ± 0.19 vs 1.28 ± 0.28, $p < 0.001$ in group 1; 1.23 ± 0.26 vs 1.44 ± 0.30, $p < 0.001$ in group 2), which was more marked in the subgroups that did not present clinical restenosis signs. In group 3, the E/A ratio decreased significantly (2.15 ± 0.32 vs 1.56 ± 0.21; $p < 0.001$). At the same time, all study pts showed a significant improvement of the EF (51.57 ± 8.82 vs 56.21 ± 5.93, $p < 0.001$), more important in the subgroups without clinical restenosis.

Conclusions: Left ventricular diastolic filling variables, altered in patients with coronary artery disease, were improved after percutaneous transluminal coronary angioplasty: significant improvement of the E/A ratio, Adt and Edt, as well as increase of the ejection fraction. This amelioration was more marked in patients who did not show clinical restenosis.

P1615 Abnormal diastolic filling patterns are related to the left ventricular function and remodelling after first acute myocardial infarction

A. Sestili, C. Coletta, N. Aspromonte, A. Danesi, R. Ricci, A. Galati, R. Bruni, V. Ceci. *Division of Cardiology, S. Spirito Hospital, Rome, Italy*

Data regarding the contribution of diastolic dysfunction on left ventricular (LV) remodeling after acute myocardial infarction (MI) are limited. Aim of this study was to evaluate the impact of the abnormal LV filling patterns on the echocardiographically detected LV function and size after acute MI.

Methods: 98 consecutive patients (pts) with first, acute MI (mean age: 58, M = 85, Killip I–II) underwent echo-Doppler examination 10 days after the admission. The following parameters were considered: 1) End-diastolic and end-systolic LV transverse diameters (EDD, ESD: mm); 2) LV ejection fraction (EF, modified Simpson rule: %); 3) Wall motion score index (WMSI, 16 segments); 4) Early-and late LV filling peak velocities (E, A: cm/sec); 5) E/A ratio; 6) Deceleration time (EDT, msec); 7) Isovolumic relaxation time (IVRT: msec). Based on LV diastolic filling pattern, pts were divided as follows: Group 1, 12 pts, with a restrictive (E/A > 2 or E/A > 1 and EDT < 140 msec) pattern; Group 2, 46 pts, with a pseudonormal (E/A > 1 and EDT > 140 msec) pattern; Group 3, 40 pts, with an impaired relaxation (E/A < 1) pattern. Moreover, EDD and ESD were calculated three months after MI and their changes were compared.

Results: Group 1 pts had larger infarct size (peak of creatine kinase: 4227 vs 2055 and 2035 U/l, $p < 0.001$), higher WMSI (1.74 vs 1.50 and 1.54, p = 0.005), lower EF (35% vs 44% and 47%, $p < 0.001$) and shorter IVRT (98 vs 108 and 136 msec, $p < 0.001$) in comparison with Group 2 and 3 pts, respectively. All other demographic and clinical variables were comparable among the three groups. At three months, LV EDD and ESD appeared significantly increased in comparison with the first evaluation both in Group 1 (+5.5 ± 2.7, +6.6 ± 3.3 mm, respectively; $p < 0.0001$) and Group 2 (+2.0 ± 2.7, +2.7 ± 3.4 mm, respectively; $p < 0.0001$), while a significant reduction was observed in Group 3 pts (−3.1 ± 3.0, −3.7 ± 3.3 mm, respectively; $p < 0.0001$).

Conclusions: A restrictive filling pattern is present in pts with impaired LV function after MI. Both the restrictive and pseudo-normal filling patterns identify pts with LV dilatation after MI, while in pts showing an impaired relaxation pattern the LV remodeling phenomenon seems to be absent.

P1616 The restrictive left ventricular filling pattern: configuration, frequency and underlying heart disease

M. Petzsch, T. Körber, K. Pulya, H. Schneider, H. Schmidt. *University Hospital, Department of Cardiology, University of Rostock, Germany*

The restrictive left ventricular filling pattern (RFP) offers typical Doppler findings, indicating abnormal compliance. It was our aim to show frequency, underlying heart disease and configuration of the RFP in a great group of patients.

Methods: M-Mode, two-dimensional and continuous wave/colour flow Doppler echocardiograms were obtained in a total of 8704 Patients (PT) with conventional systems. Pulsed wave Doppler ultrasound examination of the transmitral (early [E] and late [A] diastolic) Doppler flow velocities (DFV), E-deceleration time (E-D) pulmonary venous DFV (systolic [S], diastolic [D], atrial reversal flow [ARF]), and the isovolumic relaxation time (IVRT) was performed in an apical four- or five-chamber view. Pt with more than mild mitral regurgitation, after cardioversion of atrial fibrillation and young healthy subjects were excluded.

Results: In 74 PT (0.85%) with a mean age of 57.5 ± 11.3 years a RFP was detected. In this group the left ventricular diameter at end-diastole (LVEDD) was 62.5 ± 8.9 mm, at end-systole (LVESD) 49.1 ± 10.3 mm, left atrial diameter at end-systole (LAESD) 49.8 ± 6.7 mm, ejection fraction (EF) 26.1 ± 11.1%. The PT were in NYHA class 2.7 ± 1.1. The table shows the comparison of the Doppler parameters with an age-matched control group with left ventricular dysfunction (LVD) (LVEDD: 64.0 ± 9.7 mm, LVESD: 49.9 ± 10.7 mm, LAESD: 45.8 ± 12.1 mm, EF: 28.2 ± 13.4%)

Group	E (m/s)	A (m/s)	E-D (ms)	S (ms)	D (m/s)	ARF (m/s)	IVRT (ms)
RFP	0.91	0.34	107.4	0.27	0.65	0.30	55.8
	±0.18	±0.09	±23.4	±0.13	±0.13	±0.08	±10.2
LVD	0.60	0.73	165.8	0.46	0.40	0.27	111.4
	±0.21	±0.18	±54.8	±0.14	±0.14	±0.07	±44.7

$p < 0.001$ for all mean values between the two groups; except ARF: $p < 0.04$

Underlying heart disease: dilated cardiomyopathy (n = 12), anterior (n = 38) and inferior (n = 8) myocardial infarction, hypertensive heart disease aortic valve disease (n = 3), amyloidosis (n = 3) myocarditis (n = 1), endomyocardial fibrosis (n = 1).

Conclusion: The RFP was found in a minority of PT. This type of diastolic dysfunction is not reflected by LVEDD or EF, in our group it is dominated by ischemic heart disease. Because the RFP is associated with a worsened prognosis, it is an important echocardiographic sign.

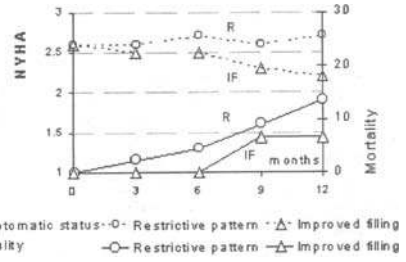
P1617 Response of the restrictive left ventricle diastolic filling pattern to valsalva manoeuvre is the predictor of the future symptomatic status in patients with left ventricle systolic dysfunction

M. Pavlovic, M. Tomasevic[1], S. Apostolovic[1], Z. Cirovic[1], L. Todorovic[1], P. Nikolic[1]. Nis, Yugoslavia; [1]*Cardiology Dept., University of Nis Cardiovascular Clini, Nis, Yugoslavia*

The aim was to evaluate the prognostic value of the response of restrictive transmitral inflow pattern to standardized Valsalva manoeuvre, in patients with an advanced left ventricle systolic dysfunction and EF < 30%.

Methods: Fifty nine patients with ischemic and dilated cardiomyopathy (mean EF 23 ± 3%), who showed restrictive left ventricle diastolic filling pattern (E/A > 2, DT < 150 msec) were examined. Mitral inflow velocities were recorded first at the end of the normal expiration and then during the strain phase of standardized Valsalva manoeuvre. Patients symptomatic status were assessed using NYHA classification.

Results: In 44 (75%) patients Valsalva manoeuvre induced decrease of both E and A velocity during the straining phase, but the restrictive left ventricle diastolic filling pattern remained unchanged (Restrictive pattern). In the remaining 15 (25%) patients E velocity was decreased and A velocity was either increased (12 patients) or slightly decreased (3 patients) and diastolic filling pattern was Improved (E/A < 2) and pseudonormalized. At the end of the follow up 11.0 ± 3.2 months period in patients, who showed no reversion of the restrictive filling pattern during Valsalva manoeuvre, there was no improvement of the symptomatic status (from 2.6 ± 0.3 NYHA to 2.7 ± 0.3) and there were 6 deaths (13.6%). In patients with improvement of the diastolic filling pattern during manoeuvre there was also improvement of the symptomatic status (from 2.6 ± 0.2 NYHA to 2.2 ± 0.3 p < 0.01) and there was only 1 death (6.7%,NS)



Conclusion: Restrictive filling pattern represents an advanced left ventricular diastolic dysfunction. Unimprovement of the filling pattern in response to preload reduction by Valsalva manoeuvre can detect patients with more adverse prognosis.

ECHOCARDIOGRAPHY IN CORONARY ARTERY DISEASE

P1618 Colour Doppler sonographic detection of artery puncture site complications after invasive cardiac procedures

K.J. Henrichs, B. Hagen, D. Boppert, D. Füllgraf, C. Solbach, D. Jürissen. *Dept.: Cardiology, Kreiskrankenhaus Lüdenscheid, Germany*

Peripheral artery puncture site complications after diagnostic cardiac catheterization (DC) or PTCA have been described at a rate between 0.21% and 6.25% with surgical repair rates of up to 2%. Diagnostic suspicion of vascular pathology on physical examination was found to be less reliable.

Therefore, 2101 unselected consecutive pts subjected to invasive procedures (DC: 1700 pts; PTCA 401 pts) during an 11-month-period underwent Colour-Duplex-Ultrasonographie (CDS) within 24 h after sheath removal, hand-compression and application of a compression bandage for 18 to 24 h. Baseline demographic and clinical characteristics and laboratory variables were collected prospectively. Primary end point was a composite of CDS-defined vascular complications: artery thrombosis (ATH), arteriovenous fistula (AVF), pseudoaneurysm (PSA) and open puncture channel (OPS) and echogenic haematome (HAM). OPC was observed in 1.19%, PSA in 4.28%, AVF in 0.48%, ATH in 0.19% and HAM in 3.9% at first CDS. OPC was found in 0.69% of males and in 2.3%% of females; PSA was found in 3.3% of males and in 6.6% of females. In the majority of pts prolonged compression was successful for resolution of puncture site pathology. Surgical repair was performed in 0.9%. Multiple logistic regression analysis identified female gender, advanced age, elevated bodymass and a platelet count of less than 120.000 as risk factors for OPC and PSA. Only in males risk of puncture site complications was higher after PTCA in comparison with DC. Sheath size did not influence the rate of puncture site complications.

P1619 Significance of resting wall motion abnormalities in two-dimensional echocardiography in patients without previous myocardial infarction referred for pharmacologic stress testing

Abdou Elhendy, Jos R.T.C. Roelandt, Marcel L. Geleijnse, Peter R. Nierop, Jeroen J. Bax, Don Poldermans, Jaroslaw D. Kasprzak, Roelf Valkema. *Thoraxcenter, Rotterdam, Netherlands*

Background. Resting wall motion abnormalities (WMA) in 2 dimensional echocardiography may be encountered in patients without previous myocardial infarction or known coronary artery disease (CAD) referred for stress testing. However, resting WMA are not established criteria for the diagnosis of CAD. Additionally, the functional significance of these abnormalities has not been evaluated by an independent technique.

Aim of the study is to assess the value of resting WMA in the prediction of an ischemic response and abnormal perfusion during dobutamine stress test.

Methods. We studied 116 patients (mean age 57 ± 13 years, 50 men) without known CAD or a history of myocardial infarction by dobutamine (up to 40 μg/kg/min) stress echocardiography and simultaneous stress and rest technetium sestamibi SPECT imaging. Ischemia was defined as new or worsening WMA and reversible perfusion defects respectively.

Results. Resting WMA were detected in 24 patients (21%). Patients with resting WMA had a higher prevalence of abnormal perfusion (75% vs 25%, p < 0.001) and ischemia by SPECT (50% vs 24%, p < 0.05) and by echocardiography (42% vs 9%, p < 0.001) compared to patients without resting WMA respectively. Stress and rest perfusion defect scores were higher in patients with than those without rest WMA (3.25 ± 2.67 vs 0.88 ± 1.77, p < 0.0001 and 1.46 ± 1.69 vs 0.21 ± 0.70, p < 0.0001 respectively). Independent predictors of the occurrence of ischemia by echocardiography were the presence of resting WMA (p < 0.01, Chi^2 = 6.7), ST segment depression (p < 0.005, Chi^2 = 11.3) and angina during the test (p < 0.05, Chi^2 = 5.3). The presence of resting WMA was the only independent predictor of an abnormal perfusion (p < 0.0001, Chi^2 = 20).

Conclusion. In patients without known CAD referred for pharmacologic stress testing, resting WMA are powerful independent predictors of an ischemic response during dobutamine stress test and identify a population with a higher prevalence and extent of myocardial perfusion abnormalities.

P1620 Automatic backscatter analysis of regional right ventricular systolic function in patients with inferior wall acute myocardial infarction using colour kinesis

T. Kürüm, C. Korucu, F. Özcelık, H. Eker, E. Öztekin, G. Özbay. *Trakya University, Faculty of Medicine, Department of Cardiology, Edirne, Turkey*

Color kinesis (CK) is a recently developed echocardiographic method based acoustic quantification (AQ) that automatically tracks and displays endocardial motion in real time. We studied whether AQ and CK may provide quantitative assessement of global and regional right ventricle (RV) function in patients with inferior acute myocardial infarction (AMI) since the evaluation of RV function has important prognostic implications in these patients.

Methods: Thirty two consecutive patients with recent (within one week) inferior AMI and 15 age- and gender-matched controls were studied. RV AQ and CK images were acquired in the apical four-chamber view. After image quality was optimized, the acquistic quantification system for endocardial border detection was activated. Once the region of interest (ROI) was drawn around the RV, all gains compensation were adjusted to optimize tracking of the blood-endocardial interface. AQ vaweforms of RV fractional area change and ejection fraction were displayed along with the electrocardiogram and the concurrent cross sectional image. CK digitized RV end-systolic images were evaluated by rewiewing the stored loops obtained in all normal subjects and patients. To evaluate the entire spatial temporal histories of RV systolic endocardial excursion, further quantitative CK analysis was performed by measuring the systolic segmental endocardial motion (SEM) and the time of systolic segmental endocardial motion (tSEM).

Results: Compared to controls, inferior AMI patients had reduced RV fractional area change (21 ± 7 vs 45 ± 6%, p < 0.01), reduced EF (26 ± 16 vs 44 ± 18%, p < 0.01), reduced mean SEM (11 ± 5 mm vs 21 ± 3 mm, p < 0.01) and reduced mean tSEM (150 ± 38 msec vs 290 ± 30 msec, p < 0.01).

In conclusion, our data suggest that RV systolic functions are influenced in inferior AMI and AQ and CK are feasible technique for investigating RV regional systolic functions in these patients.

P1621 Early detection of myocardial ischaemia during dobtamine stress echocardiography using color coded tissue Doppler imaging

M. Harada, M. Nasu, A. Tashiro, K. Hiramori. *Second Depertment of Internal Medicine, Iwate Medical Universty, Morioka, Japan*

Background: Color coded tissue Doppler imaging has been used to detect early acceleration in ventricular contractility during low dose dobutamine (DOB) stress tests. Since wall motion abnormalities (WMA) are known to occur following myocardial ischemia, it was recognized that color coded tissue Doppler imaging may enable the detection of myocardial ischemia before WMA induced by DOB stress echocardiography.

Subjects and Methods: Seven patients with severe stenosis of left anterior descending coronary artery were enrolled in this study. DOB stress echocardiography (3, 6, 12 mcg/min/kg step-wise every 5 min) was performed using SSA 370 Echo-Doppler equipment (Toshiba, Tokyo). Wall motion was determined from 4 different view angles acording to the procedure of American Society of Echocardiography. Color coded tissue Doppler images (CCTDI) were obtained from the parasternal short axis view at an early point during the systolic cycle when posterior wall velocity was highest as defined by the M-mode tissue Doppler method. Endocardial and epicardial velocities were measured by two-dimensional CCTDI in both the anterior septum (ischemic region) and the posterior wall (non-ischemic region). Each Myocardial velocity gradient (MVG) was calculated by the subtraction of epicardial velocity from endocardial velocity. MVG ratio [(MVG at stress − MVG at baseline)/MVG at baseline] between the two segments were determined.

Results: All patients showed significant MVG during infusion of the maximum dose of DOB (12 mcg/min/kg). In the non-ischemic region (posterior wall), MVG and MVG ratio during the highest dose of DOB increased significantly from 2.90 ± 0.32 to 5.62 ± 0.48 ($p < 0.05$) and from 0 to 0.966 ± 0.25 ($p < 0.05$), respectively. In contrast, in the ischemic region (anterior septum), MVG and MVG ratio values increased until 6 mcg/min/kg DOB and then decreased significantly during the highest dose of DOB (MVG, from 3.46 ± 0.32 to 0.76 ± 0.54; $p < 0.01$: MVG ratio, from 2.48 ± 0.77 to −2.20 ± 0.58; $p < 0.01$) before WMA was detected.

Conclusion: Real time determination of MVG and MVG ratio using CCTDI makes possible the detection of myocardial ischemia prior to the appearance of WMA, suggesting that this technique is a useful and safe means for detecting myocardial ischemia during DOB stress testing.

P1622 Short term prognostic value of a non geometric global Doppler index of diastolic and systolic performance in first myocardial infarction

J. Moller, E. Sondergaard, J.B. Seward[1], C.P. Appleton[2], S.H. Poulsen[3], K. Egstrup. *Department of Medicine, Svendborg Hospital, Svendborg, Denmark; [1]Cardiovascular Diseases, Mayo Clinic, Rochester; [2]Cardiovasvular Diseases, Mayo Clinic, Rochester, USA; [3]Clinical Physiology, Randers Hospital, Randers, Denmark*

Objective: To assess in an unselected population with first myocardial infarction (MI) the ability of a nongeometric global Doppler index (GDI) of combined left ventricular systolic and diastolic function, to predict in-hospital congestive heart failure (CHF), and cardiac mortality 35 days after MI.

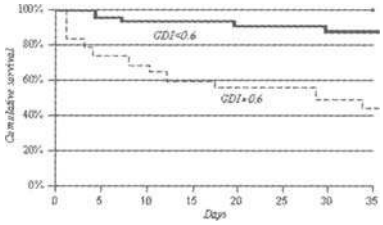
Background: Recently a nongemetric global doppler index has shown prognostic value in patients with dilated cardiomyopaty and cardiac amyloidosis, only limited data are avaliable in patients with MI.

Methods: Echocardiography was performed within 24 hours of arrival to CCU. During hospitalization Killip-class was determined on daily basis.

Results: Of 72 eligble patients aged 67 ± 11 years sustaning first MI, 70 patients (97%) were enrolled the study, 1 patient was excluded due to aortic stenosis and 1 due to dementia.

35 of 70 patients (50%) had signs and symptoms of CHF (Killip ≥ II) during hospitalization. Univariate analysis identified age, heart rate, peak creatine kinase B, GDI, E-wave deceleration time (Dt) < 140 msec, E/A ratio and WMI as predictors of CHF. Multivariate logistic regression analysis dentified GDI ($p = 0.0001$) and peak creatine kinase B ($p = 0.03$) as independent predictors of CHF.

16 patients (23%) died of cardiac causes within 5 weeks of MI. Of 24 patients with GDI > 0.6 at admission 12 patients (50%) died, of 46 patients with GDI < 0.6 4 patients died (9%), Log-Rank test $p < 0.0001$ (figure). Cox hazards analysis identified GDI ($p < 0.0001$) and Dt ($p = 0.04$) to be independent predictors of cardiac death, when compared with age, heart rate, CHF, peak creatine kinase B, and WMI.



Conclusion: A nongeometric global Doppler index (GDI) of left ventricular global function has significant prognostic value in MI.

P1623 The value of echocardiography in assessing patients post myocardial infarction

G.A. Cooke, G. McGawley[1], J. Wolfenden[1], G. Tinker[1], G. Seebass[1], R.A. Lawrance[1], K.E. Berkin[1]. *Cardiology, St James's University Hospital, Leeds; [1]Cardiology Dept, St James's University Hospital, Leeds, UK*

The AIRE study showed that clinical signs of heart failure (HF) post myocardial infarction (MI) indicate an increased risk of death which is reduced by angiotensin converting enzyme inhibitors (ACE-I). The TRACE study showed that patients with echocardiographic evidence of LV dysfunction also benefited from ACE-I, whether or not clinical HF was present. Asymptomatic LV dysfunction (ALVD) can be suspected clinically in the presence of a large anterior or repeat MI, and/or large enzyme rise. How accurate are clinicians in predicting ALVD?

Methods: The senior CCU clinician completed a short questionnaire for patients with MI. The presence of heart failure was recorded, as was any clinical suspicion of ALVD. Current or planned use of diuretics, ACE-I, and B-blockers was noted. All patients then had echocardiography within 3 days. EF was estimated visually and then calculated using the wall motion score (WMS) method as used in the TRACE study.

Results: 67 consecutive patients with definite MI were studied. Their mean EF was 43% and mean WMS 1.5. 21 had clinical evidence of heart failure, and 29 had EF < 40%. Mean EF of those with clinical evidence of heart failure was 37% range 13–60. Mean EF of those with no clinical evidence of heart failure was 45% range 7–60. 13 had EF < 40% and clinical evidence of heart failure.16 had EF < 40% but no clinical evidence of heart failure. Only 18 of the 29 patients with EF ≤40 were thought on clinical grounds to need ACE-I, and 13 of the 38 patients with EF > 40 were thought to need ACE-I. 21 patients had no clinical features to suggest ALVD and no clinical plan to start ACE-I. Their mean EF was 48.5%, range 17–60. 3 of these patients had EF < 40%. The technician estimate of EF agreed with the EF calculated from the WMS in all but 2 cases. In these 2 cases the calculated EF was only 1% point outside the range given by the technician.

Conclusions: The "Eye-ball" method of determining LV function by an experienced echocardiographer agrees well with the WMS (TRACE) method. Patients who have clinical signs of HF, often have preserved left ventricular function, whereas those with no signs of heart failure often have significant LV dysfunction. It seems difficult to define a group of patients in whom preserved LV function or ALVD can be predicted clinically. Therefore all MI patients without evidence of HF should have echocardiographic assessment of LV function to allow more rational and cost effective use of ACE-I.

P1624 Myocardial viability detected by dobutamine echocardiography in patients with chronic coronary artery disease, and long-term outcome after coronary angioplasty

T. Haque, T. Furukawa, M. Takahashi, K. Maeda, M. Kinoshita. *Internal Medicine I, Shiga University of Med. Science, Otsu, Japan*

Background: Viable but dysfunctional myocardium (VM) detected by dobutamine echocardiography (DE) predicts a post-PTCA improvement in regional left ventricular (LV) function. However, whether or not DE can predict the long-term (>2 years) outcome, including LV function, after PTCA is still unclear.

Methods: Fifty patients (age 60.4 ± 9.5 yrs) with chronic coronary artery disease and regional LV dysfunction who underwent DE 1 week before PTCA to assess myocardial viability were followed for 4.0 ± 0.8 yrs. VM by DE was defined as improvement in systolic thickening in a dysfunctional segment (in a 16 segment LV model) by ≥1 grade in a 4 point wall motion score (1 = normal to 4 = dyskinesis). Follow-up coronary artery angiography was performed at 3 months after PTCA. Regional LV function (regional wall motion score index, RWMSI) in revascularized area and LV ejection fraction (LVEF) were evaluated by two-dimensional echocardiography at 1 week, 3 months and at >2 yrs (late follow-up) after PTCA in patients remained event (cardiac death or myocardial infarction or unstable angina pectoris which required myocardial revascularization)-free.

Results: Thirty-six patients had VM and 14 had non-VM by DE. The rates of restenosis and re-PTCA were similar between patients with VM and non-VM (restenosis, 50% vs 36% and re-PTCA 19.4% vs 21.4%, p = NS, respectively). At late follow-up, 29 patients showed improvement in RWMSI (1.9 ± 0.5 to 1.4 ± 0.4, p < 0.001), 15 showed no improvement (2.2 ± 0.8 to 2.2 ± 0.8), 3 showed worsening (2.6 ± 0.2 to 2.9 ± 0.0) and 3 had cardiac events (1 non-fatal myocardial infarction and 2 unstable angina pectoris). Of the 29 patients with improvement, 27 (93%) had VM, while only 3 (20%) of the 15 with no improvement had VM and all 6 of those with poor outcomes (3 with cardiac events and 3 with worsening) had VM (Chi-Square = 28.9, p < 0.001). LVEF improved (0.53 ± 0.1 to 0.58 ± 0.1, p < 0.001) in patients with VM and improved RWMSI while deteriorated (0.38 ± 0.03 to 0.30 ± 0.03) in 3 Patients with worsened RWMSI. Patients with VM and a poor outcome had a lower mean LVEF before PTCA, and at 1 week and 3 months after PTCA (p = 0.004, < 0.001, and = 0.001, respectively), and a higher restenosis rate (p = 0.007) than patients with VM and without a poor outcome.

Conclusion: We conclude that, in patients with chronic coronary artery disease, VM detected by DE may predict long-term improvement in regional and global LV function after PTCA. However, patients with VM and persistent low LVEF and restenosis are at risk for cardiac events or worsening of LV function.

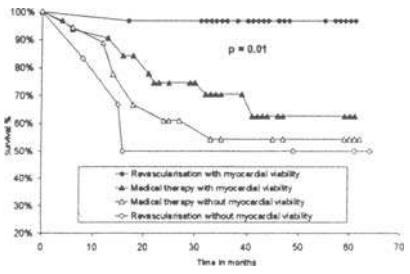
P1625 Myocardial viability by echocardiography predicts long-term survival after revascularisation in patients with symptomatic ischaemic cardiomyopathy

R. Senior, S. Kaul, A. Lahiri. *Northwick Park Hospital, Harrow, UK; University of Virginia, Charlottesville VA, USA*

Resvascularisation (Rev) improves survival in CAD pts with angina and LV systolic dysfunction however, there are insufficient long term data regarding survival benefit of Rev in pts with predominant symptoms of CHF.

Methods: Follow-up was obtained in 87 consecutive pts with CHF due to ischaemic LV systolic dysfunction (NYHA Class II–IV; LVEF: 0.25 ± 0.09) who were investigated with low dose dobutamine echocardiography (DE). Myocardial viability (MV) was defined as having either normal function or mild dysynergy at rest or severe resting dysynergy that improved or worsened on DE.

Results: 37 pts underwent Rev based on clinical grounds. At a mean follow up of 40 ± 17 months there were 22 (25%) cardiac related deaths. Multivariate analysis was performed using clinical data, drug therapy, LVEF, number of diseased vessels, number of viable segments. Results showed that the independent predictor of survival was when Rev was performed in patients with ≥5 segments of viability) from a 12 segment model); hazard ratio (95% CI): 0.39 (0.17–0.91), p = 0.01. The latter group also showed significant improvement in NYHA class (p < 0.001) and LVEF (p < 0.01) compared to the other groups.



Conclusion: Rev produced a clear survival benefit in patients with CHF due to ischaemic cardiomyopathy who have significant MV and was associated with improved symptoms and LV function.

P1626 Coronary artery disease in allograft: dobutamine echocardiography detection

L. Gastaldi, E. Donegani[1], D. Casalucci, L. Coda, M. di Summa[1]. *Dip. di Medicina Interna, Cattedra di Cardiologia, Università di Torino; [1]Dip. di Cardiochirurgia. Università di Torino, Italy*

Allograft coronary artery disease (ACAD) is the leading cause of mortality after cardiac transplantation (CT). Although angiography (angio) is considered the gold standard for diagnosis, it tends to understimate the extent of vasculopathy. Dobutamine stress echocardiography (DSE) identifies myocardial hypoperfused areas inducing local hypokinesia or akinesia.

From 1990 to 1998, 221 patients (pts) underwent CT in our Institution. Since 1993 DSE is utilized for ACAD detection in our laboratory. In the period '93–'98 sixty pts (mean age 45.2 ± 6 years, mean duration since CT 58.2 ± 32 months) had a standard DSE evaluation (dobutamine infusion schedule 5, 10, 20, 30, 40 mcg/kg/min at 5 minutes step). An 11 segments wall motion score model was used (modified ASEC's criteria) and positive DSE was defined as a new or worsening LV regional wall motion abnormality. EF%, EDV, ESV, WMSI were calculated at rest and each step. Results were compared with angio (Gao's criteria) and EMB data.

Three groups of pts were identified (values are expressed as mean ± SD):

Groups	Angio	WMSI basal	WMSI DSE	EDV% var.	ESV% var.	EF% var.
G I (48 pts)	–	1.02 ± 0.09	1.02 ± 0.09	−44.4 ± 13	−60.4 ± 24	30.2 ± 16.6
G II (9 pts)	+	1.53 ± 0.45	2.22 ± 0.50	+0.96 ± 20	84.79 ± 80	−38.16 ± 13
G III (3 pts)	–	1.15 ± 0.21	1.6 ± 0.00	−40.25 ± 14.5	−14.55 ± 2.8	−45 ± 2.8

In 48 pts (G I) angio, EMB and DSE were negative for ACAD. In 10 pts (G II) angio and DSE were positive for ACAD. In 2 pts (G III) angio was negative and DSE positive for ACAD and EMB showed intramyocardial proliferative lesions.

In conclusion: 1) Results suggest that DSE is reliable non-invasive test to detect epicardial vascular involvement; 2) Probably DSE can be a highly reliable test in the assessment of microvascular ACAD involvement which can be identified by EMB but not be predicted by angiography; 3) DSE can be used for the diagnosis and follow up of ACAD.

MISCELLANEOUS

P1627 Perivalvular complications in native valve endocarditis

C. Graupner, I. Vilacosta, J.A. San Román[1], J.V. Sanmartín[2], R. Ronderos[3], C. Sarriá[2], O. Sanz[1], C. Fernández, A. Serrador[1], G. Mújica[3]. *Hosp. Univ. de San Carlos, Madrid; [1]Hosp. Univ. de Valladolid; [2]Hosp. de la Princesa, Madrid, Spain; [3]Hosp. de San Juan de Dios, La Plata, Argentina*

The aim of this multicenter study was to assess the clinical course, predisposing risk factors, microbiological profile, and echocardiographic manifestations of patients (P) with native, left-sided valve endocarditis and perivalvular complications demonstrated by transesophageal echocardiography (TEE) or at pathology.

Methods: We have studied prospectiely 94 p (70 men; mean age 56 ± 15 years) of left-sided endocarditis (85 p had definitive and 9 p had probable Duke Criteria). The infection was on the aortic valve in 45 p, on the mitral valve in 48 p, and on both valves in one p.

Results: Periannular complications (abscesses, pseudoaneurysms or fistulae) were detected in 27 p (group I). In the remaining 67 p (group II) none of these complications were found. The latency period between the onset of symptoms and the diagnosis of endocarditis of both groups was not different. Pre-existent heart disease and predisposing risk factors had no association with peniannular complications. There were no significant differences between microorganisms of gr I and II [*staphylococcus aureus* (n = 16, 2 gI and 14 gII), *staphylococcus coagulase negative* (n = 8, 3 gI and 5 gII), *streptococci* (n = 32, 11 gI and 21 gII), *enterococci* (n = 12, 4 gI and 8 gII)]. TEE demonstrated vegetations in 86 p (26 gI and 60 gII, p = NS). No significant differences were found in the vegetation size of both groups. Atrioventricular block developed in 7 p (5 gI and 2 gII, p < 0.05). Systemic embolism occurred in 35 p (9 gI and 26 gII, p = NS). Forty five P underwent surgery (22 gI and 23 g II, p < 0.05). Twenty five p died (7 gI and 18 gII, p = NS).

Conclusions: 1 Periannular extension complicates aortic more frequently than mitral endocarditis; 2 The type of microorganism, time to diagnosis, preexisting heart disease, and predisposing risk factors were not related to the existence of these complications; 3 The frequency of systemic embolism was not higher in p with periannular extension of the infection; 4 Surgery was more frequent in these p; 5 Global mortality was similar in both groups.

P1628 Echocardiographic prognostic markers in patients with severe mitral regurgitation: ejection fraction versus dp/dt of the left ventricle

D. Chrissos, D. Kontoyianni, G. Zervopoulos, G. Andrikopoulos, D. Richter, D. Garyfallos, P. Dilaveris, P. Antonatos, J. Gialafos. *Cardiology Department of Amalia Fleming Hospital and State Cardiac Department of Hippokration Hospital, Athens, Greece*

The echocardiographic evaluation of left ventricular (LV) contractility in patients with severe mitral valve regurgitation (SVMR) can sometimes be misleading especially when based on the ejection fraction of the left ventricle (LVEF). Moreover, LVEF is poorly correlated to long-term prognosis of patients with SVMR The aim of this study was to examine the clinical importance of the rise of the LV pressure per time unit (dp/dt) as a marker of ventricular contractility with prognostic value in patients with SRMV.

Methods: We examined 86 patients (52 men and 34 women, 56 with coronary artery disease, 15 with dilated cardiomyopathy and 15 with valvular heart disease, mean age 72 ± 11 years) which were presented in the hospital with SRMV during the years 1992–95. The LVEF was calculated according to the Teicholz method and the dp/dt from the mitral regurgitation signal obtained by continuous wave Doppler. All patients were followed until December 1998. Sixty-one out of the 86 patients (71%) had died due to progressive congestive heart failure. Patients who died due to acute ischemic episodes or due to extracardiac causes were not included in the study.

Results:

	Deceased (n = 61)	Survivals (n = 25)	P value
Age (years)	73 ± 11	69 ± 10	0.128
LVESD (mm)	564 ± 112	528 ± 90	0.157
LVEDD (mm)	667 ± 90	654 ± 63	0.530
LVEF (%)	33 ± 15%	37 ± 16%	0.353
dp/dt (mmHg/sec)	659 ± 243	900 ± 256	<0.001

In multivariate analysis with age, sex, etiology of SVMR and LVEF < 35% as covariates, only dp/dt values lower than 730 mmHg/msec were significantly associated with poor prognosis [p = 0.038, odds ratio 12.1 (1.1 to 129.9)].

Conclusions: Contrary to LVEF, dp/dt was significantly increased in patients with improved long-term prognosis. Although further, specifically designed prospective studies are needed to clarify this issue it could be postulated that in patients with SVMR the echocardiographic evaluation of dp/dt is an informative prognostic tool, presenting superior prognostic value compared to LVEF.

P1629 Prediction of the situations in which the proximal flow convergence method estimates better than the regurgitant jet area the degree of angiographic severity in the mitral regurgitation

Paz Catalán, Jose L. Moya, Enrique Asín, Alberto García-Lledó, Jaime Pey, Francisco Barcia, Gonzalo Catalán, Gabriela Guzmán. *Institute of Cardiology, Ramón y Cajal Hospital, Madrid, Spain*

Background: The regurgitant jet area (RJA) and the proximal flow convergence (PFC) are two valid methods in the cuantification of the mitral regurgitation (MR), however its application in the daily clinical practice is not widespread due to its complex and time-consuming calculation. Nevertheless, there are situations in which its application is essential bearing in mind the limitations of the RJA.

Methods and results: We studied 82 patients (pats) with MR by the RJA and the PFC. In one patient the RJA could not be determined {angiographic severity degree (ASD) I} and in 6 pats it was not possible to calculate the maximum regurgitation flow (MRF) (5 pats were labeled with ASD I and 1 with degree II). The values of RJA (cut points in 6, 9.4 and 15.2 cm^2) and the MRF (cut points 16, 56 and 160 ml/sec) were determined through ROC curves, that gave the best predictions of the degrees of angiographic severity from I to IV. The correlation between severity of the MR by RJA and by angiography (A) was $r_s = 0.74$, with a degree in agreement (weighed Kappa) $\kappa_p = 0.75$. The PFC method gave a $r_s = 0.92$ with $\kappa_p = 0.91$ (a significative difference of correlation with p = 0.01). In the group of pats with eccentric jet and increased valvular mobility, as well as in those with left atrial size more than 7.5 cm, we could not find a significative statistical correlation of the RJA with the (A), however we could find it between the PFC and the (A) with $r_S = 0.92$ (p = 0.0001). In 75 pats we could compare the severity of MR through the three methods (RJA, PFC and A), in 30 pats (40%) of them there was agreement among these three methods, in 31 pats (41.4%) the severity of the MR by the PFC was in agreement with (A), however both were in disagreement with the severity by the RJA; in 6 pats (8%) the RJA was in agreement with the (A) (all of them had rheumatic valvular disease) and in disagreement with PFC; in 6 pats (8%) the RJA and the PFC were in agreement, and in disagreement with the (A), and finally in 2 pats (2.6%) the three methods were in disagreement.

The multivariable analysis of logistic regression showed the jet eccentricity as the only independent predictor (odds ratio 5.08) for a higher accurancy of the PFC versus the RJA (the PFC is in agreement with the (A) but the RJA is in disagreement with both of them).

Conclusions: 1) The PFC method presents a better correlation with the (A) than one of the RJA. 2) For the pats with eccentric jet and increased valvular mobility, as well as in those with left atrial size more than 7.5 cm, it is essential the use of the PFC bearing in mind the lack of correlation between RJA and (A). 3) The jet eccentricity is an independent predictor that provides a better estimation of the severity of the MR by the PFC, than by using the RJA.

P1630 Echocardiographic characteristics of diastolic mitral regurgitation

M. Petzsch, K. Pulya, T. Körber. *University Hospital, Department of Cardiology, University of Rostock, Rostock, Germany*

Diastolic mitral regurgitation (DMR) is rarely seen. We tried to evaluate the hemodynamic characteristics of DMR by typical Doppler findings and to consider the meaning of DMR according to these parameters.

DMR was analysed in an apical four-chamber view by M-mode colour Doppler (M/Q) tracing of the mitral regurgitant jet. From these M/Q tracings the flow of DMR was calculated by the method of the proximal isovelocity surface area (F), the duration (DU) of DMR and of diastole (DD) and the beginning (BEG) of DMR after the onset of the QRS-complex in the electrocardiogram were obtained. The regurgitant volume (RV) of DMR was calculated according to F and DU. By pulsed Doppler the stroke volume (SV) was obtained at the aortic or pulmonary valve.

DMR was found in 13 patients (mean age 53.5 ± 13 years). The underlying disease was severe aortic regurgitation (n = 5), idiopathic dilated cardiomyopathy (n = 1), cardiac amyloidosis (n = 1), hypertensive heart disease (n = 2), myocardial infarction (n = 2), high degree atrioventricular block (n = 2). The mean left ventricular diameter at end-diastole was 62.0 ± 10.3 mm (30.7 mm/m^2), at end-systole 40.2 ± 11 mm (19.9 mm/m^2), left atrial diameter at end-systole 48.8 ± 4.8 mm (24.2 mm/m^2), ejection fraction 44 ± 15%. The Doppler pattern of transmitral and pulmonary venous flow were typical for pseudonormalization with increased flow velocity during diastole. The mean heart rate was 75.3 ± 30.0 beats/minute; blood pressure: systolic 131.7 ± 26.7 mm Hg, diastolic 67.0 ± 16.6 mm Hg. Specific results are shown in the table:

DD (ms)	DU DMR (ms)	BEG (ms)	SV (ml)	RV (ml)
654.5 ± 353.9	140.3 ± 174.4	335.8 ± 86.3	110.8 ± 25.8	12.6 ± 8.7

p = n.s. for RV in the case of long or short DU DMR

A positive left ventricular-to-left atrial pressure gradient in diastole generates DMR and raises the left atrial pressure in addition to impaired left ventricular function. In some clinical situations DMR might induce deterioration of left atrial and consecutive left ventricular filling. The long diastole should be avoided in the presence of DMR, dual-chamber pacing and valve repair should be considered in the treatment strategies besides conventional medical treatment.

P1631 Association between mitral annulus calcification and aortic atheroma: a prospective transeophageal echocardiographic study

Y. Adler, M. Vaturi, N. Fink, D. Weisenberg, N. Sela, A. Sagie.
Echocardiography Unit, Dept of Cardiology, Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel

Background: Although mitral annulus calcification (MAC) has been reported to be a significant independent predictor of stroke, no causative relationship was proven. It is also known that aortic atheromas, especially those ≥5 mm thick and/or protruding and/or mobile, are associated with stroke. Therefore, we sought to determine whether an association exists between MAC and aortic atheroma.

Methods: The records of 195 consecutive patients who underwent transesophageal echocardiography (TEE) for various indications were followed prospectively. The 79 patients in whom a diagnosis of MAC was made on prior transthoracic echocardiography (TTE) were compared with 116 sex-and age-matched patients without MAC. MAC was defined as a dense, localized, highly reflective area at the base of the posterior mitral leaflet. We measured MAC thickness with two-dimensional-TTE in four-chamber view, and aortic atheroma thickness, calcification, protrusion and mobility with TEE. Aortic atheroma was defined as localized intimal thickening of ≥3 mm. A lesion was considered complex if there was plaque extending ≥5 mm into the aortic lumina and/or if it was protruding, mobile or ulcerated.

Results: No differences were found between the groups in risk factors for atherosclerosis or in indications for referral for TEE but atrial fibrillation which was more prevalent in the MAC group (13% vs 4%, p = 0.032). Significantly higher rates were found in the MAC group for prevalence of aortic atheroma (95% vs 38%, p < 0.001), atheromas ≥ 5 mm thick (73% vs 17%, p < 0.001), protruding atheromas (49% vs 11%, p < 0.001), mobile component (11% vs 3%, p = 0.021), and complex atheroma (80% vs 19%, p < 0.001). Forty-six patients had MAC thickness ≥ 6 mm and 33 <6 mm. Aortic atheroma thickness was significantly greater in the patients with a MAC ≥ 6 mm (6.9 ± 2.4 vs 5.1 ± 2.7 mm, p < 0.003). On multivariate analysis, MAC, diabetes, hypertension, age and sex were the only independent predictors of aortic atheroma (p = 0.0001, 0.01, 0.02, 0.014 and 0.029, respectively).

Conclusions: There is a significant association between the presence and severity of MAC and aortic atheroma. MAC may be an important marker for atherosclerosis of the aorta. This association may explain the high prevalence of systemic emboli and stroke in patients with MAC.

P1632 Aortic regurgitation in acute aortic dissection type A. The value of transoesophageal echocardiography in aortic valve repair/replacement decision making. 9 years study

M. Maciejewski, K. Piestrzeniewicz, M. Zielinska, R. Jaszewski, J. Zaslonka, H. Bolinska. *Clinic of Cardilogy, Institute of Cardiology, Lodz, Poland*

Aortic regurgitation (AR) frequently associates type A aortic dissection (AAD). Transoesophageal Echocardiography (TEE) can identify the mechanism of AR in pts with AAD. The mechanism of AR in AAD pts is the main guide for the decision of the surgical method for AR operation – aortic valve repair/replacement.

The results of TEE were assessed in consecutive 58 pts (M – 49, F – 9, mean age 52 (6.7) with acute AAD who underwent an operation at the period 1990–1998. 2 pts with prior aortic valve replacement were excluded from the analysis. The degree of AR was estimated on the grounds of the proximal AR jet height to annular diameter ratio. 12 pts with AAD had no or trace AR – Group (G) I. In 14 pts mild AR (II) was found – G II. In 30 pts moderate or severe AR was detected – G III. The predominant mechanism of AR was independent on AAD in 29 pts (bicuspid aortic valve or leaflet thickening) and dependent on AAD in 20 pts (geometric distortion of the valve support structures resulting in incomplete valve closure or leaflet prolapse, intimal flap prolapse.

Results:

Mechanism of AR	Group I (n = 14)	Group II (n = 14)	Group III (n = 30)
Independent on AAD (n = 29)	11 (79%)	10 (71%)	5 (17%)
Leaflet thickening	9	7	2
Bicuspid valve	2	3	3
Dependent on AAD (n = 20)		4 (29%)	25 (83%)
Incomplete valve closure		3	13
Valve prolapse		1	7
Intimal flap prolapse		0	5

Surgical procedure for AR was planed both by cardiac surgeon and echocardiographer on the grounds of TEE – Aortic valve repair or replacement was decided to be performed in 37 pts. These were all 30 pts from G III and 7 pts from G II – 4 pts with AR dependent on AAD and 3 pts with bicuspid valve. In 8% the planed procedure must have been changed intraoperatively.

Conclusions: 1. In pts with AAD the severe AR is frequently a result of AAD dependent factors, whereas in pts with mild AR it is more often due to the prior organic changes of the valves. 2. In pts with AAD and AR TEE is a helpful method in aortic valve repair/replacement decision making.

P1633 Three-year clinical follow-up of patients with spontaneous echocardiographic contrast in the thoracic aorta

C. Aggeli, C. Pitsavos, A. Frogoudaki, S. Lambrou, J. Barbetseas, P. Strebelas, C. Stefanadis, P. Toutouzas. *Department of Cardiology, University of Athens, Athens, Greece*

It has been suggested that spontaneous echocardiographic contrast in the thoracic aorta (SEC) is associated with an increased risk of future cardiovascular events.

Methods: To further elucidate this issue, the transesophageal echocardiograms (TEE) of 717 consecutive patients (pts) who were examined in our laboratory between January 1995 and December 1996 were reviewed for the presence of SEC. Pts in whom the finding was confirmed were reexamined clinically or their attending physicians were contacted by telephone and information were collected regarding the occurrence of the following events: Cardiac death, noncardiac death, stroke, peripheral embolic events and acute myocardial infarction (AMI).

Results: SEC was confirmed in 58 (8.1%) of the reviewed cases, none of whom regarded aortic dissection or thoracic aortic aneurysm. Follow-up information were collected in 45 of these pts (33 men, 12 women, aged 70 ± 10 years). The time elapsed between the index TEE and the follow-up was 38 ± 6 months (range, 25–48 months). During this period, 20 pts (45%) died, 11 of whom due to cardiac causes (6 by sudden cardiac death, 1 because of congestive heart failure, and 4 because of an AMI), 3 due to a cerebrovascular accident, and 4 due to non cardiac causes. The cause of death was not defined in 2 cases. Furthermore, 2 pts experienced a non-fatal stroke during follow-up, while no non-fatal myocardial infarctions or peripheral embolic events were reported. Five of the pts with SEC consented to undergo repeat TEE at follow-up. Four of them who underwent repeat TEE had coronary artery disease and one had chronic atrial fibrillation. All 5 pts had been receiving chronic aspirin therapy (160–325 mg o.d.), whereas no one received oral anticoagulants. Thoracic aortic SEC was shown to persist in all cases.

Conclusions: The data of the present report support the suggestion that thoracic aortic SEC is associated with considerable cardiovascular morbidity and mortality. Conventional-dose aspirin was shown not to influence the presence of SEC over a 3-year period in a small group of patients

P1634 Effectiveness of intra-venous rt-PA in the treatment of massive pulmonary and right atrial floating thrombus

G. Pierre Justin, P. Cohen-Ténoudji, P. Daoudal, F. Roques, B. Ulmer, Y. Donatien, G. Glaudon. *Département de Cardiologie, CHU de Fort de Martinique, France*

Occurrence of right atrial floating thrombus (RAFT) during the course of pulmonary embolism (PE) is a rare but probably overlooked event. Positive diagnosis is based upon echogardiographic features. Surgery is the current treatment and consists of thrombectomy during extracorporeal circulation. Therapeutic uncertainity dominates medical management and very few studies focused on effectiveness of intravenous (IV) fibrinolysis in this condition. 8 consecutive patients admitted for massive PE in whom echocardiography showed RAFT prolapsing across the tricuspid valve in diastole were eligible for fibrinolitic treatment. Echocardiographic signs of pulmonary hypertension were found in all cases. 1 patient (pt) treated by Heparin alonde died before starting fibrinolysis. 7 patients were trated with 100 mg IV of rt-PA. We gave rt-PA at the dose of 10 mg IV bolus, then 40 mg for two hours, followed by 50 mg for five hours. Rt-PA was associated with a bolus of 5000 units of Heparin. Rt-PA determinated the dissolution and dissappearence of RAFT on hour 12 of treatment, and the cocomitant disappearence of the echocardiographic signs of pulmonary hypertension. However, 2 pts needed adjunctive surgery because of evidence of persistant thrombus in pulmonary artery. At a 24 hours later evaluation, both scintigraphy and angiography showed an improvement of pulmonary perfusion. No side effects occurred during and after rt-PA infusion. Our results indicate that rt-PA acts rapidly and is save. IV fibrinolysis could be proposed as a firts line therapy for RAFT associated with PE.

P1635 Acute improvement of aortic mechanics following haemodialysis in patients with chronic renal failure

L. Soubassi[1], S. Lambrou[2], C. Aggeli[2], C. Pitsavos[2], C. Stephanadis[2], P. Soubassis[2], P. Toutouzas[2]. *[1]Renal Unit, "Alexandra" Hospital; [2]Dept. of Cardiology Hippokration University Hospital, Athens, Greece*

Aortic distensibility (AoDist) represents an important determinant of left ventricular pulsatile load and coronary blood flow. While AoDist seems to undergo marked impairment in patients (pts) with chronic renal failure (CRF), little is known regarding the potential effects of hemodialysis (HD) on this parameter.

Methods: We measured the distensibility of the proximal ascending thoracic aorta (AoDist) in 48 CRF pts (31 men, 17 women, aged 45 ± 14 years) undergoing regular HD, before and immediately after a mid-week dialysis session. Aortic distensibility was calculated as a function of changes in aortic diameter and pulse pressure, using the formula: 2 × (pulsatile change in diameter)/([diastolic diameter] × [pulse pressure]). Aortic diameters were measured by transthoracic echocardiography, while arterial pressure was measured simultaneously by sphygmomanometry at the brachial artery. All data were compared with those of a group of subjects with normal renal function (17 men, 10 women, aged 44 ± 14 years), matched to the CRF pts with respect to age and prevalence of risk factors for atherosclerosis.

Results: Aortic distensibility was significantly lower in CRF pts vs controls. A significant improvement of AoDist was noted following completion of the HD session (table).

Parameters	Controls	Pts pre-HD	Pts post-HD
Diastolic aortic diameter (cm)	2.9 ± 0.4	3.7 ± 0.6†	3.6 ± 0.6†‡
Systolic aortic diameter (cm)	3.3 ± 0.4	3.9 ± 0.5†	3.9 ± 0.5†‡
Pulsatile change of diameter (cm)	0.3 ± 0.1	0.2 ± 0.1†	0.2 ± 0.2†
Diastolic aortic pressure (mmHg)	73 ± 10	87 ± 17†	76 ± 14‡
Systolic aortic pressure (mmHg)	118 ± 14	141 ± 29†	115 ± 26‡
Arterial pulse pressure (mmHg)	47 ± 11	53 ± 19	39 ± 18‡
Aortic distensibility ($cm^2\ dyn^{-1} \times 10^{-6}$)	3.8 ± 1	1.9 ± 0.7†	2.6 ± 1.2†‡

†$p < 0.05$ compared with controls; ‡$p < 0.05$ compared with pre-HD value.

In conclusion, our data confirm the impairment of aortic mechanics in CRF and provide the additional information that AoDist is acutely improved to a significant extent immediately after an HD session. This effect, most likely passive in nature and possibly of limited duration, may however add considerably to the overall hemodynamic benefit offered by regular HD in CRF pts.

SYSTOLIC FUNCTION AND HEART FAILURE

P1636 Midwall mechanics and left ventricular geometry

A. Nicolino, F. Rengo, G. Furgi, G. Longobardi, N. Ferrara. *Cardiology Dept., Salvatore Maugeri Foundation, Telese Terme (BN), Italy*

Asymptomatic hypertensive patients exhibit subnormal left ventricular (LV) midwall fiber shortening (MWS) at rest and this finding predicts morbid events independently of age and blood pressure levels. Still unclear are the relationships between LV structure and midwall mechanics, in particular the influence of LV geometry on systolic performance.

To explore this issue, we evaluated by M-mode-2D Doppler echocardiography 1076 patients with stage I hypertension (604 F and 472 M, mean age 62 ± 11 ys). Exclusion criteria were: valvular heart disease, dilated cardiomyopathy, coronary artery disease. LV hypertrophy (LVH) criteria were LV mass index (LVMI) >134 g/m^2 in males and >110 g/m^2 in females.

355 patients had a normal LV, 88 had remodeling, 195 a concentric hypertrophy and 438 an eccentric hypertrophied ventricle. Patients with a normal LV were younger (58 ± 12 ys) and had higher MWS (19.6 ± 2.8%). Ejection fraction was normal in all groups. MWS was significantly reduced in patients with concentric remodeling (16.6 ± 2.0%) and with concentric LVH (16.0 ± 2.4%) ($p < 0.01$ in all cases). An abnormal MWS (<14%) was present in 84 patients (33 F and 51 M, age 67 ± 9 ys), 3.1% with normal ventricles, 9.1% with remodeling, 19.5% with concentric LVH, and 6.2% with eccentric LVH. 38 of these patients showed in addition a reduced fractional shortening (<26%). In a multivariate analysis only age, LVMI, systolic and diastolic blood pressure were independent predictors ($p < 0.05$) of MWS.

In conclusion: about 8% of hypertensives exhibit a depressed midwall fractional shortening despite a normal ejection fraction. Midwall fractional shortening is prevalently reduced in hypertrophied hearts with increased relative wall thickness (concentric remodeling or concentric hypertrophy patterns) as compared to normal or eccentric ventricles.

P1637 Left ventricular function by echocardiography and mortality: a population-based study

T.A. McDonagh, H.J. Dargie. *Cardiology Department, the Western Infirmary; the MRC CRI in Heart Failure, University of Glasgow, UK*

Echocardiography is frequently used to determine the presence of left ventricular systolic dysfunction (LVD). However, there are many different quantitative measures of LV in clinical usage. They are often assumed to be equivalent. A meaningful measure of abnormal LV function should give prognostic information. We report the mortality of LVD, assessed by several echocardiographic techniques, in a random, geographical sample of men and women aged 25–74

1640 attendees were studied in 1992/3. LV function was assessed by a left ventricular ejection fraction (LVEF) using the apical Biplane Simpson's Rule and Bullet methods fractional shortening (FS) and a left ventricular end diastolic dimension (LVEDD). Cut-off points for abnormality for each method were defined as being outwith or equal to two standard deviations from the mean for "normal" subjects within the population. We report all cause mortality at 4 years of follow up.

The Simpson's Rule LVEF was obtained in 89% of subjects, a Bullet LVEF in 60%, FS in 62% and an LVEDD in 63%.

LV Function Measure	4 yr. mortality rate	p value
Simpson's LVEF ≤ 34%	23%	<0.0001
Bullet LVEF ≤ 33%	5.7%	0.76
FS ≤ 0.19 (men) ≤ 0.23 (women)	7.8%	0.06
LVEDD ≥ 6.2 (men) ≥ 5.6 (women)	9.1%	0.1

By Cox Survival Regression Analysis only an abnormal LVEF by the Simpson's Rule technique predicted mortality: it remained significant in a multiple regression analysis, including age with an odds ratio of 1.5 (95%CI 1.2–2.0), p = 0.002.

In this large epidemiological study, LVEF according to the Simpson's Rule was the best predictor of mortalityand the most widely obtainable. The main reason for its lack of use clinically is its time-consuming nature. We contend that the measurement of LV function accurately is important in determining both therapeutic strategies and prognosis in patients with chronic heart failure and LV dysfunction and as such, the measurement should be as robust as possible. Simpson's Rule should be applied more frequently.

P1638 Harmonic versus fundamental echocardiography imaging for endocardial border definition

F. Veiga, I. Dionísio[1], M. Fiuza[1], P. Costa[1], C. Amaro[1], M. Lopes[1], F. Pinto[1]. *CCUL-LA3/Medicine IV; [1]Medicina IV, Faculty of Medicine of Lisbon, Lisbon, Portugal*

Background: Harmonic imaging has recently been developed in order to improve endocardial border definition.

The purpose of this study was to compare 2nd harmonic with fundamental echocardiographic imaging for endocardial border definition and assessment of segmental wall motion of the left ventricle.

Methods: 60 consecutive patients were studied during routine transthoracic echocardiography in both harmonic (H) and fundamental (F) modes. Apical (4- and 2-chamber) and parasternal long axis views were acquired using a Vingmed System 5, in both fundamental and harmonic modes. Images were digitally stored and reviewed blindly by two experienced observers for endocardial segment and wall motion contractility score. A total of 960 segments were analyzed. Quality of endocardial border delineation (EBD) was scored in a 0 to 2 scale (0 = inadequate/not seen, 1 = satisfactory, 2 = excellent).Wall motion (WMS) was scored in a 1–4 scale using the standard ASE 16 segments.

Results: In the harmonic mode 945 of 960 segments were visualized (98%) vs 851 of 960 (89%) segments in the fundamental mode ($p < 0.001$). The scores of harmonic imaging significantly showed an improvement in EBD (harmonic = 26 ± 3.8 vs fundamental = 18.6 ± 5.2; $p < 0.001$). The wall motion score also showed a statistically significant difference (harmonic = 22.9 ± 8.2 vs fundamental = 20.6 ± 7.03; $p < 0.05$). A total of 46% of all studied segments showed a significant improvement when the harmonic mode was used. Of 443 segments classified as satisfactory or not seen, 361 (81.5%) improved to excellent with the harmonic mode.The lateral, apical-septal and inferior walls showed a greater improvement with the harmonic imaging. The WMS was also altered in 118 of 960 segments (12.3%) when the harmonic mode was used.

Conclusions: Harmonic imaging markedly enhances endocardial border definition, more significantly seen in the lateral, inferior and apical-septal segments. The differences in the wall motion score are most likely the result of a better EBD, resulting in a more accurate assessment of segmental contractility. Therefore, harmonic imaging is potentially becoming an indispensable tool for the correct assessment of wall motion.

P1639 Pulmonary venous flow velocities assessed by transthoracic doppler echocardiography: relation to left ventricular systolic function

Michael Y. Henein, Elsadig Kazzam, Ihab S. Ramzy, Christine A. O'Sullivan, Marcus M. Khalil, Andrew J. Coats, Derek G. Gibson. *Royal Brompton Hospital, London, UK*

Background: During ejection LV long axis shortening causes a corresponding increase in left atrial capacity due to motion of the atrioventricular plane towards the apex. This effect is likely to influence pulmonary venous flow.

Methods: To assess possible relations between pulmonary venous flow velocities and systolic left ventricular function we studied 37 patients, age 56 ± 10 years, 23 male, using transthoracic Doppler echocardiography. Left ventricular systolic function was assessed from minor axis systolic and diastolic dimensions and long axis amplitude of motion and peak shortening velocities.

Results: None of the patients had significant mitral regurgitation. The systolic component of pulmonary venous flow correlated with both LV end-systolic diameter (r = −0.62) and peak long axis shortening velocity (r = 0.61). 15/37 patients had severe LV disease and raised left atrial pressure (transmitral E/A ratio > 1.0 and short E wave deceleration time < 120 ms). In them, the systolic pulmonary venous flow velocity held similar correlation with LV end-systolic diameter (r = −0.62) and peak long axis shortening velocity (r = 0.63). Diastolic component of the pulmonary venous flow however, did not correlate with any of LV diastolic measurements.

Conclusion: In the absence of significant mitral regurgitation the systolic component of pulmonary venous flow correlates with systolic left ventricular function. This close association seems to be independent of transmitral filling pattern and left atrial pressure.

P1640 Correlation between left ventricular systolic function and aortic dilatation in marfan syndrome and Marfan related disorders

M.C. Porciani, L. Giurlani, A. Chelucci, G. Giambalvo, B. Giusti, T. Brunelli, V. Nunziati, R. Fattori[1], G.F. Gensini[2], G. Pepe[3]. *Centro studio sindrome di Marfan, Clin Med Cardio Universita di Firenze, Florence; [1]Divisione di Radiologia, Universita di Bologna, Bologna; [2]Clinica Medica Generale e Cardiologia, Universita di Firenze, Florence; [3]Universita di Roma "Tor Vergata", Dipartimento di Medicina Interna, Roma, Italy*

In inherited disorders of Fibrillin 1, like MASS (Mitral valve prolapse-Myopia, Aortic dilatation, Skeletal involvement, Skin striae) and more consistently Marfan Syndrome (MFS) the cardiovascular involvement is characterized by mitral valve prolapse and aortic dilatation.

Subclinical alterations of diastolic function have already been described, but no alterations of systolic function have been reported. Since the aortic impedance influences the afterload and consequently the ejection force of the left ventricle (LV), we investigated the possible relationship between aortic dilatation and LV systolic function.

LV systolic function was studied in 24 patients, 16 MFS and 8 MASS with aortic dilatation by echocardiography. Significant valvular regurgitation or other cardiac alterations were absent and no patient was on cardiovascular therapy.

In the presence of normal LV-systolic parameters, a significant correlation between aortic diameter and ejection fraction (EF), fractional shortening (FS) and LV-end systolic volume (LVESV) was observed. No correlation was found between aortic diameter and LV-end diastolic volume and LV-mass (table).

Results:

	r	p
EF (%)	0.81	<0.01
FS (%)	0.64	<0.05
LVESV (ml)	−0.72	<0.01

These findings put into evidence a reduced resistance against which the left ventricle contracts and a consequent enhanced shear force during ejection of blood into the aorta in MASS and MFS. These alterations, associated with abnormal aortic wall structure, may affect the progressive dilatation and underline the relevance of negative inotropic therapy.

P1641 Non-contrast octave tissue imaging improves assessment of echocardiographic left ventricular ejection fraction: preliminary results from a multicenter study

D. Mele, D. Aschieri[1], M. Campana[2], M.G. Sclavo[3], G. Seveso[4], I. Pedini, P. Alboni, R.A. Levine[5]. *Division of Cardiology, Ospedale Civile, Cento; [1]Division of Cardiology, Ospedale Civile, Piacenza; [2]Division of Cardiology, Ospedale Civile, Gussago; [3]Division of Cardiology, Ospedale Civile, Torino; [4]Division of Cardiology, Ospedale Civile, Legnano, Italy; [5]Noninvasive Cardiac Laboratory, Massachusetts General Hospital, Boston, USA*

Background: Echocardiographic visual estimation of left ventricular ejection fraction (LV-EF) is performed routinely in clinical practice to provide a rapid assessment of global LV function but it is limited by non-optimal image quality. The aim of this study was to assess the incremental value of noncontrast harmonic imaging (Octave Tissue Imaging, OTI) in evaluation of EF compared with conventional imaging (CONV).

Methods: A) In 13 patients (pts) unselected for image quality and with distorted LVs who underwent a clinically indicated nuclear study, the standard apical 4- and 2-chamber views were acquired in a high frame rate cineloop format by both OTI and CONV modalities. Digital cineloops were transferred to a computer, separated, renamed, mixed in a pool and sent to 5 observers for analysis. Echo image quality was assessed using a 4 point scale (1 = poor and 4 = excellent); EF was visually evaluated as a continuous variable, for a total of 65 estimates for each 2D modality. B) In addition, 2 observers compared quantitative EF by biplane Simpson's method for OTI vs CONV.

Results: A) In 80% of CONV studies image quality was poor (grade 1–2) while in 71% of OTI studies it was good (grade 3–4). The EF values obtained by OTI showed a higher correlation with the nuclear measures than values obtained by CONV (0.63 vs 0.49, $p < 0.01$ by Z-transformation) with a trend for a decrease in the standard deviation of the mean error (8.8% vs 10.4%). Interobserver variability was lower by OTI than by CONV (6.5% vs 7.7%, $p < 0.05$ by F-test). B) Quantitative EF values by OTI showed a higher correlation with nuclear than those obtained by CONV (0.87 vs 0.76, $p < 0.01$) with a smaller standard deviation of the mean error (7.4% vs 13.1%, $p < 0.01$) and a lower observer variability.

Conclusions: In this initial group of pts, OTI enhanced visualization of the LV (expecially in pts with worse image quality by CONV), increased correlation of EF with nuclear and reduced interobserver variability. These benefits are even more prominent when EF is calculated by the biplane Simpson's method.

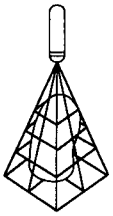
P1642 Accurate determination of cardiac output and ejection fraction by real-time three-dimensional echocardiography: comparison with gated SPECT-thallium

S.M. Müller[1], T. Bartel[2], C. Bacher-Stier[1], T. Raferzeder[1], G. Riccabono[1], O. Pachinger[1]. *[1]Departments of Cardiology, University Innsbruck, Austria; [2]University Essen, Germany*

Background: The purpose of this study was to determine the accuracy of real-time 3-D echocardiography (RT3DE) for quantification of left ventricular volume parameters and function.

Methods: In 10 patients with coronary heart disease comparative measurements of the cardiac output (CO) and the left ventricular ejection fraction (LVEF) were performed within 72 h using a VOLUMETRIX Model 1 und gated SPECT-thallium. For RT3DE a matrix phased array transducer (2.5 MHz, 512 elements) and a 16.1 receive/transmit parallel processing scheme to develop 4096 line scans interrogating all positions in a 60° pyramidal volume at 18 frames/s. Volume calculation was performed summing up 7 subvolumes previously created by manual tracing of the endocardial border in the cut planes of the data set. All measurements were carried out by 2 blinded observers and averaged.

Results: The mean difference for CO was calculated to be of about 14 ± 0.81 l/minute and for LVEF 4.3 ± 10.9%. Data acquisition took about 3 to 7 min.



Method	CO ± SD (range) l/min	LVEF ± SD (range) %
RT3DE	5.2 ± 1.2 (3.7–7.4)	53.2 ± 18.3 (26–86)
SPECT	5.1 ± 0.8 (3.5–6.2)	48.9 ± 18.6 (18–73)
r	0.72	0.83
p	0.016	0.003

Conclusions: Echocardiographic determination of CO and LVEF using RT3DE is valid. Measurements do not take up a great deal of time and, therefore, can be employed alternatively if hemodynamic monitoring is not available.

P1643 Effects of different pacing modes on left ventricular systolic function as determined by echocardiography

T. Tabata, R.A. Grimm, T.N. Mazgalev, N.L. Greenberg, D.A. Agler, D.W. Wallick, Y. Yamanouchi, J.D. Thomas. *Department of Cardiology/F15, Cleveland Clinic Foundation, Cleveland OH, USA*

Backgrond: The effect of heart rate control resulting from AV node ablation with pacemaker implantation for atrial fibrillation (AF) is believed to improve LV systolic function. Purpose: We evaluated the difference in LV systolic function resulting from different pacing conditions using a canine AF model.

Methods: Epicardial echocardiography was performed in 8 healthy mongrel dogs during induced rapid AF or right ventricular (RV) pacing. Rapid AF was induced by programmed random rapid atrial pacing. Heart rate was slowed during AF by vagus nerve stimulation (VNS). The AV junction was subsequently ablated by radiofrequency energy and random slow rate RV pacing was performed. The LV end-diastolic volume (EDV) and ejection fraction (EF) was obtained from 2D echocadiography, and the stroke volume (SV) was calculated using LV outflow Doppler velocity profile. The maximum value of the first derivative of the LV pressure curve (+dP/dt) was obtained by Millar catheter. Data were expressed as an average of more than 20 consecutive beats.

Results: 1) During rapid AF, the RR interval shortened while LVEF, SV and +dP/dt significantly decreased compared to baseline. 2) During AF with VNS, the RR interval significantly prolonged, while LVEF, SV and +dP/dt significantly increased compared to AF without VNS. 3) After ablation of the AV junction with RV pacing, the RR interval significantly prolonged, SV slightly increased, while LVEF and +dP/dt significantly decreased compared to AF without VNS. 4) There was a significant difference in the LVEF, SV and +dP/dt between AF with VNS versus ablation with RV pacing.

	Baseline (sinus)	Rapid AF	AF + VNS	Ablation + RV pace
RR (msec)	377 ± 25	348 ± 121*	583 ± 167*	527 ± 208*
EDV (ml)	29.3 ± 2.3	18.2 ± 7.0	26.3 ± 4.3*	26.3 ± 3.3*
EF (%)	60 ± 6	42 ± 25	55 ± 16*	36 ± 24*#
SV (ml)	18.2 ± 2.8	10.8 ± 8.2	17.2 ± 7.9*	11.6 ± 10.4#
+dP/dt (mmHg/s)	2727 ± 28	2644 ± 1256	2945 ± 1256*	2471 ± 1253*#

*$p < 0.0001$ vs Rapid AF, #$p < 0.0001$ vs AF with VNS

Conclusions: LV systolic function improved by reducing heart rate, while the LVSV and +dP/dt was significantly greater during AF with VNS than ablation with RV pacing. We conclude that antegrade pacing can be more physiologic than retrograde pacing, highlighting the importance of the atrial contribution to filling.

P1644 Non-invasive estimation of right atrial pressure by combined echo-Doppler measurements of the inferior vena cava in patients with congestive heart failure

Soccorso Capomolla, Oreste Febo, Giorgio Riccardi, Angelo Caporotondi, Maria Teresa La Rovere, Franco Cobelli. *"Salvatore Maugeri" Foundation Institute of Medical Care and Research Montescano (Pavia), Italy*

Background: In patients with congestive heart failure (CHF), the evaluation of right atrial pressure (RAP) provides useful therapeutic, functional and prognostic information.

Objective: To investigate whether a combination of inferior vena cava variables, measured by echo-Doppler, can provide a reliable non-invasive estimate of RAP.

Methods: One hundred consecutive pts with severe CHF (EF: 24 ± 6%) due to dilated cardiomyopathy were evaluated by simultaneous echo-Doppler and hemodynamic studies. RAP, end-expiratory (IVCDmax), end-inspiratory (IVCDmin) diameters of inferior vena cava, its index collapse (IVCIC = (IVCDmax − IVCDmin/IVCDmax) * 100) and systolic fraction of forward inferior vena cava flow (SFivcff) were measured and correlated by both single and multilinear regression analysis. The accuracy of the generated equations was tested in a separate group of 60 patients at baseline and a subgroup of 20 patients after loading manipulations, prospectively studied in the same methodological setting.

Results: All echo-Doppler variables were correlated to RAP. The IVCDmin showed the best correlation ($r = 0.84$ $p < 0.0001$). Stepwise regression analysis identified two equations for predicting RAP: 1) RAP = (6.4 * IVCDmin + 0.04 * IVCIC − 2) ($r = 0.82$ $p < 0.0001$ SEE = 1.7 mmHg) in all pts and 2) RAP = (4.9 * IVCDmin + 0.01 * IVCIC − 0.2) ($r = 0.92$ $p < 0.0001$ SEE = 1.2 mmHg) in pts without tricuspid regurgitation. In the testing group estimated and measured RAP were strongly correlated at baseline ($r = 95$ SEE 1.3 mmHg $p < 0.00001$) and after loading manipulations ($r = 0.96$ SEE 1.2 mmHg $p < 0.00001$). The agreement between invasive and non-invasive measurements of right atrial pressure in identifying patients with normal (RAP ≤ 5 mmHg), moderately increased (<5 RAP < 10 mmHg) or markedly increased (≥10 mmHg) right atrial pressure was 81% and 93% when using equation 1 or 2, respectively.

Conclusions: Our results show that in patients with congestive heart failure, indices derived from the inferior vena cava can be used to provide an accurate, non-invasive estimate of right atrial pressure.

P1645 Non-invasive estimation of pulmonary vascular resistances in patients with chronic heart failure

F. Scapellato, P.L. Temporelli, U. Corrà, E. Eleuteri, P. Giannuzzi. *"S. Maugeri" Foundation, IRCCS, Division of Cardiology, Veruno, Italy*

Pulmonary vascular resistance (PVR), by right heart catheterization (RHC), is of important clinical and prognostic value in patients (pts) with chronic heart failure (CHF), particularly for possible candidates to heart transplantation. Thus, a noninvasive estimation of PVR is desirable. We hypothesized a strict correlation between Doppler systolic pulmonary flow (PF) and PVR.

Methods: 50 consecutive pts with CHF (39 males, 57 ± 3 yrs, EF 22 ± 4%, NYHA class II–IV) underwent simultaneous hemodynamic monitoring (Swan-Ganz cath.) and echo-Doppler study. The following Doppler parameters were evaluated on PF: pre-ejection period (PEP), acceleration time (AcT), ejection time (EjT), total systolic time (Tt) and peak flow velocity (Vmax).

Results: mean PVR value was 2.8 ± 2.1 Wood. At univariate analysis all variables, except Vmax, showed a significant, although weak, correlation with PVR. The best correlation was found between AcT and PVR ($r = -0.68$). By multivariate forward stepwise analysis only PEP, AcT and Tt entered in the final equation with a cumulative $r = 0.87$. On the basis of these results and pathophysiological background, we combined these three variables in a single function to verify whether their interaction could define a closer relation with PVR: PEP to AcT ratio, normalized for Tt showed the highest correlation with PVR ($r = 0.95$).

In conclusion: although PVR is a complex parameter resulting from the interaction of several hemodynamic variables, Doppler systolic pulmonary flow signal is strictly related to PVR. PEP to AcT ratio, normalized for Tt of pulmonary systolic flow represents a reliable tool for predicting PVR in pts with CHF. This finding strongly support the contention that most CHF pts can be noninvasively investigated by echo-Doppler examination to accurately predict PVR.

P1646 Dobutamine stress echocardiography can predict extent of myocardial fibrosis in patients with dilated cardiomyopathy

P. Otasevic, J.D. Vasiljevic, Z. Popovic, S.D. Boskovic, D. Bojic, M. Miric, M. Bojic, L. Pratali[1], A.N. Neskovic. *Cardiovascular Research Center, Dedinje Cardiovascular Institute, Belgrade, Yugoslavia; [1]CNR, Pisa, Italy*

In order to assess relationship between dobutamine stress echocardiography (DSE) and myocardial fibrosis (MF) we have analyzed 24 consecutive pts with endomocardial biopsy (EMB) proven idiopathic dilated cardiomyopathy (DCM) in whom both DSE and EMB were performed in the same hospitalization.

DSE was performed using 5, 10, 20, 30 and 40 mcg/kg/min infusions, in progressive stages lasting 5 minutes each. DSE was considered positive if there was an increase >0.22 between resting and peak left ventricular (LV) wall motion score index (WMSi) that was calculated using 16-segment model. LV end-systolic (ESVi) and end-diastolic (EDVi) volume indexes, as well as EF, were calculated from apical 2- and 4-chamber views using Simpson's biplane formula. LV EMB specimens (3–5 per pt) were routinely processed and stained with Masson-trichrome. MF was calculated quantitatively using commercially available software for a representative field in each specimen, averaged and dichotomized in respect to median value. Logistic regression model, that included clinical (NYHA class, duration of symptoms, presence of 3rd heart sound, and heart rate), hemodynamic (LV end-diastolic pressure) and echocardiographic data (DSE, EDVi, ESVi, EF, and early filling deceleration time), was used to identify predictors of the extent of MF.

Results: Pts with positive DSE (14/24) had lesser extent of MF compared to pts with negative DSE (32.8 ± 6.2 vs. 20.8% ± 7.3, $p < 0.001$). Additionally, these patients had more favourable clinical, hemodynamic and echocardiographic data ($p < 0.01$, for all), except heart rate and duration of symptoms which were similar between the groups. Logistic regression model identified DSE as the only independent predictor of the extent of MF (beta −2.7, $p = 0.04$). When DSE was removed from the model, none of the variables were predictive of MF.

Conclusion: Our data indicate that wall motion improvement during DSE in pts with DCM, in contrast to other clinical, hemodynamic and echocardiographic parameters, may identify pts with lesser extent of MF. This observation may provide rationale for routine use of DSE in the assessment of pts with DCM.

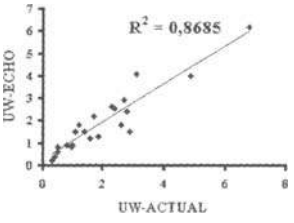
P1647 Contrast-enhanced Doppler echocardiography allows a complete haemodynamic assessment in patients with congestive heart failure

E. Traversi, F.L. Dini[1], M. Franchini, G. Micheli[1], F. Cobelli, M. Pozzoli[2]. *Cardiology Dept, S. Maugeri Foundation, Montescano; [1]Cardiology Unit, Villamarina Hospital, Piombino; [2]Cardiology Dept, Lecco Hospital, Lecco, Italy*

In patients (pts) with congestive heart failure (CHF) Doppler echo provides relevant hemodynamic information. In some pts, poor quality Doppler signals may limit feasibility and accuracy of measurements.

Methods: to assess whether contrast-enhanced DE can improve noninvasively hemodynamic estimation, we investigated 30 consecutive CHF pts by simultaneous right heart catheterization and DE performed before and after IV injection of 5- 10 ml of contrast agent (Levovist®). Cardiac output (CO)was estimated by PW-Doppler of left ventricular outflow tract; pulmonary wedge pressure (PWP) by previously validated equations including PW-Doppler mitral and pulmonary venous flow variables; right atrial pressure (RAP) by 2D-echo inferior vena cava expiratory and inspiratory diameters. Systolic and diastolic pulmonary artery pressures (PAP) were calculated by adding RAP to the pressure gradients derived from the CW-Doppler peak velocity of tricuspid regurgitation and from the end-diastolic velocity of pulmonary regurgitation, respectively. Mean PAP and pulmonary vascular resistance were then derived from these measurements.

Results: PWP was 18.3 ± 7.7 before and 17.9 ± 6.8 mmHg 30" after contrast injection. A complete assessment could be obtained only in 20 pts without using contrast while with contrast-enhanced DE it was obtained in 30. By this method, strong correlation between invasive and noninvasive variables were found: r = 0.94, SEE 0.4 l/min for CO; r = 0.98, SEE 1.6 mm Hg for PWP; R = 0.98, SEE 1.6 for mean PAP and r = 0.93 SEE 0.6 Wood units for pulmonary vascular resistance.



Conclusion: in pts with CHF contrast-enhanced DE allows complete noninvasive hemodynamic assessment and may reduce the need for right heart

P1648 Prognostic value of contractile reserve as assessed by high-dose dobutamine Doppler echocardiography in patients with severe heart failure

M. Franchini, E. Traversi, M. Pozzoli[1], G.P. Guazzotti, F. Cobelli. *Cardiology Dept, S. Maugeri Foundation, Montescano; [1]Cardiology Dept, Lecco Hospital, Lecco, Italy*

Background: In patients (pts) with heart failure (HF) the contractile reserve is impaired and the assessment of the severity of this impairment may add valuable prognostic information to baseline data.

Methods: To prove this hypothesis, we prospectively investigated 56 pts with severe HF due to dilated cardiomyopathy. Maximal cardiac power output (PO) was assessed by means of both right heart catheterization and Doppler echocardiography (D-E) simultaneously performed during a high-dose Dobutamine test. Invasive PO was calculated from the formula PO = (mean arterial pressure- right atrial pressure) cardiac output*2.22/1000. The same formula was applied for D-E but right atrial pressure was estimated from the inspiratory collapse of the inferior vena cava and cardiac output from Doppler of the left ventricular outflow tract.

Results: D-E maximal PO was strongly correlated with invasive PO (r = 0.98; SEE = 0.1 Watt). During a follow-up of 13 ± 6 months 13 pts (23%) died. At baseline, no differences were found between survivors and non-survivors in left ventricular ejection fraction (23 ± 8% vs. 21 ± 8%), cardiac index (2.1 ± 0.5 vs. 1.9 ± 0.5 l/min/m^2), and PO (0.7 ± 0.1 vs. 0.6 ± 0.1 Watt). In contrast, 11/13 pts who had a reduced contractile reserve during high-dose Dobutamine (D-E PO < 1 Watt) died; while only 2/31 pts who had a maximal PO > 1 Watt had events (p < 0.001).

Conclusions: In severe HF high-dose Dobutamine D-E allows a reliable non-invasive estimation of maximal PO. This index adds strong prognostic information to baseline indices of systolic dysfunction.

P1649 Low-dose dobutamine stress echocardiography in patients undergoing high dose potentially cardiotoxic chemotherapies

A. Martinoni, M. Civelli, D. Cardinale, G. Lamantia, A. Agazzi[1], P.F. Ferrucci[1], G. Martinelli[1], C. Fiorentini, C.M. Cipolla. *Cardiology Unit, Istituto Europeo di Oncologia, Milan; [1]Ematoncology Unit, Istituto Europeo di Oncologia, Milan, Italy*

Background: Patients undergoing high dose chemotherapies with potentially cardiotoxic drugs can develop both acute and chronic heart failure. The study evaluated heart response to low dose dobutamine infusion, in order to define the effect of various chemotherapic regimens (CT) on myocardial contractile reserve.

Population: We studied 38 patients, all females, aged 44 ± 8 (mean ± SD) years, with no cardiovascular diseases and normal left ventricular ejection fraction (EF).

Methods: EF measurements were obtained in basal conditions and after continuous infusion of dobutamine at increasing doses (0.5 mcg/kg/min, 2.5 mcg/kg/min and 5 mcg/kg/min for 10 minutes each step). Each patient underwent a basal study before the first CT and again one month later, before a second CT cycle.

Results: Before CT mean EF was 69 ± 6% in the baseline and increased to 76 ± 5% (p < 0.01) at the end of third step of dobutamine infusion (5 mcg/kg/min). One month after CT, baseline EF decreased to 64 ± 6%; the difference between pre- and post-CT is statistically significant (p < 0.01) but clinically not relevant. After CT, dobutamine infusion caused a more consistent increase in EF (74 ± 6%). Surprisingly after 5 mcg/kg/min dobutamine infusion EF did not show any significant difference between pre- and post-CT values (76 ± 6% vs. 74 ± 6%, respectively).

Conclusion: High dose chemotherapy can lead to significant, although not clinically relevant, decrease of baseline EF but no decrease in inotropic response after low-dose dobutamine infusion. We can argue that this pattern can be related not to permanent structural damage but to some kind of atypical "hybernated-like" myocardial condition.

P1650 Echocardiographic determinants-predictors of mortality rate in patients with severe congestive heart failure

J. Davceva, S. Meskovska, M. Zanteva, I. Peovska[1], D. Proevska. *Clinical Center, University Hospital, Institute for Cardiovascular Diseases, Skopje; [1]Skopje, FYROM*

The aim of the study was to estimate different echocardiographic parameters in order to characterize high-risk patients (pts) with severe congestive heart failure (CHF) and severe left ventricular dysfunction.

Methods: We studied 108 consecutive patients aged 63 ± 0.9 years, 90 man and 18 woman in sinus rhythm, with heart failure, NYHA class II–IV and ejection fraction (EF) echocardiographically estimated <30%.

Results: After period of 20 months of follow up there was 21 (19.4%) cardiac deaths. We applied univariate Cox regression analysis X^2, p, and multivariate Relative Risks witk CI 95%, to estimate significant predictors of mortality in pts with severe CHF. Our results showed that age > 65 years (p = 0.037), EF (p = 0.005), left ventricular end diastolic diameter (LVEDD) (p = 0.0031), fractional shortening (p = 0.006), left ventricular ejection time (p = 0.0015), E/A (p = 0.012), ejection time (p = 0.0125), A wave integral (p = 0.004), deceleration time of E, DT (p = 0.000), DT < 125 ms (p = 0.000), E > A (p = 0.007) were significant predictors of mortality.

In conclusion, EF < 30%, LVEDD > 7 cm, age > 65, and DT < 125 ms were independent predictors of mortality.

CARDIAC REHABILITATION: FITNESS AND EXERCISE TRAINING

P1651 Rehabilitation programme effects on congestive heart failure patients taking β-blockers

D. Curnier[2,3], M. Galinier[1,3], J. Fourcade[1], A. Pathak[1], M. Bousquet[2], S. Boveda[1], J.M. Fauvel[1], J.P. Bounhoure[1], J.L. Montastruc[3]. *[1]Rangueil University Hospital, Toulouse; [2]Cardio-pulmonary Rehabilitation Center, ST Orens; [3]INSERM U317, Toulouse, France*

Background: Training is now well accepted in stable congestive heart failure (CHF). Since few years beta-blockers (βB) are used in the treatment of CHF. The aim of this study was to compare the training response of CHF with and without beta-blockade therapy.

Methods: 34 CHF stable patients (Ejection Fraction: 31 ± 1.3%, NYHA II–III) were included consecutively in a 4 weeks training program: 45 min/6 times/week at the ventilatory threshold (Vth). Sixteen patients were taken βB and 18 not. Before and after training the subjects underwent a cardio-pulmonary exercise test. We compared the parameters of aerobic capacity before and after training by repeated measures ANOVA adjusted with ejection fraction and VO_2.

Results:

With βB	Before training	After training
VO_2 Vth (ml min^{-1})	1040 ± 28	1237 ± 28
VO_2 max (ml min^{-1})	1382 ± 32	1575 ± 32

Without βB	Before training	After training
VO_2 Vth (ml min^{-1})	1183 ± 30	1443 ± 30
VO_2 max (ml min^{-1})	1544 ± 34	1811 ± 34

VO_2 at peak exercise and at Vth increased in both groups ($p \leq 0.0001$) without any differences between the groups ($p = 0.2444$ and $p = 0.182$ respectively). Same results were found after adjustment with EF and VO_2 at the start of the training program. Comparison of the Vth increased ($p = 0.0104$) in term of VO_2 utilization percentage was the same in both groups.

Conclusion: βB therapy does not impair functional improvement induced by rehabilitation program in CHF patients.

P1652 Oxidative stress in chronic heart failure: effects of exercise

J. Niebauer, K. Webb-Peploe[1], P.S. Tsao[2], J.P. Cooke[2], A.J.S. Coats[1]. *Kardiologie, Herzzentrum der Universität Leipzig, Leipzig, Germany[1]Cardiac Medicine Dept., NHLI, London, UK; [2]Cardiovascular Medicine Dept., Stanford University School of Medicine, Stanford CA, USA*

In this study, we measured plasma nitrite, L-arginine, asymmetrical dimethylarginine (ADMA; an endogenous nitric oxide synthase inhibitor), hypoxanthine (pro-oxidant substrate for xanthine oxidase), and uric acid (putative free radical scavenging properties) to assess whether levels can be altered by exercise.

Twenty-one patients and 9 controls were randomly assigned to 8 weeks of exercise (EX; >5 d/wk, ergometer training, 30 min/d; calisthenics 9 min/d) followed by 8 weeks of detraining, and vice versa (cross-over study). L-arginine, ADMA, hypoxanthine, and uric acid were measured by high performance liquid chromatography and nitrite concentrations by Griess reaction.

Maximal exercise time increased in both groups ($p < 0.005$). Uric acid levels were highest in CHF ($p < 0.005$) but did not change after training. However, there was an inverse correlation between uric acid levels and maximal exercise time ($r = -0.32$, $p < 0.02$). Hypoxanthine levels were significantly higher in patients than in controls ($p < 0.02$), and were normalized by chronic exercise. Nitrite levels were significantly lower in CHF patients than in healthy controls. Although nitrite levels were highest after EX, changes did not reach statistical significance (p = n.s.). There were no baseline differences detected for L-arginine and ADMA; levels were not altered by exercise.

Chronic heart failure is associated with increased levels of hypoxanthine and decreased levels of nitrite. This imbalance can be beneficially modulated by chronic exercise training. Furthermore, uric acid levels are elevated in CHF and associated with diminshed exercise capacity, reflecting an impairment of oxidative metabolism.

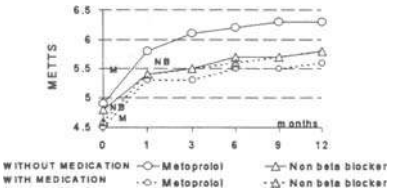
P1653 Positive effects of metoprolol on the functional capacity, during exercise conditioning in patients with the ischaemic left ventricular dysfunction can be demonstrated after discontinuation of β-blocker

M. Pavlovic[1], M. Tomasevic[1], L.J. Hadzi Pesic[2], V. Markovic[2], L. Todorovic[1], P. Nikolic[1], S. Apostolovic[1]. *[1]University of Nis Cardiovascular Clinic; [2]Institute for Rehabilitation of Cardiovascular Diseases Niska Banja, Yugoslavia*

Beta blocker treatment has been shown to improve prognosis in patients with dilated and ischemic cardiomyopathy. There are questions about possibility to achieve training effect in patients who are treated with beta blockers, because sympathetic stimulation with adequate cardiovascular response is necessary for the exercise tolerance and attainment of the training effect.

The aim of this study was to estimate the influence of chronic metoprolol treatment added to conventional heart failure therapy, in patients with the post infarction left ventricular dysfunction, on the effects of one year physical training.

Methods. Eighty nine post-myocardial infarction patients (3.4 ± 1.7 months after infarction), with left ventricular dysfunction (EF ≤ 40), without congestion, were examined. After 1 month residential exercise training program, patients continued home based unsupervised physical activity 3 times per week, during 11.1 ± 2.7 months. 47 patients (EF % 32.4 ± 1.9) received Metoprolol 50.3 ± 28.2 mg/day and 42 patients (EF% 31.7 ± 2.0) (without difference in baseline characteristics from metoprolol group) did not receive beta blocker. Patients functional capacities were examined by exercise stress testing on treadmill, before entering the training, at the end of the residential rehabilitation, on three month intervals, and also at the end of the program. Patients performed exercise tests while receiving complete medication, and these tests were used for physical training prescriptions. Exercise tests were repeated two days after stopping medication and these results were used for functional capacity measurements.



Results After the physical training program was completed, the functional capacity increased in Metoprolol group from 4.9 ± 1.6 to 6.3 ± 1.7 METs ($p < 0.001$) in significantly greater degree (28.7%, $p < 0.01$) than in the Non beta blocker group (4.8 ± 1.8 to 5.7 ± 1.9 METs ($p < 0.01$), 18.8%). In metoprolol group exercise tolerance examination perform during medication show significantly lower functional capacity than assessment after discontinuation of the beta blocker $p < 0.01$.

Conclusion Patients treated with metoprolol showed greater functional capacity improvement due to physical training than patients without the beta blocker. A few days after discontinuation of the beta blocker, heart rate and cardiac output increment during exercise is unrestricted and a real degree of the functional capacity improvement due to physical training can be assessed.

P1654 Improved exercise capacity after endurance training with theraband in patients with chronic heart failure

R. Tyni-Lenné, K. Dencker, A. Gordon[1], E. Jansson[2], C. Sylvén[1]. *Department of Physical Therapy, Huddinge Hospital, Huddinge; [1]Department of Cardiology, Huddinge Hospital, Huddinge; [2]Department of Clinical Physiology, Huddinge Hospital, Huddinge, Sweden*

Background: In chronic heart failure (CHF) there is an inability to adequately increase cardiac output during exercise. To circumvent the central cardiovascular stress of this limitation during exercise training and thereby to improve the training effect on the local muscle, is to train a minor muscle mass at a time

Aims: To test the hypothesis that comprehensive endurance training applying the concept of a minor muscle mass training can improve physical exercise capacity as well as quality of life.

Methods: 24 habitually active men and women (63 ± 9 years) with moderate CHF (left ventricular ejection fraction < 40%) were studied in a randomized controlled study with a training group of 16 patients and a control group of 8 patients. The training was performed for 8 weeks, 3 times/week with TheraBand activating one functional muscle group at a time.

Results: Peak oxygen uptake (8%, $p < 0.03$), noradrenaline level at rest (26%, $p < 0.008$), the distance walked in a six minute walking test (11%, $p < 0.002$), and the health-related quality of life measured with the Minnesota Living with Heart Failure questionnaire ($p < 0.001$) showed improvement in the training group, while no improvement was found in the control group.

Conclusions: Endurance training activating a minor muscle mass at a time markedly improves physical exercise capacity and quality of life and can be recommended for medically stable CHF patients under supervision of a physical therapist. This training method can easily be applied at home for these patients.

P1655 The improvement in peripheral vasodilatory capacity improves oxygen uptake kinetics after physical training in cardiac patients

N. Osada, H. Itoh, M. Kato, K. Omiya, Y. Akashi, A. Tajima, L.T. Fu, H. Watanabe, K. Kato, M. Murayama[1]. *The Cardiovascular Institute, Tokyo; [1]Department of Cardiology, St. Marianna University, Kawasaki, Japan*

It is well documented that the physical training improves oxygen uptake kinetics during exercise through the improvement of the cardiac output response. Since this phenomenon is noted even after the short-term training, we designed this study to clarify the contribution of peripheral vasodilatory capacity to the increase in cardiac output during exercise.

Method: Thirty two patients (mean age of 64 years) 1 week after the cardiac surgery or myocardial infarction who joined 2-week supervised aerobic training course entered the study. They underwent symptom-limited cardiopulmonary exercise tests with a cycle ergometer using a ramp protocol before and after the training. The peak hyperemic calf blood flow (CBF) was measured after 5-min. arterial occlusion with a strain gauge plethysmography before each exercise test. Peak oxygen uptake (peak VO_2), VO_2/WR, and the time constant of VO_2 at the beginning of 20 W constant work (TC) were calculated.

Results: CBF before the training was 14.6 ± 4.2 ml/min/100 ml tissue and it was significantly lower than those in normal subjects (26.5 ± 5.8). CBF showed significant correlations to peak VO_2, VO_2/WR, and TC before the training. All these parameters increased significantly by the physical training (CBF: 14.5 ± 4.2 – 15.6 ± 4.6 ml/min/100 ml tissue, peak VO_2: 15.7 ± 3.1 – 17.6 ± 3.2 ml/min/kg, VO_2/WR: 8.0 ± 2.3 – 9.2 ± 1.9 ml/min/W, TC: 53.6 ± 21.1 – 43.4 ± 17.0 sec), while the increase in CBF by the training reveled a strong positive correlation to that of TC ($r = 0.75$, $p < 0.0001$).

Conclusion: These data suggest that the blurred cardiac output response, especially at the beginning of exercise, is caused partly by the impaired peripheral vasodilatory capacity in patients after the cardiac surgery or myocardial infarction. The aerobic training improves attenuated oxygen uptake kinetics and vasodilatory capacity in these patients even it is short-term.

P1656 Improved physical fitness and quality of life in elderly patients recovering from an acute coronary event after three months of aerobic group training: a one-year follow-up, randomized controlled study

A. Ståhle[1,2], E. Mattsson[2], L. Rydén[1], R. Nordlander[1]. *Departments of [1]Cardiology, Karolinska Hospital; [2]Physical Therapy, Karolinska Institutet, Stockholm, Sweden*

Cardiac rehabilitation including exercise training is of proven value in ischemic heart disease. Still, elderly patients are frequently not encouraged to participate in such programmes. The aim of this prospective randomised controlled study was to evaluate the physiological effects and self-reported health-related quality of life after an aerobic outpatient group-training programme in subjects >65 years of age.

Methods: The study included a consecutive series of 101 patients, 20 women and 81 men, aged 65–84 (mean 71) years recovering from an acute coronary event. The patients were randomised to either a supervised outpatient group-training programme, 50 minutes three times a week during three months (n = 50) or to a control group (n = 51).

Results: The two groups were well balanced as regards clinical characteristics at randomisation. In all 101 patients completed the 3 months follow-up and 100 the 12 months follow-up. The compliance in the training group was 87%, and there were no complications during training. Exercise tolerance increased in the trained group from 104 to 122 ($p < 0.001$) and 111 watts ($p < 0.05$) after 3 and 12 months respectively. The corresponding values were 102, 105 and 105 watts among controls (ns). Parameters as quality of life, self-estimated level of physical activity, fitness and wellbeing were graded higher by the trained patients than those who served as controls at the two occasions of follow-up.

Conclusion: Organised aerobic group-training of elderly patients recovering from an acute coronary event has significant effects on physical fitness as well as self-reported health-related quality of life one year after discharge. Great care has to be taken to preserve the initial effects by continued training.

P1657 Effects of long-term exercise training in female cardiac patients aged 40–69 years

L.F. Hamm, T. Kavanagh, D.J. Mertens, J. Kennedy. *Toronto Rehabilitation Centre, Toronto ON, Canada*

Women have traditionally been under-referred to cardiac rehabilitation services and under-represented in cardiac research. This study examined the physiologic response of selected variables in 330 women between the ages of 40 and 69 years referred for outpatient cardiac rehabilitation. Variables were measured during cardiopulmonary exercise assessment using cycle ergometry at entry (A1) and after 12 months of participation (A2) in a walk/jog exercise rehabilitation programme following MI, CABG or PTCA. For analysis purposes, the women were grouped into decades of age, as indicated.

Results:

Variable	40–49 yrs (n = 43) Δ%	50–59 yrs (n = 116) Δ%	60–69 yrs (n = 171) Δ%
HR_{rest}	−6.4**	−5.7**	−3.8**
SBP_{rest}	−1.2	+1.5	+2.5*
DBP_{rest}	−1.7	−2.1	−2.6*
RPP_{200}	−9.8**	−6.8**	−3.4
HR_{peak}	+2.1	+1.6	+4.1***
Kpm $min^{-1}{}_{peak}$	+18.4***	+15.9***	+12.7***
$\dot{V}O_{2peak}$ (mL kg^{-1} min^{-1})	+5.4*	+10.1***	+8.3***
$\dot{V}O_{2peak}$ (L min^{-1})	+8.7***	+12.0***	+8.4***
RER_{peak}	+1.3	+3.6**	+6.4***
$\dot{V}_E$ (L min^{-1})	+14.2**	+14.9***	+13.7***

*$p < 0.05$; **$p < 0.001$; A2 vs. A1 within groups.

Conclusions: After 12-months of exercise training, these women demonstrated physiologic benefit from long-term exercise training with significant improvements in many cardiorespiratory variables across all 3 decades of age including physical work capacity.

P1658 Predictors of response to exercise training in chronic heart failure

M.C. Iliou, P. Sellier, L. Prunier, J.C. Verdier, O. Charron, J.F. Toussaint. *Department of Cardiac Rehabilitation, Broussais Hospital, Paris, France*

Physical training is an effective strategy to improve exercise tolerance in patients (pts) with chronic heart failure (CHF). Nevertheless, baseline patients factors which determine this beneficial effect are still debated.

In order to assess predictors of response to exercise training in CHF, we included succesive 118 pts (55.6 ± 12.1 years) with radionuclide left ventricular ejection fraction (LVEF) < 0.40 referred for a cardiac rehabilitation program (CRP). Pts were evaluated by clinical examination and symptom limited exercise test with gas analysis before and at the end of CPR. Patients were submited to training program during 23 ± 10 sessions.

Results: The mean improvement of peak VO_2 was 2.6 ± 3.0 ml/kg/mn (+19%), and of VO_2 at aerobic threshold (98 pts) was 2.2 ± 3.7 ml/kg/mn (+39%). Responders pts were defined by an improvement of VO_2 > 10%.

	Responders (n = 70)	Non responders (n = 48)	p
Age (years)*	56.0 ± 11.9	55.0 ± 12.4	NS
NYHA class*	2.20 ± 0.8	2.26 ± 0.8	NS
LVEF (%)*	26.0 ± 7.5	24.9 ± 7.6	NS
Peak VO_2 (ml/kg/mn)*	16.8 ± 3.8	19.5 ± 6.5	0.005
Peak VO_2/theoretical VO_2*	0.60 ± 0.13	0.71 ± 0.21	0.001
Compliance (%)	84.5 ± 12.7	78.7 ± 17.2	0.04

(*: baseline characteristics).

In multivariate analysis initial VO_2 and compliance are statistically ($p < 0.05$) related to post CRP improvement of VO_2.

In Conclusion, clinical status and LVEF cannot predict response to exercise training. Significant improvement of exercise tolerance in CHF is correlated with a low exercise capacity before training. Higher compliance to CRP improve the results. Patients with CHF and very low exercise capacity are target candidates for exercise training.

P1659 Combined maximal O_2-pulse and heart rate by cardiopulmonary exercise testing and ^{99m}Tc sestamibi myocardial imaging in evaluation of ischaemia in trained and untrained patients with coronary artery disease

E. Klainman[1,2], J. Lebzelter[1,2], G. Fink[2], M.R. Kramer[2]. [1]*Mishmar Hayarden Cardiac & Rehabilitation Institute, Givatayim;* [2]*Exercise Physiology Unit, Pulmonology Institute, Rabin Medical center, Petach Tiqva, Israel*

The effect of controlled exercise training in patients (pts) with coronary artery disease (CAD) is well known. The aim of the study was to evaluate and compare the ischemic degree in controlled trained vs untrained pts with documented CAD by ^{99m}TC Sestamibi myocardial perfusion imaging (MIBI-SPECT) while assessing the contribution of maximal oxygen pulse (O_2P) along with the maximal heart rate (HR) achieved during exercise by cardiopulmonary exercise test (CPET).

Methods: Forty-four male pts, aged 40–83 years, with recent angiogram underwent a MIBI-SPECT and CPET using one exercise test for both studies. Pts were divided into 3 aged matched groups: I: n = 9; normal angiogram; control group. II: n = 20; 1–3 vessel disease in angiogram; untrained group; and III: n = 15; 1–3 vessel disease in angiogram; trained group for 3–6 months by HR at the ventilatory anaerobic threshold. The degree of ischemia by MIBI-SPECT was scored as follows: 0-no ischemia; 1-mild; 2-moderate; 3-severe reversible ischemia.

Results:

	I	II	III
N°. occluded vessels	0	1.95 ± 0.83	1.93 ± 0.85
Ischemic degree	0	1.79 ± 0.95***	0.8 ± 0.65
VO_2max (ml/min)	2171 ± 536*	1608 ± 296***	1989 ± 422
O_2Pmax (% of predicted)	125 ± 24*	94 ± 11***	139 ± 29
HRmax (% of predicted)	89 ± 7**	84 ± 9***	70 ± 11

*p < 0.01 group I vs group II; **p < 0.01 group I vs group III; ***p < 0.01 group II vs group III; all values = mean ± SD.

Conclusion: Controlled exercise training in CAD pts reduces significantly the degree of ischemia at maximal achieved exercise testing probably by the improvement in maximal O_2P (related to stroke volume) along with significantly lower maximal HR but with significantly higher VO_2 max (HR × O_2P). Such an exercise training effect is considered energetically metabolic efficient for the myocardium and may explain the significant decrease of ischemic response in the trained CAD pts.

COMPUTERS IN CARDIOLOGY: INTERNET APPLICATIONS

P1660 Remote access to medical records via the Internet: is it feasible?

P.J. Lees, C.E. Chronaki[1], E.N. Simantirakis, M. Tsiknakis[1], S.C. Orphanoudakis[1], P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete;* [1]*CMI-HTA, Institute of Computer Science, FORTH, Heraklion, Crete, Greece*

This study investigated the feasibility of using Internet technology to provide access to our department's computerised medical records. The purpose of this was twofold: to share data with other departments within the same institution and to allow physicians in other regions or countries to see the clinical data of patients of theirs who may have been treated in our cardiology clinic. The study was part of a larger project to create virtual electronic healthcare records for patients on the island of Crete.

Methods: A flexible approach was chosen, designed to take full advantage of the existing database system, while retaining compatibility with available Internet software and avoiding the need for a specific computing environment on the part of the remote user. The database package employed extracts information from patients' data archives and uses it to create a hierarchical tree of linked temporary files that may be viewed using Internet browser software. These "web pages" can contain not only textual information but also digital and image data, such as ECG recordings. For security reasons, the temporary files are deleted once the transaction is completed.

Results: The above approach has led to the development of a fully functional system, which allows easy and rapid access to medical data by authorised users, through an Internet connection employing a variety of computer platforms. A demonstration version, using fictitious data, can be seen on the Internet at http://lorien.ics.forth.gr:8080/cardioS, or http://cardio.med.uch.gr/DBdemo.

Conclusions: The use of the Internet for remote access to medical records is feasible and is a useful step towards the realisation of the virtual electronic healthcare record.

P1661 A web-based multicenter multitrial coordination service

W.R.M. Dassen, C. Bonnemayer, G. de Steur[1], W.A. Dijk[1], H. Spruijt[1], M. Baljon[1]. *Department of Cardiology, Maastricht University, Maastricht;* [1]*Cadans, ICIN, Utrecht, Netherlands*

Multi-center clinical trials require a reliable communication between participating hospitals and the coordinating center. The Internet could form the ideal medium, provided the security and integrity of data could be guaranteed. To evaluate the application of the Internet for data collection in a multicenter trial, involving percutaneous transluminal myocardial revascularization using a laser catheter, a webserver was created outside the hospital's firewall. Centers participating in this trial received a unique username and password, required to access the home page of the multicenter trial coordination center, which was protected using HTAccess software. Although this webserver currently is able of maintaining a number of trial simultaneously, the username/password combination will limit access to those pages related to the specific trial. In the above-mentioned revascularization trial a questionnaire per intervention was presented, that could be filled out by the participating investigator. After completion of the form the answers were encrypted and sent to the coordinating center by e-mail. For encryption a Java applet for the Complete Columnar cipher method was used with a key provided to the investigator together with the experimental laser catheter. In a second clinical trial, performed simultaneously on this webserver, Pretty Good Privacy (an implementation of the RSA algorithm) was used as encryption tool with one public key per participating center. Due to legal regulations only 512 bit keys could be generated. An advantage of the RSA algorithm is formed by the possibility to create digital signatures or fingerprints offering more security about the sending center. In the near future this web based multicenter multitrial data server will migrate to Secure Socket Layer as the platform for data communication, based on a Trusted Third Party. However, this will require that both the coordinating center as well as all participating investigators obtain a class-3 certificate from a Certificate Authority to be able to participate in such web based clinical trials. For hospitals without such a certificate alternative modes of communication should remain available.

P1662 A web-based cardiology tutor incorporating dynamic hypertext mark-up language

G.J. Blake, M. Schranz[1], D.R. Powell[2], D.D. Sugrue[3], M.A. Blake[4]. *Cardiovascular division, Brigham and Women's Hospital, Boston MA, USA;* [1]*Saint Vincent's Hospital, Dublin, Ireland;* [2]*Massachusetts General Hospital, Boston MA, USA;* [3]*Mater Misericordiae Hospital, Dublin, Ireland*[4]*Boston Medical Center, Boston MA, USA*

Purpose: Recent advances in internet technology provide exciting opportunities for computer-based cardiology education. An assessment-linked cardiology multiple choice question (MCQ) tutor was created that is web-based and also fully reproducible on CD-ROM. The tutor utilises dynamic Hypertext Mark-up Language (HTML) to optimise interactivity with the user and is rapidly accessible from any internet-connected computer.

Methods: A randomly accessible bank of cardiology MCQs, categorised according to subspecialty was created. The pool of questions was derived from standard textbooks and recent articles in major journals such as the European Heart Journal, Circulation, and the New England Journal of Medicine. The tutor was designed to be an up-to-date, dynamic teaching aid for cardiologists and cardiologists in training. It avails of the latest internet technology to provide an instantly responsive and dynamic system. Javascript, a powerful scripting language is integrated with dynamic HTML to enhance the speed and interactivity of the teaching aid. It automatically adapts itself to the level of expertise of the user. The answers include detailed explanations and are widely referenced and linked to relevant articles on the web. Images are used extensively to complement the information provided and image-mapping further enhances the interaction between the user and the tutor.

Results and conclusion: A web-based cardiology tutor is presented that is universally accessible and personalised in an innovative fashion to the user. Utilising Javascript and dynamic HTML, it provides an up-to-date, dynamic teaching aid in cardiovascular disease.

P1663 Remote access to medical records via the internet: how to solve the language problem?

P.J. Lees, C.E. Chronaki[1], E.N. Simantirakis, S.G. Kostomanolakis[1], P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete; [1]CMI-HTA, Institute of Computer Science, FORTH, Heraklion, Crete, Greece*

The purpose of this study was to investigate the possibility of allowing physicians in other countries to access our department's computerised medical records relating to their patients. Since this hospital is in a touristic region, a significant number of foreign patients are treated in our cardiology clinic. The study was part of a larger project to create virtual electronic healthcare records for patients on the island of Crete.

Methods: A system we have developed uses information from patients' medical records to create temporary files that may be viewed by an Internet browser. An authorised user may view the information not only in Greek, the language in which the data are stored, but also in English, through an automated translation process. This is accomplished by means of a system of lookup tables which contain the equivalent terms for, say, cardiological diagnoses in both languages. This has the advantages that other languages can easily be added if necessary and that existing or future codification systems may be freely incorporated into the design. Names, addresses, etc., are transliterated from the Greek to the Latin alphabet using a specially created algorithm.

Results: The system as designed successfully displays a patient's medical data in either Greek or English, according to the user's choice, without a significant delay. A demonstration version, using fictitious data, can be seen on the Internet at http://lorien.ics.forth.gr:8080/cardioS, or at http://cardio.med.uch.gr/DBdemo.

Conclusions: Access to medical records across national boundaries can be hampered by language differences. We believe that the data translation system we have developed is a step towards solving this problem and making it possible to use the Internet for access to medical records on an international level.

P1664 CARDIOnet program, education – information program in cardiovascular medicine on Internet

D.Z.E. Rezakovic, A. Stipic. *Editorial Office, Cardionet Programme, Zagreb, Croatia*

Cardiovascular diseases are leading health problem in most countries. In developing countries, there has been an epidemiological transition from infectious diseases to cardiovascular diseases. Modern cardiology requires continuing education. Internet offers a lot of cardiology sites, but numerous programs cannot help in systematic, update and standardized education.

CARDIOnet Program has been developed as an international education – information program on Internet in cardiovascular medicine for cardiologists, especially for the countries where continuing education is missing.

The program has its own Internet computer center and developed original software for administration of documents and data bases. It is dynamic interactive program supported by data bases. Searching through data bases and documents is structured by Microsoft SQL Server and Microsoft Index Server. System is based on combined Microsoft NT and Unix platform.

CARDIOnet consists of Journal and Exhibition. CARDIOnet Journal presents educational topic volumes with 2,500 pages on Feb. 1999. Editorial policy is to present state-of-the art topic volumes in an outline, lecture-like presentation, extensively illustrated, with figure magnifications, large number of the links and prepared indexes (Authors Index, Key Word Index, Subject Index, Equipment Company Index, Trial Index, etc.) for rapid and easy navigation through texts.

CARDIOnet Exhibition (2,000 pages) has the goal to present various bussiness information (medical-scientific institutions, bibliography, publishers, meetings, government-non government organizations, associations, fairs, drug-equipment companies, etc.). The content has a standard format of presentation, making easy insight and navigation. Address Directory is suported by data bases with 800 addresses in 28 activity and 150 categories.

Program has free acess, with 20,000 registered users from 64 countries since Sep. 1997 to Feb. 1999. CARDIOnet proved to be helpful and practical site for update cardiology education.

COMPUTERS IN CARDIOLOGY: IMAGE PROCESSING

P1665 Comparison of two- and three-dimensional image reconstruction methods for the non-invasive visualization of coronary artery stenoses by contrast-enhanced electron-beam computed tomography

S. Achenbach, D. Ropers, W. Moshage, W.G. Daniel. *Department of Internal Medicine II (Cardiology), University of Erlangen-Nuremberg, Germany*

Electron beam computed tomography (EBCT) has been shown to permit non-invasive visualization of coronary artery stenoses after intravenous injection of contrast agent. Several forms of 2- and 3-dimensional image reconstruction can been applied, they have so far not been comparatively assessed concerning their ability to visualize coronary artery stenoses.

Methods: In 40 patients investigated by EBCT, 40 to 50 axial cross-sections of the heart were acquired after intravenous injection of contrast agent (3 mm slice thickness, 2 mm table feed). Next to evaluation of the original transaxial cross-sections (source images), 2-dimensional reconstructions (maximum intensity projextion [MIP] and curved multiplanar reconstruction [MPR]) as well as 3-dimensional shaded surface display reconstructions (SSD) were independently assessed concerning the presence of high-grade stenoses and occlusions in the mid and proximal segments of the coronary arteries. Results were compared to invasive coronary angiography in a blinded fashion.

Results: A total of 34 high-grade stenoses were present in the investigated patients. If all forms of reconstructions were jointly evaluated, sensitivity of EBCT was 92%, and specificity was 94%, while 22% of all coronary segments could not be assessed due to impaired image quality:

	Sensitivity	Specificity	Evaluation impossible
Source Images	91% (21/23)	93% (96/103)	21% (34/160)
SSD	58% (15/26)	95% (100/105)	18% (29/160)
MIP	92% (22/24)	90% (96/107)	18% (29/160)
MPR	81% (17/21)	88% (94/107)	20% (32/160)
Joint evaluation	92% (22/24)	94% (95/101)	22% (35/160)

In conclusion, analysis of the unprocessed source images seems to be sufficient for evaluation of contrast-enhanced EBCT data sets of the coronary arteries. Of the available image reconstruction methods, maximum intensity projections yield the highest accuracy.

P1666 A comparison of echocardiographic findings using videotape and digital recording compressed by MPEG (moving picture expert group)-2

M. Nasu, H. Kamata, Y. Sato, K. Hiramori, H. Niinuma. *Second Department of Internal Medicine, Iwate Medical University, Morioka, Japan*

Background: To utilize moving images (angiogram and echocardiogram) on inter-and intra-hospital computer networks, we have developed a multi-modality digitized moving picture central archiving system. Echocardiographic moving images are compressed by MPEG-2 encoder and sent to the center server via the Fibre Channel (sustained data rate = 26.6 megabyte/sec). We evaluated echocardiographic findings on videotapes and this digitized system.

Methods: Thirty patients underwent echocardiography using Sonos 5500 (Hewllet Pacard), Sequoia C256 (Acuson), SSA 370 (Toshiba) and SSD5500 (Aloka). Two-dimensional (2D) and M-mode (M) Echocardiographic moving images were recorded into S-VHS tape and sent to the central server simultaneously. All digital echocardiograms were analyzed blindly. We compared the parameters as following; wall motion score (WMS) according to American society of echocardiography, end-diastolic left ventricular major and minor axial dimension (LVMD and LVmD) at apical four-chamber view, intraventricular septum thickness (IVST), end-diastolic and end-systolic left ventricular dimension (EDD and ESD) obtained from M mode echocardiography between analogue data from videotape (AG) and digital data from central server (MPEG-2).

Results: WMS obtained from MPEG-2 agreed well with that from AG ($R = 0.998$, $p < 0.0001$). The parameters measured by M and 2D obtained from MPEG-2 also agreed with those from AG. The mean difference between AG and MPEG-2 was greater in 2D measurement than in M measurement.

Correlation between AG and MPEG-2

Measurements	LVMD (mm)	LVmD (mm)	IVST (mm)	EDD (mm)	ESD (mm)
AG	73.5 ± 9.8	40.6 ± 10.6	12.7 ± 3.5	48.4 ± 9.4	30.9 ± 8.6
MPEG-2	75.0 ± 10.6	43.2 ± 13.6	12.4 ± 3.8	47.9 ± 10.1	30.0 ± 9.4
Mean difference	1.0 ± 2.5	2.6 ± 6.6	−0.3 ± 1.1	−0.7 ± 2.9	0.0 ± 1.5
Correlation	0.969	0.891	0.953	0.959	0.988
p value	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001

Conclusions: Digital recording compressed by MPEG-2 is suitable for echocardiographic measurements in clinical setting.

P1667 A novel method to validate true 3-dimensional imaging of the coronary artery lumen

S. Eccleshall, N.P. Buller, J.N. Townend, E. Claridge[1]. *Cardiology Dept, QE hospital, Birmingham; [1]School of Computer Sciences, University of Birmingham, Birmingham, UK*

Three-dimensional imaging of the coronary artery lumen would be of value in the assessment and treatment of coronary artery disease. We are investigating the utility of a lesion moulding balloon catheter, which provides a 3-D luminal mould. In order to study this method in post-mortem and animal work we have developed a computer based technique to allow comparison of the balloon mould with a luminal cast.

Method: The technique was validated using a selection of straight and curved guiding catheters and sheaths of known diameters (1.96–3.63 mm) and radii of curvature. The objects were vertically mounted in a stand, designed to rotate by 22.5 degrees per turn, to give 9 views (0–180). Each image was captured with a CCD camera (JVC KY-F55B) and digitising board (Snapper) onto a computer (Sun Ultra-5), and spatially calibrated at a resolution of 0.135 millimetres per pixel. Brightness thresholding of the image was performed to identify the image edges. This information was then used to reconstruct true 3-D co-ordinates of 16 points on the perimeter of each horizontal cross-section. The orthogonal diameters (D), orthogonal cross-sectional areas (XSA), volume, centreline co-ordinates and centreline curvatures were calculated from this data, and compared with the known values. Reconstructed 3-D shapes may be viewed in any orientation.

Results: The technique takes approximately 20 seconds to analyse 1 object. The correlation coefficient (r) for the measurement of curvature was 0.99.

Results Table

	A	P	E
D (mm)	−0.01	0.10	0.07
XSA (mm sq)	−0.26	0.34	0.29

The accuracy (A (mean signed difference)), precision (P (1SD of A)) and the absolute error (E (unsigned mean difference)) of these validation studies are shown in the table.

In conclusion, we have developed a fast, accurate method of 3-D imaging and analysis of luminal casts. This method describes the true 3-D co-ordinates of the lumen border, centreline, and measures curvature of the centreline, and would therefore be an appropriate "gold standard" to use in validation studies of 3-D coronary artery imaging.

P1668 Mean echocardiographic intensity must be integrated by other grey level distribution features to characterise myocardial structure of hypertensive patients

M.A. Morales, E.M. Ferdeghini[1], M. Piacenti. *Cardiology Dept, CNR Clinical Physiology Institute, Pisa; [1]BIEIC, CNR Clinical Physiology Institute, Pisa, Italy*

So far, most of the studies on myocardial structure by 2D echocardiography have been based on the assessment of mean myocardial echo intensity (MEI) and on its systo-diastolic cyclic variations (CV). Despite disproportionate connective tissue growth which can occur in the myocardium of hypertensives (HT), studies performed on HT have failed to show differences in MEI and its CV, when compared to normal subjects. The aim of the present study was to evaluate whether statistical analysis of 2D echo grey level distribution may provide further parameters able to characterise myocardial structure in HT patients. Thirty-one uncomplicated essential HT with mild LV hypertrophy were studied; thirty-three age and sex-matched normotensive subjects were the control group (NL). Settings of the echoscanner were fixed and kept constant throughout all the recordings. Images, frozen on the echoscanner at end-diastole in the 4 chamber apical approach to obtain the best view of the iv septum, were digitised and converted in matrices of 256*256 pixels. A region of interest of 15*15 pixels was drawn inside the iv septum for the subsequent analysis. After first order statistical analysis to quantitatively describe the shape of the echo-generated grey level amplitude distribution, the following parameters were obtained: mean (index of overall echo intensity of the image), uniformity (index of tonal homogeneity) and entropy (the disorder of the grey level distribution)

Results: LV myocardium of HT showed an echo intensity comparable to that of NL (mean: 73 ± 16 vs. 71 ± 16); on the contrary HT showed an evident tonal inhomogeneity (uniformity: 0.016 ± 0.003 vs. 0.018 ± 0.004, p = 0.02) associated to a greater disorder in the grey level distribution (entropy: 4.4 ± 0.2 vs. 4.1 ± 0.2, p = 0.02). In conclusion, the recognition of this peculiar histologic condition by quantitative analysis of 2D echocardiograms needs to integrate the mean intensity by parameters related to tonal homogeneity and disorder.

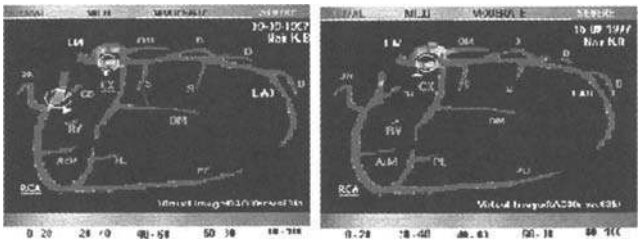
P1669 Realistic geometry cartographic imaging in evaluating patients with coronary artery disease – during pre and post intervention phase

A.G. Ravikishore, R.V. Kumar[1], P. Kumar, K.K. Tripathi[2], S. Chandra. *Cardiology Dept., Manipal Heart Foundation, Bangalore; [1]Medical Engineering, Scalene Research, Bangalore; [2]Aerospace Medicine, Defence Bioengg. & Electromed. Lab., Bangalore, India*

Based on a realistic geometry coronary artery model (RGCAM), we proposed an approach to localise abstraction in different coronary artery branches. Using kinetic modeling (k-model), we get disease dependant cartogram of cardiac haemodynamic variability. The beat-to-beat haemodynamic variability behavior, its deviation difference and correlation was calculated and a three-dimensional (3D) array was constructed and embedded on a RGCAM. The resultant images are the realistic geometry cartographic image (RGC-Imaging) representing coronary artery stenosis. This study was to assess the feasibility of using such RGC-Imaging technique in evaluating patients with coronary artery disease, during pre and post intervention phase.

Methods: Using the signals obtained and by real time simulation of the data thereof, 33,600 coronary unit three-dimensional array was generated in 8 patients (all male). The array was then embedded into the RGCAM, obtaining a realistic geometry two dimensional view in the classic LAO and RAO projection with the chosen angulation of 60 and 30 degrees respectively.

Results: All the 8 RGC-Imaging showed that the intervened vessels had reduced or no disease after intervention.



Pre and Post Intervention RGC-Images.

In conclusion: Our Modeling and Imaging studies have shown its potential in using haemodynamic variability realistic geometry cartographic Imaging techniques to assess patients during pre and post intervention phases. As the data of model simulation and reconstruction may pose some errors from the real one, the results may still be needed to be confirmed in mega clinical trials.

COMPUTERS IN CARDIOLOGY: DATABASES/DICOM

P1670 Integration of different cardiology information sources into an electronic patient record: the need for a central hospital-wide index repository

E.T. van der Velde, G. de Steur, A. Kleijhorst, P.J. Voogd, J.W. Jukema, M.J. Schalij, M.H. Baljon[1]. *Cardiology Dept., Leiden University Medical Center, Leiden; [1]Inter University Cardiology Institute, Utrecht, Netherlands*

Background: Medical review stations (MRS) available in the clinic and outpatient clinic allow access to data from the Hospital Info System (HIS). In order to access data stored in a local Cardiology Information System (CIS) (cathlab reports, echolab reports, ECG's, images) from the HIS-MRS, the present functionality needs to be extended. An important aspect of this is the need for an index database where the MRS can find which information in a local CIS is available for a specific patient.

Methods and results: In our depatment, all information about cathlab studies performed is stored in a self-developed CIS ("CARIS"), based on a traditional client/server architecture. When a cathlab study has been finished and authorized, the CARIS system sends a HL7 message with index information about the study (patient ID, study date and time, procedures performed, etc) to a central HIS repository. An Integration Engine (CAI-TDM) translates the index information from CARIS and forwards it to the HIS. With this information, the HIS-MRS can display the index items to the cardiologist. Then, by launching the CARIS client application from the MRS, a full-disclosure view on all cathlab data can be achieved. The X-ray images acquired in the cathlab are stored on a local image server. The images can be viewed on the MRS using a dedicated DICOM viewer application. Information about the available images, and the images themselves can be retrieved by the MRS via the DICOM query/retrieve (Q/R) protocol.

Presently, integration in the MRS of echolab reports and ECG's is being implemented. In the same fashion as for the cathlab data, index information will be stored in a central repository. However, the index repository will be stored on a system outside the HIS database, allowing easier implementation and modification. Access to echolab reports and ECG's is possible using a standard web-browser interface, which allows the cardiologist to experience the benefits (and drawbacks) of an universal HTML browser compared to a traditional dedicated client application.

Conclusion: The approach resulted in a robust and powerful application that provides integrated access to patient information from different sources. A central index repository is crucial for the MRS to know which information is available and where it is stored. In the future, this database might be implemented as a virtual repository, with the MRS querying the local information systems via the hospital network for all information of interest, comparable to the DICOM Q/R protocol.

P1671 Deficard – a new concept of patient management after ICD-implantation

M. Achtelik, H.J. Trappe, P. Wenzlaff. *Cardiology and Angiology Dept., University Hospital Bochum, Herne, Germany*

Background: Due to an increased number of patients receiving ICD therapy patient management and the control of patient and device realted data will become difficult. To improve patient management the DEFICARD concept was introduced in clinical cardiology. This concept consists of a database on a personal computer and a multifunctional chip card that is carried by the patient. In our phase-1 study we have followed 102 patients (pts.), mean age 57 + 11 years, after ICD implantation. The acceptance of the DEFICARD was extremely high (98%).

Results: Patients attended the outpatient clinic every two months. The DEFICARD reduced the visit significantly from 45 + 20 minutes to 23 + 12 minutes ($p < 0.05$). All data were stored and reevaluated on the card and, therefore, relevant up-to-date information was always available about the ICD and the state of health of the patients. According to our phase-2 protocol we have invited 3 additional hospitals to participate in the DEFICARD project. We will study the cooperation in patient management between our hospital and these referring centers.

Conclusion: The DEFICARD has proven suitable for all pts. after ICD implantation. It reduces the time needed in the outpatient clinic and thereby costs when treating pts. with implanted cardioverter-defibrillators.

P1672 Cardiac image communication based on the DICOM application profile: comparison with new options for lossless and lossy image data compression

R. Brennecke, U. Bürgel, F. Post, H.-J. Rupprecht, J. Meyer. *II. Medical Clinic, Johannes-Gutenberg-University, Mainz, Germany*

Background: The DICOM XA (x-ray angiographic) standard for coronary angiography allows for only one mode of lossless data compression. Advanced lossless methods or 'clinically lossless' compression may offer higher compression ratios (CR), thus potentially reducing the communication and archiving problems.

Methods: 75 difficult cases were selected from the 520 digital cine runs collected for the recent ACC/ ESC compression viability study (CVS). They were rated (scale with 5 quality scores) by 13 clinical experts from Europe and the US using a side-by-side display (fixed contrast and brightness settings) of uncompressed and compressed (JPEG6: lossy JPEG at CR = 6) cine runs. The same 75 cine runs were also compressed with lossless methods: lossless JPEG with Predictor 1 (LJPEG1, as applied in DICOM) and Predictor 7 (LJPEG7), LS-JPEG (LOCO, presumably successor for LJPEG), lossless Wavelet (LWAVE from the SPIHT algorithm) and with PNG using freely available compression software on an UltraSparc computer.

Results: The 13 reviewers considered the images compressed with lossy JPEG6 to be indiscernible from non-compressed cine runs in 78.5% of the cases and to be different, but fully equivalent in 20.9%. The remaining 0.6% (2/325) showed larger aesthetic quality differences, but still no diagnostic errors were detected. Lossy JPEG6 compression (CR = 6) is therefore regarded as 'near-lossless'. For the lossless methods, the compression ratios CR for the 75 cine runs were:

Method	LJPEG1	LJPEG7	LOCO	LWAV	PNG
Mean CR, SD	2.74 ± 0.40	2.90 ± 0.40	3.80 ± 0.81	3.56 ± 0.55	2.70 ± 0.34
Max CR	3.96	4.02	5.79	4.87	3.66
Min CR	2.01	2.13	2.41	2.38	2.10
CTIME (sec)	0.7/0.6	0.8/.0.6	0.2/0.2	1.1/1.2	1.0/0.3

where SD is the standard deviation of the mean and CTIME is time for compression/ decompression (derived for the image with maximum entropy).

Conclusion: Near-lossless image compression (JPEG6) provides compression up to CR = 6 or 7. This is an improvement by a factor of about 3 over the present DICOM standard (LJPEG1) and of about 2 over the best lossless method (LOCO).

P1673 A digital echo laboratory: clinical application of the DICOM standard

G. Belotti, A. Fedele, C. Poluzzi, C. Gatti, A. Locatelli, G. Penati, P. Negrini, G. Tommasini. *Cardiology Department, Ospedale di Treviglio, Treviglio, Italy*

A digital echo laboratory according to Feigenbaum's suggestions has been implemented. For each study, ten at least ECG-synchronized standard projections are acquired over a single cardiac cycle on a HP Sonos 2000 and recorded on magneto-optical (MO) disc. A dedicated software was developed in order to 1) review the sequences from the MO disc on a standard PC, 2) convert the files from HP TIFF proprietary format to DICOM format, 3) masterize a multisession DICOM CD-R, 4) Review the sequences from the CD-R on a standard PC. Using standard RLE lossless compression, real time playback of full resolution echo color images can be obtained on a Pentium II, 266 MHz with 32 Mb RAM and CD to DMA capabilities.

Two kinds of digital archives are used. A sequential digital archive, maintaining the HP proprietary format, is obtained by file copy of the magneto-optical disc to the CD-R. This kind of storage permits review of echo loops on a PC-based workstation as well as reversal to MO-disc for visualization on the echo machine. The second archive consists of multisession DICOM CD containing the echo history of the individual patient as well as an autoinstalling copy of the viewer program. Average time for recording and labeling images for each examination on MO was 125 + 30 sec. Average time for retrieval, display of all sequences, thorough review of the study for final diagnosis, on CD or MO for each study were calculated and compared to VHS:

	CD or MO	VHS
Retrieval (sec)	19 + 4	145 + 65
Display (sec)	155 + 47	187 + 72
Review (sec)	181 + 52	424 + 98

In conclusion, this new technique of storage make the management and consultation of the obtained archives more rapid, resulting in substantial saving of time. Furthermore, our digital archives allow all physicians in the ward to substitute conventional static photographs with the direct view of the echo sequences on the PC, with improved perception of patient's condition and a positive cultural impact.

P1674 Computer-aided quality control, documentation, result, and report generation and education in echocardiography

M. Claus, K. Kronberg, G.-H. Reil, P. Jensch[1]. *Klinik für Innere Medizin I, Kardiologie, Städtische Kliniken Oldenburg; [1]Fachbereich 10-Informatik, Carl v. Ossietzky Universität Oldenburg, Germany*

The growing number of echocardiographic examinations called for the development of a system generating Documentation and Reports (Transthoracal, Transoesophageal, and Stress Echo). The program we developed eventually contained additional features allowing Quality Control and Training.

Methods: The development is based on the following publications in echocardiography:

- ACC/AHA Guidelines for the Clinical Application of Echocardiography
- German Quality Guidelines (Deutsche Gesellschaft für Kardiologie)
- A number of standard textbooks.

The program contains the following characteristic features:

- Graphic User Interface with anatomical objects for fast and easy data aquisition.
- Automatic generation of reports and results based on standardised expressions in Echocardiography without the need for dictation
- Plausibility Checks of data entered
- (d) On-line access to a knowledge base of more than 500 examples, clinical, images, tables, and cine loops.
- Important echocardiographic websites (off-line mirrored on a server)
- Export of HTML-stylesheets for presentation of statistics on the web
- Part of the medical and economical documention system of the "Oldenburg Heart Centre".

The software was developed using ORACLE®'s developer 2000 and runs under Windows NT 4.0 and Windows 9x. It is based on a Client-Server architecture with an ORACLE® 8 database and can be used in networks of any size.

Conclusion: The practical application of the program led to an increase in time saved and a more accurate interpretation and documentation of echocardiographic examinations. As a further development storage and retrieval of DICOM images were tested.

P1675 Quality control using automated validation tools can improve interoperability of DICOM implementations

Maarten H. Baljon[1], Maarten G. Gerritsen[1], Marco Eichelberg[2], Peter Jensch[2]. *[1]ICIN, Interuniversity Cardiology Institute of the Netherlands, Utrecht, Netherlands; [2]OFFIS, R & D Institute for Computer Science Tools and Systems, Oldenburg, Germany*

Background: The overwhelming success of the acceptance of the DICOM standard by industry and the cardiology users has brought to the market many devices that are sold as being DICOM conformant. In practice interoperability between different DICOM devices is not always accomplished easily and/or completely.

Methods: Implementations of cardiac X-ray Angio DICOM data-sets on CD-R from 10 vendors were tested by 2 DICOM validation applications: (a) a checker that checks the conformance taking into account conditional rules and value domains to which data elements are restricted; (b) an application profiler to define Application Profiles and to check conformance to the defined Application Profiles. 5 DICOM CD-R viewers were used to see whether interoperability for viewing purposes did correlate with the results of the validation programs.

Results: Only 2 out of 10 tested implementations turned out to deliver data-sets on CD-R that were fully in conformance with the DICOM standard. The other 8 implementations contained errors that ranged from minor to major disrespect of the DICOM rules. The viewer interoperability test showed a high correlation with our validation results: For the 3 CD-R's that contained most serious errors most viewers were not able to show the images the way they should be shown.

Conclusion: Vendors' claims to be fully DICOM compliant could not all be sustained when the CD-R data sets were checked thoroughly. This undesirable situation may be improved significantly if proper DICOM validation tools will be used during DICOM application development. DICOM's chances for reaching device interoperability will be greatly increased if this approach is strictly adhered to.

P1676 Analysis of reproducibility of measurements of regional and global left ventricular function using quantitative digital contrast ventriculography

F. Philippot, J. Lipiecki, V. Boulet, E. Albuisson[1], H. Mansour, N. Durel, O. de Tauriac, B. Citron, F. Sheehan[2], J. Ponsonnaille. *Department of Cardiology, University Hospital, Clermont-Ferrand; [1]Department of Statistics, University Hospital, Clermont-Ferrand, France; [2]University of Washington, Seattle, WA, USA*

The aim of this study was to determine the variability (interstudy, intra- and interobserver) of measuring LV volume and function from contrast ventriculograms recorded on DICOM compact discs (CD).

Methods: 16 patients with stable ischemic heart disease and a history of an old myocardial infarction underwent two ventriculography performed using the same catheterization and imaging procedures. The images were recorded on the CD and analysed twice by two independent observers using commercial software (Sanders Data System. End diastolic (EDV), end systolic (ESV) and stroke (SV) volumes and ejection fraction (EF) were determined by the area length method. The severity of hypokinesis (HypoK) in the territory of culprit artery and of hyperkinesis in the opposite region (HyperK), and the percentage of chords with motion < -2 SD (%HypoK), and with akinesis and dyskinesis (%AK) were calculated using the centerline method.

Results: the intra and interobserver variability for all parameters was very small with correlation coefficient $r > 0.87$ ($p < 0.0001$) excepted HyperK with $r = 0.73$ ($p = 0.002$). Inter study variability are as follow:

	EDV	ESV	SV	EF	HypoK	HyperK	%HypoK	%Ak
r	0.82	0.78	0.86	0.83	0.90	0.53	0.82	0.84
r^2	0.67	0.61	0.74	0.68	0.81	0.28	0.67	0.71
SEE	1.95	2.77	0.81	1.19	0.12	0.16	1.85	1.06
Cut-off	16.8	18.6	12.3	8.94	0.75	1.35	11.7	5.71

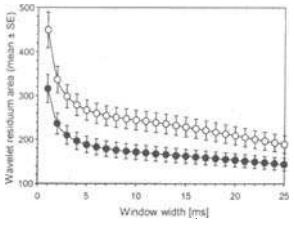
In conclusion: The cut-off values found in this study are larger than those reported for 35 mm cinefilm and should be considered when evaluating serial studies of left ventricular function from DICOM formatted CD's.

COMPUTERS IN CARDIOLOGY: OTHER ASPECTS

P1677 External cardiac modulation: evidence of wedensky phenomenon in healthy subjects and ventricular tachycardia patients

Marek Malik, David G. Benditt, Katerina Hnatkova, Lars Hegrenaes, Stephen J. Ryan, Thomas M. Munger, Nemer Samniah, Jom Bathen, Mark W. Kroll, Harold H. Hoium, Marshall S. Stanton. *Harbinger Medical Inc., Minneapolis MN; University of Minnesota Hospital, Minneapolis MN; St Jude Medical/Daig, Minnetonka MN; Mayo Clinic, Rochester MN, USA; Regional Hospital, Trondheim, Norway; St. George's Hospital Medical School, London, UK*

Subthreshold stimulation without capture reduces the stimulation threshold and changes the action potential of a subsequent suprathreshold stimulation (Wedensky Phenomenon). To investigate this phenomenon after transthoracic subthreshold stimulation (2 ms pulse of 5–40 mA between surface precordial and subscapular patches delivered synchronous with R wave detection), 60 to 200 subthreshold stimulated QRS complexes were signal averaged and compared with the same number of averaged non-stimulated complexes recorded during the same experimental session. The electrocardiographic recordings were obtained with standard orthogonal leads. In order to detect even minor changes within the QRS complex, each lead of both stimulated and unstimulated averaged complexes were wavelet decomposed (53 scales of the Morlet wavelet with central frequencies of 40–250 Hz). The wavelet residuum corresponding to the Wedensky phenomenon was obtained by subtracting the vector magnitude wavelet decomposition of the unstimulated QRS from that of the subthreshold stimulated QRS. The surface area of the residuum was investigated in windows of 1–25 ms following the stimulation. The test was performed in 47 pts with EP inducible ventricular tachycardia (mean age 63 ± 13 years, 83% male) and in 30 healthy controls (mean age 44 ± 16 years, 60% male).



20 mA stimulation (filled circles = VT patients, unfilled circles = control).

The residuum showed an increase in the spectral power of the stimulated complex that was significantly more marked in healthy volunteers ($p < 0.01$) than in VT patients (figure). Thus, Wedensky phenomenon induced by an external subthreshold stimulation can be documented in man and differentiates VT patients from controls.

P1678 Predicting survival in coronary disease: machine-learning computer models versus expert clinicians

D.F. Kong, C.H. Del Carlo, E.L. Eisenstein. *Duke Clinical Research Institute, Durham NC, USA*

Background: To be useful, computer-based algorithms must enhance the experience of human experts. We compared the prognostic ability of artificial neural network, regression tree, and Cox proportional hazards models with that of a panel of 49 cardiologists.

Methods: A series of 2,099 symptomatic, medically treated patients with significant coronary artery disease (75% stenosis of at least one vessel) were identified from the Duke cardiovascular database. Patients were divided into training (n = 1823) and testing (n = 276) subsets. A five-layer, back-propagation neural network and a cross-validated regression tree were fitted against the training set. Predicted probabilities for 3-year survival and 3-year infarct-free survival were collected from 49 cardiologists for patients in the test set. The computer models generated similar predicted probabilities for the test set patients. The C-index (equivalent to the area under a receiver operating characteristic curve) and Spearman rank correlations evaluated each predictor's ability to distinguish patients who had events from those who did not.

Results: For infarction-free survival, each of the computer models had a higher C-index than the cardiologists.

	Survival		Infarction-free Survival	
	C-index	Spearman	C-index	Spearman
Cardiologists	0.76	0.42	0.67	0.28
Regression tree	0.75	0.40	0.72	0.38
Neural network	0.80	0.48	0.73	0.39
Cox model	0.81	0.49	0.73	0.38

Conclusions: Machine learning methods, including neural networks and regression trees, may augment human clinical experience. These methods form the groundwork for future helpful clinical tools.

P1679 Neural networks versus multiple regression models to predict costs of acute myocardial infarction: GUSTO-I

D.F. Kong, C.H. Del Carlo, R.M. Califf, E.L. Eisenstein. *Duke Clinical Research Institute, Durham NC, USA*

Background: Data-mining techniques, including artificial neural networks (NN), offer new tools for understanding hospital costs. This study assessed the ability of NN and multiple linear regression (MR) models to describe hospital costs for patients with acute MI.

Methods: A total of 20,873 U.S. patients from the GUSTO-I study were randomly divided into a training set (n = 15,654) and a test set (n = 5219). Univariate analyses identified 77 candidate variables for use in NN and MR models of log (cost). Back-propagation NN and MR models were fitted against training set subgroups of increasing size, and validated against the test set.

Results: All correlation coefficients were highly significant ($p < 0.001$). Pearson correlation coefficients were similar for the overall models (NN 0.90, MR 0.89). Mean absolute residuals for the NN on the largest training set were comparable to the MR residuals on the smallest training set. Spearman coefficients showed that MR correctly ranked costs better than NN. The overall models results did not differ, by Wilcoxon rank-sum tests ($p = 0.52$).

Training	Mean Absolute Residual		Spearman r_S		Pearson r	
Set (n)	NN	MR	NN	MR	NN	MR
250	0.390	0.209	0.672	0.954	0.694	0.187
500	0.343	0.150	0.793	0.964	0.769	0.890
1000	0.329	0.146	0.794	0.968	0.777	0.833
5000	0.228	0.140	0.910	0.977	0.888	0.653
15,624	0.207	0.131	0.917	0.982	0.904	0.894

Conclusions: Nonparametric methods, such as r_S, may better reflect the performance of log (cost) models. MR techniques may be more parsimonious and efficient for small datasets. With a training set of sufficient size, NN can generate accurate descriptive cost models. This deserves further study.

P1680 Three dimensional echocardiographic data sets registered with a virtual heart model in augmented reality applications

M. Weidenbach, S. Pieper[1], S. Novak, C. Wick[1], W. Gross, D.A. Redel. *Department of Paediatric Cardiology, University of Bonn, Bonn; [1]GMD – National Research Center, Information Technology, St. Augustin, Germany*

Augmented reality applications combine real image data with virtual objects. The necessary spatial and temporal synchrony is achieved by a registration procedure. We evaluated the accuracy of the match of three-dimensional echocardiographic (3DE) data sets registered to a virtual surface model of the heart. The model was designed based on expert knowledge. Its ideal representation of the heart is currently not adapted to individual patient morphology. The augmented reality scenario is used in an echocardiographic training simulator and for orientation in 3D data sets.

Methods: Three dimensional echocardiographic data sets were acquired and postprocessed with a TomTech 3D workstation and a Vingmed System V scanner with integrated 3D capability using a 2.5 MHz transthoracic probe. A rotational stepper motor was used to acquire 3DE data sets with 60–90 scan planes. We categorized the scanned hearts in four groups: normal hearts, volume loaded left ventricles (LV), pressure loaded LV and congenital malformations. A total of 50 data sets with high image quality were analyzed. Registration was performed manually based on anatomical landmarks using the apex of the LV and the centres of the valves. A set of echocardiographic standard views were used for the evaluation. Each view shows the ultrasound image and the analogous model slice superimposed. Accuracy was evaluated measuring the overlap of the mitral-, aortic- and tricuspid valve and the areas of the left and right ventricle in the model and in the echocardiographic images respectively.

Results: The accuracy of registration was dependent on the underlying pathology of the scanned heart, yielding the best results in normal hearts and hearts with minor geometric alterations and worst in hearts with congenital heart diseases. In the latter group a registration was sometimes impossible. Registration was better using widely distributed anatomical landmarks including the left ventricular apex. Thus, data sets acquired by apical scans were more useful than those acquired by parasternal scans.

Conclusion: The result of the registration depends on the underlying pathology of the heart and the possibility to identify widely distributed landmarks in the data set. Currently the augmented reality application is used for navigation and orientation without deriving any diagnostic information from the model itself. The degree of match between the echocardiographic images and the model for this purpose is sufficient.

P1681 Neural network based approach for localization of the origin of ventricular tachycardia from body surface potential mapping

L. Reinhardt, K. Simelius, J. Nenonen, I. Tierala[1], M. Mäkijärvi[1], L. Toivonen[1], T. Katila. *Laboratory of Biomedical Engineering, Helsinki University of Technology, Espoo; [1]Cardiovascular Laboratory, Helsinki University Central Hospital, Helsinki, Finland*

Introduction: Body surface potential mapping (BSPM) data obtained during endocardial stimulation at multiple ventricular pacing sites show a broad spectrum of potential distributions. In this demonstration, BSPM sequences are analysed using a neural network approach based on self-organisation that provides a noninvasive estimation of the site of origin of stimulated ventricular activation. The localisation results are visualized on a realistic model of the endocardial surfaces of the right and left ventricles.

Methods: The Self-Organizing Map (SOM) network used in this study is arranged as a two-dimensional lattice of neurons, each of them representing a particular distribution of body surface potentials. In the initialization phase, a random potential pattern is assigned to each neuron of the SOM. For the training of the SOM network, 123-channel BSPM recordings were obtained from 86 endocardial pacing locations in 19 patients with a previous myocardial infarction. Potential distributions on the body surface from 3 paced ventricular beats for each pacing location were sampled at 5 ms intervals from the beginning to the end of the ventricular activation. Based on this procedure, altogether 8346 instantaneous potential distributions were obtained and subsequently presented to the SOM. During the training phase, the SOM network automatically extracts and organises the most prominent features of the recorded BSPM sequences until a global ordering of the network nodes has been achieved.

Ventricular activation patterns from different pacing sites are visualized as time traces on the trained SOM. Classification of the activation patterns with respect to the endocardial pacing location was performed by Learning Vector Quantization. The output of the classification yields a probability distribution for the localisation of the origin of ventricular activation.

Demonstration: During the demonstration, BSPM data are presented to SOM networks trained with different learning parameters. The organisation of the SOM in the learning process is visualised using animation tools. Time traces of the ventricular activation during endocardial stimulation are displayed. Finally, the localisation results are visualised on a realistic 3-dimensional model of the endocardial surfaces.

COMPUTERS IN CARDIOLOGY: ARRHYTHMIA AND SIGNAL PROCESSING

P1682 Artificial intelligence techniques of 12-lead holter monitoring in cyberspace

J. Nieberl, S. Khoor[1], K. Fügedi[2], F. Szaboki[3]. *BION Ltd., Budapest; [1]3rd Internal Med., Szent István Hospital, Budapest[2]Cardiology Dept., Szent István Hospital, Budapest[3]Cardiology, Centr. Railway Hospital, Budapest, Hungary*

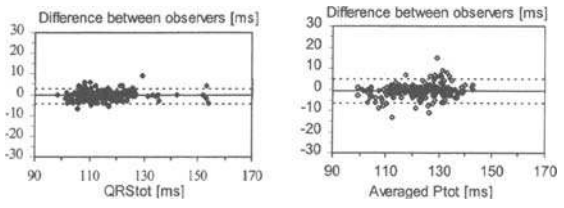
The ECG-Based-Cardiology System (www.bion.hu) includes: hypertext-based ECG Tutorial with 420 ECG demo recordings, Database server for conventional and 12-lead Holter ECG recordings. The hypertext ECG encyclopedia contains 512 articles from the literature related to the conventional and Holter ECG. The subparts of these articles were linked together and structured using fuzzy logic. An interactive on-site 12-lead Holter recorder was developed using DSP technique with an automated arrhythmia detection, ST-segment monitoring, measuring the ventricular repolarisation (QT, Qtc, Qtd). The automated measurement and interpretation of these parameters was developed by a neural network model. The interactive on-site Holter equipment could connect automatically to the PC via infra-red communication route or alarms the patient to connect to the PC. The cardiologist in the core laboratory site could communicate with the patient via the Internet. The present study compares the on-site, automated measurements of the above mentioned parameters with core laboratory results, where the manual measurements were taken place. The study population consists of the 48 h Holter recordings of 266 patients with coronary artery disease. Agreement (agr.) between categorial (yes/no)assessments were described by kappa (k) statistics, where k = (actual agr.- agr. by chance)/(1.00(maximal agr.)-agr. by chance), comparisons between groups were performed by the Mann-Whitney rank-sum test. The agreement between the local, automated ECG interpretation module of the Holter equipment and the analysis of the core ECG laboratory of 1024 episodes of automated alarming: atrial fibrillation (N = 221, kappa = 0.89, p = n.s.), ventricular run > 5 beats (28, 0.81, n.s.), II/III-AV-block (9, 0.77, n.s.), bundle branch block (17, 0.92, n.s.), pathological Q (97, 0.74, $p < 0.05$) ST-elevation (343, 0.69, $p < 0.05$) ST-depression (511, 0.63, $p < 0.02$), T-wave inversion (302, 0.71, $p < 0.02$). The results show a good overall agreement between the two sites, but the automated measurement cannot be applied blindly, without confirmation of the cardiologists via the Internet.

P1683 Interobserver agreement on measurement of signal-averaged P-wave electrocardiogram: comparison to signal-averaged QRST in normal subjects

I. Savelieva, K. Aytemir, K. Hnatkova, A. John Camm, M. Malik. *St George's Hospital Medical School, London, UK*

The interobserver agreement on measurement of signal averaged P wave was assessed in 306 ECG obtained from normal subjects (age 32 ± 8 years) using PHiRES and HiRES software (Marquette Medical Systems). The onset and offset of SA P wave were automatically detected and then manually corrected by two independent observers, and the averaged values of total filtered P wave duration (P_{tot}), RMS of the terminal 40, 30, and 20 ms (P_{40}, P_{30}, P_{20}), RMS voltage of the P wave, and P wave integral were taken for the analysis. The agreement between observers was assessed by Bland-Altman method and by the regression analysis.

Results: The interobserver agreement on QRS_{tot} was only slightly higher compared to that on P_{tot}. Figure presents Bland-Altman plots for interobverver agreement on QRS_{tot} (left) and P_{tot} measurement (right; bold line = mean of difference between measurements, dashed lines = mean ± 2 SD). Correlation coefficients were 0.98 and 0.95, respectively. For the voltage criteria, the best agreement was found for P40 followed by P30 (correlation coefficients 0.92 and 0.84, respectively; for RMS40 of signal averaged QRST r = 0.90.



Conclusion: The interobserver agreement on signal averaged Pwave did not differ from that of QRST. The best agreement was achieved for P_{tot}.

P1684 Phasic aspects of the oscillation of heart rate and blood pressure in man: cross-spectral analysis

D. Wichterle[1], V. Melenovsky[1], L. Necasova[2], J. Kautzner[2], M. Malik[3]. *[1]Third Department of Internal Medicine, First Medical School, Charles University, Prague; [2]Department of Cardiology, Institute of Clinical and Experimental Medicine, Prague, Czech Republic ; [3]Department of Cardiological Sciences, St. George's Hospital Medical School, London, UK*

Purpose: Cross-spectral analysis is frequently used for the analysis of non-random oscillations of cardiac cycles (RR) and arterial blood pressure (BP), mainly for the estimation of the baroreflex sensitivity. Phase lag between RR and BP oscillation has been studied to a lesser extent.

Methods: A population of 103 patients (73 males, 30 females) of mean age 50 ± 35 years, with coronary artery disease and/or hypertension has been studied. ECG and non-invasive continuous finger arterial pressure (Finapres) were digitized during 5 min period at rest in supine position and two 3 min periods of controlled breathing at frequencies of 6 and 20 cycles per minute. Cross-spectral indices have been assessed for the fluctuation of systolic (SBP), diastolic (DBP), pulse pressure (PP) and RR in low frequency (0.033–0.133 Hz) band (LF).

Results: Baroreflex gain was 6.8 ± 5.1, 10.1 ± 7.9 and 6.0 ± 4.8 ms/mmHg during spontaneous (SB), slow (SCB) and fast (FCB) controlled breathing, respectively. Phase lags (PL) in degrees and seconds between different modalities of BP and RR, as well as frequency (F) of the peak coherence in the LF band were as follows [means (SD)]:

Breathing:		Spontaneous	Slow (100 mHz)	Fast (333 mHz)
PP-RR	PL (degr)	−63.0 (53.5)	−70.8 (52.4)	−86.7 (72.4)
	PL (sec)	−3.2 (4.0)	−2.0 (1.6)	−4.0 (4.1)
	F (mHz)	73.8 (29.8)	100.8 (9.5)	72.7 (22.4)
SBP-RR	PL (degr)	−98.4 (43.4)	−79.1 (46.5)	−109.4 (57.8)
	PL (sec)	−4.7 (3.9)	−2.4 (1.7)	−5.1 (4.6)
	F (mHz)	73.5 (26.3)	97.6 (13.7)	72.9 (22.8)
DBP-RR	PL (degr)	−119.3 (39.3)	−94.3 (56.9)	−125.6 (51.9)
	PL (sec)	−5.3 (3.5)	−2.8 (1.9)	−5.5 (4.2)
	F (mHz)	74.9 (24.9)	97.1 (14.1)	75.6 (24.1)

Conclusion: The differences of phase lags for PP, SBP and DBP were in accordance with DeBoer's model. However, absolute values of phase lags in LF band during SB and FCB were strikingly higher (due to significantly longer period of oscillation compared to SCB) than those previously reported.

P1685 Automated analysis of distributions of atrial premature beat coupling intervals preceding onset of atrial fibrillation to detect focal atrial fibrillation

K. Hnatkova, J.E.P. Waktare, F.D. Murgatroyd, X. Guo, A. John Camm, M. Malik. *St. George's Hospital Medical School, London, UK*

Previous studies suggest that atrial premature beats (APB) trigger episodes of atrial fibrillation (AF). Unifocal APB's as the presumed cause of some cases of paroxysmal AF, as recently described. We report an automated method to investigate this phenomenon.

Method: A library of 177 beat interval files from 24-hr Holter recordings of paroxysmal AF pts was examined. AF episodes were identified by a validated technique, and 2 min of sinus rhythm (SR) preceding each AF episode and SR sections remote from AF were studied (SR after AF, AF itself, and noisy segments were excluded). The prematurity index (PI) of all beats was calculated as the ratio between the preceding RR interval duration and the median duration of the 10 preceding beats. APBs were defined as supraventricular beats with PI < 0.8. For each recording, separate histograms of the PI of APB's prior to and remote from AF were constructed. APB's of the same PI are visualised by a narrow significant peak (spike) in the distribution. Visually there was either a spike seen only prior to AF (pattern A), spikes seen in both remote and prior to AF (pattern B), or (3) no spikes present (C). To remove observer bias the presence of spikes was assessed by: (1) the width of the spike (>15 ms), (2) the proportion of all APB's which were within the spike, (3) the kurtosis of the spike (reflects the sharpness of the spike), (4) whether the spike is present at a coupling interval < 600 ms, and finally (5) the distance between the spikes in the histograms remote from and prior to AF (to define pattern B).

Results: Of 74 tapes, 8 demonstrated pattern A, 19 pattern B, and 53 pattern C. Only on 2 of 74 recordings automated and manual classification (performed by 2 independent observers) disagreed.

Conclusion: The automated analysis of histograms of PI of APB's might study the mechanism triggering AF onset.

P1686 Superconducting quantum interference devices (squids) in magnetocardiography: findings on normals in trinidad and tobago

R. Ramadhar Singh, R.S. Ramsey Saunders, C. Posthoff[1], C. Thomas[2], J. Addae[2], D. Rassi[3]. *Dept. of Physics, Medical Physics Unit, University of the West Indies, St. Augustine; [1]Mathematics and Computer Science, University of the West Indies, St Augustine; [2]Faculty of Medicine, University of the West Indies, St Augustine, Trinidad and Tobago; [3]School of Health Sciences, University of Wales, Swansea College, UK*

The objective of this study was to measure the magnetic fields of the heart of a normal volunteer using a newly accquired Superconducting Quantum Interference Device (SQUID)magnetometer. This instrument is the first of its kind to ever be introduced to the Caribbean region.The database obtained by using this instrument will be used as a reference for studies on cardiac patients.

This study involved 16 normal volunteers: 7 females, 9 males of mean age 27.4 years. Magnetic fields at 36 points on a 6x6 grid on their anterior chest wall were recorded with the detector 1 cm above the grid.Using specialized software, the data were processed to yield the Magnetocardiogram (MCG).From this the MCG P-wave, QRS complex and T wave intervals were computed. A map of the magnetic field variation over the entire grid area was also constucted for one heart cycle.

The results show that the magnetic equivalents of the P,QRS and T components of the electrocardiogram are present in all cases. The values of the P., QRS and T time intervals in the MCG were found to be 57.2 ± 8.5 ms, 51.9 ± 8.2 ms and 96.3 ± 7.6 ms respectively. Isomagnetic contour maps constructed show that there are variations in the magnetic fields of the heart for this group of healthy subjects. Further investigations will address factors contributing to these differences.

The database that is being established will serve as an invaluable tool for further research.

STUNNING, HIBERNATION AND PRECONDITIONING

P1687 Prior exposure to lipopolysaccharides and ischaemic preconditioning increase the TNFα-inhibitory serum activity in rabbits

S. Belosjorow, R. Schulz, H. Dörge, U. Schade, G. Heusch. *Department of Pathophysiology, University of Essen, Germany Medical School*

Prior exposure to lipopolysaccharides (LPS) and ischemic preconditioning (IP) reduce the infarct size resulting from ischemia/reperfusion (I/R) in rabbits. Furthermore, both LPS and IP reduce the TNFα-concentration during I/R. One potential explanation for such decline in the TNFα-concentration relates to an increased TNFα-inhibitory serum activity (TNFα-ISA). We therefore analyzed the serum TNFα-concentration and its TNFα-ISA during 30 min coronary occlusion and 180 min R in anesthetized rabbits either not exposed (controls, G1, n = 7) or exposed to LPS 72 h prior to I (G2, n = 9) or preconditioned by a single cycle of 5 min I and 10 min R (G3, n = 9). TNFα-ISA was assessed by co-incubating LPS-stimulated fresh rabbit blood with serum obtained from individual rabbits of G1–G3 and measuring TNFα-production using the WEHI assay. Heart rate and peak aortic pressure were comparable among all groups throughout the protocol. Also, regional myocardial blood flow (microspheres) was similar during control and I. With a comparable area at risk, infarct size in G1 averaged 36.9 ± 11.1 (SD)% and was reduced to 17.3 ± 11.3% ($p < 0.05$) and 13.1 ± 11.6% ($p < 0.05$) in G2 and G3, respectively. The serum TNFα-concentration was similar under control in G1 (793 ± 82 U/ml) and G3 (863 ± 244 U/ml), but was reduced in G2 (454 ± 120 U/ml, $p < 0.05$). While the TNFα-concentration increased during I/R in G1 (1119 ± 224 U/ml, $p < 0.05$), it remained unchanged in G2 and G3. The TNFα-ISA during I/R was significantly increased in G2 and G3, resulting in less TNFα-production by LPS-stimulated blood.

	Control	IP	Ischemia	Reperfusion
G1	2578 ± 240		2592 ± 542	2505 ± 358
G2	1262 ± 303$^{\#a}$		1395 ± 164$^{\#}$	1359 ± 138$^{\#}$
G3	2640 ± 380	2537 ± 320	1913 ± 400$^{*\#}$	1610 ± 148$^{*\#}$

TNFα-concentration of LPS-stimulated fresh rabbit blood (U/ml) co-incubated with serum, mean ± SD. *: $p < 0.05$ vs. Control; $^{\#}$: $p < 0.05$ vs. G1; ^{a}: $p < 0.05$ vs G3; 2-way ANOVA

Thus, cardioprotection by LPS and IP is associated with a reduced serum TNFα-concentration and increased TNFα-ISA.

P1688 Importance of proton gradient during transient ischaemia for the effect of ischaemic preconditioning on norepinephrine release and arrhythmias in rat hearts

M. Seyfarth, L. Bott-Flügel, B. Kinter, M. Ungerer, K.-L. Laugwitz, A. Schömig. *Deutsches Herzzentrum München, Munich; 1. Medizinische Klinik, Technische Universität, Munich, Germany*

Transient ischemia (TI) reduces norepinephrine (NE) release during sustained global ischemia in rat hearts indicating a neural preconditioning which may affect the incidence of ventricular arrhythmias during myocardial ischemia. We tested how neural preconditioning and ventricular arrythmias are affected by changes of transmembranal proton gradient during TI and reperfusion. NE release during sustained ischemia (30 min ligation of LAD artery) was determined by HPLC and the incidence of ventricular fibrillation (VF) was analyzed by ECG in isolated perfused rat hearts. Both, NE release and the incidence of VF were reduced during sustained ischemia by preceding TI (3 × 5 min) from 83 ± 11 to 47 ± 5 pmol/g (NE) and from 65 to 43% (VF) (each $P < 0.01$). When hearts were reperfused after each TI with an acidic medium (pH 6.2) to attenuate the reperfusion-induced transmembranal proton gradient, both, the suppression of NE release and the incidence of VF was completely abolished (NE: 85 ± 14 pmol/g; VF: 73%). Furthermore, hearts reperfused after each TI with an alkalic medium (pH 8.8) showed an increased effect of TI on NE release (31 ± 5 pmol/g) and incidence of VF (25%). Additionally, induction only of intermittent intracellular acidosis by NH4+ prepulse (3 × 10 mM) instead of TI was sufficient to suppress both NE release and the incidence of VF during sustained ischemia.

Conclusion: Ischemia-induced NE release and VF in rat hearts are suppressed both by transient ischemia. The induction of a transmembranal proton gradient either by transient ischemia and reperfusion or by transient intracellular acidosis contributes to this effect and may support data suggesting an activation of pH-regulating transporter during ischemic preconditioning.

P1689 Canine myocardial stunning is attenuated by the cardioselective synthetic glycolipid RC-552

G.T. Elliott[1], P.A. Weber[1], J. Moore[2], G. Gross[2]. *[1]Ribi ImmunoChem Research, Inc., Hamilton MT; [2]Medical College Wisconsin, Milwaukee WI, USA*

Monophosphoryl lipid A (MLA), a glycolipid produced as a derivitized purified fermentation product of *S. minnesota* R595 has been demonstrated to reduce regional myocardial stunning associated with cyclical transient ischemia in dogs when administered 24 hours prior to ischemia. A second generation synthetic glycolipid (RC-552) devoid of the residual immunostimulatory activity observed with MLA, was evaluated in a canine model of regional myocardial stunning for an acute and prolonged protective effect.

Methods: Dogs were randomized to receive IV: 1) RC-552 (35 μg/kg, 10 minute pre-ischemia); 2) RC-552 (35 μg/kg, 24 hour pre-ischemia); or 3) vehicle (equivalent volume, 24 hours pre-ischemia). Anesthetized dogs were subjected to five transient cycles of 5 minute LAD occlusion (Occ_T) and 10 minute reperfusion (Rep_T). Regional segment shortening was measured in the subendocardium by sonomicrometry using two piezoelectric crystals placed 10–15 mm apart. Radioactive microspheres were used at 5 minute occlusion (Occ) and 2 hours prolonged reperfusion (Rep) to assess transmural blood flow.

Results: Following either a 10 minute or 24 hour pretreatment with RC-552 a significant and equivalent improvement in systolic segment shortening was observed both during cyclical reperfusion and prolonged reperfusion. No drug associated effects on myocardial blood flow, mean blood pressure, heart rate, or rate-pressure product were observed.

Treatment/ Time Pre-Occ	N	% of Baseline Segment Shortening					
		Occ_T	Rep_T	Prolonged Rep			
		#1	#1	15″	30″	60″	120″
RC-552/10 min.	8	−37 ± 9	59* ± 5	44* ± 4	47* ± 4	51* ± 7	45* ± 7
RC-552/24 hrs.	7	−37 ± 9	59* ± 5	44* ± 4	47* ± 4	46* ± 6	48* ± 7
Vehicle/24 hrs.	6	−40 ± 5	34 ± 8	15 ± 5	10 ± 9	14 ± 8	11 ± 5

* $p = <0.05$ vs vehicle, ANOVA; Data from Occ_T and Rep_T cycle 2–5 not shown

Conclusion: IV administration of RC-552 (35 μg/kg) either 10 minute or 24 hour pre-occlusion resulted in improved recovery of contractility both during cyclical periods of reperfusion and throughout 2 hours prolonged reperfusion without the potential immunostimulation effect of MLA and without effect on peripheral hemodynamics.

P1690 The protein kinase inhibitor-α gene: another key to postischaemic myocardial dysfunction?

R. Knöll, K. Nevescanin, K. Schulze, M. Hummel[1], R. Zimmermann[2], W. Schaper[2], H.-P. Schultheiss. *Dept of Cardiology; [1]Dept. of Pathology Freie Universität Berlin; [2]Dept. of exp. Cardiology Max-Planck Institute Bad Nauheim, Germany*

This study was performed to identify differential expressed genes involved in myocardia stress rexponse. Several different mechanisms such as formation of oxygen radicals, calcium overload, sarcoplasmic reticulum dysfunction and proteolysis of troponin are thought to cause myocardial stunning, long-lasting reversible myocardial dysfunction following short coronary occlusions. However, none of the proposed mechanisms completely explains the phenomenon of myocardial stunning.

Methods: To overcome the above-mentioned problem we tried to clone differentially expressed genes, probably involved in the genesis of myocardial stunning. Therefore, differential display reverse transcribed polymerase chain reaction (= DDRT-PCR) was used to study RNA from postischemic pig myocardium. To clone full-length cDNAs, one of the cloned fragments (RKCU13.4.2) was used to screen a cDNA library. We identified this clone as a part of the protein kinase inhibitor alpha (= PKIαa) cDNA. By uses of a recombinant PKIα peptide (amino-acids 14–22) and a rat "working heart" model, its cardiac function was assessed.

In summary, we cloned with 4000 bp in length the porcine PKIα cDNA and showed it's inducibility by ischemia. It encodes a 76-amino-acids open reading frame with 100% homology in its active center to known sequences from different species. We show a concentration-dependent (up to 2 μMol), reversible negative inotropic effect. This may be due to the inhibition of phosphorylations via protein kinase A, especially the inhibition of the sarcoplasmic reticulum ATPase via nonphosphorylated phospholamban or the inhibition of the phosphorylation of troponin I.

In conclusion: The PKIα gene is a new stress-induced factor. We describe the full length porcine cDNA of about 4 kb and present a sophisticated new hypothesis whereby the PKIα plays a pivotal role in pathophysiological regulation leading to postischemic myocardial dysfunction.

P1691 Densities of the sarcoplasmic reticulum calcium release channel and L-type calcium channel are decreased in postischaemic ("stunned") myocardium

B. Koenigs, M. Greiser, U. Schotten, P. Hanrath. *Department of Cardiology, University Hospital Aachen, Germany*

Background: In stunned myocardium the intracellular calcium metabolism shows an imbalance. The intracellular concentration of calcium is increased and responsible for the contractile dysfunction. In this study we investigated the densities of the sarcoplasmic reticulum release channel (CRC) and L- type calcium channel (L-type) and further the calcium sensitivity of the CRC in postischemic myocardium.

Methods: In homogenates from porcine hearts after 10 minutes occlusion of the LAD and 90 minutes reperfusion, the density of the CRC and L-type were determined using ^{3}H-ryanodine and ^{3}H-PN 200 110 as radioligands. Non-ischemic porcine myocardium of the same animals served as control. For determination of the calcium sensitvity, the homogenates were incubated with 12 nM ^{3}H-ryanodine in the presence of different [Ca^{2+}].

Results: Densities of the CRC and L-type were significantly decreased ($p < 0.05$). The calcium senstivity of the CRC was unchanged. Table: Values are means ± SEM postischemic (n = 14) vs control (n = 14). EC_{50} = [Ca^{2+}] at half maximal ^{3}H-ryanodine binding with 95% confidence intervals. Bmax = maximal specific ^{3}H-ryanodine- or ^{3}H-PN 200 110-binding, $^*p < 0.05$ vs control.

	CRC Bmax	EC_{50}	L-type Bmax
postischemic	71.5 ± 7.6*	1.9 (1.81–1.96)	18.6 ± 4.18*
control	107.4 ± 6.5	1.85 (1.7–1.88)	38.1 ± 9.3

Conclusion: The decreased densites of the CRC and L- type in postischemic myocardium could be a contribute of the altered intracellular calcium metabolism.

P1692 On-line assessment of myocardial viability using electromechanical mapping

A. Keck, Y. Schwartz[1], T. Weber, C. Franke[2], T. Twisselmann, R. Küchler, M. Schlüter, R. Kitzing, Karl H. Kuck. *St. Georg Hospital, Hamburg; [2]Center for Radiology and Nuclear Medicine, Hamburg, Germany; [1]Rambam Medical Center, Haifa, Israel*

Assessment of myocardial viability immediately after diagnostic coronary angiography allows prompt decision-making with regard to therapeutic intervention. The NOGA™ system is a novel catheter-based, nonfluoroscopic endocardial mapping system which allows simultaneous acquisition of both local electrical activity and myocardial contractility. To validate its potential for assessment of viability, 51 pts (41 m, 10 f; 61.4 ± 8.2 years) with coronary artery disease underwent NOGA mapping and perfusion (SPECT, Tc-99m) and metabolism imaging (PET). Analyzed parameters: Amplitude (UV, mV), fragmentation index (FI) of the local unipolar potential, local shortening (LS, %) as a parameter for contractility. The left ventricle was divided into 9 segments.

Results:

SPECT	N	UV/meanSD	FI	LS
Normal	282	11.2 ± 4.9	1.1 ± 0.2	8.2 ± 5.0
Reversible defects/deficits	50	11.6 ± 4.8	1.2 ± 0.2	7.7 ± 7.0
Fixed defects	74	6.4 ± 3.0	1.3 ± 0.2	3.6 ± 4.5
Normal vs reversible		NS	NS	NS
Normal vs fixed		p < 0.001	P < 0.001	P < 0.001

A threshold of 4.5 mV (UV) and a FI > 1.5 identified nonviable tissue (diagnosed by PET) with a specificity of 90% and a sensitivity of 65%.

Conclusion: Electromechanical mapping allows the assessment of myocardial viability in one catheterization procedure. Patients with hibernating myocardium could be immediately revascularized without any time delay.

P1693 Structural and metabolic outcome of prolonged moderate ischaemia in pigs

R. Schulz, H. Post, A. Jalowy, H. Dörge, M. Behrends, G. Heusch. *Department of Pathophysiology, University of Essen, Germany Medical School*

It is still a matter of debate whether the chronic contractile dysfunction seen in hibernating myocardium is the result of persistent ischemia (I) or of repetitive episodes of I/reperfusion. Detailed analyses of regional flow and function during controlled I over more than 5 h are lacking. Therefore, in 16 enflurane-anesthetized swine the LAD was cannulated and hypoperfused at constant flow for 24 h and then reperfused for 2 h. Coronary inflow was reduced to decrease regional myocardial systolic wall thickening (WT, sonomicrometry) at 5 min I to 60%. Eight out of 16 swine survived the 24 h I. In 4 survivors (G 1), 14.3 ± 5.5 (SD)% of the myocardium at risk was infarcted (TTC, histology), while in other 4 survivors (G2) the myocardium remained completely viable.

	Control	5 min I	24 h I
CP G1	8.6 ± 1.6	3.1 ± 1.8*	5.7 ± 4.1*
G2	9.0 ± 1.0	3.8 ± 0.8*	8.0 ± 4.8
ATP G1	3.5 ± 0.5	2.6 ± 0.6*	1.9 ± 1.2*
G2	3.8 ± 0.8	2.5 ± 1.2*	3.3 ± 0.7#

*p ≤ 0.05 vs. Control, #p < 0.05 vs G1, 2-way ANOVA

Transmural myocardial blood flow (microspheres) was decreased to the same extent at 5 min I (0.40 ± 0.10 vs. 0.48 ± 0.10 ml/min/g) and 24 h I (0.46 ± 0.14 vs. 0.42 ± 0.10 ml/min/g) in G1 and G2, respectively. Also, the decline of WT at 5 min I (23.9 ± 6.1 vs. 23.6 ± 4.0%) and 24 h I (7.6 ± 5.2 vs. 9.5 ± 3.4%) was similar in G1 and G2. In both groups, myocardial creatine phosphate content (CP, biopsies, μmol/g wet weight) and ATP content were decreased at 5 min I. In G1, CP partially recovered, but ATP content decreased further during 24 h I. In contrast, both CP and ATP contents recovered to almost baseline at 24 h I in G2.

Conclusion: In a subset of swine, the myocardium can adapt to a 24 h I period; i.e. it remains viable and its energy metabolism recovers.

P1694 Uncoupling of mitochondrial oxidative phosphorylation preconditions the isolated rat heart

J. Minners, D.M. Yellon[1], A.K. Jonassen[1], L.H. Opie. *Cape Heart Center, University of Cape Town, Cape Town, South Africa; [1]The Hatter Institute, University College London, London, UK*

Background: Recent studies have implicated the opening of the K-ATP channel, located on the inner mitochondrial membrane, as the final effector in myocardial preconditioning (PC). To further elucidate the role of the mitochondrion in PC we applied the uncoupling agent 2,4 dinitrophenol (2,4-DNP, 50 micromolar, 5 min, 5 min reperfusion) in a model of regional ischaemia (35 min index ischaemia, 120 min reperfusion) in the isolated perfused rat heart. Risk volume and infarct size were delineated using fluorescent microspheres and triphenyltetrazolium staining respectively. Computerised planimetry was used to quantitate volumes and the% infarct within the risk zone was calculated.

Results: Base line heart rate, coronary flow, and left ventricular developed pressure were comparable in controls, PC, and DNP-treated hearts. After 5 min of DNP treatment and 5 min of reperfusion, hearts had a reduced heart rate (215 ± 66 vs. 345 ± 50, $p < 0.001$) which persisted throughout the experiment. Coronary flow and left ventricular developed pressure were similar in the three groups. Measurement of infarct size demonstrated a significant reduction of the infarct/area at risk ratio (I/R ratio: 9.0 ± 5.9 vs. 27.4 ± 6.1% in controls, $p < 0.001$) similar to the effect seen with PC (8.1 ± 3.2%, $p < 0.004$). The mitochondrial K-ATP channel blocker 5-HD (100 micromolar) given for 15 min during DNP exposure elicited irreversible contracture in all hearts tested (n = 4).

Conclusion: Transient uncoupling of the mitochondrial oxidative chain from ATP generation reduces infarct size to a similar extent as PC. This effect might not to be mediated by the mitochondrial K-ATP channel.

P1695 Mismatch of regional perfusion and local electrical activity: a new indicator for viability in chronic ischaemic myocardium?

O. Arslan, M. Schäfers[2], M. Krenz, H.-J. Bruns, F. Janssen, D. Hammel[1], H.H. Scheld[1], O. Schober[2], G. Breithardt, T. Wichter. *Interdisciplinary Center of Clinical Research, Dept. of Cardiology; [1]Dept. of Cardiovascular Surgery; [2]Dept. of Nuclear Medicine, University of Münster, Germany*

A mismatch of regional myocardial function and perfusion has been used to identify viable myocardium. To assess the relationship of local electrogram characteristics and regional perfusion, 21 patients with coronary artery disease and regional LV dysfunction were investigated. Regional perfusion was assessed by Tc-99m-MIBI-SPECT prior to elective coronary artery bypass grafting. During surgery, 102 bipolar epicardial electrograms were simultaneously recorded from the epicardium using a ventricular sock electrode and a commercial mapping system. The electrograms were matched to the findings of Tc-99m-MIBI-SPECT. According to the epicardial grid of the mapping electrode, a 3D-data matrix was computed. A total of 1302 regions (reg.) were analysed.

Tc-99m-MIBI	100–75%	75–50%	50–25%	25–0%
Number of reg.	633	550	98	21
AMP [mV]	8.6 ± 6.6	8.3 ± 7.2	9.3 ± 8.1	$4.1 \pm 4.4^{*\#}$
DUR [ms]	26.4 ± 18.0	29.2 ± 19.3	29.7 ± 20.0	$44.2 \pm 26.1^{*\#}$
A–/Dyskinesia [% reg.]	9	12	23	76

[Mean ± SD, $^{*}p < 0.001$ compared to 100–75% Tc-99m-MIBI uptake, $^{\#}p < 0.01$ compared to 75–50% and 50-25% uptake]

Only regions with severely reduced perfusion (0–25% of max. 99mTc-MIBI uptake) were characterized by low amplitudes and prolonged signal duration of electrograms. However, regions with moderately reduced perfusion (25–75%) did not show any difference in amplitude and duration of local epicardial electrograms compared to regions with normal perfusion.

Conclusion: A mismatch of mild to moderately reduced myocardial perfusion and normal epicardial electrogram characteristics was found in areas of chronic myocardial ischaemia. This mismatch of regional perfusion and electrical activity may reflect myocardial viability and may be helpful to predict recovery of regional myocardial dysfunction after revascularization in patients with chronic ischaemic myocardium.

P1696 A new porcine stent model of hibernation and assessment of myocardial viability

M. Szilard, L. Mesotten[1], X.S. Liu, A. Maes[1], J. Nuyts[1], Y.M. Huang, J.H. Huang, M. Borgers[2], L. Mortelmans[1], I. De Scheerder[3]. *Experimental Laboratory for Cardiology, University Hospital Leuven, Leuven; [1]Department of Nuclear Medicine, University Hospital Leuven, Leuven; [2]Department of Morphology, Janssen Research Foundation, Beerse; [3]Department of Cardiology, University Hospital, Leuven, Belgium*

Aim: A non-surgical porcine stent model of coronary stenosis was developed in order to investigate the relationship between chronic left ventricle (LV) dysfunction and myocardial viability.

Methods: A progressive stent stenosis in proximal LAD was produced by implantation of an oversized polymer coated stent in 21 pigs. Quantitative coronary angiography (QCA) was performed at baseline and at sacrifice. Weekly LV function was evaluated by echo and at the time of developed anterior wall motion abnormality (VMA), dobutamine stress echocardiography (DSE) and PET examination was performed. At sacrifice biopsies were taken for histology and the stented coronary artery segment was dissected for morphometriy.

Results: Based on the results the pigs were divided into three groups: In group I (n = 4), myocardial infarction was found with severe stenosis, severe VMA without improvement with DSE, "matched necrosis" pattern with PET and necrotic cells with histology. In group II and III, animals had viable myocardium in the setting of coronary stenosis, moderate to severe VMA, which exhibited normalization at low dose and sustained improvement or biphasic reaction at high dose with DSE, "matched normal" (group II; n = 9) and "mismatch" (group III; n = 8) pattern with PET. In these groups histologic evaluation showed normal morphology and in a few cells sarcomere loss and glycogen storage was observed. (see table):

PET, Morphometry and ECHO results

	PET: NH3	PET: FDG	Area stenosis	ECHO: FS	ECHO: AWT
I. Matched necrosis	57	72	96	35	21
II. Matched normal	89+	90	65*	56	52+
III. Mismatch	86+	105++	74*	47	41+

+p = 0.005 group I vs II and III, ++p < 0.005 group II vs III, *p < 0.01 group I vs II and III; ECHO values:% of baseline; Abbreviations: FS = fractional shortening, AWT = anterior wall thickening

Conclusion: In group II and III we developed a pig model of myocardial hibernation in the setting of progressive coronary stenosis, with chronic LV dysfunction, with residual inotropic reserve and viable PET patterns. Animals with "matched normal" PET pattern may correspond to repetitive stunning and with "mismatch" to chronic hibernation.

IMAGING OF LEFT VENTRICULAR DYSFUNCTION AND HIBERNATION: NUCLEAR, POSITRON EMISSION TOMOGRAPHY, ECHOCARDIOGRAPHY AND MAGNETIC RESONANCE IMAGING

P1697 Assessment of myocardial viability with dobutamine magnetic resonance imaging and pet in a porcine model of chronic left ventricular dysfunction

M. Szilard, S. Dymarkowski[1], X.S. Liu, L. Mesotten[2], A. Maes[2], Y.M. Huang, J. Bogaert[1], M. Borgers[3], L. Mortelmans[2], I. De Scheerder[4]. *Experimental Laboratory for Cardiology, University Hospital Leuven, Leuven; [1]Department of Radiology, University Hospital, Leuven; [2]Department of Nuclear Medicine, University Hospital Leuven, Leuven; [3]Department of Morphology, Janssen Research Foundation, Beerse; [4]Department of Cardiology, University Hospital, Leuven, Belgium*

Aim: Different techniques have been applied in a non-sugical porcine stent model of coronary stenosis with chronic left ventricle (LV) dysfunction to identify viable myocardium (VM) and distinguish it from myocardial necrosis.

Methods: A progressive stenosis in LAD was produced by implantation of an oversized polymer coated stent in 14 pigs. Weekly LV function was evaluated by echo. At the time of developed anterior wall motion abnormality (WMA), dobutamine magnetic resonance imaging (DMRI) (at rest and during low dose (LD) and high dose (HD); n = 14) and PET examination (n = 5) were performed. To determine the coronary stenosis quantitative coronary angiography and morphometry were done. At sacrifice biopsies were taken for histology. Additional 6 animals without stent implantation served as normal controls and underwent the same follow-up.

Results: According to the results, the stented pigs were divided into two groups. In group I (n = 5), myocardial infarction was found which was characterized by severe stenosis, akinesia with echo, severely reduced end-diastolic wall thickness, absence of contractile reserve with DMRI and necrotic cells with histology. One animal had PET examination which showed "matched necrosis" pattern.

In group II (n = 9) animals had VM in the setting of coronary stenosis, WMA with echo, decreased wall thickening at rest that exhibited improvement at LD and deterioration at HD (biphasic reaction) with DMRI. The animals that had PET showed viable patterns: "match normal" (n = 1) and "mismatch" (n = 3) patterns. Histology showed normal morphology and in a few cells sarcomere loss and glycogen storage was observed.

Morphometry, Echo and DMRI results (%)

	Morphometry	EHCO			DMRI		
	AS	FS	AWT	IPW	EF at Rest	EF at LD	EF at HD
Gr I.	90*+	9*+	2*+	46	48*	53*	51*
Gr II.	74*	16*	22*	45	52*	55*	45*
Controls	0	34*	46	47	66	70	75

*p < 0.001 vs controls, +p < 0.001 Gr I vs Gr II; Abbreviations: AS = area stenosis, FS = fractional shortening, AWT = anterior wall thickening, IPWT = infero-posterior wall thickening, EF = ejection fraction, LD = low dose, HD = high dose

Conclusions: In our animal model with severe coronary stenosis and chronic LV dysfunction, DMRI accurately detected ischemia and distinguished VM from myocardial necrosis, which was confirmed by PET and histology.

P1698 Myocardial viability assessment by endocardial electroanatomical mapping: validation of a new method by metabolic imaging using F-18 fluorodeoxyglucose positron emission tomography

K.-C. Koch, C. Stellbrink, A. Sasse, E. Ostwald[1], U. Buell[1], J. vom Dahl. *Departments of Cardiology; [1]Nuclear Medicine, University Hospital, RWTH Aachen, Germany*

Data from animal experiments and first clinical studies suggest that a recently developed catheter-based endocardial mapping system may identify the presence and absence of myocardial viability. To validate the method a comparison with metabolic imaging using PET and Fluorine-18 deoxyglucose (FDG) was performed.

Methods. Twenty-nine patients with prior (≥2 weeks) myocardial infarction were studied. All patients underwent FDG PET and Tc-99m sestamibi SPECT prior to invasive viability assessment. For quantitative nuclear analysis the left ventricle was divided into 25 regions (R) in both PET and SPECT data sets. Regional definition of myocardial viability by SPECT/PET studies was based on previous follow-up studies. The left ventricle was mapped and divided into 12 R, which were assigned to corresponding nuclear R.

Results. Regional unipolar electrogram amplitude (UA) was 12.1 ± 5.1 mV in R with normal perfusion, 9.3 ± 3.8 mV in R with reduced perfusion but preserved FDG-uptake (mismatch, p < 0.001 vs. normal), 9.2 ± 3.7 mV in R with intermediate viability (ns vs. mismatch) and 5.9 ± 2.6 mV in scar R (p < 0.001 vs. normal, p < 0.01 vs. mismatch and intermediate). Eighty-nine percent of the R with a UA of >9.3 mV were viable and 89% of the R with a UA of <6.0 mV were scar. By visual analysis, using 6 mV amplitude as threshold, mapping identified 16/20 (80%) scar areas and 20/21 (95%) areas with preserved FDG uptake.

Conclusion. These data suggest that electroanatomical mapping of the regional unipolar electrogram amplitude can be used for viability assessment in the catheterization laboratory.

P1699 Mild fixed defects on Tl-201 stress-reinjection SPECT do not improve in function post-revascularization

J.J. Bax, J.L.J. Vanoverschelde, D. Poldermans, J.H. Cornel, A. Elhendy, E. Boersma, P.M. Fioretti. *Leiden; Rotterdam; Alkmaar; Amsterdam, Netherlands; Udine, Italy; Brussels, Belgium*

Thallium-201 stress-reinjection (Tl-201 SR) imaging has a high sensitivity to predict improvement of function post-revascularization, while specificity remains suboptimal. The lower specificity can be related to the definition of viability on Tl-201 SR: both reversible defects and mild fixed defects are considered as indicators of viable myocardium. While both groups may represent viable tissue, their predictive accuracy may not be comparable. Hence, the predictive accuracy of these different viability criteria was evaluated.

Methods: 68 patients (LVEF 34 ± 9%) were studied with Tl-201 SR pre-revascularization. Regional function was studied by resting echo-cardiography (16-segment model) pre- and 3 months post-revascularization. The SPECT data were analyzed semi-quantitatively (polar maps, 16 segments). Dysfunctional segments were classified into 5 groups: 1) normal Tl-201 uptake, 2) mild-moderate (≥50% activity) fixed defects, 3) mild-moderate reversible defects, 4) severe (<50%) fixed defects, 5) severe reversible defects. Group 1, 23, 5 segments were considered viable.

Results: 1088 segments were evaluated; 545 (50%) were dysfunctional, 421 were viable and 124 nonviable on Tl-201 SR. Recovery of function occurred in 11 (9%) nonviable segments and in 170 (40%) viable segments. While incidence of recovery was 44%, 54% and 76% in groups 1, 3, 5, the incidence of recovery was only 15% in group 2 (P < 0.05).

Conclusion: Nonviable segments (group 5) do not recover function. In the viable segments, recovery occurs mainly in segments with normal Tl-201 uptake or reversible defects, while midl-moderate fixed defects do not recover. Mild-moderate fixed defect may represent nontransmural scars.

P1700 Use of ultrasonic integrated backscatter to predict recovery of function following myocardial infarction

J. Hancock, D. Chin, D.E. Jewitt, M.J. Monaghan. *Cardiology Dept, King's College Hospital, London, UK*

Cyclic variation in ultrasonic integrated backscatter (Cyclic IBS) is reduced in regions of myocardium supplied by the infarct related artery (IRA) following myocardial infarction (MI). This is thought to be due to reduced microvascular pulsatile flow in these regions. Once patency of the IRA has been restored either with thrombolysis or by coronary angioplasty (PTCA), cyclic IBS should return to normal levels provided that microvascular perfusion is re-established. Thirty patients were studied following acute MI. Cyclic IBS was measured in regions of myocardium supplied by the IRA pre thrombolysis (where possible), post thrombolysis, pre discharge and at 1 and 3 months. In addition a wall motion score index (WMSI) was determined by dividing the total wall motion score by the number of segments scored. A scoring system of 1 = normal, 2 = hypokinetic, 3 = akinetic, 4 = dyskinetic was used. Following thrombolysis, coronary angiography was performed. If the IRA was occluded PTCA was performed to restore TIMI 3 flow. 28/30 patients had TIMI 3 flow in their IRA pre discharge. An increase in cyclic IBS of >30% pre discharge compared with the initial value was used to predict recovery of wall motion.

Results: All patients had a similar WMSI initially and pre discharge. Patients whose cyclic IBS had improved significantly pre discharge had the greatest improvement in their WMSI at 1 and 3 months. See table below.

Results

No. Patients	Change in cyclic IBS (dB)	Initial WMSI	Pre discharge WMSI	1 and 3 month WMSI
12	0.18 (6%)	1.9	1.9	1.9
18	2.4 (38%)	1.7	1.7	1.17
	p<0.0001	NS	NS	p<0.0001

Conclusions: Cyclic IBS can be used to predict those patients who have restoration of perfusion at a microvascular level post MI and who will have recovery of myocardial function.

P1701 Low-dose versus high-dose dobutamine echocardiography in the assessment of myocardium viability: comparison with pet

G. Mobilia, P. Zanco[1], F. Alitto, G. Neri, G. Ferlin[1], R. Buchberger.
Montebelluna (TV); [1]Castelfranco Veneto, Italy

Low-dose (LD) (up to 10 mcg/kg/min) dobutamine echocardiography (DE) is commonly employed to search for viability (VIA). However the higher doses (HD) (up to 40 mcg/kg/min) can give important informations for the presence of VIA. Aim of this study was to compare the accuracy of LDDE alone and LD+HD DE in searching for VIA, using fluorine-18-fluorodeoxyglucose positron emission tomography (18-FDG-PET) as gold-standard.

Methods: twenty-five consecutive pts, with prior myocardial infarction, were studied by DE up to 40 mcg/kg/min (plus atropine, if necessary to reach target heart rate); every pt was also submitted to a 18-FDG-PET within 15 days of the DE. The left ventricle was divided in 16 segments (seg), both in DE and PET examination. VIA was considered present in seg with severe dysfunction at rest plus either of the following signs: 1) improvement at LD, 2) improvement at LD and worsening at HD (biphasic response), 3) improvement only at HD, 4) worsening at HD of a severe basal hypokinesia, excluding akinesia becoming diskinesia that was considered a mechanical phenomenon (ischemic response). The gold standard for VIA was considered a FDG uptake ≥ 50% at PET study.

Results: The sensitivity, specificity and diagnostic accuracy (%) of LDDE alone (sign 1) and LD + HD DE (signs 1 to 4) in searching for VIA are reported in the table.

	Sensitivity	Specificity	Accuracy
LDDE	62	88	72
LD + HD DE	87	77	84

Conclusions: Our study suggest that, in searching for VIA, DE is more accurate if is continued up to the HD, and not stopped at LD.

P1702 A head-to-head comparison of serial dual-isotope Tc-99m-tetrofosmin and 18-FDG SPECT and dobutamine stress echo for the prediction of improvement of ejection fraction in patients with left ventricular dysfunction after revascularization

D. Poldermans, J.J. Bax, R. Valkema, P.M. Fioretti, A. Elhendy, L. Maat, E.P. Krenning, P. van de Meer, J.R.T.C. Roelandt. *Erasmus Medical Center, Rotterdam, Netherlands*

Objective: To compare head-to-head the predictive value of dual-isotope simultaneous acquisition [DISA] SPECT with Tc-99m-Tetrofosmin/18-FDG and dobutamine stress echocardiography [DSE] for improvement of left ventricular [LV] ejection fraction after revascularization [CABG] in patients with ischemic LV dysfunction using radionuclide ventriculography [RNV] as a reference.

Methods: 55 patients [46 male], ejection fraction of 32 ± 9% [mean ± SD], were studied with RNV, DISA-SPECT and DSE. Both DSE and DISA-SPECT were scored using a 16-segment model. Viability by DISA-SPECT/DSE was noted if segments with severe dyssynergy at rest showed normal perfusion and FDG uptake, mildly reduced matched perfusion and FDG uptake or mismatches respectively a biphasic, sustained improvement or worsening response during DSE. Non-viability by DISA-SPECT/DSE was scored if severely reduced or absent perfusion/FDG uptake respectively a scar response was present. RNV was repeated 9 months after CABG, improvement was present if RNV increased >5%. Data are presented as odds ratio's [OR] with 95% CI.

Results: 15/55 patients showed an improved EF > 5%. By ROC analysis the optimal number of viable segments per patient related with functional recovery > 5% by DISA-SPECT and DSE was respectively 4 and 3, with a corresponding area under the curve of 69 and 81%. The OR for functional improvement of DISA-SPECT and DSE were respectively 4.1 [1–19] and 9.8 [2–73] [p = 0.03].

Conclusion: These data suggest a higher predictive accuracy of DSE compared to DISA-SPECT for functional improvement after CABG in patients with LV dysfunction.

P1703 Increased detection of viable myocardium using myocardial perfusion analysis in patients with resting wall motion abnormalities

Melda Dolan, Sanjeev Puri, Kamala Tamirisa, Jeanette St. Vrain, Elena Havens, Jean Flanagan, Kathleen Habermehl, Mark Witrey, Mort Kern, Henry Goodgold, Arthur Labovitz. *St. Louis University, St. Louis MO, USA*

Assessment of viability in patients with resting wall motion abnormalities during Dobutamine Stress Echocardiography (DSE) may not always be accurate in identifying all viable segments. However, Improvement in myocardial perfusion during DSE detected by quantitative color coded myocardial perfusion analysis (MPA) may identify viable myocardial segments. Therefore, we studied 68 patients who underwent DSE with Optison and Tc99m sestimibi. All patients had also coronary angiograms. The patients were divided into two groups, based on presence or absence of viability using nuclear imaging as gold standard. Wall thickening (WT) and MPA were performed off-line by using custom software. Using regional wall thickening, ratio of normal myocardial wall thickness to the infarcted wall was compared at baseline (WTRb) and peak Dobutamine (WTRp). Similarly, ratio of quantitative myocardial perfusion in the normal and infarct regions was calculated both for baseline (MPAb) and peak Dobutamine (MPAp)

	WTRb	WTRp	MPAb	MPAp
Viable	2.9	2.46	3.4	2.3
Non viable	2.7	2.72	3.7	3.5
p	NS	0.06	NS	0.0001

Accuracy of assessment of viability increased from 62% to 87% when quantitative perfusion analysis is added to visual interpretation of Dobutamine Stress Echocardiography.

Conclusion: Increased perfusion ratio derived from quantitative analysis is very sensitive marker for detecting myocardial viability during contrast DSE compared to wall thickening

P1704 Comparison of intermittent power harmonic contrast imaging and low-dose dobutamine stress echocardiography in predicting recovery of left ventricular function in chronic ischaemic heart disease

A. Lippolis, F. Gentile, D. Cirino, D. Esposti, E. Mangiarotti, M. Ornaghi, S. Pierini, G. Tommasini, G. Bozzi. *Cardiology Dept, Bassini Hospital, Milan, Italy*

The purpose of this study was to compare MCE using i.v. LevovistTM and DSE in the prediction of functional recovery in patients affected by CAD.

Methods: MCE following i.v. continuous infusion of Levovist (400 mg/ml) at a rate of 300 ml/h associated with triggered end-systolic Power Harmonic Imaging and DSE were performed in 19 patients affected by CAD. Apical 4 and 2 chambers views were recorded. Each segment was evaluated for Contractile Reserve (CR) by DSE and perfusion by MCE. Regional wall motion and perfusion were scored as follows: 1 = normal, 2 = hypokinetic, 3 = akinetic, 4 = dyskinetic for systolic wall thickening and 0 = non opacified or patchy opacification, 1 = homogeneous opacification, for perfusion. CR was defined as the presence of improved thickening in at least one abnormal segment during DSE or during a follow-up echocardiogram three months later.

Results: 69 dysfunctional myocardial segments were observed: 35 hypokinetic, 31 akinetic, and 3 dyskinetic. Hypokinetic segments were more likely to exhibit perfusion by MCE (15/35; 43%) and CR by DSE (16/35; 46%) than akinetic segments (perfusion was present only in 1 akinetic segment, whereas CR was seen in 6/31; 19%).

Of the 69 dysfunctional segments, 17 (25%) showed myocardial perfusion by MCE and 22 (32%) had CR by DSE. 28 segments improved at follow-up. Functional recovery occurred in 10 of 17 perfused segments (59%) and did not occur in 34 of 52 segments (65%) that did not show perfusion by MCE. Functional recovery took place in 15 of 22 dysfunctional segments with CR(68%) and in 13 of 47 segments (28%) that did not have CR. The sensitivities, specificities, positive and negative predictive values of MCE and DSE in predicting recovery of LV function are expressed in the table 1.

Table 1

	MCE (%)	DSE (%)
Sensitivity	36	54
Specificity	83	83
Positive predictive value	59	68
Negative predictive value	65	72

Conclusions: MCE with Power Harmonic Imaging and DSE had similar specificities and negative predictive values in predicting LV functional recovery.

P1705 Improved detection of viable myocardium early after myocardial infarction by delayed intermittent myocardial contrast echocardiography

R. Senior, J. Swinburn, U. Raval, A. Lahiri. *Northwick Park Hospital, Harrow, Middlesex, UK*

Detection of viable myocardium in the infarcted zone has both therapeutic and prognostic implications. Myocardial contrast echocardiography (MCE) is a new technique for the detection of microvascular integrity which is a surrogate marker of viable myocardium (VM). We have hypothesised that due to low MBF in the infarcted zone (because of residual stenosis or low cardiac output state following AMI), the rate of destruction of contrast will exceed its replenishment in this zone during shorter intermittent imaging, thereby underestimating VM. Nitrate enhanced MIBI has been shown to reliably detect VM. Accordingly, 30 consecutive patients underwent nitrate enhanced MIBI SPECT and MCE on separate days, early after AMI following thrombolysis. MCE was performed during slow IV bolus (0.5 ml) of Optison and intermittent pulse-inversion imaging was performed at intervals of 1 (early), 5 and 10 (delayed) cardiac cycles. VM was defined as presence of more than 50% MIBI uptake qualitatively in a dysynergic segment (16 segment model). A dysynergic segment was considered viable by MCE when the contrast score was 1 (1 = normal, 2 = reduced, 3 = absent) at any of the triggering intervals. Of a total of 156 dysynergic segments MIBI considered 76 segments as VM of which early MCE detected only 17 (22%) while delayed MCE detected 48 (64%) ($p < 0.001$ vs early MCE). Of the 80 non VM segments by MIBI, early MCE correctly detected 68 (85%) while delayed MCE detected 54 (70%) as non-VM (p = NS). Thus delayed intermittent MCE improved detection of viable myocardium early after AMI.

P1706 Feasibility of intracoronary contrast echocardiography for the evaluation of myocardial viability: correlation with dobutamine stress echocardiography

S. Verheye, M.Y. Salame, C. Hoyt, K.A. Robinson, W.D. Wingard, R.P. Martin, S.B. King III, N.A.F. Chronos, S.C. Frohwein. *Department of Medicine (Cardiology), Emory University School of Medicine and the Atlanta VA Medical Center, Atlanta GA, USA*

Background: Decision-making for revascularization after myocardial infarction is frequently difficult and based on the presence of myocardial viability (MV). Viable myocardium has an intact microvasculature allowing myocardial perfusion. The purpose of this preliminary study was to evaluate intracoronary contrast echocardiography (ICE) as a modality for detecting viable myocardium.

Methods: A coronary stent with a pro-thrombotic surface was implanted in 10 juvenile domestic pigs to cause severe narrowings or occlusions. All animals underwent DSE and angiography at baseline and at 28 days. ICE was performed prior to sacrifice at 28 days. For ICE, 1 ml of Optison® contrast was injected into each coronary artery during continuous 2-dimensional echocardiographic imaging. The echocardiographer was blinded to the angiograms. Videotape images underwent wall thickening (WT) scoring offline. MV was defined on DSE as decreased WT at rest, which improved at low dose dobutamine, or on ICE, as the presence of intramyocardial contrast either from ipsi- or contralateral contrast injection. The hearts were harvested and histology performed.

Results: Myocardial infarctions occurred in 5 pigs histologically and this was associated with a total coronary occlusion in the relevant territory.

Stenosis	100	100	100	100	100	90	40	40	35	20
DSE	N	–	–	+	+	+	+	+	N	N
ICE	N	–	–	+	+	+	+	N	N	N

N = Normal, +,– = presence or absence of myocardial viability.

There was 100% correlation between DSE and ICE in hearts with infarcted areas, whereas there was an 80% correlation in hearts without an infarct. In one heart, DSE was positive but ICE was normal in keeping with the angiographic finding.

Conclusions: ICE correlated well with DSE in the detecting MV in this series and may provide clinical information on MV in the catheterization laboratory during interventional procedures. Studies are ongoing to extend this data.

P1707 Determinants of left ventricular remodelling in remote stage of recanalized myocardial infarction using myocardial contrast echocardiography

T. Sakuma, Y. Hayashi, H. Fujiwara, T. Shindo, H. Ueda, M. Otsuka, S. Omura, T. Okada. *Div. of Cardiology, Tsuchiya General Hospital, Hiroshima, Japan*

The aim of present study is to elucidate major determinants of left ventricular (LV) remodeling in the remote stage of recanalized anterior myocardial infarction (MI).

Methods: Seventy two patients who underwent left ventriculography both in the acute stage (day 0) and remote stage (3 to 15 months) with recanalized anterior MI were studied. Serial myocardial contrast echocardiography using selective coronary infusion of sonicated contrast material was performed on day 0 (d0), day 1 (d1), and in the chronic stage (c) (3 to 4 week after reperfusion (R)). Relative size of initial risk area (RA ratio) and microvascular integrity (peak gray scale ratio (PGSR)) within the initial risk area were determined using computed analysis. Age, Elapsed time of recanalization (ET), Collateral grade before R (Coll) (grade 0 to 3), TIMI grade flow after R on d0, Left ventricular regional wall motion (SD/chord) on d0 (RWM), re-elevation of ST segment (ST re-ele) immediately after R, % diameter stenosis using QCA analysis on d0 (%DS), RA ratio, and PGSR (d0), or PGSR (d1), or PGSR (c) were determined as independent variables. Further, LV remodeling (i.e., LV end-systolic volume on remote stage/LV end-systolic volume on d0 is grater than 1.2) was determined as dependent variable, and multiple logistic regression analysis was performed.

Results: Results were shown on the following table.

Factor	χ^2	P value	χ^2	P value	χ^2	P value
Age	0.39	0.53	1.73	0.18	0.49	0.48
ET	0.48	0.48	0.05	0.82	0.28	0.59
Coll	2.59	0.11	2.28	0.13	0.39	0.53
TIMI	0.84	0.36	0.84	0.36	1.38	0.24
RWM	4.83	0.03	4.28	0.04	3.80	0.05
ST re-ele	0.44	0.50	2.88	0.09	0.002	0.96
% DS	2.86	0.09	2.88	0.09	0.63	0.43
RA ratio	4.64	0.03	4.02	0.05	2.53	0.11
PGSR (d0)	3.97	0.04	–	–	–	–
PGSR (d1)	–	–	4.86	0.03	–	–
PGSR (c)	–	–	–	–	3.48	0.06

Conclusions: Both relative size of the initial risk area and microvascular integrity within the initial risk area in the acute stage of MI are more important predictors of left ventricular remodeling in the remote stage of MI than those in the chronic stage of MI.

P1708 Serial assessment of cardiac remodelling after myocardial infarction in rats by MRI

M. Nahrendorf[1], K.-H. Hiller[1], F. Wiesmann[2], K. Hu[2], C. Waller[2], J. Ruff[1], A. Haase[1], G. Ertl[2], W.R. Bauer[2]. [1]*Physikalisches Institut (EP5), Universität Würzburg;* [2]*Medizinische Universitätsklinik Würzburg, Germany*

Changes in cardiac geometry and function after myocardial infarction (MI) are subject of intense research. In the present study we investigated the serial morphologic and functional changes after left coronary artery ligation in the intact rat using Magnetic Resonance Imaging (MRI).

MRI-scans were done 4, 8, 12 and 16 weeks after MI on a 7 T-scanner using an ECG-triggered Cine-FLASH-sequence: 16 contiguous short axis slices, slice thickness 1 mm, echo-time 1.2 ms, in plane resolution 230 μm. In 11 Wistar rats MI-size, left ventricular (LV) mass, LV volumes, cardiac output (CO), ejection fraction (EF), enddiastolic remote wall- (ed wth) and scar thickness (scar) and systolic myocardial wall thickening (SWT) were compared to 4 sham operated rats.

Results for 4 and 16 weeks are shown in the table. Mean MI-size was 30.2 ± 3.1%. EDV of infarcted rats at 16 weeks was correlated to MI-size ($r = 0.85$, $p = 0.001$).

	4 weeks		16 weeks	
	control	MI	control	MI
LV mass (mg)	500.6 ± 5.9	531.8 ± 19.3	511.9 ± 5.8	863.3 ± 34.4$^{*\$}$
EDV (μl)	329.8 ± 10.6	591.3 ± 40.8$^{\$}$	339.7 ± 16.4	711.3 ± 65.7$^{*\$}$
ed wth (mm)	1.44 ± 0.02	1.28 ± 0.06	1.46 ± 0.03	1.9 ± 0.05$^{*\$}$
SWT (%)	65.1 ± 5.8	53.6 ± 6.2	64.3 ± 12.3	31.7 ± 3.8$^{*\$}$
Scar (mm)		0.97 ± 0.05		0.47 ± 0.05*
EF (%)	69.0 ± 1.6	36.5 ± 2.8$^{\$}$	68.0 ± 1.9	34.2 ± 2.2$^{\$}$
CI (ml/kg*min)	256.7 ± 18.2	225 ± 7.9$^{\$}$	280.2 ± 16.12	227.9 ± 16.3$^{\$}$

Data is given in mean ± SEM. $^{*}p < 0.01$ vs. 4 weeks of the same group, $^{\$}p < 0.05$ vs control at the same time, EDV: enddiastolic volume. CI: cardiac index (CO/bodyweight).

The data are in good accordance to previous invasive and post- mortem studies. MRI is well suited for non-invasive sequential studies of LV remodeling post MI.

EXPERIMENTAL HEART FAILURE AND NEUROHORMONAL CONTROL OF HEART FAILURE

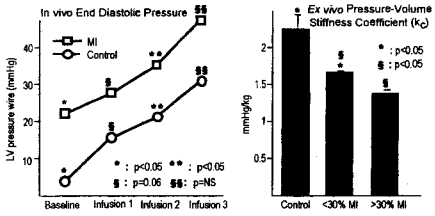
P1709 A novel closed chest in vivo assay system of post-infarction remodelling in the rabbit

R.J. Edwards, Z. Yousef, R.D. Rakhit, M.J. Wright, M.S. Marber. *Department of Cardiology, Rayne Institute, St. Thomas's Hospital, London, UK*

An intact pericardium plays a crucial role during ventricular remodelling. We present a novel closed chest model of rabbit myocardial infarction (MI) and characterise the subsequent changes in left ventricular (LV) geometry and function.

Methods: The right carotid artery of adult NZW rabbits was canulated and coronary angiography performed prior to positioning of a 0.014′ thrombogenic coil in the proximal circumflex artery. 40% of rabbits (n = 8) survived the infarct and were recanulated at 100 days. A 0.014′ pressure tipped wire measured LVEDP following 3 × 100 mls infusion of colloid. A pressure sensitive balloon was secured in the LV of excised hearts into which saline was infused at 3 mls/min. Chamber stiffness (k_c) was derived from the pressure-volume relationship. Cardiac weight, dimensions and infarct size were recorded. Controls (n = 7) did not undergo coil deployment.

Results: Mean LV mass, length, and diameter significantly increased in infarcted rabbits compared to control (7.03 v 6.06 g, 32.55 v 27.19 mm, 13.36 v 8.10 mm; all $p < 0.05$). Rabbits with MI > 30% showed a trend towards increased LV mass and diameter compared to those with MI < 30% (7.69 v 6.53 g, 15.76 v 11.56 mm), and a significant increase in LV length (35.98 v 29.97 mm; $p < 0.05$).



Conclusions: We have developed a rodent model of MI that obviates the need for pericardial excision. This assay system displays fidelity to key end points that can be related to the failing human heart and may provide a powerful tool in the investigation of experimental heart failure.

P1710 Effect of β-blockers on free radical induced cardiac contractile dysfunction

M. Flesch, C. Maack, A.T. Bäumer, M. Südkamp[1], M. Böhm. *Klinik III für Innere Medizin; [1]the Klinik für Herz- und Thoraxchirurgie der Universität zu Köln, Cologne, Germany*

Objective: Effects of hydroxyl radicals (OH•) on human myocardial contractility and on sarcoplasmic reticulum Ca^{2+}-ATPase (SERCA) activity as well as effects of the β-receptor antagonists metoprolol, carvedilol and its metabolite BM-910228 were examined.

Methods: Isometric force of contraction was determined in electrically stimulated (1 Hz, 37°C) isolated human myocardial preparations. SERCA activity was determined in isolated myocardial membrane preparations.

Results: H_2O_2 (1 mmol/l) and Fe^{3+}-nitrilotriacetic acid (Fe^{3+}-NTA, 0.1 mmol/l) used for generation of OH• induced a decrease in basal force of contraction and an increase in diastolic tension in atrial and left ventricular myocardial preparations. After challenge with OH•, the maximum positive inotropic response to Ca^{2+} (1.8–15 mmol/l) was decreased by 60% and by 39%, respectively. Effects of OH• could be blocked by catalase. Both, carvedilol and its metabolite BM-910228 significantly attenuated the OH• induced impairment of the inotropic response to Ca^{2+} in atrial myocardial preparations. Metoprolol had no significant effect. The stimulation frequency (0.5–3.0 Hz) dependent increase in force of contraction and decrease in diastolic tension was abolished after exposure of atrial trabeculae to OH•. In parallel, SERCA activity was decreased by OH• concentration-dependently as determined in myocardial membrane preparations. BM-910228 partially restored the force-frequency relationship and preserved SERCA activity.

Conclusions: OH• radicals induce an impairment of contraction and relaxation and an attenuation of the force-frequency-relationship in human myocardium, which could be due to an inhibition of SERCA. Carvedilol and BM-910228 partly prevented OH• induced contractile dysfunction. These observations could explain the improvement of ejection fraction in heart failure trials with carvedilol without a restoration of β-adrenoceptor density.

P1711 Increased xanthine oxidoreductase activity in hypertrophic and failing heart

J.W. de Jong, R.G. Schoemaker[1], R. de Jonge, E. Keijzer, C. Ceconi[2]. *Thoraxcenter, Erasmus University Rotterdam, Rotterdam; [1]Pharmacology Dept, Erasmus University Rotterdam, Rotterdam, Netherlands; [2]Centro di Fisiopatol Cardiovasc, Fondazione S. Maugeri, Brescia, Italy*

Objective: The molecular basis for heart failure is unknown, but oxygen free radicals have been implied in the genesis of this disease. Xanthine oxidase as a source of free radicals in human heart is controversial. However, recent evidence indicates that explanted human heart contains desulfo xanthine oxidoreductase, which uses NADH as substrate and generates superoxide. We tested therefore the hypothesis that xanthine oxidoreductase activity increases in hypertrophic and failing heart.

Methods: We used two rat models for our study: Group 1) Animals were treated with a bolus injection of monocrotaline, which induces right ventricular hypertrophy in some and dilated right ventricular failure in other animals; Group 2) Animals underwent coronary ligation to induce myocardial infarction. This leads to compensated heart failure at three weeks and decompensated heart failure at eight weeks post-infarction. In both models, also animals were studied in the pre-failing stage, i.e., during the development of cardiac hypertrophy. Xanthine oxidoreductase activity was measured at 30°C in myocardial extracts with 0.1 mM xanthine; xanthine disappearance and urate formation were detected at 280 nm after high performance liquid chromatography. Data analysis took place by ANOVA. Data are presented as means ± SEM.

Results: In Group 1, the hypertrophic hearts showed a non-significant 36% higher enzymatic activity in right than in left ventricles. The hearts showed also a larger xanthine oxidoreductase activity in failing right ventricle than in the unaffected left (65 ± 5 vs. 47 ± 3 mU/gram wet weight; n = 6–7, $P < 0.05$). In Group 2, activities after three and eight weeks were similar and therefore combined for statistics. The activity in the left ventricle increased from 29.4 ± 1.4 mU/g (n = 6) in sham-operated rats, to 48 ± 3 and 80 ± 6 mU/g (n = 8, $P < 0.05$ vs. sham) in the vital and infarcted left ventricular part of failing hearts, respectively. Even right ventricular activity was 30% higher (NS) in failing hearts than in sham-operated ones. In failing hearts, enzymatic activity in left ventricle increased by 46% ($P < 0.05$) compared with that in right ventricle.

Conclusion: In two rat models of heart failure, xanthine oxidoreductase activity increased in failing ventricle compared to internal (unaffected ventricle) and external controls (sham). This could indicate that oxygen free radicals, generated by (the desulfo form of) this enzyme, play a role in the etiology of the disease.

P1712 Endothelium-dependent and -independent vasoreactivity of cerebral arteries in experimental heart failure

J. Widder, L. Schilling[1], D. Fraccarollo, G. Ertl, J. Bauersachs. *[1]II. Medizinische Klinik; [2]Klinik für Neurochirurgie, Universitätsklinikum Mannheim, Germany*

Endothelial dysfunction of peripheral arteries in patients with heart failure and in experimental models has been described for the aorta, coronary arteries and skeletal muscle vascular bed. However, it has not yet been elucidated whether endothelial dysfunction is also present in cerebral vessels, which might contribute to the increased number of cerebrovascular events associated with heart failure.

Methods: We investigated in vitro the reactivity of the aorta and the basilar artery from rats with heart failure due to large myocardial infarction (≥45% of left ventricle) 12 weeks following ligation of left coronary artery (MI) or sham-operation (SO).

Results: In the aorta, the concentration-response curve of the endothelium-dependent, acetylcholine-induced relaxation (following precontraction with phenylephrine) was significantly shifted to the right and the maximum relaxation was attenuated (ED_{50} (−log) 6.58 ± 0.07, R_{max} 86 ± 3%) as compared to SO (7.12 ± 0.05, 97 ± 1%). In contrast, in the basilar artery (following precontraction with serotonin) there was no difference neither in acetylcholine (10 nM–100 μM)-induced relaxation (MI: ED_{50} (−log) 6.7 ± 0.1, R_{max} 59.5 ± 5.5%, SO: ED_{50} 6.7 ± 0.1, R_{max} 61.3 ± 4.3%) nor receptor-independent relaxation induced by the calcium ionophore A 23187 (10 nM–100 μM; MI: ED_{50} 5.8 ± 0.1, R_{max} 58.7 ± 5.4%, SO: ED_{50} 5.8 ± 0.2, R_{max} 61.8 ± 7.6. In addition, endothelium-independent relaxation induced by sodium nitroprusside was not affected in basilar artery following infarction. Moreover, contraction elicited by KCl (124 mM), serotonin (1 μM) or endothelin (1 pM–10 nM) was not altered in MI.

Conclusion: These data show that rats with chronic heart failure following myocardial infarction do not develop changes in basilar artery reactivity despite endothelial dysfunction in other vascular beds.

P1713 In vivo magnetic resonance micro-imaging in two murine models of cardiac failure

F. Wiesmann[1], J. Ruff[2], K.H. Hiller[2], E. Rommel[2], A. Haase[2], S. Neubauer[1]. [1]*Department of Cardiology, University Hospital, Würzburg;* [2]*Institute of Biophysics, University of Würzburg, Germany*

Purpose of our study was to assess the changes of left ventricular (LV) geometry, myocardial function and mass in two mouse models of cardiac failure: myocardial infarction and aortic banding.

Methods: We investigated C57bl/6 mice two weeks after surgical ligature of LAD (n = 5) or aortic banding (n = 5) by *in vivo* ECG-gated magnetic resonance imaging (MRI). Each group was compared to an age matched reference group by MRI studies 2 weeks after sham operation. (n = 5 each).

Results: MR measurements in mice with *myocardial infarction* revealed a significant increase in end-diastolic volume (EDV, 145.3 ± 12.3 μl vs. sham 64.6 ± 5.3 μl, mean ± SEM, $p < 0.001$) and end-systolic volume (ESV, 111.5 ± 15.6 μl vs. sham 27.1 ± 2.6 μl, $p < 0.001$). There was a significant decrease of ejection fraction (EF, 25 ± 5% vs. sham 58 ± 3%, $p < 0.001$), whereas stroke volume (SV, 33.8 ± 4.2 μl vs. 37.5 ± 4.0 μl, $p = 0.54$) and cardiac output (CO, 17.3 ± 3.5 ml vs. sham 18.6 ± 1.1 ml) were not significant different from sham operated mice. The end-diastolic LV anterior wall was significantly thinned (EDAW, 0.48 ± 0.04 mm vs. sham 0.93 ± 0.03 mm, $p < 0.001$), the MRI determined infarct size was 53 ± 5%. Comparison of LV mass (LVM) showed no significant differences between infarcted and sham operated mice.

MR measurements in mice 2 weeks after *aortic banding* showed an 59% increase of LVM (121.9 ± 9.1 mg vs. sham 76.8 ± 8.0 mg, $p < 0.01$) and a 53% increase of LV ED wall thickness (1.13 ± 0.07 mm vs sham 0.74 ± 0.06 mm, $p < 0.01$). However, LV SV (28.6 ± 2.4 μl vs. sham 35.1 ± 4.0 μl, $p = 0.04$) and EF (47 ± 4% vs. sham 70 ± 5%, $p < 0.01$) were significantly decreased in aortic banded mice.

Conclusions: MRI revealed significant geometric and functional changes in two murine models of cardiac failure 2 weeks after the surgical procedure. The exact time course of LV remodeling and hypertrophy in these models remains to be evaluated in detail.

P1714 Interleukin-1b and TNF-a in skeletal muscle biopsies of patients with chronic heart failure: relation to the expression of inducible nitric oxide synthase

Volker Adams, Rainer Hambrecht, Angelika Bauer, Sven Möbius-Winkler, Gerhard Schuler. *University Leipzig, Heart-Center GmbH, Leipzig, Germany*

Recently, an inverse correlation between the expression of inducible nitric oxide synthase (iNOS) and functional work capacity was described in skeletal muscle (SM) of patients (pts) with chronic heart failure (CHF). According to in vitro studies the expression of iNOS is induced by cytokines, especially TNF-a and IL-1b. The present study was designed to examine if also in vivo in the SM of CHF pts cytokines may be responsible for the induction of iNOS expression.

Method: SM biopsies and serum was obtained from forty-four pts with CHF (EF < 40%, NYHA II–III). The expression of iNOS, IL-1b and TNF-a in SM was visualized by immunohistochemistry and quantified by videodensitometry. The serum concentration of IL-1b and TNF-a was evaluated by Elisa. For in vitro experiments L6 rat skeletal myoblast or myocytes were incubated with IL-1b and/or TNF-a and iNOS induction was evaluated by quantitative RT-PCR and Western-blot.

Results: Immunohistochemical analysis of SM biopsies revealed a linear correlation between iNOS and IL-1b expression ($r = 0.66$; $p < 0.0001$) but not between iNOS and TNF-a. Measuring serum concentrations of cytokines no correlation was found between iNOS expression and IL-1b or TNF-a. The necessity of IL-1b for the induction of iNOS expression in SM was confirmed by cell culture experiments.

Conclusion: Cytokines, in particular IL-1b, regulate at least partially the expression of iNOS in SM of pts with CHF. However, serum concentrations of cytokines fail to predict the level of iNOS expression in SM.

P1715 Postischaemic heart failure in tumor necrosis factor alpha deficient mice

S. Briaud, G. Derumeaux[1], X. André-Fouët, A. Cribier[1], M. Ovize. *Unité 81, Hôpital Cardiologique, Lyon[1] Service de Cardiologie, Hôpital Charles Nicolle, Rouen, France*

There is indirect evidence that tumor necrosis factor alpha (TNF) is involved in the development of heart failure. To directly investigate this issue, we assessed postischemic LV dysfunction in TNF deficient mice. In sixty-four mice (30 controls, 16 TNF-deficient (TNF−/−), 12 sham control, 6 TNF−/−sham), myocardial infaction was produced by 90 minutes of coronary artery occlusion followed by 2 weeks of reperfusion. At day 14, regional (anterior and posterior wall thickening, AWT, PWT) and global (LV systolic fraction) LV function was assessed by echocardiography (Acuson Sequioa system). Acute myocardial infarction resulted in regional and global contractile dysfunction (table, *$p < 0.05$ vs PWT, **$p < 0.05$ vs sham).

Table

	AWT (%)	PWT (%)	LVSF (%)
Control (n = 30)	36 ± 6*	52 ± 7	28 ± 2**
TNF−/− (n = 16)	32 ± 5*	47 ± 7	26 ± 2**
Sham control (n = 12)	50 ± 4	57 ± 3	44 ± 3
Sham TNF−/−(n = 6)	55 ± 6	52 ± 8	40 ± 5

Yet, TNF deficient mice failed to develop reduced regional and global systolic dysfunction when compared to controls. This suggests that TNF alpha is not a major determinant of the development of heart failure in this model.

P1716 Cardiac troponin T as a marker of experimentally induced cardiomyopathy

M. Adamcová, V. Geršl[1], R. Hrdina[2], M. Mělka[3], Y. Mazurová[4], J. Vávrová[5], V. Palička[5], J. Macháčková[1]. *Department of Physiology; [1]Department of Pharmacology; [3]Department of Biochemistry; [4]Department of Histology, Charles University Faculty of Medicine in Hradec Králové; [2]Department of Pharmacology and Toxicology, Charles University Faculty of Pharmacy in Hradec Králové; [5]Institute of Clinical Biochemistry and Diagnosis, Hradec Králové, Czech Republic*

The cardiac effects of antineoplastic drugs were investigated in rabbits *in vivo* from the viewpoint of release of cardiac troponin T (cTnT) measured using Elecsys Troponin T STAT Immunoassay – Boehringer Mannheim (Germany).

During development of daunorubicin-induced cardiomyopathy (daunorubicin 3 mg/kg i.v., once a week, 10 weeks, n = 13), cTnT was within physiological range (i.e. cTnT < 0.1 μg/l) at the beginning of experiment, but after the 8*th* administration cTnT was significantly higher (0.31 ± 0.11 μg/l) in 46% animals with premature deaths compared with the rest of group (0.04 ± 0.03 μg/l). In the control group, the levels of cTnT were always lower than 0.1 μg/l during the experiment. Following administration of a new drug Oracin (6-[2-(2-hydroxyethyl)aminoethyl] dioxo-5,6-dihydro-11H-indeno[1,2-c]-isoquinoline hydrochloride, 10 mg/kg i.v., once weekly, 10 administrations, n = 7), no increase in cTnT levels was present. These findings correlated with the fact that only mild changes in the PEP:LVET index were found and no premature death of animals occurred in the Oracin group. Histological examination of the myocardium revealed only a very slight damage in the Oracin group in comparison with a very marked, diffuse damage in the daunorubicin group. The combination of daunorubicin and Oracin (n = 7) did not caused significant deterioration of the examined parameters which is very important from the clinical point of view.

It is possible to conclude that cTnT is a useful marker for the prediction of experimentally induced anthracycline cardiomyopathy and for the evaluation of cardiotoxic (and, possibly, cardioprotective) effects of new drugs.

P1717 Beneficial renal effects of adrenomedullin infusion in experimental heart failure

I. Pagel, R. Dietz, R. Willenbrock. *LEH, Franz-Volhard-Klinik, Charité, Berlin, Germany*

Introduction: Adrenomedullin (AM) is a peptide hormone with vasodilating and diuretic properties. While the actions of natriuretic peptides as atrial natriuretic peptide (ANP) and brain natriuretic peptide (BNP) are blunted in heart failure, the hemodynamic and renal effects of adrenomedullin are imperfectly defined.

Methods: We used the aortocaval shunt in male Wistar rats as a model of experimental heart failure and infused cumulative doses of human adrenomedullin (0.05, 0.1, 0.5 and 1 $\mu g/kg \times min^{-1}$) over 20-minute periods.

Results: In controls, AM induced a dose-depending decrease in arterial blood pressure by 6.0 ± 0.9 to 21.6 ± 3.2 mmHg. In shunt-operated rats, the hypotensive response was blunted ($p < 0.01$ vs controls). The urine flow rate, which was diminished in rats with aortocaval shunt, was raised and normalized by AM administration. Similarly, sodium excretion increased from 14.4 ± 2.8 to 23.6 ± 5.0 mmol/20 min after AM. In contrast to the blunted hypotensive effect, the renal blood flow increased in both groups (controls: 8.4 ± 1.0 to 13.1 ± 1.0 ml/min, $p < 0.001$; shunts: 5.1 ± 0.6 to 8.7 ± 1.4 ml/min, $p < 0.01$) and was paralleled by a significant increase in glomerular filtration rate in either group (controls: 2.4 ± 0.2 to 3.5 ± 0.3 ml/min, $p < 0.01$; shunts: 1.8 ± 0.3 to 3.0 ± 0.6 ml/min, $p < 0.01$).

Conclusion: Our data indicate a beneficial renal action of adrenomedullin in parallel with a mild hypotensive effect in heart failure. Thus, the infusion of adrenomedullin might have potential therapeutic value in the management of heart failure.

P1718 Soluble adhesion molecules as unique molecular markers for atherosclerosis and coronary heart disease

A.Z. Darwish, S.F. Hammmoudah[1]. *Department of Cardiology; [1]Department of Clinical Pathology, Tanta University, Tanta, Egypt*

Background: Binding and recuritment of circulating leukocytes to the vascular endothelium and further migration into the subendothelial spaces are the major processes in the development of atherosclerosis and are mediated through a diverse family of cellular adhesion molecules that are expressed on the surface of vascular endothelial cells. This study was designed to determine the ability to use circulating cellular adhesion molecules as a molecular of atherosclerosis and coronary heart disease (CHD).

Methods: plasma levels of vascular cell adhesion molecule-1 (sVCAM-1), endothelial-leukocyte adhesion molecules-1 (sE-selectin) and intercellular adhesion molecule-1 (sICAM) was evaluated in 31 patients with CHD, 35 patients with carotid atherosclerosis (CAA) and 20 control subjects.

Results: Higher levels of sE-selectin and sICAM-1 were observed in patients with CHD compared to control subjects (sE-selectin 39.3 Vs 32.8 ng/ml; sICAM-1 293.0 Vs 240.3 ng/ml). In CAA patients significant increase in sE-selectin (43.0 Vs 32.8 ng/ml) and in sICAM-1 (288.2 Vs 240.3 ng/ml) compared to control group. Levels of sVCAM-1 were not significantly different among all studied groups. Logistic regression analysis results showed that sICAM-1 and sE-selectin in patients with CHD and CAA were independent of other known CHD risk factors.

Conclusion: we defined significant relationship of sICAM-1 and sE-selectin levels with the burden of atherosclerosis as measured by carotid B-model ultrasound, and CHD indicating that, they might serve as a molecular markers of atherosclerosis and CHD development.

P1719 Relationship between angiotensin converting enzyme inhibitor dosages and the suppression of the renin angiotensin pathway in chronically treated patients with congestive heart failure

R. Isnard, F. Pousset, O. Chafirovskaia, A. Carayon, J.L. Golmard, P. Lechat, D. Thomas, M. Komajda. *Cardiol Dept, Pitié-Salpétrière Hosp., Paris, France*

An incomplete blockade of the renin angiotenin (RA) axis by long term angiotensin converting enzyme (ACE) inhibition in congestive heart failure (CHF) has been reported. However, recent studies have emphasized the efficacy of high-versus low-doses of ACE inhibitors (ACEI) in CHF.

We studied the relationship between the suppression of the RA axis and the ACEI dosages in 198 patients with CHF, chronically treated by ACEI. For each patient, ACEI dosage was standardized as percent of maximal recommended dosage for each compound. Plasma renin activity (PRA), plasma angiotensin II (AII), and plasma aldosterone (Ald) were measured in all the patients. NYHA functional class, furosemide dosages, plasma sodium, plasma norepinephrine (NE), plasma atrial natriuretic peptide and plasma endothelin-1 were also analysed.

No correlation was observed between PRA, plasma AII and plasma Ald, and ACEI dosage. Multiple regression analysis showed that (1) PRA depended on plasma sodium ($\beta = -0.19$, $p = 0.008$) and on plasma NE ($\beta = 0.19$, $p = 0.011$), (2) plasma AII depended only on PRA ($\beta = 0.28$, $p = 0.0004$) and (3) plasma Ald depended on PRA ($\beta = 0.2$, $p = 0.006$) and on plasma NE ($\beta = 0.24$, $p = 0.002$).

Thus, in chronically treated patients with CHF, there is no relationship between ACEI dosage and the degree of suppression of the RA axis. Persistent activation of this axis seems partly modulated by sympathetic activation. This finding argues for the use of combined neurohormonal blockade in addition to ACEI in the treatment of heart failure.

P1720 The effects of chronic, sustained-release moxonidine therapy on clinical and neurohumoral status in patients with heart failure

Kenneth Dickstein[1], Cord Manhenke[1], Torbjørn Aarsland[2], John McNay[3], Curtis Wiltse[3], Theressa Wright[3]. *[1]Cardiology Division, Central Hospital in Rogaland, Stavanger; [2]Hjertelaget Research Foundation, Stavanger, Norway; [3]Eli Lilly and Company, Indianapolis IN, USA*

CHF is characterized by neurohumorally mediated vasoconstriction and tachycardia, and plasma norepinephrine (PNE) is an important predictor of mortality and morbidity. Moxonidine selectively stimulates imidazoline receptors which centrally inhibit sympathetic outflow and potently suppress levels of circulating PNE.

Methods: This study evaluated 25 CHF patients (age = 69 ± 7 years, 20 males) in NYHA class II or III, stabilized on chronic therapy with diuretics and ACE inhibitors. Mean EF was 28 ± 7% and mean PNE concentration was 343 ± 132 pg/ml at baseline. Patients were randomized and titrated in a double-blind fashion to 12 weeks of oral placebo (n = 9) or sustained-release moxonidine 0.9 mg bid (n = 16). Patients' clinical status was monitored and blood was sampled weekly and twice for 12 hours at baseline and on chronic therapy, and daily following abrupt withdrawal for PNE, plasma renin activity and serum moxonidine. Heart rate and systemic arterial BP were recorded by ambulatory BP and Holter monitoring at baseline, on chronic therapy, and for 60 hours following withdrawal. Heart rate variability was assessed using standard, time-domain variables.

Results: All patients reached the target dose without drug-related serious adverse events. Apart from dry mouth, the side-effect profile (including orthostatic hypotension) of moxonidine was not significantly different from placebo. PNE was substantially reduced at the maximum dose (0.9 mg BID) by 50% ($p = 0.0005$) as compared to placebo. A significant reduction in heart rate ($p = 0.01$) was observed. Systolic pulmonary arterial pressures, as assessed by Doppler, were reduced ($p < 0.05$). A trend towards a reduction in ventricular arrhythmia during chronic therapy was seen. A 39% increase in the standard deviation of normal-to-normal intervals (SDNN) was observed during chronic moxonidine therapy ($p < 0.001$) with a significant correlation between this improvement and the reduction in PNE ($r = -0.69$, $p < 0.05$). Abrupt withdrawal of chronic therapy resulted in rapid increases in PNE, BP and heart rate to or above baseline.

Conclusions: Twelve-week therapy with sustained-release moxonidine in CHF was well-tolerated with substantial and sustained reductions in PNE and attenuation of tachyarrythmias. Due to the observed effects of moxonidine discontinuation, tapering of therapy is recommended. Trials appropriately designed to evaluate the efficacy of long-term moxonidine therapy on morbidity and mortality in CHF are warranted.

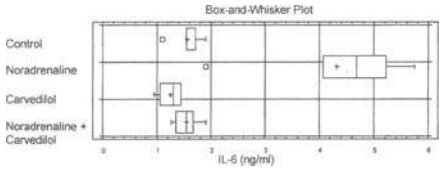
P1721 Noradrenaline stimulates cardiomyocytes to produce interleukin-6, indicative of a proinflammatory action, which is suppressed by carvedilol

U. Müller-Werdan, J. Jacoby, H. Loppnow, K. Werdan. *Department of Medicine III, University of Halle-Wittenberg, Germany*

It is a matter of debate, how cytokine release is triggered in severe heart failure. Potential players include a neurohumoral dysbalance with an enhanced sympathetic tone or an overspill of cytokines from the failing heart itself. Here we report that noradrenaline *in vitro* stimulates the release of interleukin-6 (IL-6) from cardiomyocytes (CM), in line with a previously unrecognized direct proinflammatory effect of noradrenaline on CM.

Methods: Spontaneously beating neonatal rat CM were incubated for 8–24 h in serum-free medium supplemented with or without noradrenaline (0.1–1 μM), in the absence or presence of carvedilol (10 μM). In some experiments, an inhibitor of phosphodiesterase (3-isobutyl-1-methylxanthine, IBMX, 0.5 mM) or TNF-α (20 ng/ml) was simultaneously added. The adrenergic response was documented by monitoring the beating rate. Inflammation was assessed by the IL-6 (bioassay) content of culture supernatants.

Results: In numerous experiments, noradrenaline significantly enhanced IL-6 content of CM supernatants (figure). The IL-6 release was more pronounced in the presence of IBMX or TNF-α, but suppressed by carvedilol.



Conclusion: The release of proinflammatory cytokines in heart failure may be directly linked to the enhanced sympathetic tone.

P1722 Evidence for a positive inotropic effect of bradykinin in human atrial muscle preparations

B. Drexler, M. Wilhelm, S. Wollner, S. Schmidt-Schweda, Ch.J.F. Holubarsch. *University of Freiburg, Germany, Dept. Cardiology & Angiology*

One essential difference between a therapy with angiotensin converting enzyme (ACE) inhibitors and angiotensin-antagonists is the increase in bradykinin concentrations by ACE-inhibitors. Whereas the vasodilating effect of bradykinin is well known, its myocardial effect is unknown or controversial. We investigated the effect of bradykinin on maximum developed force of isometrically contracting right atrial human muscle preparations (60 beats/min; 37° C).

Bradykinin without pretreatment (n = 18) had no inotropic effect at all. Assuming that the myocardial ACE may inactivate bradykinin, preparations (n = 14) were pretreated with enalaprilate (10^{-6} M). In 8 preparations a positive inotropic effect was observed: Maximum developed tension increased by 34 ± 6% ($p < 0.05$) at 10^{-5} M bradykinin. This effect was blocked by propranolol (10^{-5} M).

Conclusions: Bradykinin has a positive inotropic effect in the majority of human atrial preparations, which can be explained by the release of endogenous catecholamines. This finding may be of great importance regarding the clinical efficacy of ACE-inhibitors and AT-receptor antagonists.

P1723 Plasma brain natriuretic peptide as a biochemical marker for physiological pacing

M. Kinoshita, H. Horie, M. Takahashi, M. Izumi, T. Tsutamoto, Y. Nakamura. *First Department of Internal Medicine, Shiga University of Medical Science, Otsu, Japan*

Cardiac natriuretic peptides are reported to reflect various hemodynamic changes. Plasma brain natriuretic peptide(BNP) has been found to be more sensitive than ANP for predicting hemodynamic abnormalities. We investigated whether or not plasma BNP is influenced by different pacing modes or electrical stimulation.

Methods: Subjects consisted of 223 permanent pacemakers patients with sick sinus syndrome or a high degree of atrioventricular block. The patients with atrial fibrillation or spontaneous beats were excluded from the study. The implanted pacemakers were 52 VVI, 30 AAI and 82 DDD types. We selected 20 age-matched normal subjects who demonstrated atypical chest pain with normal coronary angiograms. Plasma BNP and ANP were measured at a rate of 70 beats/min after 45 minutes in the supine position. Under ECG monitoring, the pacing mode was switched from DDD to VVI in 12 patients and from DDD to AAI in 4 patients with a dual-chamber pacemaker. Plasma ANP and BNP levels were also measured 30, 60 min and 1 week after mode switching. Plasma ANP and BNP levels were both significantly higher in the non-physiological pacing group than in the physiological pacing group(ANP: 66.8 ± 6.93 vs 30.88 ± 1.45 pg/ml, $p < 0.0001$, BNP: 74.6 ± 8.38 vs 22.5 ± 1.93 pg/ml, $p < 0.0001$, respectively). Both ANP and BNP levels were similar in the DDD and AAI pacing groups. One week after switching from DDD to VVI, plasma ANP and BNP levels increased significantly, however no significant changes were observed after switching to AAI. Based on univariate regression analysis of 13 non-invasive clinical parameters, ejection fraction, pressure gradient of tricuspid regurgitation and plasma ANP and BNP correlated significantly with physiological pacing($p = 0.0056$, $p < 0.05$, $p < 0.0001$, $p < 0.0001$, respectively).Based on the final stepwise multivariate regression analysis, only low plasma BNP correlated significantly with physiological pacing.

In conclusion, plasma BNP, similar to ANP, is influenced by the pacing mode, but is not influenced by electrical stimulation. In addition, low plasma BNP is important in relation to physiological pacing.

P1724 Prognostic value of endothelin peptides in patients with heart failure

I. Cecioni, P.A. Modesti, A. Costoli, L. Poggesi, C. Rostagno, G.G. Neri Serneri. *Clinica Medica Generale e Cardiologia, University of Florence, Florence, Italy*

In addition to endothelial cells, endothelin-1 (ET-1) is also synthesized by epithelial cells in the kidney and is excreted in urine. Renal ET-1 is involved in fluid handling. An increased plasma concentration of ET-1 in congestive heart failure has been found to be associated with a poor prognosis. The aim of this study was to investigate urinary excretion of ET-1 in patients with heart failure, in the different functional NYHA classes, and its prognostic value.

We prospectively studied, for a mean follow-up period of 3.8 years, 158 patients with heart failure classified at enrollment according to NYHA criteria (class I, n = 12; class II, n = 44; class III, n = 68; and class IV, n = 34). Blood and urine samples were collected for measurement of daily urinary ET-1 and big ET-1 excretion and for plasma ET-1, big ET-1, ANP, AVP, and PRA assays. All collections were performed at least 48 h after ACE-inhibitors and diuretics withdrawal. Twenty healthy controls of equivalent age were also investigated.

Plasma concentration and urinary excretion of ET-1 in NYHA class I patients were not significantly different from those found in controls. In NYHA class II patients urinary ET-1 excretion, but not plasma ET-1 concentration, was significantly increased vs controls (9.6 ± 4.1 vs 1.7 ± 0.8 ng/gUC, $p < 0.001$, for urine; 0.77 ± 0.26 vs 0.72 ± 0.22 pg/ml, ns, for plasma). ANP plasma concentration was also enhanced in class II patients ($p < 0.01$), whereas in those patients PRA and AVP were not significantly higher than in controls. Plasma concentration of ET-1 was increased in patients in III NYHA class ($p < 0.01$) and urinary ET-1 remained elevated. During the follow-up period 76 patients died from a cardiac cause. At stepwise multivariate Cox proportional hazards regression analysis only urinary ET-1 excretion was significant independent predictor of functional class worsening ($p < 0.0001$). Conversely, plasma big ET-1 and ET-1 ($p < 0.0001$ for both), but not urinary ET-1, PRA, ANP and AVP resulted significantly independent predictors of mortality.

In conclusion 1) urinary ET-1 excretion increased in the early phase of heart failure, and 2) was an independent predictor of clinical worsening, whereas 3) high plasma levels of ET-1 and big ET-1 were independent predictors of mortality.

P1725 Elevated plasma norepinephrine levels in endstage heart failure are significantly correlated to upregulation of Na^+/Ca^{2+} exchanger protein levels

W. Schillinger, H. Schneider[1], A. El-Armouche[1], R. Ferrari[2], G. Hasenfuss. *Kardiologie und Pneumologie, Georg-August-Universität Göttingen, Göttingen[1] Med. III, Kardiologie und Angiologie, Albert-Ludwigs Universität Freiburg, Freiburg, Germany[2] Fac. di Medicina, Div. di Cardiologia, Università di Brescia, Brescia, Italy*

Recent studies reported upregulation of sarcolemmal Na^+/Ca^{2+} exchanger (NCX) and downregulation of sarcoplasmic reticulum Ca^{2+}-ATPase (SERCA) gene expression in terminal cardiac failure. Alterations in gene expression could derive from neurohumoral activation.

Plasma levels of norepinephrine (NE), epinephrine (E), atrial natriuretic peptide (ANP), plasma renin activity (PRA), aldosterone (ALD), tumor necrosis factor (TNF)-alpha, and TNF-receptors 1 and 2 (TNF-R1, TNF-R2) were determined in 26 patients suffering from endstage heart failure in the hours preceding heart transplantation. Protein abundance of NCX and SERCA was determined after cardiectomy by western blot analysis of myocardial samples. There was a significant positive correlation between NE and NCX protein levels ($r = 0.58$, $p < 0.004$). Moreover, NE plasma levels were significantly correlated to cardiac index ($r = -0.54$, $p < 0.01$). Patients with plasma NE > 900 pg/ml which has previously been shown to be an independent indicator for increased mortality in heart failure had significantly elevated NCX protein levels ($p < 0.01$). Sudden death is a major cause of mortality in endstage cardiac failure. In a subgroup of patients with a history of sustained ventricular tachycardia or ventricular fibrillation (n = 6) NE levels were significantly higher than in patients without sustained arrythmic events ($p < 0.01$). There was no significant correlation of SERCA protein levels with neither NE, nor E, ANP, PRA, ALD, TNF-alpha, TNF-R1 or TNF-R2. Furthermore, we found significant correlations of the stage of heart failure (according to Soufer Am J Cardiol 55: 1032–36) and TNF-R1 ($r = 0.56$, $p < 0.05$) and TNF-R2 ($r = 0.63$, $p < 0.01$). E and ANP significantly correlated with cardiac index ($r = -0.55$, $p < 0.01$ and $r = -0.51$, $p < 0.05$, respectively).

In conclusion, in endstage cardiac failure NCX protein levels significantly correlated with plasma NE. Significantly elevated plasma NE levels occurred in patients with a history of sustained ventricular arrythmia. Downregulation of SERCA could not be related to neurohumoral activation.

P1726 Treatment with Carvedilol improves arterial baroreflex control of heart rate in chronic heart failure. Comparison of spectral and phenylephrine techniques

A. Mortara, M.T. La Rovere, G.D. Pinna, A. Prpa, R. Maestri, S. Capomolla, F. Cobelli. *Cardiology Dept., "S.Maugeri" Foundation, Montescano (Pavia), Italy*

Since beta-adrenergic blockade (BB) in chronic heart failure (CHF) has been shown to improve signs and symptoms of ventricular dysfunction, we have investigated whether this effect is also accompanied by a restoration of vagal reflexes as assessed by the phenylephrine method (PHE) and by a spectral technique (Robbe method, SPE). Twenty consecutive CHF patients with moderate and stable CHF (age 51 ± 9 yr., NYHA CL. II-III, LVEF 24+8%, optimised therapy), underwent PHE and SPE analysis at baseline and after randomisation to receive (n = 10) or not (n = 10) BB therapy (carvedilol) for a mean period of 9 ± 3 months. At baseline PHE was computable in all patients while SPE only in 9/20 patients due to a low coherence (<0.5) in the RR and systolic pressure spectral bands. In the 9 patients with both tests measurable, mean SPE and PHE were similar (6.3 ± 4.5 and 6.8 ± 2.6 ms/mmHg, ns), but with a correlation coefficient of r = 0.51, ns. In the patients who underwent BB there was a significant improvement in NYHA CL, LVEF, Echo deceleration time and peak VO_2 (all $p < 0.05$), and PHE increased significantly from 3.7 ± 4.3 to 9.3 ± 5.9 mmHg, $p = 0.03$. After BB therapy, SPE was computable in all patients with a mean value of 9.5 ± 3.5 ms/mmHg (ns vs PHE, correlation coefficient with PHE = 0.67, $p < 0.05$). In the 4 patients with SPE measured at baseline, it increased significantly after BB (from 8.6 ± 3.1 to 12.4 ± 1.6 ms/mmHg, $p = 0.02$). No significant differences were observed in not treated patients in both hemodynamic and BRS data.

Conclusions: In CHF, treatment with Carvedilol, besides the well known effects on ventricular function, restores the capability to reflexly increase vagal activity. The PHE method seems the technique of choice in the assessment of BRS, since SPE is computable only in a limited number of patients. However, both methods, when measurable, are effective in revealing the improvement of BRS function by BB treatment.

P1727 A- and B-type natriuretic peptides respond differently to rapid reduction in cardiac preload

N.S. Ahmadi, A.I. Larsen[1], T. Aarsland[2], K. Dickstein[1], C. Hall. *Research Inst. for Internal Medicine, University of Oslo, Oslo; [1]Cardiovascular Divison, Central Hospital in Rogaland, Stavanger; [2]Hjertelaget Research Foundation, Stavanger, Norway*

Natriuretic peptides ANP and BNP with propeptides Nt-proANP and Nt-proBNP may serve as biochemical markers of cardiac preload. The purpose of this study was to detect differences between these peptides in their response to rapid reduction in cardiac preload subsequent to nitrate infusion. Sixteen men and 4 women aged 63.0 ± 10.4 years (mean ± SD) with congestive heart failure (NYHA III) and pulmonary capillary wedge pressure (PCWP) ≥ 18 mmHg, were given a 24-hour infusion of nitroglycerin (N = 8) or nicorandil (N = 12). Doses were titrated to obtain a reduction of PCWP of at least 30% and then maintained. Natriuretic peptides were measured by radioimmunoassay at baseline, 1, 3, 12 and 24 hours:

	Baseline	3 hours	12 hours	24 hours
PCWP	25.5 ± 5.7	15.3 ± 3.6*	15.5 ± 4.7*	16.7 ± 5.7*
RAP	10.6 ± 4.4	8.1 ± 2.6*	7.7 ± 3.1*	8.8 ± 4.4*
ANP	84.8 ± 50.8	49.7 ± 30.1*	52.9 ± 31.4*	64.5 ± 44.4*
Nt-proANP	1998 ± 922	1663 ± 797*	1612 ± 835*	1819 ± 928*
BNP	100.6 ± 57.7	90.0 ± 49.3	68.2 ± 36.9*	53.9 ± 31.8*
Nt-proBNP	258.2 ± 136.0	255.5 ± 128.5	205.1 ± 90.4*	156.7 ± 67.6*

RAP: Right atrial pressure; Units: mmHg; pmol/l; Mean ± SD, *p < 0.01 versus baseline.

PCWP and RAP fell rapidly within 3 hours, and then increased slightly. ANP and Nt-proANP followed the same pattern. In contrast BNP and Nt-proBNP fell steadily throughout the observation period, reaching minimum levels at 24 hours. Peptide responses were independent of type of nitrate given.

Conclusion: The A-type peptides reflect rapid changes in preload while the B-type peptides seem to respond much slower. This difference is of relevance to the interpretation of peptide measurements in the clinical setting.

P1728 Sympathetic and reflex alterations in hypertensive heart failure patients

G. Grassi, R. Dell'Oro, C. Turri, M. Magnoni, G. Bertinieri, G. Seravalle, G. Mancia. *Clinica Medica, University of Milan, Osp. S. Gerardo, Monza; Centro Fisiologia Clinica, IRCCS, Milan; Istituto Auxologico Italiano, IRCCS, Milan, Italy*

Heart failure (HF) is characterized by sympathetic activation, which is also common of hypertensive patients (H) with normal cardiac function. It is unknown, however, whether the concomitant presence of H and HF further enhances the neural abnormalities characterizing the above mentioned cardiovascular diseases.

Methods: In 8 normotensive control subjects (C, age: 54.9 ± 4.8 yrs, mean ± SEM), 7 untreated H, 10 normotensive untreated HF patients (NYHA class II–III, LVEF 39.8 ± 3.1%) and 9 untreated HF patients with H (HFH, NYHA class II–III, LVEF 39.3 ± 3.0%), all age-matched with C, we measured mean arterial pressure (MAP, Finapres), heart rate (HR, EKG) and postganglionic muscle sympathetic nerve traffic (MSNA, microneurography) at rest and during baroreceptor stimulation and deactivation induced by stepwise i.v. infusions of phenylephrine (PHE) and nitroprusside (NTP) respectively.

Results: MAP was higher in H and in HFH (108.7 ± 3.7 and 104.4 ± 4.3 mmHg respectively, $p < 0.01$ for both) than in C and in HF (88.7 ± 3.5 and 81.6 ± 3.1 mmHg), while HR was significantly increased only in HFH. MSNA values were significantly higher in H and in HF than in C (42.0 ± 2.2 and 45.5 ± 2.7 vs. 30.8 ± 2.5 bs/min respectively, $p < 0.01$ for both), a further increase being detected in HFH (59.9 ± 4.7 bs/min, $p < 0.05$). In C the mean BP increase induced by PHE caused a reflex reduction in HR (−12.3 ± 1.5 b/min) and in MSNA (−71 ± 9% i.a.), while the mean BP fall induced by NTP caused opposite effects (HR: +20.5 ± 2.3 b/min; MSNA: +115 ± 18% i.a.). While in H only baroreflex modulation of HR was impaired (−42 ± 7%, $p < 0.01$ vs C), in HF both HR and MSNA changes were attenuated (−59 ± 6 and −61 ± 7% respectively, $p < 0.01$ for both), a further attenuation being observed in HFH (−69.3 ± 8 and −68.4 ± 6% for HR and MSNA).

Conclusions: Thus the concomitant presence of HF and H triggers a sympathetic activation greater for magnitude than that found in these pathological conditions. This is accompanied by a marked impairment in baroreflex control of both vagal and sympathetic components, which is greater for magnitude than that observed in HF and in H.

P1729 Inhibitory sympathetic norepinephrine release in volume overloaded cardiac hypertrophy

H. Suzuki, K. Maehara, Y. Maruyama. *First Department of Internal Medicine, Fukushima Medical University, Fukushima, Japan*

It has been known that angiotensin II (AII) accelerate norepinephrine (NE) release from sympathetic nerve terminal during sympathetic activation in the normal heart. Therefore, cardiac NE release might be much enhanced in the process from cardiac hypertrophy to failure due to increased tissue AII and cardiac sympathetic nervous activity, while it has not been directly examined. We investigated how AII modulates cardiac NE release during sympathetic activation in volume overloaded cardiac hypertrophy in the rat.

Methods: Four weeks after operation of abdominal aortocaval shunt (group A, n = 20) or sham oepration (group B, n = 20), rats were anesthetized and pithed. The heart was perfused retrogradely in Langendorff's manner, and a balloon was inserted into the left ventricle for measurement of left ventricular (LV) pressure. Heart rate, coronary perfusion pressure and LV end-diastolic pressure were kept constant. Electrical field stimulation of sympathetic nerve (SNS) was performed from the spinal canal for 45 sec after atropine administration. SNS were repeated under constant infusion of AII (1 nM, n = 10 in each group) or AII type 1 receptor blocker, losartan (10 μM, n = 10 in each group). Coronary effluent was collected from the right atrium. Total ammount of NE released during SNS was calculated from coronary flow and NE concentration, and normalized by heart weight.

Results: In control SNS without drug administraion, NE release was significantly greater in group B than group A (21 ± 3 pmol/g vs 63 ± 13 pmol/g, $p < 0.01$). In group B, AII infusion during SNS increased NE release by 113 ± 36% compared with control SNS, however, losartan did not affect NE release. On the contrary, in group A, AII infusion during SNS decreased NE release by 31 ± 7% compared with control SNS, and losartan significantly increased NE release by 100 ± 48%. These changes of NE release by AII or losartan altered isovolumic LV pressure in a similar fasion.

Conclusions: Against our expectation, AII produced inhibitory effect on cardiac sympathetic neuron NE release in volume loaded LV hypertrophy. It would indicate a protective effect of AII to activation of cardiac sympathetic nervous system at least in the early stage of volume overloaded hypertrophy.

P1730 Isolated hearts from α_{2a}-adrenoreceptor-deficient mice show altered left ventricular function but unchanged catecholamine responsiveness

Matthias Spindler, Lutz Hein[1], Hinrik Strömer, Andrea Leupold, Stefan Neubauer. *Departments of Medicine; [1]Pharmacology, University of Würzburg, Germany*

α_2-adrenergic receptors (AR) play a central role in the regulation of the sympathetic nervous system. To date, three subtypes of α_2-AR have been identified (termed α_{2A}, α_{2B}, α_{2C}). To determine the physiological significance of these α_2-AR subtypes, the gene for the α_{2A}-AR was deleted in mice by gene targeting. Mean aortic pressure in vivo did not differ between α_{2A}-AR deficient ($\alpha_{2A}^{-/-}$) and wild type (WT) mice, but basal heart rate (HR) was increased by 45% in $\alpha_{2A}^{-/-}$ mice. Tissue catecholamine levels and myocardial β-receptor density were decreased in $\alpha_{2A}^{-/-}$ mice. To determine the effect of α_{2A}-AR disruption on the heart without the influence of the adjacent vasculature and central nervous system, we studied isovolumic isolated hearts at baseline, during increased HR and during isoproterenol stimulation.

Heart weight and heart weight/body weight ratios of 20–25 week old mice were identical for both groups. Spontaneous HR was similar for $\alpha_{2A}^{-/-}$ and wild type, but left ventricular developed pressure (DevP) was 24% lower in $\alpha_{2A}^{-/-}$ hearts (85 ± 2 vs 65 ± 4 mmHg). Furthermore, $\alpha_{2A}^{-/-}$ hearts showed significantly higher rate of pressure rise (+dP/dt/DevP) and shorter time to peak pressure (55.5 ± 2.3 vs 61.0 ± 1.4 ms) compared to WT. These differences were preserved when hearts were paced at 420 or 600 min-1. Isoproterenol dose response (10^{-10} to 10^{-7} M) for DevP, HR, +dP/dt/DevP and time to peak pressure was similar in both groups.

We conclude that chronic increase in sympathetic tone in mice lacking α_{2A}-AR leads to unique changes of left ventricular function in isolated hearts: Decreased DevP and, simultaneously, increased rate of pressure development. These transgenic mice represent a novel model to determine the impact of neurohumoral activation (as occurs in heart failure) on myocardial contractility.

P1731 Sympathetic and vascular responses to a high carbohydrate load in severe heart failure: evidence for imbalance between insulin's vasopressor and vasodilatory actions?

E.M. Scott, M.T. Kearney, J.P. Greenwood, M. Bosomworth[1], S.G. Gilbey, J.B. Stoker, D.A. Mary. *[1]Departments of Cardiovascular Medicine and Biochemistry; St James's University Hospital, Leeds, UK*

It is established that patients with heart failure (HF) are insulin resistant. Insulin has opposing vasodilatory and sympathoactivatory actions and the balance between the two appears to be altered in the context of insulin resistance. This preliminary study sought to explore the vascular and sympathetic effects of endogenous insulin, produced in response to a carbohydrate load, in patients with severe HF.

Methods: Six patients with severe HF (ejection fraction < 20%; NYHA class 3–4) on conventional therapy and six healthy controls (HC) matched for age (50 ± 6; 50 ± 6 yrs respectively) and body mass index (28 ± 1; 28 ± 1 kg/m^2 respectively) were studied. Following an overnight fast, steady state calf vascular resistance (CVR) and right peroneal muscle sympathetic nerve activity (MSNA) data were obtained over 2 min periods before, and every 10 min for 2 hours after, a 2.5 MJ carbohydrate load.

Results: Plasma insulin increased significantly ($p < 0.05$. Paired *t* test) in both groups to reach a peak of 954 ± 244 pmol/l in HF, and 1290 ± 405 pmol/l in HC. There was no significant difference in insulin profile between groups. Following the insulin peak, CVR (arbitrary units) fell significantly in HC from 54 ± 6 to 28 ± 2 ($p < 0.05$), but not in HF, and there was a significant increase in MSNA (bursts/100 beats) in HF from 59 ± 5 to 86 ± 11 ($p < 0.05$) but not in HC. Results expressed as mean ± SEM.

Conclusion: In severe heart failure the vasodilatation occurring during post-prandial hyperinsulinaemia is impaired and this may be due to a concomitant increase in sympathetic vasoconstrictor output.

P1732 Brain natriuretic peptide does not exhibit diurnal variation in patients with ischaemic heart disease or heart failure

A.H. Hannah, D.R. Murdoch, S. Clements, A. Harkness, J.J. Morton, H.J. Dargie. *CRI in Heart Failure; Cardiology Department, Western Infirmary, Glasgow, UK*

Brain natriuretic peptide (BNP) may be a useful test for the detection of LV systolic dysfunction (LVSD) and heart failure in the community and following acute myocardial infarction (MI). BNP is stable in whole blood for up to 72 hours and modern assays have excellent reproducibility. The diurnal and day-to-day variation of BNP has not been previously assessed. This is clearly an important clinical consideration and the aim of this study was to establish this.

Methods: 8 patients (7 with LVSD and 1 with normal LV function; 5 with prior MI) were enrolled in the study. They remained in the research unit for 24 hours. Blood was taken for BNP at 3 hourly intervals from 0900 hours. The patients also had blood taken in the morning on 5 non-consecutive days over the subsequent 2 weeks. Food, fluid and medications were taken as per normal. BNP was measured using the 'direct' Shionoria IRMA assay.

Analysis: The BNP data was log transformed and significance tested by paired t-test analysis. Each BNP was compared with the 0900 hr BNP sample. Each 'day' BNP sample was compared with the day 1 BNP in the same way.

Results: There was no significant difference between the BNP at time 0900 hrs and 1200, 1500, 1800, 2100, 0000, 0300, 0600 or 0900 hrs (next day). The respective p values were 0.98, 0.97, 0.82, 0.82, 0.70, 0.65, 0.59 and 0.64. Comparing day 1 BNP with days 2, 3, 4 and 5, the p values were 0.75, 0.97, 0.95 and 0.89 respectively.

Conclusion: BNP exhibits no diurnal variation, nor any day-to-day variation, in this patient group. This fact, along with its known stability in whole blood, suggests that BNP is suitable for use in clinical practice, perhaps in the diagnosis of LVSD and heart failure.

P1733 Influence of heart rate on neurohumoral parameters in patients with left ventricular dysfunction

T. Kottmann, C. Bergmeier, M. Bangert, A. Kilkowski, T. Kleemann, G. Taubert, D. Nagel[1], D. Seiler[1], J. Senges. *Herzzentrum Ludwigshafen; [1]Institut for Clinical Chemistry, Ludwigshafen, Germany*

Question: Is there an association between heart rate (HR) and neurohumoral humoral parameters in left ventricular dysfunction (LVD) and is an elevated heart rate at admission of prognostic relevance?

Methods: 428 consecutive nonselected patients with ejection fraction (EF) ≤ 45% were registrated. Follow-up time was 498 ± 287 (median 454) days. Patients: 78% male, age 64 ± 11 years, EF 29 ± 9%.

Etiology: 60% coronary heart disease, 29% dilated cardiomyopathy, 11% other.

Results: Mean heart rate at admission was 81 ± 21 bpm.

n = 428	Nor (pg/ml)	Vaso (pg/ml)	ANP (pg/ml)	Aldosteron (pg/ml)	Renin (μU/ml)	Endo (pg/ml)
HR > 81	452 ± 336	3.7 ± 5.3	464 ± 302	92.2 ± 98.9	126 ± 325	9.4 ± 5.7
HR ≤ 81	336 ± 315	3.2 ± 3.2	344 ± 237	83.7 ± 101	163 ± 875	9.4 ± 9.3
p (t-Test)	0.0005	n.s.	<0.0001	n.s.	n.s.	n.s.

nor = norepinephrine, vaso = vasopressin, endo = endothelin

21.5% of all patients died during follow-up-time. Mortality at HR > 81 bpm was 31.7%, while 15.8% of the patients with HR ≤ 81 bpm deceased.

Conclusion:

(1) In patients with LVD and HR > 81 bpm the mortality is twice higher than in patients with heart rate ≤ 81 bpm.
(2) In comparison to lower heart rates, HR > 81 bpm is associated with elevated norepinephrine and ANP. There is no association between HR and vasopressin, aldosteron, renin and endothelin.

P1734 Permanent left ventricular-based pacing decreases atrial natriuretic peptide and norepinephrine levels in patients with advanced heart failure

Y. Etienne, M. Gilard, J. Mansourati, V. Valls-Bertauld, J.J. BLANC. *Département de Cardiologie, Hôpital de La Cavale Blanche, Brest, France*

In pts with severe congestive heart failure (CHF) plasmatic levels of atrial natriuretic peptide (ANP) and norepinephrine (NE) increase in proportion to the severity of the disease. The aim of the present study was to evaluate the effect of permanent left ventricular (LV) based pacing on these indirect markers of the severity of CHF.

Methods: we included 19 pts (68.2 ± 6 years; 17 males) in stable NYHA class III (6 pts) or IV (13 pts) in spite of "optimal" medical therapy with permanent left bundle branch block. ANP and NE level determinations (ANP: high performance liquid chromatography; NE: radioimmunologic technique) were obtained just before implantation, at 1 month, 6 months, 12 months and every year thereafter.

Results: The level of ANP was 68.2 ± 45 pg/ml at baseline and 25.2 ± 12.6 pg/ml after a mean follow-up of 6.1 ± 7 months ($p = 0.001$); for NE the values were respectively 2.6 ± 1.5 pmol/ml and 1.97 ± 0.9 pmol/ml ($p = 0.11$; NS).

Conclusion: long-term left ventricular-based pacing decreases the levels of ANP and NE but significantly only for ANP. These results are arguments to consider that LV-based pacing improves 0the prognosis of severe CHF.

P1735 Haemodynamic optimization in decompensated congestive heart failure decreases circulating big endothelin-1 and endothelin-1 without affection of pulmonary or coronary concentration gradients

K. Stangl, T. Dschietzig, M. Laule, C.H. Richter, G. Baumann. *Charité Berlin, Medizinische Klinik I, Berlin, Germany*

In congestive heart failure (CHF), plasma levels of endothelin-1 (ET-1) and, in particular, big ET-1 closely correlate with the severity of disease. However, the consequences for the peptide levels of acute cardiac decompensation and recompensation are unknown. It is, furthermore, of particular interest whether acute haemodynamic changes induce any imbalances of endothelin peptides across pulmonary or coronary circulation, which both show chronically increased expression of ET-1 in CHF. We investigated, in the course of intensive care treatment of CHF patients for acute left heart decompensation (ALHD), venous concentrations of big ET-1 and ET-1 as well as concentration gradients of both peptides across pulmonary vasculature (difference between aorta/radial artery [A] and pulmonary artery [PA]) and coronary circulation (difference between coronary sinus [CS] and A) (time points: V, A, PA, 0 min, 30 min, 1, 2, 6, 12, 18, 24 h; CS, 0–2 h). Compared to patients with compensated CHF (group II, NYHA II, n = 7) and healthy individuals (III, n = 10), CHF patients with ALHD (I, NYHA III-IV, n = 7) showed significantly ($p < 0.05$) impaired haemodynamics (pulmonary capillary wedge pressure [PCWP], cardiac index [CI]) and significantly elevated plasma levels (V, A, PA, CS) of big ET-1 and ET-1. In I, application of sodium nitroprusside over 24 h significantly improved haemodynamics (PCWP, −41 ± 4%; CI +98 ± 7%)and decreased plasma levels (V, A, PA) of big ET-1 (−45 ± 7%, mean of V, A, and PA) and ET-1 (−39 ± 5%). In contrast, no significant changes were documented in II. Both in I and II, pulmonary and coronary gradients of endothelin peptides did not differ from nil at any time point investigated. We conclude that in CHF patients with ALHD acute haemodynamic optimization decreases elevated circulating big ET-1 and ET-1. Despite remarkable alterations of peptide concentrations in the course of decompensation and recompensation, pulmonary and coronary gradients for big ET-1 and ET-1 remain balanced.

P1736 Cardiovascular effects of low-dose adrenomedullin in humans

G. Barletta, R. Del Bene, C. Lazzeri[1], S. Vecchiarino[1], F. Franchi[1], G. La Villa[1]. *Cardiovascular Diseases Unit, Careggi Hospital, Florence; [1]Dept. Internal Medicine, University of Florence, Florence, Italy*

Adrenomedullin (ADM) was found to be increased in heart failure, chronic renal failure and severe hypertension.

We evaluated the cardiovascular effects of ADM incremental infusion (at 1, 2 and 3 pmol/kg ·min for 30 minutes each) in 6 healthy volunteers (mean age 29 ± 2 years) in a double blind, placebo controlled, random order, cross-over study. Doppler echocardiography was used to determine cardiac volumes, filling and emptying parameters and systemic haemodynamics in baseline conditions, during and after the infusion of ADM and placebo. High resolution ultrasound scan of the carotid artery was used to evaluate changes in vessel properties.

At the highest infusion dosage, ADM reached plasma levels comparable with those observed in disease states, and induced significant decrements in left ventricular (LV) systolic diameter ($F = 9.2$, $p < 0.0001$), mean arterial pressure ($F = 2.70$, $p = 0.03$) and systemic vascular resistance ($F = 4.20$, $p = 0.003$), and increases in the percent thickening of LV posterior wall ($F = 2.40$, $p = 0.05$), LV ejection fraction ($F = 7.50$, $p < 0.0001$) and cardiac index ($F = 2.70$, $p = 0.03$), without affecting heart rate and LV diastolic function (mitral E/A ratio, mitral E wave deceleration, pulmonary vein systolic fraction and A wave amplitude). The time-to-peak of the pulmonary flow shortened ($F = 5.60$, $p < 0.0001$). Right ($F = 2.50$, $p = 0.04$) and left ($F = 3.3$, $p = 0.01$) atrial emptying fraction increased. Distension of the carotid artery increased ($F = 2.65$, $p < 0.04$).

These results suggest that ADM contributes to the overall regulation of circulatory homeostasis mainly because of its vasodilating activity.

SOPHISTICATED MAPPING METHODS

P1737 Endocardial activation patterns in patients with atrial arrhythmias: computer-assisted animation of electrical signals recorded with a 64-electrode basket catheter

B. Zrenner, G. Ndrepepa, M. Schneider, M. Karch, I. Deisenhofer, C. Schmitt. *Cardiology, German Heart Center, München, Germany*

The three-dimensional activation patterns of cardiac arrhythmias are not completely understood due to limitations of the conventional mapping techniques. The aim of this study was to assess the value of a new mapping technique based on computer-assisted animation of multielectrode basket catheter recordings in patients with atrial arrhythmias.

The study included 33 patients (59 ± 10 years) with atrial tachycardia (AT) and 38 patients (61 ± 11 years) with atrial flutter (AFl). A software program was developed to analyze the activation patterns based on 56 bipolar electrograms recorded with a 64-electrode basket catheter deployed in right atrium (RA).

Results: In 23 patients with right AT, the animated maps revealed that arrhythmia was unifocal in 15 patients, multifocal in 4 patients, pleomorphic in 2 patients and macroreentrant in 2 patient. In 10 patients with left AT, breakthroughs on the right side of septum (1 in 8 patients and 2 in 2 patients) and a left-to-right activation of RA were demonstrated in animated maps. In patients with typical AFl, the reentry circuit was a broad activation front with preferential propagation around the tricuspidal annulus. Double potentials were recorded in the presumed positions of crista terminalis and eustachian ridge in 100% and 88%, respectively. The intercaval block was complete in 88% of patients; in 4 out of 31 episodes, there were breakthroughs posterior to vena cava superior. In 8 patients with atypical AFl, the reentry circuit involved one of the vena cava (around inferior vena vava 5 patients, around superior vena cava 2 patients) and a line of block located in posterior wall. A figure-eight reentry, with common pathway located in posterior RA, was documented in one patient.

Conclusions: The computer-assisted animation of multiple electrograms recorded with a basket catheter is a valuable mapping tool that enables the three-dimensional activation patterns of various atrial arrhythmias. The technique is appropriate for complex, short-lived or unstable arrhythmias.

P1738 Validation of the unipolar recordings to locate the site of origin of the atrial activation

J.L. Merino, R. Peinado, J. Pereira, A. Sanchez-Recalde, J.A. Sobrino. *Lab. Electrofisiologia Cardiaca, Hospital Universitario "La Paz", Madrid, Spain*

Unipolar recordings have been demonstrated predictive of the eventual ventricular ablation site in WPW syndrome. Similarly, there are some reports suggesting a similar predictive value to localise the origin of ectopic atrial tachycardia. However, to date no systematic study has been performed to validate unipolar recordings to localise the origin of the atrial activation.

Methods: We studied 19 patients without structural heart disease after successful ablation of supraventricular tachycardia. Unipolar recordings of all 4 poles and bipolar recordings of the distal pair of a steerable quadripolar catheter (2–4–2 mm interelectrode spacing) were obtained. This catheter was introduced into the right atrium and placed, first over the lateral wall, and, later, over the septal wall. The catheter was manipulated causing the tip to mechanically induce ectopy while recording. The morphology of the recorded unipolar electrograms were analysed along with the unipolar and bipolar activation times, the unipolar electrogram duration and voltage, and the dV/dt of the downstroke of the negative deflection of the unipolar electrograms. Ectopy which was superimposed over the preceding T wave, or having less than 2 mV amplitude – suggesting poor electrode-myocardium contact- in the unipolar electrogram recorded from electrode number 4, were discarded from the analysis.

Results: There was a significative association between a unipolar QS morphology and the distal electrode recording (33 out of 34). However, 54 out of 105 electrograms recorded from the proximal electrodes also showed QS patterns. A QS pattern showed 97% sensitivity and 49% specificity for the distal electrode. There were no differences between lateral or septal origins of the mechanically induced ectopy. The unipolar electrogram recorded from the most distal electrode exhibited a faster slope but there was a high overlap of values with those recorded from the proximal electrodes (Electrode#1 0.3 ± 0.3, electrode#2 0.1 ± 0.1, electrode#3 0.05 ± 0.04, and electrode#4 0.04 ± 0.03 mV/ms)

Conclusions: In isolation none of the unipolar analysed variables allow the origin of the atrial activation to be predicted. This predictive value may be even lower in the clinical setting, where ventricular repolarisation often merges with the atrial unipolar electrogram.

P1739 Non-contact mapping of complex and/or non-sustained supraventricular and ventricular tachycardia: feasibility and implications for radiofrequency catheter ablation

G. Hindricks, B. Hügl, B. Krauß, T. Ostertag, K. Wasmer, G. Schuler, H. Kottkamp. *University Leipzig, Heart Center, Leipzig, Germany*

Non-contact mapping with the Ensite 3000 System (Endocardial Solutions Inc.) was performed in 13 patients (pts.) with supraventricular (n = 9) or ventricular tachycardia (n = 4). Six of 13 pts. had complex or non-sustained tachycardia, difficult to approach or even not approachable with conventional mapping: Non-sustained ectopic atrial tachycardia (EAT; inducible for 2–6 seconds): n = 2; Accessory pathway (AP) associated with severe Ebstein anomaly: n = 1; Permanent junctional reciprocating tachycardia (PJRT): n = 1; Non-sustained ventricular tachycardia (VT, inducible for 6–21 seconds): n = 2. Prior to the mapping procedure, the geometry of the target heart chamber was established carefully to achieve a high degree of anatomical accuracy.

Results: Reconstruction of the chamber geometry was completed within 13–23 minutes. In pts. with EAT the focus could be reliably identified within the high right atrium. Analysis of maps obtained during successive runs of non-sustained EAT showed an identical origin and activation pattern. Ablation was successful in both cases. In the pt. with Ebstein anomaly the AP was localised during pre-excited sinus rhythm and successfully ablated with a single radiofrequency application. In the pt. with PJRT the atrial insertion of the pathway was localised just outside the coronary sinus and successfully ablated. In pts. with non-sustained VT both, the exit site as well as the area of slow conduction could be identified. In one pt. single radiofrequency applications proved successful while in one pt. multiple applications forming a lesions line rendered the VT non-inducible.

Conclusions: Mapping with the Ensite System is feasible to reliably identify successful target sites for catheter ablation in pts. with complex or non-sustained tachycardia. Careful establishment of the geometry of the assessed heart chamber seems to be crucial to achieve the high degree of electrical and anatomical congruence necessary for successful ablation.

P1740 Online visualization and ablation of common type atrial flutter guided by non-contact mapping: initial experiences

M.A.E. Schneider, B. Zrenner, M.R. Karch, I. Deisenhofer, A. Schömig, C. Schmitt. *1. Med. Klinik and German Heart Center, TU Munich, Germany*

A non-contact multielectrode catheter in the right atrium (RA) enables a high resolution mapping of atrial flutter (AFl) activation. A non-contact mapping (NCM) guided radiofrequency ablation (RFA) is performed by visualizing the electroanatomical isthmus of common type atrial flutter and by documenting the catheter positioning with corresponding ablation sites.

Methods: The mathematical reconstruction of 3,300 endocardial electrograms (ECG) is achieved via a 64 electrode wire braid around a saline filled 8 ml balloon. The ECG generates an isopotential map on a 3D anatomical computer model of the endocardium where also a 5 kHz signal emitted from the ablation catheter's tip is displayed. NCM guided RFA was performed in 11 patients (pt; male n = 8, age 68 ± 5 y.) during hypothesized atrial flutter. The wavefront velocities (WV) were measured at the RA lateral wall (LW), between coronary sinus and His (Cs-His), V. cava inferior and Cs (VCI-Cs), between VCI and tricuspid valve (VCI-TCV) and in an assumed electrical isthmus (Ist) of the circuit.

Results: In contrast to the surface ECG indicating a common type atrial flutter, NCM showed only in 7/11 pt the activation pattern of a counterclockwise reentry circuit. The comparison of the cycle lengths of the atrial flutter (mean 234 ± 23 msec) with the WVshowed a positiv correlation to VCI-TCV (R = 0.95) and to Ist (R = 0.63). Using an 8 mm tip ablation catheter AFl could be ablated by applying 19 ± 11 RF applications around the isthmus region or VCI-TCV. In two pt NCM displayed an activation gap that could be closed by targeted RF applications. The 4 pt showing modified patterns of AFl were also ablated successfully by RFA around the earliest activtion exit sites.

Conclusion: NCM enables an online visualization and characterization of atrial flutter activations. It is helpful to target critical zones of atrial conduction circuits.

P1741 Three-dimensional non-fluoroscopic electroanatomical mapping and modification of the sinus node for inappropriate sinus tachycardia using a novel 3D non-fluoroscopic system

F.M. Leonelli, S. Beheiry, G. Tomassoni, M. Richey, B. Wides, K. Martinez, A. Natale. *Cardiology Dept, University of Kentucky, Lexington KY, USA*

We present our result with mapping and modification of the sinus node in patients with inappropriate sinus tachycardia using a three-dimensional non-fluoroscopic mapping system (CARTO). Thirteen wormen underwent mapping and modification of the sinus node using this system. The age ranged between 18 and 47 years. All patients failed at least one anti-arrhythmic drug before the procedure. The mean heart rate (HR) at rest was 96 ± 15 beats per minute (bpm). In each patient, 3-D maps of the right atruim (RA) were created in sinus rhythm and during isoproterenol (ISO) infusion. Ablation was performed during ISO infusion starting at the site of the earliest activation. Map of the RA was recreated if a decrease in HR was observed or after ablation in the region of the earliest activation was performed without significant HR change. In each patient the earliest sites of activation were correlated to the crista terminalis location identified by the presence of split potentials during coronary sinus pacing at 500 ms. In all 13 patients the sinus rate increased with ISO infusion at 2 mg per minute between 170 to 187 bpm. Administration of ISO resulted in cranial shift of the early site of activation. Radiofrequency ablation was performed starting at the site of earliest activation and extending around for about 5 mm. In all 13 patients a decreasing HR to 105–120 bpm was associated with a caudal shift of the earliest activation which ranged from the mid postero-lateral region of the right atrium to the infero-lateral region near the inferior vena cava. The shift of the earliest site of activation ranged from 2.5 cm to 4 cm. In all 13 patients successful sinus node modification was achieved without need for permanent pacemaker. The total fluoroscopy time for sinus node modification did not exceed 13 minutes. At follow-up one patient experienced recurrence of sinus tachycardia and was successfully re-ablated.

In conclusion, this 3-D non-fluoroscopic mapping appeared to be a useful tool to achieve successful sinus node modification limiting the fluoroscopy exposure and possibly the risk of inadvertent excessive damage to the sinus node. Successful modification was consistently associated with a caudal shift of the earliest point of activation.

P1742 Electroanatomic catheter mapping and ablation of the inferior isthmus in atrial flutter: contemporary ablation without fluoroscopy?

H. Kottkamp, C. Wasmer, B. Huegl, T. Ostertag, G. Hindricks. *University Leipzig, Heart Center, Cardiology, Leipzig, Germany*

The induction of contiguous and transmural lesion lines within the isthmus between the tricuspid annulus (TA) and the inferior caval vein (ICV) for ablation of atrial flutter (AFL) may be time consuming and requires a substantial resort to fluoroscopy. The increase in the lifetime risk of fatal malignancy from prolonged radiation after catheter ablation for supraventricular tachycardia is currently under intensive discussion.

In 30 patients (pts) with typical AFL, 3-dimensional (3-D) maps of the TA-ICV isthmus were constructed with an electro-anatomical non-fluoroscopic mapping system (Carto) for precise reconstruction of the individual isthmus geometry. After definition of the distal isthmus at the TA and the proximal isthmus at the ICV by means of fluoroscopy, the induction of a contiguous lesion line was performed non-fluoroscopically. After dislocation of the ablation catheter, the electromagnetic navigation system allowed precise re-navigation to predetermined sites. In all pts, complete conduction block within the isthmus could be achieved (7.3 ± 4.7 pulses, 4-mm tip electrode), in 14 pts with the first lesion line. The overall fluoroscopy time inclusive diagnostic studies and ablation measured 8.7 ± 3.7 min. (in the last 15 pts, 6.8 ± 2.3 min). The radiation time during isthmus ablation measured 1.6 ± 1.9 min (in the last 15 pts, 0.8 ± 1.6 min), and isthmus ablation was done completely non-fluoroscopically in 6 pts.

High-density 3-D electromagnetic catheter mapping within the TA-ICV isthmus allows precise induction of contiguous and transmural lesion lines for ablation of AFL. By using electromagnetic mapping during induction of linear lesions, it proved possible to reduce the period of fluoroscopy during ablation of AFL to that of diagnostic electrophysiologic studies. This approach may have a significant impact on the long-term safety of this procedure.

P1743 Mapping of human right atrial fibrillation using a non-contact system

R.J. Schilling, N.S. Peters, A. Kadish[1], J. Goldberger[1], D.W. Davies. *Waller Department of Cardiology, St Mary's Hospital, London, UK; [1]Cardiology Department, Northwestern Memorial Hospital, Chicago, USA*

Mapping atrial fibrillation (AF) has been limited by complexities in the arrhythmia and anatomy. Non-contact mapping has the potential to overcome this by generating global simultaneous maps. The non-contact multielectrode array (MEA), which allows reconstruction of 3,360 unipolar electrograms which are superimposed onto a computer model of the endocardium thus creating isopotential maps, was used to create high resolution maps of the entire right atrium (RA) of 11 patients (pts) with AF. Pts had either sustained AF (3) for >6 months or developed AF during the study (n = 8). AF initiated in 1 pt from 2 successive atrial ectopic beats from the site of a roving contact catheter which resulted in a single reentry wavefront circuit rotating around the right atrium which rapidly degenerated to disorganised activity with 3 or 4 wavefronts being present at any time. During established AF, 4 patients predominantly had a single RA wave front, 2 had 2 wave fronts and 5 patients had 3–5 wave fronts for most of the time. The number of wavefronts present correlated with the coarseness of atrial activity seen on the EKG baseline. Periods of RA electrical silence were seen in 8 pts, after which activity emerged from consistent septal sites, either superior alone (3), superior and inferior septum (2) or superior, mid and inferior septum (3). With intravenous flecainide, 2 pts organised to AFl which terminated with isthmus block in 1 and required pace termination in the other. In the remaining pt, progressively fewer wavefronts and longer periods of electrical silence were followed by atrial tachycardia with a focus moving superiorly in the lateral RA before terminating.

Conclusion: Non-contact mapping of the RA demonstrated AF initiation and termination. It also showed different RA activation patterns in AF and that the left atrium may sustain AF in many pts.

P1744 Three-dimensional electroanatomical mapping-guided radiofrequency catheter ablation of complex atrial tachyarrhythmias following cardiac surgery

M. Shoda, Y. Fuda, M. Ohta, R. Sugiura, K. Kajimoto, N. Matsuda, N. Hagiwara, H. Kasanuki. *Cardiology Dept., Tokyo Women's Medical College, Tokyo, Japan*

The mechanism of atrial tachycardia (AT) following cardiac surgery is so complicated that the clinical outcome of radiofrequency catheter ablation (CA) has not yet become well accepted. We performed catheter-based intracardiac mapping in conjunction with the conventional method and a new three-dimensional electroanatomical mapping (CARTO; Biosense Inc.) in 22 patients (pts) presenting with post-operative atrial tachyarrhythmia. The existing structural heart disease and history of previous cardiac surgery consisted of valvular disease after replacement in 2 pts, tricuspid atresia after the Fontan procedure in 3 pts, tetralogy of Fallot after repair in 6 pts, ASD after patch closure in 8 pts, VSD after patch closure in 2 pts and ischemic heart disease after CABG in 1 pt. Twenty-seven atrial tachyarrhythmias were reproducibly induced in the 22 pts. Endocardial mapping by electroanatomical mapping system exhibited focal AT in 2 pts, incisional macro-reentrant AT in 18 pts and counterclockwise typical atrial flutter in 7 pts. Two focal ATs and 16 macro-reentrant ATs with area of slow conduction (A-SC) in the reentrant circuit were terminated by single-site facal CA (not linear) and were no longer inducible. The ablation site was the earliest excitation in focal ATs and the A-SC demonstrating concealed entrainment in macro-reentrant ATs. Linear CA between two different anatomical barriers was required to cure 2 macro-reentrant ATs without apparent A-SC and 7 typical atrial flutters. All CA procedures were successful and no complications were observed.

Conclusion: The electroanatomical mapping system is useful to understand the mechanisms of arrhythmia in patients with complicated anatomical substrate created by the previous surgery. Interestingly, linear CA is not always required to cure the incisional macro-reentrant AT which is the most common arrhythmia after open heart surgery.

P1745 Virtual RF ablation in a three-dimensional anatomical computer model of the atrium

L. Kappenberger[1], O. Blanc[2], N. Virag[2], O. Egger[2], J.-M. Vesin[2], J. Koerfer[1]. *[1]Divison of Cardiology, CHUV; [2]Signal Processing Laboratory, EPFL, Lausanne, Switzerland*

A realistic 3D anatomical model of human atria has been designed which simulates the cellular and tissue electrophysiology of atria. Since atria are constituted of thin walls, the propagation of electrical activity in atria is a problem that we can simulate with today computer power.

Methods: Based on a 2D heterogeneous and anisotropic model of conduction in the cardiac tissue that has proved to be realistic in previous experiments, we have developed a 3D anatomic model of human atria which uses a modeling of the cellular membrane ion kinetics given by Beeler-Reuter or Luo-Rudy. The simulated size of both atria is 3 cm × 3 cm × 7 cm with about 250'000 cardiac cells. Holes have been placed on the surface to simulate the veins and the valves. Normal sinus beat is initiated from the sino-atrial node (SA node) and the propagation speed-in basic conditions is 50 cm/s.

Results: Virtual electrophysiologic experiments have been performed, using an S_1–S_2 protocol. S_1 has been initiated from the SA node and several locations, sizes, intensities and timings have been tested for the ectopic beat S_2. Most of the attempts have led to nonsustained arrhythmias. However, for a given size, intensity and timing, we have identified that some locations are more likely to generate a sustained atrial flutter: the region between the inferior vena cava and the tricuspid valve and the region of the pulmonary veins. This observation correlates with the observations made in humans. After having initiated sustained atrial flutter, we have tested some antiarrhythmic interventions like RF ablation of the isthmus of Cosio. The ablation had the effect of stopping the arrhythmia and the reinitiation of the flutter after ablation was unsuccessful, showing the effectiveness of the treatment.

Conclusion: Our virtual atria can reproduce observations made on humans but with the advantage of showing details difficult to study in nature and of being reproducible. Furthermore, it allows us to study the impact of pacing and pharmacological interventions. Computer simulations are therefore a new tool for the study of arrhythmias and their treatment.

P1746 Sequence of ventricular repolarization and its correlation to that of the activation: monophasic action potential mapping in humans using an electro-anatomical mapping system

S. Yuan, O. Kongstad, E. Hertervig, M. Holm[1], S.B. Olsson. *Department of Cardiology, University Hospital, Lund, Sweden; Biosense Webster, Waterloo, Belgium*

Disturbances in myocardial repolarization are associated with the genesis of arrhythmias. However, the global sequence of repolarization and its correlation to that of the activation are little known.

Methods: Endocardial monophasic action potentials (MAPs) were recorded from 44 ± 16 left or right ventricular sites in 8 patients using an electro-anatomical mapping system (CARTO). The onset of the MAP upstroke was defined as the local activation time (AT) and the intersection between the baseline and the tangent to the steepest slope on phase 3 as the end-of-repolarization (EOR). The AT, MAP duration and EOR at each site were calculated and 10 sets of activation, EOR and MAP duration maps were constructed, 5 left and 5 right ventricular maps.

Results: (1) The EOR sequence was clearly depicted in all the 10 maps. In 8 maps, the EOR followed the same sequence as the activation, regardless during sinus rhythm, premature beats or ventricular tachycardia and the presence of normal QRS and concordant T waves, preexcitation or bundle branch blocks with secondary ST-T changes. (2) In 9 maps, the longest MAPs were recorded in the earliest activation area, while in 8 of them the shortest MAPs in the latest activation area. (3) A statistically significant negative correlation between the MAP duration and the AT was found in all the 10 maps ($r = -0.63 \pm 0.18$), but a positive correlation between the EOR and the AT in 9 maps ($r = 0.66 \pm 0.28$), the linear regression slope being less negative than −1 (-0.58 ± 0.40) for the former and less positive than +1 (0.53 ± 0.19) for the latter.

Conclusions: (1) A clearly recognizable sequence of EOR is commonly seen over the human ventricular endocardium, which verifies the existence of transventricular gradients of repolarization. (2) The ventricular endocardial repolarization frequently follows the activation sequence, regardless the activation sequence is normal or not, which suggests that the activation sequence is an important determinant for the repolarization sequence. (3) Progressively later activation associated with progressively shorter MAP duration is a general electrophysiologic feature. The magnitude of this MAP shortening relative to that of the local AT is a critical factor governing the direction of the EOR.

ECG MARKERS OF SUDDEN DEATH

P1747 High incidence of sudden death in myocardial disease due to a lamin A/C gene mutation

D. Duboc[1,2,3], H.-M. Bécane[1], G. Bonne[2], S. Varnous[2], E.-H. Hammouda[1], J-A. Urtizberea[1], M. Fardeau[1,2], S. Weber[3], K. Schwartz[2]. *[1]Institut de Myologie; [2]INSERM UR523, GH Pitié-Salpétrière, Paris; [3]Service de Cardiologie, Hôpital Cochin, Paris, France*

We have studied fifty-four members of a large French family in which 17 members presented a cardiomyopathy, transmitted as an autosomal dominant mode. In the affected members, the mean age of onset for cardiac symptoms was 33 years (ranging from 15 to 47 years) and the first symptoms were related to a severe auriculoventricular conduction defect and sinus dysfunction, requiring the implantation of permanent pace-maker in seven cases. Myocardial dysfunction occurred rapidly in the course of the disease associated to ventricular dysrhythmias and resulted in a severe dilated cardiomyopathy requiring heart transplantation in 3 cases.

Eight members of this family died suddenly and in two cases, it was the first and unique manifestation of the disease. The six remaining cases had prior history of rhythmic and left ventricular dysfunctions before sudden death and two of them died despite the implantation of a permanent pace-maker.

Genetic analysis of this new form of autosomal dominant dilated cardiomyopathy demonstrated a nonsense mutation in LMNA gene located on chromosome 1q11–q23. This gene encodes lamins A and C which are proteins of the nuclear lamina located at the inner face of the nuclear envelope.

In conclusion, the genetic modification of a component of the nuclear envelope associated with high incidence of life threatening dysrhythmias opens new insights in the molecular mechanisms exposing to sudden death.

P1748 Blockade of the human ether-a-go-go-related gene (HERG) potassium channel by amitriptyline: another mechanism for cardiotoxicity

H. Tie, S.M. Valenzuela[1], B.D. Walker, C.B. Singleton, J.A. Bursill, K.R. Wyse, S.N. Breit[1], T.J. Campbell. *Department of Medicine and VCCRI, St. Vincent's Hospital, Sydney; [1]Centre for Immunology, St. Vincent's Hospital, Sydney, Australia*

Amitriptyline, a frequently prescribed tricyclic antidepressant, impairs cardiac conduction, prolongs QT interval and produces life-threatening arrhythmias including torsades de pointes during overdoses. Most reports have focussed on sodium channel blockade by amitriptyline as a mechanism for its cardiotoxicity. The cardiac repolarizing potassium channel, IKr, is a primary target of drugs causing QT prolongation and is encoded by HERG. The effect of amitriptyline on HERG channels has not been previously reported.

Aim and methods: We examined the effect of amitriptyline on HERG stably transfected into Chinese hamster ovary (CHO-K1) cells using the whole cell configuration of the patch-clamp technique.

Results: HERG tail currents were elicited at −60 mV after a 3.9 sec depolarizing step from −80 mV to +30 mV. Amitriptyline blocked these currents in a concentration-dependent manner, with an IC50 of 10 ± 1.1 μM and a Hill slope of 1.38. Block by amitriptyline 10 μM and 30 μM displayed no voltage-dependence between −20 mV and +30 mV. Amitriptyline did not enhance the rate of current decay during prolonged (15 sec) depolarizing pulses. Channel inhibition by amitriptyline 10 μM was independent of the depolarizing pulse duration using an envelope of tails protocol.

Conclusion: In addition to blockade of cardiac sodium channels, amitriptyline also blocks the HERG potassium channel at concentrations relevant in clinical overdosage (toxic serum concentrations ~5 μM to 10 μM). This blockade likely underlies the prolongation of QT interval and torsades de pointes observed during poisoning with this drug. Our data suggests that amitriptyline preferentially binds HERG in a closed state, although a fast open-state block cannot be ruled out.

P1749 Effects of dronedarone on calcium handling in cardiac ventricular myocytes

E. Guillemare, P. Gautier, D. Nisato. *Cardiovascular Department, Sanofi Recherche, Montpellier, France*

Dronedarone (D), an amiodarone-like non-iodinated antiarrhythmic compound, is currently undergoing clinical trials. As well as amiodarone, D has been described as Na, Ca and K currents blocker. The present experiments investigate the effects of D at 37°C on action potential, shortening, Ca^{2+} transient and L-type calcium current (iCaL) of isolated guinea pig myocytes.

Action potential in isolated cells was studied in current-clamp by perforated patch technique. At 10 μM, D decreased the plateau of the action potential which suggests an inhibition of calcium current. Thus, intracellular calcium was measured using the fluorescent calcium probe indo-1 simultaneously with contraction measured using video edge-detector system. D decreased both amplitude of contraction and intracellulrar calcium with IC50 of 1.1 ± 0.4 μM and 4.4 ± 0.6 μM, respectively.

iCaL was measured by patch-clamp technique. Current-potential curves were measured between −40 and +50 mV, stepped from prepulse of −40 mV and holding potential at −80 mV. D failed to modify activation potential of iCaL. In contrast, peak current measured at 0 mV was totally blocked at 3 μM and the IC50 was 92 ± 6 nM. D-induced use-dependent block was studied using a train of 30 pulses with interpulse intervals of 0.5 s and a test pulse at 0 mV. The onset of use-dependent block was exponential yielding time constants of 1.7 s in control condition and 0.4 s in the presence of 10 nM D. The voltage dependence of iCaL inactivation was evaluated using 1 s prepulses ranging from −80 to +20 mV. After exposure to D, the inactivation curve was shifted from −23.8 ± 1.2 to −31.6 ± 0.8 mV.

These results show that D blocks iCaL in a concentration- and use-dependent relationship and induces a decrease in Ca transients and consequently in shortening.

P1750 Native versus cloned Kv1.5 channels: effects of tedisamil on human cardiac rectifier K+ channels

E. Wettwer, M. Gerwe, M.M. Tamkun[1], U. Ravens. *Abt. f. Pharmakologie & Toxikologie, Universitätsklinikum TU-Dresden, Dresden, Germany[1]Molecular Physiology and Biophysics, Vanderbilt Medical School, Nashville TN 37232, USA*

Human atrial myocytes exhibit a rapidly activated, sustained outward current Iso that corresponds to the cloned K^+ channel Kv1.5. Whilst availability of human tissue for the study of native channels is limited, there is an almost unlimited access to cloned Kv1.5 channels that are stably expressed in mouse fibroblasts. Hence new drugs with a therapeutical potential are preferentially studied in cloned channels. Here we provide a systematic comparison of the effects of the class III antiarrhythmic agent tedisamil (TED) in these two systems. The aim of our study was to validate the use of Kv1.5 in pharmacological experiments. Whole-cell voltage clamp experiments were carried out in human atrial myocytes or cultured mouse fibroblasts at room temperature. In both types of cells, TED concentration-dependently reduced the time constant of current inactivation with little influence on maximum current amplitude. The EC_{50} values for end-of-pulse current reduction were 2.0 μM for Iso and 2.8 μM for Kv1.5 The apparent acceleration of inactivation is compatible with open channel block. With 10 μM TED fractional block of Iso in atrial cells and Kv1.5 in fibroblasts developed with a time constant of 11 ± 4 ms and 31 ± 2 ms, respectively. Recovery from block was biphasic in Kv1.5 of fibroblasts, a fraction of 0.51 recovered with an ultrarapid time constant of 60 ± 21 ms, the remainder with a slow time constant of 691 ± 74 ms. We therefore conclude, that TED had similar qualitative effects in native and cloned K^+ channels. From the dissociation kinetics (recovery from block) TED is expected to be particularly effective at high frequencies.

P1751 Signal averaged electrocardiography in patients with chronic ischaemic heart diasese

C. Auguadro, F. Buzzetti, E. Nai, A. Serio, M. Grillo, C. Falcone. *Cardiology Dept, Policlinico San Matteo, Pavia, Italy*

Background: The signal averaged electrocardiography (Sa-ECG) has been widely utilised to early identify the subgroup of post-myocardial infarction patients (pts) at high risk of serious arrhythmic events.

Objectives: The aim of the present study was to define the incidence of late potentials (LPs) in a large population of pts with chronic ischemic heart disease and angiographically documented coronary artery disease (CAD).

Methods and patients: Our study population included 971 consecutive pts (787 M, 184 F, mean age 58.2 ± 8.5 yrs) who underwent ergometric stress test (EST) for clinical reasons. History of myocardial infarction (>6 months) was present in 546 (56.2%) pts; 526 (55%) pts referred angina pectoris.

The Sa-ECG was acquired in all pts immediately before EST. The LPs were considered present if two of the following three criteria were satisfied: QRS complex duration >110 msec after 25 Hz and >114 msec after 40 Hz filtering; root mean square voltage of terminal 40 msec (RMS40) <25 mV after 25 Hz and <20 mV after 40 Hz filtering; duration of low amplitude signals <40 mV greater than 38 msec at both filters of 25 and 40 Hz.

Results: LPs were detected in 185/971 (19%) pts. The clinical features, the prevalence of the most common cardiovascular risk factors, the distribution of CAD, the incidence of exercise-induced myocardial ischemia and of effort-induced ventricular arrhythmias were similar between pts with and those without Lps. The prevalence of LPs was 20.5% in pts with myocardial infarction (MI) and 17.2% in those without previous MI. Among pts with MI, Lps were present in 22% of pts with Q-MI and in 15% of those with nonQ-MI. A significant relation between Lps and an inferior myocardial infarction was documented ($p = 0.03$).

Conclusion: In a large population of pts with ischemic heart disease the prevalence of Lps was low. The clinical characteristics, the severity of CAD and the incidence of exercise-induced ischemia and ventricular arrhythmias were similar between pts with and without Lps. Among pts with MI, a significant relation between Lps and the inferior MI was documented.

P1752 Evaluation of wavelet decomposition of the signal-averaged electrocardiogram in idiopathic dilated cardiomyopathy: association with clinical and prognostic features

Y. Gang, K. Hnatkova, P.J. Keeling, M. Reardon, A.J. Camm, W.J. McKenna, M. Malik. *Cardiological Sciences, St George's Hospital Med. School, London, UK*

This study evaluated the potential usefulness of wavelet decomposition (WD) analysis of the signal averaged ECG (SAECG) in patients (pts) with idiopathic dilated cardiomyopathy (IDC). SAECGs recorded at presentation were available in 82 pts (mean age 43 ± 14 years, 60 men) with IDC (WHO criteria), and in 72 normal controls (mean age 44 ± 15, 48 men). During 24 ± 18 months of follow-up, 23 pts developed progressive heart failure, 5 suffered from sudden cardiac death and the others remained clinically stable. Four parameters of WD analysis, QRS length, maximum count, surface area, and relative length, were derived from each recording using an in-house program.

Results 1) There were significant differences in all measurements of WD between IDC pts and controls ($p < 0.0001$). 2) Significant differences in WD measurements (except for relative length) were found between pts who developed progressive heart failure and pts who remained clinically stable ($p \leq 0.001$). 3) Although numeric values of WD in sudden death pts were similar to those in stable pts, 3 of 5 sudden death pts had 3 'abnormal' measurements (defined as exceeding the mean values ± 2 standard deviation in normal controls). 4) No relationship between ventricular arrhythmias and abnormal WD analysis results was detectable. 5) The predictive accuracy of WD (≥2 abnormal measurements) for prediction of progressive heart failure is: sensitivity 74%, specificity 61%, positive predictive accuracy 45% and negative predictive accuracy 85% respectively ($p = 0.005$). 6) All WD measurements significantly correlated with left ventricular end-diastolic dimension ($r = -0.33$ to 0.35, $p \leq 0.01$).

Conclusions WD analysis of the SAECG can identify pts at increased risk of clinical deterioration, but not at high risk of arrhythmic events, in IDC.

P1753 The puzzle of paradoxical post-operative P wave shortening : the role of autonomic tone

J.M. DeCara, R.H. Falk, D. Lou, N.J. Battinelli. *Cardiology Dept, Boston Medical Center, Boston MA, USA*

Background: Prolonged P wave duration on the pre-operative signal averaged ECG (SAECG) indicates slow intra-atrial conduction and is a marker of post-coronary artery bypass (CABG) atrial fibrillation. Since cardiac surgery may result in transient atrial damage, we postulated that the post-CABG P wave SAECG would show further P wave prolongation.

Methods: 40 patients without prior AF or valve disease were studied. SAECG was performed 1 day preoperatively and on day 1 or 2 after surgery.

Results: Adequate paired (pre- and post-operative) tracings were obtained in 26 pts. CABG resulted in an unexpected and highly significant shortening of P wave duration which was associated with a significant increase in heart rate.

	Pre-operative	Post-operative	
P wave duration (msec)	118 ± 13	107 ± 11*	
Heart rate	(HR: bpm)	64 ± 7	77 ± 9*

*$p < 0.01$ compared to pre-operative value.

Regression analysis indicated a strong correlation ($r = 0.71$; $p < 0.01$) between the percentage change in pre- to post-operative HR and the change in P wave duration.

Conclusions: Following CABG, P wave duration decreases as HR increases. This most probably reflects changes in autonomic tone and points to the importance of considering HR when interpreting the P wave SAECG.

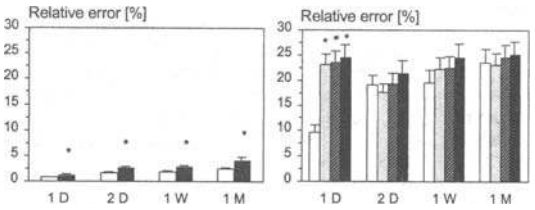
P1754 Reproducibility of the signal-averaged P wave: comparison to conventional QRST signal-averaged electrocardiogram in healthy subjects

I. Savelieva, K. Aytemir, A. John Camm, M. Malik. *St George's Hospital Medical School, London, UK*

Abnormal signal averaged P wave electrocardiogram has been recognized as a marker of a substrate for atrial tachyarrhythmias. However, reproducibility of measurement yet has not been established.

Methods: The reproducibility of the total filtered P wave duration (P_{tot}), total filtered QRS duration (QRS_{tot}) root mean square (RMS) voltage of the terminal 40 ms of the P wave (P_{40}), RMS voltage of the terminal 40 ms of the QRS (RMS_{40}) was compared in 51 healthy volunteers (30 men; age 32 ± 8). Serial SAECG was recorded twice with 5-minute interval on day 1, then once on day 2, and then 1 week and month apart. SAECG parameters were automatically recalculated after manual correction of the onset and offset of the P wave (PHiRES, HiRES software, Marquette Medical Systems). A relative error was used to assess the variability of the results.

Results: The reproducibility of QRS_{tot} and was significantly higher compared to P_{tot} in all the recordings ($p < 0.001$; left figure; open bars = QRS_{tot}; solid bars = P_{tot}; data presented as mean ± SE). The reproducibility of RMS_{40} was significantly higher compared to P_{40}, P_{30}, and P_{20} only in the 'immediate' recordings ($p < 0.008$), whereas no difference was observed on day 2, in 1 week and 1 month (right figure; open bars = RMS_{40}; dotted bars = P_{40}; hatched bars = P_{30}, solid bars = P_{20}).



Conclusion: In healthy subjects, the 'immediate' reproducibility of the P wave SAECG is significantly lower than that of the QRS SAECG. The short-and long-term reproducibility of P_{tot} remains significantly lower compared to QRS_{tot}, whereas no difference is observed between voltage parameters of both the P wave and QRS SAECG.

P1755 Laplacian cardiac electrograms: a new surface mapping system for the detection of the sequence of heart activation

G.E. Antonioli, P.P. Tarjan[1], C.C. Lu[1], T. Toselli, M.S. Argnani. *Div. of Cardiology, Arcispedale S. Anna, Ferrara, Italy; [1]Dept of Biomedical Engineering, University of Miami, Coral Gables FL, USA*

Background: The non-invasive detection of the cardiac sequence of activation is very useful for the rapid diagnosis of arrhythmias. At this purpose, a multi-channel, experimental system provided with tripolar concentric sensors for the detection of local electric activity was tested. The signal recorded is the second spatial derivative of the surface ECG at the site where the sensor is placed and it is defined Laplacian Electrogram (LECG). We refer to the zero crossing of the signal as to the Moment of Activation (MoA), representing the instant of cardiac depolarization near the center of the sensor. The processing of MoA allows the generation of isochronal and isopotential maps of heart activation.

Methods: Real time LECGs were recorded from 70 subjects (8 healthy volunteers and 62 patients with various heart pathologies, such as recent and old myocardial infarcts, left and right bundle branch block, atrial fibrillation and flutter). After a first experimental phase, LECGs from seven chest sites and standard ECG Lead II (used as time reference lead) were simultaneously recorded by means of an 8 channels A/D converter connected to a laptop computer for data collection and analysis. Automatic recognition of the MoA allows the delays of activation to be determinated between sites and on a beat by beat basis. Using these delays, isochronal maps were constructed.

Results: Conduction delays were recorded in bundle branch blocks. Comparing the MoAs at sites above the right and left ventricles, the delays could be quantited non invasively. The isochronal maps from 20 frontal and subaxillary sites showed different sequences of activation in healthy subjects and in patients with previous infarct, as the isochrones gradually converged toward the presumed centre of the infarct. Finally, the feasibility of LECGs recordings during cycloergometer exercise was explored with a discrete success.

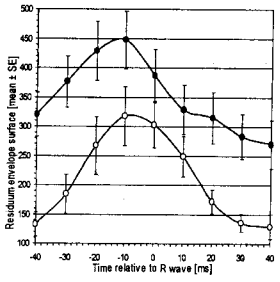
Conclusions: The portable LECG mapping system provides a new tool for understanding the propagation sequence of the heart non-invasively, in quasi-real time. The system has the potential to become a helpful tool for rapid arrhythmia diagnosis. Clinical applications are also pursued for EEG and EMG.

P1756 Wavelet decomposition of QRS complex alternans: differences between patients with ventricular tachycardia and normal healthy volunteers

Katerina Hnatkova, Marek Malik, Mark W. Kroll, Thomas M. Munger, Nemer Samniah, Lars Hegrenaes, David G. Benditt, Marshall S. Stanton, Ole Rossvoll, Harold H. Hoium, Stephen J. Ryan. *Harbinger Medical Inc., Minneapolis MN; University of Minnesota Hospital, Minneapolis MN; St. Jude Medical/Daig, Minnetonka MN; Mayo Clinic, Rochester MN, USA; Regional Hospital, Trondheim, Norway; St. George's Hospital Medical School, London, UK*

While the electrical alternans of the ST segment and T wave has been extensively researched, the alternans of the QRS complex has not been thoroughly investigated mainly because of difficulties in detecting it. In 47 patients with EP inducible ventricular tachycardia (mean age 63 ± 13 years, 83% male) and in 30 healthy volunteers (44 ± 16 years, 60% male), 120 to 400 QRS complexes were digitally recorded using orthogonal leads. The complexes with even and with odd order numbers were separately aligned and averaged. The resulting high gain signals were processed with wavelet decomposition (53 scales of Morlet wavelets with central frequencies of 40–250 Hz) and the differences between the resulting 3D spectral envelopes were computed. These created alternans related 3D spectral envelopes and were characterised by surface areas in subsequent 10 ms windows.

The surfaces of the alternans 3D spectral envelopes were substantially larger (Figure) in VT patients (filled circles) compared to controls (unfilled circles).



The differences between the groups were particularly marked within the initial and terminal portions of the QRS complex ($p < 0.00005$). Hence, (a) wavelet decomposition of alternating signal averaged ECG is capable of detecting electrical alternans within the QRS complex, (b) the QRS complex alternans is significantly more expressed in VT patients compared to healthy controls, and (c) the QRS complex alternans differs between VT patients and controls mainly at the beginning and at the end of the QRS complex.

P1757 Late potential analysis in digital Holter-ECG recordings – influence of tilt, exercise, heart rate, different lead positions and noise on the signal-averaged QRS-complex

P. Steinbigler, R. Haberl, A. Spiegl, A. Knez, G. Jilge, G. Steinbeck. *Medical Hospital I, University of Munich, Munich, Germany*

Digital recorders have enabled late potential analysis even in Holter-ECG-recordings. However, varying conditions such as tilt, exercise, heart rate, different lead positions and noise could nonspecifically affect the results.

In 30 healthy subjects standard time-domain analysis (Simson method, 40–250 Hz) was compared to analysis during different tilt (0°, 90°, 180°, 270°), bicycle-exercise (25 W), low heart rate 40–60 bpm (provoked by β-blockers), high heart rate > 90 bpm (provoked by isoproterenol), different lead positions (X,Y,Z-lead versus standard Holter lead positions), different noise (0.7 mcV versus <0.2 mcV and 0.8–1.0 mcV) using an Oxford-Medilog-FD3 recorder.

In standard time domain analysis fQRS was 91 ± 11 ms, RMS 41 ± 18 mcV and LAS 20 ± 11 ms. No healthy subject showed late potentials. Tilt 270° significantly increased fQRS (111 ± 21 ms, $p < 0.05$) and LAS (32 ± 19 ms, $p < 0.05$) but also RMS (68 ± 20 mcV, $p < 0.05$), whereas tilt 90°, 180° had no significant influences. Bicycle exercise 25 W did not significantly change time domain parameters (noise < 0.7 mcV achieved in all persons). Heart rate 40–60bpm increased fQRS (113 ± 22 ms, $p < 0.01$) and decreased RMS (20 ± 16 mcV, $p < 0.05$) (2 subjects fulfilled late potential criteria), whereas heart rate > 90 bpm (maximum 141bpm) had no significant influences. Holter-lead positions did not reveal altered time domain parameters. Signal averaging in order to decrease the noise level < 0.2 mcV increased fQRS (110 ± 17 ms, $p < 0.05$) and decreased RMS (29 ± 11 mcV, $p < 0.05$), (1 person developed late potential criteria), noise levels 0.8–1.0 mcV led to increased fQRS (109 ± 21 ms, $p < 0.05$)and increased RMS (62 ± 31 mcV, $p < 0.05$) (2 persons fulfilled late potential criteria).

Thus, time domain late potential analysis in digital Holter-ECG-recordings is only affected by extreme tilt, very low heart rate, noise < 0.2 mcV or noise > 0.8 mcV. However, if late potential analysis is performed in Holter-ECGs, information about tilt, noise and heart rate should be available.

P1758 Value of the P wave signal-averaged ECG for predicting of atrial fibrillation recurrence in patients with paroxysmal atrial fibrillation

K. Aytemir, N. Özer, S. Aksöyek, E. Atalar, B. Özin, A. Oto. *Department of Cardiology, Hacettepe University, Fac. of Medicine, Ankara, Turkey*

P wave signal averaged electrocardiography (SAECG) has been reported to be useful to identify the patients at risk for paroxysmal atrial fibrillation (PAF) during sinus rhythm. However there have been no definite methods to predict the recurrence of PAF, so the purpose of this study was to determine prospectively whether the recurrence of atrial fibrillation could be predicted by the use of P wave SAECG.

Methods: In 79 patients (57 Male, 49 ± 10 y) with at least one documented episode of PAF, P wave duration on SAECG, the left atrial diameter and the patient age were collected after 24 hours from the last PAF episodes. A bimonthly follow up was performed (6 months/pts) for identifying patients with (Group A, 21 patients) and without (Group B, 58 patients) PAF recurrence, in order to define the arrhythmic risk predictor value of P wave duration on SAECG.

Results: All results are below.

	Group A	Group B	P value
Age (year)	48.6 ± 12	50.5 ± 11	0.545
Left atrial diameter (cm)	3.6 ± 5.7	3.6 ± 5.4	0.977
SAECG P wave duration (ms)	134 ± 13	125 ± 10	0.005

In the discrimination of two groups a filtered P wave duration > 128 ms showed 71% sensitivity, 75% specificity, 51% positive and 88% negative predictive value.

Conclusion: These results indicate that P wave SAECG could be useful to identify patients at risk for the recurrence of atrial fibrillation.

P1759 QT-dispersion during life is closely related to collagen volume fraction at autopsy

C. Bonnar, V.E. Save[1], G.A. Milne[1], A.J. Robertson[1], S.D. Pringle[2], A.D. Struthers. *Department of Clinical Pharmacology, Ninewells Hospital & Medical School, Dundee; [1]Department of Pathology, Ninewells Hospital & Medical School, Dundee; [2]Department of Cardiology, Ninewells Hospital & Medical School, Dundee, UK*

Background: QT-dispersion is a marker of sudden cardiac death (SCD) in a wide spectrum of cardiovascular diseases. Myocardial fibrosis is thought to also cause SCD. We have examined whether QT-dispersion on the surface ECG during life, is related to myocardial collagen content in whole heart autopsy specimens.

Methods: 43 hearts were examined by morphometric analysis of the collagen volume fraction (CVF), using a digital image analysis system. 1,130 myocardial tissue blocks were processed and 25,824 individual fields of myocardium were examined in detail, to calculate the mean-CVF of all 43 hearts. QT and QTc-dispersion were measured manually, by a single, blinded observer, using a digitizer connected to a PC.

Results: The mean age of the patients at death was 72.5 (± 1.7) yrs, range (40.9 to 91.9) yrs. ECG's were obtained 44.0 (± 10.5) days prior to death, range (0 to 364) days. Mean QT and QTc-dispersion were 48.2 (± 3.4) msec and 59.5 (± 4.1) msec-$\frac{1}{2}$, respectively. Mean-CVF was 2.9 (± 0.5)%, range (0.3 to 14.3)%. Results required logarithmic transformation before analysis. Stepwise multiple regression analysis, using 14 clinical variables known to influence QT-dispersion and/or myocardial fibrosis, showed that mean-CVF was the only factor related to QT and QTc-dispersion. The results were highly statistically significant: $p < 0.001$, beta = 0.54 for QT-dispersion and $p < 0.005$, beta = 0.47 for QTc-dispersion.

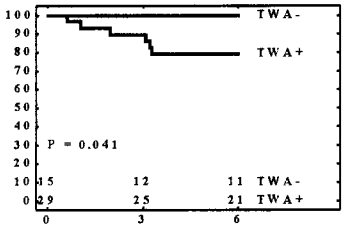
Conclusion: Our study establishes definitively for the first time, that patchy myocardial fibrosis can be detected during life by QT-dispersion on the surface ECG. It also adds enormous credence to the hypothesis that sudden cardiac death is commonly due to myocardial fibrosis causing electrical inhomogeneity.

P1760 Microvolt T-wave alternans in prediction of ventricular tachyarrhythmic events in patients with non-ischaemic dilated cardiomyopathy

T. Klingenheben, S.C. Credner, G. Grönefeld, R.J. Cohen[1], S.H. Hohnloser. *Dept. of Medicine, Div. of Cardiology, J.W. Goethe University, Frankfurt a.M., Germany; [1]Massachusetts Institute of Technology, Cambridge MA, USA*

The present study tested the hypothesis whether exercise-induced noninvasive microvolt T wave alternans (TWA) might be of predictive value in patients with non-ischemic dilated cardiomyopathy (DCM). The presence of TWA (CH2000, Cambridge Heart, Bedford, USA) was assessed in patients with DCM who were subsequently followed for at least 6 months for the occurrence of sustained ventricular tachycardia (VT), ventricular fibrillation (VF), or sudden cardiac death (SCD).

Results: A total of 56 DCM patients were studied (age 53 ± 11 years; 38 males; LVEF 28 ± 9%) of whom 16 were recipients of an implanted cardioverter defibrillator and 40 had no history of VT/VF. TWA was positive in 29 patients, negative in 15, and indeterminate in 12. During the 6 months follow-up period, there were 6 events (3 VT and 3 VF) which all occurred among TWA positive patients. The fig. depicts Kaplan-Meier analysis: the 6-months event rate in TWA positive patients was 21%.



Conclusion: The present study demonstrated that microvolt TWA appears to identify DCM patients at high risk for ventricular tachyarrhythmic events. Larger studies are required in patients without prior history of VTE to establish the utility of TWA in these patients.

P1761 Prospective evaluation of the effect of carvedilol therapy on heart rate variability in patients with dilated cardiomyopathy

J. Hoffmann, W. Grimm, V. Menz, B. Maisch. *Department of Internal Medicine and Cardiology, Philipps- University of Marburg, Marburg, Germany*

Carvedilol has been shown to improve clinical symptoms and left ventricular function in heart failure pts. However, there is limited knowledge of whether carvedilol is able to modify cardiac autonomic tone in these pts. Heart rate variability (HRV) is a noninvasive tool for measuring cardiac autonomic activity. Therefore, the effects of carvedilol therapy on HRV were prospectively assessed in 14 pts (10 m, 45 ± 13 y.) with idiopathic dilated cardiomyopathy (IDC). All pts were in stable clinical condition on constant doses of digitalis, diuretics, and ACE-inhibitors 3 mos before study entry. After a 3- to 4-week titration period, carvedilol was titrated up to 50 mg daily, or the highest dose tolerated (at least 25 mg). Maintenace treatment was then continued for 8 weeks. Digital 24-hour Holter recordings were performed at baseline and after 8 weeks of additional carvedilol therapy. The following standard time domain parameters of HRV were obtained using the Oxford Medilog 2 analysis system: HRm = mean heart rate calculated over 24 hours, SDNN = SD of all normal coupling intervals (NNs), rMSSD = the root mean square of successive differences in RR intervals among consecutive NNs, and pNN50 = percentage of adjacent NNs differing >50 ms.

Results:

	Before carvedilol	Under carvedilol	p-value
HRm (bpm)	88 ± 10	75 ± 10	<0.01
SDNN (ms)	77 ± 21	110 ± 22	<0.001
rMSSD (ms)	19 ± 7	26 ± 7	0.02
pNN50 (%)	1.7 ± 1.3	5.5. ± 4.5	<0.001

Conclusions: Carvedilol therapy leads to a significant increase in HRV parameters related to parasympathetic activity in pts with dilated cardiomyopathy. The prognostic significance of the effect of carvedilol on HRV needs to evaluated in appropriatelly designed prospective studies.

P1762 Different standards of heart rate variability measures for out- and in-hospital cardiological patients

G. Milicević, D. Cerovec, N. Lakušić, M. Majsec. *Cardiovascular laboratory, Krapinske Toplice Hospital, Krapinske Toplice, Croatia*

Values of heart rate variability (HRV) measures differ in healthy subjects and cardiological patients. The aim of the study was to establish standards – criteria for normal and pathological values of HRV for out- and in-hospital patients.

Methods: Prospective study enrolled 1242 consecutive patients, 733 out-hospital and 509 in-hospital, as well as 105 healthy volunteers, aged 51 ± 13, 56 ± 12 and 48 ± 9 years, respectively. 43% were female and 57% male. Arrhythmias of etiology other then coronary artery disease predominate in out-hospital and coronary artery disease in in-hospital pts. HRV was analysed from 24-hour Holter ECG. Limits of normal and pathologic values were determined according to percentiles of distributions of best fitted biomathematical models. Differences between groups were tested by t-test.

Results: Out- and in-hospital patients differ by all HRV measures ($p < 0.001$) (table). All variables differ by age ($p < 0.01$), and slightly by sex. In healthy, out- and in-hospital group, moderately depressed values of LF/HF ratio was 1.4–2.4, 0.8–1.5 and 0.7–1.3, and moderately elevated 4.1–5.8, 4.6–7.5 and 4.4–7.9, respectively.

Means and borderline values of HRV

	SDNN (ms)	rMSSD (ms)	pNN50 %	total power (ms2)	LF (ms2)	HF (ms2)
Healthy – am	147	46	11	4698	1085	401
Borderline	89–109	17–26	1.6–5.2	1401–3103	261–622	85–218
Out-hos – am	146	45	9	4340	841	353
Borderline	72–103	13–22	0.2–1.7	687–1781	89–256	34–89
In-hosp – am	126	40	7	3173	579	237
Borderline	49–86	11–18	0.1–0.7	284–1144	33–134	18–57

am = mean; borderline = moderately depressed; lower values are pathologically diminished!

In conclusion, different HRV standards for out- and in-hospital pts are probably result of different extent of patients daily activities and different kind of their illnesses. So, two standards are proposed for daily work with out- and in-hospital patients.

P1763 Effects of glycemic control on heart rate variability in type I diabetic patients with cardiac autonomic neuropathy

A.J. Burger, L.A. Weinrauch[1], J.A. D'Elia[1], D. Aronson[2]. *Cardiology Dept, Beth-Israel Deaconess Medical Center, Boston; [1]Endocrinology Dept, Joslin Diabetes Center, Boston; [2]Cardiology, Beth Israel Deaconess Medical Center, Boston, USA*

Background: The presence of cardiac autonomic neuropathy (CAN) is associated with a high risk of cardiovascular events such as ischemia, myocardial infarction, or sudden death. Previous studies have shown that strict glycemic control slows the deterioration of CAN as assessed by standard autonomic function tests (AFTs) but failed to show reversibility. The effect of glycemic control on heart rate variability (HRV) is unknown.

Objective: We evaluated the effect of glycemic control on HRV in type I patients with CAN.

Methods: Ten patients with early and 13 patients with advanced CAN were enrolled in a program of intensified insulin treatment. AFTs and 24-hour time and frequency domain HRV parameters were obtained at baseline, 3, 6, and 12 months.

Results: HbA1C decreased from 9.5 ± 0.4% to 8.4 ± 0.5% ($p = 0.02$) in the early CAN group, and from 9.3 ± 0.4% to 8.2 ± 0.5% ($p = 0.006$) in the advanced CAN group. Both time and frequency domain HRV indices tended to improve in patients with early CAN. The ultralow (ULF), very low (VLF), low (LF) and high (HF) frequency powers increased in patients with early CAN (Table). The improvement in HF at 12 months over baseline indicates increased parasympathetic tone. By contrast, these parameters continued to deteriorate in patients with advanced CAN. AFTs showed no significant change in both groups.

Effects of glycemic control on HRV

Groups	HRV	Baseline	3 months	6 months	12 months
Early CAN	ULF	7494 ± 1284	8430 ± 2191	8180 ± 2857	7611 ± 3606#
	VLF	737 ± 163	984 ± 505	1124 ± 624	982 ± 722*
	LF	229 ± 95	394 ± 292	462 ± 318	626 ± 563*
	HF	62 ± 30	106 ± 77	132 ± 90	183 ± 168*+
Advance CAN	ULF	5990 ± 1897	4404 ± 855	4687 ± 985	6114 ± 849
	VLF	693 ± 213	631 ± 240	572 ± 180	483 ± 84
	LF	193 ± 75	173 ± 84	171 ± 76	144 ± 33
	HF	65 ± 32	56 ± 26	46 ± 21	46 ± 8

#$p < 0.01$ compared with the advance CAN group; * $p < 0.05$ compared with the advance CAN group; +$p < 0.05$ compared to baseline.

Conclusions: A reversible metabolic component of CAN exists in a subgroup of patients even after many years of type I diabetes. Power spectral analysis of HRV allows early identification of potential reversibility as early as 1 year after the institution of strict glycemic control.

P1764 Redefining limits for the low-frequency area of heart rate variabilty helps detecting sympathetic activation

M.V. Hojgaard, N.-H. Holstein-Rathlou, E. Agner[1], J.K. Kanters. *Medical Physiology 10.5, University of Copenhagen, Copenhagen; [1]Internal medicine, CCU, Elsinore hospital, Elsinore, Denmark*

Sympathetic overactivity has been associated with sudden death in patients with heart disease. A reliable measure of sympathetic activation does not exist and its controversial whether the low-frequency area (LF: 0.04–0.15 Hz) of heart rate variability (HRV) is suitable for measuring sympathetic activity. We hypothesized that the LF area was too broadly defined and a narrower low-frequency band was better suited for detecting sympathetic activation.

Methods: Fourteen healthy subjects were examined for one hour of supine rest and one hour of 60 degr. head-up tilt during control circumstances, with beta-blockade (metoprolol) and with muscarinic blockade (atropine). The time-series of RR-intervals was dividided into successive 5-min time-series and Fourier analysis was performed. The LF area was divided into subbands (0.04 – 0.06 Hz, 0.06 – 0.08 Hz, 0.08 – 0.10 Hz, 0.10 – 0.12 Hz and 0.12 – 0.15 Hz). Powers from each 5-min analysis were then averaged for the supine period and for the tilted period.

Results: The total LF power of HRV did not change significantly with tilt. Analysis of the LF subbands revealed that in the area 0.06–0.10 Hz power rose during tilt (496 ± 22 msec2 to 992 ± 35 msec2, $p < 0.01$). The rise was abolished by betablockade (565 ± 44 msec2 to 465 ± 29 msec2, ns) and was seen again during muscarinic blockade (8 ± 1 msec2 to 29 ± 2 msec2, $p < 0.01$).

Conclusion: Total low-frequency power of HRV seems to be a poor measure of sympathetic activation in contrast to power in the 0.06–0.10 Hz area. The limits of the LF area should possibly be redefined if HRV is going to be useful in assessing autonomic activity.

P1765 Association between rate corrected QT interval and coronary risk factors: results from a cohort of 2764 apparently healthy subjects

L. Fauchier, M. Labrunie[1], P. Maison-Blanche[2], J. Tichet[3], S. Vol[3], P. Coumel[2], J.P. Fauchier, B. Balkau[1]. *Service de Cardiologie B, Trousseau University Hospital, Tours; [1]Inserm U258, Paris-Sud University, Villejuif; [2]Cardiology Department, Lariboisiere Hospital, Paris; [3]IRSA, Tours, France*

Prolongation of corrected QT interval ($QTc = QT/RR^{\frac{1}{2}}$ where RR = 60/heart rate) is a risk factor of sudden death in patients without intraventricular conduction defects and cardiac dysfunction, independent of age, history of myocardial infarction and heart rate. However, there is little information concerning the QT duration and its relation with coronary risk factors in apparently healthy subjects. Between 1994 and 1996, 2764 subjects (1484 women, 1280 Men, aged 30 to 64 years) without bundle branch block, previous myocardial infarctions, known ischemic heart disease, or diabetes and who were not taking medication that might affect QT duration had a 12-lead electrocardiogram recorded in the frame of an ongoing follow-up study, the D.E.S.I.R. study (Data from an Epidemiological Study on the Insulin Resistance Syndrome) and a determination of fasting glucose and insulin, serum lipid concentrations, tobacco and alcohol consumptions and physical activity. QT was measured automatically with a dedicated algorithm (Cardionics®) and the formula used for rate-correction was based on the best-fit regression between variables: QTk = (QT/RR)power(k) (k estimated by 0.352 for men and 0.345 for women). In men (mean QTk = 377 ± 17 ms), after adjusting for age, there was an inverse correlation between QTk and glycated hemoglobin (HbA1c) ($R = -0.12$, $p < 0.001$) and fasting insulin ($R = -0.07$, $p < 0.01$). Results remained significant after adjustment on body mass index, arterial pressure, and serum lipids. In women (mean QTk = 383 ± 17 ms), there was an inverse correlation between QTk and HbA1c ($R = -0.12$, $p < 0.001$) and fasting plasma glucose ($R = -0.12$, $p < 0.001$) and results also remained significant after adjustment on other parameters. Alcohol consumption did not affect QTk duration nor in men or women whereas high tobacco consumption ($p = 0.02$) and high physical activity ($p < 0.0001$) were associated with an increase in QTk in men.

Conclusion: After adjusting for heart rate, QT duration was influenced by glucose homeostasis, tobacco consumption and physical activity in healthy subjects. These findings may help to understand the mechanisms of sudden death in apparently healthy subjects.

P1766 Baroreflex sensitivity and heart rate variability in patients with and without sustained T-wave alternans after an acute myocardial infarction

J.M. Tapanainen, K.E.J. Airaksinen, H.V. Huikuri[1]. *Division of Cardiology, University of Oulu, Oulu; [1]University of Oulu, Division of Cardiology, Oulu, Finland*

Background: T-wave alternans (TWA) at microvolt level during exercise has been shown to be a risk marker of ventricular tachyarrhythmias. We studied possible relation of TWA to other arrhythmic risk markers of autonomic nervous system, i.e. baroreflex sensitivity (BRS) and traditional and new dynamic measures of heart rate variability (HRV).

Methods: Occurrence of sustained TWA during ergometer exercise test, BRS by phenylephrine method, standard deviation of all R-R intervals (SDNN) and short-term (detrended fluctuation analysis, DFA1) and long-term (1/f slope) fractal correlation properties of HRV from 24-hour ECG recordings were assessed in a prospective consecutive series of 162 patients after an acute myocardial infarction. QT interval dispersion (QTd) and signal-averaged ECG (SAECG) were also analyzed.

Results: There were no significant differences in either BRS or any of the HRV measures between TWA+ and TWA- patients (table). Neither did SAECG nor QTd differ between these groups.

	TWA+ (n = 24)	TWA- (n = 138)
BRS	7.2 ± 6.1	8.4 ± 7.2
SDNN	95.3 ± 22.4	98.9 ± 33.0
DFA1	1.20 ± 0.19	1.26 ± 0.26
1/f slope	−1.30 ± 0.19	−1.31 ± 0.19

Conclusions: Presence of TWA during exercise shortly after an acute myocardial infarction is not related to BRS, HRV or to other noninvasive markers of ventricular tachyarrhythmias. Future follow-up study will reveal the predictive value of TWA in arrhythmic risk stratification in relation to other arrhythmia risk factors.

P1767 Improved risk assessment in patients with chronic heart failure and healthy controls using nonlinear heart rate variability analysis

J. Brouwer, V. Demmel[1], D.J. Van Veldhuisen, J. Haaksma, G. Wiedenmann[1], H.J.G.M. Crijns. *Thoraxcenter, Dept. of Cardiology, University Hospital, Groningen, Netherlands; [1]Extraterrestrische Physik Dept, Max Planck Institut, Garching, Germany*

Background: Mortality is high in patients with chronic heart failure (CHF). Analysis of heart rate variability (HRV) has been shown to bear prognostic information in CHF patients. In this study, we evaluated the prognostic value of a new quantitative parameter of nonlinear HRV, alpha-comb, in CHF patients and healthy controls.

Methods: We applied a geometrical description of 3-dimensional Poincare plots, i.e. a graphical description of all heart beats present in a 24 hr electrocardiogram. The result of this procedure, the parameter alpha-comb, was obtained in 100 patients with mild to moderate CHF (age 59 ± 7 yr [mean ± sd], left ventricular ejection fraction [LVEF] 0.29 ± 0.09) and in 96 age-matched healthy controls.

Results: During up to 7.5 years follow up, 30 of the CHF patients died, 26 of cardiac death. The mean alpha-comb was 1.5 ± 1.1 in nonsurviving CHF patients, 2.0 ± 1.1 in surviving CHF patients and 2.6 ± 0.7 in healthy controls. In univariate and multivariate survival analysis, the relative risk for cardiac death of an alpha-comb below 2.0 was 9.6 (95%CI 2.9–32.2, $p < 0.001$) and 6.3 (95%CI 1.8–21.8, $p < 0.01$), respectively. For an LVEF below 0.30, this was 4.7 (1.8–12.4, $p < 0.01$) and 4.3 (95%CI 1.4–13.7, $p < 0.05$), respectively. Adding the criterium of an alpha-comb < 2.0 to an LVEF < 0.30 resulted in a sensitivity for cardiac death of 73% with a specificity of 83%, which is remarkably high in such a patient population. Conventional time and frequency domain parameters of HRV were not significantly related to survival.

Conclusions: Alpha-comb, a new quantitative non-linear HRV parameter based on a geometrical description of 3-dimensional Poincare plots, provides a risk assessment for cardiac mortality in CHF patients which is significantly better than that of standard HRV parameters. Compared to LVEF, the prognostic value of alpha-comb is at least as good, and, moreover, complementary. Further studies will be needed to confirm these data.

P1768 Is heart rate variability regulated from an open loop system from blood pressure variability?

L. Pranger, M.V. Hojgaard[1], E. Agner, N.H. Holstein-Rathlou[2], J.K. Kanters[3].
Dept. of Internal Medicine, CCU, Elsinore Hospital, Helsingor; [1]Laboratory of Experimental Cardiology, Dept. of Medical Physiology, Copenhagen; [2]Dept. of Medical Physiology, Panum Institute, Copenhagen; [3]Dept. of Medical Physiology, Laboratory of Experimental Cardiology, Kobenhavn, Denmark

Variations in heart rate (HRV) are known to be regulated by blood pressure via the baroreceptors. Mechanical denervation of the baroreceptors gives rise to an increase in blood pressure variability. The aim of this study was to study the effect of chemical abolition of HRV with atropine on blood pressure variability (BPV).

Methods: Ten healthy volunteers (5 men and 5 women) were examined twice during three hours of rest in supine position. The first day served as control condition, and on the second day the subjects received a bolus injection of atropin 2 mg intravenously, followed by an infusion of atropin 8 microg/(kg body weight * h). ECG and finger systolic blood pressure (Finapress) were recorded during the whole experiment. Paired series of RR-intervals and blood pressure were analyzed in the frequency domain with Fourier spectral analysis.

Results: As expected HRV were significantly decreased after parasympathetic blockade in all frequency bands (Total Power, ULF, VLF, LF and HF). However in SPV no changes at all were found in the same bands as shown in table 1.

Table 1. HRV and BPV during control period and atropine infusion in the different frequency bands. (Mean ± SE)

	RR control	RR atropine	BP control	BP atropine
log(ULF)	19.1 ± 1.1	17.0 ± 1.4*	14.9 ± 1.1	15.0 ± 1.1
log(VLF)	17.8 ± 0.2	14.8 ± 0.3*	12.9 ± 0.2	13.0 ± 0.2
log(LF)	17.0 ± 0.2	13.2 ± 0.4*	12.0 ± 0.2	12.0 ± 0.2
log(HF)	16.3 ± 0.4	10.9 ± 0.5*	10.4 ± 0.2	10.4 ± 0.2
LF/HF	2.3 ± 0.5	15.3 ± 4.3*	5.7 ± 0.8	5.9 ± 1.6
log(TP)	20.1 ± 0.8	18.0 ± 1.1*	15.8 ± 0.8	15.8 ± 0.9

*p < 0.01 compared to control.

In conclusion: BPV was not affected at all by atropine. This finding makes the classical view of HRV and BPV as a closed loop feedback system unlikely. Blood pressure affects HRV by the baroreceptors, but the influence of HRV on BPV seems negligible. It seems that the interaction from BPV to HRV is a simple feed forward network with no back propagation.

P1769 Prognostic value of heart rate variability and its evolutionary pattern very early after acute myocardial infarction

A. Doulalas[1,2], M. Flather[2], A. Pipilis[2], I. Rizos[1], I. Gialafos[1], P. Toutouzas[1].
[1]Department of Cardiology, Hippokration General Hospital, University of Athens, Greece; [2]Department of Cardiology, John Radcliffe Hospital, University of Oxford, UK

Background: Although experimental data have shown that speed of recovery of heart rate variability (HRV) after acute myocardial infarction (AMI) is related to clinical outcome in animals, no relevant information is available on humans. Furthermore, the prognostic significance of HRV very early after the acute event has not been studied comprehensively.

Methods: 108 successive pts aged 59 ± 8 years old that all received thrombolysis for AMI (5 ± 3 hours after onset of symptoms) were subjected to 24-hour ECG recording as soon as thombolysis had ended (D0) the next day (D1) and 5 ± 1 days after admission (D5). HRV was assessed and the pts were followed-up for a period of three years. Resuscitated cardiac arrests were considered cardiac deaths for the purposes of the study.

Results: During follow-up 11 pts were resuscitated or died of cardiac cause. Comparisons are shown in the table (non-survivors typed in italics).

HRV	D0	D1	D5	F
SDNN	*72 ± 20*	*62 ± 21*	*70 ± 24*	0.843
SDANN	*62 ± 19*	*52 ± 20*	*63 ± 21*	0.858
RMSSD	*35 ± 13*	*27 ± 13*	*26 ± 12*	0.911
SDNN	87 ± 36	76 ± 29	89 ± 27*	
SDANN	74 ± 30	68 ± 22*	79 ± 22*	
RMSSD	41 ± 25	35 ± 30	34 ± 16	

* = p < 0.05 from non-survivors for the same HRV measure at the same day, F for ANOVA test (interaction of repeated HRV measurements × death effect).

Conclusions: Very early after AMI, evolutionary pattern of HRV did not differ between pts that survived or died of cardiac cause in the long term. However, HRV may yield prognostic information 24-hours after the acute event, possibly offering a clinical benefit due to earlier risk stratification.

P1770 Relation between QT variability and autonomic cardiac function before episodes of non-sustained ventricular tachycardia in hypertrophic cardiomyopathy

N.E. Mezilis, F.I. Parthenakis, O.C. Philippou, E.N. Simantirakis, P.E. Vardas.
Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece

We analysed the dynamic changes in the QT interval in relation to autonomic cardiac control immediately before episodes of non-sustained ventricular tachycardia (NSVT) in patients with hypertrophic cardiomyopathy (HCM).

Methods: The study group consisted of 17 patients with HCM (11 men, 6 women) with a mean (SD) age of 60 (10) years, who had at least one episode of NSVT recorded in ambulatory 24-hour Holter monitoring (ELA MEDICAL). All sinus complexes were averaged over 30 s periods, creating 2880 templates. For each template, mean corrected QTe (time interval between the onset of QRS and the offset of the T wave), mean corrected QTa (time interval between the onset of the QRS and the peak of the T wave), their standard deviations (SDQTe and SDQTa), QTe/RR and QTa/RR were calculated. Spectral HRV was expressed as low (LF) (0.039 to 0.148 Hz) and high (HF) (0.160 to 0.398 Hz) frequency components and LF/HF was used as an index of sympathovagal balance of the heart. Five-minute segments were analysed, immediately before and 1 hour after episodes of NSVT. In order to examine the relationship between autonomic balance and ventricular repolarisation we plotted the LF/HF ratio against the Qtec and QTac using linear correlation and regression analysis.

Results: In total, 42 5-minute segments (21 episodes) were analysed. QTac was significantly higher and SDQTa lower before than 1 hour after NSVT (322 ± 20 vs. 313 ± 22, $p < 0.006$ and 2.8 ± 1.1 vs. 4.7 ± 3.6, $p < 0.03$, respectively). No differences were found in QTec, SDQTe, QTe/RR and QTa/RR. The LF/HF ratio was higher before the NSVT (3.78 ± 2.8 vs. 1.39 ± 2.3, $p < 0.02$). There was a significant correlation between the LF/HF ratio and QTac only during 5-minute periods before NSVT ($r = 0.85$, $p < 0.0001$).

Conclusion: In patients with HCM the QTac interval is prolonged before episodes of NSVT and this prolongation is related to sympathetic predominance.

P1771 Identification of sleep-related breathing disorders from the very low component of the heart rate variability

F. Roche, D. Duverney, I. Court-Fortune[1], V. Pichot, F. Costes, J.M. Vergnon[1], A. Geyssant, J.C. Barthélémy. *Physiology Laboratory-GIP Exercise, University Hospital, Saint-Etienne; [1]Dept of Pneumology, University Hospital, Saint-Etienne, France*

Cyclical low oscillations of the heart rate during night had previously been described in sleep-related breathing disorders. Thus, ECG Holter monitoring with spectral analysis of the heart rate variability (HRV) could represent a simple screening tool for detection of obstructive sleep apnea syndrome (OSAS).

The purpose of the present study was to evaluate the diagnostic yield of such method in patients referred to our sleep laboratory for clinically suspected OSAS. We correlated in 124 patients (98 males) mean (±SD) aged of a 53.8 ± 11.2, the frequency-domain HRV variables obtained from 24 h ECG Holter monitoring and respiratory disturbances indexes (RDI) assessed with complete polysomnography. The presence of an abnormal periodic breathing pattern was characterise in time-scale and evaluate on the plot of the spectrum for the interbeat interval increment as a function of inverse beat number. The occurrence of repetitive sleep apnea was associated with a spectral peak at about 0.02–0.05 $beat^{-1}$. The power spectral density of the very low frequency (VLFpsd) band (0 to 0.05 $beat^{-1}$) and the percentage of these component (%VLF) on the total power spectral density was computed.

There were no differences in clinical characteristics between patients with and without OSAS. The apparence of a VLF peak (mean frequency 0.03257 ± 0.009 $beat^{-1}$) was detected in 51 out of the 54 OSAS patients. We founded a high sensitivity (94.4%), a high specificity (97.1%) for this unique criteria. Using ROC curves, the %VLF appeared as the most powerfull separator for OSAS ($W = 0.80$, $p < 0.0001$), followed by the VLFpsd ($W = 0.79$, $p < 0.0001$). A positive correlation was founded between the RDI and, the two continuous previously described variables of HRV (%VLF: $r = 0.56$, $p < 0.001$; VLFpsd, $r = 0.50$, $p < 0.01$).

Frequency-domain analysis of HRV could thus represent an efficient tool in screening OSAS. The ease of use and of interpretation is of interest considering the high prevalence of OSAS in a general middle-agged population.

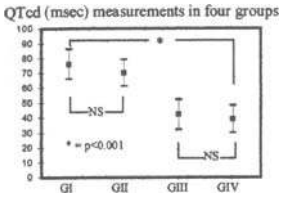
P1772 QT dispersion in patients with different aetiology of left ventricular hypertrophy

M. Zoghi, C. Gürgün, E. Ercan, F. Özerkan, H. Evrengül, L. Can, A. Akıllı, S. Payzin, H. Kültürsay. *Ege University, Department of Cardiology, Izmir, Turkey*

QT dispersion (QTd) is associated with abnormal ventricular repolarisation and cardiac arrhythmias. Left ventricular hypertrophy (LVH) is an adaptive mechanism to pressure overload and may play an important role in the development of serious cardiac arrhythmias. The purpose of this study was to detect the QTd in patients (pts) with different etiology of LVH.

Methods: We studied 86 patients with 3 different etiology of LVH and 30 healthy individuals. Study population was divided into four groups. In Group I. there were 52 pts (mean age: 54 ± 12, 36 male) with essential hypertension. Group II. Consisted of 35 pts (mean age: 50 ± 10, 26 male) with valvular aortic stenosis. There were 29 elite athletes in Group III. (Mean age: 58 ± 11, 25 male) and were 30 healthy subjects (mean age: 56 ± 9, 23 male) in Group IV. Patients in Group I. and II. had normal coronary angiograms. QTd was measured from surface ECG and Bazett's formula was used to correct QTd (QTcd) for heart rate. Left ventricular mass was determined by echocardiography (Deveruex formula) and left ventricular mass index (LVMI) was calculated in relation to body surface area.

Results: The QTd was significantly higher in Group I. and II. than Group III. and IV. ($P < 0.001$).



Group	QTcd (mesc)	LVMI (g/m2)
I	73 ± 8	196 ± 15
II	70 ± 9	184 ± 12
III	42 ± 10	221 ± 20
IV	39 ± 9	94 ± 15

Conclusion: Although left ventricular hypertrophy develops both in pathological and physiological conditions, QTd is associated with only pathological conditions. Even significant degree of left ventricular mass increase due to sportive endurance training does not induce QTd. These healthy individuals are probably less prone to develop serious ventricular arrhtyhmias.

P1773 Prognostic value of repolarisation analysis in patients with hypertrophic cardiomyopathy – comparison of QTc and QTd measurement

R. Baranowski, M. Vallverdu[1], L. Chojnowska[2], W. Poplawska[2], E. Michalak[2], L. Malecka[2], W. Rydlewska-Sadowska[2], X. Vinolas[3], P. Caminal[1], A. Bayes de Luna[3]. *Institute of Cardiology, Warsaw, Poland; [1]Institute of Cybernetics, Barcelona, Spain; [2]Institute of Cardiology, Warsaw, Poland; [3]Sant Pau Hospital, Barcelona, Spain*

We compared the prognostic value of repolarisation analysis in standard ECG and 24 h QTc measurement in pts with hypertrophic cardiomyopathy [HCM].

Material and methods: Retrospective study – standard 12-leads ECG (50 mm/s) and Holter recordings of 50 HCM in age 15–50 y (on no medications) was performed. QT, QTd and QTc (Bazett formula) were measured in standard ECG and QT, QTc beat by beat during 24 h ECG.The presence of more than one risk factor [RF > 1] (family history of SCD, history of syncope, history of VT, blood pressure decrease during exercise test) was treated as high risk. During the follow up (12–66 months) 7 sudden deaths were recorded. This group [SCD] was compared with 43 survivors [sHCM].

Results: QTc was prolonged in SCD group in standard and Holter ECG – 474 ± 45 vs 425 ± 31 ms ($p = 0.001$) and 465 ± 15 vs 416 ± 27 ms ($p < 0.0001$). QTd was also increased in SCD group – 57 ± 16 vs 40 ± 13 ms ($p = 0.002$). These pts had also more clinical RF (1.8 ± 1 vs 0.9 ± 0.9, $p = 0.02$). Prognostic value of different parameters is presented in the table.

Table

	SCD (7 pts)	sHCM(43 pts)	Sens.	Spec.	Pred. accurac.
QTcECG > 440 ms	7 pts	14 pts	100%	67%	72%
QTcECG > 450 ms	4 pts	12 pts	57%	72%	70%
QTcHol > 440 ms	7 pts	6 pts	100%	86%	88%
QTcHol > 450 ms	7 pts	4 pts	100%	91%	92%
QTd > 50 ms	5 pts	11 pts	71%	74%	74%
>1 RF	5 pts	14 pts	71%	67%	69%

Conclusions: 1. Prognostic value of repolarisation alterations analysis seems to be high in HCM pts. 2. The highest predictive accuracy was obtained with 24 h QTc analysis. 3. This results should be verified in prospective study.

P1774 The effect of heart rate on T-wave alternans with or without organic heart disease

K. Tanno, N. Watanabe, Y. Minoura, R. Katsumata, T. Adachi, S. Ryu, T. Asano, C. Obara, Y. Kobayashi, T. Katagiri. *Showa University, Tokyo, Japan*

Microvolt T wave alternans (TWA), that measured by a spectral method (CH2000. CAMBRIDGE HEART. Inc), has been associated with increased susceptibility to life-threatening ventricular tachyarrhythmias (VT). However, not a small number of false positive results are concerned.

Methods: The aim of this study is to evaluate the effect of heart rate on TWA of patients with or withiut organic heart disease (OHD) and/or VT. We measured TWA during right atrial pacing in consecutive 127 patients (60 ± 18 years, M/F = 74/53) undergoing electrophysiologic study. Twelve pts have OHD and VT, 40 pts: OHD+/VT−, 5 pts: OHD−/VT+, 70 pts: OHD−/VT−. Recordings of TWA were made with atrial pacing at 80, 90, 100, 110, and 120 beats/min (bpm). Positive TWA was defined as an alternans voltage 1.9 μV for a period at least 1 minute in at least VM, X, Y, Z, or adjacent two precoidal leads and an increasing alternans voltage with pacing rate.

Results: The number of TWA positive patients at each group.

	80	90	100	110	120 bpm
OHD+/VT+	2 (17%)	6 (50%)	8 (67%)	9 (75%)	11 (92%)
OHD+/VT−	1 (3%)	5 (13%)	8 (20%)	15 (38%)	16 (40%)
OHD−/VT+	0	1 (20%)	1 (20%)	1 (20%)	1 (20%)
OHD−/VT−	0	0	2 (3%)	8 (11%)	14 (20%)

TWA was not seen at sinus rhythm in any group.

The predictive value of TWA for OHD+/VT+ at each pacing rate.

bpm	Sens.	Spec.	P.P.V	N.P.V	Accuracy
120	0.916	0.691	0.261	0.986	0.717
110	0.750	0.752	0.265	0.962	0.752
100	0.666	0.891	0.421	0.957	0.867
90	0.500	0.941	0.500	0.941	0.894
80	0.167	0.990	0.333	0.909	0.902

P.P.V: Positive Predictive Value, N.P.V: Negative Predictive Value

Conclusions: 1). Sensitivity increased with incresing pacing rate, but specificity was declined. 2). Pts with OHD+ have high incidence of false positive results with increased heart rate, that should be paid attention.

P1775 A new index of heart rate variability

M. Sosnowski, S. Latif[1], E. Clark[1], M. Tendera, P.W. Macfarlane[1]. *3rd Division of Cardiology, Silesian Medical School, Katowice, Poland; [1]University of Glasgow, Department of Medical Cardiology, Royal Infirmary, Glasgow, UK*

Background: Analysis of heart rate variability (HRV) over a 24-hour period has been studied in both time and frequency domains. All methods suffer from poor repeatability and a simple, easy to understand outcome. For this reason, a new index of HRV was developed.

Methods: Scattergrams (Poincare plots) of 24-hour normal to normal RR interval variability were calculted for 210 middle aged healthy subjects (173 men, 37 women, mean age 49.5 ± 6.0 years). All had been examined by a physician and none had signs or symptoms of cardiovascular disease. The plots were divided into 256 squares each of $0.01s^2$ area. In each square, the total number of points was counted. If N1 and N2 represent the two highest counts from any of the squares, NN represents the total number of all normal RR intervals and NN50 is the number of intervals that differ from successive intervals by more than 50 ms, then the new index is as follows:

HRV fraction = [1 − (NN1 + NN2)/(NN − NN50)].100%

which is a number that varies between 0 to 100%.

Results: The mean normal value was 52.7 ± 8.58% with a 96 percentile range of 35.12–70.28%. The HRV fraction was significantly lower in females than in males (48.74 ± 8.43% versus 53.58 ± 8.39% $p = 0.002$).

In 165 patients, day to day reproducibility was assessed. The correlation co-efficient for the HRV fraction was 0.781 compared to 0.666 for the triangular index.

Conclusion: The new HRV fraction is simple to compute and easy to understand (cf LV ejection fraction) and overcomes many of the limitations of existing measures of HRV. It has been shown to have greater prognostic value than other time domain indices in a separate study of perioperative morbidity and mortality.

P1776 Ultrashort-term heart rate variability increaces and long-term variability decreaces prior to spontaneous ventricular fibrillation

Eleni (Helen) Hatzinikolaou, E. Repas, K. Klebetsanis, C.H. Arabatzis, G. Katsaris. *B' Cardiology Department, R. G. Hospital G. Papanikolaou, Thessaloniki, Greece*

Decreaced heart rate variability (HRV) is recognized as a long-term predictor of sudden death in post-myocardial infarction patients. It is not known if acute changes in HRV precede the onset of ventricular fibrillation (VF). The purpose of this study was to determine if changes in HRV occur prior to spontaneous VF.

Methods: The Medtronic Jewel + TM ICD stores 1000 RR intervals prior to the last detected episode of VF and 1000 RR intervals prior to interogation. We compared time domain analysis of HRV for the intervals recorded immediately prior to detected VF with HRV for baseline RR intervals recorded at routine ICD follow-up. Twelve episodes of VF were analyzed in 10 patients (8 men, 2 women; ages 62 ± 11 years; LV ejection fraction 25 ± 12%). Spontaneous VF was diagnosed by stored electrograms as the abrupt onset of a polymorphic rhythm with mean cycle length < 250 ms. Episodes of VF preceded by ventricular tachycardia were excluded. Ultrashort-term HRV, was measured by the number of normal intervals which differed from the preceding interval by >50 ms (pNN50). Long-term variability was measured by the standard deviation of the average RR intervals of 5 successive 200 interval segments (SDANN).

Results: The mean VF cycle length was 220 ± 45 ms. pNN50 (ultrashort-term variability) increased prior to VF; 22 ± 18 vs 64 ± 72, p = 0.03), suggesting an increase in vagal tone. SDANN (long-term variability) decreased prior to VF; 44 ± 41 ms vs 18 ± 14 ms, p = 0.03. Sinus cycle length was not significantly different: 820 ± 135 ms at baseline vs 780 ± 220 ms prior to VF; p = NS.

Conclusion: Ultrashort-term HRV increaces and long-term HRV decreases immediately prior to VF. Calculation of pNN50 and SDANN may permit ICDs to predict spontaneous VF.

P1777 Failure of heart rate variability measurements to predict all cause cardiac mortality post-infarction

M. El-Harari, C. Albers[1], P.C. Adams[1], J.P. Bourke. *Cardiology Dept, Freeman Hospital, Newcastle upon Tyne; [1]Cardiology Dept, Royal Victoria Infirmary, Newcastle upon Tyne, UK*

Purpose: This study aimed to determine the predictive power of heart rate variability [HRV] in a cohort of infarct patients discharged from hospital on optimum post MI drug therapy.

Methods: 204 consecutive post-MI patients were studied in the period 1996–97. 135 (66%) had received thrombolysis on admission. At discharge 163 (80%) were taking Aspirin, 135 (67%) B-blockers, 83 (41%) ACE-inhibitors, 36 (18%) statins and 30 (15%) warfarin. HRV was measured 3–6 days post MI, from an ECG record of 1024 QRS sinus complexes. Patients were followed for 1 year or until death.

Results: During follow up, 19 (9.3%) patients died, 16 (7.8%) of cardiac causes (cardiac failure 3, reinfarction 7, sudden 6). No patient was documented to have sustained VT. There was no statistically significant difference in mean (standard deviation [SD]) of any time domain or frequency domain measurements of HRV between survivors and patients who died of cardiac causes.

HRV variables measurements

	Survivors (n = 185)	Cardiac deaths (n = 16)
Mean RR (ms)	973 (173)	934 (217)
SDNN (ms)	46 (31)	37 (22)
Mean DRR (ms)	26 (45)	23 (25)
SDSD (ms)	22 (26)	21 (26)
RMSSD (ms)	35 (52)	31 (36)
LF/HF ratio	22 (1.6)	23 (1.7)

SDNN = SD of all RR intervals; DRR = difference between all RR, SDSD = SD of successive difference between RR; RMSSD = root mean square of successive difference; LF/HF = lower/ high frequency power ratio.

Conclusion: Contrary to previous studies, HRV failed to predict all cause cardiac mortality. Probable explanations for this include low overall cardiac and sudden death rates. Both the negative result and low event rates however may be explained by the increased use of thrombolysis during MI and/or by beta blocker and ACE-inhibitors use during recovery.

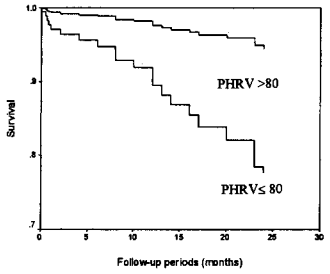
P1778 Postural heart rate variability for predicting mortality after acute coronary syndrome

W. Moleerergpoom, P. Sritara, S. Boonbaichaiyapruk, S. Hathirat, O. Sriwattanakomen, S. Tanomsup, S. Yamwong, K. Likittanasombat, P. Chandanamattha, S. Cheepudomwit. *Division of cardiology, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand*

Background: Heart rate variability (HRV) derived from standard 24-hour electrocardiogram (SHRV) on patients after acute myocardial infarction has been used to assess autonomic control of heart rate and to predict mortality. However, this technique is expensive and time consuming.

Objective: To evaluate a new, simple, inexpensive and easy to perform HRV technique, derived from supine-upright difference in RR intervals called "Postural Heart Rate Variability (PHRV)", as a predictor of mortality after acute coronary syndrome.

Methods & Results: 100 consecutive patients (mean age 63 years, range 29–86 years, 60 males and 40 females) admitted to the coronary care unit with diagnosis of acute coronary syndrome (acute myocardial infarction and unstable angina), in sinus rhythm and hemodynamically stable state, were studied. SHRV and PHRV were assessed from each patients simultaneously during the acute phase of acute coronary syndrome. Baseline clinical characteristics and all drugs used were recorded. Primary end-point was all-cause mortality. Patients were followed up for 24 months (mean 17.7 months), 30 died and 39 developed congestive heart failure (CHF). There were moderate correlation between SHRV and PHRV (r = 0.53, p < 0.05). The PHRV of the dead vs survivors were 64.4 ± 43.5 vs 95.8 ± 73.9 ms, p < 0.05, and of those with and without CHF 67.5 ± 43.6 vs 101.5 ± 78.8 ms, p < 0.05. Lower PHRV were also observed in patients with diabetes (DM) and hypertension (HT). Different cut-off values of PHRV were searched for calculating sensitivity and specificity and then plotted on Receiver Operator Characteristics curve (ROC curve). PHRV ≤ 80 ms provided sensitivity of 86.7%, and specificity of 40.6% with positive and negative predictive values in these population of 33.9% and 86.7% respectively. PHRV ≤ 80 ms had Odd Ratios for predicting all-cause mortality 4.9 (1.1–22.2) p = 0.03, after adjusted for age, heart rate, CHF, DM, HT, history of angina, smoking, CABG/PTCA and drugs used.



Conclusion: A simple technique of heart rate variability, derived from supine-upright RR intervals called Postural Heart Rate Variability, was found to correlate moderately with standard 24-hour heart rate variability method. It can be used as an independent predictor for mortality after acute coronary syndrome.

P1779 Baseline heart rate is an independent risk predictor in patients with coronary artery disease

S. Behar, E. Kaplinsky. *For the BIP Investigators; Neufeld Cardiac Research Institute, Sheba Medical Center, Tel Hashomer, Israel*

We investigated the impact on long-term mortality of heart rate (HR) among 11,575 unselected patients (pts) with coronary artery disease (CAD) screened but not included in the BIP Study. The characteristics and outcome of pts divided into three subgroups according to their baseline HR (Group 1 – HR < 65 b/min (n = 2370); Group 2 – 65–75 b/min (n = 6018); and Group 3 – >75 b/min (n = 3126) were as follows:

	Group 1	Group 2	Group 3
Men (%)	80	79	76
Age (mean)	60.2 yrs	59.8 yrs	59.6 yrs
Prior MI (%)	67	72	73
Diabetes (%)	15	21	27
Hypertension (%)	34	32	36
Smoking (%)	11	11	13
Total cholest. (mean)	222.2 ± 34	224.7 ± 34	224.2 ± 35
NYHA ≥ 2 (%)	24	28	34
Aspirin (%)	61	57	55
β-Blockers (%)	53	33	22
Ca-Blockers (%)	50	51	50
Digoxin	3	4	7
Crude 5 yr mort. (%)	8.7	12.9	18.4
Hazard Ratio*	1.0	1.47	2.06
and 95% CI	–	(1.26–1.72)	(1.75–1.43)

**Adjusted for: age, gender, prior MI, diabetes, NYHA class, β-Blockers, Ca-Blockers and ACE-I use.*

Conclusion: This study suggests that the baseline HR is an independent mortality predictor in pts with CAD. However, it remains to be proven that reduction of HR will improve the outcome of pts with CAD.

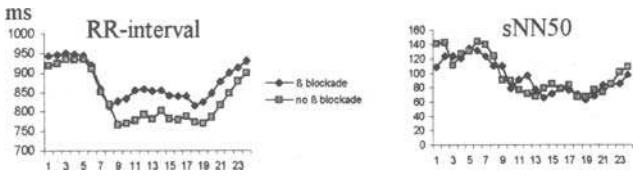
P1780 Effects of β-blockade on the circadian profile of time domain heart rate variability in patients surviving acute myocardial infarction

H. Bonnemeier, A. Brandes, N. Kluge, U. Wiegand, H.A. Katus, Jürgen Potratz. *Medical Clinic II, Medical University Lübeck, Germany*

Beta blockade (BB) has proven to be of beneficial effect in patients (pts) recovering from acute myocardial infarction (AMI). However, data on the effects of BB-therapy on heart rate variability (HRV) – marker of sympathovagal balance – are surprisingly rare.

Methods: We enrolled 185 consecutive pts 13 ± 2.5 days after AMI (83 anterior, 102 inferior; 137 underwent thrombolytic therapy). 126 pts received metoprolol 50–200 mg/day, 59 pts had no BB therapy. There were no significant differences between the two groups regarding age, gender, peak creatine kinase level, left ventricular ejection fraction, infarct site and size. HRV parameters (sNN50, pNN50, SDNN, rMSSD and RR-interval) were analysed from 24-hour-Holter monitoring and were calculated as hourly mean values.

Results: Pts with BB therapy exhibited significantly longer RR-intervals at daytime. At nighttime the course of RR-cycle lenght was not significantly different from that in pts without BB. The morning decrease was sharper in pts with no BB therapy. Time domain HRV parameters showed a circadian profile, however, there were no significant differences in pts with and without BB therapy in both, day- and nighttime.



Conclusion: BB therapy dampens the day-night-difference of RR-cycle lenght in pts after AMI, but it does not affect the circadian profile of time domain HRV. Our finding suggests, that hourly measured time domain HRV is independent of any BB therapy in pts after AMI.

P1781 Determinants of the parasympathetic enhancement during the "diving" reflex

G. Spadacini, C. Passino, C. Valenti, V. Spallone[1], G. Finardi, L. Bernardi. *Internal Medicine Dept, IRCCS S.Matteo – University of Pavia, Pavia; [1]Dept of Endocrinology, Tor Vergata University, Rome, Italy*

The origin of the diving reflex (apnea + face immersion in cold water, causing sustained vagal activation) is unclear. To assess the relative contribution of apnea, immersion and water temperature, we recorded RR interval (RR), calibrated respiration and systolic blood pressure (SBP) in 11 volunteers (29 ± 2 yr) breathing through a snorkel, before (4 minutes, NO-APN) and during 40 s apnea (APN), while the face was maintained in air (AIR), warm (28°C, WW) or cold (12°C, CW) water. We measured ventilation and sympatho-vagal balance by spectral analysis (low- and high-frequency, respiratory components, HF and LF, markers of vagal and sympathetic activity) of RR and SBP. Compared to NO-APN-AIR, NO-APN-CW and NO-APN-WW increased RR, RR variability (standard deviation, SD) and%HF, while reduced%LF (mean: from 772 ± 26 to 834 ± 37 to 822 ± 32 ms, $p < 0.05$; SD: from 48.8 ± 4.2 to 66.9 ± 6.2 to 57.9 ± 6.1 ms, $p < 0.05$; HF: from 42.7 ± 7.6 to 51.4 ± 5.9 to 53.3 ± 6.8%, $p < 0.05$ LF: from 52.9 ± 7.4 to 36.8 ± 4.2 to 38.4 ± 7.4%, $p < 0.005$), without change in breathing frequency and depth. WW and CW conditions gave similar results. SBP remained unchanged in NO-APN conditions (both mean and spectral values). APN provoked no change in RR, markedly reduced all HF (absence of breathing), but increased the RR-LF (from 6.38 ± 0.25 to 6.90 ± 0.17 ln-ms^2, $p < 0.005$) and SBP-LF powers (from 2.28 ± 0.29 to 3.44 ± 0.21 ln-mmHg^2, $p < 0.005$), regardless of AIR, WW or CW.

The evident vagal activation seen during the "diving" reflex appears to be due to water immersion in itself rather than the apnea, with little or no effect of water temperature

P1782 Cardiocirculatory coupling during sinusoidal baroreceptor stimulation and fixed-frequency breathing

C. Keyl, M. Dambacher, A. Schneider, C. Passino[1], U. Wegenhorst, L. Bernardi[1]. *Anaesthesiology Dept, University of Regensburg, Regensburg, Germany; [1]Internal Medicine Dept, IRCCS S.Matteo – University of Pavia, Pavia, Italy*

The question, as to whether respiratory sinus arrhythmia (RSA) is mainly created by a central coupling between respiration and heart rate, or by baroreflex mechanisms, is controversial. In the case of a major contribution of baroreflexes to RSA, cardiocirculatory coupling during breathing, and during cyclic baroreflex stimulation, should show similarities.

We applied a sinusoidal stimulus to the carotid baroreceptors (neck suction, NS) and generated heart rate fluctuations of the same magnitude as RSA with a frequency near, but different from the breathing frequency (0.2 Hz vs. 0.25 Hz) and at a lower frequency (0.1 Hz) in 17 healthy subjects, aged 29–39 years. Measurements were performed supine and upon 60° tilting, to assess the effects of changed autonomic activity. The data were analyzed by Fourier transform, transfer function and phase analysis.

Respiratory fluctuations in systolic blood pressure (SBP) preceded sinus arrhythmia with a time lag equal to that between baroreceptor stimulation and oscillations in RR intervals (0.62 ± 0.18 s vs. 0.57 ± 0.28 s). Although NS at 0.1 Hz largely increased SBP fluctuations, the spontaneous phase relations between blood pressure (leading) and RR intervals (lagging) remained unchanged. During NS at 0.2 Hz, RR interval fluctuations generated only a minor response in SBP (five times less than spontaneous respiratory blood pressure fluctuations). Head-up tilt increased the time lag between NS and the other signals.

The observed similarities between the effects of baroreceptor stimulation and spontaneous sinus arrhythmia do not support the hypothesis that the origin of RSA, in healthy subjects, is predominantly a central phenomenon which secondly generates fluctuations in blood pressure. The lack of increase in SBP fluctuations during 0.2 Hz NS suggests that respiration affects blood pressure mainly by mechanical (stroke volume) rather than autonomic mechanisms, and that RSA depend on blood pressure fluctuations and not vice versa.

P1783 Assessment of QT dynamicity by evaluation of QT/RR relation from 24-hour Holter ECGs in patients after myocardial infarction

Y. Gang, X.H. Guo, M. Gallagher, K. Hnatkova, M. Reardon, J. Poloniecki, A.J. Camm, M. Malik. *Cardiological Sciences, St. George's Hospital Medical School, London, UK*

To evaluate the QT dynamic in patients (pts) after acute myocardial infarction (MI), 14 pts (age 60 ± 7 years, 12 men) who died suddenly (SCD) within 1 year after MI and 14 pair-matched (age, sex, left ventricular ejection fraction, infarct site, thrombolytic therapy) pts who remained event-free after MI (survivors) for ≥3 years were studied. Fourteen normal subjects served as controls (CON, age 55 ± 9 years, 11 men). QT and RR intervals were automatically measured on a beat-to-beat basis with visual control from 24-h ambulatory ECGs using Pathfinder 700 (Reynolds Medical, UK). Mean hourly values of the QT/RR slope ($QT = \alpha + \beta RR$) and corrected QT interval at 1000 ms of RR interval ($QT1s = \alpha + 1000\beta$) were derived for each subject. The circadian rhythm of ventricular repolarisation was examined by harmonic regression analysis.

Results 1) There was a trend towards a significant difference in 24-h mean value of QT1s between study groups (408 ± 26 v 381 ± 43 and 386 ± 22 ms, $p = 0.06$ by ANOVA). A significant difference was found between SCD and CON (408 ± 26 v 386 ± 22 ms, $p = 0.02$). 2) The QT1s differed significantly between study groups ($p = 0.038$) only in day time (09:00–19:00), during which period QT1s was significantly longer in SCD than in CON (409 ± 33 v 380 ± 27 ms, $p = 0.02$), and tended to be longer than in survivors (409 ± 33 v 379 ± 42 ms, $p = 0.08$). 3) The 24-h mean value of QT/RR slope was significantly different between study groups ($p = 0.04$), showing significantly steeper slope in SCD than in CON (0.15 ± 0.07 v 0.09 ± 0.02, $p = 0.008$). 4) During the day, the QT/RR slope differed significantly between study groups ($p = 0.04$) and the difference was less marked at night ($p = 0.08$). The slope was significantly steeper in SCD than in CON in both day and night ($p < 0.05$). 5) A marked circadian variation of QT1s and the slope was observed in CON, which was blunted in survivors and SCD.

Conclusions Abnormal repolarisation behaviors, characterised by longer QT1s and impaired adaptation of QT to variations in RR intervals, were found in SCD. Lethal ventricular tachyarrhythmias may be provoked by the altered repolarisation dynamics in pts after MI.

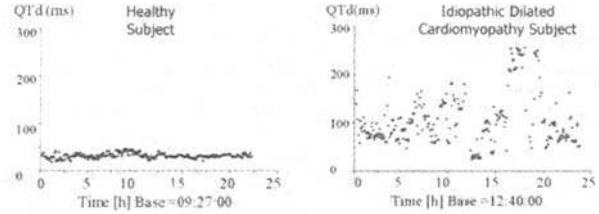
P1784 New algorithm for QT dispersion analysis in XYZ-lead Holter ECG: description and validation

P. Caminal, M. Vallverdu, X. Vinolas[1], J.L. Alonso[1], R. Jané, P. Laguna[2], M.V. Pitzalis[3], P. Rizzon[3], W. Zareba[4], A. Bayes de Luna[1]. *ESAII, Centre de Recerca en Enginyeria, Univ. Politec. de Catalunya, Barcelona; [1]Cardiology Dept, Hospital Santa Creu i Sant Pau, Barcelona; [2]Ing. Electr. y Comunicacion, Universidad de Zaragoza, Zaragoza, Spain; [3]Institute of Cardiology, University of Bari, Bari, Italy; [4]University of Rochester, Rochester NY, USA*

QT dispersion (QTd) in surface ECG has been proposed as a simple measure for arrhythmic risk assessment. QTd analysis in 3 orthogonal leads (OL) correlates with 12 leads measurements. The automatic measurement of QT in digital Holter recordings has been developed and validated, however, automatic QTd analysis in Holter is not widely available. The aim of this work is to develop and validate a new computer algorithm for beat-to-beat analysis of QTd (QTmax-QTmin) in Holter recordings.

Material & Methods: The proposed algorithm has been organized in three steps: 1) a single-lead detector of significant points is applied to each of the 3 leads, 2) the QT interval is measured in each lead and finally 3) the QT dispersion is obtained. A set of 1000 beats (50 initial beats of 20 subjects) of 3 leads (X,Y,Z) digital Holter ECG recordings (200 Hz, Burdik USA) from the IDEAL database were used for the validation of the algorithm. These beats present different T-wave morphologies and different noise levels. The automatic results (AUT) have been compared with those obtained manually by two cardiologists (C1&C2).

Results: Total number of beats analyzed 810/1000 (noisy beats rejected). Mean value of QTd was: 10.6 ± 2.8 ms C1; 11.2 ± 2.7 ms C2; 10.6 ± 1.7 ms AUT. Mean ± SD values of differences were AUT-C1 = 0.62 ± 12 ms, AUT-C2 = −0.34 ± 11.9 ms, C1-C2 = 0.26 ± 13.1 ms.



24-hours dyamic behavior of QTd.

Conclusions: 1) A new automatic algorithm for QTd analysis in digital Holter recordings is described; 2) Automatic QTd measurements are comparable to manual measurements; 3) Automatic QTd analysis provides an objective measure (unaffected by inter observer variability) of dispersion of repolarization allowing therefore to study its dynamic behavior what may be of potential clinical benefit.

P1785 Morlet wavelet analysis of Holter recordings in acute anterior myocardial infarction patients may be used for early prediction of patent infarct related artery after thrombolysis

A. Boufidou, N. Maglaveras[1], I. Chouvarda[1], S. Mohlas, A. Kontopoulos, G. Louridas. *A' Cardiology Clinic – Medical School, Aristotelian University, Thessaloniki; [1]The Medical School, Aristotelian University, Thessaloniki, Greece*

Wavelet (WV) transform is a non stationary spectrotemporal analysis technique enabling detection of small, transient signals hidden in the QRS complex and the ST segment of the ECG. The objective was to study whether WV transform through-out the QRS and ST segment in acute myocardial infarction (AMI) pts can predict patent infarct related artery following thrombolytic treatment.

Methods: 25 pts with anterior AMI, without history of previous MI, aged 21–70, underwent thrombolysis during the first 6 hrs after onset of pain. All pts had 2 lead Holter recordings for the first 48 hrs following onset of thrombolysis and for 24 hrs prior to discharge (7th or 10th day). During stay all pts underwent coronary angiography. 19 had patent infarct related artery and 6 non patent. Holter data (V1 lead) were digitized at 800 Hz for Morlet WV analysis. Three frequency bands were examined. Band 1: 200–160 Hz, 2: 150–100 Hz, 3: 90–50 Hz. WV parameters averaging was done over 3–5 consequitive beats at the onset of lysis 1, 2, 4, 6, 12, 18, 24, 48, 168 or 240 hrs after lysis. The parameters used were the Mean (MN) and Maximum (MX) values of the WV in all 3 bands in the QRS, the ST, the last 40 msec of QRS (J-40) and the first 40 msec of ST (J+40).

Results: We observed statistically significant differences of all but 3 of the above mentioned parameters between pts with patent and non patent infarct-related artery at the 6th hr after lysis. Discriminant analysis of the WV parameters showed that 6 hrs following lysis results in the following Wavelet Parameter Index (WVI):

$$WVI = -2,767 * MN3QRS + 36,544 * MX3QRS + 1213,852 * MN1(J+40) + 0.942 * MN3(J-40) - 322.62 * MX1ST - 1,581$$

where 1, 2, 3 represent the frequency bands. If WVI < 1.84 the artery was considered patent, otherwise non patent (table).

	WVI < 1.84	WVI ≥ 1.84
Pts with patent infarct related artery (n = 19)	n = 18	n = 1
Pts with non patent infarct related artery (n = 6)	n = 0	n = 6

p = 0.0001, Sensitivity = 95%, Specificity = 100%, Positive Predictive Accuracy = 100%, Negative Predictive Accuracy = 86%

In conclusion Wavelet parameter Index (WVI) can predict as early as 6 hours following lysis the patent infarct related artery in AMI pts and might be a useful tool for noninvasive assessement of successful thrombolysis.

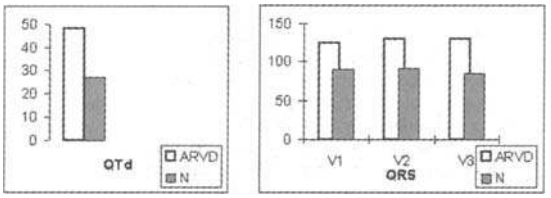
P1786 Qt dispersion in patients with arrhythmogenic right ventricular dysplasia

D. Poçi, N.I.L.S. Edvardsson[1]. *Gothenburg; [1]Cardiology Dept., Sahlgrenska Hospital, Gothenburg, Sweden*

Arrhythmogenic right ventricular dysplasia (ARVD) is characterized by recurrent ventricular tachycardia (VT) of RV origin. Nonuniform recovery of ventricular excitability may facilitate the development of VT of reentrant mechanism.

We analyzed 17 patients with well-documented ARVD (RV tachycardia with left bundle brunch block (LBBB) morphology, positive echo- and angiocardiography criteria, late potentials (LP). The mean age was 37 ± 13 years old and eleven patients were males (65%). All patients were off antiarrhythmic drugs. The QT and the T peak-T end (Tp-Te) intervals, QT dispersion (QTd), QRS duration and T wave morphology were evaluated using the precordial leads V1-V6 and were compared with data of 15 sex- and age- matched healthy subjects. Patients with right bundle brunch block (RBBB) pattern were excluded. Data were manually measured twice by the same observer.

Results: The QTd was significantly different in ARVD patients compared to normal subjects ($p < 0.05$). The QT interval and QRS duration were significantly longer in the ARVD group. There was no difference in the Tp-Te interval between the two groups. LP were present in 13 patients (76%); the T wave was negative in 71% of the ARVD patients in lead V2 and 65% in V3; No intra-observer difference in measurements was present.



Conclusion: The QTd and the QRS duration were significantly increased in patients with ARVD compared with normals. In the absence of complete or partial RBBB pattern, the QT dispersion and the QRS width in the surface ECG separated the ARVD patients from the normal subjects. They might therefore be useful as simple screening criteria in apparently healthy subjects with an episode of monomorphic VT of LBBB morphology or with a history of not yet documented paroxysmal tachycardias.

P1787 QT interval dynamicity in patients with coronary artery disease

K. Aytemir, N. Özer, E. Sade, S. Aksöyek, S. Kes, A. Oto. *Hacettepe University, Faculty of Medicine, Dept. of Cardiology, Ankara, Turkey*

It has been well known that repolarisation abnormalities are related with the development of serious ventricular arrhythmias and show circadian variations. The purpose of this study was to investigate the QT dynamicity in a group of patients with coronary artery disease (CAD) proved by coronary angiography.

Methods: Twenty-hour Holter recordings were obtained from 50 healthy subjects (25 women, mean age 43 ± 11 years) and 84 patients with CAD (40 women, mean age 45 ± 10 years) using Ela Medical Holter system. Algorithm automatically measured the QT end (QTe), RR interval (ms), and the slopes of the linear regressions of QTe plotted againts the corresponding RR interval (QTe/RR) from the entire 24 hours tracing and four segments of 6 hr defined: morning (06–12), day (12–18), evening (18–24), night (00–06).

Results: QTc end values:

	24 hour	Morning	Day	Evening	Night
Patients	436 ± 34	442 ± 23	437 ± 29	438 ± 27	435 ± 32
Controls	423 ± 34	428 ± 26	426 ± 31	424 ± 19	422 ± 16
P value	0.05	0.04	0.05	0.03	0.02

Slopes of QTe/RR:

	24 hour	Morning	Day	Evening	Night
Patients	0.14 ± 0.1	0.11 ± 0.07	0.14 ± 0.1	0.15 ± 0.2	0.16 ± 0.1
Controls	0.18 ± 0.05	0.14 ± 0.1	0.16 ± 0.2	0.17 ± 0.1	0.18 ± 0.1
P value	0.04	0.05	0.06	0.07	0.06

Conclusions: These results show that patients with CAD have abnormal repolarisation behaviour, characterised by increased mean QTc end and depressed adaptation of QT to variations in RR interval especially during the morning. These findings may be an explanation for the increased sudden cardiac death risk during morning hours.

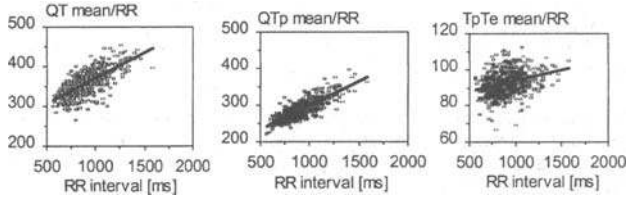
P1788 Relation between early and late phases of ventricular repolarization and cardiac cycle length in 1,100 normal subjects

I. Savelieva, A. John Camm, M. Malik. *St George's Hospital Medical School, London, UK*

The characteristics of the T wave and QT interval components have been hypothesised to be as important as the QT interval duration itself. Investigation of physiologic difference in phases of ventricular repolarisation and their relation to cardiac cycle length may explain mechanisms of arrhythmogenesis.

Methods: QT, QT_{peak} (QT_p) and T_{peak}-T_{end} (T_pT_e) intervals were evaluated in 1100 healthy volunteers (age 33 ± 12; 910 men) by QT Guard software (Marquette Medical Systems). To assess relation between phases of repolarization and cardiac cycle length, the slopes of linear regressions of QT, QT_p and T_pT_e intervals plotted against the corresponding RR interval were compared.

Results: In all subjects, QT and QT_p interval were strongly dependent on RR interval ($r = 0.82$ and 0.81, respectively; $p < 0.0001$), while T_pT_e interval showed only a weak correlation with heart rate ($r = 0.30$, $p < 0.02$). QT/RR and QT_p/RR slopes were significantly steeper than that of T_pT_e/RR (0.1311 and 0.1283 vs 0.0116; $p < 0.05$; see Figure). The steepness of QT/RR and QT_p/RR slopes decreased, and in T_pT_e/RR slopes increased with age. This was more pr onounced in women, whereas the same relation in men remained stable in all age groups.



Conclusion: QT_p interval strongly depends on heart rate, while T_pT_e interval is less rate-dependent suggesting stronger autonomic modulations of the early phase of ventricular repolarization. Prolonged early phase of repolarization at slower heart rate may be responsible for mechanisms of arrhythmogenesis.

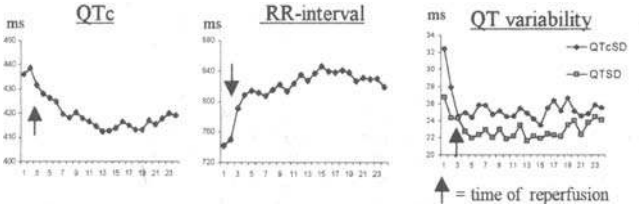
P1789 QT interval dynamicity during direct PTCA: effects of reperfusion on ventricular repolarization in acute myocardial infarction

H. Bonnemeier, F. Hartmann, S. Schulenburg, U. Wiegand, H.A. Katus, G. Richardt. *Medical Clinic II, Medical University Lübeck, Germany*

Effective treatment of acute myocardial infarction (AMI) may reduce possible substrates for serious arrhythmias. We sought to evaluate the influence of early coronary artery reperfusion by primary angioplasty (PA) on beat-to-beat QT interval dynamics, a measure of temporal fluctuations of ventricular repolarization.

Methods: We prospectively investigated 89 consecutive patients (pts) (17 female, 72 male; 59.3 ± 3.2 years of age) with a first AMI (45 inferior, 44 anterior). Peak creatine kinase level was 1090 ± 854 U/l. Reperfusion was successfully achieved by PA in all pts (TIMI flow before reperfusion 0.65, after reperfusion 2.71). Continuous beat-to-beat QT interval measurement was performed from 24-hour Holter monitoring, which was initiated at admission.

Results: Reperfusion of the infarct related artery in AMI caused a significant continuous decrease of both, parameters of QT interval (QT, QTc, Qta, Qtac) and QT interval variability (QTSD, QTcSD, QTaSD, QTacSD). RR-interval increased significantly after reperfusion.



Conclusion: Reperfusion leads to a significant continuous decrease of the QT interval and beat-to-beat QT interval variability, reflecting heterogeneity of ventricular repolarization. Reduction of QT interval variability and its associated risk of malignant ventricular arrhythmia may contribute to explain the beneficial effect of early reperfusion by PA in AMI.

P1790 Effect of short-term exercise rehabilitation on heart rate variability, exercise tolerance and total ischaemic burden in patients after myocardial infarction

L. Bryniarski, K. Kawecka-Jaszcz, B. Bacior, M. Rajzer, J. Kawwa[1], J. Grodecki, W. Żwirski[1]. *I Cardiac Dept. Jagiellonian University, Kraków; [1]Centre of Cardiac Rehabilitation, Rabka, Poland*

The favourable effect of long-term physical training on the autonomic nervous system has been proved, whereas the effect of short-term rehabilitation in patients after myocardial infarction (MI) is still not clear.

The aim of the study was to assess exercise tolerance, heart rate variability (HRV) and total ischemic burden (TIB) in 24 hr ECG recording (HM) and exercise stress test (EXT) in patients after MI undergoing a 27-day exercise rehabilitation.

Material and Methods: 115 patients after a first MI were randomized to two groups matched for age, sex, infarct location, left ventricular function and work capacity (WC). Group A (64 patients) underwent a 27-day early postdischarge training; group B (51 patients) was not exercised. In all patients echocardiography, HM and EXT were performed at baseline and at 27 days.

Results: At baseline both groups were similar with respect to EXT duration, time-domain HRV parameters, (LVEF) and TIB.

	SDNN (ms)	rMSSD (ms)	pNN50 (%)	EX Time (s)	W (Watt)
Group A: n = 64					
At baseline	96.3 ± 26.0	24.1 ± 13.5	4.5 ± 6.6	516.9 ± 194.4	98.8 ± 26.9
p	p < 0.001	p < 0.001	p < 0.001	p < 0.001	p < 0.001
After training	123.9 ± 29.4	28.9 ± 8.7	7.6 ± 6.0	670.3 ± 244.5	124.6 ± 32.6
Group B: n = 51					
At baseline	106.6 ± 30.0	26.1 ± 11.3	5.5 ± 6.3	499.9 ± 188.7	101.0 ± 26.9
p	p > 0.05	p < 0.001	p < 0.001	p > 0.05	p > 0.05
At end of study	108.0 ± 26.3	21.0 ± 7.3	2.8 ± 3.7	495.9 ± 193.0	100.0 ± 27.4

After training HRV parameters and WC increased significantly in group A. Early training did not affect LVEF in group A (60 ± 7.9 vs 63.0 ± 10.3%) and LV size. In group B the indices of parasympathetic activity deteriorated. TIB remained unchanged in both groups. In group A the circadian pattern of SMI was changed – the number of SMI episodes in the morning hours was lower.

Conclusion: Short-term physical training in patients after a first MI improves HRV parameters and exercise tolerance. This is not associated with TBI reduction, but the circadian pattern of SMI is changed.

P1791 Double Inheritance of a mutation in the long QT syndrome

I. Denjoy, P. Richard[1], M. Berthet[2], C. Donger[2], H. Hammoude[3], A. Cobo[1], E. Villain[4], B. Hainque[1], P. Coumel, P. Guicheney[2]. *Cardiology Dept, Lariboisière Hospital, Paris[1] Service de Biochimie, Hopital Pitié-Salpétrière, Paris[2] INSERM 153, Hopital Pitié-Salpétrière, Paris, France[3] Cardiology Dept, Sainte Ode, Belarus[4] Cardiology, Hopital Necker-Enfants Malades, Paris, France*

Long QT syndrome (LQTS) is a familial cardiac disorder characterized by prolonged ventricular repolarization and syncope or sudden death due to ventricular tachyarrhythmias. In the autosomic dominant form, (Romano-Ward syndrome), affected subjects are heterozygous carriers of a mutation in one of the LQTS genes KCNQ1, HERG, KCNE1 or SCN5A. In the recessive form associated with congenital bilateral deafness, (Jervell and Lange-Nielsen), affected subjects are either homozygous carriers of a mutation *in* KCNQ1 or KCNE1 or heterozygote compound carriers. However, one case of homozygous mutation *in* KCNQ1 has been reported without deafness. The prevalence of double inheritance of a mutation in a LQTS genotyped population is unknown.

Methods: 54 genotyped Romano-Ward families were analyzed. All subjects underwent clinical examination, a 12-lead ECG and DNA analysis. Subjects were considered as affected in case of QTc > 460 ms or QTc > 440 ms associated to bradycardia or abnormal T wave, or syncope or torsades de pointes.

Results: A single mutation was found in KCNQ1 in 35 families and in HERG in 15 families. In 2 families, the probands were homozygous carriers of a mutation in KCNQ1 (A300T in one family and R533W in the other) without any deafness. In a third family, the proband and her most severely affected sister were carriers of 2 mutations, one in HERG (2592+1G-A) and one in KCNQ1 (A341E). In a fourth family, both parents of the proband were carriers of a mutation in KCNQ1 (1893insC). However, none of their children including the proband are homozygous carriers so far.

Conclusion: Double inheritance of a mutation in one of the LQTS genes can be evidenced without deafness. Genetic testing should be performed in both sides of the family of affected subjects.

P1792 Demonstration of two different ion channel mutations in long QT syndrome probands

C. Napolitano, M. Correia[1], P.J. Schwartz[2], M. Memmi, E.K. Ficker[3], E. Ronchetti, A.M. Brown[3], W. Lintner[4], W. Shimizu[5], S.G. Priori. *Molecular Cardiology Dept., Fondazione Salvatore Maugeri, Pavia, Italy; [1]St. Maria Univ. Hospital, UTIC A Cordeiro, Lisbon, Portugal; [2]Dept. of Cardiology, Policlinico San Matteo-Univ of Pavia, Pavia, Italy; [3]Case Western Reserve University, Rammelkamp Research Center, Cleveland OH, USA; [4]Cardiology Dept., Bolzano Hospital, Bolzano, Italy[5] National Cardiovascular Center, Osaka, Japan*

Four disease genes, KvLQT1, HERG, SCN5A, and KCNE1 are implicated in the Long QT Syndrome (LQTS). Recent evidence suggests that the clinical manifestation of the disease may be largely heterogeneous within the same family or within patients with the same molecular defect. Thus, genetic or epigenetic factors play a critical role in the clinical phenotype. We tested the hypothesis that additional mutations may be present in genotyped individuals and account for phenotypic differences within the same family. We screened the entire coding sequence of the four LQTS genes in 20 genotyped patients affected by the Romano-Ward variant of LQTS. In three probands (15%) we were able to demonstrate the presence of two simultaneous genetic defects not present in 200 control individuals (400 chromosomes). In family 1 the proband, a 5 year old boy with prolonged QT interval and a history of syncope, inherited two mutations, one in KvLQT1 from the asymptomatic father (QTc: 435 ms) and one in HERG from the asymptomatic mother (QTc: 430 ms). In family 2, two missense KvLQT1 mutations were present in the proband, a 16 old girl with a history of exercise-induced syncopal episodes, one located in the S6 transmembrane (tm) segment, inherited from the father, and one in the carboxy terminus, inherited from the mother. In family 3, the proband inherited from the mother a missense mutation in the S5 tm segment of HERG and presented a splice error mutation in exon 21 of the SCN5A gene. In vitro expression of mutations identified in family 1 confirmed loss of function thus establishing a pathogenetic link with the disease.

These data demonstrate for the first time the simultaneous presence of two independent mutations in LQTS patients. They also support the hypothesis that multiple defects of cardiac ion channels may act as modifiers of the clinical phenotype in LQTS. Finally, these results point to the presence of a higher than expected prevalence of silent carriers of genetic defect of cardiac ion channels in the general population.

P1793 Clinical consequences of homozygous premature truncation of the HERG protein

A. Wilde[1,4], M. Alders[2], Th Hoorntje[3], P. van Tintelen[5], M. Mannens[2]. *[1]Depts of Cardiology; [2]Clinical Genetics, AMC, Amsterdam; Depts of [3]Pediatric Cardiology; [4]Cardiology; [5]Clinical Genetics, UMCU, Utrecht, Netherlands*

In Long QT Syndrome (LQTS) heterozygosity for a given mutation in one of the three K^+ channel genes ($LQT_{1, 2 or 5}$) gives rise to prolongation of the cardiac action potential, because the aberrant protein encoded by the mutated gene exerts a dominant negative effect on channel function with resultant less K^+ current. Homozygosity for mutations in KVLQT1 and KCNE1 have been associated with the recessively inherited Jervell and Lange-Nielsen syndrome. HERG, involved in LQT_2 is the gene encoding the rapid component of the delayed rectifier I_{Kr}. In a consanguineous family a stillbirth was followed by the premature birth of a child in distress due to severe ventricular arrhythmias in the presence of marked QT-prolongation. LQTS was diagnosed, β-blocker therapy installed and a pacemaker implanted. The patient developed well and remained symptom-free after 1.5 years. All 15 exons of the HERG gene were amplified from genomic DNA and analyzed by SSCP. We identified a duplication of bp 557 to 599 in exon 4, resulting in a frameshift and a premature stop codon in the S1 domain. In the index patient this duplication was present on both alleles, so no functional HERG protein is anticipated. The same mutation was found heterozygously in both parents, and was not present in a healthy sister. Analysis of DNA isolated from amniotic fluid cells and paraffin-embedded tissues derived from the stillborn brother revealed that he also carried the duplication homozygously.

It is concluded that absence of I_{Kr} gives rise to a severe cardiac phenotype with no indication of malfunction of any other organ, suggesting specific cardiac expression of I_{Kr}. In contrast to murine models, lack of I_{Kr} is not lethal in humans.

P1794 Clinical course of the disease in the family members of Jervell-Lang-Nielsen syndrome and LQT1 syndrome probands

W. Zareba, A.J. Moss, G.M. Vincent[1], P.J. Schwartz[2], S.G. Priori[3], J.L. Robinson, M.L. Andrews. *Cardiology, University of Rochester, Rochester; [1]Cardiology, LDS Hospital, Salt Lake City, USA; [2]Cardiology, University of Pavia, Pavia[3] Molecular Cardiology, Fundation S. Maugeri, Pavia, Italy*

Background and Purpose: The LQTS pts with the Jervell-Lange-Nielsen syndrome (JLN) have longer QTc and more severe course of the disease than pts with the Romano-Ward syndrome. The JLN is mainly caused by mutations of the KVLQT1 gene encoding IKs potassium channel. The same gene is also mutated in LQT1 patients. We aimed to determine and compare the clinical course of the disease in non-deaf affected family members (AFM; defined as QTc > 0.46 sec) of JLN patients and AFM of KVLQT1 probands.

Methods and Results: We identified 27 non-deaf AFM from 40 JLN families and 108 AFM from 10 LQT1 families. Results of univariate comparison between two groups are shown in the Table below. The multivariate Cox model predicting first CE event showed that AFM from LQT1 families had significantly higher (HR = 4.63; p = 0.003) risk of CEs than non-deaf AFM from JLNS families. Male gender was the only other independent predictor of cardiac events (HR = 1.75; p = 0.04) in AFM from JLNS and LQT1 families.

Affected JLN vs LQT1 Family Members

	AFM of JLN (N = 27)	AFM of LQT1 (N = 108)	p value
Age at last contact (yrs)	40 ± 24	33 ± 23	0.730
Females	15 (56%)	57 (53%)	0.796
1st degree relationship to proband	11 (41%)	39 (36%)	0.656
QTc	0.49 ± 0.02	0.51 ± 0.04	0.003
Beta-blockers	4 (15%)	53 (49%)	0.001
Cardiac Events	4 (15%)	51 (47%)	0.002
Median age at 1st cardiac event	15	9	0.363

Conclusions: Affected family members from LQT1 families have higher risk of cardiac events than non-deaf affected family members from JLNS families. This observation suggests different penetrance of the mutant KVLQT1 gene in the JLN and LQT1 families.

P1795 QT interval in twins

N. Carter[1], H. Snieder[3], S. Jeffery[1], R. Saumarez[2], C. Varma[2], L. Antionides[3], T. Spector[3]. [1]*Dept. of Medical Genetics, St George's Hospital Medical School, London;* [2]*Dept. of Cardiological Sciences, St George's Hospital Medical School, London;* [3]*Twin Research & Genetic Epidemiology Unit, St Thomas' Hospital, London, UK*

Dominant long QT syndrome causing syncopal attacks and sudden death, has been mapped to several gene loci and functional mutations in these ion channel genes have been identified[1]. The recessive Jervell and Large Neilsen syndrome causing prolonged QT interval and deafness can be related to "disruptive" mutations in the KVLQT1 gene. Although it appears that the likelihood of sudden death from a given cardiac event differs depending on the gene that is mutated to produce LQT, the influence of other background genetic or environmental factors is unclear.

The study cohort was comprised of 301 female Caucasian twin pairs [103 monozygotic (MZ) and 198 dizygotic (DZ) pairs] aged 18–71 years ascertained through a national media campaign in the UK. Zygosity was determined by questionnaire and confirmed with DNA fingerprinting. QT interval and interbeat interval (RR) were measured "blind" by a trained observer from routine 12 lead ECG traces and the corrected QT (QT_C) was calculated from the equation $QT_C = QT/\sqrt{RR}$.

Mean QT_C (SD) values were 413 (25) ms for MZ and 412 (25) for DZ twins. QT_C was significantly correlated with age ($r = 0.24$, $p < 0.001$). Intraclass correlations were larger than zero for both MZ ($r = 0.30$, $p < 0.001$) and DZ twin pairs ($r = 0.20$, $p < 0.0025$) pointing to a significant familial resemblance. The difference between rMZ and rDZ suggests a small heritability.

Maximum Likelihood model fitting confirmed a significant age effect (ACE *with age* vs. ACE *no age:* χ^2 [1] = 29.0, $p < 0.001$) and a significant familial resemblance that could be explained either by additive genes (AE vs. E: χ^2 [1] = 11.2, $p < 0.001$) or common environment (CE vs. E: χ^2 [1] = 10.7, $p < 0.005$). However, the model including age, additive genetic and unique environmental influences gave the most parsimonious explanation of the data, based on the lowest AIC. In this model age explained 6% (95% CI: 2–10) and additive genetic factors (i.e. the heritability) 25% (95% CI: 11–38) of the variance, the remaining variance being due to unique environment or measurement error.

Thus we find a small heritability for QT_C, which in conjunction with unique environmental effects are the major influences on QT variability.

P1796 Identification of a de-novo mutation in sudden infant death syndrome

H. Wedekind[1,4], T. Bajanowski[2], G. Jorch[3], B. Brinkmann[2], H. Funke[4], G. Breithardt[1,4], E. Schulze-Bahr[1,4], W. Haverkamp[1]. [1]*Department of Cardiology and Angiology;* [2]*Institute for Legal Medicine;* [3]*Dept. of Pediatrics of the University of Münster;* [4]*Institute for Arteriosclerosis Research at the University of Münster, Germany*

Sudden infant death syndrome (SIDS) is a death of a apparently healthy infant dying unexpectedly. It is the leading cause for death among infants between one month and one year of age. There have advanced a number of theories on causes of SID including cardiac disorders, respiratory infections, abnormal function of the nervous system with pathological breathing and sleep patterns. Recently, prolongation of the QT interval was suspected to be involved in a significant number of SIDS victims. To test the hypothesis we performed genetic analysis of the four known genes causing the long QT syndrome (LQTS) in infants with premature unexpected death.

DNA from 20 SID victims was prepared and PCR products (150–400 bp) of *KVLQT1* (LQT1), *HERG* (LQT2) *SCN5A* (LQT3) and *KCNE1* (LQT5) were generated. Single strand conformation polymorphism (SSCP) was then performed followed by sequence analysis of abnormal band shifts in SSCP on an ALF*express* DNA Sequencer connected to an external thermostatic circulator.

In one of the 20 samples we were able to detect one missense mutation in the SCN5A gene, which was localized in the DIII S4–5 region of the α-subunit of the sodium channel and leads to an aminoacid change from alanine to proline (Ala1330Pro). ECG analysis of the deceased infant showed a prolonged QT-interval of 0.6 sec, both parents had normal QT-intervals (0.40 and 0.42 sec). Sequence analysis failed to detect the same mutation in the parents, paternity was proved with paternity analysis.

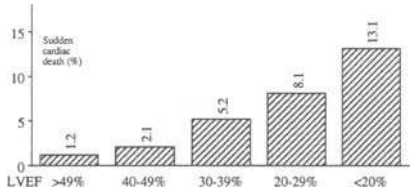
Our results show that the congenital long-QT syndrome has to be taken into consideration as a potential cause for SIDS. Further studies are necessary to assess its incidence in SIDS victims.

PREDICTORS OF SUDDEN CARDIAC DEATH

1797 Left ventricular ejection fraction predicts sudden rather than non-sudden cardiac death?

C. Ehlers, T. Brüggemann, G. Steinbeck[1], D. Andresen. *Dept of Cardiology, Urban Hospital Berlin;* [1]*Klinikum Großhadern, University of Munich, Germany*

In patients following myocardial infarction (MI-pts.) left ventricular ejction fraction (EF) has shown to be predictive for non sudden cardiac mortality rather than sudden cardiac death (SCD). Thus, it is questionable wether EF should be used for risk stratification to select candidates for an implantable cardioverter/defibrillator (ICD). In a prospective risk stratification study 928 consecutive acute MI-pts (707 males, mean age: 59 ± 9 yrs) underwent radionuclide ventriculography 10–15 days after the acute event. Mean EF was 46 ± 15%. EF ≥ 50% was found in 44% (n = 407) of pts, 40–49% in 25% (n = 232), 30–39% in 16%, (n = 153), 20–29% in 11% (n = 99), and <20% in 4% (n = 38). The mean follow up was 28 ± 16 months.



Conclusions: This is the first study which demonstrates that even a very low EF predicts SCD and thus is helpful to identify candidates for a prophylactic ICD implantation.

1798 Risk of sudden and non-sudden cardiovascular death in patients with congestive heart failure following an acute myocardial infarction

S.Z. Abildstrom, C. Rask-Madsen, M. Ottesen, C. Torp-Pedersen, L. Kober. *Dept. of Cardiology, Gentofte University Hospital, Copenhagen, Denmark*

Congestive heart failure (CHF) following acute myocardial infarction (MI) is known to be associated with an increased risk of both death of all-cause and sudden cardiovascular death (SCD). The aim of the present study was to compare the incidence of SCD and non-sudden cardiovascular death (non-SCD) in consecutive MI patients with or without congestive heart failure (CHF) and to identify risk markers of SCD within the CHF-group.

Methods: We analysed data from 6676 consecutive patients admitted alive with acute MI to 27 Danish hospitals over a period of 2 years. The patients were screened for the TRACE study. Follow up was 2–4 years and all deaths were classified by an event committee. SCD was defined as cardiovascular death within one hour of onset of symptoms. CHF was defined as requirement of treatment for CHF during hospital stay and/or at discharge.

Results: Of the 5983 patients alive at discharge 2952 (49%) had CHF. During follow-up 1659 deaths occurred of which 535 were classified as SCD and 726 as non-SCD. Presence of CHF significantly increased the all causes mortality (ACM) as well as mortality due to both SCD (SCM) and non-SCD (non-SCD) at all times ($p = 0.0001$ between CHF/no-CHF in all three types of mortality).Multivariate regression analysis proved CHF to have value predicting any type of death independent of other known risk factors. Within the group having CHF we found age, left ventricular systolic dysfunction, previous MI and history of arterial hypertension to be independently associated with SCD.

	ACM (%) 1-yr/2-yr/3-yr	SCM (%) 1-yr/2-yr/3-yr	Non-SCM (%) 1-yr/2-yr/3-yr
No CHF	7/10/14	2/4/5	3/5/6
CHF	22/33/40	8/12/15	11/17/20

Conclusion: CHF following MI is independently associated with an increased absolute risk of both SCD and non-SCD. Age, left ventricular systolic dysfunction, previous MI and history of arterial hypertension are independent risk markers of SCD within the CHF-group.

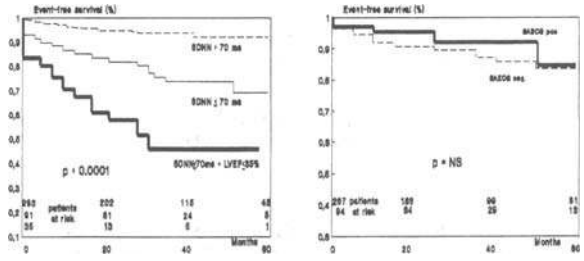
1799 Comparison of measures of autonomic tone and the signal-averaged ECG for risk stratification after myocardial infarction: results of a prospective long-term follow-up trial in 411 consecutive patients

T. Klingenheben, S.C. Credner, *O.* Mauss, G.C. Grönefeld, S.H. Hohnloser. *Department of Medicine, Division of Cardiology, J.W. Goethe University, Frankfurt/Main, Germany*

Data on the prognostic value of the signal averaged ECG (SAECG; time domain) with respect to vulnerability to ventricular tachyarrhythmias (VT/VF) post myocardial infarction (MI) compared to heart rate variability in patients treated to contemporary guidelines are sparse.

Methods: A total of 411 consecutive MI pts underwent noninvasive risk stratification at hospital discharge (8 ± 6 days after MI) including SAECG (time domain; late potential positive with 2 of 3 criteria: QRS > 114 ms; LAS > 38 ms; RMS40 < 20 μV) and heart rate variability (HRV) from 24 hour Holter recording (SDNN; cut-off value: 70 ms).

Results: In 42/411 pts a prospectively defined endpoint (death; sustained VT/VF; resuscitation from cardiac arrest) occurred after 33 ± 26 months of follow-up. The figure depicts Kaplan-Meier survival analysis for HRV (left) and SAECG (right). *On* multivariate analysis, only HRV and LVEF were independent risk markers.



Conclusion: In patients with MI treated according to modern therapeutic guidelines (open infarct artery; beta-blocker therapy), analysis of the SAECG in the time domain is not useful for risk stratification. Measures of autonomic tone, in contrast, yield a high predictive value with respect to identifying high-risk pts.

1800 Is abnormal signal-averaged electrocardiogram in time or frequency domain analysis an independent predictor of mortality post acute myocardial infarction and what is the optimal time of recording?

G. Kazianis[1], S. Feggos[1], D.V. Cokkinos[2], A. Economou[1]. [1]*Cardiology Dept, 7th IKA Hospital;* [2]*Onasis Cardiac Surgery Center, Athens, Greece*

Background: In previous studies an abnormal (abn) signal-averaged electrocardiogram (SAECG) was founded to be an unfavorable predictor after acute myocardial infarction (AMI); however there seems to be no agreement on its independent predictive value, the appropriate mode of analysis and the optimal time to be recorded, elements that comprise the aim of this study.

Methods: We prospectively studied 705 pts, aged 63.5 ± 0.47 (SE) yrs, in sinus rhythm, with a first AMI. SAECG (ART, 40 Hz filtered, noise level < 0.5 μV) was recorded in all pts in the 1st (before thrombolysis), 3rd and 7th day post AMI. As late potentials (LP) in time domain (Td) analysis in pts with QRS on the surface ECG < 120 ms were taken fQRS > 114 ms and either LAS > 38 ms or RMS < 20 μV whereas in pts with QRS ≥ 120 ms were taken fQRS > 155 ms and either LAS > 55 ms or RMS < 17 μV. In frequency domain analysis, spectral temporal mapping (STM) was considered abn if a normality factor < 30% was derived from analysis (ART, FFT plus, TM software) of x, y or z lead. Twenty-one other variables from clinical (Killip class at admission, maxCPK and maxCPK-MB), ECG (presence or absence of BBB, site of AMI, QRS score (day 8), for estimation of infarct size [based on R and Q wave duration and R/Q and R/S ratio] Lown ≥ IVa ventricular arrhythmias on Holter (day 1) number of vessel diseased on angiography and ejection fraction on echo (day 8)) were considered.

Results: During follow-up of 28.5 ± 0.75 (SE) months there were 118 (18.5%) cardiac deaths. In multivariate logistic regression analysis only age (p = 0.000) and EF (p = 0.000) were the independent prognostic indices of mortality whereas Killip class at admission and LP on day 1 had independent marginal significance (p = 0.06, p = 0.07 respectively).

Conclusions: In pts with a first AMI only age and EF were the strong independent indices of mortality. LP in Td on day 1 before thrombolysis and Killip class at admission were associated to mortality with a trend.

1801 Fractal analysis of heart rate variability as a predictor of mortality after acute myocardial infarction

J.M. Tapanainen, P.E. Bloch Thomsen[1], M. Rosenqvist[2], M.J. Koistinen[3], C. Torp-Pedersen[1], L. Kober[1], H.V. Huikuri[3]. *Division of Cardiology, University of Oulu, Oulu, Finland;* [1]*Department of Cardiology, University of Copenhagen, Copenhagen, Denmark;* [2]*Department of Cardiology, University of Stockholm, Stockholm, Sweden;* [3]*Division of Cardiology, University of Oulu, Oulu, Finland*

Depressed heart rate variability (HRV) and reduced left ventricular (LV) systolic function are known risk markers for mortality in patients after an acute myocardial infarction (AMI). The aim of this study was to compare fractal and traditional HRV measures in predicting mortality in a consecutive series of patients surviving an AMI.

Methods: A population of 479 patients was studied in four centers (Nordic ICD Pilot Study). As a measure of LV systolic function, wall motion index (WMI) was assessed by echocardiography. Standard deviation of consecutive RR-intervals (SDNN) was analyzed from a 24-hr-ECG recording 5–14 days after AMI. As a fractal measure, the short-term scaling exponent DFA1, was calculated using detrended fluctuation analysis.

Results: The mortality was 7.1% (34/479) after a follow-up of 13 ± 6 months. In univariate analysis, low DFA1, reduced SDNN and depressed WMI were predictors of mortality (table). In multivariate Cox regression analysis, including also clinical variables, reduced DFA1 was the most powerful predictor of death, relative risk of death being 1.7 (95% confidence interval 1.1–2.8).

Parameter	Odds Ratio	95% C.I.*	PPA**
DFA1 < 0.85	4.3	1.6–11.6	22%
SDNN < 70 ms	2.3	1.1–4.9	12%
WMI < 1.3	2.0	1.0–4.1	11%
DFA1 < 0.85 and WMI < 1.3	10.8	3.2–36.1	42%

*C.I. = confidence interval, **PPA = positive predictive accuracy.

Conclusion: Fractal analysis gives more powerful prognostic information than traditional analysis of HRV or measure of LV function. Combination of impaired LV function and altered fractal HR dynamics has high accuracy in predicting mortality of patients surviving AMI.

1802 Identification of patients at risk of sustained monomorphic ventricular tachycardia after myocardial infarction using body surface potential mapping

J. Kautzner, L. Nečasová, Z. Anger[1], P. Stovicek[1]. *Department of Cardiology, Institute for Clinical and Experimental Medicine;* [1]*Department of Medicine II, Charles' University Medical School I, Prague, Czech Republic*

Among various approaches to identify subjects at risk of sustained monomorphic ventricular tachycardia (SMVT) after myocardial infarction (MI), body surface potential mapping (BSPM) has been shown to provide valuable noninvasive information on arrhythmogenic substrate. Predictive value of different parameters obtainable from BSPM is unknown.

Methods: Simultaneous ECG recordings (5 sec) from 80 regularly spaced unipolar leads over the torso, standard 12 leads, and orthogonal XYZ leads were obtained (500 Hz sampling frequency, 12 bit per sample) in a training study population (18 post-MI patients with documented SMVT, age 54.8 ± 13.7 years and 20 post-MI without VT during 6 months follow-up, age 59.7 ± 11.5 years). QRS and QTc duration was measured from XYZ leads. The QRST-area was calculated in each lead and spatial features of its body surface distributions were represented by Karhunen-Loeve (K-L) coefficients. Single-beat late potentials were extracted by singular value decomposition (SVD) of the QRST interval and subsequent time-domain analysis was performed.

Results: First 16 K-L coefficients (F 1–16), QRS, QTc, and the results of the time-domain analysis of SVD signal were used to enter forward stepwise discriminant analysis. Five best discriminant parameters were selected (QRS, F 12, F 4, F 1, QTc), and subsequently tested in 52 subjects (26 post-MI patients with documented SMVT, mean age 59.0 ± 7.4 years, and 26 post-MI without VT during 6 months follow-up, mean age 58.7 ± 11.0) who underwent the same recordings. Sensitivity and specificity of this technique to identify subjects with VT was 80.8% and 73.1%, respectively.

In conclusion, combination of the above 5 BSPM-derived parameters identifies post-MI patients with SMVT with a very high accuracy.

ABLATION OF ATRIAL FLUTTER

1803 Prediction of definitive atrial flutter radiofrequency ablation based on simplified assessment of complete cavotricuspid isthmus block

M. Pons, P. Becassis, F. Razcka, C. Piot, M. Ferriere, J.M. Davy. *Cardiologie B, CHU Montpellier, France*

Complete cavotricuspid isthmus block (IB) was assessed by a simplified method in 40 patients after successful radiofrequency ablation of atrial flutter (AF).

Methods: A quadripolar catheter was placed on the lateral right atrium. After AF termination, counterclockwise IB was assessed by low lateral atrial pacing (quadripolar catheter) and by recording atrial septal activation with ablation catheter. Clockwise IB was assessed by recording right lateral atrium activation during CS os pacing with ablation catheter. Complete IB was defined by shortening the interval between the double potential recorded by ablation catheter on the lesion (A1, A2) when pacing high lateral compare to low lateral atrium pacing. Data from 10 patients (R) with either reinducible AF by atrial pacing (6) or spontaneous AF recidives (4) were compared with data from 30 patients (S) with definitive success (follow-up: 8 ± 6 months).

Results: R and S patients exhibited bidirectional IB without differences for lateral or septal atrium activation times when pacing the opposite side. Complete IB was achieved for 27 group S patients but was absent in all R patients ($p < 0.05$). When switching from low to high lateral atrial pacing, Spike-A1 increased (18 ± 10 and 19 ± 12 ms resp. in S and R; NS), while Spike-A2 decreased for S and increased or remained stable for R (resp.: −5 ± 15 vs 10 ± 12 ms; $p < 0.01$). A1A2 shortening was S: −19 ± 20 vs R: −9 ± 10 ms ($p < 0.01$).

Conclusion: AF recurence or inducibility was possible despite conventional criteria of bidirectionnal IB. Demonstration of complete IB by this simple method was more effective to predict definitive succes of AF radiofrequency ablation.

1804 Identification of a conduction gap for successful focal reablation in patients with recurrent atrial flutter after initial bidirectional block

F. Ouyang, M. Volkmer, S. Ernst, L. Wang, G. Senatore, P. Hansen, J. Hebe, R. Cappato, K.-H. Kuck. *St. Georg Hospital, Hamburg, Germany*

Of 210 pts referred for catheter ablation of common-type atrial flutter (AFL) between 1/96 and 10/98, 10 pts (9 male, age 60 ± 8 yrs) experienced recurrent AFL during a mean 2.8 mos FU; bidirectional isthmus conduction block (CB) had been achieved in the initial procedure with 14 ± 9 RF pulses. The aim of the study was to further characterize the electrophysiological properties of recurrent AFL and to localize a conduction gap (CG) in the initially created linear lesion using either conventional techniques and/or the electroanatomical mapping system CARTO.

Methods and results: Of the 10 pts, 6 had counterclockwise AFL, 3 clockwise AFL and 1 both types. The mean cycle length of recurrent AFL was not different compared to that before the first procedure (234 ± 26 ms vs. 244 ± 41 ms, n.s.). CGs along the prior linear lesions were identified during coronary sinus pacing in 6 pts and during AFL in 3 pts by using local electrogram criteria (double or fragmented atrial potential in the initial linear lesion or CARTO); single CGs were identified at the annular district in 2 pts, at the intermediate district in 2 and at the caval district in the remaining 5 pts. In 1 pt, no attempts were made to find a CG, but bidirectional CB was achieved by creating an additional linear lesion. 2.1 ± 1.4 RF pulses delivered at sites of CG resulted in bidirectional isthmic CB in 9 pts. No AFL recurred during 15 ± 10 mos FU.

Conclusion: The recurrence rate of AFL after initial bidirectional CB was 4.8%. In pts with recurrent AFL, the CG along the initial linear lesion could readily be identified by local electrogram criteria (single or fragmented atrial potential) as well as by the CARTO system. The CG could be closed with only a few RF pulses.

1805 Unidirectional conduction block on the crista terminalis during sinus rhythm in the patients with and without typical atrial flutter

T. Itagaki, A. Yoshida, H. Kurogane, T. Kajiya, A. Takarada, T. Hayashi, Y. Tsumura, S. Yamada, Y. Yoshida. *Cardiology Dept, Himeji Cardiovascular Center, Himeji, Japan*

Purpose: It has been revealed that during the typical atrial flutter(AFL), the tricuspid annulus(TA) is the anterior and the crista terminalis(CT) is the posterior barrier with a block line in the right atrium(RA). We investigate the conduction properties of the CT during sinus rhythm in the patients with and without AFL.

Methods: We performed electrophysiological test in 7 patients with AFL(CL:235 ± 45 ms) and in 5 patients without the history of AFL who had reentrant supraventricular tachycardia. In the patients with AFL, a 10-pole electrode catheter with 2-mm interelectrode distance was positioned along the CT under the fluoroscopy guidance, where we could observe the double potentials(DP) during AFL. In the patients without AFL, after the catheter ablation procedures, atrial pacing from the coronary sinus os was performed then the catheter was positioned at the CT where the DP was observed. Atrial pacing from the low septum(LS) and then from the low lateral wall(LL) were performed at pacing cycle length(PCL) from 600 ms to 200 ms during sinus rhythm.

Results: In all patients with AFL, a block line with the DP was observed along the CT during LS pacing regardless of PCL. On the other hand, during LL pacing at shorter PCLs(225 ± 25 ms) the DPs were observed along the CT indicating the presence of a block line, but at longer PCLs the DP couldn't be observed. Similarly in all patients without AFL, LS pacing always demonstrated the presence of a block line with DP along the CT, and LL pacing at shorter PCLs (250 ± 30 ms) also demonstrated the presence of a block line.

Conclusions: It is suggested that the crista terminalis plays a role as a fixed block line in the transverse conduction from septum to lateral wall, but as a functional block line from lateral wall to septum during sinus rhythm.

1806 Atrial fibrillation in patients with typical atrial flutter: is there any role for the crista terminalis?

Angel Arenal, Jesús Almendral, Julián Villacastín, Nicasio Pérez, Sergio González, José L. Rojo, Mercedes Ortiz, Juan L. Delcán. *HGU Gregorio Marañón, Madrid, Spain*

Background. The occurrence of atrial fibrillation (AF) in patients with type I atrial flutter (AFI) remains an important clinical problem. In AFL, the Crista Terminalis acts as a functional line of block that prevents the short-circuiting between the posterior (P) and lateral (L) wall (W).

Methods. In 22 patients (61 +− 7 years) with AFL (cycle length 234 +− 23 ms) we compared the electrophysiologycal properties of the CrT in 16 lone AFL and in 6 patients with history of AFL/AF. Multiple electrograms were recorded at the right atrium, coronary sinus and CrT. CrT was identified during AFL by recording double electrograms between the LW and PW. Decremental pacing trains were delivered, from 600 ms to 2 to 1 local capture, at the LW and PW or coronary sinus ostium (CSO).

Results. At least 5 bipolar electrograms were recorded along the CT from the high to the low atrium next to the inferior vena cava. No double electrograms were recorded during sinus rhythm at that area. Fixed transversal conduction block along all the CrT (detected by the appearance of double electrograms at all recording sites and cranio-caudal activation sequence on the opposite side to the pacing site) was observed in 2/16 AFL patients and in 2/6 AFL/AF patients. No differences were observed in the pacing cycle length at which transversal block appeared at the CrT. Nevertheless fractionated electrograms longer than 80 ms were only observed at the CrT in 6/6 AFL/AF and 1/16 AFL patients ($p < 0.01$) at a pacing cycle lengths longer than 300 ms.

Conclusion. Conduction disturbances at the CrT may influence in the appearance of AF in patients with AFL.

1807 Unipolar electrograms to confirm isthmus block after radiofrequency ablation of typical atrial flutter

J. Villacastin, J. Almendral, A. Arenal, M. Ortiz, N.P. Castellano, S. Gonzalez, J. Garcia, E.P. David, T. Ripoll, J.L. Delcan. *Hosp. G. Marañon, Madrid, Spain*

Objective: To examine the utility of the unipolar electrograms (UNIP) to confirm bi-directional block along the isthmus between the tricuspid annulus (TA) and the inferior vena cava (IVC). We hyphotesized that pacing from the coronary sinus ostium (CSos), the UNIP recorded at the other side of the line of radiofrequency application, close to the inferolateral TA, could change from a biphasic "RS" morphology (suggestive of conduction along the TA-IVC isthmus) before, to a positive monophasic "R" UNIP morphology (suggestive of termination of the wave front against the line of block) after achievement of clockwise isthmus block (CIB). Similar findings could be observed after counterclockwise isthmus block, (CCIB), pacing from the inferolateral TA.

Patients and Methods: In 15 patients (P) who underwent ablation of atrial flutter (AFI) a line of bi-directional block was created in the TA-IVC isthmus, confirmed by comparing the timing and the sequence of 10 standard bipolar electrograms of a multipolar catheter positioned along the TA. The ablation catheter was used to record the UNIP.

Results: Pacing at a cycle length of 500 ms from the CSos before CIB, the UNIP recorded at the inferolateral TA was "RS" in all P. After CIB, the interval between the stimulus artifact and the UNIP increased a mean of 45 ± 13 ms and changed to "R" in 13 P and to "Rs" in 2 P. Pacing from the inferolateral TA before CCIB, the UNIP obtained at the septal side of the line of block, was "RS" in all P, After CCIB, the interval between the stimulus artifact and the UNIP increased a mean of 40 ± 11 ms and changed to an small "R" in 14 P and to "Rs" in 1 P. Pacing from the CSos, in two P we observed a prolongation time of the stimulus-UNIP interval after RF applications despite showing "RS" morphology. In both of them, after obtaining CIB we observed conversion from "RS" to "R" UNIP.

Conclusion: UNIP are useful to recognize bi-directional TA-IVC isthmus block, even in the presence of slow conduction through the TA-IVC isthmus and could reduce the number of catheters (and recording channels) for RF ablation of AFI.

1808 Specific re-ablation in recurrences of atrial flutter: high-resolution electromagnetic catheter mapping of gaps within the tricuspid annulus–inferior caval vein–isthmus

H. Kottkamp, B. Krauss, K. Wasmer, G. Hindricks. *University Leipzig, Heart Center, Cardiology, Leipzig, Germany*

The endpoint of catheter ablation of the tricuspid annulus (TA)-inferior caval vein (ICV)-isthmus during treatment of atrial flutter (AFL) is complete bidirectional conduction block. An incompletely damaged isthmus, with a small gap and slow conduction, may reveal double potentials and reversal of conduction around the annulus during pacing of the coronary sinus (CS), thereby simulating conduction block but allowing clinical recurrences and complicating re-ablation.

In 16 patients (pts) with recurrences of AFL after ablation or with induction of an incompletely damaged isthmus during the initial ablation session, three-dimensional (3-D) maps of the TA-ICV isthmus were constructed for precise definition of the individual isthmus anatomy (Carto system). High-density electro-anatomical mapping during CS stimulation allowed precise identification of discrete gaps within the noncontiguous lesion lines. In 9 pts, an incompletely damaged isthmus could be identified although the recording of double potentials and complete reversal of conduction around the TA simulated conduction block. In 8 pts, the gap was found close to the TA, in 5 pts close to the ICV, and in 3 pts in the middle part of the isthmus, respectively. The electromagnetic navigation system allowed precise re-navigation to the predetermined sites of conduction breakthrough. In all pts, specific gap ablation was successfully performed with 3.2 ± 3.3 radiofrequency pulses for induction of complete conduction block.

High-resolution electro-anatomical re-mapping of the isthmus after ablation allowed precise verification of the linearity of the lesions along with proof of induction of complete conduction block and differentiation from incomplete block through small gaps exhibiting slow conduction. Precise 3-D re-navigation to the gaps substantially facilitated specific re-ablation in AFL recurrences.

POTASSIUM CHANNEL AND THE LONG-QT SYNDROME

1809 Human atrial conduction properties correlate with the relative expression of connexins 40 and 43

P. Kanagaratnam, P.M. Patel, N.J. Severs[1], N.S. Peters. *Imperial College School of Medicine, St. Mary's Hospital, London; [1]Imperial College School of Medicine, London, UK*

Background: As a major determinant of intercellular conductance, gap-junctional coupling is also considered a principal determinant of myocardial conduction velocity. The aim of this study was to test the hypothesis that the quantities of the predominant atrial gap junctional proteins, connexin40 (Cx40) and connexin43 (Cx43), affect the atrial conduction velocity in humans.

Methods: Epicardial mapping was performed on 16 patients undergoing cardiac surgery using an array of 56 unipolar electrodes with 3.5 mm interelectrode spacing, before atriotomy or cardioplegia. During sinus rhythm, the conduction velocity was measured over the trabeculated portion of the right atrial free wall. An excision biopsy from the mapped region was processed for quantitative confocal immunodetection of Cx40 and Cx43. Six highly confocal (<1 μm) randomly selected fields were acquired for each patient. Using differential wavelength filtering, connexin labelling, connective tissue autofluorescence and lipofuscin autofluorescence were quantified using PCimage analysis software.

Results: There was no correlation between the conduction velocity and the quantities of Cx40, Cx43 or total connexin signal (Cx40+Cx43). However, the ratio of expression of connexins correlated with conduction velocity during sinus rhythm ($p < 0.005$, $r^2 0.58$), such that as the proportion of Cx40 increased (and Cx43 decreased), the conduction velocity decreased. Furthermore, during pacing the ratio of expression of connexins correlated with the degree of decrementation of atrial conduction velocity ($p < 0.005$, $r^2 0.51$), such that atria with the lowest proportion of Cx40 showed the greatest decrementation. There was no correlation between conduction velocity and the quantity of connective tissue autofluorescence.

Conclusions: In human atria, the relative expression Cx43 and Cx40 correlates with right atrial conduction velocity during sinus rhythm. Interactions between different connexin types may be an important determinant of atrial conduction velocity and may also influence interval dependant conduction properties.

1810 Phenotypic characteristics of long-QT syndrome patients with different mutations of the SCN5A sodium channel gene

W. Zareba, J. Benhorin[1], A.J. Moss[2], B. Kerem[1], A. Medina[1], J.L. Robinson[2], M.L. Andrews[2]. *Cardiology, University of Rochester, Rochester, USA; [1]Cardiology, Bikur Cholim Hospital, Jerusalem, Israel; [2]Heart Research-Cardiology, University of Rochester, Rochester, USA*

Background and Purpose: Several mutations of the SCN5A gene have been reported in the LQT3 variant of the long QT syndrome. To further characterize phenotype by mutation in LQT3, we identified two large LQT3 families, one with the KPQ mutation, and the other with the D1790G mutation. Both mutations cause abnormal inactivation of the sodium channel, yet, only the KPQ causes also sustained inward sodium current.

Methods: The family carrying KPQ mutation consisted of 160 family members (42 genetically tested) and family carrying D1790G mutation consisted of 101 family members (66 genetically tested).

Results: Comparison of gene mutation carriers is provided in the table below.When comparing cardiac events (syncope, aborted cardiac arrest, or cardiac death prior to beta-blocker therapy) in all family members regardless of genotyping and ECG data, there were 13 (8%) pts with cardiac events in KPQ family and 6 (6%) pts with cardiac events in D1790G family (ns). There were 3 cases of cardiac events with documented sinus arrest (without torsade de pointes) in D1790G family and none in KPQ family. The median age at first event was higher in KPQ than D1790G families (18 vs. 10 years, respectively; $p = 0.11$).

LQT3 Pts with KPQ and D1790G Mutations

	KPQ (n = 15)	D1790G (n = 26)	p value
Median age at diagnosis (yrs)	18	18	ns
Median follow-up (yrs)	9	10	ns
Males	11 (73%)	12 (46%)	0.114
HR (bpm)	71 ± 18	83 ± 25	0.111
QTc (ms)	530 ± 50	494 ± 46	0.025
QTmc (ms)	403 ± 87	352 ± 73	0.057

Conclusions: Two different intragenic mutations of the SCN5A sodium channel gene channel contribute to somewhat distinct phenotypic presentation of LQT3 patients. In comparison to KPQ patients, those with D1790G mutations exhibit shorter QTc, higher heart rate, earlier onset of cardiac events, and possibly increased risk of sinus node arrest.

1811 The rapid and the slow component of the delayed rectifier potassium current in undiseased human ventricular myocytes

N. Iost[1], L. Virág[1], M. Opincariu[2], J. Szécsi[2], A. Varró[1], J.G. Papp[1]. *[1]Department of Pharmacology and Pharmacotherapy; [2]Department of Cardiac Surgery, Albert Szent-Györgyi Medical University, Szeged, Hungary*

There are large inter-species variations in the delayed rectifier potassium current (I_K). The very few available data regarding I_K in man originate from diseased hearts in the presence of Cd^{2+} and Ba^{2+}, which cations fundamentally alter the properties of IK.

Methods: Therefore, the characteristics of I_K (including activation and deactivation kinetics) were studied in 32 myocytes isolated from 16 undiseased human left ventricle, by applying the whole cell configuration of the patch-clamp technique at 37 C°. Nifedipine was used to block I_{Ca}.

Results: The E-4031 sensitive rapid component of I_K (I_{Kr}) was found to be present in all myocytes. The current-voltage relationship of the I_{Kr} tail current showed apparent inward rectification. The activation of the current started at −10 mV and reached its maximal amplitude (0.274 ± 0.062 pA/pF, n = 10) at 20 mV. The activation of the I_{Kr} was fast (τ = 36.6 ± 3.2 ms, n = 6) with relatively slow biexponential deactivation kinetics (τ_1 = 600.0 ± 53.9 ms and τ_2 = 6792 ± 875.7 ms, n = 5). In the presence of forskolin in the extracellular and phosphate in the intracellular solutions, an E-4031 insensitive and chromanol 293B sensitive tail current, which represented the slow component of I_K (I_{Ks}), was also observed. The maximal amplitude of I_{Ks} tail was 0.206 ± 0.035 pA/pF at 50 mV, n = 6, ie. 75% of the amplitude of I_{Kr}. The time constant for activation of I_{Ks} was rather slow (1096.8 ± 126.5 ms, n = 6) and for deactivation it was relatively rapid (109.9 ± 11.6 ms, n = 12)

Conclusion: It is concluded that both I_{Kr} and I_{Ks} exist in undiseased human ventricle. The recorded I_K resembled I_K detected in dog ventricular myocytes but substantially differed from I_K measured in myocytes from guinea pig ventricle. I_{Kr} and I_{Ks} probably play an important role in the frequency dependent and pharmacological modulation of repolarization in human ventricle.

1812 External pH modulates HERG potassium channel properties

J. Bérubé, M. Chahine, P. Daleau[1]. *Quebec Heart Institute, Laval Hospital, Research Center, Sainte-Foy; [1]Department of Medicine, Faculty of Medicine, Quebec, Canada*

Among factors which are involved in early ventricular arrhythmias during acute myocardial ischemia, decrease in pHo is certainly of special importance. Although pH was shown to modulate ionic membrane currents including potassium channels, its effects on HERG (human eag-related gene) are still unknown. We expressed HERG, known to encode the cardiac potassium channel IKr, in CHO cells and investigated effects of external pH (pHo) using the whole-cell patch-clamp technique. HERG currents were elicited from a holding potential of −80 mV by depolarizing pulses (−50 to +40 mV, 10 mV steps) followed by repolarization to −60 mV. When pHo was lowered from 7.4 to 6.0, current amplitude was decreased and kinetics of activation and deactivation were faster. For example, for a +10 mV pulse, current amplitude decreased from 1503 ± 356 to 1284 ± 404 pA (*P < 0.05) and rapid time constants (bi-exponential fitting) of activation and deactivation decreased respectively from 181 ± 18 to 88 ± 31 ms and from 143 ± 16 to 61 ± 11 ms (*P < 0.05). However, the half activation voltage ($V\frac{1}{2}$) was not significantly changed. When pHo was rised from 7.4 to 8.0, activation was accelerated and $V\frac{1}{2}$ negatively shifted. For example, for a +10 mV pulse, activation time constant changed from 127 ± 26 to 46 ± 5 ms and $V\frac{1}{2}$ was shifted from −2.1 ± 4.7 to −24.5 ± 3.8 mV (*P < 0.0025). (*data expressed as mean ± SEM; n = 5)

We conclude that alterations of HERG channel by pHo, particularly the faster deactivation observed at low pHo, could have consequences for the onset of arrhythmias during cardiac ischemia.

1813 Human inward rectifier K^+ currents are affected by a G-protein β3 subunit gene polymorphism

D. Dobrev, E. Wettwer, S. Schüler[1], W. Siffert[2], U. Ravens. *Pharmakologie & Toxikologie, Universitätsklinikum TU-Dresden, Dresden[1] Herz-Kreislaufzentrum Dresden, Dresden[2] Institut für Pharmakologie, Universitätsklinikum Essen, Essen, Germany*

A C825T-polymorphism has been recently identified in the gene encoding for the G(beta3)-subunit of pertussis-toxin sensitive G-proteins. When expressed in in-vitro systems, the T-allele gene produces the splice variant G(beta3)-s, resulting in enhanced activity of signal transduction. Here we tested the hypothesis, that patients carrying the T-allele exihibit the G(beta3)-s phenotype and that the resulting enhancement of signal transduction should be detectable in the acetylcholine stimulated K^+ current (IK,ACh), an effector system directly activated by G(beta,gamma) dimers. Patients undergoing cardiac surgery (mainly coronary bypass) were genotyped for the C825T-polymorphism. Atrial inward rectifier K^+ currents (IK1, IK,ACh) were studied with single cell voltage clamp techni-ques. IK1 was measured with depolarizing ramp pulses and quantified as inward current at −100 mV corrected for cell capacitance. The values were (mean ± s.e.m; in pA/pF): CC-allele carriers −5.00 ± 0.40 (CC; n = 80 cells/26 patients), CT −4.53 ± 0.38 (n = 93/23) and TT −7.94 ± 0.72 (n = 25/7); p < 0.05 for TT vs. CC and CT (one-way ANOVA). The increased background IK1 is not affected by atropine (1 μM), excluding spontaneously active M2-acetylcholine receptors. Upon activation of IK,ACh by superfusion with carbachol (2 μM), current increased by (in pA/pF) −5.81 ± 0.43 in CC (n = 66), −6.62 ± 0.36 in CT (n = 86), and −4.95 ± 0.75 in TT (n = 19), p < 0.05 for TT vs. CT. In contrast to the above hypothesis, the T825-allele is not associated with enhanced IK,ACh but background IK1 is increased in homozygous T-allele carriers instead. The nature of this finding remains to be elucidated.

1814 Mitochondrial ATP-sensitive K channels mediate anti-infarct tolerance afforded by activation of adenosine A1 and bradykinin receptors in the heart

T. Miura, H. Kita, T. Miki, K. Shimamoto. *2nd Dept. of Internal Medicine, Sapporo Medical University, Sapporo, Japan*

We examined if mitochondrial ATP-sensitive K channels (mitoKATP) are effectors at the end of signals from A1 and bradykinin (BK) receptors.

Methods: Isolated buffer-perfused rabbit hearts were used. [Protocol 1] Infarction was induced by 30-min global ischemia/2-h reperfusion, and its size was measured by tetrazolium and expressed as a% of area at risk (%I/R). The heart received no drug, A1 receptor agonist (1 uM R-PIA), a mitoKATP opener (100 uM diazoxide), a protein kinase C (PKC) inhibitor (200 nM calphostin C), a mitoKATP blocker (30 uM 5-hydroxydecanoate, 5-HD), or combination of these agents before ischemia. [Protocol 2] Infarction was induced by 30-min coronary occlusion/2-h reperfusion with or without preischemic infusion of BK (500 nM), a selective blocker of sarcolemmal KATP (HMR1883, 20 uM), 5-HD, or combinationn of these agents. [Protocol 3] Mitochondria were isolated from hearts with or without 30-min global ischemia after diazoxide or vehicle infusion. Their respiratory functions were determined.

Results:[Protocol 1] R-PIA reduced%I/R from 50 ± 7 in the control to 13 ± 3. This protection was abolished by calphostin C (%I/R = 54 ± 4) and by 5-HD (%I/R = 60 ± 9). Diazoxide mimicked the effect of R-PIA (%I/R = 11 ± 4), and this effect of diazoxide was abolished by 5-HD (%I/R = 45 ± 7) but not by calphostin C (%I/R = 13 ± 7). Neither calphostin C nor diazoxide alone modified%I/R. [Protocol 2] BK reduced%I/R from 38 ± 5 in the control to 12 ± 3. This effect was abolished by 5-HD(%I/R = 43 ± 8) but not by HMR1883 (%I/R = 12 ± 3). HMR1883 alone had no effect on%I/R (42 ± 8). [Protocol 3] State III respiration and respiratory control index were reduced after 30-min ischemia, and these changes were significantly attenuated by diazoxide pretreatment.

Conclusion: These results support the hypotheis that signals from A1 and BK receptors, via PKC, lead to opening of mitoKATP, which reduces mitochondrial damage and lethal injury in the cardiomyocytes during ischemia.

MANAGEMENT OF VASOVAGAL SYNCOPE

1815 Mechanisms of vasovagal syncope: an age-dependent phenomenon?

W.K. Shen, P.A. Low, A. Jahangir, D.O. Hodge, S.C. Hammill. *Mayo Clinic, Rochester MN, USA*

Age related physiologic changes in cardiovascular regulation are well recognized. Although recent data suggest triggering mechanisms of vasovagal (VV) syncope are likely protean, age-dependent hemodynamic responses to orthostatic stress in pts with VV syncope have not been defined. In this prospective study, we examined age-dependent cardiomotor (HR, SV), vasomotor (BPs, TPR), and preload (EDV) conditions in 45 pts with tilt table (70°, up to 45 mins)-induced VV syncope. Pts were divided into 3 age groups: Group I, age < 30 yrs (mean 17 ± 4 yrs, n = 15); Group II, age 30–59 yrs (mean 42 ± 9 yrs, n = 15); Group III, age ≥ 60 yrs (mean 70 ± 7 yrs, n = 15). Hemodynamic parameters were monitored continuously by impedance cardiography and photoclamp plethysmography. Results are summarized below:

At baseline supine, HR was indistinguishable among 3 groups, while SV (ml): 125 ± 22, 96 ± 27, 78 ± 27, (p = 0.004, ANOVA, group I, II, III, respectively), and EDV (ml): 192 ± 43, 163 ± 46; 126 ± 43 (p = 0.002) were significantly lower in the older pts, while TPR (dyne.s.cm^3): 966 ± 297, 1386 ± 594, 1713 ± 538 (p = 0.0002) was significantly higher in the older pts. In response to tilt (at 1 min), before any symptoms developed, a 45% ± 16% increase in HR occurred in group I pts while only a 13% ± 16% increase occurred in group III pts (p = 0.0004). The difference in HR response was associated with significant differences, between group I & III pts, in SV: −33% ± 15% vs −2% ± 20%, (p = 0.001), in EDV: −23% ± 17% vs 9% ± 24% (p = 0.0001) and in TPR: 22% ± 54% vs 2% ± 16% (p = 0.04).

Conclusions: 1) Lower SV and EDV at baseline in older pts suggest intravascular volume depletion may be a significant component of VV syncope in the elderly. 2) Increases in HR and TPR in response to tilt, consistent with sympathetic activation, are more pronounced in the younger pts preceding syncope. 3) Diverse age-dependent mechanisms are present in pts with VV syncope.

1816 Paroxetine prevents refractory vasovagal syncope in young patients

E. Di Girolamo, C. Di Iorio, P. Sabatini, L. Leonzio, A. Barsotti. *Cardiosurgical Department Chieti, Italy*

Serotonin may play a major role in the mechanisms leading to neurocardiogenic vasovagal syncope. To establish whether serotonin re-uptake inhibition by paroxetine could prevent refractory vasovagal syncope in young patients the following study was undertaken.

Methods. Forty-six consecutive young patients (19 male and 27 female, mean age 33.7 ± 6.5 years) with recurrent syncope and positive tilt test, and in whom previous therapies with beta-blocking, vagolytic, negative inotropic or mineral corticoid agents were ineffectual, poorly tolerated or contraindicated, randomly received either paroxetine at 20 mg once a day or placebo tablets. The response to head-up tilt test was reevaluated after one month of treatment, and the clinical effect was noted over a mean follow-up of 30.5 ± 9.6 months.

Results. After one month of treatment 14 patients (60.9%) in the paroxetine group as compared with 9 patients (39.1%) in the placebo group became tilt negative (p < 0.001). Over a 30 month follow-up 19 patients (82.6%) versus 11 patients (47.8%) in the paroxetine and placebo groups, respectively (p < 0.0001) remained symptom-free and no spontaneous syncope was experienced. Side effects of paroxetine administration were negligible and only one patient (4.3%) asked to be discontinued from the drug for severe recurrent headache.

Conclusions. Paroxetine was found to significantly improved symptoms of young patients with vasovagal syncope in whom previous traditional therapies were ineffectual, poorly tolerated or contraindicated.

1817 Specificity and positive rate of head-up tilt testing potentiated with sublingual nitroglycerine in elderly patients with unexplained syncope

C. Mussi, A. Valli, I. Tolve, G. Salvioli. *Chair of Geriatrics, Cardiac Autonomics Laboratory, University of Modena, Italy*

Introduction. Head-up tilt testing (HUTT) potentiated with nitroglycerine is extensively used to increase the diagnostic yield of unexplained syncope, but the method is not extensively performed, and its diagnostic value is not already proved in an elderly population. The aim of the study is the assessment of the specificity and total positive rate of potentiated HUTT in detecting the vasovagal origin of unexplained syncope in an elderly population.

Methods. 128 elderly patients (mean age 71.6 ± 5.1 years) with syncope of unknown origin and 101 subject in a control group (mean age 70.1 ± 4.7 years) were studied. The patients and the control subjects were tilted upright to 60 degrees for 45 minutes. If syncope did not occur, sublingual nitroglycerine (0.4 mg) was administered, and observation was continued for 10 minutes. Positive responses to HUTT were defined as the reproduction of syncope or presyncope according to VASIS definition.

Results. During the unmedicated phase syncope occurred in 26 (20%) patients and in no members of the control group. After nitroglycerine was administered, syncope occurred in 53 (41%) patients and in 2 (2%) members of the control group. The total positivity rate of the test was 62% with a specificity of 98%.

Conclusions. HUTT potentiated with sublingual nitroglycerine provides an adequate specificity and positivity rate in elderly patients with unexplained syncope; therefore it can be proposed as a useful diagnostic tool also in an elderly population.

1818 Psychiatric profile of patients undergoing head-up tilt test for evaluating recurrent unexplained syncope

C. Kouakam, D. Lacroix, P. Baux[1], M. Allioua[1], D. Klug, M. Jarwé, P. Delfaut, S. Kacet. *Cardiology Dept, Lille University Hospital, Lille; [1]Psychiatry Dept, Lille University Hospital, Lille, France*

Background: Anxiety disorders and panic attacks are generally associated with a variety of symptoms patterns most commonly including palpitations, tachycardia or lipothymia, but in some cases including syncope (S).

Methods: The aim of the study was to assess relationship between symptoms of psychiatric disorders (PD) and recurrent unexplained S of presumed vasovagal origin. The study group consisted in 40 patients (aged 42 ± 18 years) undergoing 60° head-up tilt test for evaluating recurrent unexplained S (group S), and 40 age- and sex-matched control patients free of known chronic PD admitted in our departement for arrhythmia (group C). All of them underwent a semi-standardized psychiatry questionnaire (MINI International Neuropsychiatric Interview) with ICD-10 (International Classification of disease, 10th revision) criteria in order to assess their profile. For the purpose of analysis, responses were categorized into scores of 0 to 20 (absence) and > 20 (presence) for anxiety, 0 to 15 (no symptoms), 15 to 20 (moderate) and > 20 (severe intensity) for depression according respectively to Hamilton anxiety and MADRS scales.

Results: General PD were found in 65% (n = 26) of group S patients and 35% (n = 14) of group C patients (p = 0.01). Detailed analysis revealed that sub-profiles of anxiety disorders and panic attacks were more frequent in group S patients when compared to controls (12 vs 5, and 8 vs 4 respectively), whereas sub-profile of depression was similar in both group (6 vs 5, ns). In addition, group S patients had a mean score of 25 ± 5 for anxiety compared with 22 ± 4 in group C (p = 0.004), whereas mean score for depression did not significantly differ between the 2 groups (23 ± 5 vs 25 ± 5, ns). Considering group S patients, no difference could be found between those with positive (n = 25) and negative (n = 15) head-up tilt results with respect to age, sex, number of syncopal episodes and sub-profiles of anxiety, panic attacks or depression.

Conclusion: Patients with unexplained S of presumed vasovagal origin have more frequent episodes of anxiety disorders and panic attacks on standardized investigation when compared to age- and sex-matched control patients with arrhythmias. This may have an impact on their management and clinical outcome.

1819 Autonomic function testing in patients with various types of vasovagal syncope

P. Mitro, R. Rybár, E. Rybárová[1], D. Trejbal. *Department of Internal Medicine II, Medical Faculty, P. J. Safarik University, Kosice; [1]Department of Clinical Biochemistry, University Hospital, Kosice, Slovakia*

Objective of this study was to determine if differences in basal autonomic tone are observed between patients with various types of vasovagal syncope (VVS).

Methods: In 60 patients with clinicaly suspected VVS head- up tilt testing (HUT) was performed. HUT was positive in 39 pts (12 men, age 34 ± 13) and negative in 21 pts (11 men, age 32 ± 15). Type of vasovagal reaction was classified according to VASIS classification as mixed (type I, 24 pts), cardioinhibitory (type II, 7 pts) and vasodepressor (type III, 8 pts). Expiratory-inspiratory ratio (E/I) during deep breathing, 30:15 ratio during active standing-up and the Valsalva ratio (VR) were used to evaluate vagal responsiveness. Maximal increase ase in HR after standing-up (ΔF) and the increase in plasma noradrenaline and adrenaline levels in response to standing for 5 minutes (ΔNA, ΔA) were considered as markers of sympathetic responsiveness. In addition spectral analysis of heart rate variability was evaluated in each group of patients.

Results: No significant differences in autonomic tone were observed between pts with various types of reactions during HUT. Results are summarised bellow.

	Type I	Type II	Type III	Negative HUT
E/I	1.29 ± 0.12	1.36 ± 0.11	1.27 ± 0.12	1.24 ± 0.09
30:15 ratio	1.08 ± 0.10	1.11 ± 0.14	1.13 ± 0.17	1.15 ± 0.32
VR	1.70 ± 0.035	1.60 ± 0.31	1.76 ± 0.037	1.59.0 ± 0.35
ΔF	26.70 ± 10.02	30.21 ± 6.92	31.99 ± 10.03	29.85 ± 13.38
ΔNA (pg/ml)	293.2 ± 175.2	232.0 ± 100.9	308.1 ± 54.1	308.6 ± 140.9
ΔA (pg/ml)	60.4 ± 47.1	62.9 ± 48.3	64.2 ± 28.7	59.1 ± 29.0
LF (ms^2)	191.66 ± 94.0	167.14 ± 96.0	198.57 ± 124.2	197.6 ± 119.6
HF (ms^2)	174.16 ± 75.9	155.42 ± 71.8	177.71 ± 103.4	177.33 ± 91.6
LF/HF (ms^2)	1.10 ± 0.14	1.02 ± 0.14	1.10 ± 0.05	1.08 ± 0.17

In conclusion: Different hemodynamic reactions during HUT cannot be explained by differences in basal autonomic tone in patients with VVS.

1820 Midodrine hydrochloride in the treatment of vasovagal syncope and essential hypotension: haemodynamic effects and the influence on life quality

S. Nedogoda, E. Mazhbitz. *Department of Therapy and Family Medicine, Medical Academy, Volgograd, Russian Federation*

The **aim** of this of this prospective, nonrandomized study was to evaluate the usefulness, haemodynamic effects and the influence on life quality (LQ) of alpha-agonist midodrine hydrochloride, which was use in the treatment of vasovagal syncope and essential hypotension.

Methods: 44 patients (mean age 36 year, 19 men) with history of recurrent syncope and positive of head-up tilt testing were included (28 patients with type I, 11 patients with type II, 5 patients with type III according to VASIS classification) in the study. In all patients before oral therapy with midodrine was started ambulatory blood pressure monitoring ABPM) was performed. Initial dose was 2.5 mg two times daily. When necessary the dose was increased to 5 mg two times daily.). LQ was evaluated using validated questionnaire of the Psychological General Well-Being (PGWB) index.

Results: After midodrine hydrochloride treatment 90% of patients had no inducible presyncope or syncope on repeated tilt table testing. Midodrine produced significant increase in systolic (22 ± 3 mm Hg, $p < 0.01$) and diastolic (11 ± 1 mm Hg, $p < 0.001$) blood pressures compared to placebo (2 ± 5 and 2 ± 3 mm Hg, respectively). Upright blood pressure 12 hours after administration was significantly greater with midodrine (116 ± 6/7 ± 6 mm Hg) vs. placebo (84 ± 7/54 ± 4 mm Hg, $p < 0.05$). Motionless standing time, a measurement of functional capacity, also improved with midodrine (238 ± 43 vs. 77 ± 28 seconds). The well-being was worse in compare with that of control group at baseline (PGWB total mean score for syncope-hypotension patients was −78.1 vs. control 95.6). It improved on midodrine treatment by 11.2 ($p < 0.001$).

In conclusion midodrine appears to be highly effective in preventing and treatment of all types of vasovagal syncope and essential hypotension and it improve LQ at that patients.

TRIGGERS FOR ATRIAL FIBRILLATION

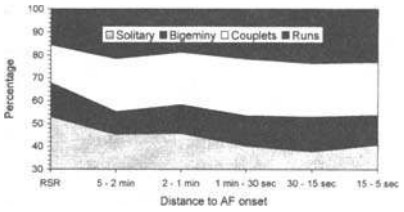
1821 Trends in complexity of atrial arrhythmias before atrial fibrillation onset

J.E.P. Waktare, K. Hnatkova, F.D. Murgatroyd, A.J. Camm, M. Malik. *St Georges Hospital Medical School, London, UK*

It is now becoming apparent that in a subset of subjects with paroxysmal atrial fibrillation (AF), a focal atrial tachycardia is responsible for the arrhythmia. It is known that atrial premature beats (APB's) increase before AF onset, but the pattern of arrhythmia has not been studied.

Methods: Holter recordings were performed on 177 subjects with paroxysmal atrial fibrillation. All recordings were subjected to standard automated analysis and manual editing. AF episodes were identified by a previously validated technique and this information combined with the beat interval data. APB's (approximated by short RR intervals) were identified and classified as being solitary, part of a couplet, a bigeminal rhythm or a run. The proportion of APB's belonging to each classification at each timepoint prior to AF onset was calculated.

Results: 600 episodes from 76 recordings in 39 pts (24 male, 62 ± 13 years old) met the selection criteria. The proportion of all APB's which were solitary fell from 53% remote from AF to 41% 5 seconds before AF onset ($p = 10^{-8}$, see figure). This fall was largely due to an increase in atrial couplets (17% → 23%, $p = 10^{-4}$) and runs (16% → 23%, $p = 10^{-5}$) with the number of bigeminal beat remaining unchanged (15% → 13%, p = NS).



Conclusion: Prior to AF onset, the complexity of APB patterns increases, suggesting that these arrhythmias may progress to an atrial tachycardia underlying the AF in some subjects.

1822 Predominant origin of ectopy triggering atrial fibrillation from the pulmonary veins: mapping and ablation in 100 patients

M. Hocini, M. Haïssaguerre, P. Jaïs, D.C. Shah, A. Takahashi, S. Garrigue, J.T. Peng, J. Clémenty. *Hôpital du Haut-Lévêque, 33604 Bordeaux-Pessac, France*

Curative catheter ablation of atrial fibrillation (AF) may target either the substrate (linear ablation) or the initiating trigger. This report presents the results of mapping and ablation of ectopy triggering AF in 100 consecutive patients.

Methods: These patients (pts) included 77 men and 23 women with a mean age of 53 ± 12 years; 29 had structural disease. Spontaneous initiations of AF were mapped using multielectrode catheters in the pulmonary veins (PV). The accuracy of mapping was confirmed by RF ablation resulting in acute disappearance of ectopy and AF.

Results: Of 181 foci (1 focus = 47; 2 foci = 23; 3 foci = 20; >3 foci = 6 pts) 3 were from the lateral right atrium, 2 from the septum and the posterior left atrium in 4. 172 trigggers (95%) originated from the PV: left superior (65) and inferior (42), right superior (50) and inferior (15). AF was initiated in most cases by 2 or more consecutive focal discharges with an irregular cycle length of 182 ± 57 ms. Ablation was performed along the intra PV course of foci between the source and the exit. 7 pts had adverse effects (1 tamponnade, 1 stroke, 5 PV stenosis of whom 4 were asymptomatic). During a follow-up of 7 ± 6 months, 65 patients were free of recurrence of AF without anti-arrhthymic drugs.

Conclusions: The PV are the main source of ectopy initiating paroxysms of AF. Catheter ablation of these triggering foci leads to cure of AF.

1823 Differences in pulmonary vein electrograms between patients with paroxysmal atrial fibrillation and controls

D.C. Shah, P. Jaïs, A. Takahashi, M. Hocini, M. Haïssaguerre, J. Clémenty. *Hôpital du Haut-Lévêque, CHU de Bordeaux 33604 Pessac, France*

Introduction: The pulmonary veins (PV) have been recently documented to be the almost exclusive source of trains of ectopics which initiate paroxysms of atrial fibrillation. Electrogram markers of pulmonary vein arrhythmogenic capability have not been described.

Methods: Bipolar electrograms (EGM) recorded in sinus rhythm from within 2, 3 or 4 pulmonary veins in 15 control patients (11 M, 4 F, mean age 45 ± 15 years, no structural heart disease, no atrial fibrillation) were compared with those at ablation sites in 14 age matched patients (12 M, 2 F, 43 ± 6 years) with pulmonary vein ectopy initiated atrial fibrillation. The presence of local venous activity, its complexity, electrogram duration, delay between atrial and local pulmonary vein activity (in sinus rhythm), amplitude ratios, PV-atrial conduction times (CT) and PV precocity relative to the P wave during ectopy produced by mechanical stimuli and spontaneous ectopy (in controls and patients respectively) were compared.

Results: The following significant ($p < 0.05$) differences were found:

	No of PV EGM deflections	Total EGM duration	PV-Atrial CT	PV Precocity
Controls	1.6 ± 0.7	63 ± 14 ms	68 ± 25 ms	−43 ± 26 ms
Patients	2.2 ± 0.9	79 ± 19 ms	105 ± 40 ms	−80 ± 33 ms

Conclusions: There are significant differences (ranging from obvious to none) in electrogram complexity and veno-atrial conduction dynamics between controls and arrhythmogenic pulmonary veins probably related to anatomy, anisotropic behaviour and gap junction distribution.

1824 Postoperative electrophysiologic evaluation of radiofrequency pulmonary veins isolation

P. Adragão, J. Melo[1], R. Teles, C. Aguiar, D. Bonhorst, R. Seabra-Gomes. *Cardiology Department; [1]Cardiothoracic Surgery Department, Santa Cruz Hospital, Carnaxide, Portugal*

Purpose: The aim of this study is to assess the left atrial electrophysiologic properties after bilateral pulmonary veins isolation (BPVI) using intraoperative radiofrequency ablation.

Methods: We evaluated prospectively 20 Pts (mean age 59 ± 11 years) with rheumatic mitral valve disease and atrial fibrillation (AF) submitted to concommitant valve surgery and BPVI. After AF surgery, epicardial pacing electrodes were placed on the LA posterior wall, in and out of the isolated zones, and on the right ventricle. In the 11 sinus rhythm Pts, before discharge, simultaneous electrograms of all sites were acquired at rest and during pacing of isolated zones and non-isolated atrial tissue. The resting amplitude of electrogram signals in and outside atrial isolated zones were compared. During programmed electrical stimulation, one milisecond pulses were used and stimulus amplitude was progressively increased (maximum 28 mA) until atrial capture occurred. Minimum stimulus amplitude required for atrial capture was recorded for each pacing site.

Results: In all sinus rhythm Pts, electrogram amplitude inside the isolated zones was <25% of non-isolated atrial tissue. Pacing within the isolated zones required a significantly higher pulse amplitude for atrial capture detection (13.5 ± 9.3 mA vs 8.5 ± 4.5 mA for pacing of non-isolated atrial tissue). In two Pts, no atrial capture was detected when pacing isolated right pulmonary veins, even with maximum pulse amplitude.

Conclusion: Radiofrequency applications caused a significant decrease in atrial electrogram signal amplitude. Pacing of isolated atrial tissue required higher pulse amplitudes for capture detection in non-isolated atrium zones. Further studies are needed to define the criteria for electrically isolated zones and to establish their correlation with efficient supression of AF.

1825 Paroxysmal atrial fibrillation of focal origin: high recurrence rate after initial successful catheter ablation

T. Arentz, P. Ott, J. Rosenthal, T. Blum, G. Bürkle, K. Peters, D. Kalusche. *Herz-Zentrum Bad Krozingen, Germany*

Recent reports indicate that paroxysmal atrial fibrillation may be of focal origin, amenable to radiofrequency catheter ablation (ABL) therapy.

Methods: We screened pts with frequent (>2 episodes/week) refractory paroxysmal atrial fibrillation and identified those with frequent monomorphic atrial extrasystoles (AES) or atrial tachycardias on resting or Holter ECG, with the aim ABL. The origin of the atrial extrasystoles or tachycardias was mapped during the ablation procedure. The procedure was declared successful if after ABL no further atrial ectopic activity was observed during 60 min. The pts were followed in the hospital by continous Holter monitoring over 72 hours.

Results: In 13 pts meeting the above inclusion criteria, catheter ablation eliminated a single atrial focus (location of the focus: inside the pulmonary veins [PV] 10, right atrium 3). In 6 of 10 pts with focus ablation in the PV, recurrence of atrial ectopic activity was noted on Holter monitoring after 12–36 h. In one pt a second PV focus (previously not apparent) was identified and successfully ablated; in 3 patients the same focus was reablated with primary success during a second procedure, but with recurrence of 2; 2 pts have not been restudied but the origin of the recurrent atrial activity appears different than the ablated focus based on resting ECG analysis. Overall 9 of the 13 pts are off antiarrhythmic drugs and without symptoms (mean follow up 14 ± 12.5 months).

Discussion: Atrial fibrillation of focal origin can be identified by careful analysis of resting and/or Holter ECG. ABL therapy has a high acute success rate; however, there appears to be a high recurrence rate for foci located in the PVs, and repeat procedures are necessary. In addition, foci previously not apparent can be seen after initially successful focus ABL.

EXERCISE TESTING IN HEART FAILURE AND HYPERTENSION

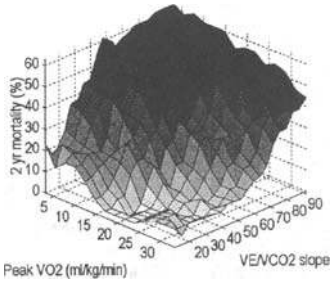
1837 Enhancement of exercise hyperpnea is a powerful prognostic marker independent of peak oxygen consumption in chronic heart failure

D.P. Francis, W. Shamim, L.C. Davies, J.S. Chambers, S.D. Anker, A.J.S. Coats. *National Heart & Lung Institute, London, UK*

Background: Reduced peak oxygen consumption (peak VO_2) during exercise is a known adverse prognostic factor in chronic heart failure (CHF). However increased exercise hyperpnea (VE/VCO_2 slope), may also be an adverse marker.

Methods: 301 CHF patients underwent cardiopulmonary exercise testing, using a modified Bruce protocol. Peak VO_2 and VE/VCO_2 slope were determined with a pneumotachograph and mass spectrometer.

Results: During a median follow-up of 33 months, 87 patients died. Univariate Cox proportional-hazards analysis revealed powerful predictive value in both peak VO_2 and VE/VCO_2 slope ($p < 0.0001$ for each). More importantly, bivariate mortality analysis identified independent prognostic value peak VO_2 ($p = 0.0003$) and VE/VCO_2 slope ($p < 0.0001$). The graph demonstrates the relationship of mortality to peak VO_2 and VE/VCO_2 slope, using a model which does not assume linearity of risk or of interaction between peak VO_2 and VE/VCO_2 slope.



Conclusion: During cardiopulmonary exercise testing, the VE/VCO_2 slope gives valuable prognostic information independent of peak VO_2. In the worst prognostic group by peak VO_2 (<10 ml/kg/min) patients are classifiable by VE/VCO_2 slope into a range of 2-year mortalities from 20% to 60%. Even in the best prognostic group by peak VO_2, enhanced VE/VCO_2 slope identifies a subgroup at elevated risk.

1838 Kinetics of oxygen consumption recovery after a symptom-limited exercise test in chronic heart failure: an index of habitual physical activity and deconditioning

U. Corrà, A. Giordano[1], E. Bosimini, F. De Vito, P. Giannuzzi. *Division of Cardiology; [1]Bioengeegnery Department "S. Maugeri" Foundation, IRCCS, Veruno (NO), Italy*

In daily life, chronic heart failure (CHF) patients (pts) typicallly complain symptoms long after exercising, and a prolonged post-exertional kinetics of oxygen consumption (kVO_2) has been described.

Methods: The relationship between kVO_2 after incremental exercise test and habitual physical activity and deconditioning has been investigated in 85 CHF pts (59 + 8 yrs, 87% male, in NYHA class I–III, mean EF 22 ± 8%), who performed an incremental bicycle exercise test limited by fatigue or dyspnea (mean peak VO_2 16.4 ± 4 ml/kg/m'). Recovery was defined as the period starting when the workload was removed and the analysis of VO_2 vs time was assessed in the first 3 min following effort. kVO_2 recovery was evaluated as T1/2, the time to reach 50% of peak value. Habitual physical activity level was evaluated by an interviewer-determined scoring (AcS range 0–9) considering leisure-time, occupational activities and hospital admissions. T1/2 was significantly negatively correlated to peak VO_2 ($r = -0.65$, $p < 0.01$) and AcS ($r = -0.62$, $p < 0.01$). T1/2 was significantly prolonged in pts with different fuctional capacity (A, 34 pts; peak VO_2: ≤15 ml/kg/m' T1/2 129 ± 13 sec., B, 37 pts; peak VO_2: 15–20 ml/kg/m' T1/2 95 ± 20 sec.; C, 14 pts; peak VO_2 ≥ 20 ml/kg/m' T1/2 75 ± 7 sec., $p < 0.01$). Pts with prolonged T 1/2 (group A ≥ 120 sec and group B ≥ 90 sec) compared with those with shorter T1/2 (group A < 120 sec and group B < 90 sec) had a significantly lower AcS (group A: 3.8 ± 2 vs 4.9 ± 2, Group B: 4.8 ± 2 vs 6.3 ± 1, $p < 0.05$), whereas peak VO_2 was similar (group A: 12.7 ± 1 vs 13.3 ± 2 ml/kg/m', group B: 16.3 ± 1.5 vs 17.2 ± 2 ml/kg/m', NS). In group C, AcS and peak VO_2 were similar in pts with short T1/2 (<60 sec) or prolonged T1/2 (≥60 sec).

In conclusion, in CHF, kVO_2 is negatively correlated to peak VO_2 and AcS and it's notably delayed in pts with severe funtional impairment. In pts with similar peak VO_2, a prolonged kVO_2 is associated with a lower AcS, as a result of greater activity restraint during daily life. Thus the analysis of kVO_2 may enhance the understanding and management of symptoms in CHF pts.

1839 Resting pulmonary function is an important determinant of exercise capacity in patients with heart failure

Pompilio Faggiano, Anna Gualeni, Antonio D'Aloia[1], Nicolino Ambrosino, Marco Pagani, Amerigo Giordano. *Cardiology Division, S. Orsola Hospital; [1]Spedali Civili, Brescia; S. Maugeri Foundation IRCCS Gussago, Italy*

In patients (pts) with heart failure (CHF) the mechanisms responsible for exercise intolerance have not been fully defined. Abnormalities in pulmonary function seem to play a relevant role in determining the peak exercise oxygen uptake (VO_2). In order to clarify the relative contribution of resting hemodynamic profile and pulmonary function, 162 male pts (mean age 59 ± 9 yrs) with CHF (NYHA class II–IV, LVEF: 23 ± 7%) underwent spirometry, lung volumes (TLC) and diffusion (DLCO), mouth inspiratory and expiratory pressures (MIP, MEP; 91 pts). Right heart catheterization and a symptom-limited cardiopulmonary exercise test were performed within 3–4 days.

Results: mean value peak VO_2 was 13 ± 4 ml/kg/m. Resting hemodynamic parameters did not show any significant correlation with peak VO_2; furthermore, there were no differences in hemodynamics between pts with peak VO_2 ≤ or >14 ml/kg/m. On the other hand, there was a significant correlation ($p < 0.05$), although of low degree, between peak VO_2 and forced vital capacity ($r = 0.35$). DLCO was significantly higher in pts with peak $VO_2 > 14$, compared to those with $VO_2 \leq 14$ ml/kg/m (21.6 ± 6.9 vs 17.7 ± 5.5, $p < 0.001$). Using a stepwise regression analysis, the respiratory and/or hemodynamic parameters which significantly correlated with peak VO_2 resulted to be DLCO (most important) and MEP with an overall R value of 0.60.

Conclusion: these data confirm previous studies showing a poor correlation between resting indices of cardiac function and exercise capacity. On the other hand, several pulmonary function parameters were related to peak VO_2. Particularly, lung diffusion and respiratory muscle function (as assessed by MEP) seem to be important determinants of exercise intolerance in heart failure.

1840 Increased sympathetic nerve activity during repetitive rhythmic forearm exercise in patients with chronic heart failure

R. Yuyama, F. Yuasa, M. Hikosaka, M. Motohiro, T. Sugiura, T. Iwasaka. *Cardiovascular center, Kansai Medical University, Osaka, Japan*

Sympathetic nerve activity is increased at rest in patients with chronic heart failure(CHF), but less is known about sympathoexcitation during exercise in patients with CHF. Accumulation of muscle metabolites during rhythmic exercise cause an increase in sympathetic nerve activity by stimulation of the muscle metaboreflex in patients with CHF. The aim of this study was to evaluate whether muscle sympathetic nerve activity(MSNA) is further accelerated with repetitive rhythmic exercise in patients with CHF.

Methods: Fifteen patients with CHF(LVEF 38 ± 10%) and 10 age-matched controls were studied. Each subjects performed two equivalent symptom limited rhythmic handgrip(RHG) exercise at 30% of maximal voluntary contraction separated by 5 min rest. MSNA was recorded micronerographically from the left peroneal nerve. Heart rate and blood pressure were measured during RHG.

Results: CHF patients fatigued prematurely during RHG. Heart rate and blood pressure response during the first and second RHG were similar in both groups. At rest, the discharge rate of MSNA was higher in CHF patients than in controls(21 ± 8 vs 42 ± 6, $p < 0.05$). MSNA burst frequency was similar in both groups (44 ± 5 vs 51 ± 11: NS) at the end of first exercise. After the cessation of RHG, MSNA rapidly returned to the baseline in both groups. However, MSNA at the end of second RHG was higher in CHF patients than in controls (59 ± 9 vs 42 ± 6, $p < 0.05$). Furthermore, the increase in MSNA from rest was larger during the second RHG compared to the first RHG in CHF patients(42% vs 33%, $p < 0.05$), but there was no significant difference in controls (110% vs 105%, NS).

Conclusions: Repetitive RHG exercise caused increase in sympathetic nerve activity in patients with CHF, which have a role in the progression of heart failure with excessive daily activity.

1841 Influence of arterial baroreflexes on postexercise blood pressure response in patients with left ventricular dysfunction

F. Yuasa, M. Hikosaka, R. Yuyama, M. Motohiro, T. Sugiura, T. Iwasaka. *Cardiovascular Center, Kansai Medical University, Osaka, Japan*

Arterial baroreflexes regulate cardiovascular response to exercise in patients with normal humans and left ventricular(LV) dysfunction, but less is known about the relation between arterial baroreflexes and postexercise blood pressure (BP) response in patients with LV dysfunction. The aim of this study was to examine the influence of arterial baroreflex sensitivity (BRS) on central and peripheral hemodynamic responses during recovery from maximal exercise.

Methods: BRS was assessed by the regression line between phenylephrine-induced increase in systolic blood pressure and attendant changes in the R-R interval in 40 uncomplicated patients with LV dysfunction (LV ejection fraction < 45%). All the patients underwent symptom-limited bicycle exercise and hemodynamic variables were observed during recovery.

Results: In all patients, the average BRS was 5.6 ± 2.6 msec/mmHg. At 2 and 5 minutes of recovery, mean BP had a positive correlation with systemic vascular resistance ($r = 0.72$, and 0.62: $p < 0.01$), but not with cardiac output. BRS correlated inversely with mean BP ($r = -0.57$ and -0.55: $p < 0.05$) and systemic vascular resistance ($r = -0.53$ and -0.47: $p < 0.05$). Moreover, BRS had modest but significant correlation with percentchange decrease in mean BP from peak exercise to 2 and 5 minutes of recovery ($r = 0.40$ and 0.35: $p < 0.05$), indicating that patients with lower BRS have a higher systemic vascular resistance and mean BP during recovery than those with normal BRS.

Conclusions: Decrease in BRS reflect delayed postexercise BP response in patients with LV dysfunction.

1842 Hypertensive patients have significantly higher MDA and VIP levels during exercise compared to normal individuals

Th. Makris, A. Hatzizacharias, P. Krespi, J. Vythoulkas, D. Xanthis, E. Kitsou, V. Votteas, M. Kyriakidis. *Cardiology Dept. and Nuclear Medicine Dept., "LAIKON" Hospital and Medical School, University of Athens, Greece*

Lipid peroxidation, has been proposed to play a relevant role in the development and progression of atherosclerosis. This process is mediated by O_2 radicals and among its final cytotoxic products the most important are aldehydes, malyndialdehyde (MDA) being the most significant one. The vasoactive intestinal polypeptide (VIP) is a systemic and coronary vasodilator with some positive inotropic properties. This study was designed in order to evaluate MDA and VIP plasma changes in both hypertensive patients (pts) before the initiation of any medical treatment and in normotensive volunteers during exercise test.

Methods: 20 pts (16 M, 4 F) mean age 56.8 ± 5.2 yrs and mean body mass index (BMI) 24.1 ± 2.3 with essential hypertension (Group H) and 14 normotensive volunteers (12 M, 2 F) mean age 55.9 ± 4.8 yrs and BMI 23.7 ± 3.1 (Group N) were studied. The two groups were matched for age and BMI. An exercise test according to Bruce protocol was performed in all, hypertensives and normotensives. Coronary angiography has been performed also in the whole study population in order to exclude coronary artery disease. The plasma MDA and VIP concentrations were determined at rest (baseline) and at peak exercise by the thiobarbituric acid assay and by RIA method respectively.

Results: The results of our measurements are shown below:

	Group H (n = 20)	Group N (n = 14)	
MDA (baseline) μmol/ml	102 ± 0.32	120 ± 0.75	p = NS
MDA (peak exercise) μmol/ml	144 ± 0.53	129 ± 0.35	p = NS
	p < 0.001	p = NS	
VIP (baseline) pmol/ml	13.41 ± 3.07	9.21 ± 2.50	p < 0.001
VIP (peak exercise) pmol/ml	16.57 ± 3.20	10.22 ± 2.13	p < 0.001
	p < 0.01	p = NS	

Conclusions: The results of our study suggest that: 1) Hypertensive pts have significantly higher peroxidation during the exercise test compared to normal volunteers. 2) Hypertensives have significantly higher VIP levels at rest and during exercise than normal volunteers. This phenomenon may be the expression of a massive vasodilators mobilization in order to protect the myocardial perfusion.

BENEFITS OF PHYSICAL TRAINING

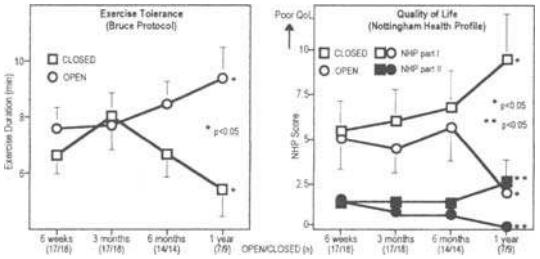
1843 Exercise tolerance and quality of life after myocardial infarction with respect to patency of the infarct-related artery: interim results of The Open Artery Trial (TOAT study)

Z. Yousef, C. Bucknall, M. Webb-Peploe, M.S. Marber. *Department of Cardiology, Guys and St Thomas' Hospitals, London, UK*

Introduction: The TOAT study is a randomised trial of intervention v medical management in asymptomatic patients following anterior myocardial infarction (AMI). 12 month follow-up data on exercise tolerance (ET) and quality of life (QoL) is presented.

Methods: Symptom-free patients <75 yrs with an occluded left anterior descending artery (LAD) are randomised 5–28 days post 1st Q-wave AMI to: OPEN (PTCA + stent to LAD + medical therapy), or CLOSED (medical therapy alone). Follow-up at 6 weeks and 3, 6, and 12 months post AMI includes ET (Bruce protocol) and QoL (Nottingham Health Profile – NHP).

Results: To date, 37 patients with similar baseline characteristics have been randomised; 18 to OPEN (14 M, 4 F, age 57.3 ± 8.3 yrs) and 19 to CLOSED (14 M, 5 F, age 58.2 ± 11.0 yrs). Data expressed as mean ± SEM.



Conclusions: Delayed intervention is associated with significantly improved ET and self perceived QoL (NHP part I), in addition to a significantly enhanced lifestyle (NHP part II) 12 months post AMI. Intervention even in the absence of symptoms may be beneficial.

1844 Exercise training benefits patients with ischaemic and non-ischaemic cardiomyopathy

A.P. Sindone, N.L. Sammel[1], V.L. Baker[1], P.S. Macdonald[1], A.M. Keogh[1]. *Cardiology Dept., Concord Hospital, Sydney; [1]Cardiac Rehabilitation Dept., St Vincent's Hospital, Sydney, Australia*

Exercise training improves symptoms, exercise capacity and haemodynamics in heart failure. It is not known whether this response differs with the cause of heart failure, as non-ischaemic cardiomyopathy (CM) patients may have skeletal as well as cardiac muscle abnormalities.

Method: Compared ischaemic (isch) CM and non-ischaemic (non-isch) CM patients randomised to 12 weeks of exercise training. Before and after the program, they underwent: cardiopulmonary exercise tests, New York Heart Association (NYHA) classification, quality of life questionnaires, right heart catheterisation and measurement of heart rate variability (HRV), plasma noradrenaline (NA), adrenaline (Adr) nitrates, endothelin (ET), atrial (ANP) and brain natriuretic peptides (BNP) and N-Terminal BNP (NT-BNP).

Results: 51 patients underwent exercise training (26 isch CM, 25 non-isch CM), 44 men/7 women, age 55 ± 12 years and LVEF 0.26 ± 0.08 units. The isch CM group was significantly older than the non-isch CM group (63 vs 48 years, $p = 0.0003$) with higher levels of ANP (71 vs 44.7 pmol/l, $p < 0.04$), BNP (38.9 vs 28.6 pmol/l, $p < 0.05$), NT-BNP (218 vs 141 pmol/l, $p < 0.04$) and ET (2.71 vs 2.11 pmol/l, $p < 0.03$) and more impaired HRV. Despite this, they did not differ significantly in response to exercise training. Isch CM (% Change) vs Non-isch CM (% Change): Heart Rate −7% vs −7%, Blood Pressure −15% vs −8%, Pulmonary Capillary Wedge Pressure −11% vs −15%, Pulmonary Vascular Resistance −25% vs-6%, Systemic Vascular Resistance −13% vs −15%, NYHA Class −36% vs −26%, Peak Oxygen Uptake 4% vs 11%, Exercise Duration 25% vs 38%, NA −16% vs −27%, Adr −72% vs −31%, ANP −15% vs −23%, BNP −16%vs −21%, NT-BNP −27% vs −23%, ET −9% vs −1%, Nitrates 13% vs −6%.

Conclusions: Exercise training leads to similar improvements in symptoms, exercise capacity, haemodynamics and neurohormonal abnormalities regardless of the patients' age or the underlying diagnosis.

1845 Effects of long-term moderate exercise training on functional capacity, quality of life and sexual behaviour in chronic heart failure

R. Belardinelli, I. Paolini, A. Purcaro. *Istituto Lancisi, Ancona, Italy*

Recent reports have shown that short-term exercise training (ET) improves the aerobic capacity of patients with chronic heart failure (CHF). However, the effects of long-term ET on functional capacity, quality of life (QOL) and sexual activity are not well defined.

Methods: Fifty-nine patients (57 ± 14 years) with stable CHF in sinus rhythm were randomized into 2 groups. A group (T = 30) underwent supervised ET at 60% of peak VO_2 3 times a week for 8 weeks, then twice a week for 12 months. A group (NT = 29) was not exercised. Medications were not changed during the study. At baseline, 2nd and 14th month all patients underwent a symptom-limited incremental exercise test with gas exchange analysis on a cycle ergometer. At same times, QOL was assessed by the Minnesota Living with Heart Failure Questionnaire and sexual activity profile (SAP) by questionnaire.

Results: Significant changes were observed only in trained patients. Peak VO_2 increased by 18% at 2 months ($P < 0.005$) and 21% at 14 months ($P < 0.001$). QOL also improved in trained patients and paralleled peak VO_2 ($r = 0.80$; $P < 0.001$). In group T, SAP was unchanged at 2 months. However, SAP was significantly improved from baseline at 14 months (score: +22%; $P < 0.01$ T vs NT) and was correlated with changes in QOL ($r = 0.73$; $P = 0.01$).

Conclusions: Long-term moderate ET significantly improves functional capacity as well as QOL. Both improvements were evident after 2 months and were maintained at 14 months. The beneficial effect of ET on SAP was more delayed and was correlated with changes in QOL.

1846 Correction of coronary endothelial dysfunction in patients with coronary artery disease by regular physical exercise

R. Hambrecht, A. Wolf, S. Erbs, A. Linke, J. Hofer, C. Walther, N. Schoene, S. Gielen, G. Schuler. *Univ. of Leipzig, Heart Ctr, Leipzig, Germany*

Endothelial dysfunction is a key feature of early atherosclerosis contributing to myocardial ischemia in patients (pts) with coronary artery disease (CAD). This study was designed to determine whether exercise training corrects coronary endothelial dysfunction in pts with CAD.

Methods: 18 patients were prospectively randomized to a training group (T) or an inactive control group (C). At beginning (B) and after 4 weeks (E), pts received serial intracoronary infusions of acetylcholine (ACH) to assess endothelium-mediated vasodilation. Average peak flow velocity (APV) was invasively measured using a Doppler flow wire, vessel diameter was determined by quantitative coronary angiography.

Results: At B pts in T and C had similar responses to acetylcholine doses of 0.072, 0.72, and 7.2 μg/min with respect of percentage of change in vessel diameter and APV. After exercise training ACH-induced coronary artery vasoconstriction was significantly blunted in response to 7.2 μg/min ACH by 61% (from −0.41 ± 0.06 to −0.16 ± 0.08 mm; $p < 0.01$ vs. C). In training pts the percent change in APV at the initial study in response to increasing doses of acetylcholine were 13 ± 7, 37 ± 12, and 78 ± 17 percent. The responses to acetylcholine after 4 weeks of exercise training were 29 ± 8, 76 ± 21 and 144 ± 31 pecent, respectively ($p < 0.01$ vs C). Coronary flow reserve as assessed by adenosine infusion increased by 28% (from 2.8 ± 0.2 to 3.6 ± 0.3; $p < 0.05$ vs. C).

Conclusions: In patients with CAD physical exercise improves endothelium-dependent vasodilation of coronary conduit and resistance vessels, probably because of endothelial relaxing factors released in response to cell membrane shear stress induced by pulsatile blood flow.

1847 Effects of physical training on peripheral markers of endothelial dysfunction in patients with chronic heart failure

S. Adamopoulos, J. Parissis, C. Kroupis, M. Georgiadis, D. Karatzas, G. Karavolias, K. Koniavitou, D. Kremastinos. *2nd Department of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

Objective: Previous studies have shown an abnormal expression of cellular adhesion molecules and cytokines in patients with chronic heart failure (CHF), which may be related to endothelial dysfunction characterizing this syndrome. Our study investigates the effect of physical training on serum activity of some peripheral inflammatory markers associated with endothelial dysfunction, such as granulocyte-macrophage colony-stimulating factor (GM-CSF), soluble intercellular adhesion molecule-1 (sICAM-1) and vascular cell adhesion molecule-1 (sVCAM-1) in patients with CHF.

Methods: Serum levels of GM-CSF, sICAM-1 and sVCAM-1 were determined by commercially available ELISA tests in 12 patients with stable CHF (ischaemic heart failure 6/12, dilated cardiomyopathy 6/12, NYHA II–III) before and after a 12-week program of physical training in a randomized cross-over design. In addition, the functional status of CHF patients was evaluated by using cardiorespiratory exercise stress test (VO_2max). Patients with infections, malignancies or other inflammatory diseases were excluded from the study.

Results: Physical training produced a significant reduction in serum GM-CSF (26.9 ± 2.1 vs 18.7 ± 1.3 pg/ml, $p < 0.001$), sICAM-1 (378 ± 36 vs 327 ± 34 ng/ml, $p < 0.02$) and sVCAM-1 (1275 ± 121 vs 1134 ± 116 ng/ml, $p < 0.04$) as well as a significant increase in VO_2max (14.9 ± 0.6 vs 16.3 ± 0.7 ml/kg/min, $p < 0.05$). A significant correlation was also found between percentage changes in VO_2max values and sICAM-1 ($r = -0.71$, $p < 0.02$) as well as sVCAM-1 levels ($r = -0.66$, $p < 0.04$).

Conclusions: Physical training causes a significant decrease in peripheral inflammatory markers associated with endothelial dysfunction in patients with CHF. These changes may be related to the training-induced improvement in functional status of CHF patients.

1848 Physical training copes pain in syndrome X

B. Eriksson, R. Tyni-Lenné[1], R. Hallin[2], J. Svedenhag[3], K. Jensen-Urstad[4], K. Bergman[1], S. Stryan[1], C. Sylvén. *Department of Cardiology, Huddinge Hospital, Huddinge; [1]Department of Physical Therapy, Huddinge Hospital, Huddinge; [2]Department of Neurophysiology, Huddinge Hospital, Huddinge; [3]Department of Clinical Physiology, Huddinge Hospital, Huddinge; [4]Department of Clinical Physiology, South Hospital, Stockholm, Sweden*

Background and aim: No effective and rational treatment for patients with Syndrome X (Sdm X, anginal chest pain, positive exercise stress test and angiographically normal coronary arteries) has previously been reported. The aim was to test if Sdm X, as a chronic pain disorder may respond to physical training both as regards pain experience and physical capacity.

Methods: 14 female patients aged 41–65 years continued a rehabilitation programme consisting of 30 min exercise on a bicycle ergometer at 50% of max exercise capacity 3 days/week for 8 weeks. Exercise testing before and after the training period with peak VO_2 measurement.

Results: Exercise capacity increased markedly, 28 ± 10% after training (from 98 ± 9 W to 126 ± 13 W, $p < 0.0003$) and peak VO_2 with 18 ± 10% (from 1.2 ± 0.1 l/min to 1.5 ± 0.2 l/min, $p < 0.003$). The time to pain onset was prolonged with 90 ± 44% (from 3 ± 1 min to 6 ± 2 min, $p < 0.002$). Posttraining pain intensity at pre-training peak exercise load decreased by 41 ± 37%, $p < 0.05$. Maximum pain score, however, remained unchanged. There was an increase in max heart rate (from 137 ± 11 to 152 ± 10 bpm, $p < 0.001$), max systolic blood pressure (from 193 ± 12 to 204 ± 12 mmHg, $p < 0.05$) and double product (from 235 ± 30 to 310 ± 29 bpm · mmHg · 10^{-2}, $p < 0.001$) during exercise.

Conclusion: Syndrome X patients are physically deconditioned but improve their exercise capacity, peak VO_2 and time to pain onset after 8 weeks of physical training. This is the first study showing that physical training is a new and effective treatment in this patient group improving coping of pain.

PHARMACOLOGICAL THERAPY OF ATRIAL FIBRILLATION

1849 Intravenous versus oral amiodarone for the conversion of atrial fibrillation of recent onset

G.E. Kochiadakis, N.E. Igoumenidis, H.E. Mavrakis, M.E. Marketou, M.D. Kaleboubas, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

In a prospective, randomized, placebo-controlled study, we compared the efficacy and safety of amiodarone (amio), administered orally (p.os) versus intravenously (iv), for the treatment of recent onset atrial fibrillation (AF).

Methods: We studied 204 patients (95 men), aged between 34 and 86 years (mean 65 + 11) with AF lasting < 48 hours. Fifty-five pts received amio p.os 2000 mg over 24 hours divided into 4 doses, and then 200 mg × 4 the next day), 80 received amio iv (300 mg for 1 hour followed by 20 mg/kg for the next 24 hours, and then 15 mg/kg the next day), while 69 were given placebo (the first 24 hours iv, the next day orally). Cardiac output (CO) and cardiac index (CI) were evaluated invasively before and 24 hours after the start of amio administration in 28 pts (15 iv and 13 p.os group).

Results: There were no significant differences in the basic clinical data between the three groups. Conversion to sinus rhythm was achieved within 48 hours in 49 of the 55 pts (89.09%) receiving amio p.os, in 71 of the 80 (88.75%) receiving the drug iv, and in 42 of the 69 (60.86%) of the controls (p: NS for iv versus p.os group, $p < 0.05$ for both groups versus controls). The mean time to conversion was 15 + 12 hrs, 10 + 11 hrs and 9 + 11 hrs in the three groups, respectively ($p < 0.05$ for oral group versus the others). The smaller the LA the greater the probability of conversion. Amio delivered iv decreased CO and CI at 24 hours. This decrease was non-significant but might have become so if more patients had been studied.. In the iv amio group 8 pts had a fall in blood pressure and 12 pts had thrombophlebitis, but interruption of therapy was not necessary. No other complications were seen.

Conclusions: Amio, whether delivered p.os or iv, is highly effective for the conversion of recent onset AF to sinus rhythm; neither manner of administration is statistically superior to the other. Oral administration appears to have fewer side effects than iv, while iv has a more rapid action.

1850 Oral dofetilide for conversion of atrial fibrillation/flutter to sinus rhythm: time to cardioversion and duration of hospital stay

K.S. Channer, R. Greenbaum, R. Lebman, L. Yellen, M. Berk, R. Zoble. *Cardiology Dept, Royal Hallamshire Hospital, Sheffield, UK*

Dofetilide (D), a new class III antiarrhythmic, converts up to 30% of patients (pts) with chronic atrial fibrillation/flutter (AF/AFI) to sinus rhythm (SR). Timing of conversion (CV) and proarrhythmic events were examined during the administration of D in patients with AF/AFI. Two double blind placebo controlled trials, SAFIRE-D and EMERALD, enrolled 996 patients with AF/AF1. Of these 638 [564 AF/74 AFI, mean age 65.6 yrs, mean duration of AF/AF1 4.1 months, 49% NYHA class II heart failure] were randomised to D [125, 250, 500 ug BID]. Since D is predominantly renally excreted, pts with renal impairment received a lower dose according to a pre-specified algorithm. Following the initial dosing, QT interval was measured and the dose was reduced or stopped if QT prolongation was excessive. Pts were monitored in hospital and DC cardioverted if they did not cardiovert within 72 hours of starting D.

Results: In total, 13 of 217 (6%), 22 of 215 (10%), and 61 of 206 (30%) pts in the 125, 250 and 500 ug D groups respectively pharmacologically cardioverted (CV). The timing of cardioversion for the three groups combined is summarised below.

Time from first dose (hrs)	0–6	0–12	0–18	0–24	0–30	0–72
Cumulative (%) converting	28	33	45	65	87	100

Four of the 5 cases (1 male; 4 female; 1 pt 250 μg; 4 pts 500 μg) of torsades de pointes occurred during the first 3 days. The overall prevalence of torsades de pointes was 0.8%. Therefore, the following approach is suggested for CV with D to minimise proarrhythmia risks. Initial drug administration should occur in hospital with ECG monitoring. Dosing should be based on calculated creatinine clearance and QT interval response. For pts who do not convert within 24–30 hours of D therapy, DC-CV should be considered. Pts should be monitored for the first 5 doses of D, or for a minimum of 12 hours after electrical or pharmacological CV to normal SR, whichever is longer.

Conclusion: Based on the fact that 87% of the pts who cardioverted on D did so within 30 hours, we conclude that this approach should minimise hospital stay while allowing for identification and treatment of any proarrhythmias.

1851 Comparative efficacy and safety of intravenous antiarrhythmic agents for conversion of recent onset atrial fibrillation

A. Mortara, C.H. Davies, Y. Bashir. *Departement of Cardiology, J. Radcliffe Hospital, Oxford, UK*

Active management of pts with recent-onset atrial fibrillation (AF) to restore sinus rhythm may be warranted to alleviate symptoms, reduce the risk of thromboembolism or avoid/shorten hospitalisation. Although attempted pharmacological cardioversion is widely practiced as first line treatment, little is known about the comparative efficacy and safety of available agents. We have reviewed all published studies since 1980 involving conversion of recent-onset AF by IV antiarrhythmic agents. 22/46 studies were selected based on the following criteria: [i] randomized enrollment, [ii] recent-onset AF (≤7 days), [iii] detailed data about drugs' efficacy and safety. Efficacy rates in termination of AF were analyzed at <3 hrs and 12–24 hrs. Data from multiple studies are presented as pooled estimates of the percentage of pts converting to sinus rhythm (±95% CI). Occurrence of atrial flutter (Fl.) and/or severe tachyarrhythmias (Arr.) are reported as major adverse events:

	Pts	<3 h (% ± 95% CI)	Pts	12–24 h (% ± 95% CI)	Fl or Arr. (n.)
Flecainide	240	77 (65–90)*§		N/A	3/240
Propafenone	173	53 (42–64)*	147	73 (55–91)*	2/173
Amiodarone	95	47 (18–76)*	169	78 (68–89)*	0/95
Ibutilide	37	46*	N/A	3/37	
Digoxin	173	22 (17–28)	136	49 (46–53)	2/173
Placebo	299	15 (8–22)	290	44 (40–49)	2/299

(*$p < 0.001$ vs placebo, §$p < 0.001$ vs amiodarone and propafenone).

Although only limited data are available for some drugs, using meta-analysis techniques, flecainide emerges as the most effective agent for rapid conversion of AF with a good safety profile. Amiodarone and propafenone are as effective but with a slower onset of action. These findings may have important clinical and cost implications for shortening or avoiding hospitalisation and merit further investigation.

1852 Dose response of azimilide for prevention of atrial fibrillation or flutter

S.J. Connolly, R.L. Page[1], S.R. Marcello[2], D.J. Schnell[2], W.E. Willkinson[3], E.L.C. Pritchett[3]. *Hamilton ON, Canada; [1]University of Texas, Southwestern, Dallas TX; [2]Cinncinatti; [3]Duke University, Durham NC, USA*

Azimilide (AZ), an investigational class III antiarrhythmic agent, was studied in 3 randomized, placebo controlled trials with a total of 906 patients using once daily doses of 35, 50, 75, 100, and 125 mg or placebo in patients with symptomatic atrial fibrillation or atrial flutter (AF/FL), two-thirds of whom had structural heart disease. In each study the primary outcome variable was the first symptomatic recurrence of supraventricular tachycardia documented using transtelephonic ECG monitoring. Efficacy data from all 3 trials was tested for a dose-response relationship using a log-rank trend test with placebo = 0 mg and all 5 AZ doses. Data were stratified by trial to control for variation in placebo group event rates.

Results: The log-rank trend test was statistically significant with chi-square = 10.3 and p = 0.001. The 125 mg dose demonstrated a statistically significant treatment effect with hazard ratio (HR)(Placebo:AZ) of 1.81 (95% CI 1.27, 2.57). The 100 mg dose was evaluated in 2 separate studies with HRs of 1.32 (p = 0.15) and 1.38 (p = 0.08). The pooled HR for the 100 mg dose was 1.35 (95% CI 1.05, 1.72; p = 0.02) Torsade de pointes occurred in 5 patients on AZ and in no patients on Placebo.

Conclusions: AZ demonstrates a dose-response relationship over the dose range of 35–125 mg once daily in patients with symptomatic AF/FL; doses of 100 mg and 125 mg daily are associated with clinically important antiarrhythmic effects.

1853 Survival in patients treated with azimilide for atrial fibrillation and other supraventricular arrhythmias

E.L.C. Pritchett, S.J. Connolly[1], R.L. Page[2], S.R. Marcello[3], D.J. Schnell[3], W.E. Wilkinson. *Dept. of Medicine, Duke University Medical Center, Durham NC, USA; [1]Cardiology Dept., McMaster University, Hamilton Ontario, Canada; [2]Internal Medicine, University of Texas Southwestern, DallasTX; [3]Procter & Gamble Pharmaceuticals, Cincinnati OH, USA*

Azimilide is a novel class III antiarrhythmic drug that blocks both IKr and IKs and that was developed for use in patients with supraventricular arrhythmias. Efficacy of azimilide in preventing symptomatic arrhythmia recurrences was tested in 3 randomized, placebo-controlled clinical trials of patients with atrial fibrillation, atrial flutter or paroxysmal supraventricular tachycardia (PSVT). The purpose of this report is to describe the effect of azimilide on survival by pooling data from these 3 trials.

Methods: A total of 1091 patients (958 with atrial fibrillation, atrial flutter or both and 133 with PSVT) were enrolled in the 3 trials. Among these patients 328 were assigned randomly to placebo, and 763 were assigned to azimilide doses between 35 mg daily and 125 mg daily. Patients were followed until their first symptomatic arrhythmia recurrence was documented by electrocardiogram or for a maximum of 9 months (2 studies) or 6 months (1 study) as specified in the respective protocols.

Results: Average length of follow-up was 96.5 days in the azimilide group and 82.5 days in the placebo group. There were 3 deaths in 328 placebo patients and 6 deaths in 763 azimilide patients. The observed mortality rate was 3.0 per 100 patient-years in the azimilide group and 4.0 in the placebo group. The hazard ratio (azimilide:placebo) for mortality was 0.77 with 95% confidence interval (0.19, 3.1).

Conclusion: Although the confidence interval was broad, the point estimate from these pooled data of 3 randomized trials did not demonstrate any substantial favorable or adverse effect of azimilide on mortality in patients with supraventricular arrhythmias.

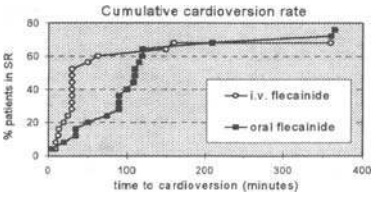
1854 Chemical cardioversion of acute atrial fibrillation: a randomized, double-blind trial of oral versus intravenous flecainide

N.J. Alp, J.A. Bell, M. Shahi. *Cardiac Unit, Royal Berkshire & Battle Hospitals, Reading, UK*

This is the first double-blind trial to compare oral versus intravenous (i.v.) flecainide as a loading dose for the cardioversion of acute atrial fibrillation (AF).

Methods: A randomised, double-blind, double-dummy trial. 50 patients with acute non-rheumatic AF (<48 hrs duration), aged 31–89 years were included. Flecainide was given either as an i.v. infusion (2 mg/kg over 30 mins) or as an oral solution (4 mg/kg) with appropriate placebos. We measured: safety; the time to cardioversion; and the proportions of patients in sinus rhythm (SR) at 2 hrs and at 8 hrs after treatment.

Results: The mean time to cardioversion was 42 mins for i.v. flecainide, and 116 mins for oral flecainide (2 tail t-test, $p < 0.01$). However, there was no significant difference in the proportions of patients cardioverted by 2 hrs (64% both groups) and 8 hrs (68% i.v.; 76% oral) (χ^2 test, n.s.).



Conclusion: These results suggest oral loading doses of flecainide may have a role in the pre-hospital treatment of acute AF.

ATRIAL FIBRILLATION AND EMBOLIC RISK

1855 Prothrombotic alteration of the endothelial haemostatic balance in patients with non-valvular atrial fibrillation

R. Winkler, B. Klein, M. Vater, R. Gök, M. Kempf, H. Beeck[1], P. Hellstern[1], B.R. Winkelmann, J. Senges. *Herzzentrum Ludwigshafen; [1]Institut für Hemostaseologie, Ludwigshafen, Germany*

Background: Systemic hemostatic abnormalities may contribute to the high risk of thromboembolic events in patients (pts) with nonvalvular atrial fibrillation (NAF). The aim of the study was to assess differences in endothelium-dependent coagulation factors in NAF versus sinus rhythm (SR).

Methods: In the LURIC (Ludwigshafen Risk and Cardiovascular Health)-study 1478 consecutive pts who were hospitalized for elective diagnostic coronary angiography were enrolled. Pts with coumarine therapy, acute coronary syndrome, valvular heart disease or any other acute or serious disease were excluded. NAF was documented in routine ECG. Fasting blood samples were drawn in the early morning to minimize circadiane variation.

Results: 1382 pts were in sinus rhythm (age: 61 ± 9 years, 63% male, CAD 80%, CMP 7%) and 175 pts showed atrial fibrillation (age: 65 ± 10 years, 73% male, CAD 74%, CMP 18%). No difference was seen in fibrinogen, factor VII, CRP, D-dimers, prothrombin time, regular alcohol consumption, and arterial hypertension between the two groups.

	SR (n = 1382)	NAF (n = 175)	p
Endothelial Prothrombotic Factors:			
Von Willebrand factor-antigen (U/dL)	164 ± 71	188 ± 82	<0.01
Thrombomodulin (μg/L)	54 ± 26	52 ± 22	0.08
Free protein S (U/dL)	101 ± 28	87 ± 31	0.001
Protein C (U/dL)	111 ± 23	91 ± 26	<0.001
Endothelial Fibrinolytic Factors:			
tPA-activity (IU/ml)	0.7 ± 0.6	0.75 ± 0.7	0.04
PAI-1-activity (IU/ml)	27 ± 56	34 ± 80	<0.001
Thrombotic Clinical Events:			
Venous thrombosis	4.1%	8.1%	<0.001
Stroke/transitoric ischemic attack (TIA)	8.1%	17.7%	<0.001

Conclusion: 1. As expected Pts with NAF had significant more often a history of venous thrombosis and stroke/TIA. 2. The endothelial-dependent hemostatic profile was significantly more prothrombotic in Pts with NAF (increased PAI-1 and vonWillebrand factor, decreased protein C- and free protein S) than in SR. Significant changes in the balance of the endothelial hemostatic system may contribute to the higher rate of thromboembolic events in pts with NAF.

1856 Tissue factor and von Willebrand factor expressions increased in the atrial tissue of the fibrillating atrium

N.M. AL-Saady, R. Gurtu, L. Luddington, M.J. Davies, A.J. Haven, N. Maarouf, M.M. Gallagher, A.J. Murday, A.J. Camm. *Department of Cardiological Sciences, St. George's Hospital Medical School, London, UK*

Right atrial appendage biopsies were collected from 8 pts with atrial fibrillation (AF) and 10 control pts with sinus rhythm (SR) at the time of elective coronary artery bypass grafts.

Method: Double immunohistochemical staining was carried out using monoclonal antibodies against human TF (American Diagnostic Inc.), CD 68 to identify macrophages and EN4 as a specific endothelial cell mark. Also an antibody to vWf (Dako, UK) was used. Immunohistochemical sections were evaluated by two investigators who were blind to the disease entity being investigated and the clinical characteristics of the patients. The total number of macrophages (M) as well as those expressing TF (MTF) were counted. The percentages of macrophages expressing TF (%MTF) were then calculated. The percentage endocardial endothelium expressing vWf was rated as 1, 2, 3 and 4 by two investigators. 1 ≤ 25%, and 4 = 100% expression of vWf.

Results: vWf expression was increased in the AF group ($p = 0.01$). 1/8 pts in AF group expressed <25% vWf, compared to 8/10 in the SR group ($p = 0.015$). No endothelial expression of TF was identified. 3 pts in the SR group were excluded from the TF study because of diabetes mellitus. Results were presented as mean (+sd) and p value below.

	MTF	M	%MTF	vWf
SR	1.23 (0.6)	16.74 (4.4)	7.17 (3.0)	1.4 (1.0)
AF	7.29 (4.5)	32.86 (6.5)	22.41 (14.3)	2.75 (1.0)
p	0.0036	0.0001	0.016	0.011

This report is the first to show an association between AF and both MTF and vWf expressions in the atrial tissue of patients with AF.

Conclusion: These results suggest specific therapy to the prevention of atrial thrombus.

1857 Anticoagulant therapy in atrial fibrillation: experience in an Italian teaching hospital

W. Ageno, L. Steidl, B. Nardo, R. Cattaneo, R.L. Codari, F. Ambrosini, E. Barlocco, R. Santillo, D. Imperiale, A. Venco. *Dept of Clin and Biol Sciences, University of Insubria, Varese, Italy*

Atrial fibrillation (AF)is the most common chronic arrhythmia, and its prevalence has been estimated around 6% among patients older than 65 years. The rate of stroke in patients with AF is 5 times higher than in those without. Oral anticoagulant treatment (OAT)has been shown to reduce by 2/3 the risk of stroke and its administration is currently recommended, particularly in patients older than 65 years. Nevertheless, recent investigations have found a significant underuse of OAT.

Methods: We have carried out an observational cross-sectional study in one Italian University Hospital to evaluate the prevalence of AF among hospitalized patients in a single day and to assess previous and current antithrombotic treatment. In 2 different days 8 trained physicians examined the charts of all hospitalized patients and verified the presence of AF on the ECG.

Results: A total of 1301 charts were examined. The prevalence of AF was 7.9%, 103 patients of whom 11 were present in both visits. The average age was 78.7 (s.d. ± 9.39), 7 patients < 65, and 55 > 75. Males were 44, females 48. There were 78 patients (84.8%) with chronic AF, and 14 (15.2%) patients whose AF was diagnosed for the first time during hospitalization. Among patients with chronic AF, 9 had contraindications to OAT (2 dementia, 3 alcohol abuse, 2 prior falls, 2 prior bleeding). Of the 69 remaining, 24 (34.7%) were treated with OAT (age 72.7 ± 8.04), 18 (26.1%) before hospital admission, whereas 6 (8.7%) were started in hospital. Of the former group 2 also had prosthetic valves, of the latter 2 had OAT started because of venous thromboembolism. Antiplatelets were administered to 33 (42.3%, age 81.7 ± 8.29) patients, 25 (32%) before admission. Of 78 patients, 35 (44.8%) did not receive any antithrombotic therapy before admission, 21(26%) during hospitalization. Patients admitted for acute ischemic stroke were 13 (14.1%, age 81.3 ± 8.46), 12 with chronic AF, and 1 with newly diagnosed AF. None of them was treated with OAT, 10 with antiplatelet agents. Of all patients, 30 (32.6%) had a history of cerebrovascular accidents, 28 of whom had chronic AF. Only 5 (17.8%) were on OAT, 19 (67.8%) were on antiplatelets.

Conclusions: The use of OAT in patients with AF is dramatically low and the rate decreases with increasing age. A high number of patients does not receive any antithrombotic treatment. A significant rate of patients not receiving OAT are admitted for stroke. Hospitalization improves the quality of the treatment, but the results are still poor. Continuous efforts to promote the use of OAT for stroke prevention are necessary.

1858 Anticougulant use in new onset atrial fibrillation: Canadian Atrial Fibrillation Registry (CARAF)

S.J. Connolly, C.R. Kerr[1], M. Talajic, G. Klein, M. Green, J. Boone[1], R. Sheldon, P. Dorian, K.H. Humphries[1], J.J. Spinelli[1]. *Hamilton ON; [1]University of British Columbia, Vancouver BC, Canada*

The Canadian Registry of Atrial Fibrillation (CARAF) is a natural history follow-up registry of 896 patients with new onset atrial fibrillation (AF) with mean follow-up of 3 years. Patients were recruited from emergency departments (445), physician offices (315) and in hospital (136). These patients have been followed annually without directed intervention by the CARAF investigators. Antithrombotic therapy (AT) was done by community physicians. There were 434 men and mean age was 61 years. At 1 year, 27.3% received warfarin, 35.0% ASA, 2.5% both and 35.2% no AT; with virtually no change over 3 years.Warfarin use was greater in chronic AF (111/192, 58%) compared to paroxysmal AF (46/256, 18%) or no recurrent AF (50/334, 15%). In patients with any risk factor for stroke (age > 65 years, diabetes, prior stroke, CHF, or hypertension warfarin use was 35.6% compared to 19.3% for those without any risk factor ($p < 0.001$). Patients with any risk factor were more likely to receive warfarin if they had chronic AF (53.8%) than if they had paroxyxmal AF (23.8) or no recurrent AF (15.8%) ($p < 0.05$). The risk of stroke during the first 2 years of follow-up was 2.4% per year and 60% of strokes occurred in patients not on warfarin at the time of stroke.

Conclusion: In recent onset AF, warfarin use remains low even in patients with known risk factors for stroke and with chronic AF. There appears to be considerable underuse of proven effective therapy in these patients.

1859 Paroxysmal non-rheumatic atrial fibrillation does not show a prothrombotic state

Vicente E. Climent, Vanessa Roldán, Alicia Ibáñez, Francisco Marín[1], Juan V. Martínez-Tur, José V. Monmeneu[1], Vicente Bodí[1], Fernando García de Burgos[1], Pascual Marco, Francisco Sogorb. *General Hospital of Alicante; [1]General Hospital of Elche, Spain*

Anticoagulation is not recommended in paroxysmal atrial fibrillation < 48 hours of duration however prospective studies to assess the presence of a prothrombotic state have not been undertaken in this setting.

Methods: We studied 24 patients with paroxysmal non-rheumatic atrial fibrillation, who restored sinus rhythm by spontaneous or pharmacological cardioversion before 48 hours, without anticoagulant therapy. Atrial mechanic function was assessed by transmitral inflow in transthoracic echocardiography, E wave/A wave ratio (E/A) and A wave velocity time integral/total velocity time integral ratio ($\int A/\int T$) were measured. Thrombomodulin (Th) and von Willebrand factor (vW), markers of endothelial damage, were measured. D-dimer (DD) as hypercoagulable state marker was measured. Blood samples and echocardiographic studies were performed at 1st, 3rd, 7th and 30th days after cardioversion. Results are expressed as median and 25–75th percentile values.

Results: There were no correlation between endothelial cell function markers, DD and echocardiographic findings.

	1st day	3rd day	7th day	30th day	
E/A	0.89 (0.74–0.98)	0.82 (0.70–0.99)	0.79 (0.70–1.22)	0.74 (0.59–1.23)	NS
$\int A/\int T$	0.38 (0.35–0.46)	0.37 (0.34–0.43)	0.34 (0.29–0.45)	0.41 (0.35–0.46)	NS
Th	11.1 (9.8–13.1)	11.5 (8.6–14.8)	10.1 (7.9–14.3)	13.7 (9.6–17.0)	NS
vW	136.0 (105.0–178.5)	123.0 (106.0–169.8)	127.0 (90.5–173.5)	143.0 (107.5–163.0)	NS
DD	2.10 (0.71–7.11)	3.04 (0.63–8.61)	2.89 (0.78–5.85)	1.35 (0.62–1.92)	NS

Conclusions: Patients with paroxysmal non-rheumatic atrial fibrillation did not show a prothrombotic state. The findings of this study support non-anticoagulant-therapy attitude.

1860 Thromboembolic events in non-valvular atrial fibrillation: no evidence of a difference in the endothelial-dependent haemostatic system in dilatated cardiomyopathy versus coronary artery disease

R. Winkler, B. Klein, M. Vater, R. Gök, M. Kempf, H. Beeck[1], P. Hellstern[1], B.R. Winkelmann, J. Senges. *Herzzentrum Ludwigshafen; [1]Institut für Hemostaseologie, Ludwigshafen, Germany*

Background: Systemic hemostatic abnormalities have been described in patients (pts) with nonvalvular atrial fibrillation (AF). The aim of the study was to assess influences of different heart diseases causing AF on the endothelial-dependent hemostatic system.

Methods: In a LURIC (Ludwigshafen Risk and Cardiovascular Health)-substudy 148 pts who underwent elective coronary angiography with AF in routine ECG were enrolled. Pts with coumarine therapy, acute coronary syndrome, valvular heart disease and any other acute or serious disease were excluded. Blood samples were drawn in the morning to minimize circadian variation.

Results: There was no difference in fibrinogen, factor VII, CRP, D-dimers, prothrombin time, regular alcohol consumption and the rate of venous thrombosis between the groups.

	CAD + AF (n = 118, male 76%)	CMP + AF (n = 30, male 90%)	p
Clinical Data:			
Stroke/transitoric ischemic attack (TIA)	21%	13%	**0.001**
Systemic Hypertension	61%	40%	**0.01**
Age	66 ± 10 years	62 ± 10 years	**<0.05**
Endothelial Prothrombotic Factors:			
Von Willebrand factor antigen (U/dL)	181 ± 73	169 ± 72	0.5
Thrombomodulin (μg/L)	51 ± 22	43 ± 18	0.4
Protein S-activity (U/dL)	97 ± 37	93 ± 25	0.2
Protein C (U/dL)	89 ± 27	99 ± 30	0.3
Heparin Co-Factor II (U/dL)	102 ± 13	106 ± 10	0.4
Endothelial Fibrinolytic Factors:			
tPA-activity (IU/ml)	0.74 ± 0.6	0.7 ± 0.7	0.4
PAI-1-activity (IU/ml)	29 ± 37	27 ± 21	0.7

Summery: The increased rate of stroke/TIA in Pts with CAD and NAF may be explained by the higher age of these pts and a higher prevalence of hypertension. It could not be explained by differences in endothelial-dependent fibrinolytic or prothrombotic activity between CAD and CMP.

UNSTABLE ANGINA: PROGNOSIS, BCG AND CRP

1861 Prevalence and predictive accuracy for the detection of coronary artery disease of marked t-wave inversion in multiple precordial leads

E. González-Torrecilla, E. Pérez-David, H. Bueno, J.A. García-Robles, R. Muñoz, J.L. Delcán. *Cardiology Department, Hospital General Universitario "Gregorio Marañón", Madrid, Spain*

The presence of marked inverted T-waves in multiple precordial leads is considered a sign of high likelihood of significant coronary artery disease (CAD). Its current prevalence and predictive accuracy for the detection of patients (P) with significant CAD are not well known.

Methods: 309 consecutive P (193 males, 116 females; 65 ± 12 yr) without prior CAD diagnostic testing were admitted because of possible unstable angina. P with bundle branch block or previous anterior myocardial infarction were excluded. Each P was analyzed for the presence at admission or the development during the first 24 hours of new and sustained (>24 h) T-wave inversion (>2 mm) in ≥3 precordial leads. We assessed the prevalence of this finding and its potential diagnostic value for the detection of significant (≥70% stenosis) CAD and the identification of significant left anterior descending (LAD) stenosis in the 224 P who underwent coronary angiography.

Results: marked T-wave inversion in the precordial leads was observed in 57 P (18.4%; 95% CI: 14–23%); 53 of them underwent coronary angiography. Sensitivity (Sen), specificity (Spe), and predictive values (PV) of this finding for the detection of significant CAD and LAD stenosis were:

	Sen	Spe	+PV	−PV
CAD (145 P)	25% (36/145)	78.5% (62/79)	68% (36/53)	36% (62/171)
Males (115 P)	26% (30/115)	82.5% (33/40)	81% (30/37)	28% (33/118)
Females (30 P)	20% (6/30)	74% (29/39)	38% (6/16)	55% (29/53)
LAD (97 P)	33% (32/97)	83.5% (106/127)	60% (32/53)	62% (106/171)
Males (73 P)	37% (27/73)	88% (72/82)	73% (27/37)	61% (72/118)
Females (24 P)	21% (5/24)	75.5% (34/45)	31% (5/16)	64% (34/53)

In conclusion, the presence of marked T-wave inversion in multiple precordial leads in P with suspected unstable angina (1) has a prevalence of about 18%; (2) its predictive power for detection of significant CAD is poor; (3) it shows a high specificity and a substantial positive predictive value only in males.

1862 Immediate exercise testing in low risk patients with acute chest pain

Carel C. de Cock, E. Belt, D. Mollema, C.A. Visser. *Medical Center VU, Amsterdam, Netherlands*

To assess the value of immediate exercise testing (IET) in the triage of patients presenting with acute chest pain a group of 319 consecutive patients was evaluated. Patients included had chest pain with atypical features, non-diagnostic electrocardiogram and no history of coronary artery disease. All patients underwent symptom limited exercise testing according to the Bruce protocol within 24 hours of admission (median 2 hours). Seven patients were admitted because of exercise induced transmural ischemia (4 pts) or arrhythmias (3 pts). Negative IET was present in 195 pts (63%), non diagnostic IET (<70% maximal predicted heart rate) in 69 pts (22%) and positive IET in 48 pts (15%). During 6 month follow-up, 21 patients had adverse coronary events; 11 patients had unstable angina, 8 had myocardial infarction and 2 had sudden death. Patients were divided on the basis of acute (<6 hour) or recent (>6 hour) complaints.

Results:

	Total group (n = 312)	Acute group (n = 104)	Recent group (n = 208)
Sens (%)	24	14	57
Spec (%)	82	82	89
NPV (%)	93	86	97

NPV = negative predicted value

We conclude that immediate exercise testing is useful for the triage of pts presenting with chest pain but has limited value in pts with acute (<6 hr) chest pain.

1863 In unstable angina reduced heart rate variability is not predictive of an adverse in-hospital outcome

Ernesto R. Ferreirós, Carlos P. Boissonnet, Rodolfo Pizarro, Gianni Corrado, Arturo Cagide, Oscar Bazzino. *Department of Cardiology, Hospital Italiano de Buenos Aires, Argentina*

Reduced heart rate variability (rHRV) correlates with in-hospital outcome in patients with acute myocardial infarction. Its potential role for prognostic assessment in unstable angina has not been established. Our objective was to determine the prognostic value of rHRV for prediction of adverse in-hospital outcome in patients with unstable angina (UA).

Methods: 210 consecutive patients (p) with UA without prior myocardial infarction (MI) nor total CK elevation post admission were included. Continuous ECG Holter recording for assessment of silent ischemia and heart rate variability was performed during the initial 24 hours. Measurement of C-reactive protein level (CRP) at admission and a 2-D echocardiogram during the initial 24 hours to detect regional wall motion abnormalities were also performed (median time elapsed since the beginning of pain 12 hours; range 0–24 hours). An in-hospital follow-up period was conducted to determine the occurrence of a primary combined end point of recurrent ischemia (death and/or acute myocardial infarction and/or refractory angina and/or recurrent angina and/or silent ischemia).

Results: Mean age was 66.1 ± 11.3 years, 62.9% were male; 63.3% received prior treatment with aspirin, and 43.8% had ST segment depression (↓ST) on admission ECG. Overall levels of C-reactive protein (CRP) at admission were 0.5 (0.3–1.0)* mg/dl and those of fibrinogen were 333.9 ± 89.6† mg/dl respectively. Prevalence of silent ischemia (SI) was 25.7%. Prevalence of acute left ventricular wall motion abnormalities (LVWMA) was 42.8% (CI 95% 36.0–49.8). The rate of events during the in-hospital period was: death 3.8%, myocardial infarction 8.1%, refractory angina 15.2%, recurrent angina 25.7% and silent ischemia 25.7%. The rate of the primary combined end point of recurrent ischemia (RI) was 42.4% during the in-hospital period.

	p with RI	p without RI	p
n (%)	89 (42.4)	121 (57.6)	-
SDNN†	87.1 ± 27.0	89.0 ± 27.7	ns
SDNN Index†	43.9 ± 18.1	46.2 ± 14.9	ns
SDANN Index†	74.3 ± 24.5	74.9 ± 27.0	ns
pNN50†	8.1 ± 10.6	9.7 ± 10.9	ns
RMSSD†	30.5 ± 16.5	31.6 ± 15.4	ns

(*expressed as median and 25–75% interquartile ranges, †expressed as mean ± SD)

Reduced heart rate variability was also not associated with: elevated CRP levels (>0.3 mg/dl), fibrinogen levels above 400 mg/dl, ↓ST or the presence of LVWMA.

Conclusions: Reduced heart rate variability in patients with unstable angina is not useful as a marker for increased risk of in-hospital recurrent ischemic events.

1864 Prognostic value of clinical and ECG variables in patients with suspected unstable angina: results of the Proyecto de Estudio del Pronostico de la Angina (PEPA)

E. Lopez de Sa, J. Lopez-Sendon, A. Bethencourt[1], X. Bosch[2]. *Cardiology Dept, Gregorio Maranon Institute, Madrid; [1]Palma de Mallorca; [2]Barcelona, Spain*

Background: Unstable angina (UA) and non-Q wave myocardial infarction (non-Q MI) includes a broad spectrum of patients. However, little prognostic information is available of clinical and ECG variables in large, prospective unselected samples of patients.

Methods: The prognosis of clinical and ECG variables obtained at hospital admission was prospectively evaluated in 4115 consecutive patients considered to have UA or non-Q MI when first seen by a cardiologist. The recruitment period was from October 1995 to September 1996 at 18 centers in Spain.

Results: The total 90 days' mortality was significantly higher ($p < 0.001$) in women, age > 65 y, previous MI, peripheral vascular disease, previous stroke and diabetes. Total 90 days' mortality in the different groups of Braunwald's classification was: Class I: 4.3%, Class II: 1.7%, Class III: 6.7% (NS); Class A: 5.8%, Class B: 5.1% and Class C: 8.9% ($p = 0.03$); previous treatment: without: 4.3%, standard: 6.0%, maximal: 9.0% ($p = 0.03$); abnormalities of ST-T on first ECG: yes 7.1%, no: 2.5% ($p < 0.001$). Only the following, were identified as independent risk for 90 days' mortality in the multivariate analysis (RR; 95% CI): heart failure (1.7; 1.4–1.9), age > 65 y (1.5; 1.3–1.8), diabetes (1.4; 1.2–1.7), ST-T abnormalities (1.4; 1.2–1.7), and peripheral vascular disease (1.3; 1.1–1.6)

Conclusion: Very simple clinical and ECG variables are useful to evaluate the prognosis of patients with suspected UA or non-Q MI.

1865 Superiority of C-reactive protein over the exercise treadmill test for non-invasive risk stratification of patients recovering from unstable angina

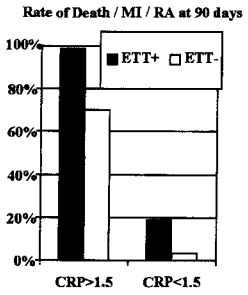
Ernesto R. Ferreirós, Carlos P. Boissonnet, Rodolfo Pizarro, Pablo García Merletti, Gianni Corrado, Arturo Cagide, Oscar Bazzino. *Department of Cardiology, Hospital Italiano de Buenos Aires, Argentina*

The exercise treadmill test (ETT) is routinely employed for non-invasive risk stratification in patients recovering from an acute ischemic event. In unstable angina, elevated C-reactive protein (CRP) levels were shown to be an independent marker of high risk for recurrent ischemic events. Our objective was to compare the prognostic value of the symptom-limited treadmill test with CRP levels for non-invasive risk stratification in patients (p) with unstable angina discharged without in-hospital events or revascularization procedures.

Methods: During a 6 month period, 105 consecutive p with unstable angina and without prior myocardial infarction nor total CK elevation post-admission were included.

Measurement of CRP was performed at hospital discharge. The ETT was performed at hospital discharge or within the week following hospital discharge. A 90 day follow-up was conducted to determine the occurrence of a primary combined end point (death (D) and/or acute myocardial infarction (MI) and/or refractory angina (RA)).

Results: Mean age was 65.5 ± 11.7 years, 63.8% were male; and 48.6% had ST segment depression (↓ST) on admission ECG. The rate of in-hospital revascularization was 27.6%.



Rate of Death/MI/RA at 90 days.

The rate of in-hospital D and/or MI and/or RA was 21.9% and from discharge to day 90 the rate of the primary end point was 28.6%. A cut-off point of 1.5 mg/dl was established for CRP levels based on the Receiver Operating Curves of the 90-day outcome. CRP at discharge was > 1.5 mg/dl in 29.3% of the p. ETT showed the presence of inducible ischemia in 41.0% of the p. On univariate analysis CRP > 1.5 mg/dl was associated to the highest event rate, but the combination with the ETT results further improved its prognostic significance (shown in figure). In a Cox regression model for predicting the primary end point at 90 days, which included age, ↓ST, silent ischemia, and ETT results, the strongest independent marker was CRP at discharge > 1.5 mg/dl (HR 3.0 CI 95% 1.9–5.0; p < 0.001). The ETT was not an independent predictor in the Cox regression model (HR 0.9 CI 95% 0.7–2.0; p = ns).

Conclusion: In unstable angina CRP at discharge > 1.5 mg/dl is a strong independent marker of an adverse 90-day outcome. These results support the use of a combination of inflammation markers (CRP) and exercise induced ischemia (ETT) to identify p with high or low risk for coronary events.

1866 C-reactive protein level in patients with unstable angina pectoris: association with myocardial perfusion and functional abnormalities on gated SPECT imaging and angiographic morphology

M. Aksoy, A. Emre, M. Gürsürer, H. Aksu, E. Arıkan, M. Öç, M. Eren, Ü. Sohtorik, B. Ersek. *Dept. of Cardiology, Siyami Ersek Thoracic and Cardiovascular Surgery Center, İstanbul, Turkey*

Elevated C-reactive protein (CRP) has been reported to identify high-risk patients (pts) in unstable angina. We examined the relation of plasma CRP concentration to myocardial perfusion, function and coronary, morphology in pts hospitalized with unstable angina pectoris.

Methods: We studied 96 pts within 6 hours of the onset of symptoms. Blood samples were drawn at admission and at 24 hours to assess CRP levels. Gated SPECT was performed within 1–6 hours after the injection of 30 mCi Tc-99m sestamibi. All pts had coronary angiography in hospital course. SPECT images were interpreted using 20-segments with a 5 point scale (0 = normal, 4 = no uptake) for perfusion and a 4 point scale (0 = absent, 3 = normal) for wall motion. Perfusion index and wall motion index were derived by adding the score of all segments and dividing these by 20. Left ventricular ejection fraction was measured on left ventriculography.

Results: 8 pts had no coronary artery disease (CAD) and none of them had CRP in the 5th quintile (≥2.9 mg/L). The remaining 88 pts with CAD were divided into two groups according to plasma CRP level:

	Quintiles 1–4, n = 72	Quintile 5, n = 16	p
Perfusion index	0.74 ± 0.29	1.01 ± 0.37	0.002
Wall motion index	2.50 ± 0.39	2.21 ± 0.42	0.009
No. of diseased vessels	1.88 ± 0.75	1.91 ± 0.73	NS
Pts with ICT	18 (25%)	6 (37%)	NS
TIMI flow	2.49 ± 0.05	2.05 ± 0.9	0.01
Pts with complex lesion	29 (40%)	8 (50%)	NS
Ejection fraction	59.3 ± 14	49.3 ± 13	0.01

ICT = Intracoronary thrombus

Conclusion: Elevated CRP is associated with a greater degree of myocardial hypoperfusion and wall motion abnormalities and the angiographic findings of lower ejection fraction and decreased TIMI flow.

IMPROVING THE OUTCOME OF ACUTE MYOCARDIAL INFARCTION

1867 Mortality in patients with acute myocardial infarction treated with reperfusion therapy, beyond the clinical trials

J. Morais, L. Coelho, M.J. Maldonado, F. Franco, M.E. Morais, M. Freitas, L. Providencia. *Cardiology Dept., University Hospital, Coimbra, Portugal*

Reperfusion therapy (RT – primary PTCA or fibrinolysis) within the first few hours of acute myocardial infarction (AMI) is a very well established procedure. However, regarding the inclusion and exclusion criteria, the randomised clinical trials rarely express the real world. In the present paper the authors are looking at a single centre registry putting in evidence the most relevant differences with the reference trials.

A consecutive series of 417 patients (pts) with AMI admitted in a single tertiary centre were managed with RT-fibrinolysis – 265 (63%); primary PTCA – 152 (37%). Demographic characteristics, risk factors and previous coronary disease were similar between the two groups. In the group of pts treated with PTCA the anterior topography was more frequently found (69.1% vs 49.4%; p < 0.0001).

Results: In-hospital mortality rate was 10.0% – 42 pts (1ªPTCA – 8.6%; FBR – 10.9%; ns). Mortality was influenced by (survived vs non-survived): age (62.1 vs 71.8; p < 0.0001); gender female (19.5% vs 50.0%; p < 0.0001); Killip cl > I at admission (13.0% vs 33.3%;p = 0.001); late treatment, (<6 hrs – 74.6% vs 59.5%; p < 0.05). Intracranial bleeding was the cause of death in 3 fibrinolysed pts). The outcome was not influenced by reperfusion modality. Mortality by age group was: <60 – 2.5%; 61–70 – 8.8%; 71–80: 19.5%; >80–22.7%. The mean time from symptoms onset to treatment and the prevalence of anterior AMI were the most relevant different baseline characteristics when the present cohort is compared with the reference trials (PAMI, GUSTO I, GUSTO IIb).

Conclusions: In the present cohort mortality rate is slightly higher than reported in published trials, not influenced by reperfusion modality and justified by differences in baseline characteristics: treatment started later and anterior AMI is more prevalent, expressing a higher risk population. Older age, female gender, late treatment and K. Class > I at admission were the predictive factors for death.

1868 Hospital profiles and clinical outcomes stratified by on-site cardiac catheterization availability: an INTIME-II substudy

J. Llevadot, R.P. Giugliano, E.M. Antman, C.H. McCabe, A. Foxley[1], A. Skene[1], R. Wilcox[2], P. Chew[3], K.-L. Neuhaus[4], E. Braunwald. *Cardiovascular Division, Brigham and Women's Hospital, Boston MA, USA; [1]Nottingham CTDC, Nottingham; [2]University Hospital, Nottingham, UK; [3]Bristol-Myers Squibb, Princeton NJ, USA; [4]Stadtische Kliniken Kassel, Kassel, Germany*

Background: Availability of on-site cardiac catheterization strongly influences patient mangement and may be associated with a distinct hospital profile. The relationship between availability of catheterization, hospital profile, and clinical outcomes is not well studied in megatrials of thrombolysis for acute myocardial infarction (AMI).

Methods: We surveyed all 855 hospitals from 35 countries participating in InTIME-II (nPA vs tPA in AMI) regarding location, size, teaching status, patient management, and on-site facilities (catheterization, angioplasty and cardiac surgery). Hospitals were stratified by on-site availibility of cardiac catheterization as: 24 hours, day time only, and no availability.

Results: 100% of hospitals responded to the survey (see table). *Clinical outcomes by catheterization availability and hospital profile will be available after data unblinding in March 1999 and will be presented.

Hospital characteristics

	24 h	Day	None	p (trend)
Number of hospitals	264	215	376	–
City/Referral	88%	75%	52%	<0.0001
< 300 beds	22%	21%	47%	0.01
300–700 beds	41%	52%	42%	0.9
>700 beds	37%	27%	11%	<0.0001
Teaching hospital	79%	69%	47%	<0.0001
Lytic decision by cardiologist	80%	74%	43%	<0.0001
Inpatient care by cardiologist	94%	87%	55%	<0.0001
On-site angioplasty	93%	56%		
% Primary PTCA for AMI	30% **	7%**	–	<0.0001**
On-site CABG	74%	28%	–	<0.0001
30 d event rate (death, MI, stroke)	*	*	*	*

Percentages reflect column percent

Conclusions: In this AMI megatrial, hospitals with 24 hour on-site catheterization tend to be larger, city, teaching hospitals, with patients generally managed by cardiologists. Hospitals with day catheterization had a profile that was intermediate between those centers with 24 h availability and those with no catheterization lab. These differences may be important when comparing clinical outcomes between hospitals stratified by the availability of on-site facitilities.

1869 Non-Q and "incomplete-Q" myocardial infarction after thrombolysis is associated to reinfarction in a six-month follow-up

C. Tajer, A. Charask, W. Taddei, A. Salvatti, A.J. Gant Lopez, S. Molteni, H. Doval, R. Diaz, E. Paolasso, F. Van der Werf[1]. *International TPA-SK mortality trial and ECLA group; Buenos Aires, Argentina; [1]Leuven, Belgium Universitiy*

Succesful thrombolysis (TL) is associated to a limitation of ECG indexes of necrosis. We explored the rate of development of Q waves at discharge in leads with ST segment elevation (ST↑) on admission, and its prognostic implications in the follow up.

Methods: 7605 pts were discharged alive in the International tPA/SK mortality trial. We analysed the ECG of pts with ST↑ >= 0.1 mV in >= 3 contigous leads on admission, and excluded pts with bundle branch block, poor quality of the ECG or incomplete follow up. An index of Q development in leads with ST↑ was calculated: (n of leads with Q at discharge in leads with ST↑ on admission/n leads with ST↑ on admission) × 100. Six months follow up for reinfarction and death was performed. A total of 5253 pts were included.

Results: 1) no Q development, index 0%, (non Q MI) was observed in 975 pts (18.6%), 2) index 10 to 40% ("incompleted" Q) in 771 (14.7%) and 3) index > 40% ("completed" Q wave) in 3507 (66.7%). Reinfarction is summarised in the table

	Prevalence		Reinfartion		Odds and 95% CI
	n	%	n	%	
Non Q	975	18.6	60	6.2*	1.95 (1.39–2.7)
"Incompleted" Q	771	14.7	45	5.8*	1.84 (1.24–2.6)
"Completed" Q	3507	66.7	114	3.3	1

*p < 0.001 vs "completed Q".

Death rate was 2.8% in the "completed" Q group, 3.5% in the "incompleted Q" group and 3% in the non Q group, p NS. Reinfarction was associated with mortality during follow up: death rate was 28% in the 219 pts with reinfartction and 1.8% in pts without reinfarction, p < 0.001.

Conclusions: non Q MI or incomplete Q development after thrombolysis at discharge predicts a higher risk of reinfarction during the follow up.

1870 Women with acute myocardial infarction are treated less aggressively than men

T. Heer, R. Schiele, A.K. Gitt, F. Fischer, H. Wienbergen, C. Dommke, H.G. Glunz, G. Berg, P. Limbourg, J. Senges. *For the MITRA Study Group; Herzzentrum Ludwigshafen, Germany*

Acute myocardial infarction (AMI) in women occurs at higher age and has a higher mortality compared to men. We examined if there is a specific gender difference regarding acute treatment and mortality.

Methods: Within the MITRA study 6066 consecutive patients with AMI were registered in 54 hospitals in south-west Germany from 6/94 until 2/97. The percentage of women was 34% (2033). We examined if there was a gender difference concerning comorbidity, initial presentation, treatment and mortality.

Results:

	Women	Men	p-value
Primary PTCA	6.5%	9.3%	<0.0001
Thrombolysis	41.3%	50.5%	<0.0001
Beta blockers	49.8%	58.6%	<0.0001
Mortality	20.1%	12.2%	<0.0001

There was no significant difference in therapy with ACE inhibitors and Aspirine. Multivariate analysis adjusting for 22 variables (including age) showed that women receive thrombolysis or primary PTCA less frequently than men (OR 0.76; 95% CI 0.62–0.92).

Conclusion: Women with AMI are treated less aggressively than men. The multivariate analysis shows that recanalisation therapy (thrombolysis or primary PTCA) is underused in women. This is associated with a higher hospital mortality.

1871 Prior treatment with aspirin as a predictor of better coronary thrombolysis in patients with acute myocardial infarction

E.R. Ferreiros, C.P. Boissonnet, P. Oberti, R. Pizarro, A. Cagide, O.O. Bazzino. *Dept. of Cardiology, Hospital Italiano, Buenos Aires, Argentina*

Prompt and complete recanalization of the occluded infarct-related artery is crucial in limiting the size of the infarct and improving the survival rate. Our objective was to study the relation among prior treatment with aspirin (P-ASA), the achievement of complete coronary reperfusion (CR+), the size of the infarct and the in-hospital survival rate in patients (p) with acute myocardial infarction (AMI) receiving thrombolytic therapy with streptokinase (SK).

Methods: During a 5 year period, 792 consecutive p were admitted to the coronary care unit with diagnosis of AMI. 585 presented ST segment elevation ≥ 1 mm in two or more contiguous leads at hospital admission, receiving SK 233 p (39.8%). We analyzed in this group the relation among P-ASA, the achievement of CR+ (resolution of ST segment elevation ≥ 70% at 60 minutes), the size of the infarct (peak creatine kinase levels) and the in-hospital survival rate.

Results: Mean age was 61.5 ± 13.0 years, 79.4% were male, 29.6% had preinfarction angina (PA), 17.6% had prior history of AMI (P-AMI) and 3.4% had prior history of heart failure (P-HF). The AMI localization was anterior in 126 p and inferior in 107 p. At the time of admission mean systolic arterial pressure (SAP) was 126.5 ± 25.6 mmHg, mean heart rate was 80.0 ± 19.5 bpm and Killip & Kimball classification (KK) was type A in 74.2% of the p, B in 20.2%, C in 2.1% and D in 3.4%. 126 p (54.0%) received P-ASA. 107 p (45.9%) achieved CR+. The rate of in-hospital death was 16.3%. On univariate analysis P-ASA was associated with the highest CR+ rate (70.6% CR+ with P-ASA versus 16.8% CR+ without P-ASA; OR 5.6, CI95% 1.2–26.5; p < 0.01). The peak CK values were 1029.3 ± 771.1 UI/L in the group of p with P-ASA and 2136.4 ± 681.0 UI/L without P-ASA (p = 0.025); and the rate of in-hospital death 7.9% and 26.2% respectively (RR 0.30, CI 95% 0.15–0.60; p < 0.001). In a logistic regression model for predicting CR+, which included age > 70, PA, time "door to SK", P-AMI, P-HF, KK ≥ B and AMI localization, the strongest independent marker was P-ASA (OR 5.4, CI95% 1.2–20.5; p < 0.01). P-ASA was not an independent marker of increased risk for in-hospital death in a logistic regression model adjusted for age > 70, P-AMI, KK ≥ B, AMI localization and SAP < 100 (OR 1.4, CI95% 0.7–3.4; p = NS).

Conclusions: In p with AMI and P-ASA, SK more frequently obtained CR+, resulting in smaller infarct sizes. These results suggest that better platelet inhibition may improve the results of reperfusion strategies in AMI.

1872 Bundle-branch block, acute myocardial infarction and thrombolysis. Too much and too little?

G. Gunnarsson, P. Eriksson, G. Kallstrom, A.M. Svensson, M. Dellborg.
Department of Medicine, Sahlgrenska University Hospital/Östra, Gothenburg, Sweden

Purpose: The selection of patients with acute myocardial infarction (AMI) for thrombolytic therapy is of great importance for outcome. This selection is made on clinical symptoms and electrocardiographic (ECG) findings. Patients with bundle branch block (BBB) are a diagnostic problem. Studies on thrombolytics have shown that patients with BBB and AMI have worse clinical outcome compared to patients with normal QRS duration on ECG and they benefit from thrombolytic therapy. We have made a prospective multicenter study addressing the question of early diagnosis, treatment and outcome regarding patients with chronic BBB and clinical suspicion of AMI.

Methods: A prospective multicenter study with 14 Swedish centres. Patients with BBB and chest pain <6 hours on admission and clinical suspicion of AMI were included. ECG was registered on admission and after 12–24 hours. The patients were monitored with continuos vector cardiography for 12–24 hours. Diagnosis of AMI was made with cardio-specific markers.

Results: 265 patients were included. Male/female ratio was 70/30. Mean age was 74.8 years. Left bundle branch block (LBBB) was present in 63% and right bundle branch block (RBBB) in 37%. 121 (46%) had AMI. The use of thrombolytics was as follows: Of all patients 12%, of LBBB and AMI 18% and RBBB and AMI 34%. Of those treated with thrombolytics a substantial percentage did not have AMI (see table).

	All BBB	LBBB	RBBB
AMI	28	14	14
Non AMI	5	3	2

Diagnosis and BBB amongst patients treated with thrombolytics: n = 33

Conclusion: Patients with BBB and clinical suspicion of AMI may be under-treated with thrombolytics. However of those receiving thrombolytics 18% of patients with LBBB and 13% of patients with RBBB do not have an AMI and may thus be over-treated. A more accurate tool is needed for identifying patients with AMI and BBB eligible for thrombolytic treatment.

GROWTH FACTORS AND CELL PROLIFERATION

1873 De-differentiated smooth muscle cells in human coronary atherosclerotic lesions express a new mitogen-inducible nuclear orphan receptor gene

A. Castello, C. Cases-Langhoff, J. Martinez-Gonzalez, L. Badimon.
Cardiovascular Laboratory, Cardiovasc.Res.Cter-IIBB/CSIC-HSCSP, Barcelona, Spain

Background: De-differentiation (activation, migration and proliferation) of smooth muscle cells (SMC) in the vascular wall has a key role in the development of spontaneous atherosclerosis and is generally held responsible for restenosis following balloon angioplasty and the failure of coronary bypass grafts. Interest has therefore focused on the regulation of SMC. Quiescent SMC respond to a variety of growth factors by dedifferentiating and re-entering the cell cycle, and these changes in the phenotype are mediated by changes in gene expression. The aim of the project was the identification of genes specifically expressed during differentiation of SMC in response to mitogens.

Methods and Results: Primary cultures of coronary artery SMC were obtained by the explant method and mRNA-differential display of stimulated versus arrested SMC in vitro was performed. An inducible cDNA was cloned, sequenced and characterized. Northern blot and the in situ hybridization technique were used to confirm the inducibility of the cloned cDNA. We have cloned a mitogen-inducible nuclear orphan receptor in porcine SMC (NOR-1), and characterized its inducibility in SMC in vitro and in vivo. The expression of NOR transcripts is induced within 30 min by several mitogens, including PDGF, thrombin and serum, which activate different signal pathways. Moreover, we have directly associated NOR with atherosclerosis. In situ hybridization analysis shows that NOR mRNA is expressed by SMC in immature and growing zones of diet-induced porcine atherosclerotic lesions and human coronary plaques.

Conclusion: We have identified for the first time the expression of NOR-1 gene in mitogen induced SMC in vitro and have found NOR-1 highly expressed in human atherosclerotic plaques. NOR is an immediate early gene, member of a subfamily of the nuclear receptor superfamily, and has typical steroid receptor structure. The role of NOR as a transcription factor regulating the expression of specific secondary genes for SMC may be a key point in the progression of atherosclerosis-restenosis.

1874 Inhibition of restenosis by an orally available cell cycle inhibitor

J. Ruef, K. Peter, T.K. Nordt, C. Bode, C. Patterson[1]. *Division of Cardiology, University of Heidelberg, Germany; [1]Division of Cardiology, University of Texas Medical Branch, Galveston TX, USA*

Progression of vascular smooth muscle cells (VSMC) through the cell cycle is among the final common signaling events in vasculoproliferative diseases. Thus, targeting the cell cycle is of interest with respect to proliferative events such as restenosis. However, tools combining effectiveness and simple application have not yet entered clinical practice. Flavopiridol is a potent and specific, orally available inhibitor of cyclin-dependent kinases. Flavopiridol (75 nM) significantly inhibited human aortic VSMC proliferation induced by bFGF (10 ng/ml) and thrombin (2 U/ml), ($p < 0.05$). Flavopiridol, at concentrations up to 100 nM, had no effect on the viability of untreated VSMC. Flavopiridol (75 nM) significantly inhibited growth factor-induced activity of cyclin-dependent kinases, as measured by histone H1 phosphorylation ($p < 0.05$). The inhibitor exhibits high substrate specificity, since no effects on MAP kinase activation were noted. Induction of cell cycle-related proteins cyclin D1, proliferating cell nuclear antigen (PCNA) and phosphorylated retinoblastoma protein was blocked by flavopiridol. To test for the growth inhibiting potency of flavopiridol in vivo, a rat carotid artery injury model was employed. Flavopiridol was administered orally (5 mg/kg) and neo-intima formation following balloon injury was monitored. Compared to the controls, treatment with flavopiridol resulted in reduction of neointima size by 35% and 39% at 7 and 14 days, respectively, following balloon injury ($p < 0.05$); PCNA expression was reduced significantly ($p < 0.05$). In summary, flavopiridol effectively inhibits VSMC proliferation in vitro and in vivo by specifically targeting cell cycle regulatory elements. This compound, readily available for oral uptake, might represent a therapeutic tool in prevention and treatment of proliferative vascular diseases.

1875 Platelet-derived microparticles stimulate mitogenesis of coronary artery smooth muscle cells by a PDGF-independent mechanism

A.-A. Weber, H.-O. Köppen, K. Schrör. *Institut für Pharmakologie, Heinrich-Heine-Universität, Düsseldorf, Germany*

Platelet-derived growth factor (PDGF) is regarded as the most important mitogen secreted from activated platelets. We have previously shown that isolated platelet surface membranes exhibit a very potent mitogenic activity for coronary artery smooth muscle cells (SMC) (Schrör et al., Platelets 1998; 9:424). This study investigates possible mitogenic effects of platelet-derived microparticles.

Methods: Platelet microparticles were prepared from stimulated platelets by differential centrifugation. The effects of microparticles on p42/p44 MAP kinase phosphorylation (Western blot), c-fos expression (Western blot), DNA synthesis ([^{3}H]thymidine incorporation), cell proliferation (increase in cell number), and cell migration (wounded layer migration assay) were studied in cultured bovine coronary artery SMC.

Results: Microparticles concentration-dependently stimulated MAP kinase phosphorylation, c-fos expression and mitogenesis of SMC. These mitogenic effects were significantly higher than maximal effects of PDGF-BB. Microparticle-induced SMC mitogenesis was heat-sensitive (75° C, 15 min), while the effects of PDGF were not. In addition, neutralizing anti-PDGF antibodies prevented PDGF-induced DNA synthesis but did not significantly inhibit the effects of microparticles. In contrast to PDGF, which potently stimulated SMC migration, microparticles had only a minor migratory effect.

Conclusion: These results demonstrate a novel role of platelet-derived microparticles as inducers of SMC proliferation. The mitogenic effects of microparticles are independent of PDGF.

1876 PDGF-BB stimulates nuclear translocation of NFkB in human vascular smooth muscle cells without degradation of IkB: a novel mechanism of NFkB activation?

M. Braun, A.-A. Weber, N. Zimmermann[1], K. Schrör. *Institut für Pharmakologie, Heinrich-Heine-Universität, Düsseldorf[1] Thorax- und Kardiovaskuläre Chirurgie, Heinrich-Heine-Universität, Düsseldorf, Germany*

The transcription factor NFkB is thought to play a key role in the regulation of proliferation of smooth muscle cells in atherogenesis (Bourcier et al., J Biol Chem, 1997;272;15817). In unstimulated cells, the heterodimer NFkB is located in the cytoplasm bound to the inhibitor protein IkB. In the present concept of NFkB activation the phosphorylation and degradation of IkB is a prerequisite for nuclear translocation of NFkB and its subsequent activity on gene expression.

Methods: This study investigates the mechanism of NFkB activation by platelet-derived growth factor-BB (PDGF-BB, 20 ng/ml) compared to tumor necrosis factor-a (TNFa, 10 ng/ml) in cultured human smooth muscle cells (saphenous vein). IkB phosphorylation and degradation was studied by Western blotting. Translocation of NFkB (p65) was detected by Western blotting using nuclear extracts.

Results: Stimulation with TNFa resulted in a transient phosphorylation of IkBa (maximum after 10 min) and subsequent IkBa degradation and nuclear translocation of NFkB (maximum after 15 min). Stimulation with PDGF-BB also resulted in nuclear translocation of NFkB (maximum after 30–60 min). In contrast to TNFa no phosphorylation and degradation of IkB was detectable. Neither TNFa nor PDGF-BB induced degradation of the IkB-b isoform.

Conclusions: These data demonstrate, that the PDGF-BB-induced NFkB translocation into the cell nucleus is independent of IkBa degradation. PDGF-BB therefore appears to be the first mediator that induces an IkB-independent NFkB activation.

1877 Endothelin-1 markedly potentiates human smooth muscle cell growth to PDGF: effects of ET-A and ET-B receptor blockade

Z. Yang, N. Krasnici, T.F. Lüscher[1]. *Institut of Physiology, Cardiovascular Research, Zürich[1] Cardiology, University Hospital Zürich, Zürich, Switzerland*

Endothelin-1 (ET-1) is a well known potent vasoconstrictor peptide via activation of both ET-A and ET-B receptors. While the role of ET-1 in cardiovascular disorders with dysregulation of vascular tone is well documented, its mitogenic effects on vascular smooth muscle cells (SMC) remain controversial. Some studies demonstrated potent mitogenic effects of ET-1 and others showed no proliferative effects. We investigated the role of ET-1 in human SMC growth and its interaction with platelet-derived growth factor (PDGF).

Methods: SMC were cultured from human aorta in medium without any growth factors and cell proliferation was assayed by ^{3}H-thymidine incorporation. PDGF receptor expression, activation of mitogen-activated protein kinase (MAPK), cell cycle regulators such as cyclin-dependent kinase2 (Cdk2), Cdk inhibitor (p27Kip1) and retinoblastoma protein (pRb) were analyzed by immunoblotting.

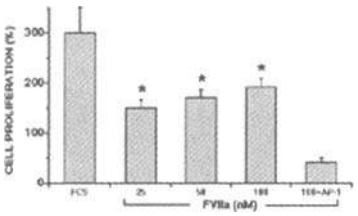
Results: ET-1 (1 to 100 nmol/L) on its own was unable to stimulate ^{3}H-thymidine incorporation, but dramatically potentiated the effect of PDGF-BB (1 ng/ml) up to 68-fold ($p < 0.001$). Most of the potentiating effects (88%) were blocked by the ET-A receptor antagonist LU135252 (1 to 10 μmol/L) and slightly further by the ET-A/B receptor antagonist bosentan ($p < 0.05$). ET-1 stimulated MAPK, but it neither potentiated PDGF induced MAPK activation nor overexpressed PDGF receptors. While PDGF-BB (10 ng/ml, 24 hours) markedly activated Cdk2, hyperphosphorylated pRb and downregulated p27kip1, ET-1 had no regulatory effects on the cell cycle regulatory proteins.

Conclusion: In human SMC, ET-1 activates MAPK but has no mitogenic effects on its own. However, ET-1 markedly potentiates proliferation to PDGF mainly via ET-A receptors. This may represent an important function of ET-1 for vascular structural changes in patients and provide new therapeutic opportunities for ET-1 receptor antagonists.

1878 Activated coagulation factor VII promotes smooth muscle cell proliferation in vitro

P. Cirillo, P. Golino, A. Guarino, R. Napoli[1], M. Ezban[2], M. Ragni, C. Buono, D. Leosco, M. Chiariello. *Division of Cardiology, University of Naples Federico II, Naples; [1]Internal Medicine Dept, University of Naples Federico II, Naples, Italy; [2]Novo Nordisk, Copenhagen, Denmark*

Smooth muscle cell (SMC) proliferation is a key event in the development of atherosclerosis and restenosis following coronary angioplasty. Tissue Factor (TF) is a transmembrane glycoprotein which forms a high affinity complex with factor VII/VIIa (FVIIa) and activates the extrinsic coagulation pathway. We have shown that TF is up-regulated in the media of vessels following vascular injury and thrombus formation. The aim of the present study was to investigate whether binding of FVII/FVIIa to TF promotes SMC proliferation, besides activating the extrinsic coagulation cascade. SMCs isolated from the aortas of New Zealand white rabbits, were grown in DMEM + 10% fetal calf serum (FCS). At 70% confluence, SMCs were made quiescent by removing FCS from the medium. Twenty-four hours later, cells were stimulated for 24 hrs with increasing concentrations of human recombinant FVIIa. SMC proliferation was evaluated by measuring the degree of ^{3}H-Thymidine incorporation. Control experiments included addition of FCS (positive control), and AP-1, a monoclonal antibody against rabbit TF which prevents FVIIa binding to TF. Furthermore, another set of experiments was performed using active site-blocked FVIIa (FVIIai), which binds to TF but has no enzymatic activity. FVIIa induced a dose-dependent increase in SMC proliferation, which was almost completely prevented by AP-1 (figure; *$p < 0.05$).



In contrast, none of the dose of FVIIai employed resulted in a significant stimulation of proliferation. Thus, FVIIa binding to TF induces SMC proliferation in vitro. This effect requires the enzymatic activity of FVIIa, as FVIIai did not stimulate proliferation. This phenomenon might play a role in the pathophysiology of restenosis following vascular injury in vivo.

NITRIC OXIDE: EXPERIMENTAL RESULTS

1879 Nitric oxide prevents hypertension and thromboembolism in transgenic mice with polyglobulia

F. Ruschitzka, M. Gassmann[1], R. Labugger, T. Quaschning, R. Wenger[1], G. Noll, T.F. Lüscher. *Cardiology Dept., University Hospital, Zurich; [1]Physiology Dept., University Zurich-Irchel, Zurich, Switzerland*

Background: Despite being known that nitric oxide (NO) induces vasodilatation and inhibits platelet aggregation and vascular smooth muscle cell proliferation in vitro, a beneficial effect of NO in preventing vascular disease in vivo has not been provided so far. Considering that polyglobulia is associated with an high incidence of cardiovascular complications, such as arterial hypertension and thromboembolism, we sought to assess the function of NO in polyglobulic mice.

Methods: We generated a novel transgenic mice model overexpressing human erythropoietin (Epo) from the platelet derived growth factor B chain (PDGF-B) promoter.NO bioavailability was assessed as endothelium-dependent and -independent function in response to acetylcholine (ACh, 0.01–300 μmol/L) and sodium nitroprusside (SNP, 0.01–300 μmol/L) in isolated aortic rings (n = 7; wildtype siblings served as controls). eNOS protein levels were determined by western blot analysis.

Results: In one transgenic line serum Epo level increased up to 20-fold, and Epo expression was detected in serum, brain, testis and lung. In turn, Epo overexpression induced marked erythrocytosis resulting in an hematocrit value of up to 80%. Notwithstanding very high hematocrit levels, transgenic mice survive 10 to 12 months and do not develop hypertension, stroke or myocardial infarction. Western blot analysis revealed a 10 fold increase of eNOS in aorta of transgenic mice compared to wild-type control animals. In the transgenic aorta, basal NO release as assessed by contraction to NO-synthase inhibitor L-NAME and NO-mediated, endothelium-dependent relaxations in response to ACh were significantly increased, whereas endothelium-independent relaxation to SNP remained unchanged. Similarly, vasorelaxation to thrombin, a potent endogenous stimulus of NO formation and release, was also increased indicating enhanced bioavailability of NO in transgenic animals.

In conclusion, our novel transgenic mouse model of Epo-induced severe polyglobulia provides first evidence that constant NO release by eNOS maintains normotension and prevents vascular disease in vivo.

1880 Transfection of human saphenous vein endothelial cells with the inducible nitric oxide synthase inhibits expression of intercellular adhesion molecule-1 and leukocyte adherence

S. Lindemann, M. Sharafi, K. Veit, W. Ibe, J.-P. Boissel, M. Buerke, J. Meyer, H. Darius. *Department of Medicine II, University of Mainz, Germany*

Background: Polymorphonuclear leukocytes (PMN) adhere to activated endothelial cells, promote vascular cell damage and disturb their growth regulation mechanisms. Enhanced PMN-adherence might occur due to a diminished basal nitric oxide (NO) release and adhesion molecule upregulation in vascular endothelial cells following ischemia/reperfusion or angioplasty.

Methods: A cDNA fragment with the coding sequence of the iNOS was cloned into a mammalian expression plasmid with a cytomegalovirus promotor sequence. A liposome-mediated transfection into human saphenous vein endothelial cells (HSVEC) was performed and expression of intercellular adhesion molecule-1 (ICAM-1) was measured with a cell surface ELISA following TNF-stimulation (300 U/ml). PMN-adhesion was determined in a cell adhesion assay by epifluorescent microscopy using fluorescent green labeled PMN.

Results: Transfection of HSVEC with the iNOS gene reduced ICAM-1 expression to 37% of maximal ICAM-1 expression compared to non-transfected TNF-stimulated cells. iNOS transfection resulted in reduced PMN-adhesion (31% of maximal PMN-adhesion). Additional treatment of transfected HSVEC with the NO-donors SIN-1 (0.01–1 mM) or SNAP (3–30 μM) did not further diminish ICAM-1 expression and PMN-adhesion. In contrast TNF-stimulated HSVEC which were not transfected showed a significant concentration-dependent reduction in ICAM-1 expression and PMN-adhesion following treatment with SIN-1 and SNAP (SIN-1 1 mM 57 ± 8% of maximal ICAM-1 expression, SNAP 30 μM 35 ± 16% of maximal PMN-adhesion, $p < 0.05$, ± SEM). Inhibition of NO generation with L-NMMA (20 μM) clearly elevated ICAM-1 expression and PMN adhesion.

Conclusion: Transfection of vascular endothelial cells with the iNOS gene is a novel approach to substitute nitric oxide. Substitution of NO by transfection with iNOS effectively substitutes NO diminishing adhesion molecule expression and PMN adherence.

1881 Protection from collar-induced intimal thickening by shear stress: role of nitric oxide

G. Marano, S. Palazzesi, A. Vergari[1], A.U. Ferrari[2]. *Lab. Farmacologia, Ist. Sup. Sanita, Rome; [1]Ist Anestesia e Rianimazione, Univ Cattolica S. Cuore, Rome; [2]Clinica Medica Generale, Centro Fisiologia Clin e Ipertensione, Milan, Italy*

Nitric oxide (NO) has potent relaxant and antiproliferative effects on vascular smooth muscle cells, which may represent a potent antiatherosclerotic mechanism. Since a major stimulus for NO release is flow-related wall shear stress (WSS), we examined i) the effect of increased WSS on neointima formation (collar model, see below), ii) the role of NO in the antiproliferative effect of increased WSS, and iii) the adaptation of carotid artery (CA) diameter to increased WSS.

Methods: Intimal thickening of the left common CA (LCCA) was produced in New Zealand White rabbits by enclosing the vessel into a non-constrictive silicone collar (group 1). High WSS was induced by further ligating the right internal CA (RICA, group 2). To evaluate the role of NO, nitro-L-arginine methyl ester (L-NAME) was administered at subpressor doses (15 mg kg^{-1} day^{-1}, group 3). At day 14 after surgery, BP, heart rate, CA flow velocities, diameters and WSS were assessed "in vivo". Intimal area and intima/media area ratio were histomorphometrically measured post-mortem.

Results showed that RICA ligation caused WSS to increase and neointima formation to be inhibited; the inhibition was reversed by l-NAME treatment. In group 2, CA diameter was about 20% larger than in groups 1 and 3 ($p < 0.05$).

Groups	n	WSS(dyne cm^{-2})	Intimal area(mm^2)	I/M area ratio (%)
Gr. 1 (LCCA collar)	8	58.8 ± 5.1	0.150 ± 0.030	29.00 ± 3.00
Gr. 2 (collar + RICA lig.)	8	69.1 ± 4.7*	0.040 ± 0.003*	8.00 ± 2.70*
Gr. 3 (collar + lig. + l-NAME)	8	129.2 ± 7.7*°	0.160 ± 0.030°	30.00 ± 3.00°

Means ± SEM; *$p < 0.05$ vs group 1, °$p < 0.05$ vs group 2

In conclusion, we demonstrate that in rabbit carotid arteries with collar-induced intimal thickening, a chronic increase in shear stress i) inhibits intimal thickening via NO production, and ii) produces a significant flow-dependent arterial enlargement that is also due to NO production, and that tends to normalize shear stress.

1882 VEGF receptor-2 (KDR) regulates endothelial function and angiogenesis via strong activation of eNOS-and iNOS-expression and via nitric oxide release in endothelial cells

Jens Kroll, Johannes Waltenberger. *Department of Internal Medicine II, Ulm University Medical Center, Ulm, Germany*

Vascular Endothelial Growth Factor-A (VEGF-A) is an endothelial-specific growth factor that induces angiogenesis, i.e. sprouting of capillaries from preexisting vessels *in vivo*. Endothelial nitric oxide synthase (eNOS) is an essential molecule in mediating VEGF-A-induced angiogenesis and endothelial function via production of nitric oxide (NO). It is unclear, however, which of the VEGF-receptors is mediating the signal for induction of eNOS expression and expression of other NOS isoforms and for the generation of NO in endothelial cells.

Human umbilical vein endothelial cells (HUVEC) were stimulated with VEGF-A for 24 hours and the expression of eNOS- and iNOS-protein was evaluated using Western blot analysis. VEGF-A induces expression of both eNOS and iNOS in HUVEC. Using porcine aortic endothelial cells overexpressing either VEGF receptor-2 (PAE/KDR cells) or VEGF receptor-1 (PAE/Flt-1 cells) stimulation of VEGF receptor-2 was found to upregulate both eNOS- and iNOS-protein, while stimulation of VEGF receptor-1 did not influence NOS expression. Moreover, formation of cGMP in endothelial cells as a marker for NO formation is exclusively mediated over VEGF receptor-2 in response to VEGF-A-stimulation.

In summary, only VEGF receptor-2, but not VEGF receptor-1, mediates stimulation of eNOS-and iNOS-expression and formation of NO in endothelial cells. These data further support the functional importance of VEGF receptor-2 in endothelial activation and angiogenesis.

1883 Oxidative stress is a major contributor to age-related endothelial dysfunction

B. van der Loo, R. Labugger[1], J. Kilo, M. Bachschmidt[2], D. Gygi[1], C. Barandier[1], D. Atar, T. Malinski[3], V. Ullrich[2], T.F. Lüscher. *Cardiology Dept., University Hospital Zurich, Zurich; [1]Cardiovascular Research, Institute of Physiology, Zurich, Switzerland; [2]Faculty of Biology, Department of Biochemistry, Konstanz, Germany; [3]Institute of Biotechnology, Oakland University, Rochester MI, USA*

Aging alters vascular function by exerting functional changes on endothelial cells. However, the nature of age-related endothelial dysfunction is not yet fully understood. We investigated whether increased breakdown of nitric oxide (NO) due to augmented production of free radicals such as superoxide (O_2^-) might be a mechanism involved in biological aging.

Aortas were used from 4–6 months old (Y; n = 8), 19 months old (M; n = 7) and 32–35 months old (O; n = 8) normotensive male rats and cut into rings 0.5 cm long. Rings were mounted in organ chambers connected to a force transducer for recording of isometric tension. For endothelium-dependent relaxations, vessels were contracted with norepinephrine ($2–3 \times 10^{-7}$ mol/L) until a plateau (about 70% of KCl 100 mmol/L) was reached and then relaxed with 10^{-10}–10^{-5} mol/L calcium ionophore A 23187 or acetylcholine (Ach). For endothelium-independent relaxations, deendothelialised rings were relaxed with sodium nitroprusside (SNP). In situ measurements of NO were carried out using a porphyrinic microsensor placed on the endothelial surface of vessels. NO release was induced by A 23187 (10^{-6} mol/L) and amperometric mode was used to detect changes of NO concentration. O_2^- concentration in tissue was determined by a chemiluminescence method using a scintillation counter.

Relaxations to both endothelium-dependent agonists were dramatically reduced in aortas obtained from old rats as compared with ones from young adult and middle-aged rats. Maximal responses to Ach were −95.4 ± 2.2% in young, −88.6 ± 2.5% in middle-aged and −61.5 ± 3% in old rats and to A 23187 −75.4 ± 0.8% in young, −73.9 ± 4.1% in middle-aged and −46.5 ± 3.6% in old rats (for both agonists Y vs O and M vs O: $p < 0.0001$; Y vs M: ns). Endothelium-independent relaxations to SNP were unaffected by age. Maximal NO levels measured by the porphyrinic microsensor were significantly lower in aortas obtained from old and from middle-aged rats compared with aortas from young rats (Y: 1197 ± 76 nmol/L; M: 831 ± 119 nmol/L; O: 340 ± 54 nmol/L; Y vs O: $p < 0.0001$, M vs O: $p = 0.0006$, Y vs M: $p = 0.0064$). Reciprocal changes in O_2^- release were observed. In aortic tissue of old rats there was a nearly threefold increase in O_2^- production (6058 ± 731 cpm/mg) compared with young (2302 ± 617 cpm/mg) and middle-aged (2145 ± 426 cpm/mg) animals (Y vs M: ns; Y vs O and M vs O: $p < 0.0001$).

In conclusion, oxidative stress, as reflected by elevated O_2^- levels, either due to an increased production and/ or to alterations of antioxidant defense systems, plays an important role in age-dependent endothelial dysfunction.

1884 Cardioprotection during ischaemia/reperfusion by an endothelin-A receptor antagonist is dependent on nitric oxide production in the pig

A.T. Gonon, A. Gourine, J. Pernow. *Department of Cardiology, Karolinska Hospital, Stockholm, Sweden*

Background: It has previously been shown that endothelin (ET) receptor antagonists protect the myocardium from ischaemia/reperfusion (I/R) injury. The mechanism behind this effect is unclear. The aim of the study was to elucidate the possible interaction between ET_A receptor antagonism and nitric oxide (NO) during I/R.

Methods: Anesthetised pigs were subjected to 45 min of ischaemia by ligation of the left anterior descendens coronary artery (LAD) followed by 4 h of reperfusion. Vehicle (n = 7), the selective ET_A antagonist LU 135252 (LU; 0.1 mg/kg, n = 7), the combinations of LU and the NO substrate L-arginine (1 mg/kg, n = 7) (LU + L-arg), or LU and the NO synthase inhibitor L-NMMA (0.2 mg/kg, n = 5) (LU + L-NMMA) were given into the LAD during the last 10 min of ischaemia and the first 5 min of reperfusion.

Results: There were no statistically significant differences in coronary flow, pulmonary capillary wedge pressure, mean arterial pressure, heart rate, or rate pressure product between the groups at the end of reperfusion. The area at risk was similar in all four groups. The infarct size of the vehicle group was 79 ± 6% of the area at risk. LU and LU + L-arg reduced the infarct size to 40 ± 6% and 35 ± 8%, respectively ($p < 0.05$ vs. vehicle). There was no significant additional cardioprotective effect of the combination of LU + L-arg compared to LU alone. Administration of L-NMMA completely prevented the infarct limiting effect of LU (infarct size 84 ± 4%; $p < 0.05$ vs. LU alone).

Conclusion: Local administration of LU and LU + L-arg during the last period of ischemia protects the myocardium from I/R injury by similar degrees. Inhibition of NO synthase reversed the cardioprotective effect of ET_A antagonism, suggesting that it is dependent on production of NO.

BASIC MECHANISMS FOR THE DEVELOPMENT OF DILATED CARDIOMYOPATHY

1885 Familial non-X-linked dilated cardiomyopathy: prevalence, inheritance and clinical characteristics

A. Repetto, A. Gavazzi, M. Giraldi, L. Scelsi, C. Inserra, M.L. Laudisa, M. Ceresa, B. Dal Bello[1], C. Campana, E. Arbustini[1]. *Division of Cardiology, IRCCS Policlinico S.Matteo, Pavia; [1]Department of Pathology, IRCCS Policlinico S.Matteo, Pavia, Italy*

Prevalences of overall famililal dilated cardiomyopathy (DCM), including X-linked forms, vary depending from different strategies of investigation. Aims of our study were to assess the prevalence of familial non-X-linked DCM, diagnose early asymptomatic cases, identify preclinical markers in relatives of index patients (pts), evaluate inheritance and characterize clinical phenotypes.

An accurate screening was carried out in 402 relatives of 89 consecutive pts diagnosed with DCM by invasive and non invasive methods, including endomyocardial biopsy. In all male index pts, known X-linked DCM were excluded with immunohistochemical and molecular methods. Relatives underwent clinical examination, echocardiographic, electrocardiographic and creatine-phosphokinase (CPK) determination.

Results: 25 out of 89 index pts (28%) had at least one proven affected relative. Juvenile familial rapidly progressive disease affected 4 youths (<20) who underwent emergency transplantation. In one family AV block was the first sign of the disease. Inheritance was autosomal dominant in 11, and not determined in 10. In 4, mitochondrial DNA pathologic mutations were found. In familial group, 21 alive members were diagnosed with DCM; 15 of them were totally unaware of their disease. In index pts of familial DCM transplantation ($p = 0.015$) and atrial fibrillation ($p = 0.03$) were more frequent and left bundle block branch ($p = 0.03$) less frequent. In corresponding relatives, the prevalence of combined instrumental abnormalities was higher in familial DCM ($p = 0.04$).

Conclusions: familial non X-linked DCM was diagnosed in 28% of DCM pts; 4 pts showed a juvenile dramatic phenotype. The immediate benefit of relative screening was the identification of 15 affected, unaware pts, all younger than 30. Relatives with instrumental abnormalities entered a regular follow-up protocol.

1886 Left ventricular enlargement in relatives of dilated cardiomyopathy patients: indication for early angiotensin-converting enzyme inhibition?

Z.T. Bilińska, E. Michalak, J. Grzybowski, B. Kuśmierczyk-Droszcz, M. Skwarek, J. Janas, W. Rydlewska-Sadowska, W. Rużyłło. *National Institute of Cardiology, Warsaw, Poland*

There is increasing awareness of familial nature of dilated cardiomyopathy (DCM) and of the fact that a sizable proportion of DCM relatives has left ventricular enlargement (LVE).

We screened 300 relatives (Rels) (mean age 28.7 years, 154 male, 219 1st degree) of 58 consecutive DCM patients (5.2/family); the diagnosis of DCM was based on WHO criteria. Familial DCM was defined as >1 affected member with DCM. The study protocol included: clinical examination, 12-lead electrocardiogram and two-dimensional echocardiogram. LVE was defined according to method of Henry (%LVEDD > 112). Besides, we measured N-terminal ANP plasma levels by radioimmunoassay in 81 Rels and assessed these values in relation to LVE.

280 Rels had a diagnostic echocardiogram (93.4%); 42 were found to be hypertensive (14%) and were assessed seperately. Familial DCM was defined as >1 affected member with DCM.

Based on the screening we have identified 14 asymptomatic Rels (5.7%) with DCM from 12 families. Thus, we found that familial prevalence of the disease was 20.7% (12/58 families). Of the 246 asymptomatic Rels 80 (32.5%) were found to have LVE. N-terminal ANP plasma levels were higher in Rels with LVE than in those without LVE ($p < 0.05$).

We reassessed with the same protocol 106 Rels after 3.8 ± 1.5 years. Of the 36 Rels with LVE during screening phase (36/106, 33.9%) 9 (25%) progressed to DCM. This was accompanied by a rise in N-terminal ANP plasma level ($p < 0.0001$). Mean percentage fractional shortening in the whole group decreased from 33.1 ± 5.5% to 30.7 ± 4.7%; $p = 0.001$.

Our study demonstrates that: 1) familial DCM is observed in at least 21% of the patients; 2) LVE is common in relatives of patients with the disease and may represent early disease changes; 3) systematic follow-up is necessary to identify relatives who progress to DCM; 4) neurohormonal activation in relatives with LVE indicates that ACE-inhibition may be useful in halting/delaying progression from LVE to DCM.

1887 Mitochondrial DNA mutations and polymorphisms in idiopathic dilated cardiomyopathy

J. Marin-Garcia, Y. Hu, R. Ananthakrishnan, M.J. Goldenthal. *Molecular Cardiology Institute, Highland Park NJ, USA*

In the human genome, single nucleotide substitutions are the most common form of sequence variation and disease-causing mutation. In this study, we report the DNA sequence analysis of all the tRNA and structural genes of mitochondrial DNA (mtDNA) derived from cardiac tissues of 27 patients (16 adults, 11 children) with idiopathic dilated cardiomyopathy (IDC). Multiple changes in mtDNA sequence were found relative to control sequences. Novel mutations were found in 12 tRNA genes (including Phe, Ile, Ala, Asn, Cys, Asp, Lys, Arg, His, Leu, Thr) as well as previously reported tRNA changes (MITOMAP) in 6 genes (Ile, Leu, Asp, Gly, Arg, Thr). Novel mtDNA mutations (13) specifying amino acid residue changes were found in COI, COII, COIII, ND3, ND6 and cytb. An additional 26 mtDNA point mutations resulting in amino acid substitutions were found which have been previously reported (MITOMAP). None of the mutations previously found in association with hypertrophic cardiomyopathy were detected In addition, a large number of polymorphic nucleotide changes with no amino acid substitution were present equally distributed throughout the mitochondrial genome. While the majority of these changes represent previously reported polymorphisms, a significant number of new nucleotide substitutions were present in IDC patients. The pathogenicity of these mtDNA mutations and polymorphisms, and their potential contributory role in the severity of cardiomyopathy are currently being studied.

1888 Apoptosis detected by DNA fragmentation and anti-transglutaminase staining in enterovirus-associated dilated cardiomyopathy

U. Lotze[1], J. Busch[1,2], A. Aschoff[2], B. Glück[3], H. Sigusch[1], H. Kühnert[1], G. Dannberg[1], G. Jirikowski[2], A. Stelzner[3], H.R. Figulla[1]. *[1]Department of Internal Medicine; [2]Anatomy; [3]Virology of Friedrich-Schiller-University Jena, Germany*

In patients with endstage heart failure a higher rate of apoptosis (Apo-R) of the myoctes has been found as opposed to normal control subjects. However, the relation between Apo-R and cardiac enterovirus infection in idiopathic dilated cardiomyopathy (DCM) is not yet known. Therefore, the purpose of the present study was to investigate the Apo-R of myocytes from right ventricular endomyocardial biopsies in patients (P) with enterovirus-positive and enterovirus-negative DCM.

Methods: The Apo-R was assessed histochemically in 18 consecutive P (13 male, mean age 49 ± 10 years) with idiopathic DCM (LVEF < 55%) on semithin sections (1 μm) using in-situ end labelling with bromodesoxyuridine (BrdU) for demonstrating DNA-fragmentation. Since DNA-fragmentation alone is not specific for apoptosis, an additional staining of the transglutaminase, which represents an essential enzyme in the late phase of apoptosis, was performed. All myocytes showing both DNA-end labelling with BrdU of the nuclei and a positive anti-transglutaminase staining in the cytoplasm were defined as apoptotic. The enterovirus genome was detected by enterovirus-specific polymerase chain reaction (One-Step-RT-PCR).

Pat. with DCM (n = 18)	LVEDD (mm)	LVEF (%)	PCWP (mmHg)	DNA-end labelling + anti-transglutaminase (% positive) = Apo-R
PCR positive (n = 8)	68 ± 10	46 ± 7	17 ± 9	8 ± 3
PCR negative (n = 10)	68 ± 8	38 ± 11	14 ± 7	14 ± 5
	NS	NS	NS	p = 0.01

Conclusion: Enterovirus-positive DCM did not significantly differ from enterovirus-negative DCM with regard to hemodynamic parameters, but showed a significantly lower Apo-R. Our results favour the concept that enteroviruses produce protein inhibitors of apoptosis as has been already shown for other viruses.

1889 Increased expression of tumour necrosis factor-α-converting enzyme and tumour necrosis factor-α in advanced left ventricular dysfunction in human dilated cardiomyopathy

M. Satoh, M. Nakamura, H. Saitoh, H. Satoh, I. Segawa, K. Hiramori. *Second Department of Internal Medicine, Iwate Medical University School of Medicine, Morioka, Iwate, Japan*

The expression of tumor necrosis factor-α (TNF-α) has been posited as an important factor in left ventricular (LV) dysfunction associated with dilated cardiomyopathy (DCM). TNF-α-converting enzyme (TACE) has recently been purified and its complementary DNA cloned. The aim of this study was to determine whether TACE expressed with TNF-α in myocardium and whether TACE and TNF-α contribute to LV dysfunction in DCM.

Methods: Myocardial tissues were obtained from DCM patients (n = 51, age 56 ± 14 yrs) and 10 control subjects (CS) using endomyocardial biopsy. TNF-α and TACE mRNA levels were measured by a novel real time quantitative reverse transcriptase-PCR method. The expression of these proteins was also examined immunohistochemically.

Results: TACE mRNA expression increased to a significantly greater extent in the DCM group than in CS (TACE/GAPDH, 7.72 ± 2.40 vs 0.04 ± 0.02, p < 0.05). TNF-α mRNA expressed in the DCM group (TNF-α/GAPDH; 1.40 ± 0.31), while no expression was seen in CS. A positive correlation was found between TNF-α and TACE mRNA levels (r = 0.701, p < 0.001). TACE immunostaining was found in cytoplasm of myocytes in 22 DCM patients. TNF-α immunostaining was positive in myocytes and endocardium in 25 DCM patients. The differences in TNF-α and TACE mRNA levels between the 2 subgroups of DCM divided by LV geometry and LV systolic function are shown in the table.

	LV systolic diameter (mm)		LV ejection fraction (%)	
	<50 (n = 28)	≥50 (n = 23)	<35 (n = 15)	≥35 (n = 36)
TACE/GAPDH	1.81 ± 0.65	6.81 ± 1.11*	7.63 ± 1.59	2.58 ± 0.60*
TNF-α/GAPDH	0.89 ± 0.39	2.02 ± 0.46*	2.40 ± 0.77	0.98 ± 0.27*

Mean ± SD; *p < 0.05

In conclusion: These findings suggest that expression of TACE and TNF-α in myocardium may possibly play an important role in the progression of LV dysfunction in human DCM.

1890 Endothelin receptor density is closely related with cardiomyocyte diameter in dilated cardiomyopathy

P.A. Modesti, S. Vanni, X. Jianming, A. Vetere, G. Galanti, G.F. Lisi[1], G. Sani[2], G.G. Neri Semeri. *Clinica Medica Generale e Cardiologia, University of Florence, Florence; [1]Thoracic and Cardiovascular Surgery, University of Siena, Siena; [2]Department of Cardiosurgery, University of Cagliari, Cagliari, Italy*

Endothelin-1 have contractile and growth effects on cardiomyocytes both in vitro and in vivo. In the present study the relationship between cardiac function, cardiomyocyte diameter and ET-1 receptor density was investigated in 39 hearts from transplant recipients with heart failure (III or IV NYHA class) due to either idiopathic dilated (DCM, n = 22) or ischemic cardiomyopathy (ICM, n = 17) and from five potential donors excluded from organ donation for non cardiac reasons.

ET-1 receptor density was significantly higher in myocytes from ICM than from DCM (62 ± 4 vs 43 ± 6 fmol/mg, p < 0.01) without differences in Kd. The average diameter of myocytes was larger in ICM (20.1 ± 1.8 μm) than in DCM patients (17.2 ± 0.9 μm, p < 0.001) and controls (15.2 ± 1.5 μm, p < 0.001). At univariate and multivariate stepwise regression analysis the ET receptor density on cardiomyocytes was positively related to the average diameter of myocytes (r = 0.85, p < 0.0001) but not with ejection fraction, fractional shortening and end systolic stress.

In competition studies ETA (PD155080) and ETB (BQ 788) selective antagonists revealed that the ETA subtype represented about 90% of total ET-1 receptors in myocytes from both patient groups as confirmed at the mRNA level by in situ hybridization studies (ETA and ETB cDNA probes from ATCC). Furthermore Northern studies of mRNA ETA and ETB receptors revealed that ETA but not ETB mRNA expression were significantly related with myocyte diameter (r = 0.73, p < 0.001; and r = 0.33, ns respectively).

In conclusion ETA but not ETB receptor density is closely related with cardiomyocyte diameter in dilated cardiomyopathy.

INFECTIVE ENDOCARDITIS – NEW INSIGHTS INTO DIAGNOSIS AND PROGNOSIS

1891 Value of new diagnostic criteria in prosthetic valve endocarditis

G. Habib, J.F. Avierinos, G. Derumeaux, C. Médail, J.P. Casalta, F. Biou, M. Garcia, P. Ambrosi, D. Raoult, R. Luccioni. *Cardiologie B, La Timone Hospital, Marseille, France*

Background: Duke criteria (DC) have been shown to be sensitive in diagnosing native valve infective endocarditis (IE), but their accuracy in pts with prosthetic valve endocarditis (PVE) are not known. We recently proposed modified Duke criteria (MDC) in which serologic diagnosis of Q fever was accepted as a major criterion and IE was considered as "definite" even when only 1 major and 2 minor criteria were present in pts with prior antibiotic therapy and typical echocardiographic findings.

Objectives: To assess the value of DC and MDC in pts with PVE.

Methods. DC and MDC were applied in 131 consecutive pts with proved IE (with pathological confirmation in 93 cases). Blood cultures (BC), serology of Q fever, transthoracic and transoesophageal echocardiography (TOE) were performed in all. Fourty-two pts with PVE (group 1) (16 bioprosthetic, 23 mechanical, 3 homografts) were compared with 89 pts with native IE (group 2).

Results: Using DC, the sensitivity for diagnosis of IE was lower in group 1 than in group 2 (64 vs 84%, p < 0.01), 15 (36%) of 42 pts with proved PVE being misclassified as "possible IE" using DC. The causes for misclassification were negative BC in 8 pts (resulting from prior antibiotic therapy in 6), Q fever IE in 3 pts, and a negative TEE in 3 pts. Application of MDC resulted in a better diagnosis of PVE, with sensitivities of 81 and 92% in groups 1 and 2, respectively.

Conclusion: (1) clinical diagnosis of IE is more difficult in pts with prosthetic than in pts with native IE.

(2) DC have a relatively low sensitivity in these pts.

(3) Use of MDC allows improvement in the clinical diagnosis of PVE

1892 Molecular diagnosis of endocarditis – a new Duke's criterion?

B.C. Millar, J.E. Moore, P. Mallon, M.J. Crowe, R.B. McClurg, M.D. Curran[1], J.A.P. Earle[2], B. Rima[2], P.G. Murphy. *Bacteriology Dept., [1]Immunogenetics and Histocompatability, Belfast City Hospital, Belfast; [2]Genetic Engineering Dept., The Queen's University of Belfast, Belfast, UK*

Infective endocarditis is associated with a high degree of morbidity and mortality. Duke's criteria is now recognized as the most accurate diagnosis and classification of this disease. The aim of this current study was to examine blood culture material from such patients both by cultural and novel molecular techniques. The molecular approach of PCR amplification of genes specific for bacteria (16S rRNA) and fungi/yeast (28S rRNA) and sequencing was used to identify the possible microbial agent(s) responsible for the infection. Blood culture material from six patients were positive by both culture (Staphylococcus aureus, coagulase negative staphylococci [CNS], Streptococcus mitis (2), MRSA, Haemophilus influenzae) and PCR (S. aureus, S. epidermidis, S. gordonni, S. mitis/pneumoniae, MRSA, H. influenzae/aegyptus), respectively. Blood culture material from four patients were negative by culture except for isolated cultures which were classified as environmental contaminants namely Corynebacterium spp., Micrococcus spp., CNS and Propionibacterium spp, which were also identified by PCR. However, blood culture material from one patient revealed the presence of DNA from Propionibacterium acnes in three sets of blood cultures, indicating that it may have been the causative agent. Seven patients' blood culture were culture-negative but PCR-positive for Acinetobacter spp. (1), Nocardiodies spp. (2), Nocardiodes albus (1), Candida-like spp. (1). Bacterial DNA was identified in three other patients but the sequence data was mixed and could not confirm the identity of the organism detected. These findings were analysed along with the patients' clinical background in light of the Duke's criteria.

These results demonstrated that (i) all patients who were classified as definite or possible endocarditis cases by Duke's criteria were positive by PCR, (ii) all patients who were rejected as having endocarditis according to this criteria were negative by PCR except for one patient who had bacteraemia originating from a different source. These findings indicate that a molecular approach may aid in the diagnosis of endocarditis and should therefore be included as an additional criterion in the Duke's classification scheme. In conclusion, molecular identification of the aetiological agents responsible for endocarditis directly from blood culture material will enable specific treatment directed at this agent to be commenced at an earlier stage of the disease and hence reduce the need for valve replacement.

1893 Clinical course of infective endocarditis in the late nineties: preliminary results of the ALKK endocarditis registry

O. Benetka[1], M. Block[1], O. Sangha[2], F. Praetorius[3], M. Gottwik[4], R. Uebis[5], K.L. Neuhaus[6], R. v. Essen[1]. *On behalf of the ALKK, Arbeitsgemeinschaft Leitender Kardiol. Krankenhausärzte; [1]Stiftsklinik Augustinum München; [2]Bayr. Forschungsverbund LMU München, [3]Städt. Kliniken Offenbach; [4]Klinikum Nürnberg-Süd; [5]Klinikum Aschaffenburg; [6]Klinikum Kassel, Munich, Germany*

Recent multicenter clinical data on infective endocarditis (IE) is not available. Therefore, the ALKK conducted a prospective registry on cases of IE diagnosed between January 1996 and December 1998.

Methods: Using a standardized questionaire, more than 70 parameters concerning the patient's demography, predisposing factors, the source of IE, its clinical manifestation, the performed diagnostic and therapeutic procedures as well as the course of the disease were assessed and evaluated in a preliminary descriptive analysis of 327 patients from 51 hospitals.

Results: The patients (59% male) were on average 59 ± 17 years old. Symtoms of IE started on average 43 ± 38 days prior to diagnosis. In 44% of patients IE complicated preexisting heart disease.

At the time of hospitalization the temperature was 39.1 ± 1.2°C, heart murmurs were heard in 56% of patients, the ESR (erythrocyte sedimentation rate) was elevated to 75 ± 4 mm/h, 19% of patients showed enlargement of the spleen and 6% cutaneous lesions. 12% of patients presented with neurological complications and 26% heart failure NYHA III/IV.

The aortic valve was infected in 52% of patients, the mitral valve in 51% and the tricuspid valve in 5%. Infections frequently involved mechanical (13%) or biologic (8%) prosthetic valves, or rarely mitral valves after surgical repair. 73% of all patients had positive blood cultures, Staph. aureus in 31%, Streptoccocus in 24%, Enterococcus in 12%, and Staph. epidermidis in 4%.

Every 4th patient had undergone antibiotic therapy prior to hospitalization and before blood cultures were obtained. Almost every other patient was treated without an antibiogram. 16% of the patients died, 33% suffered NYHA III/IV, 17% had cerebral and 14% peripheral emboli, 4% needed dialysis. 39% received a prosthetic valve.

Thus, even in the late nineties infective endocarditis is often treated without an antibiogram and causes severe morbidity and significant mortality.

1894 Determination of long-term prognostic factors of mortality in infective endocarditis from a consecutive series of 173 patients

C. Selton-Suty, T. Doco-Lecompte, B. Brembilla-Perrot, A. Grentzinger, P. Houplon, V. Baty, P. Canton, B. Hoen, Y. Juillière. *Cardiology, CHU Nancy-Brabois Brabois, France*

In order to study long-term prognostic factors of infective endocarditis (IE), we prospectively included all the patients who were treated as IE at our university Hospital between November 1990 and December 1997. All initial parameters concerning clinical and bacteriological features were collected. A questionnaire was sent in June 1998 to every patient's general practitioner and cardiologist to collect information about his/her health, and the need for secondary valvular surgery.

Among the 172 pts enrolled, 35 (20.3%) died during the inital hospital stay. As 14 (8%) pts were lost of follow-up, 123 pts were included in our follow-up study (92 M/31 F, 56 ± 16 yrs, 47 pathologically definite, 76 clinically definite IE according to the Duke criteria). Among them, 24 (19.5%) died during the FU period (9 cardiac causes, 7 extra-cardiac causes, 8 unknown reasons), and 11 pts (8.9%) needed secondary valvular surgery. Mean follow-up duration was 3.7 ± 2.1 yrs. Kaplan-Meier survival was 58.2 ± 9.5% at 7 yrs. The effects of the following parameters on long-term mortality were tested by univariate (log-rank) and multivariate (Cox model) analysis: age, previous IE, preexisting heart disease, valvular prostheses, fever, site of IE, causative micro-organisms, extracardiac manifestations, cerebral embolism, significant valvular regurgitation, vegetation at echocardiography, need for valvular surgery during the initial period. Univariate analysis identified age ($p = 0.001$) and lack of initial valvular surgery ($p = 0.05$) as significant factors of mortality. In multivariate analysis, age was the only independant predictor of long-term mortality (RR 1.06, 95% CI 1.02–1.1, $p = 0.002$).

IE still has a high short-term and long-term mortality, probably partly resulting of the high incidence among the elderly. Valvular surgery might be considered more often during the acute phase of IE.

1895 Risks of infective endocarditis in patients with minimal and mild aortic regurgitation

R. Mury, G. Schenk, B.C. Aeschbacher. *Cardiology, University Hospital Berne, Switzerland*

Background: It is not known, if **minimal or mild** aortic regurgitation (AR) is a predisposing situation for the development of infective endocarditis (IE) of the aortic valve

Methods: Of 17,065 echocardiographic examinations, 1878 fulfilled the inclusion criteria (minimal or mild aortic AR, no aortic stenosis, no prosthetic valve in aortic position and no heart transplantation). Events causing possible bacteremia according to the recommendations of the American Heart Association of 1997 and cases of IE were evaluated by a questionnaire. Cause of death was identified.

Results: Return rate was 99.2%, 12 patients prefered not to answer. Mean age was 65 ± 15 years (range 15–92), male 60.3%, female 39.7%, mean follow-up was 31.9 ± 15.9 months (range 7–67), total follow-up 3794 patient-years. Total bacteremia producing events were 2783 (1.95 per patient, 0.73 per patient-year), 254 patients (18%) hold an antibiotic prophylaxis passport. Two patients have had documented IE of the aortic valve according to Duke's criteria resulting in a calculated incidence of 52 IE/100,000 patient-years. Both had no preventable bacteremia producing event.

Conclusion: The calculated incidence rate of 52 IE/100,000 patient-years in patients with minimal or mild AR was inexpectedly high and is comparable to the risk of patients with mitral valve prolaps and audible systolic murmur. Consequently recommendations for prophylactic use of antibiotics should include minimal and mild AR. However, in both cases no preventable bateremia producing event was present. Large scale studies will be necessary to elucidate the efficacy and cost-effectiveness of antibiotic prophylaxis to prevent IE in patients with moderatly increased risk.

1896 Pacemaker endocarditis. main characteristics

E. Palacios[1], C. Sarriá[1], I. Vilacosta[2], C. Graupner[2], O. Sanz[3], J.A. San Román[3], J.V. Sanmartín[1], W. Stoermann[2], F. Pérez Gómez[2], R. Morales[2]. *[1]Hospital de la Princesa, Madrid; [2]Hospital Universitario de San Carlos, Madrid; [3]Hospital Universitario de Valladolid, Spain*

The objetive of this study was to describe the clinical course, microbiological profile, echocardiographic characteristics, and risk factors of patients (P) with pacemaker endocarditis (PE).

Methods: We analyzed 25 p of PE with definitive Duke criteria that were prospectively recruited (18 male, mean age 63 years)

Results: Main predisposing factors for infection were local: persistance of more than one lead in 17 p and more than one generator or electrode replacement in 11 p. The most common port of entry was skin erosion in 10 p and pouch infection in 6 p. Causal microorganisms were coagulase negative *staphylococci* in 17 p, *S. aureus* in 4 p, polymicrobial in 2 p, and culture negative in 2 p. Lung infiltrates compatible with septic embolism were found in 8 p. Time to diagnosis was 52 days (1–270). Transthoracic echocardiography was negative for PE in 21 p. Transesophageal echocardiography (TEE) was positive in 20 p: vegetation (veg) lead in 14 p, tricuspid veg in 1 p, veg lead plus tricuspid veg in 5 p, mural veg in 1 p, no veg in 5 p. Initial treatment was cardiotomy in 18 p (group I) percutaneous removal in 3 p (group II), and medical treatment without prosthetic removal in 4 p (group III). Lead extraction was incomplete in 1 p from gr I and in other from gr II, both of them relapsed and 1 developed a local thrombosis. There were 2 relapses and 1 local thrombosis in gr III, one of them died when percutaneous lead removal was attempted. Twenty one p become cured (17 p in gr I, 2 p in gr II, and 2 p in gr III). Cardiotomy was performed in 2 p that relapsed: 1 p cured, and 1 p relapsed due to incomplete lead extraction. Two p with retained leads required long term oral supressor antibiotic therapy for an adequate infection control.

Conclusions: Main risk factors for PE were local. The most common port of entry was generator pouch skin erosion. Main pathogens were coagulase negative *staphylococci*. TEE was very sensitive for PE diagnosis. Presence of retained material was an important predisposing factor for recurrence or thrombotic complications. Cardiotomy was the most succesful treatment.

CARDIOPROTECTION: NEW STRATEGIES

1906 Cloning of an AMP-selective cytosolic 5′-nucleotidase-I that produces adenosine inside cells

Graciela B. Sala-Newby, Andrzej C. Skladanowski[1], Andrew C. Newby. *Bristol Heart Institute, University of Bristol, Bristol, UK; [1]Department of Biochemistry, Medical University of Gdansk, Gdansk, Poland*

In the heart, adenosine increases blood flow and decreases excitatory nerve firing, thereby reducing rate and force of contraction. It also preconditions the heart against injury by prolonged ischaemia. Based on indirect kinetic arguments, an AMP-selective cytosolic 5′-nucleotidase designated cN-I has been implicated in adenosine formation but this has not been cloned or shown directly to produce adenosine during ATP breakdown.

Methods: We purified cN-I from pigeon heart for partial protein sequencing. We then designed degenerate antisense oligonucleotide primers for touchdown PCR to generate a fragment with which to screen a pigeon ventricle cDNA library in λZap II. A full-length cDNA clone was obtained and then subcloned into the eukaryotic expression vector pTargeT. COS-7 cell were transfected using lipofectamine with pSV-β-galactosidase as a control for transfection. Cells were incubated with 10 μM EHNA and 50 μM 5′-amino-5′-deoxyadenosine to inhibit adenosine deaminase and kinase respectively. 10 mM 2-Deoxyglucose and 1 μM FCCP were added to inhibit glycolysis and mitochondrial ATP synthesis. Nucleosides and nucleotides were measured by HPLC and cell viability by LDH release.

Results: The full length clone encoded a novel 40 kDa peptide, unrelated to the IMP/GMP selective cytosolic 5′-nucleotidase (cN-II) or the ecto-5′-nucleotidase (e-N) that have already been cloned. Its mRNA was most abundant in heart, brain and breast muscle. Immunolocalisation in heart showed a striated cytoplasmic location suggesting association with contractile elements. Transient expression in COS-7 cells, generated a 5′-nucleotidase which catalysed adenosine formation from AMP that was increased during ATP breakdown.

In conclusion: We have cloned and expressed cN-I and provided definitive evidence of its ability to produce adenosine during ATP breakdown. Future experiments will address its function in the heart.

1907 Transient activation of adenosine A_1 receptors induces delayed cardioprotection in rats: role of Mn-superoxide dismutase

A. Dana, A.K. Jonassen, D.M. Yellon. *The Hatter Institute, UCL Hospitals & Medical School, London, UK*

We have previously described delayed preconditioning in rabbits 24–72 h after transient adenosine A_1 receptor activation which is associated with enhanced activity of the mitochondrial antioxidant manganese superoxide dismutase (Mn-SOD). In this study we further examined the role of Mn-SOD in mediating delayed cardioprotection. Wistar rats received a single iv bolus of the selective adenosine A_1 agonist 2-chloro-N^6-cyclopentyladenosine 75 μg/kg (CCPA) or saline vehicle (SAL). They were also treated with a 22-mer phosphorothioate oligodeoxynucleotide (ODN) with sequence anti-sense (AS-ODN) to the initiation site of rat Mn-SOD mRNA at a dose of 5 mg/kg by slow iv infusion. The sense (S-ODN) and scrambled ODN (Scr-ODN) were used as controls. 24 h later, rats were anaesthetised, hearts isolated and Langendorff perfused with Krebs-Henseleit buffer at constant pressure. Hearts were subjected to 35 min regional ischaemia and 2 h reperfusion. Risk zone (R) and infarct size (I) were determined with fluorescent microspheres and tetrazolium staining respectively. CCPA treatment significantly reduced the I/R ratio (*$p < 0.0001$) compared to the control group. This protection was completely abolished by prior treatment with AS-ODN which on its own had no effect on infarct size. S-ODN or Scr-ODN did not affect CCPA induced delayed cardioprotection.

	SAL	CCPA	AS-ODN+		S-ODN+	Scr-ODN+
			CCPA	SAL	CCPA	CCPA
n	12	9	8	8	8	7
I/R (%)	42.1 ± 3.8	22.3 ± 3.3*	39.4 ± 2.8	44.5 ± 4.9	24.7 ± 3.9*	29.3 ± 1.8*

Figures are Mean ± S.E.M. *$p < 0.0001$ vs other groups (1-way ANOVA)

This is the first study to show that transient adenosine A_1 receptor activation induces delayed cardioprotection in the rat. These results also strongly suggest an important role for Mn-SOD as a potential end-effector of this protection.

1908 Myocardial infarct size is reduced by post-ischaemic treatment with dipyruvyl-acetyl-glycerol and the associated elevation in pyruvate levels

W.C. Stanley, K.M. Kivilo, P. Hallowell[1], H. Brunengraber[1]. *Dept. of Physiology and Biophysics, Case Western Reserve University, Cleveland OH; [1]Dept of Nutrition, Case Western Reserve University, Cleveland OH, USA*

The beneficial effects of pyruvate in organ reperfusion injury has been widely documented, nevertheless the therapeutic use of pyruvate has been hindered due to the lack of an appropriate delivery method. Pyruvic acid is unstable for infusion and high rates of sodium pyruvate infusion cause sodium overload. Dipyruvyl acetyl glycerol (DPAG) ester was developed as a novel method for intravenous pyruvate delivery. This approach allows one to deliver pyruvate a high rate without the confounding effect of sodium toxicity. We tested the cardioprotective effect of this novel compound in an anesthetized open chest pig model of myocardial infarction. Ischemia was induced by total occlusion of the distal 2/3 of the left anterior descending coronary artery for one hour. This was followed by two hours of reperfusion. During the two hour reperfusion period animals were either left untreated (n = 7) or treated with an intravenous infusion of DPAG at the rate of 8.0 mg/kg*min. Infarct size was measured on blinded samples by the tetrazolium staining method. Treatment with DPAG resulted in an elevation in arterial pyruvate levels to 0.688 ± 0.132 mM, compared to 0.001 ± 0.001 mM in untreated animals. Treatment with DPAG resulted in a 35% reduction in infarct size, from 30.8 ± 4.6% of the area at risk for infarction in the control group to 20.1 ± 4.2% of the area at risk in the treatment group ($p < 0.05$).

In conclusion peripheral intravenous infusion of DPAG during the post-ischaemic reperfusion period elevates arterial pyruvate levels and reduces myocardial infarct size. Thus DPAG is an effective means to deliver high amounts of pyruvate systemically, and elicit the cardioprotective effects of pyruvate.

1909 Protection of the reperfused ischaemic pig myocardium by selective stimulation of myocardial EP3 receptors

T. Hohlfeld, J. Meyer-Kirchrath, K. Schrör. *Institut für Pharmakologie, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany*

We have previously identified G protein coupled prostaglandin EP3 receptors in porcine myocardium, which are upregulated during acute myocardial ischemia (Hohlfeld et al., Circ Res 81:765, 1997). Here, we report that EP3 receptor stimulation by a selective agonist improves myocardial tolerance against ischemic myocardial injury. Anesthetised open-chest minipigs (25–35 kg bw.) were subjected to coronary (LAD) occlusion for 1 h and susequent reperfusion for 3 h. The selective EP3 receptor agonist M&B 28.767 (1 nmol/min) or vehicle were infused into the LAD (i.c.), starting 20 min prior to ischemia, until the end of reperfusion. In vehicle-treated pigs, infarct size (tetrazolium staining) was 76 ± 7% of the area at risk. EP3 receptor stimulation by MB significantly reduced infarct size to 36 ± 7% (n = 7–8 per group, $p < 0.01$) and significantly ($p < 0.05$) reduced transcardiac creatine kinase release by 48%. For further analysis, regional myocardial contractile function was recorded (sonomicrometry) during i.c. infusion of M&B 28.767 to non-ischemic hearts (n = 6). While EP3 receptor stimulation did not alter basal left ventricular contractility, the positive inotropic effect of the beta-adrenergic agonist isoprenaline (3 μg/min, i.v.) was almost prevented. This is consistent with additional data from in vitro studies, that demonstrate coupling of transfected porcine EP3 receptors (CHO cell line) to an inhibitory G protein. Similar results were obtained with the nonselective EP receptor agonist PGE1 (1 nmol/min, i.c.). In control experiments, the EP2 selective agonist butaprost was inactive.

It is concluded that myocardial EP3 receptors mediate the protection from ischemic myocardial injury by E-type prostaglandins. This effect may involve the prevention of deleterious actions caused by the ischemia-induced overflow of catecholamines.

1910 Ischaemia/reperfusion-induced myocardial and coronary dysfunction in adult and aged hearts: protective effects of the inhibition of Na-H exchange and of endothelin receptors

S. Besse[1], P. Assayag[1,2], S. Tanguy[1], J. de Leiris[1], F. Boucher[1], B. Swynghedauw[3]. [1]*ESA CNRS 5077, Université Joseph Fourier, Grenoble;* [2]*Service de Cardiologie, Hôpital Bichat;* [3]*INSERM U127, Paris, France*

The senescent heart is vulnerable to low-flow ischemia, which induces greater myocardial and coronary tone alterations. Na-H exchange (NHE) is involved in myocardial calcium overload, and endothelin is suspected to induce coronary vasoconstriction during ischemia and reperfusion (I/R). We investigated the effects of the inhibition of NHE with HOE642 (10^{-6} M), and of the endothelin receptors with Bosentan (10^{-5} M) on hearts of 4 (adult) and 24 (senescent) month old rats (mo) subjected to I/R. Isolated hearts were subjected to low-flow ischemia (45 min at 15% of initial coronary flow (CF)) and reperfusion, without (4 mo-I/R; 24 mo-I/R) or with HOE642 (4 mo-HOE; 24 mo-HOE), or with Bosentan (4 mo-BOS; 24 mo-BOS). Active tension (AT) and CF were recorded at baseline and after 5 and 30 min of reperfusion.

Results: mean ± SEM (in % of baseline values).

	AT		CF	
	5 min	30 min	5 min	30 min
4 mo-I/R (n = 9)	83 ± 4	77 ± 4	87 ± 8	73 ± 6
4 mo-HOE (n = 10)	79 ± 5	68 ± 6	73 ± 8	68 ± 10
4 mo-BOS (n = 9)	75 ± 5	73 ± 3	127 ± 11*	121 ± 12*
24 mo-I/R (n = 9)	74 ± 6	50 ± 7†	75 ± 11	52 ± 9†
24 mo-HOE (n = 8)	94 ± 4*	90 ± 6*	99 ± 11	96 ± 17*
24 mo-BOS (n = 7)	90 ± 3	80 ± 4*	111 ± 4*	111 ± 9*

*$p < 0.05$ vs age-matched I/R group. †$p < 0.05$ 24 mo-I/R vs 4 mo-I/R group.

Conclusion: 1) Post-ischemic contractile and coronary dysfunctions are greater in the senescent rat heart 2) Inhibition of endothelin receptors fully restores coronary flow during reperfusion in senescent as in adult hearts, suggesting a predominant role of endothelin on I/R-induced coronary alterations, and improves senescent contractile recovery 3) NHE inhibition markedly improves contractile recovery in the aged heart, suggesting an important role of NHE in I/R alterations of the aged myocardium.

1911 Potential cardioprotective role of insulin at reperfusion by a possible anti-apoptotic mechanism

A.K. Jonassen[1], B.K. Brar[2], O.D. Mjøs[1], M.N. Sack[3], D.S. Latchman[2], D.M. Yellon[3]. [1]*Dept. Medical Physiology, University of Tromsø, Norway; Dept. of Molecular Pathology, Windeyer Insitute of Medical Sciences, UCL;* [3]*The Hatter Institute, UCL, United Kingdom Hospitals & Medical School*

Early and complete reperfusion of ischaemic myocardium is essential for tissue salvage, but can paradoxically contribute to cell death (reperfusion injury). Although the majority of cell death during myocardial ischaemia-reperfusion results from cellular necrosis, we hypothesise that programmed cell death (apoptosis) may contribute to overall myocyte death during the reperfusion period. We investigated the potential cardioprotective role of insulin (0.3 mU/ml) given at the moment of reperfusion in isolated rat hearts subjected to 35 min regional ischaemia and 120 min reperfusion. We also describe experiments in isolated rat cardiomyocytes undergoing 6 h of lethal hypoxia and 2 h of reoxygenation, investigating the possible contribution of an anti-apoptotic effect of insulin to its cardioprotective action. The effect of inhibiting the signalling pathways with respect to protein tyrosine kinase and phosphatidylinositol 3-kinase (PI3-kinase) was assessed using 0.1 μM Lavendustin A (Lav) and 1 μM Wortmannin (Wort), respectively. Reperfusion/reoxygenation treatment with insulin significantly reduced infarct size and the percentage of apoptotic cells, and this protective effect was abolished by either Lav or Wort.

	Isolated Hearts		Isolated myocytes	
Group	n	% I/R	% apoptosis (TUNEL)	% apoptosis (Annexin V)
Control	7	46.2 ± 2.5	49.2 ± 3.1	65.0 ± 2.9
Ins at reperfusion	9	23.3 ± 2.8*	28.5 ± 1.8*	34.5 ± 2.4*
Lav alone	6	50.3 ± 3.1	58.5 ± 3.0	67.8 ± 4.3
Ins + Lav	6	50.3 ± 6.5	61.0 ± 4.2	54.2 ± 7.1
Wort alone	5	51.1 ± 5.5	65.2 ± 3.1	60.5 ± 1.5
Ins + Wort	6	50.9 ± 4.6	54.8 ± 2.0	52.5 ± 2.5

Mean ± s.e.m. *$P < 0.001$ vs. control group; (1-way ANOVA). Ins = insulin.

These data strongly suggest that the cardioprotective effect of insulin during reperfusion may be due to attenuation of ischaemia/reperfusion-induced apoptosis, and may be mediated via tyrosine kinase and/or PI-3-kinase activated signalling pathways.

STENTING PERIPHERAL ARTERIES

1912 Renal artery stenting with intravascular ultrasound guidance

G. Dangas, J.R. Laird, Jr., R. Mehran, J.M. Ahmed, G.S. Mintz, A.J. Lansky, A.D. Pichard, L.F. Satler, K.M. Kent, M.B. Leon. *Cardiovascular Research Foundation, Washington Hospital Center, Washington DC, USA*

Background. Renal artery stenting is becoming the preferred revascularization strategy for atherosclerotic renal artery disease.

Methods. We used IVUS to understand the pathology of renal artery atherosclerotic disease and evaluated the value of IVUS guidance on renal artery stenting in 109 consecutive patients (age 70 ± 8, 45% men, 45% diabetics) in 136 renal arteries (71% ostial). The lesion cross-sectional area (CSA) was compared to the reference CSA; negative remodeling was defined as lesion CSA < reference CSA.

Results. Negative remodeling was the main feature in 96% of ostial vs. 69% of non-ostial lesions ($p = 0.04$). EEM CSA was 34.4 ± 13.3 mm^2 at the reference site vs. 25.4 ± 11.0 mm^2 at the lesion ($p = 0.01$). Procedural success was 100%. IVUS determined the need for further stent expansion in 38%, and additional stenting in 2.5%. Mean contrast volume used was 74 ± 25 ml. Although baseline creatinine was >1.8 mg/dl in 50%, only 7% developed post-stent renal failure (1.8% dialysis), which was transient in 90%. Quantitative results and correlation of IVUS and QCA:

	QCA	IVUS	r
Pre-reference diameter, mm	5.3 ± 1.2	4.9 ± 1.0	0.71
Pre-lesion min diameter, mm	1.9 ± 0.8	1.9 ± 0.6	0.51
Final lesion min diameter, mm	5.1 ± 0.7	4.9 ± 1.0	0.63

$P < 0.0001$ for all.

Significant decreases in arterial pressure were noted during long-term follow-up: both systolic (145 ± 21 vs. 170 ± 25, $p < 0.001$) and diastolic (74 ± 12 vs. 84 ± 16 baseline, $p < 0.001$) measurements decreased.

Conclusions. 1) Negative remodeling is common in renal arteries. 2) IVUS measurements are reliable and may therefore limit angiographic imaging and lower the contrast volume used 3) IVUS derived further dilatation/stenting was required in greater than one third of cases despite optimal angiographic result 4) Renal artery stenting is a safe and effective technique with favorable long-term outcome.

1913 Femoropopliteal stenting: results, indications – choice of the stent

M. Henry, M. Amor, Z. Chati, I. Henry, K. Tzvetanov. *U.C.G.I., Polyclinique, Essey-les-Nancy, France*

Purpose: To retrospectively study safety, efficacy, mid/long-term results of femoro-popliteal stenting. To try to select the best suited stent depending on location and characteristics of lesion and access site.

Methods: 700 lesions in 669 symptomatic pts (M: 66%, F: 34%, mean age: 65.9 ± 10.3 years) with femoro-pop. occlusive diseases (stenoses: 373, occlusions: 312, aneurysms: 15) treated with 3 types of stents: balloon expandable (Palmaz: 126, Long Medium Spiral: 68), self-expandable nitinol (Sinus: 150, Instent: 143, Medicorp Expander: 94), covered (Cragg: 93, Corvita: 26). Indications: post-PTA residual stenosis: 78%, dissection: 13%, restenosis: 9%. Mean lesion length: Palmaz: 3.8 cm, Long Medium: 6.8 cm, nitinol: 5.9 cm, covered stent: 9.5 cm.

Results: Immediate technical success: 98%, clinical: 97%. Acute thrombosis more frequent with covered stents (9% vs 2.5%). In the lower part of superficial femoral artery (SFA) and in popliteal artery, balloon expandable stents can be compressed and lead to higher restenosis rate than nitinol stents (50% vs 15%). Primary (PI) and secondary patency (PII): Palmaz stents at 4 years: PI: fem.: 65%, pop.: 50%, PII respectively: 95%, 69%. Long Medium Spiral at 3 years: femoropop: (upper part of pop. artery): PI: 77.5%, PII: 90%. Nitinol stents at 4 years: PI: femoral: 82%, popliteal: 84%, PII respectively: 91 and 94% (no difference for lesions < or >8 cm). With covered stents at 27 months at fem.-pop. level: PI: 64%, PII: 76%.

Conclusion: Femoro-popliteal stenting seems safe, efficient. Balloon-expandable stents seem particularly indicated for the 2 upper thirds of SFA (to be avoided for lower part and for popliteal artery). Self-expandable nitinol stents may be implanted in any artery, particularly in popliteal artery and flexion sites. Covered stents are rather indicated for aneurysms. Their results are not better than nitinol stents for the treatment of long lesions.

1914 Continous stenting after recanalization of long superficial femoral artery occlusions improves one-year results

D. Scheinert, H. Steinkamp, M. Schröder, Giancarlo Biamino[1].
Charitè-Campus Virchow Klinikum, Humboldt University Berlin; [1]Center for Cardiology and Vascular Intervention, Hamburg, Germany

Implantation of endovascular stents in case of relevant dissections or residual stenoses improves acute interventional results after recanalization of long chronic SFA-occlusions. However, due to rapid progression of obstructive disease restenoses are observed frequently both proximally or distally of the stented segment. The objective of this study was to assess whether continous stenting of the entire recanalized vessel may improve the results after Excimer laser assisted recanalization (ELA) of SFA -occlusions.

In 110 patients a total of 367 stents (Wallstent n = 312, Palmaz n = 55) were implanted to stabilize recanalized SFA-occlusions, which evidentiated relevant dissections of the vessel wall. Patients were subgrouped according to the length and the continuity of the stented segment. Group A (n = 62): only partial stenting of the former occlusion, mean occlusion length (MOL) 21.4 cm, mean length of stented segment (MSL) 10.4 cm; Group B (n = 48): continous stenting of the SFA, MOL 22.1 cm, MSL 25.6 cm, no gaps between the stents. Technical success and primary patency rates after 6 and 12 months are given in the table.

Group	Technical Success <30% stenosis	Primary Patency 6 months	Primary Patency 12 months
A	60/62 (96.8%)	46/62 (74.2%)	30/62 (48.4%)
B	47/48 (97.9%)	43/48 (89.6%)	33/48 (68.8%)
Significance	p = n.s.	p < 0.01	p < 0.001

In conclusion, continous stenting of the entire recanalized vessel segment in case of relevant dissections after ELA of SFA-occlusions may improve the patency rate after 1 year. These results need to be validated prospectively.

1915 New approach to treatment of pseudobifurcational lesions

V. Tzifos, B. Reimers[1], C. Di Mario, A. Dharmadhikari, S. Sacca[1], R. Albiero[2], P. Pascotto[1], F. Airoldi, I. Sheiban, A. Colombo. *Interventional Cardiology Unit, Istituto Scientifico HSR, Milan; [1]Div. of Cardiology, Ospedale Civile, Mirano; [2]Interventional Cardiology, Columbus Hospital, Milan, Italy*

Objective: To assess the angiographic and clinical result of a new method to treat pseudobifurcational lesions (stenosis involving only the parent vessel proximal to bifurcation, with ostia of the daughter branches preserved).

Patients and lesions: Fifteen pseudobifurcational lesions were consecutively treated in the last nine months with the technique described below. All lesions were type B2 or C. Lesion distribution was LCX/OM in 4 cases, LAD/DIAG in 2 cases, crux cordis (RCA) in 5 cases, and LMCA in 4 cases (2 of them unprotected). Mean reference vessel diameter was 3.1 ± 0.6 mm for the main vessel and 2.73 ± 0.4 mm for the daughter branch. All patients were treated with ASA and Ticlopidine. Clinical follow-up was available for all patients.

Technique: Both branches were predilated using a double wire technique. Subsequently a stent was hand-crimped on two appropriately sized balloons; this stent "sandwiched" the balloons leaving their distal portion uncovered. The balloons were then advanced on the two wires until the stent hit the carina of the bifurcation. The simultaneous balloon inflation flared the distal part of the stent towards both branches creating a funnel just proximal to the bifurcation.

Results: The stent crimped on 2 balloons could successfully be delivered in 14 cases (93.3%). Residual stenosis was 7.4 ± 6% in the main vessel. In 11 cases (79%) patency of daughter branches was completely preserved and in 3 (21%) the implantation of an additional stent was required. In these cases residual stenosis was 12 ± 4.8%. We had no in-hospital major events. At a mean four-month clinical follow-up, the frequency of composite end points of death, AMI, and target vessel revascularization was 0%.

Conclusions: The technique is relatively easy to perform and does not commit the operator to side branch stenting if not needed. The main advantage is that the access to both branches is maintained throughout the procedure and stenting either one or both of them, if required, is easy to perform.

1916 Six-month follow-up results of the Femoral Artery Stent Study (FASTEST)

H. Sievert[1], A. Wurzel[1], E. Starck[2], A. Fach[1], R. Schräder[1], D. Scherer[1], H. Merle[1], H. Spies[1], R. Ensslen[1], W. Pfeil[1]. *[1]Cardiovascular Center Bethanien CCB; [2]Red Cross Hospital, Frankfurt, Germany*

In a prospective randomized trial patients were randomized after successful conventional balloon angioplasty of a femoral artery lesion to no further interventional treatment (PTA), implantation of conventional stents (Stent) or implantation of a Dacron covered stent (Endo).

Follow-up (FU) angiogram was performed after 6 months or earlier, if indicated for clinical reasons.

	PTA	Stent	Endo	P
n	40	41	25	
Proc. Success	100%	100%	96%	N.S.
Thromboembolic compl.	0	10%*	16%*	<0.05*
MLD pre (mm)	0.7 ± 0.9	0.8 ± 0.9	0.8 ± 0.9	N.S.
MLD post (mm)	3.7 ± 0.7	5.2 ± 1.0*	4.2 ± 1.0*	<0.01*
MLD FU (mm)	2.0 ± 1.5	2.8 ± 1.5	2.1 ± 1.7	N.S.
Re-Stenosis (>50%) FU	65%	35%*	59%	<0.05*
Total occlusion FU	14%	11%	23%	N.S.

In conclusion, conventional stents as well as Dacron covered stents led to improved acute results compared to conventional balloon angioplasty alone. However, there is an increased risk of acute and subacute thromboembolic complications. After 6 months the restenosis rate was lower after implantation of conventional stents but not after implantation of Dacron covered stents compared to conventional balloon angioplasty.

1917 Long-term follow-up after stenting for iliac stenoses and occlusions

M. Schröder, D. Scheinert, H. Steinkamp, G. Biamino[1]. *Charitè-Campus Virchow Klinikum, Humboldt-University Berlin; [1]Center for Cardiology and Vascular Intervention, Hamburg, Germany*

Implantation of endovascular stents is a commonly used technique for percutaneous treatment of iliac stenoses. In contrast, the long-term efficiency of stents after recanalization of long iliac occlusions (LIO) remains uncertain. The objective of this study was to compare the results after stent-supported recanalization of iliac artery stenoses and occlusions.

In 458 patients a total number of 960 stents were implanted to stabilize suboptimal results after recanalization of high grade iliac stenoses (mean 87.2 ± 8.3%) (group A: n = 296) or total occlusions (group B: n = 211). The target lesion was localized in the common iliac artery (A: n = 133, B: n = 67), the external iliac artery (A: n = 96, B: n = 74) or both vessel segments (A: n = 68, B: n = 71). Length of the stented segment was significantly larger in group B (10.2 cm vs. 5.62 cm, $p < 0.01$).

Accordingly, more stents were needed after recanalization of LIO (3.1 vs. 1.46, $p < 0.01$). Comparing the clinical situation, we found a shorter walking capacity in group B as well as a reduced Ankle-Brachial-Index (ABI), measured after standarized treadmill test (0.55 ± 0.27 vs. 0.41 ± 0.18).

Results: A primary technical success (residual stenosis < 30%) could be achieved in 98.1% (group A) and 89.6% (group B) of patients, respectively. Clinically, a marked improvement of +2 or +3 grades according to the AHA-criteria was found in 144 pts. (69.9%, group A) and 179 pts. (84.4%, group B). During the mean follow-up of 19.5 months the primary patency rates were 87.0% in group A and 81.2% in group B. In the majority of cases reobstruction could be successfully treated by PTA, leading to secondary patency rates of 93.1% (group A) and 89.1% (group B).

In conclusion, endovascular stenting provides an effective treatment option for iliac stenoses as well as LIO. A high long-term patency has been proven in both groups.

LOCAL DRUG DELIVERY AND COMPOUND ELUTION USING STENTS: CLINICAL AND EXPERIMENTAL RESULTS

1927 Local delivery of low-molecular-weight heparin decreases restenosis rate after coronary stenting: final results of the POLONIA randomized study

R.S. Kiesz, P. Buszman[1], M.M. Rozek, J.L. Martin[2], E. Deutsch[3], E. Gaszewska[1], M. Rewicki[4], M. Kosmider[5], P. Seweryniak[6], M. Tendera[1]. *Medicine/Cardiology Dept., UTHSC, San Antonio TX, USA; [1]Upper Silesian Cardiology Centre, Katowice, Poland; [2]Jefferson Health System, Philadelphia; [3]Cornell Medical Center, New York, USA; [4]National Institute of Cardiology, Warsaw[5]Lodz Medical School, Lodz[6]Internal Ministry Hospital, Warsaw, Poland*

Intimal hyperplasia has been observed to be the primary cause of restenosis after stenting. Furthermore, recent findings suggest that low molecular weight heparin, at high concentration, inhibits smooth muscle cell (SMC) proliferation. We investigated whether intramural delivery of Enoxaparin prior to stenting decreases in-stent restenosis rate in patients receiving reduced systemic anti-coagulation. We randomly assigned 100 patients from 4 centers, who presented with single lesion, single vessel disease to local administration of Enoxaparin via drug delivery/balloon angioplasty catheter (Transport) prior to stenting (LDD) versus systemic heparinization (SH). All patients were treated with balloon expandable stents (NIR). The primary study endpoints included late luminal loss and in-stent restenosis, using a binary definition at 6 months. The secondary endpoints included activated clotting time at the end of the procedure, subacute stent closure, MI, emergent CABG, death, and target lesion revascularization.

Clinical follow up was available in all patients, and angiographic follow up at 6 month was completed in 99% of patients. At six months, late loss and in-stent restenosis in the LDD and SH groups were, respectively, 0.76 ± 0.42 mm (30.5 ± 13.0%) and 1.07 ± 0.49 mm (43.6 ± 18.2%). The activated clotting time was 146.9 ± 39.8 sec in the LDD group and 381.9 ± 182.2 sec in the SH group. There was one subacute closure and one MI in the SH group. There were no deaths or emergent CABG. Target vessel revascularization was 6% in the LDD group and 22% in the SH group ($p = 0.05$).

Conclusions: Intramural delivery of Enoxaparin prior to stenting significantly reduces late luminal loss, in-stent restenosis and target lesion revascularization rates. No subacute closure was observed despite reduced systemic heparinization.

1928 Local delivery of nadroparin for the prevention of neointimal hyperplasia following stent implantation: final results of the IMPRESS trial

N. Meneveau, J.-P. Bassand, G. Grollier[1], B. Farah[2], J.M. Lablanche[3], K. Khalife[4], J. Machecourt, N. Danchin, J.-E. Wolf, J.-B. Hak[5]. *Service de Cardiologie, Hôpital Univ. Saint-Jacques, Besançon[1]Cardiology Dept, Hopital Cote de Nacre, Caen[2]Cardiology Dept, Hopital Tenon, Paris[3]Cardiology dept, Hopital Cardiologique, Lille[4]Cardiology Dept, Hopital General, Metz, France[5]Cordis, Roden, Netherlands*

Purpose: The IMPRESS trial is a prospective randomized multicentre trial, designed to assess immediate and long term results of local low molecular weight heparin delivery (nadroparin) following coronary stenting.

Methods: 250 patients, submitted to balloon angioplasty followed by successful stent implantation were randomized into control group (none local drug delivery) or local delivery of nadroparin (5,000 IU anti-Xa in 3 ml of saline with the Crescendo catheter a microporous infusion catheter). Inclusion criteria were: age <75 years and >20 years, de novo type a or b lesions, lesion length < 15 mm, native coronary arteries with a reference diameter ^{3} 3 mm, implantation of only 15 mm Palmaz-Schatz stent as primary choice or justified either by unsatisfactory result, elastic recoil or dissection. The primary endpoint was the late loss in MLD at 6 month follow-up angiography. Secondary endpoints included% restenosis (>50% DS), acute procedural results, and major adverse cardiac events (MACE: death, myocardial infarction, repeat angioplasty, bypass surgery) at 8 weeks and 6 months follow-up.

Results: In total 250 patients were enrolled into the study. Local delivery of nadroparin was successful in 124 patients (99.2% success rate) and was not associated with an increase in coronary artery dissections, distal embolization or abrupt arterial closure. There were no differences in MACE at any time point (88.8% vs 89.6% of event free survival at 6 months in the control and nadroparin groups, respectively).

Angiographic data

	Control (n = 125)	Nadroparin (n = 125)	p value
Acute gain (mm)	1.86 ± 0.46	1.82 ± 0.5	0.39
Late loss (mm)	0.84 ± 0.62	0.88 ± 0.63	0.48
Net gain (mm)	1.01 ± 0.75	0.94 ± 0.74	0.56
Restenosis (%)	20	24	0.50

Conclusion: Intramural delivery of nadroparin (5,000 IU in 3 ml of normal saline) via the Crescendo catheter after stent deployment: (1) has no effect in reducing restenosis, (2) is technically feasible as successful delivery was achieved within the lesion site in 99% of cases, (3) is safe as intramural delivery was not associated with an increase in peri-procedure clinical or angiographic complications.

1929 Local angipeptin delivery from coronary stents in porcine coronary arteries

J. Armstrong, J. Gunn, C.M. Holt, N. Malik, L. Rowan[1], P. Stratford[1], D.C. Cumberland. *Cardiovascular Group, Division of Clinical Sciences (NGH), University of Sheffield, Sheffield; [1]Biocompatibles Ltd, Farnham, UK*

Background: Local drug delivery from polymer coated stents is a novel concept to prevent restenosis. Angiopeptin has previously been shown to reduce intimal hyperplasia. We aimed to characterise the release kinetics and distribution of [^{125}I]angiopeptin loaded onto phosphorylcholine-(PC) coated BiodyvYsio stents *in vivo*.

Methods: PC-coated stents were loaded with 8.3 μg (± 0.8) [^{125}I]angiopeptin. The stents were deployed into porcine LADs, with the RCA and Cx as non-stented controls. Surface radioactivity was measured over the first 30 mins, and also immediately before sacrifice. The pigs (n = 8) were killed at 1 and 24 hrs, & 7 and 28 days. [^{125}I]angiopeptin in blood, urine and tissue samples was quantified.

Results: 99% of the time zero post-deployment radioactivity (Geiger surface count) persisted at 30 min and 43% at 7 days. The mean level of [^{125}I]angiopeptin present in blood 5 min following stenting was 0.40 ng/ml and 0.49 ng/ml after 1 hr, and fell to zero by 7 days. Maximum levels of [^{125}I]angiopeptin were detected in the arterial wall around the stent at all time-points; 506 pg/mg wet weight at 1 hr (artery alone), 419 pg/mg at 24 hrs (artery alone), 387 pg/mg at 7 days (artery alone) and 209 pg/mg at 28 days (artery and stent). [^{125}I]Angiopeptin was also detected in proximal and distal regions of the LAD. Less than 1 pg/mg was detected in the Cx and RCA. The maximum level of [^{125}I]angiopeptin in tissue other than the heart was detected in kidney at 24 hrs post-stenting (2.09 pg/mg). After 7 days 1.25% of the [^{125}I]angiopeptin initially loaded onto the stent remained.

Conclusion: Efficient, sustained and truly local delivery of [125I]angiopeptin into coronary artery wall can be achieved by loading onto a PC-coated stent. These data provide sufficient evidence to justify performing an efficacy study.

1930 Activated protein C-eluting stent inhibits platelet deposition in an in vivo model

R.S. Foo, K. Hogrefe, J.H. Baron, D.P. de Bono, A.H. Gershlick. *Div. of Cardiology, Dept. of Medicine and Therapeutics, Leicester University, Leicester, UK*

In previous experiments, we have shown that Activated Protein C (APC) is an extremely potent endogenous antithrombotic. It could be loaded onto polymer-coated stents to produce a biexponential elution profile and significantly reduced fibrin thrombus in vitro. We now aim to determine the in vivo efficacy of these stents in reducing platelet thrombosis in a balloon injury rabbit iliac artery model.

Method: Male NZ white rabbits were used. Rabbits received Aspirin and Ticlopidine for 5 days before operation. ^{111}In-labelled autologous platelets was given to the rabbit 1 h before operation. At operation, balloon injury was performed to both iliac arteries via arteriotomy. After injury, stents were deployed at the injury site under visual guidance. Flow through the stented arteries was monitored using perivascular flowprobes. After 2 h, rabbits were sacrificed and stented arteries removed and gamma-counted for platelets deposition. Systemic clotting time was measured during operation. APC-loaded, albumin (alb)-loaded and plain polymer-coated stents (p-s) were deployed with the operator blinded to the stent type.

Results: None of the APC stents occluded (0/14) as compared to more than half of the plain stents (9/15). Alb-stents and plain stents that did not occlude sustained only non-biphasic flow at extremely low flowrates (0.2–0.56 mL/min). Percentage of remaining flowrate was higher in APC-stent as compared to plain stent ($p < 0.001$) and higher in APC-stent as compared to alb-stent ($p < 0.001$). APC-stent had significantly less platelet deposition as compared to both plain and alb-stents ($p < 0.005$). No change in systemic clotting time was noted throughout operation.

Conclusion: APC-eluting stents significantly inhibit platelet thrombosis in vivo and may be useful for intervention in high risk situations.

1931 Successful gene transfer to swine coronary arteries using a polymer-coated DNA-eluting stent

B.D. Klugherz, P.L. Jones[1], W. Chen[1], N.F. Meneveau, F. Wade-Whittaker, R. Levy[1], R.L. Wilensky. *Cardiovascular Dept., University of Pennsylvania Health Sys., Philadelphia PA; [1]Cardiology Dept., Children's Hospital of Philadelphia, Philadelphia PA, USA*

Background: Catheter-based gene delivery to the arterial wall is limited by both the need for prolonged incubation times to achieve efficient transgene expression and the absence of a sustained DNA release mechanism. A DNA-eluting stent may overcome these limitations. The objectives of this study were to engineer a biodegradable polymer-coated DNA-eluting stent, to characterize its in vitro release kinetics, and to determine the in vivo transfection efficiency in nonatherosclerotic porcine coronary arteries.

Methods: DNA emulsions were prepared by mixing reporter plasmid DNA encoding beta-galactosidase or green fluorescent protein with a volatile polymer solution. Rat aortic smooth muscle cells (SMC) in culture were exposed to samples of dessicated emulsion to assess in vitro transfection. The emulsions were applied to the surface of Crown stents (Cordis, Warren, NJ), and the kinetics of DNA release into saline were measured. Coated stents were hand-crimped on 3.0 or 3.5 mm angioplasty balloons and deployed in swine left anterior descending or left circumflex coronary arteries (n = 6). Coronary arteries were harvested at 5–7 days for analysis. Nuclear counterstaining was used to estimate transfection efficiency. DNA extraction followed by PCR was performed to assess site specificity of transgene expression.

Results: Optimal transfection in vitro was observed using an intermediate DNA concentration (14 μg/mL) and polylysine condensation. DNA release profiles from the coated stents in vitro were characterized by a rapid burst phase followed by exponential slowing. Reporter transgene expression was observed in all arteries in the DNA treated group, but in none of the control arteries. Transfection efficiency was 1.14 ± 0.08% (mean ± SEM, range 0.21–1.65%). Systemic transgene expression was excluded using PCR.

Conclusions: Successful gene transfer to the arterial wall was demonstrated using a biodegradable polymer-coated DNA-eluting stent, with a consistent transfection efficiency. This technique may prove useful for the treatment of pathologic vascular processes, such as atherosclerosis or in-stent restenosis.

1932 E2F1 and cyclin E directed ribozymes as a tool to inhibit smooth muscle cell proliferation after percutaneous transluminal angioplasty

G. Grassi, A. Kuhn, J.J. Schnorr, H. Köhn, M. Grassi[1], G. Bauriedel[2], R. Kandolf. *Department of Pathology, Tübingen, Germany[1]Department of Chemical Engineering, Trieste, Italy[2]Department of Cardiology, Bonn, Germany*

A major problem following coronary interventional procedures such as percutaneous transluminal angioplasty (PTA) is the re-narrowing of the vessel lumen (restenosis) at the site of dilatation that occurs in a high percentage of cases. Although restenosis is a complex process, one of the most crucial events is the induction of proliferation of the vascular smooth muscle cells and their migration into the intimal space. Therefore, we based our gene therapy project on the inhibition of vascular smooth muscle cell growth by hammerhead ribozymes. Hammerhead ribozymes are short catalytic RNA molecules capable of inducing the site-specific cleavage of a phosphodiester bond within a RNA molecule. As ribozyme targets we have chosen the mRNA species coding the proteins E2F1 and cyclin E which play a key role in the transition from G1 to S phase during the cell cycle.

Methods: ribozyme accessible cleavage sites were mapped on the two full length mRNAs species by the RNase H digestion technique. On the basis of these results four ribozymes targeted against E2F1 mRNA and six ribozymes targeted against cyclin E mRNA were generated with 8 nucleotides per binding arm and tested in vitro under single turnover conditions. Cleavage reactions were performed under physiological conditions of temperature and pH. The most active ribozymes had kreact/Km ratios in the range of 50–80 × 10,000/M min which are among the best published kreact/Km ratios for ribozymes targeted against long structured mRNAs. For the best ribozymes the effect, on the cleavage efficiency, of the binding arm length variations was also tested generating ribozyme either with 5 or 12 nucleotides per side. As a result of these experiments, we found that the optimal binding arm length was in the range of 8–12 nucleotides. The in vivo effectiveness of the most active ribozymes was then tested in human smooth muscle cells grown either in the presence or in the absence of the specific active ribozyme. To check the possible ribozyme antisense effect, cells were also grown in the presence of the inactive ribozymes bearing a mutation in the active core which abolishes the catalytic activity but not the possibility to bind to the target. Cell cycle progression was evaluated by facs analysis.

In conclusion our data represent the first example of in vitro highly active ribozymes targeted against cyclin E and E2F1 mRNAs. In addition, preliminary in vivo studies indicate that our ribozymes can significantly reduce smooth muscle cells proliferation.

VASCULAR REMODELLING: CLINICAL ASPECTS

1936 MMP inhibition following balloon angioplasty inhibits constrictive remodelling in favour of expansive enlargement: an intravascular ultrasound study in pigs

M.J. Sierevogel, G. Pasterkamp, E. Velema, D.P.V. De Kleijn, B.J.G.L. De Smet, C. Borst. *Experimental Cardiology Dept., Utrecht University Medical Center, Utrecht, Netherlands*

Background: Constrictive remodeling is the major determinant of restenosis following balloon angioplasty. Previously, we demonstrated that inhibition of Matrix Metalloproteinases (MMPs) significantly reduces late lumen loss after balloon angioplasty by inhibition of constrictive arterial remodeling. It is unknown whether inhibition of constrictive remodeling occurs in favour of expansive remodeling (enlargement) or whether expansive remodeling is blocked by inhibition of MMPs as well.

Methods: Balloon angioplasty was performed in 33 femoral and internal iliac arteries in 11 pigs. Pigs were randomly divided into 4 groups: 1 control group (n = 6 vessels) and 3 groups in which Marimastat, a MMP- inhibitor which can be administered orally, was administered for 2 weeks (n = 10 vessels), 4 weeks (n = 7 vessels) and 6 weeks (n = 10 vessels) respectively. Marimastat treatment was started one day prior to the intervention. Pigs were terminated 42 days after intervention. 30 MHz intravascular ultrasound was performed at all time-points. At regular sites, intravascular ultrasound images of each balloon dilated area were matched pre-, post interventional and at follow-up. For each matched segment the mode of remodeling (shrinkage/enlargement) was determined by the difference in the vessel area (VA) between post intervention and at follow up (control group: n = 23, pooled Marimastat group: n = 94). The segments were divided in 3 groups: compensatory enlargement (VA change > +5%), no remodeling (VA change −5 to +5%), and shrinkage (VA change > −5%). Data of the different Marimastat groups were pooled since no significant differences were observed among groups.

Results: see table (*$p < 0.01$).

Remodeling and marimastat

	Shrinkage	No remodeling	Enlargement
Control (n = 23)	22 (= 96%)	0	1 (= 4%)
Marimastat (n = 94) *	24 (= 25.5%)	24 (= 25.5%)	46 (49%)

Influence of marimastat on the remodeling mode following balloon angioplasty.

Conclusion: MMP inhibition following balloon angioplasty inhibits constrictive remodeling in favour of expansive enlargement. Whether MMP inhibition does actively affect expansive enlargement remains to be investigated.

1937 The "Glagov effect" is a rare event in native coronary arteries in vivo

A. Athanasiadis, A. Baumbach, H. Mahrholdt, M. Oberhoff, K.R. Karsch. *University of Tübingen, Department of Cardiology, Tübingen, Germany*

In the majority of patients with coronary artery disease a compensatory enlargement of the left main stem and the left anterior descending coronary artery was observed post mortemand this was described as the "Glagov effect". This current in vivo study was performed to determine the occurrence and incidence of compensatory vessel enlargement in arteries with hemodynamically relevant lesions before coronary intervention with intravascular ultrasound.

Methods: In 308 patients intracoronary ultrasound (CVIS, 3.2 F) was used to analyze the vessel dimensions prior to coronary intervention. The target vessel was the left anterior descending coronary artery in 172 patients, the circumflex artery in 25, and the right coronary artery in 111 patients.

Results: The prestenotic vessel area (EEM CSA) was 20.2 ± 9.0 mm^2, the intrastenotic EEM CSA 18.1 ± 5.7 mm^2, and the poststenotic area 16.7 ± 5.4 mm^2 in the total group. In 74 patients an intrastenotic vessel enlargement was found whereas in the majority of patients (n = 234) a significant reduction of the intrastenotic vessel area by 2.3 mm^2 was present.

In conclusion, these results indicate that in-vivo and in the presence of hemodynamically relevant lesions compensatory vessel enlargement is a rather rare event. The data indicate that in the majority of patients remodelling will result in a decrease of the vessel area (shrinkage). Thus, the "Glagov effect" cannot be postulated as a predominant pheonomenon in native coronary arteries in-vivo.

1938 Differential results after coronary intervention due to pre-existing vessel enlargement

M. Gyöngyösi, P. Wexberg, P. Yang, A. Hassan, D. Glogar. *Division of Cardiology, 2nd Department of Internal Medicine, University Medical School of Vienna, Austria*

We have previously shown that adaptive remodeling is associated with a significantly higher degree of restenosis severity, and that pre-existing AR is a significant independent predictor for occurrence of major adverse cardiac events (MACE). The aim of this study was to examine, which factors (clinical, angiographic or procedural) may be responsible for the paradoxical worse clinical outcome of the patients with pre-existing adaptive remodeling of the target lesion.

Method Clinical (age, gender, coronary risk factors), quantitative angiographic (minimal lumen diameter, reference diameter and %diameter stenosis), qualitative (soft/hard plaque, plaque eccentricity, presence of calcification, thrombus and rupture) and quantitative IVUS (minimal lumen cross-sectional are /CSA/, external elastic membrane /EEM/ CSA, plaque CSA and plaque burden) data on 81 patients were compared. Adaptive vs constrictive remodeling was defined if the EEM CSA of the target lesion was greater/smaller than that of the proximal/distal reference EEM CSA.

Results 31 patients exhibited adaptive remodeling (57 ± 14 y, 81% men, Group AR), while constrictive remodeling was found by 20 patients (64 ± 8 y, 70% men, Group CR), and no remodeling in 30 patients (61 ± 10 y, 77% men, Group NR). MACE at six months follow-up was significantly more frequent in patients in Group AR than in Group CR and NR (43% vs 15% and 23%, $p < 0.05$). Clinical data, pre- and postinterventional quantitative angiographic and qualitative IVUS data did not differ significantly between the three groups. The preangioplastic EEM CSA, plaque CSA and postinterventional plaque CSA were significantly greater in Group AR (table)

	Before intervention			After intervention		
	EEM CSA [mm^2]	Plaque CSA [mm^2]	Plaque burden [%]	EEM CSA [mm^2]	Plaque CSA [mm^2]	Plaque burden [%]
Group AR	17.2 ± 4.8*	12.8 ± 4.3*	75.1 ± 10.9	17.5 ± 4.8	8.5 ± 3.1*	49.6 ± 12.4*
Group CR	12.5 ± 4.8	8.8 ± 4.0	67.8 ± 8.0	15.1 ± 6.6	6.3 ± 4.1	44.1 ± 11.7
Group NR	15.6 ± 3.8	10.6 ± 4.5	72.5 ± 14.3	16.9 ± 4.6	6.9 ± 3.1	40.9 ± 10.5

*$p < 0.05$ between Group AR vs CR and NR

Conclusions Patients with adaptive remodeling have a higher plaque burden after intervention due to the significant greater amount of residual plaque, this factor may be responsible for the higher rate of restenosis and MACE in patients with pre-existing adaptive remodeling.

1939 Regional vascular remodelling: assessment of distribution and contribution to the lumen narrowing by intravascular ultrasound

R. Füssl, E. Kranenberg, U. Kiausch, F. Baer, H.W. Höpp. *Klinik III für Innere Medizin, University of Cologne, Germany*

The purpose of this study was to evaluate the distribution of regional vascular remodeling and its influence on the lumen dimensions in vivo. Sixty-three patients with 68 coronary lesions were imaged by intravascular ultrasound (IVUS) before transcatheter therapy. Quantitative measurements of lumen area (LA), total arterial area (TAA) and plaque area (PA = TAA − LA) were performed at the lesion site and at the proximal and distal reference site. Three different groups of vascular remodeling were determined based on IVUS measurements: 1) positive remodeling = stenosis TAA > maximal reference TAA; 2) intermediate remodeling = maximal reference TAA ≥ stenosis TAA ≥ minimal reference TAA; 3) negative remodeling = stenosis TAA < minimal reference TAA.

In 57% of lesions TAA in the stenosis was not between the proximal and distal reference TAA: 29% of lesions (20/68) had positive, 28% (19/68) negative and 43% (29/68) intermediate remodeling. In the negative remodeling group, reduction of TAA contributed to 40% of lumen narrowing, in the positive remodeling group TAA was 21% enlarged ($p < 0.001$). Lesions with negative remodeling exhibit a lesser PA, lesions with positive remodeling a larger PA than other vessels (8.2 ± 2.4 mm^2, 13.8 ± 3.7 mm^2; 10.8 ± 3.7 mm^2; $p < 0.001$).

Distinct vascular remodeling occurred in the majority of atherosclerotic lesions and appeared to be a bidirectional process. Overall the frequency of positive and negative remodeling was almost balanced. In lesions with negative remodeling PA was less than expected, reduction of TAA contributed to 40% of lumen narrowing. In lesions with positive remodeling vessel enlargement compensated for 21% of plaque accumulation.

1940 Baseline remodelling of native denovo coronary lesions is predictive of target lesion revascularisation after stent implantation

J.M. Ahmed, G. Dangas, G.S. Mintz, R. Mehran, M.K. Hong, M.A. Peterson, J.R. Laird, L.F. Satler, K.M. Kent, M.B. Leon. *Washington Cardiology Center, Washington DC, USA*

Coronary artery stenting eliminates late lumen loss due to arterial constriction, and instent restenosis is due to neointimal hyperplasia. To study the impact of baseline arterial remodeling (REM) on target lesion revascularsation (TLR) after stenting in native coronary arteries, we used pre-interventional intravascular ultrasound (IVUS) in 701 patients with 813 denovo coronary lesions. REM was determined by comparing the lesion external elastic membrane area (EEM) to the mean reference (Ref) EEM. REM was defined as positive (+REM: lesion/Ref EEM ≥ 1.0, n = 352) or negative (−REM: lesion/Ref EEM < 1.0, n = 461). Target lesion revascularisation (TLR) rate was compared between two groups at 12 months follow-up.

	−REM	+REM	P
Diabetes (%)	24.0	29.9	0.08
Ref luminal area (%)	8.4 ± 0.1	8.1 ± 0.2	0.1
Final stent area (%)	7.7 ± 0.1	7.6 ± 0.1	0.6
Final luminal area (%)	7.6 ± 0.1	7.5 ± 0.1	0.3
TLR (%)	9.5	11.3	0.03

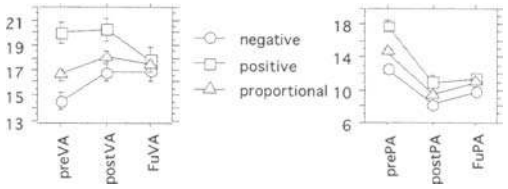
We therefore **conclude** that denovo lesions with +REM, as defined by pre-intervention IVUS, have a higher TLR after stenting compared to lesion with −REM. The probability of TLR after stenting increases with increasing +REM. Documentation of baseline −REM may indicate that the lesion is less prone to develop exaggerted neointimal hyperplasia.

1941 Vessel remodelling before directionary coronary atherectomy effects on chronic vessel response

T. Kobayashi, E. Tsuchikane, M. Kirino, T. Nakagawa, H. Takami, M. Sakurai, N. Awata, T. Kobayashi. *Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan*

Recent studies have been reported that vessel remodeling before intervention is one of factors of restenosis. However, the effects of remodeling on chronic vessel response after angioplasty have been unknown. We examined the relation between vessel remodeling before directionary coronary atherectomy (DCA) and chronic vessel response at follow-up (Fu) by serial intravascular ultrasound (IVUS) study. In 152 lesions, which was de novo and underwent IVUS guided DCA, serial IVUS study was performed at pre, post and at Fu (mean duration 194 days). Vessel area (VA) and lumen area (LA) was measured and plaque area (PA) was calculated. Vessel remodeling was defined as following. Negative remodeling group (n = 39): proximal reference (Rp) VA > distal reference (Rd) VA > lesion (L) VA, Proportional remodeling group (n = 87): RpVA > LVA > RdVA, Positive remodeling group (n = 26): LVA > RpVA > RdVA.

Results: Serial changes in VA and PA are shown as follows.



Chronic vessel shrinkage was significantly largest in the positive remodeling group. However, the change of plaque was not significantly difference among these three groups. We concluded that positive remodeling before DCA accelerates vessel shrinkage.

CLINICAL RESULTS OF ENDOVASCULAR IRRADIATION

1942 Dosing comparison of radiation sources of intracoronary brachytherapy

D. Meerkin[1], I.R. Crocker[2], T. Fox[2], J.-C. Tardif[1], M. Joyal[1], R. Bonan[1]. *[1]Montreal Heart Institute, Montreal PQ, Canada; [2]Emory University, Atlanta GA, USA*

Background: Recently both β and γ radiation have been effectively used to reduce post PTCA restenosis. It has been assumed, due to its greater penetration that γ sources result in a more homogeneous dose to the vessel wall (VW). The object of this analysis was to determine the influence of source selection (Sr/Y^{90}-β and Ir^{192}-γ) on VW and normal tissue.

Methods: IVUS was performed in all 30 patients in the Canadian arm of the BERT study. Inclusion criteria included angioplasty in native coronary arteries 2.5–3.5 mm diameter. Retrospective analysis of dosing was performed on 22 patients using the iplan (Atlanta GA) treatment planning system. Images were captured every 2.5 mm over the treated segment. Two non-centered sources were modeled. The first a γ source train comprising eight 3 mm long seeds with 1 mm interseed spacing, as used in the SCRIPPS trial and secondly a β source train comprising twelve 2.5 mm long seeds with no interseed gaps. Dose volume histograms were constructed for the vessel wall volume as well as for the normal tissue as represented by the volume of tissue extending 3 mm beyond the EEM. D10, D90 and means were then extracted from the DVH for each source.

Results:

Dose (Gy)	Gamma	Beta*
Mean	**11.9**	**12.3**
D90	**7.4**	**6.6**
D10	**18.5**	**19.9**

*p = ns γ vs. β

Conclusions: In this group of patients, there was no statistical difference between the doses that would have been delivered to the vessel wall had the source been a γ source rather than the β-emitter used. The dose delivered to the perivascular normal tissue however would have doubled with the use of γ radiation. In mid sized native coronary arteries γ radiation appears to offer no dosimetric advantage over a β-emitter.

1943 Regional analysis of dosimetry and volumetric morphological changes in coronary segments treated with β-radiation following successful balloon angioplasty

M. Sabaté[1], J.P.A. Marijnissen[2], S.G. Carlier[1], I.P. Kay[1], W.J. van der Giessen[1], V.L.M.A. Coen[2], J.M.R. Ligthart[1], A. den Boer[1], P.C. Levendag[2], P.W. Serruys[1]. *[1]Department of Cardiology-Heart Center Rotterdam; [2]Department of Radiotherapy, Daniel den Hoed Cancer Center Rotterdam, Netherlands*

Beta-radiation therapy (β-rad) appears to be feasible and safe in the treatment of "de novo" coronary stenoses. Inhomogeneity of dose distribution and anatomical aspects of the treated atherosclerotic plaque, such as, type of tissue or presence of dissection after balloon angioplasty (BA), may influence the outcome of irradiated lesions. We evaluated the influence of dose distribution and morphological characteristics of coronary stenoses treated with β-rad following successful BA in 18 consecutive patients treated according to the BERT-1.5 Trial.

Methods: The site of angioplasty was irradiated using a β-emitting Sr-90 source. Using the sidebranches as anatomical landmarks, the irradiated area was identified and volumetric assessment was performed by 3-dimensional (3-D) intracoronary ultrasound imaging after treatment and at 6-months. Image acquisition was performed by ECG-triggered pullback and 3-D reconstruction of the image by the contour detection system. The type of tissue, the presence of dissection and the luminal, plaque and total vessel volumes were assessed every 2 mm within the irradiated area. The minimal dose absorbed by 90% of the adventitial volume (D90adv) was calculated in each 2 mm-segment. Segments with > 180° arc of calcium and sidebranches occupying > 90° of circumferential arc were excluded.

Results: 206 coronary segments were included. Fifty-five segments were defined as soft tissue, 129 hard tissue and 22 normal or intimal thickening. Dissection was observed in 32 segments. Plaque volume showed a higher increase in normal segments as compared to soft and hard segments (+9.9 ± 10 mm^3 vs. +3.8 ± 6.4 mm^3 vs. +1.4 ± 4.4 mm^3, respectively; $p < 0.01$). However, D90adv was lower in normal segments (4.2 ± 2.6 Gy vs. 5.8 ± 2.0 Gy in soft tissue vs. 5.5 ± 2.5 Gy in hard tissue; $p < 0.01$). Dissected coronary segments showed a lower increase in plaque volume than non-dissected (+1.2 ± 3.7 mm^3 vs. +3.3 ± 6.8 mm^3, respectively, p = 0.01). D90adv was significantly higher in dissected segments (6.5 ± 2.4 Gy vs. 5.4 ± 2.6 Gy in non-dissected; p = 0.01). The multiple linear regression analysis identified the independent predictors of the plaque volume at follow-up: plaque volume post-treatment (p = 0.0001), type of plaque (soft p = 0.21 and hard p = 0.03 as compared to normal), D90adv (p = 0.0001).

Conclusion: Differences in tissue composition and dose distribution play a fundamental role in the volumetric changes after β-rad therapy following BA.

1944 Maintained efficacy of intracoronary β-radiation for restenosis prevention at one year

D. Meerkin, J.-C. Tardif, G. Lucier, M. Joyal, A. Arsenault, R. Bonan. *Montreal Heart Institute, Montreal PQ, Canada*

The effectiveness of beta radiation in reducing post angioplasty restenosis at six months has recently been reported. The durability of this treatment has not been demonstrated and this intervention may potentially alter the natural history of restenosis. This, coupled with the possibility of late side effects makes more prolonged follow up essential.

Methods: A total of 30 patients (pts) underwent PTCA and beta radiation therapy with a closed end 5F non centered catheter in doses of 12–16 Gy for restenosis prevention in the Canadian arm of the Beta Energy Restenosis Trial. All 30 pts underwent 6 month angiographic and IVUS follow up. One year clinical follow up including provocative nuclear perfusion imaging was also performed. Beyond 6 months, angiography and PTCA were symptom driven. Two year angiographic follow-up has recently commenced.

Results: Between 6 months and one year, one patient developed angiographic restenosis. Target lesion revascularization was therefore performed in 4 patients and target vessel revascularization in 7 patients by one year. There have been no deaths during the first year of follow up.

Conclusion: The clinical efficacy of post PTCA beta radiation achieved at 6 months is predominantly maintained at one year. No late side effects or complications were identified in this group of patients. Although close follow up of this patient group is essential, these results are most encouraging for the long term effects of catheter based beta radiation for restenosis prevention.

1945 β-Energy to prevent restenosis: the Rotterdam contribution to the BERT 1.5 trial – 1 year follow-up

A.L. Gijzel[1], A.J. Wardeh[1], W.J. van der Giessen[1], M. Sabate[1], V.L.M.A. Coen[2], I.P. Kay[1], J.M.R. Ligthart[1], A. den Boer[1], P.C. Levendag[2], P.W. Serruys[1]. [1]*Thoraxcenter, Heart Center Rotterdam;* [2]*Department of Radiotherapy;* [2]*Daniel den Hoed Cancer Center Rotterdam, Netherlands*

Introduction BERT 1.5 is a multicenter trial at Emory University Hospital, Rhode Island Hospital-Providence, the Montreal Heart Institute and the Thoraxcenter Rotterdam to evaluate safety and efficacy of β-irradiation following PTCA to prevent restenosis in pts with de novo single lesions in coronary arteries.

Methods After successful balloondilatation a 30 mm train of 12 Strontium-90 β-emitting seeds was hydraulically railed to the lesion through a 5 F radiation deliverycatheter. Pts were randomized to a dose of 12, 14 or 16 Gy After a dwelling time of at maximum 3.33 min. (16Gy) the elements were returned into a transfer device and the catheter was removed. In 26% additional stenting was performed for recoil or dissection.

Results From Apr to Dec 1997 we enrolled 21 male and 10 female pts in the BERT 1.5 trial. Pts had stable angina CCS 2 (n = 7), 3 (n = 14), 4 (n = 4) or unstable angina pectoris Braunwald class 1C (n = 2) or 2B (n = 2). Lesions treated were in LAD (n = 16), LCX (n = 7) and RCA (n = 8). In 1 pt the Beta-catheter could not cross a proximal calcified plaque. No major adverse cardiac events occurred in hospital. At 1-month follow up all pts but 2 had a reduction in anginal class. At 6-months, 18 pts had no angina, 11 pts had stable angina and 2 pts had unstable angina. Angiographic restenosis (DS > 50% in irradiated segment) was seen in pts (26%). (4 refusals) Quantitative Coronary Analysis of these 27 angiograms showed a median late loss index of 0.25 (range −0.81 to 3.43). At 1 year follow up 4 pts had angina pectoris, 22 pts (71%) were eventfree, 1 pt underwent CABG, 7 pts underwent repeat PTCA, 2 pts had MI and 1 pt had CVA.

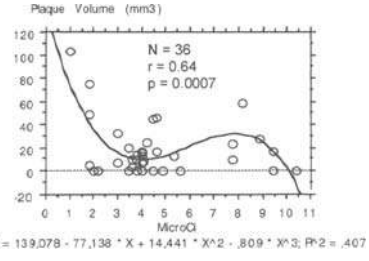
Conclusion. Our experience with 31 pts indicates that the technique is feasible and safe. A restenosis rate of 26% at 6 months was observed and at 1 year follow up clinical results were well preserved.

1946 Radioactive ^{32}P β-particle emitting stents in patients with coronary artery disease reduce in-stent neointimal hyperplasia in a dose-related manner: a serial volumetric IVUS study

R. Albiero, M. Adamian, N. Corvaja, T. Nishida, C. Briguori, M. Sallam, M. Vaghetti, A. Amato, C. Di Mario, A. Colombo. *Columbus Hospital, Milan, Italy*

Restenosis after stenting is mainly due to intimal hyperplasia. We have previously reported that in patients with CAD, ^{32}P radioactive β-emitting stents (Isostent) with an initial activity level of 0.75–6.0 μCi reduce in-stent late loss at 4–6 month follow-up in a dose related manner. Aim of this study was to analyze the relationship between the stent radioactivity level at the time of implantation and the subsequent in-stent plaque volume increase measured by IVUS at 4–6 month FU.

Methods: We analyzed 36 lesions in which a single 15 mm long radioactive ^{32}P β-particle-emitting stent was implanted and in which a serial IVUS study (post-stenting and at 4–6 month FU) was performed. Two types of slotted tubular stents were implanted: initially the Palmaz-Schatz (0.75–3.0 μCi) and later the BX Isostent (3–12 μCi). IVUS imaging was performed using a motorized transducer pullback. In-stent plaque area was measured on 15 slices analyzed 1 mm apart and the plaque volume computed using the Simpson's rule. The graph below summarizes the results.



Conclusions: In-stent intimal hyperplasia decreses with increasing initial stent radioactivity levels. The points were best fitted by a sigmoidal curve obtained by regression with a polynomial model of 3rd order. A complete analysis including other stents already implanted with higher initial activity levels (12–20 μCi) will be available at the time of presentation.

1947 Acute results of the Vienna P-32 Dose Response study: radioactive BX stents at high activity for reduction of restenosis after coronary interventions

P. Wexberg, M. Gottsauner-Wolf, C. Kirisits[1], A. Hefner[2], A. Lansky[3], N. Weismann[4], H. Sochor, V. Sreeharsha[5], P. Probst, H.D. Glogar. *Clinic for Internal Medicine II, Dept. of Cardiology;* [1]*Clinic for Radiotherapy and Radiobiology, Dept. of Radiophysics, Univ. of Vienna;* [2]*Austrian Research Center, Seibersdorf, Austria;* [3]*Washington Hospital Center, Washington DC;* [4]*Georgetown University, Washington DC;* [5]*Isostent Inc., Belmont CA, USA*

Beta-particle emitting stents have been found to have an activity dependant antiproliferative effect on vascular smooth muscle cells in animal models of restenosis. However, an efficient activity to reduce restenosis in humans has not been clearly determined yet.

Methods: The Vienna P-32 Dose Response Study is designed to test the safety and efficacy of beta-emitting stents with a higher initial activity (up to 24 μCi) in up to 60 consecutive patients with either de novo lesions, in-stent restenosis, or restenosis after PTCA. Optimal stent deployment is guided by intravascular ultrasound (IVUS), and angiographic and IVUS data are evaluated in two independent Core labs. Patients are treated with aspirin (100 mg) for at least one year and ticlopidine (500 mg) for 90 days after stenting. They will undergo clinical follow up at 30 days, and angiographic and IVUS follow up at 6 and 12 months. In the first six weeks of the study, 13 radioactive BX IsoStents (3.0 and 3.5 mm diameter, 15 mm length) containing P-32 were implanted in ten lesions (6 LAD, 1 RCX, 3 RCA) in ten patients. Seven lesions were de novo, and three were in-stent restenoses.

Results: In the first ten patients there were no adverse procedural or in-hospital events, and all stents could be successfully implanted. Mean activity at the time of implantation was 15.16 ± 5.56 μCi (range 7.2–19.8 μCi). Mean lumen area as measured in on-line IVUS increased from 2.64 ± 1.32 mm^2 at baseline to 7.55 ± 1.26 mm^2 ($p < 0.001$) after stent implantation.

Conclusion: Preliminary data suggest, that P-32 coated BX stents at high activity can be safely implanted in both de novo and in-stent restenotic coronary lesions with no acute major adverse cardiac events. 30 day and 6 month follow up data will be presented.

GUIDANCE FOR PERCUTANEOUS INTERVENTIONS (PART I)

1954 Vessel response in ICUS versus angiographically guided stent placement: a substudy analysis from the Optimization with ICUS to reduce stent restenosis (OPTICUS) trial

K.H. Henneke, M. Rothman, D. Koschyk, J. Ge, E. Regar, J. Rieber, H. Mudra. *For the OPTICUS Investigators; Klinikum Innenstadt, University of Munich, Germany*

Background: The application of predefined ICUS criteria of optimized stent expansion may reduce traumatic vessel response. We prospectively compared neointimal formation as well as reference vessel response between ICUS and angiographically guided stent optimization strategies.

Methods: A 6 months follow up ICUS-substudy of the multicenter OPTICUS trial was prospectively designed in 150 patients. Patients were randomized to ICUS-guided stent placement (ICUS) to reach primarily the ICUS-criteria of optimized stent-expansion or to angiographically guided (ANGIO) stent deployment. Recordings from motorized mechanical catheter pullbacks (0.5 mm/sec) were digitized and analyzed with the aid of a three-dimensional analysis software package using minimal cost contour detection algorithms. Using volumetric ICUS measurements, reference segment plaque burden (mean plaque volume/mean vessel volume) as well as neointima burden (neointima volume/mean stent volume) were calculated.

Results: In both groups, preinterventional angiographically determined reference diameter (RD) and diameter stenosis (DS) were similar (ANGIO: RD 2.99 mm, DS 65.2%; ICUS: RD 3.02 mm, DS 66.6%). Interim substudy results in 50 single stent implantation procedures at a mean of 6 ± 1 months follow-up:

	ICUS (n = 23)	ANGIO (n = 27)	p
Maximal stent area (mm^2)	11.55	9.63	0.056
Neointima burden (%)	13 ± 16	22 ± 18	0.041
Proximal reference plaque burden (%)	43 ± 17	53 ± 19	0.043
Distal reference plaque burden (%)	40 ± 24	46 ± 13	0.330

Conclusion: These preliminary results show a trend towards larger stent area and reduced neointima proliferation in ICUS versus ANGIO guided stent placement. There is no evidence of excessive vessel response within the reference segments in patients with ICUS guided balloon sizing for optimized stent expansion.

1955 Clinical outcome after stent implantation with versus without intravascular ultrasound guidance: eighteen month follow-up of the "restenosis after intravascular ultrasound stenting" (RESIST) study

F. Schiele, N. Meneveau, M.-F. Seronde, P.-M. Liu, S. Gupta, B. Bertrand[1], N. Danchin[2], J.P. Bassand. *Department of Cardiology, Hopital Saint-Jacques, Besançon[1] Cardiology Dept, Hopital Michallon, Grenoble[2] Cardiology Dept, Hopital Brabois, Vandoeuvre, France*

Background: One hundred and fifty five patients were randomized to routine stent deployment with versus without IVUS guidance. At 6 months, a 20% larger lumen cross sectional area (L-CSA) was found in the IVUS group, but differences in restenosis rate and in minimal lumen diameter (MLD) were non significant. The clinical translation of a 20% larger L-CSA remains unclear.

Methods: Clinical event was defined as death, myocardial infarction, or the need for ischemia/symptom-driven target lesion revascularization. The clinical follow-up was performed over 18 months. Follow-up-information was obtained from hospital records and telephone contact with the patient to determine the occurrence of major clinical events and the symptoms level.

Results: Clinical follow-up was completed for all 155 patients. Two patients died (one in each group), repeat angioplasty was performed in 26/76 patients in the group without IVUS and in 19/79 in the group with IVUS. During the follow-up, a second restenosis was observed in six patients and treated by surgery (2 patients from the non IVUS group) and by repeat angioplasty (2 in each group), using balloon in 2 cases and rotational atherectomy plus balloon in 2. A total of 52 revascularization procedures were performed, 31 in the non IVUS group and 21 in the IVUS group ($p = 0.03$). Event free survival was 48/76 (63%) versus 59/79 (75%), non-IVUS vs IVUS, $p = 0.059$. The only independent predictor of clinical event, according to multivariate logistic regression analysis, was stent L-CSA at stent implantation, odds ratio 0.56 per additional mm^2,(95% CI = [0.40; 0.76], $p < 0.001$).

Conclusions: A significantly larger L-CSA was observed at stent implantation and at 6 months. We thus conclude that the larger L-CSA resulting from IVUS guidance led to a trend towards better clinical outcome, but which was only of borderline significance ($p = 0.059$). The number of revascularization procedures was lower in the IVUS group ($p = 0.03$).

1956 Guiding balloon dilatation by IVUS measurements: the Upsize pilot trial

Andreas Baumbach, Stephen Schroeder, Heiko Mahrholdt, Karl K. Haase, Christian Herdeg, Anastasios Athanasiadis, Martin Oberhoff, Karl R. Karsch. *Medical Clinic III, University of Tübingen, Germany*

Background: Recent trials report a reduction of restenosis using intracoronary stents and suggest that this is a result of the high immediate luminal gain. The present study was based on the assumption that optimising balloon dilatation may result in equivalent acute and longterm outcome.

Methods: Preinterventional intravascular ultrasound was performed in 252 patients (pts) with 271 lesions. Quantitative assessment of the vascular dimensions was performed online. The balloon diameter was adapted to the diameter of the external elastic membrane, regardless of dimensions assessed by quantitative coronary angiography. The mean balloon diameter was 4.1 ± 0.5 mm.

Results: Acute events occurred in 5 patients (two repeat-PTCA, one CABG, two CABG with death). Angiographic dissection occurred in 157 pts (58%). Stent implantation for flow limiting dissection was necessary in 3 pts. A GPIIb/IIIa antagonist was administered in 5 pts. The one year clincal event rate was 15%: 5 pts experienced a myocardial infarction, 15 repeat PTCA of the target vessel, 8 pts underwent elective CABG. Control angiography was performed in 178 patients (71%). The angiographic restenosis rate was 19%.

Conclusion: Despite the use of larger balloons, the strategy of balloon dilatation guided by preinterventional intravascular ultrasound appears to be safe in the acute setting. The longterm outcome in this initial series seems to be favourable and is comparable to the results achieved with stent implantation. These results warrant verification in a randomised trial.

1957 Deferral versus performance of PTCA based on coronary pressure derived fractional flow reserve: the DEFER study

G.J.W. Bech, N.H.J. Pijls, B. De Bruyne[1], E.D. de Muinck[2], J.C.R. Hoorntje[3], J. Escaned[4], P.R. Stella[5]. *On behalf of the DEFER investigators; Catharina Hospital, Eindhoven; [2]Academic Hospital, Maastricht; [5]Academic Hospital, Utrecht; [3]Isala Clinics, De Weezenlanden, Zwolle, Netherlands; [1]Cardiovascular Center Aalst, Belgium; [4]Hospital Universitario San Carlos, Madrid, Spain*

Many patients undergo PTCA, without prior documented evidence of inducible ischemia. In such patients it is unknown whether performance of PTCA improves clinical outcome. This prospective randomized study compared clinical outcome in those patients after deferral versus performance of PTCA, based on fractional flow reserve (FFR), which is an accurate invasive index of inducible ischemia.

Methods: Included were patients with chestpain, admitted for PTCA of 1 stenosis (>50% by visual estimation) without documented evidence of inducible ischemia (absent, negative, or in-conclusive non-invasive testing). Just prior to PTCA, FFR of the target lesion was calculated by the ratio of adenosine induced hyperemic distal coronary pressure to aortic pressure. If FFR < 0.75 (equivalence of inducible ischemia) PTCA was performed as scheduled. If FFR ≥ 0.75 (making inducible ischemia unlikely) patients were randomized to deferral or performance of PTCA.

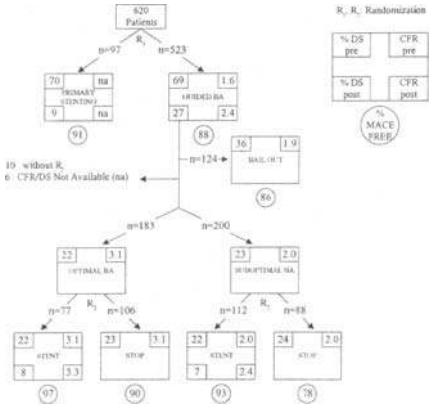
Results: A total of 326 patients were included. In 185 patients FFR was ≥ 0.75. These patients were randomly assigned to deferral (n = 89, group A) or performance of PTCA (n = 96, group B). In the remaining 141 patients (group C) FFR was <0.75 and PTCA was performed anyway. Baseline and QCA characteristics were identical in all 3 groups. At follow-up of 9 ± 3 months event-rates were 3%, 9%, and 16% in group A, B, and C, respectively. Kaplan-Meier event-free survival at 1-year in group A, B, and C was 93%, 87%, and 84%, respectively. Improvement in average functional class during follow-up occurred in all groups and was similar in group A and B, but was significantly higher in group C.

Conclusions: In 43% of all patients, admitted for PTCA without documented proof of inducible ischemia (stress test negative, in-conclusive, or just not performed) inducible ischemia could still be proven by coronary pressure derived FFR < 0.75. These patients improved by PTCA. In the patients without ischemia, as concluded by FFR ≥ 0.75, performance as compared to deferral of PTCA did not improve event-free survival nor functional class.

1958 DEBATE II:fFinal results of the 6-month follow-up

P.W. Serruys[1], B. de Bruyne[2], E. Sousa[3], J.J. Piek[4], T. Muramatsu[5], C. Vrints[6], P. Probst[7], R. Seabra-Gomes[8], I. Simpson[9], V. Voudris[10]. *[1]Thoraxcenter Rotterdam; [4]Academisch Medisch Centrum, Amsterdam, Netherlands; [2]Cardiovascular Center, OLV Hospital, Aalst; [6]University Hospital Antwerp, Edegem-Antwerp, Belgium; [3]Instituto Dante Pazzanese, Sao Paulo, Brazil; [5]Kawasaki Central Hospital, Kawaka-Shi Kan, Japan; [7]Allgemeines Krankenhaus der Stadt Wien, Vienna, Austria; [8]Hospital Santa Cruz, Linda-A-Velha, Portugal; [10]Onassis Cardiac Surgery Center, Athens, Greece*

Abstract: The primary objective of the DEBATE II was to evaluate whether we can identify by QCA on-line (DS, Diameter Stenosis) and intracoronary flow velocity reserve (CFR) a population in which after optimal balloon angioplasty (OBA: DS < 35%, CFR > 2.5) stenting will not further improve the clinical outcome (MACE) and conversely a subgroup of pts in whom stenting should be preferred to balloon.



Conclusions: Stenting further improves the clinical outcome (97% vs 90%, Log Rank test, $p = 0.046$) of pts having undergone an optimal balloon angioplasty, raising the legitimate question as to whether all pts fulfilling the inclusion criteria in this trial should have been stented.

1959 DEBATE II: analysis of the flow velocity profile in the stented and non-stented, optimal and suboptimal groups

M. Albertal, G. Van Langenhove, P. Serrano, S.G. Carlier, M.A. Costa, J.L. Guermonprez, P.M. Schoefield, E. Verna, J.A. Belardi, P.W. Serruys. *On behalf of the Debate II investigators; Thoraxcenter and Cardialysis, Rotterdam, Netherlands; Hospital Broussais, Paris, France; Papworth Hospital, Cambridge, UK; Ospedale di Circolo, Varese, Italy; Instituto Cardiovascular de Buenos Aires, Buenos Aires, Argentina*

Coronary flow reserve (CFR) has been shown to have a clinical predictive value after balloon angioplasty (BA). The aim of this study was to further analyze the flow velocity profile in various subsets of patients in the Debate II trial, in which the concept of provisional stenting is investigated.

Methods: 620 patients were randomized to guided balloon angioplasty or direct stenting (n = 97). Optimalization (DS% < 35% and a CFR > 2.5) of BA (OBA) was attempted in 84% (n = 523), successful in 38% (n = 200), generating 23% (n = 124) of bail-outs stenting and 34% (n = 183) of suboptimal results (SOBA). A second randomization further assigned the patients to additional stenting or no further treatment. We compared the resting (b) hyperemic (h) average peak velocities (APV) and CFRs in target and normal reference vessels (REF) of the 4 subrandomized patient groups: SO BA, OBA, without and with additional stenting (SOBA + S, OBA + S).

Results:

	SOBA N = 88	OBA N = 106	SOBA + S N = 112	OBA + S N = 77
DS (%)	22^{+}	23^{+}	7	8
Pts DS < 35%	87%	100%	93%	100%
Pts CFR < 2.5	94%	0%	99%	0%
b-APV (cm/s)	23*	17	22*	16
h-APV (cm/s)	43	45*	49^{+}	52^{+}
CFR	1.9	3*	2	3.2*
CFR REF	2.6	3*	2.5	3.2*
RelCFR (CFR/CFRREF)	0.8	1*	0.8	1.1
MACE 180 days	21.6%$^{*+}$	10.4%$^{+}$	7.1%	2.6%

* optimal vs suboptimal ($p < 0.05$). $^{+}$ stent vs balloon ($p < 0.05$)

Conclusion: 1) CFR is confirmed to be of prognostic value. 2) CFR of the target vessel following intervention seems to be related to the vasoregulatory function of the non-treated normal vessel. 3) The failure to normalize the CFR (<2.5) in the suboptimal group appears to be explained by a high b-APV, a finding which should be further elucidated.

ELECTROPHYSIOLOGICAL MODULATION BY CARDIOVASCULAR DRUGS

1973 Effects of metoprolol and atenolol on short-term resting heart rate variability in patients with unstable angina

Yu. A. Zuikov, I.S. Yavelov, O.V. Averkov, N.A. Vaulin, N.A. Gratsiansky. *Institute of Physico-Chemical Medicine, Moscow, Russian Federation*

It was previously suggested what lipophilic β-blockers (BB) due to their centrally-mediated action could enhance vagal activity to a greater degree than hydrophilic ones. In order to test this hypothesis an open comparative randomised trial was conducted on 75 patients (45 men) aged 35–69 years (mean 57.3 ± 8.4) with acute unstable angina (n = 65) and non-Q-wave myocardial infarction (n = 10). Mean of normal RR intervals (RRNN), very low (VLF; 0.003–0.04 Hz), low (LF; 0.04–0.15 Hz) and high (HF; 0.15–0.40 Hz) frequency powers together with LF/HF ratio were assessed on short ECG strips (512 RR intervals) at supine rest on admission and after 1 week of hydrophilic atenolol (n = 40) or lipophilic metoprolol (n = 35) use. Dose of BB was titrated to suppress symptoms of myocardial ischemia and to decrease heart rate below 60 bpm. Average daily dose of atenolol was 148 ± 70 mg, of metoprolol – 282 ± 137 mg. HRV parameters were compared with t-test after logarithmic transformation because of skewed data distribution.

		Atenolol (n = 40)	Metoprolol (n = 35)	p
Baseline	RRNN, ms	837 ± 143	837 ± 142	0.98
	ln (VLF, ms^2)	5.9 ± 1.1	5.9 ± 0.7	0.77
	ln (LF, ms^2)	5.5 ± 1.0	5.6 ± 0.8	0.84
	ln (HF, ms^2)	5.1 ± 1.0	5.1 ± 0.9	0.99
	LF/HF	1.7 ± 0.9	1.8 ± 0.9	0.65
1 week of BB therapy	RRNN, ms	1086 ± 145**	1036 ± 153**	0.13
	ln (VLF, ms^2)	6.1 ± 0.7	6.1 ± 0.8	0.96
	ln (LF, ms^2)	6.2 ± 0.7**	6.0 ± 0.6*	0.15
	ln (HF, ms^2)	6.2 ± 0.7**	5.9 ± 0.7**	0.08
	LF/HF	1.1 ± 0.5**	1.2 ± 0.5*	0.39

$^{*}p < 0.01$; $^{**}p < 0.001$ compared to baseline

Results are shown in the table (mean ± SD). Administration of both BB was associated with increase of RRNN, HRV and relative augmentation of vagal activity (decrease of LF/HF ratio). RRNN and HRV parameters did not differ between atenolol and metoprolol groups at admission and after 1 week of BB treatment. Thus in patients with acute unstable angina and non-Q-wave myocardial infarction atenolol and metoprolol exerted similar action on HRV obtained in standardised conditions.

1974 The comparative value of low-dose sotalol vs. metoprolol in the prevention of postoperative supraventricular arrhythmias

O. Abdulrahman, H.T. Dale[1], V. Levin[1], M. Hallner[1], T. Theman[1], C.A. Hassapoyannes. *Cardiology Dept, USC and WJB Dorn VAMC, Columbia SC; [1]St. Luke's Hospital, Bethlehem PA, USA*

Background: Supraventricular arrhythmias occur commonly following open heart surgery and can significantly prolong hospital stay or prompt thromboembolism. Although beta-blockers have been used successfully, sotalol with its beta-blocking and class III antiarrhythmic properties may be better suited for prevention of such arrhythmias. To test this hypothesis, we compared the efficacy and safety of low-dose sotalol with those of metoprolol.

Methods: In a prospective and double-blind fashion, 191 eligible, consecutive patients (mean age 64 years; 142 men) undergoing open heart surgery were randomly assigned to receive sotalol or metoprolol within 24 hours following extubation. Of these patients, 93 were treated orally with sotalol 40 mg, q 12 hours for one day and 80 mg b.i.d. for 5 days thereafter, while 98 patients received metoprolol 25 mg, q 12 hours for one day and 50 mg b.i.d. for the ensuing 5 days.

Results: Demographics and clinical characteristics did not differ between the two groups. Supraventricular arrhythmias occurred in 16% of all patients while atrial fibrillation was the commonest type. Length of hospital stay was longer among patients who developed supraventricular arrhythmias [9.2 ± 3.5 vs. 7 ± 4, P = 0.01]. A smaller number of patients developed supraventricular arrhythmias in the sotalol group [9 (10%) vs. 22 (22%); P = 0.028, chi square]. Non-sustained ventricular tachycardia was recorded in 2 patients in each group. There were no episodes of torsade de pointes and no deaths in either group. Bradyarrhythmias necessitating cessation of treatment occurred in 3 patients receiving sotalol (3.2%) and in 7 patients receiving metoprolol (7.1%); P = NS

Conclusions: Low-dose oral sotalol was used for short intervals following cardiac surgery without mortality or significant morbidity. Our data indicate that sotalol is well tolerated compared to metoprolol and is more efficacious in the prevention of supraventricular arrhythmias following open-heart surgery.

1975 Chronic amiodarone therapy does not increase epicardial dispersion of repolarization in the isolated porcine heart

D. Lacroix, K. Sautière, B. Dumotier, M. Adamantidis, D. Grandmougin, D. Klug, S. Kacet, B. Dupuis. *Pharmacology Dept. and Cardiology Dept. Cardiology Hospital, University of Lille, Lille, France*

Drug-induced Torsades de Pointes are thought to propagate through reentry due to non-uniform prolongation of repolarization. The low arrhythmogenic potential of amiodarone has been related to a lack of increase in repolarization dispersion on the body surface but the effects at the epicardial level are not documented. Activation-to-recovery intervals (ARI) were mapped epicardially from 128 unipolar electrograms in isolated-perfused intact porcine hearts with an interelectrode distance of 2.5 mm. Group I consisted of 7 controls, Group II animals (n = 7) were fed with amiodarone 20 mg/kg/day over 30 days while Group III animals (n = 7) received 50 mg/kg/day. Myocardial concentrations of amiodarone and n-desethyl-amiodarone in Group II and III encompassed the values found in clinical studies.

Results: In control hearts, mean ARI was frequency dependent (from CL = 500 to 1500 ms) and peaked at 288 ± 14 ms at CL = 1000 ms. ARI dispersion (computed as ARIs SD) was frequency independent peaking at 8.9 ± 4.6 ms and generated smooth gradients that were mainly dipolar. In Group II, mean ARIs were longer than controls at all pacing CLs ($p < 0.05$) peaking at 325 ± 30 ms at CL = 1000 ms, ARI dispersion peaked at 11.3 ± 2.9 ms and was not statistically different from controls. In Group III, mean ARI were further prolonged mainly at long CLs and peaked at 390 ± 27 ms at CL = 1500 ms. Again, ARI dispersion was not different from controls peaking at 9.3 ± 2.7 ms.

In conclusion, Chronic Amiodarone induces Class III effects in ventricular porcine epicardium that are concentration dependent and reverse frequency dependent but does not affect dispersion of repolarization, this may explain in part its low arrhythmogenic potential.

1976 HERG potassium channels are a pharmacological target of the class III antiarrhythmic drug amiodarone

C.A. Karle, D. Thomas, S. Kathöfer, W. Schöls, J. Kiehn. *Department of Cardiology, University of Heidelberg, Germany*

The class III antiarrhythmic drug amiodarone is a potent therapeutic agent in the clinical management of ventricular tachycardias. Experimental data have shown that amiodarone inhibits the rapid component of the delayed rectifier potassium current (I_{Kr}) in native cardiomyocytes. In this study, we used the two-microelectrode voltage-clamp technique and the Xenopus-oocyte expression system to study the effects of amiodarone on cloned potassium channels encoded by the human ether-a-go-go related gene (HERG), which is the genetic basis of I_{Kr}.

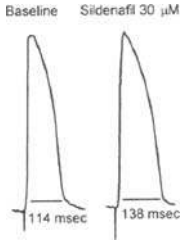
Results: Amiodarone blocked HERG channels with an IC_{50} of 9.8 μM and a maximum outward tail current reduction of 62.8%. The block consisted of two main components; a closed channel block that could not be reversed within the time of experiments and an open channel block with a slow unblock, having a recovery time constant of 73 seconds at −80 mV. Inactivation of the HERG channels during strong inward rectification at very positive potentials could not prevent amiodarone block. The block of open channels was cumulative, voltage-dependent and use-dependent with stronger block at higher stimulation rates.

Conclusions: This study provides the first analysis about amiodarone effects on the cloned HERG potassium channel, which is an important target for the pharmacological therapy of arrhythmias. With respect to the desired antiarrhythmic effect of amiodarone, our results indicate that the drug is a potent blocker of closed, open and inactivated HERG channels. The profile of action of amiodarone on HERG, with a use-dependent block of open channels at high stimulation rates may explain the positive outcome of the clinical amiodarone trials regarding ventricular tachycardias.

1977 Lengthening of cardiac repolarization and block of the rapid component of the delayed rectifier potassium current by the phosphodiesterase V inhibitor, sildenafil (Viagra®)

P. Geelen, B. Drolet, J. Rail, A. Émond, V. Fortin, G.E. O'Hara, J. Turgeon. *Quebec Heart Institute, Laval Hospital, Sainte-Foy PQ, Canada*

Several cases of unexpected death have been reported following use of sildenafil in patients predisposed to cardiac ischemic events due to their underlying pathology (coronary artery disease, diabetes). Although acute episodes of coronary ischemia could account for some of these deaths, we hypothesized that patients treated with sildenafil may also be at risk for pro-arrhythmia due to unsuspected cardiac electrophysiological effects of the drug. Studies were undertaken in 12 isolated, buffer-perfused guinea pig hearts which demonstrated prolongation of cardiac repolarization by sildenafil 30 μM (figure).



In addition, experiments using isolated guinea pig ventricular myocytes (n = 5) and HERG transfected human embryonic kidney 293 cells (n = 30) demonstrated block of the rapid component of the delayed rectifier K^+ current (I_{Kr}): activating current was 50% decreased at 100 μM.

Conclusions: Sildenafil possesses direct cardiac electrophysiological effects similar to class III antiarrhythmic drugs. These effects are observed at concentrations that can be found in conditions of impaired drug metabolism (e.g. during co-administration of another CYP3A4 substrate) or after drug overdose and form the basis of a new hypothesis to explain sudden death during sildenafil treatment.

1978 Electrophysiologic properties of endothelin receptor: a blockade in patients with coronary artery disease

T.M. Kolettis, Z.S. Kyriakides, D. Lefteriotis, A. Papalambrou, D.J. Webb, D.Th. Kremastinos. *2nd Department of Cardiology, Onassis Cardiac Center, Athens, Greece; Western General Hospital, Edinburgh, UK*

Endothelin-1 (ET-1) is a coronary vasoconstrictor, produced by endothelial cells. Animal studies have indicated that ET-1 may have significant electrophysiologic (EP) actions, independent of myocardial ischemia. We investigated the EP properties of ET_A blockade in patients (pts) with 1-vessel coronary artery disease.

Methods: Immediately after coronary angiography, a basic electrophysiologic study was performed before and after an intracoronary (ic) infusion of normal saline (NSAL) or BQ-123, a selective endothelin receptor-A antagonist (Clinalfa, CH) at a rate of 300 nmol/min for 20 min. BQ-123 or NSAL were administered randomly, in the non-diseased coronary artery. Statistical analysis was performed using t-test for dependent variables.

Results: 25 pts were studied. 14 pts (10 male, mean age 59 ± 9, mean EF: 56 ± 12%) received BQ-123 [left coronary artery (LCA): 8 pts, right coronary artery (RCA): 6 pts]. 11 pts (7 male, mean age 60 ± 9%) received NSAL [LCA: 7 pts, RCA 4 pts]. No complications were observed. No changes were found in heart rate, arterial blood pressure, or in basic conduction intervals.

	QT	QTc	CSNRT	ERP-AVN	ERP-RV
Baseline	373 ± 30	394 ± 36	258 ± 135	309 ± 87	226 ± 20

cSNRT: max corrected sinus node recovery time, ERP: effective refractory period, AVN: AV node, RV: right ventricle

Conclusions: In patients with 1-vessel coronary artery disease, high-dose ic ET-A receptor blockade causes QT interval prolongation, without affecting sinus or AV nodal function.

EMERGING THERAPIES FOR CARDIAC DISEASES: FROM BENCH TO BEDSIDE

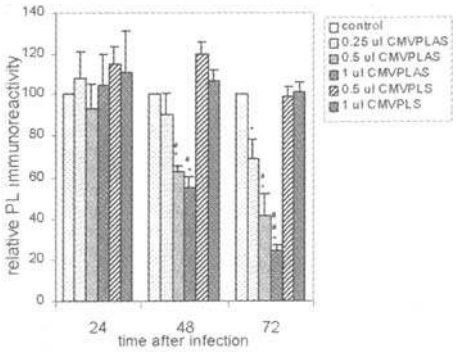
1983 Adenovirus-based phospholamban antisense RNA expression as potential gene therapy approach for the improvement of diastolic dysfunction

W. Poller, K. Eizema[1], K. Besztarosti[1], S. Schneider-Rasp[2], J. Lamers[1]. *Cardiology and Pneumology Dept., University Hospital Benjamin Franklin, Berlin, Germany; [1]Biochemistry Dept., COEUR, Erasmus Universiteit Rotterdam, Rotterdam, Netherlands; [2]Institute of Biochemistry & Pathobioch, University of Würzburg Medical School, Würzburg, Germany*

Background: Downregulation of the genes encoding the sarcoplasmic reticulum Ca^{2+} ATPase (SERCA2) and the beta-adrenergic receptors is thought to be causally related to the disturbed myocardial Ca^{2+} homeostasis and beta-adrenergic signal transduction in heart failure. SERCA2 is inhibited by phospholamban (PL) so that SERCA pump activity should be enhanced by either SERCA gene transfer or by inhibition of PL expression. We have investigated the influence of adenovirus-mediated PL-antisense-mRNA expression in cardiac myocytes (CMC) on cellular Ca^{2+} homeostasis.

Methods: A set of CMV promotor-controlled recombinant adenovectors was developed expressing either a partial PL-sense-mRNA (Ad5CMVPLs) or an otherwise identical PL-antisense-mRNA (Ad5CMVPLas). A second set of vectors carried an endothelin-inducible ANF-promotor instead. Neonatal rat CMC were used as target cells, Ca^{2+} homeostasis was analyzed using published methods.

Results: (1) The PL-antisense vector Ad5CMVPLas suppressed endogenous PL-mRNA expression strongly starting on day 2. The control vector Ad5CMVPLs had no influence showing that the antisense vector effect is PL-specific. (2) The effect of the vector Ad5CMVPLas on endogenous PL-protein expression is summarized in fig. 1. There was a strong, time-dependent suppression of PL-protein content of the target CMC down to 20% of baseline on day 3. (3) High dose Ad5CMVPLas vector resulted in a significant stimulation of maximal Ca^{2+} uptake of the CMC at pCa 6.5.



Antisense phospholamban suppression.

Conclusions: Adenovirus-mediated transfer and expression of PL-antisense-mRNA results in a strong and specific suppression of the SERCA-inhibitor phospholamban in cardiac myocytes. This antisense strategy is a new potential gene therapy approach towards improvement of diastolic cardiac dysfunction.

1984 Increased heart function by S100A1 gene therapy

S.T. Pleger[1], B.S. Manning[2], J. Hata[2], P. Most[1], P. Ehlermann[1], W.J. Koch[2], H.A. Katus[1], A. Remppis[1]. [1]*Medizinische Klinik II, Medizinische Universität zu Lübeck, Germany;* [2]*Department of Surgery, Duke University, Durham NC, USA*

The Ca^{2+} binding protein S100A1 is significantly downregulated in human end stage heart failure. Since this protein has been shown to enhance the caffeine induced Ca^{2+} release, we hypothesized that this finding might causally be related to altered Ca^{2+} transients in human cardiomyopathy. In order to better understand the intracellular function of S100A1, we established a model of S100A1 gene therapy in rabbit myocardium. S100A1 cDNA was cloned into an adenoviral shuttle behind a CMV-promotor, while green fluorescent protein (GFP) was introduced into the shuttle as reporter gene. S100A1 adenoviral infection of myocardium was performed with 2×10^{11} virus particles (n = 6 animals). Rabbits infected with empty virus (2×10^{11} virus particles; n = 6) and rabbits injected with saline (n = 11) served as controls. Efficacy of infection was controlled by GFP detection. Overexpression of S100A1 was confirmed by northern and western blotting. Hemodynamic data were gained on day 7 under basal conditions and isoproterenol stimulation (0.1, 0.5, 1 μg/kg/min iv). *Empty-virus* rabbits showed a reduced contractility +dP/dt (−10%; $p < 0.01$) and a decreased systolic ejection pressure SEP (−9%; $p < 0.02$) as compared to saline controls. This loss of contractility caused by the *empty virus* induced T-cell myocarditis was overcompensated by S100A1 adenoviral infection leading to an increase of +dP/dt by +18% ($p < 0.03$) and SEP by +11% ($p < 0.06$). Compared to saline controls S100A1 transgenic rabbits showed an increase of +dP/dt and SEP by 5% (n.s.). These data demonstrate for the first time that the S100A1 adenoviral gene transfer leads to an improvement of contractility and might thus be of great interest for gene therapy of heart failure.

1985 Cardiomyoblast-mediated ex vivo gene transfer into the infarcted myocardium

S. Aboulafia-Etzion, J. Leor, I. Barbash, O. Manor, Y. Granot, A. Battler. *Cardiology Dept, Ben-Gurion University, Beer-Sheva, Israel*

Gene transfer to the heart for investigation and therapy of diseases is a rapidly expanding field with a potential clinical application. Introduction of therapeutic genes, such as those encoding for growth factors, into the ischemic myocardium may improve collateral circulation, enhance healing, function and viability. However, introduction of therapeutic genes into the infarcted myocardium is seriously limited because of the intense inflammatory response. We examined the possibility that cardiomyocytes could be genetically marked or modified before being grafted to the infarcted heart under conditions applicable to the clinical setting. In addition, we tested the hypothesis that this approach may be superior to direct injection of adenoviral vector. Rats were subjected to extensive myocardial infarction by permanent LAD coronary artery occlusion. We delivered a replication-defective recombinant adenovirus carrying the beta-galactosidase reporter gene (4x10E11 OD/ml) to cultured rat fetal cardiac myocytes. Almost all fetal cardiomyocytes in the primary culture expressed beta-galactosidase 24 hours after recombinant adenovirus transfection. These cells (1x10E6) were transplanted into the infarcted rat hearts 7 days after induced myocardial infarction (n = 3). Another group of infarcted rats (n = 3) was subjected to direct injection of adenovirus carrying the same reporter gene. Expression of the beta-galactosidase gene in the grafted cells was demonstrated by staining with X-gal, resulting in a blue color. Transgene expression was recognized 7 days after transplantation and was significantly greater than expression achieved by direct injection of adenovirus into myocardial infarction.

Conclusions: Our findings demonstrate that ex vivo gene transfer to the infarcted myocardium is feasible and significantly more efficient than direct adenoviral vector mediated gene delivery. Our results suggest that the ex vivo approach may eliminate one of the major hurdles facing the application of gene therapy to myocardial infarction.

1986 Growth hormone attenuates pathologic remodelling and decreases myocardial noradrenaline content in the rats with postinfarct heart failure

E. Omerovic[1], E. Bollano[1], R. Fahrani[1], M. Basetti[2], V. Kujacic, B. Soussi[2], Å. Hjalmarsson[1], F. Waagstein[1], J. Isgaard[3]. [1]*Wallenberg;* [2]*Lundberg Laboratories, Sahlgrenska University Hospital;* [3]*Research Centrum for Endocrinology and Metabolism, Sahlgrenska University Hospital Gothenburg, Sweden*

Background: Increasing experimental evidence suggests that growth hormone (GH) may have beneficial effects in the treatment of heart failure. However, the mechanisms behind these positive effects are poorly understood. The aims of this study were: 1) to investigate the effects of GH on cardiac function, remodeling and energy metabolism in the postinfarct phase 2) to evaluate the effect of GH on myocardial noradrenaline content.

Methods: Myocardial infarction (MI) of left ventricular (LV) anterolateral wall was induced by ligation of the left coronary artery in male Sprague-Dawley rats (200–250 g). Three different groups were studied: MI rats treated with GH (GH, n = 11) (3 mg/kg/day), MI rats placebo treated (P, n = 10), and sham operated rats (S, n = 7). All rats were investigated with transthoracic echocardiography and ^{31}P magnetic resonance spectroscopy (for estimation of myocardial energy status) at 3 days and 3 weeks after MI. Myocardial catecholamines content was analyzed by high performance liquid chromatography with electrochemical detection.

Results: The results are summarized in the table. Treatment with GH attenuated increase in LV volumes and improved LV systolic function. Myocardial content of noradrenaline was markedly decreased (42%) in the GH group compared to P.

	ΔEF %	ΔEDV ml	ΔESV ml	LV/BW mg/g	NA ng/g
GH	$6.6 \pm 5.2^{*}$	$15.1 \pm 2.1^{*}$	$9.3 \pm 1.5^{*\#}$	2.5 ± 0.05	$385 \pm 37^{*\#}$
P	-15.6 ± 6.6	$24.3 \pm 2.5^{\#}$	$17.6 \pm 2.3^{\#}$	2.4 ± 0.06	661 ± 86
S	1.6 ± 5.2	8.7 ± 2.2	3.1 ± 1.5	2.8 ± 0.09	583 ± 67

EF = ejection fraction, EDV = end distolic volume, ESV = end systolic volume, LV/BW = left ventricular index, NA = noradrenaline, * = $p < 0.05$ v. Placebo; # = $p < 0.05$ v. sham

Conclusion: GH attenuates pathological remodeling and improves systolic function of LV without induction of LV hypertrophy. The marked decrease in myocardial content of NA after GH treatment may protect myocardium from adverse effect of catecholamines during postinfarct remodeling phase.

1987 Pharmacokinetics of recombinant fibroblast growth factor-2 after intracoronary administration in patients with severe coronary artery disease in a phase I study

Rene A. Braeckman[1], Corine Dietz[1], M.J. Whitehouse[1], Roger J. Laham[2], Michael Simons[1], Mark Leimbach[3], Nicolas A. Chronos[3]. [1]*Chiron Corporation, Emeryville CA;* [2]*Beth-Israel Deaconess Medical Center, Boston MA;* [3]*Emory University, Atlanta GA, USA*

Background: FGF-2, a powerful mitogen capable of inducing angiogenesis in animal models, has undergone Phase I testing in patients with severe coronary artery disease (CAD) who remain symptomatic despite optimal medical management and are suboptimal candidates for standard revascularization procedures.

Methods: In a dose-escalation protocol, rFGF-2 was delivered as a single 20 minute infusion divided between two major sources of coronary blood supply. Doses (ug/kg) studied were 0.33 (n = 4), 0.65 (n = 4), 2 (n = 8), 6 (n = 4), 12 (n = 4), 24 (n = 8), 36 (n = 10), 48 (n = 10). Patients were pretreated with 40 U/kg heparin 1–95 min before the start of the rFGF2 infusion. Concentrations of rFGF-2 in the EDTA plasma samples were measured by a commercially available ELISA.

Results: The rFGF-2 plasma concentrations followed a bi-exponential curve with an initial (first hour) steep decline over several log scales (distribution phase), followed by a more moderate decline (elimination phase). Peak rFGF-2 plasma levels increased proportionally with dose from approximately 1 to 1000 ng/mL, and areas under the plasma concentration-time curves (AUC) increased linearly with dose. The mean (±SD) value for the terminal elimination half-life ($T_{1/2}$) was 1.9 ± 2.2 hr; for the elimination clearance (CL) was 264 ± 150 mL/hr/kg; and for the volume of distribution (V_{ss}) was 184 ± 74 mL/kg. Across patients, greater systemic rFGF-2 exposure (AUC) was observed when heparin pretreatment was given closer to the start of the rFGF-2 infusion. This is consistent with slower clearance of circulating heparin/FGF-2 complexes.

Conclusions: The pharmacokinetics of rFGF-2 after a single intracoronary dose of rFGF-2 in patients with CAD were linear and predictable.

NEW ASPECTS OF ENDOTHELIAL DYSFUNCTION IN HEART FAILURE

1993 Improvement of endothelial dysfunction in patients with congestive heart failure during treatment with carvedilol

J. Refsgaard, F. Andreasen[1], O. Goetzsche. *Department of Cardiology, Aarhus Amtssygehus, Aarhus C; [1]Dept. of Pharmacology, Aarhus University, Aarhus, Denmark*

Congestive heart failure (CHF) is a condition with endothelial dysfunction, where antioxidants has been shown to improve forearm blood flow via endothelium dependent mechanisms. Carvedilol, a non-selective, vasodilating beta-blocker, with antioxidant properties, might therefore be beneficial on endothelium-dependent regulation of vasomotion. The thesis was tested in a randomized, double-blinded, placebo-controlled study.

Methods: We randomised 60 patients with CHF (EF 31 ± 8,NYHA II-III) to receive either carvedilol (C), n = 40, 25 mg b.i.d. or placebo (P), n = 20 additional to standard therapy. Measurements of brachial artery diameter were done utilizing 7.0 MHz vascular probe, and were performed at rest, during reactive hyperemia (an endothelium-dependent stimulus to vasodilaion = Flow Mediated Dilation (FMD)), after 10 minutes resting, and finally after administration of sublingual nitroglycerin (an endothelium-independent vasodilation = Nitroglycerin Induced Dilation (NID)). FMD and NID were calculated in relation to resting diameters (mean of 16 measurements) before (Pre) and after (Post) 23 weeks therapy. Seven patients (5 C, 2 P) dropped out of the study, and tapes from 3 patients (2 C, 1 P) were not readable. The groups were comparable by age, blood pressure, cholesterol, blood glucose and HbA1C (see table).

	Carvedilol (n = 33)	Placebo (n = 17)
FMD% Pre	2.06	2.41
FMD% Post	6.28*	2.32
NID% Pre	13.9	13.5
NID% Post	15.0	13.3

*P = 0.003 vs placebo, values are mean.

Conclusion: Carvedilol appears to improve endothelial function in patients with CHF. A general improvement in endothelial function during treatment with carvedilol, could contribute to the decrease in mortality, which has been shown earlier. However, further prospective studies should be performed to clarify the importance of reversing endothelial dysfunction.

1994 Improvement in vascular endothelial function in patients with heart failure treated with β-blockers

A. Gonta, G. Dan, C. Stanescu, M. Vintila. *Cardiology Dept, University Hospital "N.G.Lupu", Bucharest, Romania*

In patients with chronic heart failure long term administration of beta-blockers induces clinical and haemodynamic improvements. Even if the beneficial effect of ACE inhibitors (ACEI) on the endothelial function was proved, little is known about the effect of beta-blockers on the vascular endothelial function in patients with heart failure.

We hypothesized that chronic beta-blockade in heart failure could have a beneficial effect on the peripheral vascular endothelial function as manifested by the improvement of percent increase of brachial artery diameter following 5 min. of upper arm arterial occlusion.

Methods: We included 45 patients with chronic heart failure (NYHA class more than II, EF 27% ± 7.5). They were randomized in 2 groups of treatment: group A treated with ACEI and group B treated with ACEI + Metoprolol in progressively increasing doses. The two groups had similar baseline characteristics. At inclusion and after 16 months of treatment the percent change in brachial artery (%BA) diameter after 5 min. of upper arm blood pressure cuff occlusion was measured using a 7.5 MHz echographic transducer.

Results: At baseline both groups had similar%BA (6.45% ± 5.5 vs. 6.37% ± 5.7; p: NS). After 16 months follow-up%BA in group A was 10.3% ± 4.7 ($p < 0.01$ vs. baseline) and in group B was 13.7% ± 5.2 ($p < 0.01$ vs. baseline and $p < 0.05$ vs. group A).

Conclusion: Chronic administration of beta-blockers (Metoprolol) could enhance the improvement of endothelial-dependent vasodilatation obtained in patients with heart failure treated with ACEI.

1995 Antioxidative treatment reduces endothelial cell apoptosis induced by congestive heart failure serum

L. Rössig, A. Haase, A.M. Zeiher, S. Dimmeler. *Molecular Cardiology, Department of Internal Medicine IV, University of Frankfurt, Germany*

Congestive heart failure (CHF) is associated with increased serum levels of proinflammatory cytokines. Apoptosis of endothelial cells induced by proapoptotic cytokines could contribute to endothelial dysfunction observed in patients with heart failure. We measured apoptosis rates of endothelial cells exposed to serum of CHF patients and determined the effect of antioxidative treatment.

Results: In endothelial cell culture, application of serum of patients with CHF induced apoptosis ($p < 0.05$ vs. healthy volunteers). Endothelial cell apoptosis was significantly correlated with clinical NYHA staging of patients ($p < 0.05$) and with TNFα serum levels as a marker of proinflammatory activity ($p < 0.001$). Coincubation with either vitamine C (100 μM) or the antioxidative β-blocker carvedilol (5 μM), which improves the clinical performance of patients with CHF, suppressed the proapototic activity of CHF serum ($p < 0.005$ and $p < 0.001$, respectively), whereas the β-blocker propranolol had no effect. Apoptosis induction in endothelial cells by TNFα (50 ng/ml) was as well antagonized by vitamine C or carvedilol. To demonstrate the *in vivo* relevance of antioxidants as mediators of endothelial cell survival in CHF, we treated heart failure patients with vitamine C. Serum drawn from patients following a 3 day treatment with 2.5 g oral vitamine C per day lead to significantly lower proapoptotic activity in cultured endothelial cells compared to serum of the same patients before treatment ($p < 0.05$).

In conclusion, these data suggest that endothelial cell apoptosis induced by activation of the proinflammatory cytokine cascade could be involved in the pathophysiology of endothelial dysfunction in CHF. The antiapoptotic activity of antioxidants such as carvedilol or vitamine C on the endothelium could contribute to their beneficial effect in heart failure.

1996 Endothelial dysfunction secondary to oxidative stress impairs left ventricular relaxation in pressure-overload hypertrophy

P.A. MacCarthy, A.M. Shah[1]. *Departments of Cardiology, U niversity of Wales Coll Medicine, Cardiff; [1]Kings College London, UK*

Endothelium-derived NO enhances LV relaxation via direct effects on cardiac myocytes. We have previously shown that the NO-mediated LV relaxant effect of bradykinin (BK) and substance P (sub P), is blunted in guinea pigs with compensated pressure-overload LVH, 3 weeks after aortic banding. In this study, we investigated potential underlying mechanisms. The expression of eNOS protein in whole LV homogenate (Western blot) was similar in banded (n = 6) and sham-operated (n = 5) animals (7.6 ± 0.5 vs 7.8 ± 1.0 densitometric units respectively; P = NS). Isolated ejecting hearts of banded animals were studied at varying pre-load, constant afterload and constant, paced heart rate. LV pressure was measured by a 2F Millar catheter. Changes in the timing of onset of LV relaxation, assessed by the time to dP/dt_{min} (TdP/dt_{min}, ms), after addition of sub P (100 nM) or BK (10 nM) were measured with and without pre-treatment with the anti-oxidants vitamin C (vit C, 10 μM) or deferroxamine (Def, 0.5 mM).

Results are shown below.

$\Delta TdP/dt_{min}$ (ms)		+Vit C	+Def
Sub P	0.9 ± 1.9	−5.9 ± 1.5*	−8.9 ± 2.2*
BK	−3.4 ± 1.8	−8.8 ± 1.5*	−8.3 ± 1.3*

$n \geq 6$ in each group. All values ± SEM. *P ≤ 0.05 vs sub P/BK alone

Neither vit C nor Def had an effect on LV pressure, dP/dt_{max} or coronary flow. Thus, acute administration of anti-oxidants restored the ability of sub P and BK to enhance LV relaxation in LVH.

Conclusions: 1) cardiac endothelial dysfunction associated with pressure-overload LVH may be secondary to increased oxidative stress and decreased bioavailability of NO; 2) endothelial dysfunction impairs NO-mediated enhancement of LV relaxation.

1997 Asymmetrical-dimethyl-arginine, an inhibitor of the nitric oxide synthase: relation to endothelium-mediated vasodilation and peak oxygen consumption in patients with chronic heart failure

Burkhard Hornig, Naoshi Arakawa, Christian Probst, Ulf Landmesser, Rainer Boeger[1], Stefanie Bode-Boeger[1], Juergen Froehlich[1], Helmut Drexler. *Department of Cardiology and Angiology; [1]Department of Clinical Pharmacology; Medical School of Hannover, Germany*

Flow-dependent, endothelium-mediated vasodilation (FDD) is reduced in patients with chronic heart failure (CHF) possibly due to reduced formation of nitric oxide (NO) from ist precursor L-arginine. We hypothesized that plasma levels of asymmetrical-dimethyl-arginine (ADMA), a competitive antagonist of L-arginine, are increased in CHF leading to reduced availability of NO. Accordingly, FDD of the radial artery was determined in 37 patients with CHF (NYHA III) and 27 healthy controls (N). Diameter (high resolution ultrasound; precision 2 μm) and blood flow (BF; ml/min) were measured at rest and after wrist occlusion (8 min). Plasma levels of L-arginine and ADMA were measured using HPLC, L-arginine/ADMA ratio was calculated. Peak oxygen consumption was determined by spiroergometry.

	FDD (%)	ADMA (μmol/l)	L-arginine/ ADMA-ratio	peak oxygen consumption (ml/kg/min)
Normals	15.3 ± 0.6	0.99 ± 0.1	106 ± 7	40.1 ± 2.2
CHF	7.1 ± 0.7*	4.16 ± 0.6*	24 ± 6*	14.7 ± 0.6*

(all data mean ± SEM; *p < 0.01 vs. N).

There was an inverse correlation between ADMA plasma levels and FDD ($r = -0.79$; $p < 0.01$) and between ADMA plasma levels and peak oxygen consumption ($r = -0.72$; $p < 0.01$) and a positive correlation between L-arginine/ADMA-ratio and FDD ($r = 0.85$; $p < 0.01$) respectivly peak oxygen consumption ($r = 0.75$; $p < 0.01$).

Conclusion: In patients with chronic heart failure plasma levels of the NO-synthase inhibitor ADMA are increased up to 400%. There is an inverse correlation to endothelium-mediated vasodilation and peak oxygen consumption.

1998 Spironolactone suppresses vascular ACE and improves endothelial dysfunction in patients with chronic heart failure

C.A.J. Farquharson, A.D. Struthers. *Department of Clinical Pharmacology and Therapeutics, Ninewells Hospital and Medical School, Dundee, UK*

Background: The RALES study has shown that spironolactone, when added to conventional therapy for chronic heart failure, has an added beneficial effect on cardiovascular mortality. We wished to test the hypothesis that this benefit was in part due to improvement in endothelial dysfunction and/or increased suppression of the vascular renin-angiotensin axis.

Methods: A randomised, placebo controlled, double-blind cross-over study was performed on 10 patients with NYHA Class II–III chronic heart failure taking standard diuretic/ACEI therapy, comparing 50 mg spironolactone daily (1 month) vs placebo. Brachial artery endothelial function was assessed by bilateral forearm venous occlusion plethysmography using *acetylcholine* and *N-monomethyl-L-arginine*, with *sodium nitroprusside* as a control vasodilator. In addition, vascular ACE activity was assessed using *angiotensin I*, with *angiotensin II* as a control vasoconstrictor.

Results: Spironolactone significantly increased the forearm blood flow response to acetylcholine (percentage change in forearm blood flow (mean ± SEM): 177 ± 29% vs 95 ± 20% spironolactone vs placebo; $p < 0.001$), with an associated increase in vasoconstriction observed with L-NMMA (−18 ± 4% vs −35 ± 6% placebo vs spironolactone; $p < 0.05$). There was no significant difference in blood flow between treatments with regards to nitroprusside (290 ± 98% vs 281 ± 47% placebo vs spironolactone; p = NS). The angiotensin I response between treatments was also significantly reduced with spironolactone (−42 ± 8% vs −35 ± 8% placebo vs spironolactone; $p < 0.05$), with no statistical differences observed with the control vasoconstrictor angiotensin II.

Conclusion: Spironolactone improves endothelial dysfunction and inhibits vascular ACE in patients with chronic heart failure. This provides a novel mechanism for its beneficial effect on cardiovascular mortality.

NEW ANTIPLATELET TREATMENTS IN UNSTABLE ANGINA AND ACUTE MYOCARDIAL INFARCTION

2012 Evaluation of combination therapy with tirofiban and enoxaparin in patients with unstable angina and non-Q-wave myocardial infarction

M. Cohen, P. Theroux, S. Weber, P. Laramee, S. Borzak, J.G. Diodati, T. Huynh, I.B. Squire, L.I. Deckelbaum, A.R. Thornton, K.E. Harris, F.L. Sax, H. White. *MCP Hahnemann University, Philadelphia PA; Merck Research Laboratories, West Point, USA*

Tirofiban (T) (AGGRASTAT®) an intravenous platelet GP IIb/IIIa antagonist, and enoxaparin (E) (LOVENOX®, CLEXANE®), a low molecular weight heparin, have been shown to be effective at reducing cardiac ischemic events in separate trials of unstable angina and non-Q wave MI (UA/NQMI). The combination of these agents may offer further therapeutic benefit. The present study randomized patients with UA/NQMI to double-blind treatment with T (0.1 μg/kg/min iv) for 48–108 hours coadministered with either E (1 mg/kg sc q 12 h) (n = 26) or unfractionated heparin (UH) (iv adjusted to aPTT) (n = 27) to evaluate pharmacodynamics and safety. Coadministration of T and E was generally well tolerated. No patient discontinued T and E treatment due to adverse events. Administration of T with E vs UH resulted in lesser variability and a trend towards greater inhibition of platelet aggregation (IPA) using 5 μM ADP agonist.

Median IPA%	T and E (N = 25)	T and UH (N = 24)	p-value
Hour 24	88.0	83.9	0.06
Hour 30	88.8	86.4	0.10
Hour 48	87.6	83.5	0.05
Average	87.1	85.4	0.08

More patients achieved target IPA > 70% in the T + E group (88% vs 62%, p = 0.05). Median bleeding time (BT) was 21 minutes for T + E vs ≥30 minutes for T + UH (p = NS). For a given level of IPA, BT was less prolonged with T + E than T + UH (adjusted mean BT 19.9 vs 24.6 minutes, p = 0.03). There was an increase in nuisance cutaneous bleeding in the T + E group (46% vs 18%). However, there were no major or minor bleeding events in either group by the TIMI criteria.

Conclusions: The lower adjusted BT and more consistent IPA of T + E vs T + UH support the therapeutic potential of combining these two agents. These data are consistent with prior data which show differential pharmacodynamic effects of E and UH on platelet aggregation.

2013 First report of an intravenous and oral glycoprotein IIb/IIIa inhibitor administered in patients: results of TIMI 15B

R.P. Giugliano, C.H. McCabe, M. Frey[1], H.S. Müller[2], J.-F. Tamby[3], B.K. Jensen[3], S.B. Nicholas[4], L.K. Jennings[5], R.J. Wise[6], E. Braunwald. *Cardiovascular Division, Brigham and Women's Hospital, Boston MA; [1]Heart Center of Sarasota, Sarasota; [2]Cardiology Division, Montefiore Medical Center, Bronx; [3]Rhone-Poulenc Rorer, Collegeville, USA; [4]Rhone-Poulenc Rorer, Antony Cedex, France[5]Haematology Division, University of Tennessee, Memphis[6]Haematology Division, Brigham and Women's Hospital, Boston MA, USA*

Background: Intravenous platelet glycoprotein IIb/IIIa receptor blockade is beneficial in high-risk unstable angina and angioplasty. RPR 109891 is a unique competitive inhibitor because it is available in both IV and oral formulations.

Methods: We performed a phase II double-blind placebo- controlled dose-ranging trial in patients with acute coronary syndromes who were randomized to 24–96 hrs of IV RPR 109891 followed by 1 of 6 different doses of oral RPR 109891 for 1 mth vs IV placebo followed by oral placebo. Inhibition of platelet aggregation (IPA) to ADP-20 uM and receptor occupancy (RO) were measured in 110 pts; plasma drug levels and safety information were collected in all patients.

Results: 192 patients (median age 60 years, 75% men, 49% with UA) were enrolled in 4 countries. Preliminary results (aggregate data for all patients including those receiving placebo) were as follows: at end of IV infusion the median IPA was 83%, while median IPA 4 hours post oral drug was 43%. Median RO was 86% at end IV infusion and 82% 4 hours post oral drug. Major hemorrhage occurred in 9 patients (4.7%) during the IV phase and in 7 patients (4.2%) during the oral phase. Thrombocytopenia (<90 K) occurred in 23 pts (11.9%), of which 9 pts had associated bleeding. Unblinded data by dose group will be available after March 1999 and will be presented.

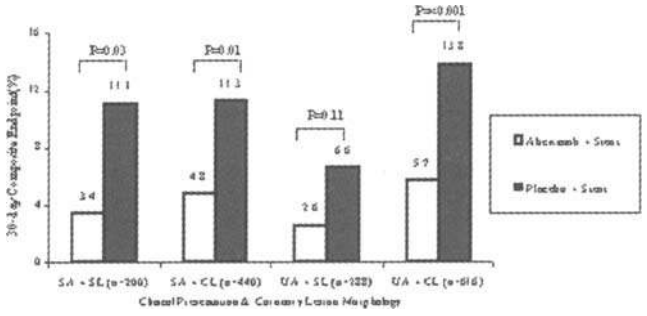
Conclusions: A strategy of IV followed by oral GP IIb/IIIa inhibition with RPR 109891 can achieve moderate-high degrees of platelet inhibition, although poor bioavailability and thrombocytopenia represent challenges to its oral administration.

2014 Which patients should receive abciximab in the contemporary stent era?

V.B. Patel, D.J. Moliterno, A.M. Lincoff, C. Balog, S.G. Ellis, E.J. Topol. *Cardiology Dept., The Cleveland Clinic Foundation, Cleveland OH, USA*

Background and Objective: While abciximab, a potent IIb/IIIa inhibitor, is effective at reducing ischemic events during PCI, its use in the contemporary stent era has been limited by cost issues. With this in mind, we reviewed the largest prospective stent trial (EPISTENT) to discern which stent patients derive greatest benefit from adjunctive IIb/IIIa therapy. To simplify patient selection during stenting, we categorized patient as having stable angina (SA) or unstable angina (UA) and as having a simple [type A,B1] lesion (SL) or complex [type B2,C] coronary lesion (CL).

Methods and Results: Of the 2305 EPISTENT patients with stable or unstable angina, 760 were randomized to stent plus abciximab and 784 to stent plus placebo. The addition of abciximab provided a marked reduction in clinical events (30-day death, MI, urgent revasc) in both stable and unstable angina patients (Figure). Abciximab therapy provided the highest risk group (UA+CL) a 59% relative and 8.1% absolute risk reduction (13.8% vs 5.7%, p = 0.001) and the lowest risk group (SA+SL) a 69% relative and 7.7% absolute risk reduction (11.1% vs 3.4%, p = 0.03). Importantly, these absolute and relative benefits persisted at 6 months.



Outcomes by angina and lesion definition.

Conclusion: The use of abciximab in conjunction with stents substantially improves clinical outcome in a wide spectrum of patients with a large relative (~50%) and absolute (~8%) reduction in adverse clinical events. Though cost remains an important issue, the strikingly similar benefit in high-risk and low-risk patients makes it difficult to preferentially recommend abciximab therapy for a specific group of stent patients.

2015 Bailout use of abciximab in complicated PTCA: results from the Italian registry RICORDA (Registro Italiano sulle COndizioni d'uso di Reopro Durante Angioplastica)

I. Simonetti, M. Gallopin[1], S. Klugmann[2], G.F. Gensini. *Istituto di Clin Med Gen e Cardiologia, Universita di Firenze, Florence; [1]CNR Institute of Clinical Physiology, Pisa; [2]Cardiologia, Ospedale Niguarda, Milan, Italy*

Aim: The R.I.CO.R.D.A. registry was created with the aim of monitoring the early Italian experience on the clinical use of abciximab (ReoPro) in the setting of high risk coronary angioplasty (PTCA). Indications for enrollement included clinical presentation (acute myocardial infarction (MI), unstable angina), complex coronary anatomy (type C lesions, diffuse coronary disease, intracoronary thrombosis), or procedural factors, such as deployment of long or multiple stents, coronary dissection, acute coronary occlusion, etc. Abciximab administration was either elective (i.e. pre-PTCA) or in the course of a complicated precedure (bailout administration).

Results: From June 1996 to January 1998, 359 patients undergoing PTCA on 443 lesions were enrolled in 24 catheterization laboratories. In 91/359 patients (25%), abciximab was administred as bailout, and in the remaining cases as a pre-treatment before PTCA. The incidence of death, coronary artery bypass grafting (CABG), Q wave and large non-Q wave MI, small non-Q wave MI and recurrent ischemia in the elective group were 1.9%, 1.9%, 2.6%, 6.7% and 3.4%, respectively. In the bailout group, corresponding figures were 4.4% (ns), 3.3% (ns), 16.5% ($p < 0.01$), 16.5% ($p < 0.01$), and 12.1% ($p < 0.01$). Heparin dose during PTCA was quite variable. Overall, 46% of patients were administered a dose of heparin 5,000 U or less, while the remaining received a higher dose, more often 10,000 U. As expected, the latter group showed a significantly higher incidence of bleeding complications (25% vs 10%; $p < 0.01$). The incidence of bleeding was almost double in patients treated with abciximab in bailout (29% vs 15%; $p < 0.01$), due to the higher heparin dose used in this group (mean ± SD: 9,253 ± 3,341 U vs 6,649 ± 3,156 U; $p < 0.01$).

Conclusions: Bailout use of abciximab occurred in a quarter of patients enrolled in this registry. The incidence of adverse cardiac events and bleeding complications in the elective abciximab group was comparable with that reported in the major large scale international trials. The bailout group showed a higher incidence of both cardiac events and bleeding complications.

2016 Remarkable consistency of benefit of ADP receptor blockade compared with aspirin across a variety of endpoints, including avoidance of rehospitalization

D.L. Bhatt, E.J. Topol, W. Hacke[1], A.T. Hirsch[2]. *Cardiology Dept., The Cleveland Clinic Foundation, Cleveland OH, USA; [1]Neurology Dept., Univ of Heidelberg Medical School, Heidelberg, Germany [2]Minnesota Vascular Disease Center, Univ of Minnesota Medical School, Minneapolis, USA*

In a large, international trial of 19,185 patients with atherosclerotic vascular disease, the ADP receptor antagonist, clopidogrel, was compared with aspirin for the primary outcome cluster of vascular death, ischemic stroke, or myocardial infarction (MI). Although an 8.7% relative-risk reduction (RRR) was noted for the overall trial primary endpoint, important secondary endpoints had not been ascertained. This is especially true in the case of repeat hospitalizations in such patients, which represent a considerable economic burden and may further reflect efficacy in an active-control comparison of antiplatelet agents.

Results: RRRs and the 3-year event rates for clopidogrel vs. aspirin are shown below (on-treatment analysis) (see table).

Endpoint	3-year event rates	RRR (p-value)
Stroke (all causes, fatal/non-fatal), MI (fatal/non-fatal)	Clopidogrel 10.32% Aspirin 12.14%	12.2 (0.017)
Death (all causes), non-fatal stroke (all causes), MI	Clopidogrel 14.35% Aspirin 15.71%	7.2 (0.113)
Vascular death, non-fatal stroke (all causes), MI, hospitalization for angina, TIA or limb ischemia	Clopldogrel 26.24% Aspirin 27.72%	7.4 (0.022)

There was a significant reduction of 9.3% in the incidence of rehospitalization for clopidogrel compared with aspirin (13.9% vs 15.3%; p = 0.032), and this was consistent across individual outcomes of unstable angina, transient ischemic attack (TIA), or limb ischemia. By multivariate analysis for reduction of vascular death, stroke, MI, or hospitalization, clopidogrel therapy was an independent predictor (p = 0.015).

Conclusions: The use of clopidogrel led to a highly consistent demonstration of superiority over aspirin, and both confirmation and extension of this benefit is reflected in the avoidance of hospitalizations related to atherosclerotic disease.

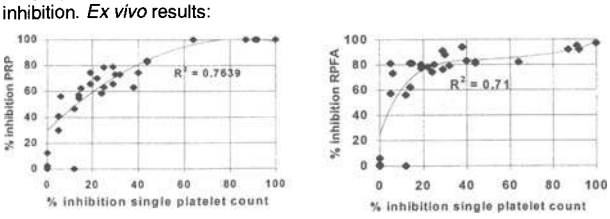
2017 A whole blood assay for ex vivo monitoring of glycoprotein IIb/IIIa antagonists

R.F. Storey, J.A. May, R.G. Wilcox, S. Heptinstall. *Cardiovascular Medicine, University Hospital, Nottingham, UK*

Background: Platelet rich plasma (PRP) turbidimetry, the standard method for monitoring GPIIb/IIIa antagonists, has many limitations and only measures inhibition of platelet macroaggregation. We have used a whole blood (WB) assay for monitoring inhibition of microaggregation, comparing this with PRP turbidimetry, WB impedance aggregometry and Accumetrics Rapid Platelet Function Assay (RPFA).

Methods: *In vitro* studies were performed to assess the effects of fradafiban, an intravenous GPIIb/IIIa antagonist, on platelet aggregation in WB and PRP using ADP 30 μM as agonist, in order to validate a WB assay based on single-platelet counting. *Ex vivo* studies were performed on blood from patients with unstable angina (n = 8) randomised to receive either oral lefradafiban (the prodrug of fradafiban) or placebo. Blood samples were taken before and during treatment and analysed by 4 methods: (1) PRP turbidimetry (2) WB impedance aggregometry (3) RPFA, Accumetrics (4) WB single-platelet counting assay.

Results: There was good correlation between PRP turbidimetry, RPFA and single-platelet counting assay inhibition values ($R^2 > 0.7$). Impedance aggregometry showed complete inhibition at low levels of GPIIb/IIIa blockade. Single-platelet counting and RPFA were most discriminating at high levels of inhibition. *Ex vivo* results:



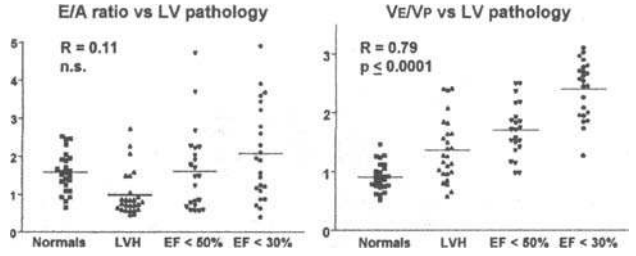
Conclusion: The whole-blood single-platelet counting assay is an ideal tool for monitoring GPIIb/IIIa antagonists in the predicted therapeutic range, providing information on inhibition of microaggregation.

ECHO DOPPLER INSIGHTS INTO LEFT VENTRICULAR FILLING

2018 Evaluation of left ventricular diastolic function by the ratio of maximal flow velocity of the early filling wave to its propagation velocity

B.A. Popescu, A.C. Popescu, E. DiSegni, E. Kaplinsky, V. Guetta, S. Rath, B. Rabinowitz, M.S. Feinberg, E. Schwammenthal. *Heart Institute, Chaim Sheba Medical Center, Tel Hashomer; Sackler School of Medicine, Tel Aviv, Israel University*

Active left ventricular relaxation creates a small intraventricular gradient which determines the propagation velocity of the early filling wave from the base of the left ventricle to the apex (V_P), which can be assessed by color M-Mode echocardiography. Impaired relaxation will reduce V_P and cause vortex formation as blood flow entering the ventricle interacts with stagnant blood within the cavity. In this case maximal particle velocity during early filling (V_E), assessed by pulsed wave Doppler, will significantly exceed V_P. We therefore hypothesized that the ratio of V_E to V_P will be directly correlated to the severity of left ventricular pathology and examined 96 consecutive subjects: 25 normals, 26 patients with LVH, and 45 patients with reduced EF. While the E/A ratio showed an expected U-shaped relation to the severity of LV pathology, V_E/V_P showed a direct linear correlation. Out of 24 patients with a $V_E/V_P > 1.85$ 19 patients (79%) had either a history of pulmonary congestion or developed it within 6 months.



Conclusion: V_E/V_P is a parameter of diastolic function which increases directly with the severity of left ventricular pathology and potentially predicts outcome.

2019 Different effect of inotropic stimuli and preload changes on intraventricular pressure gradients during rapid early left ventricular filling

K. Steine, M. Stugaard[1], O.A. Smiseth[1]. *Med. Dept., Aker Hospital, Oslo; [1]Institute for Surgical Research, Rikshospitalet, Oslo, Norway*

Objectives: This study investigates mechanisms of LV intracavitary early diastolic flow.

Methods: In twelve anaesthetised dogs we measured LV pressures at the mitral tip and in the apex, intraventricular velocities by color M-mode Doppler, and LV volume by sonomicrometry. We investigated responses to isoprenaline, to ischaemic LV failure by coronary microembolization, and to changes in preload by volume loading.

Results: Modulation of LV inotropy caused marked changes of the early diastolic mitral-to-apical pressure gradient, from 1.4 ± 0.6 to 3.2 ± 1.8 ($p < 0.05$) after isoprenaline and to 0.6 ± 0.5 mmHg ($p < 0.05$) after coronary micro-embolization, and inflow tract peak velocity increased from 0.51 ± 0.03 to 0.71 ± 0.13 m/s ($p < 0.05$) and decreased to 0.35 ± 0.10 m/s ($p < 0.05$), respectively. Volume loading, however, did not change the mitral-to-apical pressure gradient, although inflow tract velocity increased moderately from 0.56 ± 0.08 to 0.65 ± 0.09 m/s ($p < 0.05$). The different responses to increased inotropy and increased preload were associated with opposite effects on LV end-systolic volume and time constant of isovolumic relaxation (tau), which both decreased ($p < 0.05$) with isoprenaline and increased ($p < 0.05$) with volume loading.

Conclusions: Inotropic stimuli modified intraventricular flow and the mitral-to-apical driving pressure by changing the rate of LV relaxation, and appeared to enhance apical suction. Elevation of preload did not change the mitral-to-apical pressure gradient, and the increased flow velocities were attributed to increased left atrial pressure. These findings have implications for how to interpret intraventricular filling patterns in a clinical context.

2020 Changes in filling dynamics and stroke volume due to atrial relaxation during early diastolic transmitral flow acceleration

A. Rónaszéki[1], A. Aubert, H. Ector, H. De Geest. *[1]Elisabeth Hospital, Cardiology, Budapest, Hungary; University Hospital, Cardiology, Leuven, Belgium*

Atrial relaxation (AR) during early diastolic transmitral flow acceleration (ED-Facc) may change filling dynamics and stroke volume (SV).

Methods: To analyse these changes micromanometric transmitral pressure gradient (TMPG), pulsed wave Doppler transmitral flow velocity profile and SV were measured and compared in EDFacc with and without AR in AV blocked, AV paced (80 bpm) dogs (N: 17).

Results: The duration and time integral of positive early diastolic TMPG decreased (37.6 ± 15.2 ms vs. 65.3 ± 17.0 ms, $p < 0.001$; 4.5 ± 59.9 mmHg*ms vs. 90.9 ± 58.1 mmHg*ms, $p < 0.05$; mean ± SD), but the reversed early diastolic TMPG did not change significantly (113.5 ± 35.0 ms vs. 108.2 ± 38.9 ms, NS; 89.1 ± 62.7 mmHg*ms vs. 85.2 ± 59.6 mmHg*ms, NS), EDFacc time shortened (41.9 ± 12.8 ms vs. 55.6 ± 12.6 ms, $p < 0.05$), EDFacc increased (996.1 ± 471.8 cm/s^2 vs. 823.6 ± 227.8 cm/s^2, $p < 0.05$), peak velocity fell (36.9 ± 8.5 cm/s vs. 43.9 ± 8.0 cm/s, $p < 0.05$), deceleration time did not change significantly (128.8 ± 33.4 ms vs. 131.2 ± 36.6 ms, NS), deceleration decreased (306.7 ± 120.3 cm/s^2) vs. 362.4 ± 128.8 cm/s^2, $p < 0.05$) and SV was smaller (67.8 ± 10.0% vs. 100%, $p < 0.001$) in EDFacc influenced by AR.

Conclusion: AR during EDFacc has unfavourable effect on filling dynamics and on SV explaining the hemodynamic background in some severe pacemaker syndrome.

2021 Propagation velocity of mitral inflow by colour M-mode is not independent of loading conditions in congestive heart failure

J.M. Van Dantzig, W.R.M. Dassen, C.M.H.B. Lucas, E.C. Cheriex. *Cardiology Dept., Academisch Ziekenhuis Maastricht, Maastricht, Netherlands*

Background: Interpretation of LV diastolic function is confounded by load-dependence of parameters used to asses it. The propagation velocity (PV) of mitral inflow into the LV has been proposed as a load-independent descriptor of LV diastolic function. Accurate assessment of diastolic function is especially advantageous in systolic dysfunction.

Methods: We examined changes in PV induced by sublingual nitroglycerin (NTG) 1.2 mg, an intervention known to decrease LA pressures. Twenty-one patients with LVEF < 40% by 2-D echo were included, while non-sinus rhythm, significant aortic valve disease, mitral stenosis or prosthesis were excluded.

Results: Age was 63 ± 14 (38–90) yrs, 5 were women, and 11 had an ischemic etiology. Mean LVEF was 32 ± 6 (21–40)%. At baseline, there was a significant correlation between E-velocity and PV (r = 0.69). Changes induced by NTG are shown in the Table. A significant decrease in E/A velocity ratio and an increase of E-wave deceleration time demonstrated that NTG succesfully lowered LA pressure. Similarly, pulmonary venous peak systolic-to-diastolic flow velocity ratio (S/D) increased. Heart rate was unchanged. Propagation velocity significantly decreased after NTG. No differences in response of PV to NTG was observed between ischemic and idiopathic etiology.

	E/A	E dec.time	S/D	PV (cm/s)	heart rate
Basal	1.9 ± 0.3	171 ± 10	0.9 ± 0.1	26 ± 2	66 ± 2
NTG	1.4 ± 0.2	203 ± 14	1.3 ± 0.1	22 ± 2	67 ± 3
% change	27	18	40	13	
P	0.005	0.002	0.004	0.03	NS

Changes induced by 1.2 mg NTG sublingually (mean ± SEM)

Conclusion: We found a decrease of PV after an intervention known to decrease LA pressure. This suggests that PV and LA pressure are positively correlated. It may be speculated that decreased PV after NTG is related to decreased atrio-ventricular pressure gradients.

Our findings indicate that PV may be subject to similar drawbacks as are the conventional parameters of LV diastolic function in congestive heart failure.

2022 Ratio of left ventricular peak E-wave velocity and flow propagation velocity assessed by colour M-mode Doppler echocardiography in first myocardial infarction: prognostic and clinical implications

J. Moller, E. Sondergaard, J.B. Seward[1], C.P. Appleton[2], K. Egstrup. *Department of Medicine, Svendborg Hospital, Svendborg, Denmark; [1]Cardiovascular Diseases, Mayo Clinic, Rochester; [2]Cardiovasvular Diseases, Mayo Clinic, Rochester, USA*

Objective: To determine the ability of the ratio of peak E-wave velocity and flow propagation velocity (E/FPV) measured with color M-mode echocardiography to predict in-hospital heart failure, and cardiac mortality in an unselected consecutive population with first myocardial infarction (MI).

Background: Several experimental studies indicate color M-mode echocardiography to be a valuable tool in the evaluation of diastolic function, but data regarding the clinical value are lacking.

Methods: Doppler echocardiography was performed within 24 hours of arrival at CCU. Highest Killip class was determined during hospitalization. Patients were divided in groups according to E/FPV < 1.5 and ≥1.5.

Results: 70 of 72 (97%) eligible patients were enrolled in the study. During hospitalization 35 patients were in Killip class II. In patients with E/FPV ≥ 1.5 Killip class was significantly higher compared to patients with E/FPV < 1.5 ($p < 0.0001$). Multivariate logistic regression analysis identified E/FPV ≥ 1.5 to be the single best predictor of in-hospital heart failure when compared with age, heart rate, E-wave deceleration time < 140 msec(Dt), ejection fraction, wall motion index (WMI) and enzymatic infarct size. At day 35 survival in patients with E/FPV < 1.5 was 97%, and in patients with E/FPV ≥ 1.5, 58% ($p = 0.0002$). Univariate Cox analysis identified Dt, E/FPV, age, WMI, Killip class II, heart rate, and enzymatic infarct size to be predictors of cardiac death. Cox proportional hazards model identified Dt, E/FPV ≥ 1.5 and age to be independent predictors of cardiac death, in the model Dt was superior to age and E/FPV.

Conclusions: E/FPV ≥ 1.5 measured with color M-mode echocardiography in the acute phase of MI was a strong predictor of in-hospital heart failure. In the prediction of cardiac death E/FPV was superior to systolic measurements, however E-wave deceleration time < 140 msec. was the most powerful predictor of cardiac death.

2023 Pulsed doppler-color M-mode E/Vp ratio for estimating mean left atrial pressure: an early postoperative coronary artery bypass grafting study

S. Martins, R.M. Soares[1], L. Branco, F. Neves[2], J.M. Ramos, C. Salomão, J. Roquette[2], A.M. Antunes. *Cardiology Dept., Hospital de Santa Marta, Lisbon; [1]Lisbon; [2]Cardiothoracic Surgery, Hospital de Santa Marta, Lisbon, Portugal*

Purpose: to evaluate the utility of the information obtained by combining the Doppler peak early transmitral velocity (E) with the color M-mode Doppler flow propagation velocity (Vp) for estimating mean left atrial (LA) pressure in early postoperative of coronary artery bypass grafting (CABG).

Methods: we studied 62 consecutive patients (pts) (48 males, 60 ± 14 years, sinus rhythm), 5.1 ± 2.3 hours after CABG, under mechanical ventilatory support. From the analysis of pulsed Doppler transmitral flow we obtained peak E and late (A) velocities (cm/s), E/A ratio and E wave decceleration time (EDcT – ms). We also measured the color M-mode Doppler Vp (cm/s) as the slope of the first aliasing velocity during early filling, from mitral valve plane to 4 cm distally into the left ventricle (LV) cavity, and we calculated E/Vp ratio. Simultaneously, LA pressure (LAp – mmHg) was obtained using LA line placed during surgery. All measurements were done at end-expiration.

Results: 10 pts (16%) were not considered due to inadequate echocardiographic images. In the remaining 52 pts: E = 57 ± 17 (23 to 111), A = 52 ± 19 (20 to 113), E/A = 1.3 ± 0.7 (0.3 to 3.5), EDcT = 149 ± 44 (50 to 240), Vp = 49 ± 19 (19 to 86), E/Vp = 1.36 ± 0.74 (0.43 to 3.64) and LAp = 10 ± 6 (2 to 25). We found a significant correlation between LAp and E ($r = 0.51$), E/A ($r = 0.68$), Vp ($r = -0.73$) and E/Vp ($r = 0.95$). The E/Vp provided the best correlation ($Z > 4.47$ – $p < 0.0001$) and best estimated LAp (LAp = 7.48xE/Vp-0.06, SEE = 1.8 mmHg). Using this equation to calculate LAp, the mean difference between the measured and estimated LAp from E/Vp (Bland-Altman analysis of agreement) was 0.04 ± 1.69 mmHg (mean − 2 SD = −3.34, mean + 2 SD = 3.42).

Conclusions: the ratio of peak E wave over the color M-mode propagation velocity during early LV filling can be assessed in the majority of pts in the first hours after CABG and compared to standard measurements of transmitral Doppler flow provides a better estimate of mean left atrial pressure.

RIGHT VENTRICULAR PERFORMANCE

2024 Three-dimensional echocardiographic paraplane and omniplane analysis for accurate right ventricular volume calculation: a comparison with magnetic resonance imaging

Youssef F.M. Nosir, Maarten H. Lequin, Anita Dall'Agata, Jaroslaw D. Kasprzak, Wim B. Vletter, Jaap Stoker, Ron T. vanDomburg, Folkert J. Ten Cate, Silija E.C. Spitaeles, Jos R.T.C. Roelandt. *From Thoraxcenter, Erasmus University, Rotterdam, Netherlands; Cardiology Department, Al-Hussein University Hospital, Al-Azhar University, Cairo, Egypt*

Our aim was to study the measurements accuracy of three-dimensional echocardiography (3DE) using three different methods of analysis for right ventricular volume (RVV) calculation, using magnetic resonance imaging (MRI) as the reference standard. Precordial 3DE acquisition was performed in 12 patients at 2-degree rotational intervals with ECG and respiratory gating. MRI was performed at 0.5 T. End-diastolic (ED) and end-systolic (ES) RVV and ejection fraction (EF) were derived using Simpson's rule at 9-mm slices for MRI. While for 3DE RVV and EF were calculated by paraplane analysis (3DS) with 8 equidistant parallel RV short axis slices, omniplane analysis (OMN) with 8 RV long axis views obtained at 22.5° of rotation and by biplane modified Simpson's method with two orthogonal RV long axis views. Endocardial borders were traced manually in all methods.

Results. The mean ± SD of ED- and ES-RVV (ml) and EF (%) from MRI were (143 ± 70 and 85 ± 40 and 40 ± 11), from 3DS were (141 ± 72 and 86 ± 44 and 40 ± 12), for OMN were (141 ± 74 and 87 ± 46 and 38 ± 11) and those from BMS were (140 ± 74, 84 ± 45 and 41 ± 12) respectively. There were no significant differences between measurements of RVV and EF obtained from MRI and 3DE methods (p = NS). There were closer limit of agreements between measurements obtained by both 3DS and OMN methods with MRI (± 16, ± 16 and ± 6.6) and (± 18, ± 18 and ± 6.6) than that between BMS and MRI (± 24, ± 21 and ± 11.8) for calculating ED- and ES RVV and EF respectively. There was smaller interobserver variability for 3DS and OMN than that for BMS.

Conclusions. Precordial 3DE rotational acquisition for RV reconstruction is feasible. 3DE using both paraplane and omniplane analysis produce more accurate and reproducible measurements of RVV than that from BMS as compared to MRI.

2025 Doppler-derived acceleration rate of right ventricular early filling reliably predicts right atrial pressure at baseline and after loading manipulations in patients with chronic heart failure

F. Scapellato, P.L. Temporelli, U. Corrà, E. Eleuteri, E. Bosimini, A. Imparato, P. Giannuzzi. *"S. Maugeri" Foundation, IRCCS, Division of Cardiology, Veruno, Italy*

Although it has been recently suggested that the analysis of Doppler diastolic tricuspid flow (DTF) may be useful in estimating right atrial pressure (RAP) in patients (pts) with chronic heart failure (CHF), its value has not been fully elucidated.

Methods: 136 CHF pts (57 ± 8 yrs), 23 in atrial fibrillation, underwent simultaneous echo-Doppler and hemodynamic monitoring (Swan-Ganz cath.). The effects of different loading conditions were also investigated in 18 pts, during nitroprusside infusion (unloading) and in 13 other pts during a 2' active legs elevation (overloading). The following Doppler parameters were considered: peak flow velocity E, acceleration rate (Ac), acceleration time (Ac-T) and deceleration time (DT) of early DTF (in all study pts), peak flow velocity during atrial contraction A and peak E/A velocity ratio (only in sinus rhythm pts).

Results: RAP ranged from 0 to 20 mm Hg (5.5 ± 4.5 mm Hg). At univariate regression analysis all Doppler variables, but A velocity ($r = 0.16$), were well correlated with RAP both in the total population (E: $r = 0.70$; DT: $r = -0.72$; Ac-T: $r = -0.75$; Ac: $r = 0.98$) and when pts with atrial fibrillation (E: $r = -0.82$; DT: $r = -0.83$; Ac-T: $r = -0.75$; Ac: $r = 0.98$) and sinus rhythm (E: $r = 0.68$; E/A: $r = 0.46$; DT: $r = -0.70$; Ac-T: $r = -0.75$; Ac: $r = 0.98$) were separately considered. The best correlation was between Ac and RAP. At multivariate analysis Ac was the strongest and sole independent predictor of mean RAP ($r = 0.98$). In unloading condition (RAP ranging from 10 ± 4 to 3 ± 3 mm Hg), E velocity ($p < 0.05$), E/A velocity ratio ($p < 0.01$) and Ac ($p < 0.0005$) decreased, while DT and Ac-T increased ($p < 0.01$). In overloading condition (RAP ranging from 2 ± 1 to 7 ± 3 mm Hg) the opposite changes were observed: Ac increased ($p < 0.05$) while DT and Ac-T decreased ($p < 0.05$). In both loading conditions, at multivariate analysis, Ac was again the best and sole independent predictor of RAP, with $r = 0.98$.

In conclusion: acceleration of early diastolic tricuspid flow, easy to obtain in all pts with heart failure, represents a highly reliable and accurate tool for predicting and monitoring RAP.

2026 Evaluation of right ventricular ischaemic dysfunction with dobutamine stress echocardiography

S. Matskeplishvili, E. Asimbekova, M. Ousherzon, I. Koksheneva. *Bakoulev Sci. Cen. Card-Vasc. Surgery, Moscow, Russian Federation*

Ischemic dysfunction of the right ventricle (RV) is often ignored during stress testing whereas it is important in patients with multivessel coronary artery disease undergoing myocardial revascularization and affects prognosis.

Objective: To assess feasibility and diagnostic value of dobutamine stress-echocardiography (DSE) in identification of RV dysfunction in patients with coronary artery disease.

Patients and Methods: Study group consisted of 88 male consecutive patients (38–74 years, mean 53 ± 4.7) with the history of at least one MI. Posterior MI was present in 31 case. All patients underwent complete clinical investigation including coronary angiography that revealed multivessel disease in 77 cases. DSE was performed according to the standard protocol with dobutamine (DOB) infusion of 5, 10, 15, 20, 30, 40 mcg/kg/min and analysis of RV wall motion in 7 segments.

Results: Patients were divided into 3 groups: group 1 – with normal resting RV function (32 pts, WMSI = 1.0), group 2 – with dysfunction of interventricular septum, but normal RV (19 pts, WMSI = 1.5) and group 3 – with baseline RV wall motion abnormalities (37 pts, WMSI = 2.0). In group 1 – abnormalities of RV wall motion developed in 25 (81.3%) pts with high doses of DOB (WMSI = 1.6, $p < 0.01$). In group 2 – RV function improved with low doses of DOB (WMSI = 1.2, $p < 0.05$) and deteriorated with high doses (WMSI = 1.5, $p < 0.05$). In group 3 – WMSI decreased with low doses of DOB (1.1, $p < 0.01$), but with high doses of DOB, 26 (70.3%) pts developed asynergy in previously abnormal, but improved, or normal segments (WMSI = 1.7, $p < 0.01$). RV wall motion abnormalities were always accompanied by LV asynergy of various degree.

Conclusion: 1) DSE can detect RV dysfunction in patients with CAD; 2) Impairment of RV wall motion is reversible with low doses of DOB in the majority of segments; 3) Abnormality of RV systolic function in patients with normal RV wall motion is due to the extensive involvement of interventricular septum.

2027 The excursion of the tricuspid annular plane can help to find patients with right ventricular infarction

B. Fredriksson, O. Bech Hansen[1], K. Caidahl[1], C. Olausson[1], P. Svenningsson, M. Beckman-Suurkula[1]. *Department of Medicine, Boras Hospital, Boras; [1]Department of Clinical Physiology, Sahlgrenska Hospital, Gothenburg, Sweden*

Right ventricular (RV) infarction is important to identify for adequate treatment of patients having acute myocardial infarction. We hypothesized that echocardiographic measurement of the systolic excursion of the tricuspid annular plane (TAPSE) could be a useful tool to distinguish patients with RV infarction in a group of patients with acute myocardial infarction.

Methods: Forty-eight patients with acute myocardial infarction and fifteen healthy volunteers were investigated. Fourteen of the patients had electrocardiographical signs of RV infarction (Group A). The other thirty-four patients formed group B and the healthy volunteers constituted group C. The mean age was 74, 75 and 73 years, respectively. There was no difference between group A and B regarding left ventricular ejection fraction and RV systolic pressure. TAPSE of the RV free wall and of the septal segment were measured using the apical four-chamber view.

Results: TAPSE measurements of the RV free wall was in group A: 13 mm, in group B: 20 mm and 25 mm in group C (group A vs. group B and group A vs. group C, $p < 0.001$, respectively). In order to diminish influence of body size TAPSE measurements were corrected for body length, Group A: 8 mm/m, group B: 12 mm/m, group C: 15 mm/m. (Group A vs. B and group A vs. C, $p < 0.001$, respectively). The septal TAPSE measurements did not differ significantly between the groups.

Conclusion: TAPSE of the RV free wall was easily measured. In the setting of acute myocardial infarction it could distinguish patients having RV infarction. TAPSE can be a useful echocardiographic measure of right ventricular function in the coronary care unit.

2028 Combining assessment of right ventricular systolic and diastolic function: a new approach in patients with advanced lung disease

M.I. Burgess[1], Y. Haider[2], S. Lok[2], J.J. Egan[2], S.G. Ray[1]. *[1]Department of Cardiology; [2]Northwest Lung Centre, Wythenshawe Hospital, Manchester, UK*

Aim: Right ventricular performance (RVP) is an important prognostic factor in patients with pulmonary vascular disease and a quantitative non-invasive method of assessment remains a major challenge. We studied the use of an echocardiographic index of global myocardial performance (IMP) which is based on Doppler-determined time intervals and represents the sum of the right ventricular isovolumic contraction and relaxation times divided by the right ventricular ejection time.

Methods and Results: Doppler studies were performed to assess RVP in 70 patients with idiopathic pulmonary fibrosis (IPF), 27 matched normals and 5 patients with primary pulmonary hypertension (PPH). IMP was correlated with pO_2 and right heart catheter data (n = 25). Measurement of the IMP was possible in all study subjects. Non-invasive estimation of pulmonary artery pressure by Doppler evaluation of tricuspid regurgitation was possible in 56% of IPF patients. The mean IMP was 0.35 ± 0.10 in normals, 0.52 ± 0.23 in IPF patients ($p < 0.001$ vs normals) and 1.11 ± 0.42 in PPH patients ($p = 0.04$ vs IPF patients). There was a significant correlation between the IMP and pO_2 and mean pulmonary artery pressure ($r = -0.49$, $p = 0.001$ and $r = 0.59$, $p = 0.005$ respectively). In the IPF group mean IMP was 0.62 in patients with $pO_2 < 60$ mmHg (room air) compared to 0.38 in patients with $pO_2 \geq 60$ mmHg ($p < 0.001$). Mean IMP for IPF patients with significant pulmonary hypertension (mean PA pressure ≥ 30 mmHg) was 0.71 compared to 0.46 in those without pulmonary hypertension ($p = 0.02$). An IMP value of >0.55 (mean + 2SD in normals) identified those IPF patients with significant pulmonary hypertension with a sensitivity of 78% and specificity of 71%.

Conclusion: The IMP provides a simple, non-invasive assessment of global RVP in IPF patients with secondary pulmonary hypertension and relates closely to clinically important physiological variables.

2029 Right ventricular function by Doppler tissue imaging in patients with chronic obstructive lung disease and pulmonary hypertension

P. Caso, M. Galderisi[1], A. D'Andrea, G. Lagioia, C. Cioppa, B. Liccardo, A. Izzo[1], N. Mininni. *Division of Cardiology, Monaldi Hospital; [1]Chair of Emergency Medicine, Federico II University, Naples, Italy*

Aim of the study was to assess right ventricular function in patients affected by chronic obstructive lung disease (COLD) with or without pulmonary hypertension (PH) by pulsed Doppler Tissue Imaging (DTI).

Methods: Standard Doppler-echo and right ventricular DTI was performed to 20 patients with COLD without PH (mean age = 63 years), 10 patients with both COLD and PH, i.e. with pulmonary artery systolic pressure (PASP) > 36 mm Hg (mean age = 61 years) and 10 healthy subjects, comparable for age and sex prevalence to the other 2 groups. PAPS was estimated by continuous-wave Doppler as the peak regurgitation velocity + estimated right atrial pressure. By standard Doppler, transtricuspid peak velocities E and A and their ratio were determined. DTI sample-volume was placed at the level of tricuspid annulus, measuring both myocardial systolic indexes (peak and time-velocity integral of S wave) and diastolic indexes as peaks and time-velocity integrals of E_m, A_m E_m/A_m ratio, relaxation time (RT_m).

Results: Transtricuspid E/A ratio was not significant among the 3 groups. Despite no difference of myocardial systolic indexes, patients with COLD and PH showed in comparison with patients without HP and controls lower E_m/A_m ratio ($p < 0.001$ and $p < 0.01$ respectively) and longer RT_m ($p < 0.0001$ and $p < 0.001$) In the overall population including subjects with at least minimal trucuspid regurgitation, a significant direct relation was found between PASP and DTI RT_m ($r = 0.80$, $p < 0.00001$).

In conclusion, pulsed DTI tricuspid pattern distinguishes patients with COLD having or not PH. The relation found between the degree of RTm lengthening and PASP underscores the ability of DTI to identify patients with different levels of PH. These findings suggest potential clinical use of DTI to assess PH also in subsets of patients with COLD and high transthoracic acoustic impedance, where adequate tricuspid flow is not measurable.

COMPUTER DEMONSTRATIONS

D2044 Injection catheter for computer guided intramyocardial drug delivery: precision assessment in the animal model

A. Keck, K. Krause, R. Malisius, Karl H. Kuck. *St. Georg Hospital, Hamburg, Germany*

Agents provoking angiogenesis have recently been introduced for surgical management of ischemic myocardium. The availability of an injection catheter for intramyocardial delivery of such agents would have the potential to overcome the drawbacks of a surgical approach. Precise application with regard to the ischemic region is indispensable for angiogenetic response.

Methods: The NOGA™ technology allows a 3-dimensional (3D) reconstruction of the endocardial contour of the left ventricle, using ultralow magnetic fields. Location and orientation of the tip of a special catheter is visualized relative to the endocardium in real time, allowing accurate navigation to the ischemic region. The catheter is provided with a needle which can be advanced from its tip. Intramyocardial dye injection (pig model, toluidine, 0.5 ml) was performed at 52 sites. Each injection site was marked on the 3D reconstruction of the endocardial contour. Distances were measured between these virtual sites and compared to the distances of identified injection locations in the sacrificed hearts.

Results: 46/52 injection could be identified macroscopically. Mean depth of stained tissue was 8 mm, mean width was 9 mm. The mean deviation of the distances measured on the virtual contour from the distances assessed in the sacrificed heart was 3.2 mm.

Conclusion: The computer-aided injection catheter is a precise instrument for local delivery of substances into the myocardium. This may be of particular importance for non-surgical treatment of ischemic myocardium with agents provoking angiogenesis.

D2045 A new computer method for analyzing contractile movement of myofibril under cardiotonic drugs

Y. Shimizu[1], T. Tsutsumi, Y. Takeyama, A. Iwasawa, R. Nakamura[2], Y. Okamoto[3]. *[1]Division of Cardiology; [2]Clinical Pathology, Showa University Fujigaoka Hospital, Yokohama; [3]Chiba Institute of Technology, Narashino, Japan*

The purposes in this study are to report a newly developed computer method for analyzing contractile movement of myofibrils in a single cardiac myocyte, and to evaluate the kinetic changes of that under cardiotonic drugs.

Methods: the cultured beating myocytes stimulated at 0.5 Hz were prepared from the rat heart. The microscopic views of the cells were stored in video tapes. After recording the myocyte images under normal perfusate (N; 1.0 mM/l Ca^{2+}), digoxin (Dig; $10^{-6, -7, -8}$ M) or pimobendan (Pim; $10^{-6, -7, -8}$ M) was added to the perfusate. The beating myocyte images were repeatedly recorded. Then consecutive video pictures in each experiment were taken into the computer for analysis. In order to analyze the movement of myofibrils, trajectories of markers characterizing it were selected on a single cell image. Those are traced by means of the maximum correlation method. When a marker M is specified in a frame, a square region M′ which has maximum correlation of the gray scales with M is searched in the next frame, and then M is considered to move to M′. If a marker at a point (r) in a frame moves to a point (R) in the next frame, the cell movement is specified by the correspondence between 2D vectors **r** and **R: R = f (r).** In a small region, the function (f) can be correspondence well by a linear function **R = Ar + v,** where **v** is a 2D vector representing translation and **A** is a 2 × 2 matrix representing rotation and transformation. The **v** and **A** can be determined by means of least square method from several pairs {r, R} obtained from the above method.

Results: the maximum displacement of the markers under Dig. (10^{-6} M) were 7.2 ± 1.5 μ m (n = 50) that was larger than N (5.3 ± 1.2 μ m; n = 50), the same dose of Pim. (5.2 ± 0.6 μ m; n = 50). The maximum velocity of contraction (mV_C) to relaxation (mV_R) ratio was dose-dependently increased under Dig., but decreased under Pim. Average mV_C/mV_R were 0.48 ± 0.05 (n = 50) in N, 0.99 ± 0.21 (n = 50) under of Dig. (10^{-6} M), 0.28 ± 0.05 (n = 50) under Pim. (10^{-6} M). The magitudes of rotations and transformations of the small square region under Dig. were dose-dependently increased in both contraction and relaxation phases, and under Pim. the magnitude of transformation were only increased in the earlier phase of contraction.

In conclusions: this computer methods can supply the new knowledge on the kinetics of myofibrils in a single myocyte. The exaggerated contractile movement induced by Dig. was essentially different from the contractile movement under Pim. The contractile movement induced by Pim. may require less energy because Pim. influenced only transformation in the contraction phase. Accordingly it is suggested that Pim. might be clinically beneficial to long term treatment for severe cardiac failure.

STENTING IN SPECIFIC SUBGROUPS

P2046 Coronary interventions: is being a woman a risk factor?

M. Adamian, J. De Gregorio, N. Kobayashi, N. Corvaja, L. Di Francesco, R. Albiero, I. Moussa, M. Vaghetti, C. Di Mario, J. Moses, A. Colombo. *Centro Cuore Columbus, Milan, Italy; Lenox Hill Hospital, New York NY, USA*

Increased awareness to women's health issues has prompted considerable interest in assesing the outcome of coronary artery disease in the female population. Our purpose was to evaluate whether outcome in coronary interventions can be a gender related phenomenon.

Methods: We analyzed the results of percutaneous revascularization in 247 consecutive women (374 lesions) and 2113 men (3468 lesions) treated between 1995–98. All patients were treated with antiplatelet therapy. 6 month angiographic follow-up was obtained in 75% of patients.

Results:

	Female	Male		Female	Male
Mean age*	64 ± 10	59 ± 10	Ref diam, mm*	2.8 ± 0.5	2.9 ± 0.6
EF, %	62 ± 11	61 ± 11	Pr MLD, mm*	0.7 ± 0.5	0.8 ± 0.6
Unst ang, %*	38	28	Fin MLD, mm*	2.7 ± 0.8	2.8 ± 0.8
Asymp. pt, %*	11.7	17.9	B/A ratio	1.2 ± 0.2	1.2 ± 0.2
Hyperten, %*	61.5	49.3	Pro success%*	94.8	98.3
Elev. cholest, %	64.3	58.6	Fin CSA, mm*	7.7 ± 2.6	9.5 ± 3.3
Diabetes, %*	14.9	8.3	St thromb, %*	2.0	0.8
Smoker,*	34.4	60.5	TLR, %	27.2	27.7
MVD, %*	53.3	63.7	Restenosis, %	37.2	34.6
Compl. les, %	66.2	63.3	MACE, %, Hospital*	3.6	0.9
Ost and prox location, %*	56.7	48.6	1 month*	4.8	1.3
Les leng, mm	12.7 ± 9	13 ± 8	6 month*	9.8	4.7

*$p < 0.05$; MLD minimal lumen diameter; MIP maximal inflation pressure; MVD multivessel disease; TLR target lesion revascularization; 6 month MACE = post procedure MI, CABG, death.

Sub-analysis shows that differences in clinical outcome became insignificant (p = NS) when vessel size in the two groups is matched.

Conclusion: Female patients have a significally lower procedural success and higher incidence of acute, intermediate and long-term MACE, most probably, because of the differences in clinical and lesion characteristics with smaller vessel size playing a major role.

P2047 Validity of appropriateness criteria for indication of coronary artery by pass surgery and angioplasty in predicting outcome of patients suffering from coronary artery diseases

G. Filardo, A.P. Maggioni[1], G. Mura[2], F. Valagussa[3], L. Valagussa[3], A. Liberati[2]. *Health Services Research, Mario Negri Institute, Milan; [1]ANMCO Research Center, Florence; [2]Health Services Research, Mario Negri Institute, Milan; [3]Cardiology Division, Ospedale San Gerardo, Milan, Italy*

Objective: To assess whether appropriateness criteria set by a multispecialties panel of experts for cardiac re-vascularization procedures in Italy predicted for patient outcomes.

Design: Prospective cohort study using information obtained from: 1) revascularization laboratories; 2) patients' hospital medical records; 3) death certificates from administrative sources.

Setting: Sixteen Northern Italian hospitals belonging to the National Health Services (NHS).

Participants: Out of 2718 consecutive patients undergoing a coronary angiogram during the recruitment period (February – May 1995), a total of 1213 (44%) had an indication deemed appropriate by the expert panel to receive a re-vascularization procedure (either coronary artery bypass graft (CABG) or percutaneous transluminal coronary angioplasty (PTCA).

Main Outcome: For the entire patient cohort (n = 1213) total (both unadjusted and adjusted) mortality (with a minimum follow-up of 9 months) was assessed according to receipt of a re-vascularization procedure.

Results: Patients who received re-vascularization within 9 months since the index angiogram had lower mortality than those who did not (4.8% vs 10.6%, P = 0.001). This association held true after adjustment for relevant risk factors such as extent of coronary artery disease, clinical symptoms, and cardiac surgical risk index (adjusted OR = 0.46; 95% confidence intervals (CIs) = 0.28–0.77) and was confirmed when outcome was assessed using survival analysis (adjusted hazard ratio = 0.29; 95% CIs = 0.18–0.48).

Conclusions: Appropriateness criteria set by a multispecialty expert panel in Italy appeared to validly predict patients outcomes. These results strongly urge the need of monitoring the possibility that underuse of effective procedures may jeopardize patients outcome and provide some further evidence of validity of the RAND/UCLA appropriateness methodology in the area of interventional cardiology.

P2048 In-hospital and 6-month outcomes of coronary angioplasty and non-elective stenting in dialysis patients

F. Beygui, J.P. Metzger, C. Le Feuvre, G. Helft, G. Dambrin, A. Vacheron. *Cardiology Department, Necker Hospital, Paris, France*

Outcome of coronary angioplasty (PTCA) in dialysis patients is reported to be poor in small series.

Methods: We studied immediate angiographic results, in-hospital complications and 6 month outcome of PTCA, with or without stenting, performed in 119 patients with long-term dialysis. The results were compared to those of 1328 non-dialysis patients undergoing PTCA during the same period [12/93–12/97]. Indications for stenting were post-PTCA diameter stenosis ≥ 35%, threatening dissection and bail-out after balloon PTCA. All patients were followed-up ≥6 months.

Results:

	Dialysis n = 119	Non-dialysis n = 1328
Stenting (%)	38*	26
Angiographic success (%)	91	91
In-hospital:		
Death (%)	2.5	1
MI (%)	3.9*	1.5
Follow-up:		
Angina (%)	58†	35
Death (%)	2.5†	0.2
TLR (%)	41*	28
MACE (%)	52†	37

*p < 0.05, †p < 0.01, MACE: death/MI/CABG/PTCA

Outcomes were comparable between dialysis patients with optimal result after balloon PTCA and those with stent implantation.

Conclusions: Compared to non-dialysis patients, balloon PTCA provides more sub-optimal angiographic results in dialysis patients, requiring higher rates of stenting. Despite comparable final angiographic results, in-hospital and 6 month outcomes are poorer in dialysis patients.

P2049 Angiographic outcome of different coronary interventions in patients with chronic renal failure with or without haemodialysis

M. Haude, D. Welge, D. Baumgart, J. Ge, C. von Birgelen, H. Eggebrecht, A. Kribben, A. Daul, T. Philipp, R. Erbel. *Cardiology Department and Department for Nephrology and Hypertension, University-GHS Essen, Germany*

Coronary balloon angioplasty (PTCA) in patients (pts) with chronic renal failure is reported to be limited by a high incidence of restenosis and target lesion revascularization. The role of newer interventional techniques such as stents or rotablation (Rota) is unclear. In a retrospective analysis, we evaluated the angiographic outcome of coronary interventions in 125 pts with chronic renal failure (creatinine ≥ 2.0 mg/dl, no hemodialysis, group 1) and in 75 pts with chronic hemodialysis (0.5 to 7 years; group 2). The rate of angiographic restenosis defined as a more than 50% diameter stenosis at six month by quantitative coronary angiography (CMS, Medis, Leiden, the Netherlands) and ischemia driven target lesion revascularization were identified in each group.

Results:

	Group 1		Group 2		p
	Restenosis	TLR	Restenosis	TLR	
PTCA	6 of 8 (75%)	4 of 8 (50%)	6 of 8 (75%)	5 of 8 (63%)	1.0
PTCA+ Stent	10 of 32 (32%)	9 of 32 (28%)	3 of 10 (30%)	3 of 10 (30%)	0.756
Rota+ PTCA	8 of 18 (44%)	7 of 18 (40%)	6 of 12 (50%)	5 of 12 (42%)	0.943
Rota + PTCA + Stent	19 of 67 (28%)	17 of 67 (26%)	12 of 45 (26%)	11 of 45 (24%)	0.986
P	0.049	0.031	0.043	0.041	

In conclusion, rotablation plus stenting provides significantly better results on restenosis and TLR in pts with chronic renal failure with no impact of hemodialysis on these findings.

P2050 Prediction of long-term survival and improvement of LV function after PTCA in patients with ischaemic heart failure

P. Buszman, M. Tendera, A. Gruszka, B. Bialkowska. *3rd Department of Cardiology, Silesian Medical School, Katowice, Poland*

The aim of this prospective observational study was to assess the value of simple clinical data for prediction of the long term outcome after PTCA in patients with ischaemic heart failure.

Material and Methods: Eighty-five patients with symptomatic coronary artery disease (CCS angina class≫2), impaired left ventricle function (EF < 35%) and suitable for total or incomplete percutaenous revascularisation were enrolled into the study. The mean period of observation after PTCA was 21.4 ± 10.6 months. Basic demographic, clinical and angiographic data were analysed to find simple predictors of long-term survival and improvement of LV function. Additionally, a new EKG index (EKG-Ix) was developed to show the value of routine EKG in a such prediction. Kaplan-Meier (product-limit) survival analysis and multivariate regression were performed to reach statistical conclusions.

Results: Demographic and clinical data are shown in the table below. The Kaplan-Meier one year survival was 90 ± 3%. All deaths could be observed in a high risk group (27 patients) with three vessel disease, LV-EF < 25% and disqualified from CABG (one year survival 69.1%, conf. interval 50.5–87.7%). In this group a value of EKG-Ix < 5 discriminated a subgroup of patients with extremely poor prognosis (85.6 vs 15% mortality, Fischer test: p = 0.002). Multivariate regression analysis showed that EKG-Ix was the only good predictor of LV function improvement (p < 0.0001).

Demographic and clinical data

Age	56.4±10.2	Hypertension	39 (49%)	Previous CABG	8 (94%)
Male	67 (79%)	Smoking	54 (63%)	Disqualification	
NYHA class II/III/IV	3/49/33	Diabetes	15 (18%)	from CABG	54 (66%)
CCS class II/III/IV	4/34/47	Hyperlipidemia	50 (59%)	Risk (Cleveland score)	12±9%
				Total revascularisation	42 (45%)

Conclusions: The results suggest that simple clinical parameters may be helpful in prediction of good long term outcome in patients with ischaemic LV dysfunction suitable for percutaneous revascularisation.

P2051 In-hospital outcome and long-term follow-up after coronary stenting in patients with severe left ventricular dysfunction

P. Richard, M. Angioï, A. Grentzinger, I. Abdelfattah I, R.M. Rodriguez, Y. Juillière, N. Danchin. *Department of Cardiology, CHU Nancy-Brabois, France, 54500*

Though conventional PTCA can be performed in patients with poor LV function, it carries an increased risk of in-hospital complications and whether it can improve survival remains uncertain. Intracoronary stenting with combined antiplatelet therapy has increased the safety of coronary angioplasty procedures. The aim of this study was to assess the in-hospital and long-term outcome in pts with poor LV function treated with intracoronary stents. A consecutive series of 78 pts (65 men; mean age 65 ± 11 years) with LVEF ≤ 35% (mean LVEF 29 ± 6%) treated with intra-coronary stenting from 1995 through 1997 was followed-up for an average of 15 months. Pts with PTCA ≤ 24 hours of AMI were excluded. Most pts had 2-vessel (47%) or 3-vessel disease (37%). PTCA was performed on 1 vessel in 66 pts; 104 of the 110 lesions attempted were stented (1.2 stent/lesion). Mean stents length was 21 mm. Complete revascuarisation was achieved in 24 pts (31%). Primary success rate (residual stenosis < 50% and no in-hospital complication) was 97% (76/78 pts); there was one non-Q wave MI caused by side-branch occlusion (1%), and one failure of stent deployment. No patient was lost to follow-up. Of the 13 deaths during FU, 8 were caused by intractable heart failure. Kaplan Meier probability of survival was 88% at 6 months, 85% at 1 year and 75% at 2 years. There was no non fatal MI during FU but 16 pts (20%) were re-admitted for congestive heart failure; 10 pts had target vessel revascularisation (1 CABG, 9 re-PTCA) and 5 pts had PTCA of another artery. In patients alive at FU, 14% had stable angina, and 19% described incapacitating dyspnea. Therefore, intracoronary stenting appears to offer an acceptable alternative to CABG in pts with severely depressed LVEF, with very few in-hospital complications. Long-term follow-up, however, remains complicated by the frequent occurrence of fatal or non fatal congestive heart failure.

P2052 Small-vessel stenting with two different dedicated stents

F. Airoldi, C. Di Mario, A. Anzuini, M. Carlino, C. Briguori, A. Dharmadhikari, V. Tzifos, I. Sheiban, R. Albiero, A. Colombo. *San Raffaele Hospital and Columbus Hospital, Milan, Italy*

Introduction: A few preliminary studies of coronary stents implanted in vessel < 3.0 mm have provided conflicting results. The stents used in the previous studies however were designed to achieve an optimal scaffolding and wall coverage in the 3.0–4.5 mm vessel. We evaluated the results of elective stenting in small coronary arteries (<3.0 mm) employing two dedicated stents: NIR 5 cells stent, 19 mm of length (Medinol-SciMed) and the slotted tubular Mini stent, 11 or 15 mm of length (Cordis, J & J Inc).

Materials and methods: We treated 89 denovo or restenotic lesions in 83 pts with clinical or objective evidence of myocardial ischemia (age 63 ± 10 yrs, M/F 47/16). The lesion distribution was: 19 LAD (12 distal segment), 17 diagonal artery, 16 right coronary artery, 13 Cx, 8 posterolateral-RCA, 7 obtuse marginal, 3 posterolateral-of circumflex, 3 ramus and 3 posterior descending. Stent expansion was performed at 12–16 atm. All patients received aspirin and ticlopidine for four weeks.

Results: Stent deployment was successul in all lesions but two cases in the MINI group (1 diagonal and 1 LAD); in both cases stents were retrived without problems. No case of acute or subacute thrombosis, nor in-hospital complications were observed. Six-month angiographic follow-up was available in 31 pts (35%) NIR/MINI 15/16. Quantitative angiographic data are listed below (expressed in mm):

	Pre PTCA			Post STENT		Follow-up	
	Les length	Ref diam	% sten	Ref diam	% sten	% sten	Rest rate
NIR (n = 41)	11 ± 6	2.3 ± 0.4	76 ± 17	2.6 ± 16	9 ± 10	56 ± 24 (n = 15)	60%
MINI (n = 48)	12 ± 6	2.3 ± 0.5	75 ± 16	2.5 ± 0.4	11 ± 11	52 ± 20 (n = 16)	50%

p = n.s. for all comparisons between the two groups (unpaired T-test)

All remaining patients have been scheduled for an angiographic six-month follow-up that will be completed at the end of July.

Conclusions: Stenting in small vessels with dedicated stents is associated with a high procedural success and no increase in stent thrombosis. No difference was observed in immediate results between NIR 5-cell and Mini stents. Our preliminary follow-up results indicate unacceptably high restenosis rates. Probably a larger patients population needs to be evaluated to have a definitive answer to this problem.

P2053 The BESMART study: in-hospital clinical and angiographic results

R. Koning, K. Khalife, M. Gilard, P. Commeau, J. Lipiecki, M. Bedossa, P. Brunel, M.C. Morice, T. Lefèvre, L. Maillard, P. Coste, P. Richard, F. Schiele, P. Guyon, A. Cribier, J. Puel. *On behalf of the BESMART investigators, University of Rouen, France*

Background: The BESMART (BEstent in SMall ARTeries) study is an ongoing french prospective randomized multicenter trial comparing stent (Bestent, Medtronic inc.) implantation versus balloon angioplasty in small coronary arteries (<3 mm) in order to evaluate the immediate results and 6-month angiographic restenosis rate (380 Pts to be enrolled).

Methods: Pts with documented myocardial ischemia and with a de novo lesion in a native coronary artery < 3 mm diameter were included. The use of a balloon ≥ 3 mm diameter was an exclusion criteria. The Bestent was manually crimped on a 2.5 mm diameter balloon. After stenting, Pts received ticlopidine (500 mg/d) and aspirin (160 mg/d). The CMS 3.0 version (edge detection) was used by an independant corelab for quantitative angiographic analysis (QCA) of reference diameter, minimal lumen diameter (RD, MLD) and % diameter stenosis (% DS).

Results: To date, 249 consecutive Pts (61 ± 10 yrs) with 258 lesions were randomized to PTCA (n = 124 pts) or stent (n = 125). On basis of intention to treat, procedural success rate was 99% with both techniques. Major adverse events were: death (PTCA 0, stent 0), myocardial infarction (PTCA 3, stent 4), rePTCA (PTCA 2, stent 2) and hematoma (PTCA 1, stent 1). In 31 Pts of PTCA group (25%) there was a crossover to the stent group because of unsatisfactory results of PTCA. QCA results:

	PTCA		Stent	
	Pre	Post	Pre	Post
RD (mm)	2.17 ± 0.37	2.36 ± 0.41	2.18 ± 0.38	2.46 ± 0.38
MLD (mm)	0.80 ± 0.28	1.73 ± 0.48	0.71 ± 0.27	2.13 ± 0.38
% DS	64 ± 11	27 ± 14	67 ± 12	13 ± 11

Conclusions: The preliminary in-hospital results of this multicentric study show that stenting is feasible and safe in small coronary arteries and is associated with results at least comparable to those of PTCA.

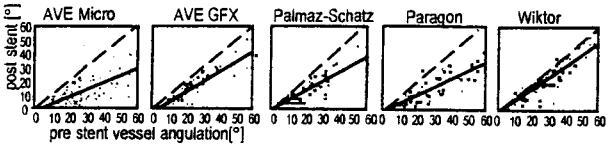
P2054 Differential behaviour of stents in curved vessels dependent on their design

M. Gyongyosi, P. Yang, D. Glogar. *The Austrian Wiktor Stent Study Group and the Paragon Stent Trial Investigators; Division of Cardiology, 2nd Department of Internal Medicine, University Medical School of Vienna, Austria*

Stent implantation changes the arterial geometry, therefore we examined the straightening effect of different stents on arterial curve and the possible asociation between changes in vessel angulation and occurrence of major adverse cardiac events (MACE).

Method: Pre-, post-stent and follow-up (FUP) vessel angulation (angles defined by the tangents of the proximal and distal parts of stenosis or stent) after implantation of 148 sinusoidal ring (76 AVE Micro and 72 AVE GFX), 89 tubular slotted tube (Palmaz-Schatz), 78 cell-type (Paragon) and 181 coil (Wiktor) stent were compared and correlated to the occurrence of MACE. Receiver operating characteristic curves were used to determine the maximal vessel angulation (as cut-off point by different stents), which can be safely stented with a less incidence of MACE.

Results: Different stent types straighten the tortuosed vessel to a different degree; coil stents influenced the vessel curve to a lesser extent in comparison with the other stents (figure).



Stenting of a tortuosed vessel with an angulation of more than 28° with AVE Micro, 30° with AVE GFX or Paragon, 32° with Palmaz-Schatz and 34° with Wiktor stent was associated with higher incidence of MACE. After six months FUP, tubular, cell-type and ring stents, but not coil stents exhibited a further decrease in vessel angulation (table).

Vessel angulation [°]	Pre-stent	Post-stent	Follow-up
AVE Micro	32.2 ± 19.5	19.6 ± 14.8*	17.0 ± 12.2
AVE GFx	36.3 ± 24.8	26.3 ± 20.2*	21.2 ± 15.4
Palmaz-Schatz	32.0 ± 18.3	17.7 ± 14.5*	12.4 ± 10.8+
Paragon	38.8 ± 24.8	26.8 ± 18.4*	20.2 ± 14.4
Wiktor	34.6 ± 22.6	30.0 ± 21.2	31.1 ± 22.3

*p < 0.05 between pre-post stent, +p < 0.05 between post-stent and FUP in the same stent group.

In **conclusion**, flexible coil stent does not have an implication on vessel angulation, therefore stenting of tortuous vessel with coil stent could be recommended.

P2055 Coronary stent placement in two or more vessels: 1-year clinical and angiographic outcome and comparison with single-vessel stenting

T. Schilling, A. Kastrati, J. Dirschinger, J. Mehilli, J. Pache, N. von Welser, H. Schühlen, F.J. Neumann, A. Schömig. *Deutsches Herzzentrum; 1. Med. Klinik rechts der Isar, TU München, Munich, Germany*

The issue of the optimal treatment option for patients (pts) who need multivessel revascularization is not fully resolved. They are often referred to aortocoronary bypass surgery. However, recent advances in interventional cardiology may be beneficial also for this category of pts.

Methods: A consecutive series of 3212 pts without acute myocardial infarction (MI) is included. Pts were divided in 2 groups: group MV composed of 334 pts with same session stenting in ≥2 vessels (309 in 2 vessels, 25 in 3 vessels), and group SV composed of 2878 pts with single-vessel stenting. All pts had 1-year clinical follow-up. 6-month angiography was performed in 2700 pts. All angiograms were assessed with QCA.

Results: In comparison with pts in the SV group, pts in the MV group were older, more often men, with higher frequency of diabetes and unstable angina, more often reduced left ventricular function, prior bypass surgery and MI. One-year follow-up results are presented:

	MV	SV	P
Procedural success, %	98.8	98.3	0.52
Death, %	4.8	3.6	0.28
Death or MI, %	6.9	5.4	0.27
Bypass surgery, %	5.1	2.5	0.007
Target lesion repeat angioplasty, %	16.9	16.9	0.99
Any of the above events, %	28.4	22.7	0.02
Angiographic late lumen loss, mm	1.23 ± 0.87	1.17 ± 0.84	0.16
Angiographic restenosis rate, %	36.0	32.5	0.15

Conclusions: Despite the more frequent presence of high risk characteristics, stenting multiple vessels in these pts is not associated with any significant increase in mortality and MI rate as compared with single-vessel stenting. If corroborated by randomized studies, this may become a strategy of choice for pts needing multivessel revascularization.

P2056 Preliminary clinical experience of bifurcarted coronary stent

B. Chevalier, B. Glatt, P. Guyon, T. Royer. *Centre Cardiologique du Nord, Saint-Denis, France*

Many options have been proposed to cover complete bifurcation lesion with coronary stents, using step by step techniques. Bifurcated stent (BS) is a theoritical one-step alternative. In the setting of a preliminary feasibility study, 12 pts were treated, from 06/98 to 10/98, with a XT Carina Bard* on 8 LAD/diagonal and 4 Circumflex/obtuse marginal branch bifurcations. Baseline lesion were D type in 11 and C type in 1. Procedure was conducted through a 9 F access using a 23 mm long Carina. One failure was related to proximal calcification and another one to the lack of legs rotation in a calcified bifurcation. These 2 cases were treated with stenting in main branch and balloon in side branch. There was one nonQ MI (3 times CK upper limit). Off-line QCA results (mm):

	RD	preMLD	postMLD
Proximal main branch	3 ± 0.32	0.72 ± 0.42	3.05 ± 0.46
Distal main branch	2.9 ± 0.4	0.74 ± 0.42	2.91 ± 0.37
Side branch	2.6 ± 0.57	0.7 ± 0.27	2.52 ± 0.57

RD: reference diameter, MLD: minimal lumen diameter

At this time, clinical follow-up ranged from 3 to 8 m. One pt underwent re-PTCA for symptomatic restenosis at 4 m., 3 pts need revascularisations in non-target vessels. A systematic angiographic was planned at 7 months in all pts, among whom 1 pt had isolated restenosis in the side branch without re-PTCA.

Thus, these preliminary feasibility results are encouraging and allow to consider larger study to validate this strategy.

P2057 Triple vessel stenting for triple vessel disease: a two-centre prospective study

S. Hernandez, B. Villegas, M.-C. Morice, P. Dumas, J. Fajadet, T. Lefèvre, C. Loubeyre, Y. Louvard, J. Marco. *Institut Cardiovasculaire Paris Sud, Antony; Clinique Pasteur, Toulouse, France*

Randomized clinical trials have shown that multivessel coronary stenting is feasible and provides similar short-term suvival as CABG in selected pts. However, the unknown and probably low frequency of triple-vessel (3V) 'treatable' with triple stenting has not yet been assessed and may reduce the clinical impact of these studies in everyday practice.

We conducted this prospective two-center study to assess the frequency and short- and mid-term results of 3V PTCA combined with elective stent implantation.

Population: From Jan 1996 to Jan 1999 in a total of 6,810 PTCA procedures, 115 pts (1.69%) were treated by PTCA and elective stenting for 3V disease whatever the indication. Mean age was 62.9 years (range 35–85), 83% were male and 13 pts (11.4%) were diabetic. The procedure was performed in 1 session in 77.6% and 362 vessels were dilated. (3.07/pt): left main coronary artery (3.5%), LAD (85.2%), diag (27.2%), circ. (48.6%), marginal (53.5%), RCA (84.3%), PLA (4.3%), PDA (7.8%) and graft (1.7%). Pts received 362 stents (4.06 stent/pt, range 3–10). Mean total stent length was 66.9 ± 24.9 mm. In-hospital complications included 2 emergency CABG (1.7%) and 2 myocardial infarctions (1.7%), 2 pts (1.7%) died. Mean hospital stay was 2.7 ± 2.2 days. Follow-up: no systematic angiogram was performed, however, all pts but one (99.1%) were followed clinically for 1 to 36 months (mean 16.7). During this period, 2 pts died, 2 were operated on, and 22 (19.1%) were dilated. Event-free survival at 16 months was 72.2%. No clinical or angiographic procedural characteristics were found to be predictors of events.

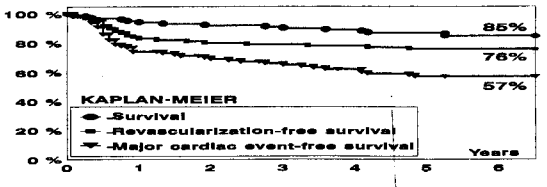
In conclusion, very few pts are eligible for 3V stenting; when eligible, feasibility is high and immediate results are satisfactory. However, long-term event-free survival will remain lower than what can be expected after CABG as long as the restenosis problem will not be solved.

P2058 Percutaneous coronary revascularization for multivessel disease in the stent era: acute and long-term outcome

J.J. Alonso, F. Fernández-Avilés, J.M. Durán, F. Gimeno, B. Ramos, A. Ortiz, L. de la Fuente, O. Sanz, J. Paniagua, R. Palomino. *Hospital Universitario, Valladolid, Spain*

To assess the efficacy of coronary stenting (CS) in the setting of multivessel disease we followed 583 consecutive pts (62 ± 10 yr., 86% male) with multivessel coronary disease who underwent CS. Indication for PTCA was unstable angina in 63% of pts and 16% were diabetics. Seven percent of pts had previous heart failure and 52% previous myocardial infarction. Mean ejection fraction was 0.59 ± 13 and the mean number of diseased vessels was 2.4 ± 0.5. Clinical follow-up was completed for 94% of pts (follow-up duration: 3 ± 18 months, range: 18–78). In 70% of pts revascularization was accomplished by means of Stent exclusively, while in the remaining 30% the procedure combined Stent and balloon.

Initial clinical success (angiographic success without major complication at one month) was 87%. The incidence of angiographic restenosis for any of treated vessels was 34% (Stented vessels: 31%, ballooned vessel: 45%). The long-term evolution is shown in the figure:



The multivariate analysis (logistic regression) showed that diabetes (OR: 1.46, 95%CI: 1.13–1.88), the minimal lumen diameter after PTCA and the occurrence of AMI during the procedure (OR: 2.2 95%CI: 1.15–3.88) were independent predictors of major adverse cardiac events in the long-term follow-up.

Thus, initial outcome and long-term survival and revascularization free survival are acceptable in pts with multivessel disease treated with percutaneous revascularization using Stent.

P2059 Coronary stenting for isolated left anterior descending stenosis: acute and 6-month clinical and angiographic results

P. Montorsi, P.M. Ravagnani, D. Trabattoni, F. Fabbiocchi, A. Loaldi, S. Galli, A.L. Bartorelli. *Institute of Cardiology, University of Milan, CNR, Fondazione Monzino, IRCCS, Milan, Italy*

We evaluated acute and mid-term safety and efficacy of coronary stent implantation for isolated LAD stenosis.

Methods: 401 pts (mean age 58 ± 10 yrs) were enrolled from May '92 through June '98. Indication for revascularization was stable and unstable angina and acute myocardial infarction in 61.5%, 29% and 9% of pts, respectively. Coronary stenosis (mean lenght 15 ± 8 mm, range 7–40 mm) was located at the ostium (8.5%), proximal (50%), middle (41%) and distal (0.5%) segment of LAD artery. Lesion type was A in 4.1%, B in 44% and B2-C in 52% of pts. Different types of stent were implanted (Palmaz-Schatz: 48.5%, NIR: 20%, Multilink: 15%, beStent: 8%, AVE: 4%, others: 4.5%) according to lesion morphologic characteristics, with an elective indication in 86% of pts. Multiple or long stents (>16 mm) were deployed in 11% and 31.5% of pts, respectively. High pressure post-dilation was routinely used (maximal inflation pressure of 15 ± 2.5 atm). The antithrombotic treatment was anticoagulation in 25%, aspirin alone in 17.5% and aspirin + ticlopidine in 58.5%.

Results:

Acute (401 pts):		6-mos F/U (288 pts, 71.8%):	
Procedural success	98.5%	Death	0%
Stent thrombosis	0.5%	Q-MI	0.7%
Major bleeding	1.1%	Angina	8.6%
Urgent CABG	0.8%	Total TLR	14.1%
Death	0.8%	– *RePTCA*	11.1%
Q-MI	2.3%	– *CABG*	3.1%
Any event	8.5%	Event Free Surv.	85.9%
		Restenosis Rate	26%

Independent predictors of 6-month were diabetes, previous CABG, reference vessel diameter between 2.8 and 3.2 mm, and % post-procedure stenosis.

Conclusions: coronary stenting is a safe and effective treatment in pts with isolated LAD stenosis. The high acute procedural success and the long-term event-free survival compares favorably with previous randomized studies despite more complex coronary anatomy and unstable clinical presentation.

P2060 Unprotected left main stenting with elective or stand-by cardiopulmonary support

M. Romero, J. Suárez de Lezo, A. Medina[1], M. Pan, E. Hernández[1], J. Segura, F. Wanguemert[1], E. Caballero[1], D.J. Pavlovic, J.R. Siles, J.R. Castroviejo. *Reina Sofía Hospital, University of Córdoba; [1]Pino Hospital, University of Las Palmas, Spain*

The increasing experience with percutaneous stent treatment for unprotected left main coronary lesions leads to the search of the best technique and safest methods for adequate revascularization, even in complex patients (pts). Percutaneous cardiopulmonary support (CPS) during the procedure provides a safe environment to achieve a tailored designed strategy. Since September 92 to January 99 we have studied 69 pts with unprotected left main coronary stenosis who were treated with stent implantation. The mean age was 62 ± 11 years; the clinical condition was unstable angina in 55 (80%), acute myocardial infarction in 5 (7%) (4 of them in cardiogenic shock) and stable angina in 9 (13%). Elective CPS was used in 29 patients as a prophylactic measure because of: 1) poor left ventricular function (n = 2), 2) unstable hemodynamic condition (n = 8), 3) repair needing complex bifurcation procedures (n = 12) and 4) the need for combined right coronary artery revascularization (n = 7). In 13 pts more than 1 indication for CPS was present. In the remaining 40 pts, stand-by CPS was available (groin access for possible fast canulae insertion, if needed); in 7 of them the CPS was established once observed the inability to proceed without hemodynamic deterioration. In 29 pts ultrasound guidance was used for bifurcation assessment. Primary success (adequate revascularization with 30 days event-free survival) was obtained in 65 (94%). Major 1-month complication included: peri-interventional death 3 (4%) and myocardial infarction 1 (2%). No subacute stent thrombosis was observed. A close clinical follow-up was obtained in all survival and 41 (59%) were angiographically re-evaluated at a mean of 6 ± 5 months. Late major adverse clinical events (death, surgery, myocardial infarction or additional percutaneous revascularization) were observed in 12 pts (18%). The remaining 54 pts remain symptoms free after 16 ± 16 months.

Conclusion: Elective or stand-by CPS allows for safe and adequate stent revascularization of unprotected left main, even in complex clinical and/or anatomic conditions.

P2061 Is the angiographic guidance sufficient for optimal stent deployment in ostial stenoses? Insight from IVUS

M. Adamian, C. Di Mario, C. Briguori, T. Nishida, B. Reimers, M. Vaghetti, L. Di Francesco, N. Corvaja, R. Albiero, A. Colombo. *Centro Cuore Columbus, Milan, Italy*

Precise positioning of stents in ostial lesions under fluoroscopic guidance is difficult because of poor stent visibility and angiographic foreshortening or overlapping. In this study the adequacy of stent deployment in ostial stenosis was evaluated with intravascular ultrasound (IVUS) in 86 consecutive patients (90 native de-novo lesions).

Methods: Based on stent position relative to the vessel ostium we distinguished 3 groups: "optimal" – stent deployed within ± 1 mm to ostium (39 lesions); "too proximal" defined as >1 mm protrusion from the ostium (mean 2.7 mm, range from 1.5 to 7.0 mm; 32 lesions) and "too distal" defined as >1 mm distal to the ostium (mean 1.7 mm, range from 4.5 to 1.5 mm; 19 lesions). Aorto-ostial lesions were: in RCA 18%, LAD 46%, LCX 10% and branch-ostial 19%. All deployed stents were balloon expandable with PS-154 used in 46 lesions (50%). Rotational and directional atherectomy were used in 23% and 14% of lesions, respectively. Angiographic follow-up was obtained in 86% of eligible patients 6.8 ± 2.0 months after stenting.

Results: There were no statistically significant differences in clinical characteristics among the 3 groups.

	Optimal	Too Proximal	Too Distal
Type B2 & C les, %*	67	68	74
Calcium, %*	28	19	21
RVD (pre/final), mm*	3.3 ± 0.5/3.4 ± 0.4	3.1 ± 0.6/3.4 ± 0.4	3.1 ± 0.3/3.3 ± 0.5
MLD (pre/final), mm*	1.1 ± 0.7/3.3 ± 0.6	1.0 ± 0.6/3.3 ± 0.5	0.9 ± 03/3.2 ± 0.7
B/V ratio*	1.11 ± 0.30	1.19 ± 0.21	1.16 ± 0.16
Acute gain, mm*	2.27 ± 0.73	2.29 ± 0.78	2.19 ± 0.85
Late loss, mm*	0.94 ± 0.83	1.10 ± 0.95	0.93 ± 0.99
Loss index*	0.45 ± 0.42	0.67 ± 0.82	0.42 ± 0.33
Fin stent CSA, mm^{2*}	9.83 ± 2.66	9.70 ± 2.39	9.5 ± 3.37
Fin vessel CSA, mm^2	17.43 ± 4.76	17.33 ± 4.40	17.25 ± 5.36
Restenosis/TLR, %*	25/25	22/20.7	19/18.7

*p = NS; RVD = reference vessel diameter; MLD = minimal lumen diameter; TLR = target lesion revascularization.

Conclusions: With modern stents and angiographic guidance precise stent positioning can be achieved in most cases with a trend to moderate stent protrusion. Suboptimal (too proximal or too distal) stent position within the small range observed does not predict an increased risk of restenosis.

P2062 Immediate results of the RAP study: a randomized trial that compares stent and balloon angioplasty in small vessels

E. García, M. Gómez-Recio, J. Pasalodos, A. Bethancourt, J. Zueco, A. Iñiguez. *For the RAP investigators; Madrid, Spain*

The RAP study (Restenosis en Arterias Pequeñas) is a multicenter prospective randomized trial which compares the results of Bestent implantation versus balloon angioplasty in 440 patients with lesions located in small vessels. The primary endpoint of the study is to compare angiographic restenosis of each group at six months. Secondary endpoints include the incidence of Major Adverse Cardiac Events at six months. Cost- effectiviness at one year will also be analysed for patients in each group. Patient and procedural characteristics include: 1 or 2 de novo focal lesions located in a native coronary artery with a reference diameter between 2.2 and 2.7 mm. Balloon angioplasty is performed with a balloon ≤ 52.75 mm. In the stent arm, a small Bestent mounted on a 2.5 mm balloon is deployed and post dilation if necessary, is performed with a ≤2.75 mm semicompliant balloon.

Results: We report the inmediate results of the first 295 (149 balloon and 146 stent) patients having completed a 30 day follow up. Mean reference diameter of the target vessel was 2.29 ± 0.36 mm. There were 20 (13%) cases cross-over to stent and 2 (1.5%) to balloon. Target lesion location was: LAD-Diagonal (54%), Circunflex-Obtuse marginal (34%) and Right coronary (12%) Procedural succees was obtained in 98% in the stent and 96% in the balloon group. Twenty six (8.8%) major adverse cardiac events have been accounted at 30 day follow up: 17 (11.4%) in the balloon and 9 (6.1%) in the stent arm. Post-procedure average minimal luminal diameter (MLD) in the stent group was 0.42 mm larger than the MLD obtained in the balloon group.

In conclusión: The inmediate analysis of the first 295 patients enrolled in the RAP study shows good inmediate result in both groups with a tendency toward better angiographic and clinical results in the stent arm. Enrollement is expected to be finished in July 1999.

P2063 Treatment of small vessels with complex lesions

C. Briguori, M. Adamian, M. Vaghetti, R. Albiero, C. Di Mario, A. Colombo.
Centro Cuore Columbus, Milan, Italy

The impact of stenting on small vessels (<3.0 mm) with complex lesions (B2-C) is controversed. In this study we retrospectively evaluated clinical and angiographic follow-up in patients with complex lesions in small vessels, treated with in lab successful percutaneous transluminal angioplasty (SPOBA) or with elective stent implantation (Stent).

Methods: SPOBA group (n = 207) and Stent group (n = 202) were comparable for all clinical and angiographic characteristics, except vessel treated (p = 0.001) and target lesion location (p = 0.003). Major adverse cardiac events (MACE) were evaluate at 30 days and at >6 months. Angiographic follow-up was performed in 227/349 (65%) of elegible patients.

Results: Angiographic success was 95% in SPOBA group and 98% in Stent group (p = NS). There was no difference in procedural, and in-hospital cardiac events. Follow-up is shown below:

	SPOBA	Stent*	p
MACE Early	6/207 (2.9%)	1/202 (0.5%)	0.25
MACE Late	10/137 (6%)	17/131 (13%)	0.10
TLR	24/104 (22.4%)	63/158 (39.9%)	0.003
Restenosis Rate	29/92 (31%)	60/135 (44%)	0.05

By logistic regression analysis, vessel diameter (p = 0.0017), final balloon pressure (p = 0.0023), and stent length (p = 0.007) were the predictors of restenosis.

Conclusion: Stent implantation in small vessels with complex lesions does not improve both early and late outcome, and seems to negatively influence the occurrence of restenosis compared to successful POBA.

P2064 Stenting of small coronary arteries: interim report from a randomized multicenter trial in patients with a vessel reference diameter of 2.3-2.9 mm. The SISA study

M. Schalij, S. Douchet[1], B. De Bruyne[2], M. Vrolix[3], D. Hilton[4], P. Chenu[5], W. Udayachalerm[6]. *Cardiology Dept., Leiden University Medical Center, Leiden; Netherlands; [1]Cardiology Dept., Montreal Heart Institute, Montreal, Canada; [2]Cardiology Dept., Aalst; [3]Aalst, Belgium; [4]Victoria; [5]Mont Godinne, Canada; [6]Bangkok, Thailand*

Background: The Stenting In Small Arteries trial (SISA) is a randomized, multicenter, worldwide stent study in 350 pts with a reference diameter (RD) of the target vessel of 2.3–2.9 mm. Angiographic F-U after 6 mos and clinical F-U at 12 mos will be obtained.

Methods: Pts with one de-novo lesion in native coronary arteries and stable angina are included. Either a standard PTCA procedure was performed or a Medtronic BeStent (8 mm or 15 mm length) was implanted. Before inclusion the RD of the target vessel was calculated using on-line quantitative coronary analysis (QCA) measurements. During the procedure pts received 10,000–15,000 U of heparin. After the procedure pts were treated with aspirin and ticlopidin (stent patients only) for 28 days.

Results: Thusfar 262 pts (128 stent pts, 134 PTCA pts, age: 60 Y, 81 F) have been included. The RD before inclusion was: 2.52 ± 0.23 mm (stent pts) and 2.50 ± 0.20 mm (PTCA pts). The procedural success rate (<50% residual diameter stenosis (DS) with a decrease in DS of > 20% after the procedure) was 97.9% for the whole group. Crossovers: Stent to PTCA: 3(1.1%); PTCA to Stent: 21(8%). The clinical success rate (procedural succes without MACE at discharge) was 93.9%. Complications at one month (n = 170): death: 0, Q-wave MI: 3 (1.7%), Non Q-wave MI: 4(2.3%), CABG: 2(1.2%), Re-PTCA: 5(2.9%).

Conclusion: Stenting of small vessels with a RD of 2.3–2.9 mm is feasible and relatively safe. Interim results for 350 patients will be available at presentation.

P2065 Clinical and angiographic long-term follow-up of stenting for long coronary lesions

D. Carrié, M. Elbaz, G. Mayoux, S. Mourali, J. Fourcade, M. Andrieu, J. Puel.
Department of Cardiology, Purpan Hospital, Toulouse, France

In order to assess the role of the stent length on long-term PTCA results, we retrospectively compared 732 consecutive patients (study period: 25 months) receiving 843 coronary stents using 20 mm as a threshold to separate short and long stenting. The stents used were: NIR stents (9, 16, 25 or 32 mm), Wiktor I stents (10, 20 or 30 mm), Bard XT stents (6, 11, 15, 19, 34 mm).

Results are presented in the table.

Conclusions: In comparison with short lesions, coronary stenting on long lesions can be safely used with a high rate of primary success, a low rate of subacute thrombosis and a similar TLR at long term follow-up.

	≥20 mm	<20 mm	p
n (pts)	202	530	
Lesion length (mm)	14.72 ± 5.9	10.29 ± 3.65	<0.0001
Stent length (mm)	23.23 ± 4.85	14.15 ± 2.9	<0.0001
Stent/lesion ratio	1.81 ± 0.81	1.52 ± 0.6	<0.0001
– "de novo"	147 (72.8%)	361 (68.1%)	
– bail out	15 (7.4%)	47 (8.9%)	
– restenosis	40 (19.8%)	122 (23%)	
Procedural success	195 (96.5%)	515 (97.2%)	ns
Clinical success	186 (95.4%)	489 (94.9%)	ns

*TLR (Target lesion revascularization) – Kaplan Meier – 614 stenosis

P2066 One-year follow-up after long (>40 mm) coronary stenting

M. Pezzano, B. Chevalier, R. Mohammadzadeh, P. Guyon, B. Glatt, T. Royer.
Centre Cardiologique du Nord, Saint-Denis, France

Coronary artery reconstruction (CAR) defined as the treatment of a >40 mm long native coronary segment is a limitation of balloon angioplasty. In order to assess safety/efficacy of stent-assisted CAR, we studied 163 pts (60 ± 11 y.) consecutively treated with CAR on 164 lesions using stents (S). Indication was predominantly: unstable angina 40%, recent MI 34%. Artery (RCA 54% LAD 36% Circumflex 10%) diameter was 3.03 ± 0.58 mm. S were deployed with a 3.29 ± 0.4 mm balloon at 11 ± 2 atm. Mean treated length was 53 ± 19 mm. MLD went from 0.52 ± 0.5 mm up to 2.9 ± 0.5 mm. Technical succes rate was 95.2% (1.8% S loss). Pts received a ticlopidine/aspirin drug regimen. Stent thrombosis rate was 3%. We noted no emergent CABG or death but 2 cases of Q MI (1.2%) and 3 cases of nonQ MI (1.8%). Clinical success rate was 97%. At 6 m. follow-up, we noted 2 cardiac deaths (1.4%), 34 recurrent angina (25%) and target late revascularisation (TLR) in 20 pts (14.7%). TLR increased in single stenting group from 8% (6 m.) to 10.7% at 12 m. and in multiple stenting group from 21.3%* to 24.7%* at 12 m. (* = p < 0.05 versus single stenting group). Reintervention was associated with a higher number of S/lesion (2.4 ± 1.1 vs 1.8 ± 0.8, p < 0.05).

Thus, CAR is highly feasible and associated with a good outcome at 12 months in case of single stenting.

P2067 A matched comparison between spot stenting and traditional stenting for the treatment of long lesions

Joseph De Gregorio, Nobuyuki Kobayashi, Milena Adamian, Issam Moussa, Bernhard Reimers, Yoshio Kobayashi, Remo Albiero, Carlo Di Mario, Jeffrey Moses, Antonio Colombo. *Centro Cuore Columbus, Milan, Italy; Lenox Hill Hospital, New York NY, USA*

Various approaches in the treatment of long lesions have to date yielded disappointing results. In this retrospective analysis we compared the technique of utilizing long stent lengths (LS) with full lesion coverage vs the approach of spot stenting (SS) where IVUS guided PTCA is performed and short stents are placed only in the segments of a lesion where IVUS criteria are not met (CSA > 5.5 mm2 or >50% of reference vessel CSA at the lesion site). The SS group (70 patients with 87 lesions) and the LS group (688 patients with 769 lesions) had similar baseline clinical and lesion characteristics including lesion complexity and reference vessel diameter (2.97 ± 0.5 vs 3.04 ± 0.5, p = ns). The SS group contained significantly longer lesions (28 ± 11 vs 23 ± 8, p < 0.01).

Characteristic	SS	LS	p
Mean age	60 ± 11	60 ± 10	ns
LVEF%	60 ± 11	60 ± 12	ns
3 vessel disease, n (%)	24 (37)	190 (28)	ns
Calcified lesion, n (%)	27 (31)	125 (17)	<0.05
Stents/Lesion	1.3 ± 0.6	1.6 ± 1.0	<0.05
Stent length (mm)	21 ± 13	29 ± 17	<0.05
Max inflation press. (atm)	14.6 ± 3.5	15.3 ± 3.4	<0.05
Balloon/artery ratio	1.25 ± 0.2	1.18 ± 0.2	<0.05
Min lumen diameter pre (mm)	0.7 ± 0.4	0.8 ± 0.5	<0.05
Final min lumen diameter (mm)	2.8 ± 0.7	3.0 ± 0.5	<0.05
Stent thrombosis, n (%)	1 (1.1)	15 (1.9)	ns
Procedural MACE, n (%)	3 (4.3)	32 (4.7)	ns
Restenosis, n (%)	14 (25)	183 (39)	<0.05
Target lesion revasc., n (%)	12 (17)	165 (31)	<0.05

Angiographic follow-up was achieved in 77% of eligible lesions.

Conclusions: Despite the use of shorter stent lengths to treat longer lesions, the SS group had similar short-term event rates but significantly better long-term outcome with lower restenosis rates and TLR.

P2068 Coronary artery reconstruction by stenting. initial and long-term clinical and angiographic evolution

F. Fernández-Avilés, B. Ramos, J.J. Alonso, J.M. Durán, F. Gimeno, J. Rodriguez, O. Sanz, J. Paniagua, L. de la Fuente, I. Gómez. *Hospital Universitario de Valladolid, Valladolid, Spain*

Background: Coronary reconstruction (CR) by stenting (non-interrupted covering of a coronary segment longer than 40 mm) is frequently used for treating long lesions or coronary dissection but its impact on restenosis and clinical outcome is not well-known.

Methods: To assess the clinical and angiographic evolution after CR, as well as the differences between elective and unplanned CR, we followed 89 consecutive pts who underwent CR in 90 arteries. Reconstruction required ≥40 mm of non-interrupted stent covering. The procedure was elective in 54 pts (ELR group) and unplanned (long dissection) (LDR group) in 24 pts. The stented segment length was 56 ± 17 mm. Patients from ELR group were older (ELR: 65 ± 10 yr., LDR: 59 ± 10 yr., $p < 0.01$) and no other baseline differences between groups were found. Long-term clinical follow-up was completed for 97% of pts at 19 ± 11 months.

Results: Initial success (angiographic success without major complications at 30 days) was achieved in 91% of cases whereas 5 pts (5.5%) suffered subacute occlusion, 3 pts (3%) needed urgent CABG and 1 pts died. Initial outcome was similar in both groups apart from a higher rate of optimal result (96 vs 80%, p = 0.03) and a lower incidence of vascular complications (22 vs 4%, p = 0.04) in ELR group. Both groups had similar long-term clinical and angiographic outcome. Six-month restenosis (50%-QCA criterion) rate was 55% (95% CI: 42–68%) but only 35 patients (35%) developed symptoms. During follow-up, 7 pts (8%) had cardiac death and 20 pts (23%) needed target vessel revascularization (TVR). The incidence of major adverse cardiac events (readmission, TVR or death) was 35%.

Conclusion: Coronary reconstruction by stenting is associated with a high, incidence of angiographic restenosis and an acceptable clinical outcome, without differences between elective and unplanned (dissection) reconstruction.

P2069 Immediate and medium-term outcome following the treatment of very long (50 mm) chronic coronary artery occlusion

F. Leonardo, I. Sheiban, G.M.C. Rosano, M. Montorfano, F. Marsico, P. Pagnotta, V. Tzifos, G. Cianci, C. Di Mario, A. Colombo. *Interventional Cardiology Unit, Istituto Scientifico HSR, Milan, Italy*

The long term angiographic patency and the angiographic variables associated with long term angiographic success of coronary artery stenting for chronic (>6 months) coronary artery occlusion of very long lesions (>50 mm) is not known. Aim of the present study was to evaluate the early results and outcome following the treatment of very long chronic coronary artery occlusion. Between January and December 1998 we treated 220 chronic occlusions of these and 45 of these (45 patients) were ^{3} 50 mm long. An early angiographic success of coronary stenting for lesions >50 mm was obtained in 39 patients (86%). A total of 102 coronary stents (2.3 ± 1.1 stent/patient) were implanted. No major complications were observed during the procedures and in-hospital stay. During a 7.6 ± 2 months follow-up, 18 (46%) patients remained angina free, no reinfartion occurred. Twenty seven (70%) patients with early angiographic success underwent angiographic follow-up. Significant restenosis (^{3}50%) was observed in 13 patients (48%), and complete reocclusion was observed in 4 patients (14.8%). The mean stenosis angiographic follow-up was 51 ± 33%. A significant correlation was observed between restenosis and number of stents used (R 0.52) and percent of residual stenosis (R 0.73). All total reocclusion during the follow-up were observed in vessels with a post-procedure mld < 2.75 mm.

In conclusion, although coronary artery stenting for long (>50 mm) chronic occlusion is feasible, safe and is associated with a low incidence of adverse clinical events, these complex and expensive procedures are still associated with a high 6-month restenosis rate.

P2070 Elective stenting of the unprotected left main artery: acute and long-term result

M. Adamian, C. Briguori, J. De Gregorio, T. Nishida, M. Sallam, M. Vaghetti, R. Albiero, C. Di Mario, A. Colombo. *Centro Cuore Columbus, Milan, Italy*

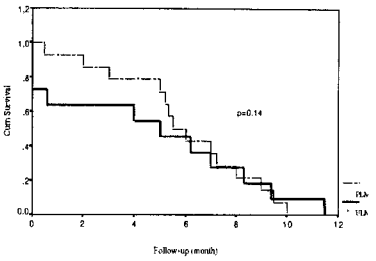
Elective stenting in patients with unprotected left main coronary artery (ULM) has generally been judged to be contraindicated, primarily due to the potential for consequences of abrupt closure and of restenosis. Recent improvements in stent implantation technique and post-stent antithrombotic regimen prompted us to evaluate the role of elective stenting of ULM.

Methods: we analyzed 85 consecutive patients (90 lesions) which underwent elective stenting of ULM (45 patients, 46 lesions) and compared them with 40 patients (44 lesions) with protected left main (PLM). All patients received aspirin and ticlopidine. Intraoartic balloon pump (IABP) was used in 53% in ULM group and in 31% of patients from PLM group (p = 0.04). Angiographic follow-up was obtained in 78% and 71% of the patients, respectively.

Results: The only different clinical factor was left ventricular ejection fraction (60.1% in ULM-group vs 52.4% in PLM group; p = 0.009). There were no significant differences in lesion characteristics (p = ns).

	ULM	PLM	p
Debulking, %	39	50	ns
Ac/Subac St Thromb, %	0	0	ns
Acute MACE, n (%)	5 (11.1)*	0	0.03
1 mo MACE, n (%)	7 (15.5)	1 (2.5)	0.03
6 mo MACE, n (%)	17	8.3	0.3
Restenosis/TLR, %	24/19	26/21	ns

*3 CABG; 2 Q-wave MI. MACE = major cardiac adverse event; TLR = target lesion revascularization.



Subanalysis in patients who have had a IABP showed a strong tendency toward procedural MACE in ULM group (p = 0.08).

Conclusions: In selected patients with good left ventricular function, elective stenting of ULM can be performed with a moderate risk of periprocedural complications. Long-term follow-up and repeat angiography shows similar clinical outcome and restenosis rate in patients with protected and unprotected left main coronary artery.

P2071 Comparison of debulking plus stenting versus stenting alone for aorto-ostial saphenous vein graft lesions: immediate and late clinical outcome

J.M. Ahmed, M.K. Hong, R. Mehran, G. Larrain, K. Kent, A.D. Pichard, L.F. Satler, G.S. Mintz, G.W. Stone, M.B. Leon. *Washington Hospital Centre, Washington DC, USA*

Background: Stent implantation in saphenous vein graft (SVG) aorto-ostial lesions may improve procedural and late clinical outcome. However the impact of debulking prior to stent implantation in this complex lesion subset is not known.

Methods: We studied 320 consecutive patients with 340 lesions treated with Palmaz-Schatz stent implantation under intrvascular ultrsound guidance in aorto-ostial SVG disease. Debulking with excimer laser or transluminal extraction catheter was performed in 133 patients prior to stenting and 107 patients received stents without prior atheroablation.

Results: Baseline clinical and lesion characteristics, and procedural success were similar between the groups.

	Debulking + Stent	Stent alone
Diabetes	38.7%	27.9%
In-hospital complications	0.7	3.1
Procedural success	99%	100%
MACE at 1 year follow-up	44%	39%
TLR	29.6%	23.4%

TLR = target lesion revascularisation; MACE (death, MI and any repeat revascularisation).

Conclusion: We therefore conclude that there is no difference in the immediate procedural outcome, late clinical events and TLR between patient undergoing debulking prior to stenting or stenting alone. These results question the value of debulking prior to stenting in SVG/aorto-ostial lesions. This important issue needs further investigation.

P2072 Procedural outcome and follow-up after saphenous vein graft treatment

V. Tzifos, I. Sheiban, C. Stefanadis[1], A. Dharmadhikari, F. Leonardo, A. Catanoso, M. Adamian[2], P. Toutouzas[1], C. Di Mario, A. Colombo. *Interventional Cardiology Unit, Istituto Scientifico HSR, Milan, Italy; [1]Cardiology Dept., University of Athens, Athens, Greece; [2]Interventional Cardiology, Columbus Hospital, Milan, Italy*

The aim of the present study was to evaluate the impact of improved strategies over the last 3 years on procedural early and late outcome in diseased SVG.

Methods: 194 consecutive patients (pts) underwent interventional procedure on 278 SVG lesions (65% B2 and C) during the last 3 years. Mean graft age was 8.8 ± 5.5 years. 89% of lesions were stented (directional coronary atherectomy in 2.1% prior to stenting) and 11% received only PTCA. 39 covered stents were deployed. In 11 pts the Guard Wire (PercueSurge) temporary occlusion and aspiration system was used to prevent distal embolization. Lesion location was aorto-ostial in 21% of pts, midgraft in 53.5% and distal anastomosis site in 25.5%. Total occluison and thrombus containing lesions were treated in 13.6% and 11%of cases respectively. Reo-Pro was given in 15% of pts.

Results: Angiographic success was obtained in 266 lesions (95.7%) 11/12 failures were in total occlusions. Quantitative angiographic results are summarized below. In-hospital MACE occurred in 6 (3.09%) patients (1 death and 5 myocardial infarctions). Clinical success rate was 92.6%. 6-month angiographic follow-up was obtained in 121 patients (62%). Restenosis occurred in 35 (18%). 12-month clinical follow-up was obtained in 186 patients (96%). Nine patients (4.6%) died, 3% had a myocardial infarction, 22.1% had a re-PTCA procedure at the target vessel and 3.6% had a new CABG surgery.

	RD (mm)	MLD (mm)	DS (%)
Pre-treatment	3.46 ± 0.96	0.64 ± 0.65	80.9 ± 16.75
Final	3.63 ± 0.79	3.34 ± 0.83	7.53 ± 12.14

RD: reference diameter, MLD: min. lumen diameter, DS: Diameter stenosis.

Conclusion: SVG revascularization procedures can now be performed, even in complex lesions, with low periprocedural adverse events. Although, the need for repeat revascularization is still higher than in native arteries, approximately 70% of pts are free from major cardiac events after one year.

P2073 Stenting of territories with prior coronary bypass grafts: should the target be the vein graft or the native vessel?

R. Mehran, G. Dangas, M.A. Peterson, J.M. Ahmed, M.K. Hong, G. Dangas, L.F. Satler, K.M. Kent, G.W. Stone, M.B. Leon. *Washington Hospital Center, Washington DC, USA*

Background: Interventions in saphenous vein grafts (SVG) are associated with increased morbidity and mortality when compared to interventions in the native vessels. The relative risks and advantages of native coronary vs. saphenous vein graft stenting in patients who present with SVG stenosis are poorly understood.

Methods: We evaluated the in-hospital and one year major adverse cardiac events (MACE) including death, MI, or target lesion revascularization (TLR) after elective stenting in 1451 SVG lesions of 935 consecutive patients and in 1092 native coronary lesions of 718 consecutive patients with prior CABG and SVG disease.

Results: Adjunct Abciximab was used 15.2%. In hospital MACE was similar (1.9% vs. 1.8%, p = NS), but SVG stenting was associated with a higher incidence of non-q wave MI (18% vs. 13%, p = 0.04). Long-term results:

Follow-up (1 year)	Native Coronaries n = 718	SVG n = 935	p
Death (%)	4.3	9.1	0.001
MI (%)	2.3	4.5	0.001
TLR (%)	19.1	16.9	NS
MACE (%)	29.6	32.7	NS

Independent predictors of late death or MI included SVG location (OR 2.1), post procedural non-Q wave MI (OR 2.5), and low LV ejection fraction (OR 0.80).

Conclusion: In patients with prior CABG, SVG stenting is associated with higher post-procedural MI and higher late major events including death and MI, compared with native coronary stenting. Our data suggest that revascularization of the native vessel rather than the SVG should be the preferred interventional choice in this clinical setting.

P2074 Transcatheter microcoil embolisation of side branch of the left internal mammary artery in patients with recurrent angina and anterior wall ischaemia after coronary artery bypass grafting

J.M. Ahmed, M.Y. Salame, P.N. Silverton, R.J. Vecht, D.C. Cumberland. *Northern General Hospital, Sheffield, UK*

Background: Angina following coronary artery bypass grafting (CABG) may be caused by coronary steal due to a large side branch of the left internal mammary artery (LIMA). Objective evidence of reversal of anterior wall ischaemia due to trancatheter microcoil embolisation (TME) of unligated side branch of LIMA is lacking. We aimed to assess the effect of TPME in patients re-presenting with angina and documented anterior wall myocardial ischaemia post CABG.

Methods: We studied 6 males (44–75 yrs) who underwent complete revascularization; (2 patients had a solitary LIMA graft to the left anterior descending (LAD) artery, the other 4 had a LIMA graft to LAD plus vein grafts to both the circumflex and right coronary arteries) and re-presented (6–72 months, mean 23.6 months post-CABG) with angina (Canadian Class III–IV) and coronary angiography (11–96 months post-CABG, mean 34.2) showing patent grafts and a large unligated LIMA side branch with reversible anterior wall perfusion defects on dobutamine-tetrofosmin SPECT. TPME was performed via the femoral artery using a 7 French LIMA guide catheter (Cordis), 0.014 inch floppy guidewire, Tracker 18 catheter and coil pusher-16 (Target Therapeutics). After coil deployment, LIMA angiograms were performed to confirm the occlusion of the side branch and SPECT studies were repeated at, 22–40 days. Patients were followed up at 3 and 6 and 12 months clinically.

Results: TPME was successful in all six cases and resulted in reversal of the perfusion abnormalities detected on myocardial SPECT. One patient had a minor stroke with full recovery. All patients were free of angina at 3 and 6 and 12 months.

Conclusion: TPME of LIMA side branch is effective in relieving angina and reversing anterior wall ischaemia.

P2075 Angioplasty of mammary artery grafts after coronary surgery: a multicentre experience including stented patients

H. Le Breton, D. Bendas[1], Ph. Commeau[1], Ph. Druelles[2], C. Leclercq, Ph. Brunel[3], C. Descaves[2], D. Crochet[3], F. Thomas, M. Bedossa. *Department of Cardiology, CHU Rennes; [1]Department of Cardiology, Centre Hospitaler Privé St Martin, Caen; [2]Department of Cardiology, Clinique St Laurent, Rennes; [3]Department of Cardiology, CHU Nantes, France*

Background: Early recurrent ischemia after coronary artery bypass surgery may be related to mammary artery graft stenosis, mainly at the site of anastomosis. The goal of this multicenter registry was to collect a large experience with the percutaneous transluminal coronary angioplasty (PTCA) of mammary arteries (MA) including stented patients and a systematic clinical follow-up.

Method: Since July 1991 to February 1998, 87 patients (pts) (62 ± 9 years, 77% males) underwent PTCA within an internal MA in a mean time of 29 ± 34 months after surgery. Of the 87 pts, 80 had dilatation of the distal anastomosis. Thirty five percent of pts were in unstable angina. The approach was femoral in 68 pts (78%).

Results: Initial angiographic success of the MA angioplasty was achieved in 68 pts (78%). In 24 pts (27%), balloon PTCA was followed by an attempted stent implantation, successfully in 23 pts. Of the 19 pts with failed MA angioplasty, one required a urgent redo CABG and two a delayed CABG surgery. One unsuccessful case lead to an anterior myocardial infarction. No pt died. Clinical follow-up was obtained in 98% of pts (25 ± 20 months). Six pts died (7%). The actuarial rate of pts alive and free of major events (myocardial infarction, CABG) at 4 years was 88 ± 10%. Most of the pts were either asymptomatic or had stable angina class I or II at follow-up. Thirteen pts required revascularization during the follow-up period, but only 8 pts returned with a focal IMA restenosis. Six pts underwent a new PTCA and two a repeat CABG.

In conclusion, PTCA of MA and stenting can be safely performed with however a lower success rate than in native vessels and is associated with good mid-term results in successfully dilated patients.

PROGNOSIS AFTER ACUTE CORONARY SYNDROME

P2076 The long-term prognosis in 30-day survivors after acute myocardial infarction in the pre and thrombolytic eras: a national study

S. Behar, S. Gottlieb, E. Kaplinsky. *Neufeld Cardiac Research Institute, Sheba Medical Center, Tel Hashomer, Israel*

Early mortality after AMI declined significantly in the reperfusion era. Late mortality improvement remains questionable. We compared the 4-year mortality rate among 30-day survivors after AMI hospitalized in Jan–Feb, 1982–83 (n = 839) with 814 counterparts hospitalized in Jan–Feb, 1992.

	1982–83 (n = 839)	1992 (n = 814)	p Value
Men	77%	77%	NS
Mean age	62 ± 11	62 ± 12	NS
Prior MI	25%	27%	NS
Diabetes	19%	23%	0.05
Hypertension	39%	36%	NS
Current smoking	36%	38%	NS
P. edema/CHF	19%	12%	0.001
Aspirin	2%	79%	0.001
β-Blockers	15%	35%	0.001
ACE-Inhibitors	-	20%	0.001
Thrombolysis	-	46%	0.001
Coronary angio.	0.7%	24%	0.001
PTCA/CABG	-	11%	0.001
Mortality			OR* (95% CI)
4-year	28%	20%	0.76 (0.67–0.86)

** Mortality risk of 1992 vs. 1981–83 adjusted for age, gender, past MI, diabetes, CHF, hypertension and smoking*

Conclusion: The characteristics of MI survivors in both periods were comparable, but the management was totally different. This study suggests that changes in management of AMI in the '90s as compared with the '80s was associated with a better long-term prognosis in hospital survivors after AMI.

P2077 In patients with a patent infarct artery, rapid 50% ST-segment recovery is associated with improved regional wall motion at 48 hours

Jacqueline Andrews, Ivan T. Straznicky, John K. French, Mayanna Lund, Arthur Maas, Cindy Green, Mitchell Krucoff, Harvey D. White. *For the HERO-1 Investigators; Cardiovascular Research Unit, Green Lane Hospital, Auckland, New Zealand*

Both early ST recovery and a patent infarct artery after thrombolytic therapy are associated with improved outcome after infarction. In patients with a patent infarct artery (TIMI 2 or 3 flow) at 90 minutes, it is not known whether the beneficial effect of rapid ST recovery is maintained.

Methods: We examined the effect of rapid 50% ST recovery on chord motion in the infarct zone by contrast ventriculography at 48 hours in patients with TIMI 2 or 3 flow at 90 minutes. Patients with acute myocardial infarction had continuous ST monitoring, received aspirin and streptokinase, and were randomised to intravenous heparin or one of two doses of Hirulog. Time to Steady State Recovery was to the first ECG showing 50% ST recovery sustained for 4 hours.

Results: Of 137 patients, 40 had TIMI 2 and 57 had TIMI 3 flow. The table below compares Time to Steady State Recovery (either ≤ or >45 min or 60 min) with chord motion in patients with TIMI 2 or 3 flow:

	TIMI 2						TIMI 3					
	≤45 min	>45 min	P	≤60 min	>60 min	P	≤45 min	>45 min	P	≤60 min	>60 min	P
Mean Chord Score	−1.2	−2.5	*0.048*	−1.2	−2.5	*0.03*	−1.4	−2.5	*0.01*	−1.6	−2.5	*0.04*
% Chords Abn	17.8	52.3	*0.02*	15.3	55.5	*0.01*	19.9	49.4	*0.002*	28.3	48.8	*0.07*

Conclusion: Rapid 50% ST recovery is associated with improved infarct zone wall motion at 48 hours even amongst patients with a patent infarct artery. Resolution of ST elevation may therefore be a more accurate marker of myocardial reperfusion than epicardial artery patency.

P2078 Prognostic value of coronary blood flow velocity investigated by intracoronary Doppler in patients with acute myocardial infarction after successful coronary angioplasty

A. Furber, F. Prunier, S. Boulet, P. L'Hoste, A. Tadéi, P. Geslin. *The University Hospital, Angers, France*

The objective of this study was to determine the prognostic value of coronary blood flow velocity investigated by intracoronary Doppler in patients with acute myocardial infarction within one year of angiographically successful coronary angioplasty.

Methods: In 40 patients (mean age 60.2 ± 15.4 y) who were consecutively referred for direct or rescue PTCA because of a primary myocardial infarction either inferior (n = 22) or anterior (n = 18), average peak velocity (APV) was measured after coronary angioplasty using a 0.014 doppler guidewire. Cardiac events were defined as cardiac death (CD), myocardial infarction (MI), congestive heart failure (CHF) and myocardial revascularization (REV).

Results. Subsequent PTCA was successful (percent diameter stenosis < 40%, TIMI 3) in 38/40 patients. Distal APV, which was 18.7 ± 10.4 cm/s, appeared highly varied quantitatively speaking. An adverse outcome was present in 6/40 patients (2 CD, 1 MI, 2 CHF, 3 REV) during in hospital follow-up and in 15/40 patients (2 CD, 2 MI, 5 CHF, 7 REV) during one-year follow-up. Distal APV was significantly lower in patients with in-hospital and one-year cardiac events than in those with cardiac event free (10.6 ± 6.0 cm/s vs 20.1 ± 10.4 cm/s, $p < 0.03$; 14.7 ± 8.3 cm/s vs 21.1 ± 10.9 cm/s, $p < 0.05$; respectively). An abnormal distal APV < 10 cm/s is independent predictor of one-year adverse cardiac events (66.6% vs 29%, $p < 0.04$) and hospitalization for congestive heart failure (44.4% vs 9.7%, $p < 0.01$).

Conclusion. Thus, APV disparity seems to be a useful and safety tool for enhancing patient characterization, to isolate a subset of risk patients for subsequent cardiac events.

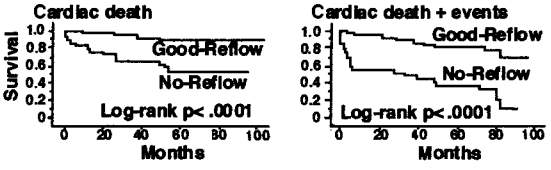
P2079 Angiographic no-reflow is an independent early predictor of long-term cardiac complications and mortality in patients with acute myocardial infarction recanalized by angioplasty

I. Morishima, T. Sone[1], H. Tsuboi[1], J. Kondo[1], H. Mukawa[1], H. Matsui, Y. Toki, T. Ito, K. Okumura. *Internal Medicine II, Nagoya University, Nagoya;* [1]*Department of Cardiology, Ogaki Municipal Hospital, Ogaki, Japan*

Angiographic no-reflow (NR) refers to substantial coronary antegrade flow reduction (less than TIMI 3 flow) without mechanical obstruction occasionally seen after recanalization. Our aim was to elucidate the importance of angiographic NR as a predictor of long-term outcome in the patients with AMI.

Method: We studied 119 consecutive patients with their first AMI successfully recanalized by PTCA without residual stenosis ≥ 50%, or major dissection or thrombus that may restrict coronary flow. The patients were divided into either NR (n = 29) or good-relow (TIMI 3) (GR, n = 90) based on the angiogram obtained at the end of PTCA, and were followed up (69 ± 14 months) with regards to cardiac death and cardiac events including cardiac rupture, recurrent AMI, congestive heart failure, and malignant arrhythmia.

Results: Kaplan-Meier event-free survival curves are as follows:



Multivariate Cox regression analyses disclosed the following variables as early independent predictors of event-free survival:

	Variable	b ± SE	Relative Risk	P value
Cardiac death	No-reflow	1.67 ± 0.50	5.31	<.001
	Age ≥ 70	1.02 ± 0.50	2.76	0.040
Cardiac death + events	No-reflow	1.48 ± 0.35	4.39	<.001
	Killip class ≥ 2	0.80 ± 0.36	2.22	0.027

Conclusion: Angiographic NR may be an independent early predictor of adverse long-term outcome in the patients with AMI.

P2080 Is carotid artery intima-media thickening a reliable marker of early atherosclerosis?

J. Mayet, P. Patel[1], M. Starmans-Kool[1], N. Chapman[1], A.D. Hughes[1], R.A. Foale, S. Thom[1], A.V. Stanton[1]. *Cardiology Dept., St Mary's Hospital, London; [1]Peart-Rose Clinic, St Mary's Hospital, London, UK*

It is widely believed that carotid artery intima-media thickening represents an early marker for the development of atheroma. It has been shown to be related to the all of the commonly accepted risk factors for cardiovascular disease, including left ventricular hypertrophy. However, carotid intima-media thickening might also be expected to occur in response to an increased shear wall stress; if this were to be the case it would caution the increasing enthusiasm for the use of this measurement as a marker for cardiovascular risk.

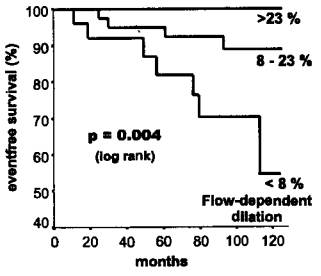
In order to test the hypothesis that an increased carotid artery wall shear stress may cause an increase in carotid intima-media thickness (IMT) 24 athletes (professional footballers) were compared to 14 age, sex and race matched control subjects. Each subject underwent bilateral common carotid and femoral ultrasonography and echocardiography. The athletes had a significantly greater left ventricular mass index compared with the controls – 135 (127–143) versus 104 (91–116) g/m^2, $p < 0.001$. In addition, they had a greater carotid IMT – 0.55 (0.52–0.57) versus 0.51 (0.48–0.54) mm, $p < 0.05$. However, carotid artery diameters, femoral IMT and femoral artery diameters were similar – 6.0 (5.9–6.2) versus 5.8 (5.6–6.1) mm, 0.43 (0.42–0.45) versus 0.43 (0.41–0.45) mm and 8.3 (8.0–8.6) versus 8.4 (8.0–8.7) mm, respectively.

The increased carotid IMT in the athletes is likely the result of the high cardiac output that is periodically delivered during exercise, causing an increased carotid wall shear stress. This is an important observation, since it suggests that an increased carotid IMT cannot be relied on as a marker of early atherosclerosis.

P2081 Impaired flow-dependent dilation of coronary arteries is predictive of subsequent adverse coronary events during long-term follow-up

V. Schächinger, M.B. Britten, A.M. Zeiher. *Dept. of Internal Medicine IV, Div. of Cardiology, J. W. Goethe University, Frankfurt/Main, Germany*

Experimental studies indicate, that endothelial dysfunction plays a key role in the pathogenesis of coronary artery disease. However, so far, no clinical data are available linking endothelial dysfunction to prognosis of patients. Thus, in 103 patients, endothelium-dependent, flow-dependent dilation of epicardial arteries (FDD) after infusion of 7 mg papaverine or 2.4 mg/min adenosine as well as endothelium-independent dilation (i.c. nitroglycerin, 250 μg) was assessed by quantitative coronary angiography. Then, long term follow up (FU; 13–125; median 94 months) was performed. Cardiac events were defined as sudden death, myocardial infarction, unstable angina, PTCA or coronary bypass surgery.



Results: Patients with cardiac events during FU had initially a significantly impaired FDD compared to patients without events (8.5 ± 8.6%, n = 11 vs. 17 ± 10%, n = 92; p = 0.01). By cox regression analysis, FDD was significantly associated with development of future events (p = 0.02). Patients with FDD > 23% (upper quartile, n = 25) experienced no event, whereas patients with FDD < 8% (lowest quartile, n = 25) had 7 events (figure). In addition, NTG-response was reduced in patients with events (23 ± 11% vs. 36 ± 20%; p = 0.04). However, this association was not significant by cox regression analysis (p = 0.06).

Conclusion: Impaired flow-dependent dilation is associated with cardiac events during long term follow up. This finding underscores the crucial role of endothelial dysfunction for progression of coronary artery disease.

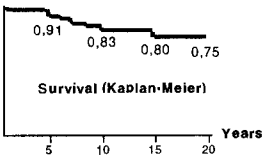
P2082 Vasospastic angina: long-term follow-up

M. Abeytua, R. Moreno, J. Soriano, J. Elízaga, J. Botas, J. Bermejo, N. Pérez-Castellano, J. Portales, E. García, J.L. Delcán. *Department of cardiology, Hospital Gregorio Marañón, Madrid, Spain*

The objective of this study was to assess the long-term outcome of patients (P) with symptomatic vasospastic angina without significant coronary lesions.

Methods: All 86 consecutive P with vasospastic angina without significative coronary lesions were prospectively followed-up for a mean of 8.8 years (range 0.5–22 years). The diagnosis of coronary spasm (CS) was established in presence in one of the following criteria: 1) ↑ST during angina; 2) positive ergobasine test; 3) CS at angiography not induced by catheter. Coronariography was performed in all patients and provocative ergobasine test in 74. All of them were discharged on calcium channel blockers. An angiographic reevaluation was performed in presence of effort angina or myocardial infarction at a long-term. Follow-up was obtained in all P (100%).

Results: Mean age was 51.2 years, and 76 (88.4%) were male. The outcome was: 10 P (12%) died; 5 (6%) suffered a myocardial infarction; 25 (29%) had a recurrent rest angina; 13 (15.1%) developed effort angina; 49 (59%) were alive and free of events at the end of the follow-up. The cause of death was cardiac in 5 P (50%), all of them sudden death. Development of significative coronary lesions at angiography was demonstrated in 13 P (15%).



In conclusion: Vasoespastic angina without significative coronary lesions is associated with a low long-term mortality. However, sudden death is the main cause of mortality, and recurrent ischemia is frequent despite treatment with calcium channel blockers. Development of significative coronary lesions was demonstrated in 15%.

P2083 Clinical characteristics and long-term prognosis of 91 patients with myocardial infarction and normal coronary angiogram

A. Da Costa, K. Isaaz, E. Faure, S. Mourot, A. Cerisier, D. Juillard, J.P. De Pasquale, M. Lamaud. *Div. of Cardiology, University of Saint Etienne, France*

Background. Few data exist concerning the prognosis of patients (pts) with myocardial infarction (MI) and angiographically normal coronary arteries.

Methods. A group (Gr) of 91 pts admitted in our institution between january 1990 and december 1998 for a MI with normal coronary angiogram (smooth contours and no focal diameter reduction) (34 females/57 males; mean age 50 ± 13 yrs, range 24–78 yrs) (Gr I) were matched for age, sex, and year of MI onset with a Gr of 91 MI pts with coronary artery stenosis (>50% diameter stenosis) (Gr II).

Results. The percent of smokers was similar between the 2 groups; higher prevalence of coronary heart disease family history, obesity, hypertension, hypercholesterolemia and diabetes mellitus were found in GR II (p = 0.043 to 0.0001). In Gr I, coronary spasm was found in 13%, congenital coagulation disorders in 11%, collagen tissue disorders in 2.2%, embolization in 2.2%, and oral contraceptive use in 1.1%. LV ejection fraction (LVEF) at hospital discharge was higher in Gr I (60 ± 13%) than in Gr II (55 ± 13%, p = 0.04). The mean follow-up was 35 months (range 1–100 months). Kaplan-Meier event-free survival, with end-points defined as death, reinfarction, heart failure and stroke was 75% in Gr I vs 62% in Gr II (p = 0.01). Univariate predictors of any event in Gr I were LVEF (p = 0.03), age (p = 0.02), diabetes (p = 0.01), and smoking (p = 0.03). Using Cox multivariate analysis, independent predictors of long-term outcome in Gr I were LVEF (p = 0.003) and diabetes (p = 0.004).

Conclusion. Patients with MI and normal coronary angiogram have a better long-term prognosis than MI patients with coronary artery stenosis. In MI patients with normal coronary angiogram, the only two independent risk factors for cardiovascular events are left ventricular function and diabetes.

P2084 Prognostic value of step-by-step ischaemic diagnostics following uncomplicated acute myocardial infarction

H. Völler, M. Jereczek, W. Kamke, C. Dovifat, Th. Peine, K. Wegscheider[1]. *Klinik am See, Rüdersdorf/Berlin; [1]Institute of Statistics and Economics, University Hamburg, Germany*

After acute myocardial infarction (AMI), invasive diagnostics and therapeutic procedures are performed routinely in a high percentage of patients, especially in Germany. A more reluctant approach based on non-invasive diagnostic methods in patients with uncomplicated AMI would be socioeconomically preferable, but only if the prognosis is not compromised.

Method: Between 10/96 to 12/97, 318 consecutive patients (median 65 years, range 22–88 years, 65% men, 35% women) with first uncomplicated myocardial infarction were included for non-invasive ischemic diagnostics. Depending on the evidence of ischemic signs in an exercise ECG (n = 110) or during stress echocardiography (n = 90) or the occurrence of recurrent angina pectoris (n = 36), the patients were assigned to group I (n = 195, invasive) or group II (n = 123, conservative) and were then followed for 12 months with regard to the composite primary endpoint 'death or myocardial infarction (MI)' and secondary endpoints (death alone, death, MI or hospitalization for cardiac reasons, PTCA or CABG).

Results: There were no differences between the groups in terms of age, sex, infarct location, thrombolytic therapy or left-ventricular function. 56 (29%) of the group I patients were treated by coronary surgery, 77 (39%) by PTCA and 62 (32%) conservatively. After a median follow up of 14 months, the primary endpoint was experienced by 15 group I patients (7.7%) and 8 group II patients (6.5%, logrank test n.s.). Similarily, there were no significant group differences in terms of the secondary endpoints (death: group I: n = 10, 5.1% versus group II: n = 6, 4.9%, death, MI or hospitalization: group I: n = 30, 15.4% versus group II: n = 21, 17.1%).

Conclusion: Following first uncomplicated myocardial infarction, conservatively treated patients with no signs of ischemia revealed a one-year prognosis that was comparable to the prognosis of patients who were diagnosed by invasive techniques and conditionally treated by PTCA or CABG.

P2085 Stress hyperglycemia and prognosis of myocardial infarction in nondiabetic and diabetic patients: a systematic overview

S.E. Capes, D. Hunt, K. Malmberg[1], H.C. Gerstein. *Department of Medicine, McMaster University Medical Center, Hamilton ON, Canada; [1]Department of Medicine, Karolinska Hospital, Stockholm, Sweden*

A systematic review and meta-analysis of the literature was done to determine the risk of in-hospital mortality or cardiogenic shock after myocardial infarction (MI) in nondiabetic and diabetic patients with "stress" hyperglycemia at the time of admission.

Two independent MEDLINE searches of English-language articles from 1966 to October 1998, a computerized search of Science Citation Index from 1980 to September 1998, and hand searching of bibliographies were done. The retrieved citations were reviewed independently by two researchers to identify all retrospective and prospective cohort studies in which in-hospital mortality or cardiogenic shock were described in relation to admission blood glucose level. 13 articles describing 14 studies were identified.

Study quality was assessed based on specific methodologic criteria. Whenever possible, the relative risk of in-hospital mortality and/or cardiogenic shock in hyperglycemic compared to normoglycemic patients was calculated. Other relevant descriptive information was abstracted from each study.

Relative risks were calculable in 10 of 14 studies. Data from nondiabetic patients (in 6 studies) and diabetic patients (in 4 studies) were analyzed separately. Nondiabetic patients whose admission blood glucose at the time of MI was ≥ 6.1–8 mM (110–144 mg/dL) had a 4.0-fold increased risk of in-hospital mortality (95% confidence interval 2.89–5.55), and nondiabetic patients with an admission blood glucose > 10 mM (180 mg/dL) had an increased risk of cardiogenic shock. In diabetic patients, admission hyperglycemia did not significantly increase the risk of mortality or cardiogenic shock.

In conclusion, stress hyperglycemia on admission with MI is strongly associated with an increased risk of in-hospital mortality and cardiogenic shock in nondiabetic patients. Such an association was not observed consistently in diabetic patients.

P2086 A risk-score for prediction of cardiac mortality after an episode of unstable coronary artery disease

B. Lindahl, H. Toss, A. Siegbahn, P. Venge, L. Wallentin. *Dept. of Cardiology and dept. of Clinical Chemistry, University hospital, Uppsala, Sweden*

The contributions of different pathophysiological mechanisms operating in unstable coronary artery disease (UCAD) and hence, the prognosis, differs considerable. Therefore, an early assessment of these mechanisms is important in order to be able to adequately risk stratify the patient. We therefore developed a risk score for prediction of cardiac mortality based on, easily available, clinical-, laboratory-and ECG-variables mirroring different mechanisms.

Methods: The patients were participating in FRISC – a double blind, randomised, placebo controlled trial of l.m.w. heparin (dalteparin) in UCAD and followed for at least 3 years. A risk score with a maximal of 8 points was developed based on 7 variables, who were independently associated with an increased risk of cardiac death in a Cox regression analysis: age ≥ 70 (**1p**), diabetes (**1p**), history of CHF (**1p**), ≥1 anti-anginal drugs on admission (**1p**), ST-segment depression on admission (**1p**), C-reactive protein ≥ 10 mg/L on admission (**1p**) and elevated (≤24 h) troponin T (0.06–0.6 μg/L **1p;** ≥0.6 μg/L **2p**).

Results: The median age at inclusion of the 917 patients were 70 years (25^{th}–75^{th} perc. 63–75) and 65% were males. After 3 years there were 114 (12.4%) deaths of which 91 (9.9%) were cardiac in origin.

Risk points	0–2 n = 254	3–4 n = 420	5–6 n = 226	7–8 n = 17
1-month c. mort., %	0	1.0	4.0	17.6
1-year c. mort., %	0.4	4.0	14.6	29.4
3-years c. mort., %	0.8	7.4	22.6	41.2

Conclusion: With this risk score based on variables easy to obtain within the first 24 hours after admission, large subsets of UCAD patients with low (≤2 p) and high (≥5 p) short- and long-term cardiac mortality, respectively, might be identified. However, the risk score has to be validated in prospective studies.

P2087 Superoxide dismutase activity in platelet: an independent predictor of long-term prognosis after acute myocardial infarction

S.V. Shalaev, E.S. Petrik, T.D. Zhuravleva, N.I. Kuznetsova, S.V. Petrik. *Institute of Clinical and Preventive Cardiology, Tymen, Russian Federation*

Animal, clinical and pathologic studies have established platelet thrombus formation as the key event in the etiology of acute coronary syndromes.

The purpose of this study was to investigate the prognostic significance of main phospholipid platelet (ptl) contents, lipid peroxides products and antioxidant enzymes in ptl, measured before hospital discharge, in patients (pts) with acute myocardial infarction (MI). We studied 147 consecutive pts (all men, age 50 ± 9, first AMI in 80%, Q-wave MI in 76%). At the time of hospital discharge, 24-hour electrocardiogram Holter monitoring and quantitative two-dimensional echocardiographic were performed in all pts. Follow-up was for 19 ± 9 months. During follow up, there were 17 cardiac deaths (10 sudden death and 7 fatal MI). According to univariate Cox analysis, the variables identified as significant predictors of cardiac death were: left ventricular aneurysm (LVA) (relative risk [RR] 5.61; 95% confidence interval [CI] 2.12–14.81, p = 0.0005), left ventricular ejection fraction < 40% (RR 4.53; 95% CI 1.68–12.18, p = 0.003), previous MI (RR 4.24; 95% CI 1.64–11.02, p = 0.003), superoxide dismutase (SOD) activity in ptl (RR 0.61; 95% CI 0.39–0.95, p = 0.03), left ventricular end-systolic volume (RR 1.05; 95% CI 1.002–1.09, p = 0.04), anterior location of Q-MI (RR 4.94; 95% CI 1.08–22.6, p = 0.04). Multiple stepwise Cox regression analysis identified the SOD activity in ptl (RR 0.36; 95% CI 0.19–0.69; χ^2Wald = 9.51, p = 0.002), previous MI (RR 6.77; 95% CI 1.69–27.12; χ^2Wald = 7.3, p = 0.007), anterior location of Q-MI (RR 6.67; 95% CI 1.29–23.54; χ^2Wald = 5.1, p = 0.024), LVA (RR 4.52; 95% CI 1.21–16.88; χ^2Wald = 5.0, p = 0.025) as independent predictors of cardiac death.

In conclusion, our data suggest that reduced activity of SOD in ptl, measured at hospital discharge, is an independent predictor of cardiac death in the 19 ± 9 months following acute MI.

P2088 Chronotropic incompetence after acute myocardial infarction: prognostic impact and relationships with heart rate variability

M. Emdin, M.S. Lauer[1], P. Landi, M. Raciti, C. Michelassi, G. Nassi, M.G. Trivella, C. Passino, A. L'Abbate, C. Carpeggiani. *Cardiology Dept, CNR Institute of Clinical Physiology, Pisa, Italy; [1]Cleveland Clinic Foundation, Cleveland OH, USA*

The association of chronotropic incompetence and its relation with autonomic dysfunction has not been characterized after acute myocardial infarction (AMI), as well as its prognostic value.

Methods: patients at discharge after AMI (290, 263 men, <65 years, 55 ± 8 m ± sd) underwent graded exercise testing, and 24 hr Holter monitoring. Chronotropic incompetence was assessed as a low chronotropic index (CRI), a measure of exercise heart rate that accounts for age, resting heart rate, and peak VO_2, whereas relevant time and frequency heart rate variability HRV indices were averaged on the 24 h period from Holter ECG recording: in particular, RR interval total power, low frequency (LF), and high frequency (HF) power (both in absolute and normalised units – nu), as well as LF/HF ratio, were computed by means of autoregressive spectral analysis. Stepwise multiple regression analysis was applied to the HRV indexes, adjusting for age, sex and an echocardiographic index of left ventricular function (WMSI = wall motion score index).

Results: A significant positive relationship was found between CRI and a spectral index of parasympathetic drive (HFnu, $r = 0.22$, $p < 0.01$), whereas a negative correlation was found with sympathetic markers (LF nu, $r = -0.28$, $p < 0.001$, LF abs, $r = -0.21$, $p < 0.01$) and LF/HF ratio, an index of sympatho-vagal balance ($r = -0.23$, $p < 0.01$). During follow-up there were 70 endpoint events (9 deaths, 17 new AMI, 44 revascularisation procedures). After adjusting for age, gender, effort ischemia, WMSI, and other confounders, low CRI remained predictive (Kaplan-Meier – KM – rates 31.5% vs. 11%, adjusted RR 1.53, 95% CI 0.95–2.49, P = 0.08).

Conclusions: parasympathetic withdrawal and reciprocal sympathetic overactivity is associated with chronotropic incompetence during physical stress in subacute phase of an AMI. Moreover, chronotropic incompetence is independently predictive of major events among patients undergoing stress testing as part of post-AMI evaluation.

P2089 Recurrent ischaemia in patients with clinical heart failure but preserved left ventricular systolic function after acute myocardial infarction

K.S. Spargias, A.S. Hall, D.C. Greenwood[1], P.J. Thorley, J.G.F. Cleland[2], L. Erhardt[3], S.G. Ball. *Yorkshire Heart Centre; [1]Subunit for Medical Statistics, University of Leeds, Leeds; [2]Dept of Cardiology, University of Hull, Hull, UK; [3]Dept of Cardiology, University of Lund, Malmö, Sweden*

The occurrence of clinical heart failure (HF) after acute myocardial infarction (AMI) is an adverse prognostic factor even when left ventricular (LV) systolic function is preserved. We examined whether clinical HF but preserved LV systolic function after AMI is associated with an excess of residual and recurrent ischaemic events.

Methods A cohort of 508 patients with overt clinical HF and a LV ejection fraction (EF) measured 6.9 ± 4.9 days after AMI were identified from patients recruited to the AIRE study. 25 patients also underwent early myocardial perfusion studies. Clinical outcomes during an average of 15-month follow-up in those with an EF ≥ 0.45 (n = 163) were compared with those with EF < 0.45 (n = 345) using time to event statistical analysis.

Results The risks of death or developing severe HF were lower with EF ≥ 0.45 versus EF < 0.45 (14.1% vs. 22.1%, logrank p = 0.049; 9.2% vs. 20.9%, p = 0.002). In contrast, those with EF ≥ 0.45 were at a higher risk of recurrent ischaemic events indicated by the combined end-point of need for surgical or catheter-based revascularization or reinfarction or hospitalization for angina (HR 1.50, 95% CI 1.06 to 2.13, p = 0.021). In the subgroup who had myocardial perfusion studies those with EF ≥ 0.45 had 1.00 ± 1.26 LV segments which manifested partial or complete reperfusion whereas those with EF < 0.45 had 0.07 ± 0.47 such segments (p = 0.04).

Conclusions Patients with clinical HF after AMI and preserved LV systolic function have a lower mortality than those with reduced LV systolic function, but are at increased risk of recurrent ischaemic events.

P2090 Atherosclerosis of the descending aorta predicts cardiovascular events independently of left ventricular function: a transesophageal echocardiography study

A. Varga, N. Gruber[1], E. Jebelovszki[1], M. Csanady[1], T. Forster, E. Picano. *Institute of Clinical Physiology, Pisa, Italy; [1]2nd Department of Medicine, Albert Szent-Gyorgyi University, Szeged, Hungary*

The aim of our study was to evaluate whether the presence of atherosclerosis on the descending aorta as assessed by transesophageal echocardiography (TEE) has any prognostic impact in predicting cardiovascular events in non-revascularized patients.

Methods: The initial study group consisted of 238 consecutive in-hospital patients referred for TEE testing. Of these, 34 patients were excluded for early revascularization. The remaining 204 patients (99 females, mean age 58 ± 11 years) were followed up for at least 2 years (mean 29 ± 8 months). The atherosclerotic process on the descending aorta was scored as follows: 0 – no sign, 1 – intimal thickening, 2 – plaque < 5 mm, 3 – plaque > 5 mm, 4 – plaque with ulcerated or mobile parts.

Results: In the follow-up period there were 23 cardiovascular events: 14 cardiac deaths, 4 fatal strokes, 5 non-fatal myocardial infarctions. During TEE significant atherosclerosis (score ≥2) was observed in 82 patients. Nine events occurred in 122 Patients with TEE score ≤1 and 14 in 82 patients with TEE score ≥2 (7% vs 17%, p < 0.05). By multivariate analysis, only left ventricular function with EF < 40% (OR 3.0, CI 1.3–7.1) and TEE atherosclerotic plaque ≥2 (OR 2.4, CI 1.0–5.5) predicted cardiovascular events.

Conclusion: Atherosclerosis of the descending aorta observed during transesophageal echocardiography is useful predictor of cardiovascular events in non-revascularized patients.

SOCIAL AND ECONOMIC ISSUES IN ACUTE CORONARY SYNDROMES

P2091 Is permanent heart damage, too high a price for cocaine?

M. Irurita, C. Culebras, J. Huidobro, D. Romero, O. Medina, J.C. Rodriguez, D. San Roman, F. Jimenez, J. Irurita, V. Nieto. *Las Palmas, Spain*

Cocaine is a powerful manifold cardiovascular toxic with a myriad of pharmacological and electrophysiological potentially deleterious actions.

We analyzed 39 successive occasional users presenting to the emergency room with cardiovascular symptoms following cocaine inhalation. A total of 17 patients (P) suffered acute strokes, atrial fibrillation, pulmonary edema, bronchospasm, upper digestive tract bleeding, retinal thrombosis, syncope or hypertensive crisis. Up to 23 patients complained of chest pain., 5 (22%) had angina and myocardial infarction (MI) was confirmed in 14 cases (61%). Infarctions occurred in young males (33.5 years mean age); only 5 P had other cardiovascular risk factors besides smoking (79%). All P underwent thrombolysis; angiographic studies performed on the 13 survivors revealed complete single vessel occlusion in 8 cases (62%) and absence of significant disease in the remaining 38%. Successful percutaneous rescue revascularization (PTCA & stent) was performed in 62.5%. Up to 93% of MI were asymptomatic after a 2-year follow-up and were still non-smokers.

In conclusion: Occasional inhalation of cocaine can induce life-threatening complications in young and otherwise low risk individuals. Chest pain is a major symptom, often related to acute ischemia (78%). Lytic therapy achieves low reperfusion rates in cocaine-induced thrombosis but occluded vessels remain patent following percutaneous rescue procedures.

P2092 Role of a dedicated unit for evaluation of patients with chest pain and non-diagnostic ECG presenting to the emergency department

A. Conti, G. Saade, M.L. Sica, R. Innocenti, I. Olivotto, S. Grifoni, F. Daviddi, L. Degl'Innocenti, F. Falcini, G. Berni. *Emergency Department, Azienda Ospedaliera Careggi, Florence, Italy*

Background: The correct evaluation of chest pain (CP) remains a major problem in the E.R. (5% of patients in Europe), involves very high costs and requires a well planned investigational program. In this study, we investigated the clinical utility of assessing pts with chest pain and non-diagnostic ECG with a validated clinical chest pain score in order to identify those at high risk for coronary events and to standardize the admission to the chest pain unit (CPU).

Methods and Results: During 1996–1998, we evaluated a total of 5467 consecutive pts (age 65+17 years) with CP and non-diagnostic ECG, using a clinical score based on location, radiation, character of CP and associated risk factors and symptoms (Stowers et al, J. Nucl. Cardiol 1995). Patients with a score <4 were considered "low risk" and discharged from the E.R. (n = 3684; 67%); these pts had a 3% readmission rate, but only a <1% final diagnosis of CAD. Patients with a score >4 ("high risk") were admitted to the CPU for further investigation (n = 1783; 33%) including ECG monitoring, serial 12-lead ECG, cardiac enzymes and echocardiograms. Resting MIBI myocardial scintigraphy was performed in pts >40 years, >3 risk factors. Maximal exercise tolerance tests and stress-echocardiograms were performed when the final diagnosis was still uncertain at 24 hours from admission. All pts with >1 positive test underwent urgent angiography. Evidence of CAD was found in 19% of pts (n = 1018) within 6 hours from admission: of these 1018 pts, 22% had acute myocardial ischemia and were transferred to CCU for aggressive management, whereas the remaining 78% without clinical instability were tranferred to the wards. Conversely, the nature of CP remained unclear at 6 hours in 765 pts (14%). Of these, 299 pts (5.5% of total study group) were later found positive for CAD (angiographically confirmed in 89%) based on >1 test including raised cardiac enzymes (40%), late ECG changes (44%), positive exercise test (10%) and positive nuclear scan (9%).

Conclusions: Triage based on clinical presentation allows effective risk stratification of patients with chest pain and non-diagnostic ECG. Among "high risk" patients, non-invasive management in a dedicated unit allows a 19% early and 5.5% delayed detection of acute myocardial ischemia, allowing selective usage of costly intensive care beds and angiographic facilities.

P2093 Acute myocardial infarction occurring in the hospital: patients characteristics and hospital outcome compared to infarctions occurring outside

R. Zahn, R. Schiele, B. Frilling, H. Keller[1], M. Kersten[2], M. Gottwik[3], T. Voigtländer[4], J. Senges. *Herzzentrum Ludwigshafen; [1]Kreiskrankenhaus Rastatt; [2]Krankenhaus Frankenthal; [3]Klinikum Nuremberg; [4]Universität Mainz, Germany*

Patients suffering an acute myocardial infarction (AMI) while being hospitalised (in-hospital AMI = I-AMI) are poorly characterised compared to patients with AMI occurring outside the hospital (pre-hospital AMI = P-AMI).

Methods: Between 6/1994 and 1/1997 5888 consecutive patients (pts) with P-AMI and a pre-hospital delay of less than 12 hours or I-AMI were registered at 54 hospitals by the prospective MITRA trial.

Results: 403 (6.8%) of these pts suffered an I-AMI and 5485 pts (93.2%) a P-AMI.

	I-AMI (n = 403)	P-AMI (n = 5485)	OR or p-value
Age (years, median)	70 (61/74)	66 (56/74)	0.001
Male gender	55.7%	67.4%	0.61 (0.5–0.8)
Anterior AMI	54.9%	48.2%	1.31 (1.1–1.6)
Re-infarction	36.7%	15.5%	3.15 (2.5–3.9)
Diagnostic first ECG	64.2%	72.6%	0.68 (0.6–0.8)
Reperfusion therapy	56.6%	58.3%	ns
Postinfarction angina	16.6%	14.7%	ns
In-hospital reinfarction	7.7%	4.7%	1.69 (1.2–2.5)
In-hospital mortality	27.3%	13.9%	2.33 (1.9–2.9)

Median time from onset of symptoms until start of reperfusion therapy was 55 minutes for I-AMI and 180 minutes for P-AMI. Hospitals with the facilities to perform balloon angioplasty showed a higher proportion of I-AMI compared to hospitals without such facilities (7.9% versus 6.4%; OR = 1.26 (1.02–1.56).

Conclusion: In non-selected pts with AMI, I-AMI account for 6.8% of all cases. Compared to pts with P-AMI, pts with I-AMI represent a high risk subgroup. The proportion of pts treated with reperfusion therapy was not different between the groups. However, hospital mortality was about twice as high in I-AMI (27.3% vs 13.9%, OR: 2.33 (1.9–2.9)).

P2094 Mortality and quality of life four months after myocardial infarction: effects of depression and anxiety

D. Lane, C. Ring, G.Y.H. Lip[1], D. Carroll. *School of Sport and Exercise Sciences, University of Birmingham, Birmingham; [1]University Department of Medicine, City Hospital, Birmingham, UK*

Depression and anxiety following myocardial infarction (MI) have been implicated in cardiac-related mortality. Less is known about the influence of depression and anxiety on quality of life among survivors.

Methods: Between 2–15 days post-MI, 288 patients completed questionnaires including the Beck Depression Inventory (BDI), State-Trait Anxiety Inventory (STAI), and the Dartmouth COOP, which measures quality of life. There were 215 men and 73 women. Average age at entry was 62.7 years, mean number of years of education was 10.1, and 93% were Caucasian. At four-month follow-up, 25 had died, all from cardiovascular causes. Questionnaires were readministered to survivors.

Results: Neither depressive symptomatology nor state or trait anxiety, measured at entry predicted mortality. The Peel Index, a prognostic device for grading the severity of infarction, was significantly associated with 4-month mortality.

	Four-month survival status	
	Alive	Dead
Depression (BDI)	7.71 ± 6.33	7.84 ± 5.54
State Anxiety (STAI)	33.55 ± 11.88	32.17 ± 21.11
Trait Anxiety (STAI)	31.97 ± 10.45	29.58 ± 9.43
Peel Index	10.59 ± 5.10	14.79 ± 5.51*

*$p < 0.05$

In contrast, initial BDI scores and STAI measures of state and trait anxiety predicted four-month quality of life among survivors. The Peel Index did not predict quality of life. In a regression model in which both depression and anxiety were entered, initial BDI scores afforded the best independent prediction of quality of life.

Conclusions: At odds with some, but not all, previous research, depression and anxiety following myocardial infarction did not predict short-term mortality. However, depression was predictive of quality of life of those patients who had survived at follow-up.

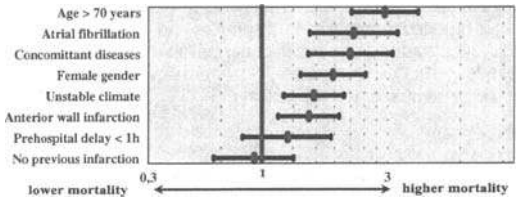
P2095 Influence of the climate on incidence and inhospital mortality of acute myocardial infarction: results of the MITRA study

A.K. Gitt, K. Bucher[1], S. Schneider, R. Schiele, H. Wienbergen, T. Heer, F. Fischer, H.G. Glunz, P. Limbourg, J. Senges. *For the MITRA-study-group; Herzzentrum Ludwigshafen, Cardiology; [1]Deutscher Wetterdienst, Medizin-Meteorologie, Freiburg, Germany*

The influence of the climate on the incidence of acute myocardial infarction (AMI) has been discussed controversially based on results of very different regional observations.

Methods: MITRA is a registry of 54 clinics in the Southwest of Germany, in which consecutive patients (pts) with AMI have been enrolled to document actual clinical practice and clinical outcome in AMI. Because of the very homogenous climate in this area we brought together the daily meteorological data and the data of AMI-pts of the time between July 1994 and January 1996. Based on 13 biosynoptical climate classes we defined stable (classes 1–3 and 8–13) and unstable (classes 4–7) climate. We examined the influence of the unstable climate on the incidence of AMI and on inhospital mortality.

Results: During the observational period 3327 pts (median age 66 y, 66.7% male, prehospital delay 165 min) with AMI had been enrolled. Unstable climate was present on 220/580 days (38%). We did not find any difference in daily AMI incidence between unstable and stable climate (5.9 ± 2.6 vs 5.9 ± 2.6, p = 0.29). There were no differences in pts characteristics (age, gender, prehospital delay, anterior wall AMI, reinfarction) on the days with unstable as compared with stable climate. The multivariate analysis identified the unstable climate as an independent determinant of inhospital mortality (OR 1.47, 95% CI 1.10–1.97):



Conclusion: Unstable climate did not influence the incidence of AMI. Pts at risk for AMI dependent on climate could not be identified. Unstable climate on the day of AMI was associated with a marked increase of inhospital mortality after AMI.

P2096 Compared prognostic factors in the elderly and in younger patients after myocardial infarction: one-year results from the nation-wide French USIK study

N. Danchin[1], L. Vaur[2], N. Genès[2], M. Angioï[1], J. Ferrières[3], J.P. Cambou[3].
[1]CHU Nancy-Brabois, 54500; [2]Laboratoires Roussel, Paris; [3]ORSMIP, Toulouse, France

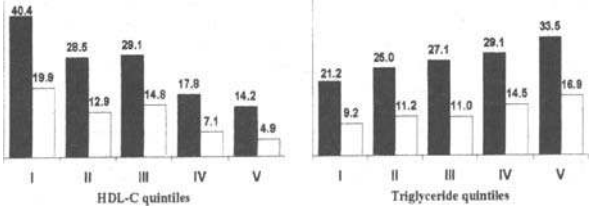
Elderly patients have a poorer prognosis after myocardial infarction. However, whether predictors of adverse outcome are the same in the elderly and in younger pts is unclear. The aim of the USIK study was to collect information on the management and outcome of pts admitted to a CCU for acute MI, on a nation-wide scale. All pts admitted <48 hours of symptom onset during the month of November 1995 were prospectively included and followed-up for 1 year. Compared with younger pts (n = 1165), pts >70 years (n = 929) were less likely to be men (55% vs 84%), had more often hypertension, diabetes mellitus, history of stroke or peripheral vascular disease, prior MI or prior CHF. Reperfusion therapy by thrombolysis or primary PTCA was used more scarcely in the elderly (24% vs 55%). Five-day mortality was 14% vs 4% ($p < 0.0001$) and 1-year mortality (Kaplan Meier) was 67% vs 91% ($p < 0.0001$). By Cox multivariate analysis, age, history of heart failure, history of MI and anterior location of MI were independent predictors of 1-year outcome both in young and elderly pts; female gender was an adverse prognostic factor in young pts, while history of stroke or PVD were adverse factors in the elderly. In pts alive at 5 days, age, diabetes, history of heart failure, anterior MI were independent predictors of one year outcome regardless of age; use of reperfusion therapy was an independent predictor of improved survival in the elderly only (RR 0.40, 95% CI: 0.24–0.67).

Conclusion: age, history of heart failure, anterior MI are adverse prognostic factors, regardless of the age of the pts. In the elderly, extent of atherosclerosis (history of stroke or peripheral vascular disease) also has an independent prognostic significance. Reperfusion therapy is associated with improved 1-year prognosis in the elderly, but is not a significant prognostic factor in younger pts, stressing that it has a particularly beneficial effect in pts >70 years of age.

P2097 The long-term association of HDL cholesterol and triglyceride with mortality of women with coronary heart disease

M. Benderly, M. Haim, U. Goldbourt. *For the Bezafibrate Infarction Prevention (BIP) Study Group; BIP coordinating Center, Neufeld Research Institute, Sheba Medical Center Tel-Hashomer, Israel*

The efficacy of reducing blood levels of triglycerides (TG) and raising HDL cholesterol (HDLC) in men with coronary heart disease (CHD) using gemfibrozil has recently been demonstrated. Insufficient data exist concerning the prognosis of women with varying blood levels of these variables and no pertinent intervention has been aimed at a sufficiently large sample of women. We followed up 2,513 women, aged 40–74, screened for participation, but not included in the BIP study, over a mean period of 5.1 years. Age adjusted mortality rates/1000 person years (all-cause in black; CHD in white), by TG and HDLC baseline quintiles were:



Mortality increased stepwise with increasing TG and declined with increasing HDLC. Multivariate analysis using Cox regression indicated a covariate-adjusted hazard ratio (HR) of 0.85 for mortality associated with a HDLC increment of 10 mg/dl (95% CI, 0.75–0.96). The adjusted HR associated with an increment of 1 log TG was 1.37 (95% CI, 1.04–1.88) prior to adjustment for baseline HDLC. Upon adjustment for the latter, HR declined to 1.10 (95% CI, 0.80–1.50). Correction for regression dilution bias made negligible difference. Contrary to findings reported from CHD-free samples, no synergism of low HDLC (<35 mg/dl) and elevated TG in terms of association with mortality was noted. The issue of low HDLC and elevated TG in women with CHD requires a trial with a substantial number of female patients.

P2098 Treatment of AMI by cardiologists is associated with a lower intrahospital mortality: results of the Myocardial Infarction Registry in Germany

S. Wagner[1], R. Schiele[2], S. Schneider[2], F. Fischer[2], R. Grube[3], J. Senges[2].
For the MIR study group; [1]Dep. of Cardiology, Klinikum Bruchsal; [2]Herzzentrum Ludwigshafen; [3]Krankenhaus Freiberg, Germany

Purpose: To determine the effect of specialty care on in-hospital mortality in patients with acute myocardial infarction in Germany.

Methods: The Myocardial Infarction Registry (MIR) is a multicenter, prospective registry with 217 participating hospitals in Germany. The primary aim of the study is to optimise therapy strategies in the treatment of AMI. All patients with q-wave AMI, admitted within 96 hours after the onset of pain were included from 12/96–5/98. The use of the combined therapies improving prognosis (reperfusion therapy, aspirin, betablocker and ACE-inhibitor) was documented. The treatment by a cardiologist was compared to the treatment by physicians with a high volume of AMI patients.

Results: In total 14598 patients with AMI were registered.

	Cardiologist n = 4683	Non-cardiologist n = 9915	p value
Age (years)	66	67	ns
Male (%)	66	64	ns
Prehospit. delay (min)	192	195	ns
Diagnostic ECG (%)	69	65	<0.001
Thrombolysis (%)	34	37	ns
Primary PTCA (%)	20	5*	<0.001
Aspirin (%)	92	90	ns
Betablocker (%)	55	53	ns
ACE-Inhibitor (%)	51	54	ns
Inhospital mortality (%)	14	16	<0.001

*referred to a center with PTCA facilities

Conclusions: Treatment of patients with AMI by a cardiologist is associated with a lower intrahospital mortality which may be the result of a higher rate of diagnostic first ECG's and the presence of a catheterization laboratory with PTCA facilities.

P2099 Panic disorder based chest pain and/or palpitations in patients presenting at the first heart aid

P.M.J.C. Kuijpers, A. Honig, S. Braat[1], C. de Zwaan[1], H.J.J. Wellens[1].
Psychiatry Dept, Academic Hospital Maastricht, Maastricht; [1]Cardiology Dept, Academic Hospital Maastricht, Maastricht, Netherlands

Background: In the literature an important number of patients presenting with chest pain at the emergency department have no cardiac abnormalities after screening but are found to suffer from a panic disorder (PD): numbers range from 25% to 47%. No information is available on the magnitude of this problem in the Netherlands.

Methods: During 3 months all patients coming to our emergency department for cardiac complaints called First Heart Aid (FHA) with chest pain or palpitations and who were sent home after diagnostic procedures excluded a cardiac cause requiring admission, received an informed consent form and the Hospital Anxiety and Depression Scale (HADS) questionnaire. Patients scoring above the cut off score of 8 on the HADS were considered as having a possible PD and were invited for a Mini International Neuropsychiatric Interview (MINI). The psychiatric diagnosis according to the Diagnostic and Statistical Manual (DSM) IV criteria, was made after the MINI.

Results: In 3 months 205 of 621 patients presenting with chest pain or palpitations at the FHA were sent home after screening: there were 52% males and 48% females. The study group consisted of 205 patients. 133 of 205 patients (65%) gave informed consent. Of this group 71 patients (53%) scored above the cut off score on the HADS. Following a structured interview 79% had a panic disorder. A depressive disorder was found in 50%. In 14% no psychiatric diagnosis could be made after the interview.

Conclusions: Panic disorder and/or depression are common problems in patients presenting with chest pain or palpitations to a FHA. 50% of the patients sent home scored above a preset cut off on the HADS. After a structured interview, in 79% of the patients panic disorder was confirmed while depression was diagnosed in 50% of the patients. Only 4 patients (6%) were suspected as panic disorder by the cardiologist. Further studies should be conducted to improve recognition and treatment of panic disorder based chest pain or palpitations.

P2100 Cost benefit analysis on the use of glycoprotein blockers versus conventional antiplatelet therapy alone in acute coronary syndromes

L. Melilli, R. Arora. *Interventional Cardiology Dept., Columbia University, Katonah NY, USA*

Background: Results from recent clinical trials demonstrate the benefits of tirofiban plus heparin versus heparin alone in management of acute coronary syndromes (ACS). These clinical benefits included significantly reduced incidence of refractory ischemia, and the composite endpoint of reduced mortality, infarction, re-hospitalization for unstable angina, and refractory ischemia in PRISM-PLUS. However, the combination of tirofiban-heparin was associated with greater incidence of bleeding versus heparin alone, which may make this combination approach less cost-effective in clinical practice.

Methods: This cost analysis was conducted to determine the cost-effectiveness of tirofiban-heparin versus heparin alone. Wholesale drug costs and mean 1996 New York State Medicare/Medicaid charges were applied to drug, ACS-related procedure rates, and complication-related procedure rates reported in PRISM-PLUS for up to 6 months.

Results: Heparin alone was associated with cost-savings of $477.19 per patient in drug costs and $85.59 per patient in procedure-related costs for patients with bleeding complications requiring transfusion. Heparin alone also was associated with overall cost savings over the combination ($562.78 per patient) and was the more cost-effective therapeutic approach. Combined tirofiban-heparin therapy required an additional expenditure of only $12.80 per refractory ischemia episode avoided, and only $8.15 per patient to achieve the combined endpoint of lives saved, and infarctions, re-hospitalizations for unstable angina, and refractory ischemia episodes avoided.

Conclusion: While tirofiban-heparin therapy is less cost-effective than heparin alone, added costs become incremental when clinical benefits for patients with ACS are considered.

P2101 Cost benefit analysis of tissue plasminogen activator versus primary coronary angioplasty in treatment of acute myocardial infarction

L. Melilli, R. Arora. *Interventional Cardiology Dept., Columbia University, Katonah NY, USA*

Background: Recently, GUSTO IIb demonstrated modest clinical advantages for angioplasty over tissue plasminogen activator (t-PA) in treatment of acute myocardial infarction (AMI). This cost analysis was conducted to compare the cost-effectiveness of these two treatment approaches.

Methods: Wholesale drug costs and mean 1996 New York State Medicare/Medicaid charges were applied to drug, procedure, and complication rates reported in GUSTO IIb for up to 30 days. Cost effectiveness was assessed for lives saved; complications avoided; and the composite endpoint of lives saved, and nonfatal reinfarctions and disabling strokes avoided at 30 days.

Results: Angioplasty resulted in lower per patient drug ($49 versus $3,447) and complication-related charges ($49 versus $2,804) versus t-PA. t-PA resulted in lower per patient procedure-related charges ($3,447 versus $18,242) versus angioplasty. Overall mean per patient charges were lower for t-PA ($17,315) than angioplasty ($20,605). t-PA was more cost effective than angioplasty for lives saved (−$2,605); complications avoided (−$3,370); and composite endpoint of lives saved, and reinfarction and disabling strokes avoided (−$2,090).

Conclusion: t-PA resulted in greater overall cost savings and cost effectiveness than angioplasty at 30 days post AMI. This was due to lower procedure-related charges for t-PA that were not offset by lower drug- and complication-related charges with angioplasty.

INFLAMMATORY MARKERS AND TROPONINS IN UNSTABLE CORONARY DISEASE

P2102 Anti-endothelial cell antibodies: a marker of the immune system activation in unstable angina and a new risk factor for restenosis after percutaneous transluminal coronary angioplasty

A. Farsi, M.P. Domeneghetti, T. Brunelli, A.M. Gori, S. Fedi, C. Giglioli, M. Falai, A. Lombardi, M. Chioccioli, R. Abbate. *Clinica Medica Generale e Cardiologia, Centro Regionale Trombosi, Florence, Italy*

Background: In recent years the evidence of the role of immuno-mediated inflammation in the development and progression of atherosclerosis has accumulated and several species of autoantibodies have been demonstrated to be involved in ischaemic heart disease (IHD). The objectives of this study were: 1) to evaluate the prevalence of anti-endothelial cell antibodies (AECA) in patients with IHD and the eventual association with restenosis after percutaneous transluminal coronary angioplasty (PTCA); 2) to check if beta 2-glycoprotein I (beta2-GPI) is the major target antigen of AECA;

Methods: 93 patients (72 M and 21 F; age 62.4 ± 9.3) with IHD referred to undergo PTCA and 105 healthy subjects, matched for age and sex were included in the study. IgG and IgM AECA were detected using an ELISA technique on human umbilical vein endothelial cells (HUVEC). AECA positive sera were evaluated for IgG and IgM anti-beta2-GPI by ELISA and tested in the presence or in the absence of purified human beta2-GPI on HUVEC cultured in serum-free medium.

Results and Conclusions: Twelve of 93 (12.9%) IHD patients and only one of 105 control subjects (0.95%) were IgG AECA positive. The prevalence of AECA was higher (21.6%; 11/51) in patients with unstable angina (UA) than in patients with effort angina (EA) (2.4%; 1/42; $p = 0.01$). Three of 12 AECA positive sera were also positive for anti-beta2-GPI IgG antibodies. Sera positive for both antibody specificities showed a marked decrease in endothelial cell binding when tested on HUVEC cultured in serum-free medium. In all cases the binding was restored by the addition of purified human beta2-GPI. The rate of angiographically documented restenosis was 66.7% in the AECA positive and 14.8% in the AECA negative group ($p = 0.0004$).

Our results suggest a possible role for AECA in the immune-mediated inflammation in UA. In IHD patients beta2-GPI is not the only AECA target antigen. The high rate of clinical recurrences after PTCA, confirmed by angiography in AECA positive patients is in line with such a role and suggests further large scale "ad hoc" studies.

P2103 Interleukin-6 release in the coronary circulation of patients with acute coronary syndromes

E.N. Deliargyris, R.J. Raymond, T.C. Theoharides[1], W.C. Boucher[1], D.A. Tate, S.C. Smith Jr, G.J. Dehmer. *Cardiology Dept, University of North Carolina, Chapel Hill NC; [1]Pharmacology and Exp. Therapeutics, Tufts University, Boston MA, USA*

Elevated circulating levels of interleukin (IL)-6 are present in patients with acute coronary syndromes (ACS). It is unknown if this represents active IL-6 production from unstable coronary plaques or is simply a systemic inflammatory response. We sought to identify the site of IL-6 production in patients with ACS.

Methods: In 48 patients undergoing cardiac catheterization we obtained samples from the femoral artery (FA), femoral vein (FV), left main coronary artery (LMCA) and coronary sinus (CS) before contrast administration. The patients were grouped as no CAD if there was no stenosis >50% present ($n = 20$), stable CAD if they had at least one stenosis >50% and no clinical instability ($n = 20$), and ACS if they presented with a Q-wave MI, a non-Q MI, or unstable angina ($n = 8$). IL-6 was measured by ELISA (R&D Systems, Minneapolis, MN) and values are expressed in pg/ml.

Results: Patients with no CAD and stable CAD had similar IL-6 levels at all sampling sites (p = NS). In patients with ACS IL-6 levels were higher in the FA ($p = 0.02$), FV ($p = 0.01$) and CS ($p = 0.004$) when compared to patients without ACS. There was no difference between the LMCA and CS in patients without ACS (4.6 ± 8.7 vs 4.6 ± 8.3 pg/ml, respectively, p = NS), however in ACS patients there was a significant difference between the LMCA and CS (10.1 ± 11.1 vs 28.8 ± 34.8 pg/ml, respectively, $p = 0.03$) suggesting ongoing release from the coronary circulation. Since IL-6 levels are also elevated in CHF, we compared left ventricular ejection fraction in patients with and without ACS and found no significant difference between the two groups (56 ± 10% vs 54 ± 18%, respectively, p = NS).

In conclusion, we found that in ACS elevated IL-6 levels are not just a systemic inflammatory reaction, but are due to active cardiac release. Our findings further support the central role of inflammation and cytokine production in the process of plaque destabilization and the genesis of acute coronary syndromes.

P2104 Troponine T levels after very brief coronary oclusions

C. Capdevila, M. Portolés, A. Hernández, V. Pallarés, A. Chirivella, S. Martí, L. Andrés, P. Morillas, J. Cosín. *Centro de Investigación, Hospital Universitario La Fe, Valencia; Unión de Mutuas (Castellón); Clinica Medicis; Vila-Real Castellón, Spain*

In a new model of stunned myocardium due to very brief, repeated coronary occlusions, we have seen a progressive deterioration of the systolic function including structural alterations, mainly at the mitochondrial level. Cardiac troponine T is a regulatory contractile protein usually not found in the blood. Its appearance in blood is a clear signal of myocardial damage. In the present work we have studied biochemically the plasma levels of glutathion (GSH), ATP, troponine T, and creatine kinase (CK) activity and the CK-MB percent in our animal model. twenty successive complete occlusions, each one lasting 2 min, were provoked in the left anterior descending coronary artery, with 3 min recovery intervals between occlusions.

Methods: Venous blood samples from 10 dogs were collected at baseline, during the last reperfusion period, and 24 h and 10 days after ischemia. Samples were centrifuged and plasma separated and stored at −80°C until analysis. GSH, GSSG, ATP and total CK were examined using standard enzymatic protocols. CK-MB isoenzyme was separated by electrophoresis on agarose. Troponine T were measured by Elecsys Troponine T assay supplied by Boehringer-Mannheim.

Results: Our model of stunned myocardium did not show significant variations either in the plasma levels of GSH/GSSG (baseline: 115 vs 155 ug/dl) or ATP (13.9 vs 15.4 umol/dl) after ischemic protocols. The values were completely recovered 10 days after the last coronary occlusion, and the percentage of CK-MB did not show any modification during the 4–24 h after the last ischemia. However, troponine T was detected in plasma after ischemia (baseline: <0.01; ischemic: 0.316 ng/ml, $p < 0.001$); 24 h after the ischemia protocol the levels of troponine T were also increased (0.634 ng/ml, $p < 0.001$). However, these levels return to baseline values at 10 days.

Conclusions: Small variations in the GSH/GSSG, ATP, and CK-MB plasma levels during ischemia suggest weak, reversible myocardial damage with our stunned myocardium model. However, our data point to a progressive deterioration of the systolic function with some structural alterations without necrosis, as shown in the alterations of troponine T plasma levels. We can conclude that troponine T is the most sensitive, specific marker for myocardial cell damage after very brief ischemia.

P2105 Comparison of qualitative versus quantitative determination of troponin T in unstable coronary artery disease

B. Lindahl, Erik Diderholm, P. Venge, L. Wallentin. *The FRISCII study group; Dept. of Cardiology and Clinical Chemistry, Uppsala, Sweden*

In unstable coronary artery disease (UCAD) an elevated troponin T (tnT) has been associated with an increased risk for subsequent cardiac events. Already minor elevation of tnT in the range of 0.06–0.2 μg/L implies an adverse prognosis. A rapid test for qualitative analysis of tnT on whole blood has been developed (TropT2/CardiacT, Roche diagnostics) with a detection limit of 0.1 μg/L. In the present study we compared the qualitative tnT test with a standard quantitative tnT test in a large group of UCAD patients.

Methods: Blood samples were obtained from 3022 patients at randomisation, into a multicenter trial of UCAD (FRISCII). The diagnosis was established by history (81% chest pain at rest last 48 hours) and signs of ischemia in ECG or biochemical markers of cardiac damage. The blood samples were taken for immediate qualitative analysis of tnT at each centre by the nurse on duty. Aliquots of plasma was stored frozen at −70C for subsequent central quantitative analysis of tnT (Elecsys, Roche diagnostics).

Results:

	Quantitative tnT, μg/L			
Qual.-tnT	<0.05	0.05–0.19	0.2–0.39	≥0.4
Negative	1026 (95.4)	272 (52.3)	123 (29.4)	105 (11.5)
Positive	50 (4.6)	248 (47.7)	296 (70.6)	902 (88.5)

The sensitivity, specificity, positive and negative predictive value for detection of a tnT ≥ 0.1 μg/L for the qualitative test was 79, 91, 92 and 76%, respectively.

Conclusion: In patients with a clinical suspicion of UCAD a positive qualitative tnT test indicates myocardial damage (tnT > 0.05 μg/L) with a high degree of certainty. However, a negative qualitative tnT test might still be associated with myocardial damage in a considerable proportion of UCAD patients. Therefore, quantitative determinations of tnT is recommended for evaluation of diagnosis and prognosis in UCAD.

P2106 Discordant results for cardiac troponins in patients with renal failure asymptomatic for ischaemic heart disease

K. Lang, S. Schindler[1], C. Forberger[2], G. Stein[1], H.R. Figulla. *Klinik für Innere Medizin III, Friedrich-Schiller-Universität Jena, Jena[1] Friedrich-Schiller-Universität Jena, Klinik für Innere Medizin IV, Jena[2] Institut für Klinische Chemie, Friedrich-Schiller-Universität Jena, Jena, Germany*

Overall mortality in patients with endstage renal failure is determined by cardiovascular diseases. Thus, it is important to diagnose myocardial lesions with certainty. We studied whether patients on chronic haemodialysis (64 M, 41 F, 3× haemodialysis per week) without overt symptoms of coronary heart disease would have increased serum levels of cardiac Troponin T and cardiac Troponin I (exclusion criteria: acute coronary syndromes < 3 months, systemic autoimmune diseases, hereditary muscle diseases, malignancies, trauma < 3 months, known myocarditis, idiopathic dilatative or hypertrophic or restrictive cardiomyopathies)

For analysis we used TropT®sensitive-rapid assay (bedside-test, cut off 0.1 ng/mL), Troponin-T-ELISA (cut off 0.1 ng/mL), Stratus®cardiales Troponin I (ELISA, cut off 0.1 ng/mL), Troponin I-bedside test (cut off 0.4 ng/mL) and CK-MB concentration (cut off 4.7 ng/mL).

	TnT-bedside	TnI-bedside	TnT-ELISA	TnI-ELISA	CK-MB
Assay with elevated result	41%	27%	22%	7%	2%
Several assays elevated per pt.	32%	21%	20%	7%	2%

In chronic haemodialysis patients who were asymptomatic for ischaemic heart disease elevated serum markers were displayed by Troponin T-bedside-assay in 41%, by Troponin I-bedside assay in 27%, by quantitative Troponin-T-assay in 22% and by quantitative Troponin I-assay in 7%. Frequently more than one assay per individual patient indicated elevated serum markers.

The increased serum levels of cardiac troponins were not a result of neither uraemic perimyocarditis (pericardial effusion), changes in the hemodialysis regimen, pulmonary congestion nor consistent with a certain aetiology of renal failure. For explanation cross reacting antibodies or the extracardial expression of cardiac troponins have to be considered. In the diagnosis of acute coronary syndromes in patients with endstage renal failure the assays for Troponin T and Troponin I have to be assessed with great care because of reduced specificity. Especially rapid bedside assays have lower specificity than quantitative assays. Whether or not in these patients elevated serum levels of cardiac troponins are of prognostic value needs to be investigated.

P2107 Quantification of the prognostic role of cardiac troponins through a cumulative meta-analysis of the available clinical trials

F. Ottani, M. Galvani[1], F. Nicolini[2], D. Ferrini[1], A. Pozzati[3], G. Di Pasquale[3], F. Rusticali[1], A. Jaffe[4]. *Fond "Sacco"-ONLUS, Div. Cardiology Osp. Bentivoglio, Bologna; [1]Fond "Sacco"-ONLUS, Div. Cardiology Osp. Morgagni, Forli[2] Fond "Sacco"-ONLUS, Forli[3] Div. Cardiology Osp. Bentivoglio, Bologna, Italy[4] SUNY Health Science Center, Syracuse NY, USA*

Multiple studies have shown that elevation of either of the cardiac troponins T (cTnT) or I (cTnI), are predictive of adverse outcomes in patients (pts) with acute coronary syndromes (ACS). However, the relative risk of adverse outcome in pts with cardiac troponins elevations varies in the available studies from 2 to 31 fold. To conclusively quantify on a larger database the relative risk of cardiac troponins elevations, we conducted a meta-analysis of the 20 available studies to separately assess the risk of nonfatal MI and cardiac death in pts without ST-segment elevation (noSTup) and in pts with ST-segment elevation (STup).

Methods: We used two statistical models, which gave comparable results, to better control for heterogeneity in calculating the odds ratio (OR): the fixed-effects model by Mantel-Haenszel-Peto and the random effects model of DerSimonian and Laird. OR were calculated for short (30 days) and long-term (6 mos-3 yrs) follow-up, and separately for cTnT and cTnI.

Results: Among 4,722 patients with noSTup, those with elevated troponins showed a 4.84 fold higher risk (95% CI: 3.61 to 6.48, $p < 0.0001$) of death or nonfatal MI during short-term follow-up and a 2.6 fold increase (95% CI: 1.94 to 3.44, $p < 0.0001$) long-term. Among 13,227 patients with STup, elevated troponin levels carried a 2.8 fold higher risk (95% CI: 2.31 to 3.41, $p < 0.0001$) at 30 days and a 3.9 fold increase (95% CI: 2.47–6.63, $p < 0.0001$) long term. cTnT and cTnI provided similar information, eg. for all patients, a risk of 4.43 fold (95% CI: 3.4 to 6.30) and 4.43 (95% CI: 2.95 to 6.67) respectively; p = NS.

Conclusions: Patients with ACS who have elevations of either of the cardiac troponins have a substantial increase in risk during both short and long-term follow-up. The risk is high enough that identitifcation of these patients should result in attempts to craft specific treatment regimens for this group. cTnT and cTnI share the same capability of predicting adverse outcome in such pts.

P2108 Vascular inflammation and future ischaemic events in acute coronary syndromes

N. Mulvihill, J.B. Foley, R. Murphy, K.S. Lee, P. Crean, M. Walsh. *Department of Cardiology, St. James Hospital, Dublin, Ireland*

Elevated levels of the acute phase reactant C-reactive protein are predictive of an adverse outcome in patients presenting with the acute coronary syndromes of unstable angina (UA) and subendocardial infarction (SEMI). We set out to determine if soluble cellular adhesion molecules (sCAMs), which reflect the endothelial inflammatory process underlying acute coronary syndromes, could be used as prognostic markers in patients presenting with UA and SEMI.

Methods: Patients with UA and SEMI had serum samples taken at presentation and were followed for 6 months. Ischaemic end points were defined as (i) recurrent UA, (ii) non fatal MI and (iii) cardiovascular death. Soluble ICAM-1, VCAM-1, E-selectin and P-selectin levels were measured using an ELISA technique. Data are expressed in ng/ml as mean ± SEM.

Results: 87 patients enrolled in the study (male/female = 70/17, mean age 62 ± 10 yrs). 27 patients (31%) had ischaemic events during follow up (15 recurrent UA, 6 non fatal MI and 6 deaths). Levels of soluble VCAM-1 were significantly higher in those patients who had ischaemic events during follow up (888 ± 54 ng/ml event group v's 713 ± 26 ng/ml non event group, $p < 0.02$). There was no significant difference in the levels of soluble ICAM-1, E-selectin or P-selectin between the ischaemic event and non event groups (359 ± 15 ng/ml v's 314 ± 15 ng/ml for ICAM-1, 55 ± 4 ng/ml v's 57 ± 4 ng/ml for E-selectin and 109 ± 10 ng/ml v's 115 ± 6 ng/ml for P-selectin respectively).

Conclusion: Elevated levels of soluble VCAM-1, reflecting coronary vascular inflammation, are predictive of future ischaemic events in the 6 months following presentation in patients with UA and SEMI.

P2109 An assessment of the relative value of cardiac markers in the early triage of "high-risk" patients with chest pain

Graham S. Hillis, Ning Zhao, Pamela Taggart, William C. Dalsey, Antoinette Mangione. *Department of Emergency Medicine, Albert Einstein Medical Center, Philadelphia PA, USA*

Few previous studies have compared the relative value of simple, widely available, rapid biochemical tests in the early in-hospital triage of patients who would otherwise be considered to be at high risk for adverse events. The aim of the current study was, therefore, to evaluate the utility of cardiac troponin I (cTnI), creatine kinase-MB mass ($CK\text{-}MB_{mass}$), myosin light chain-1 (MLC-1) and myoglobin (Mgb) in identifying 'high risk' patients with chest pain who will experience serious cardiac events (SCEs) in hospital.

Methods: Cardiac TnI, $CK\text{-}MB_{mass}$, MLC-1 and Mgb levels were obtained on 208 patients with chest pain who were at >7% risk of acute myocardial infarction (AMI), but without new ST segment elevation on their presenting electrocardiogram (ECG). Samples were taken on admission (0 h) and at 4, 8, 16 and 24 h. The sensitivity, specificity, positive and negative predictive value (PPV & NPV) of patients suffering a SCE in hospital were determined for each marker and time-point. SCEs included cardiac death, AMI, cardiac arrest, life threatening cardiac arrhythmia, cardiogenic shock and urgent coronary revascularisation.

Results: Admission levels of all markers were poor predictors of SCEs in hospital but improved substantially thereafter. Mgb was the least sensitive marker, with lowest NPV. cTnI and $CK\text{-}MB_{mass}$ were the most useful prognostic indicators. If both of these markers were negative at 0, 4 and 8 h, then 99% (95% confidence interval 96–100%) of patients remained free from SCEs during their hospital stay. The only SCEs not predicted in this manner were revascularisation procedures and their associated complications. Additional tests after 8 h, or the inclusion of additional markers, did not further improve predictive accuracy.

Conclusions: Patients with high risk clinical features who have negative cTnI & $CK\text{-}MB_{mass}$ 0, 4 and 8 h after admission have a favourable in-hospital prognosis and could be considered for early triage out of CCUs.

TROPONIN ELEVATION IN ACUTE CORONARY SYNDROMES

P2110 Possible reasons for the prognostic value of troponin T on admission in patients with ST-segment elevation myocardial infarction

G. Frostfeldt, B. Lindahl, A. Nygren, P. Venge, L. Wallentin. *Cardiothoracic Center and Department of Clinical Chemistry, University Hospital, Uppsala, Sweden*

Troponin-T (**tn-T**) on admission seems to be associated with an increased mortality in patients with ST-elevation myocardial infarction (**AMI**). Also other factors e.g. a recent previous infarction, the rate of TIMI grade 3 flow after thrombolysis, the time from onset of chest pain to treatment (**delay**) and the size of the infarction are related to mortality.

Methods: In the present trial 101 patients with AMI were included, all with ST-elevation and Streptokinase treatment. We investigated the delay, the incidence of repeated episodes of chest pain the last 24 hours (**h**) before admission, the level of Tn-T at entry (cut-off level of 0.1 ug/L), and the size of infarction (tn-T level at 72 h). A coronary angiography was performed after 24 h and the rate of TIMI grade 3 flow and grade of stenosis in the infarct-related artery (**IRA**) were measured. The patients were followed for 2.5–4.5 years.

Results: Fifty-six (55%) patients had tn-T > 0.1 ug/L on admission.

Tn-T (ug/L)	<0.1	≥0.1	p-value
Repeated chest pain < 24 h	11%	50%	<0.001
Median delay from onset h	2.0	4.2	<0.001
Rate of TIMI grade 3 flow	72%	50%	0.03
Median tn-T at 72 h	5.7	7.0	NS
Mortality (2.5–4.5 years)	9%	25%	0.0035

In a multivariate analysis (Cox regression) these factors were evaluated regarding relations to mortality during follow-up. Repeated chest pain was a prognostic independent variable with odds ratio (**OR**) of 4.2 (95% CI, 1.4 to 12.8). None of the other factors were significant independent risk factors although the rate of TIMI grade 3 flow in IRA showed a trend with OR of 2.8 (95% CI, 0.9 to 8.6).

Conclusion: The present trial verified the relation between tn-T on admission and long-term mortality in patients with ST-elevation MI. One explanation to this relation might be that repeated chest pain the day before the infarction identifies patients with poor outcome based on previous myocardial damage and therefore elevated tn-T at admission. An additional possible explanation might be the less successful reperfusion in those with elevated tn-T.

P2111 Prognostic value of new biochemical markers in unstable angina

C. Aguiar, J. Ferreira, R. Teles, M. Ribeiro, A. Timóteo, M. Almeida, R. Seabra-Gomes. *Cardiology Department, Santa Cruz Hospital, Carnaxide, Portugal*

Background and Purpose: Elevated cardiac-specific troponins (cTn) are valid predictors of adverse events in patients (Pts) with acute coronary syndromes. Our aim was to assess the prognostic value of new biochemical markers-CK-MB mass and Myoglobin (Myo) – in Pts with unstable angina.

Methods: We prospectively studied 144 consecutive Pts (mean age 63 ± 12 years; 19% female) hospitalized for rest angina in the previous 48 hours associated to ischemic electrocardiographic changes and without elevation of conventional total CK and CK-MB activities within 24 hours after admission. Measurements of total CK and CK-MB activities, cTnI (negative < 0.1 μg/L) CK-MBmass (negative < 5 ng/mL) and Myo (negative < 45 μg/L) were performed on admission and every 6 hours during the first day of hospitalization. We used a composite 30 day event rate of death, non-fatal myocardial infarction (MI) or recurrent myocardial ischemia.

Results: Elevation of cTnI was detected in 46 Pts (32%), of CK-MBmass in 40 Pts (28%) and of Myo in 55 Pts (38%). At 30 days follow-up, 4 Pts (2.8%) had died, 3 (2.1%) experienced non-fatal MI and 36 (25.0%) recurrent myocardial ischemia. In 40 Pts (27.8%), at least one event occurred during follow-up. The table shows the combined frequency of events at 30 days follow-up with respect to each biochemical marker analysed.

Marker	Any Event (%)	P
cTnI pos	43.5	0.008
cTnI neg	20.4	0.008
CK-MBmass pos	43.9	0.006
CK-MBmass neg	19.4	0.006
Myo pos	27.8	NS
Myo neg	28.7	NS

Conclusion: In this population of Pts with unstable angina, elevation of CK-MBmass had a similar prognostic value to cTnI with respect to prediction of death, non-fatal MI or recurrent ischemia in the 30 days follow-up. Elevation of Myo did not identify Pts at risk for these events.

P2112 Relationship of troponin T and C-reactive protein with transient myocardial ischaemia in patients with unstable angina

G.A. Lanza, A.G. Rebuzzi, A. Sestito, D. Cianflone, L.M. Biasucci, G. Liuzzo, F. Crea, A. Maseri. *Istituto di Cardiologia, Policlinico A. Gemelli, Rome, Italy*

Both transient myocardial ischemia (TMI) on 24-hour ECG Holter monitoring (HM) and plasma levels of troponin T (TnT) and C-reactive protein (CRP) have been shown to predict clinical events in unstable angina (UA). However, the correlation of TnT and CRP levels with TMI has never been appropriately investigated.

TnT and CRP levels were measured and HM was performed within 24 hours from admission in 129 UA pts. (93 men, 63 ± 10 yrs). TMI on HM was diagnosed in case of ST segment depression (rectilinear or downsloping) or elevation > 1 mm, lasting for >1 min.

Episodes of TMI were detected in 11 of 16 pts (68.8%) with high (>0.2 μg/L) and in 38 of 113 pts (33.6%) with low TnT levels ($p < 0.01$). On the other hand, TMI episodes were found in 30 of 66 pts (45.4%) with high (>3 mg/L) and in 19 of 63 pts (30.2%) with low CRP levels ($p = 0.07$). Furthermore, TMI was detected in 9 of 13 pts (69.2%) with high levels of both TnT and CRP, in 23 of 56 pts (34.8%) with high levels of either TnT or CRP, and in 17 of 60 pts (28.3%) with low levels of both TnT and CRP ($p = 0.02$). The number of ischemic episodes and the total daily time of TMI were not significantly different between pts with and those without high levels of TnT, CRP, or both.

In conclusion, in UA pts: (1) TMI on HM is more closely associated with increased levels of TnT than of CRP; (2) TMI is less frequent in pts with low levels of both TnT and CRP; (3) however, TMI is somewhat independent of TnT and CRP levels, suggesting that these biochemical markers of prognosis have some limitations for assessing the severity of the ischemic activity of the disease.

P2113 Admission levels of fatty acid-binding protein and troponin I and inhospital ischaemic events in patients with unstable coronary artery disease

I.R. Trifonov, A.H. Katrukha, O.V. Averkov, I.S. Yavelov, N.A. Vaulin, N.A. Gratsiansky. *Center for Atherosclerosis, Institute of Physico-Chemical Medicine, Moscow, Russian Federation*

Background: Heart fatty acid binding protein (FABP) has been recently proposed as an early marker of myocardial damage. Cardiac troponin I (TnI) is an accepted marker of cardiac muscle injury and its value for prognosis of recurrent coronary events is believed to be proven. The aim of this study was to compare admission levels of FABP with those of TnI in patients with unstable angina (UA) and non-Q-wave infarction (nQ-AMI) with and without complications during hospitalization.

Methods: Serum FABP and TnI (HyTest, Finland) levels were measured in 59 pts (mean age ± SD – 62 ± 8.9 years, 35/59% male) at admission within 24 h from index angina attack (mean ± SD – 5.2 ± 5 h). Fifty pts had UA and 9 pts – nQ-AMI (confirmed by serial total CK). Ischemic events (IE) (Q wave AMI and attacks of angina at rest > 10 min) were registered during period of hospitalization which lasted 17.4 ± 7.05 days.

Results: FABP exceeded >0.6 ng/ml in most of the pts – 42 (71%) while TnI level was elevated (>0.4 ng/ml) in 16 (27%) pts. IE occurred in 20 pts (Q-wave AMI in 2 and attacks of rest angina in 18).

Patients	FABP (ng/ml)	TnI (ng/ml)
With IE (n = 20)	26.4; 11.2–52*	0.18; 0.07–0.44
Without IE (n = 39)	7.2; 1.5–23.1	0.14; 0.05–0.40

(median; 1–3 interquartile range, *$p < 0.001$ vs without IE)

FABP level exceeded 0.6 ng/ml in 19/20 pts (95%) with IE and in 23/39 pts (59%) without IE, ($p = 0.009$). The incidence of elevated TnI level at admission was similar in pts with (6/20, 30%) and without (19/39, 25.6%) IE ($p = 0.9$). The prognostic utility of markers was as follows:

	Sensitivity	Specificity	Positive predictive value	Negative predictive value
FABP	45.2%	94.1%	95%	41%
TnI	37.5%	67.4%	30%	74.3%

Conclusion: In this group of patients with unstable coronary artery disease characterized by relatively short interval from index attack of angina to blood sampling admission level of fatty acid binding protein was often elevated and turned out to be more powerful predictor of inhospital ischemic events than admission level of troponin I.

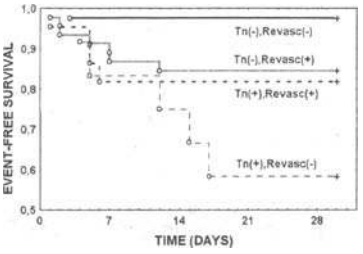
P2114 Prognostic impact of elective myocardial revascularization in unstable angina: influence of cardiac troponin I levels after admission

J. Ferreira, C. Aguiar, R. Teles, M. Almeida, D. Cavaco, A. Timóteo, M. Ribeiro, J. Figueira[1], E. Melo-Gomes[1], R. Seabra-Gomes. *Cardiology Department; [1]Biochemistry Laboratory, Santa Cruz Hospital, Carnaxide, Portugal*

Background: Prognostic benefit of myocardial revascularization (MyoRevasc) in patients (Pts) with unstable angina (UA) stabilized with medical therapy is uncertain. Troponin (Tn) I may help selection of Pts for MyoRevasc.

Objective: We sought to examine the influence of elective MyoRevasc according to cardiac TnI levels after admission for UA.

Methods: We measured serial TnI and CK-MB levels (on admission and every 6 hours during the first 24 hours) in 164 consecutive Pts admitted to our CCU with UA defined as angina at rest in the previous 48 hours with ischemic ECG changes and normal CK-MB levels. We excluded 41 Pts that presented recurrent myocardial ischemia and underwent urgent coronariography. The remaining 123 Pts stabilized with medical therapy and were enrolled in analysis. TnI was considered positive if any value was >0.1 ng/ml. We used a 30 day composite event rate of death or myocardial infarction or re-hospitalization for UA.



Results: TnI was positive in 36 Pts. Elective MyoRevasc was performed in 68 Pts (22 TnI positive). Event-free survival in TnI negative Pts was 84.8% after elective MyoRevasc and 97.6% in Pts not revascularized ($p = 0.036$). In TnI positive Pts, event-free survival was 81.2% after elective MyoRevasc and 64.3% in Pts not revascularized ($p = 0.092$).

Conclusion: Elective MyoRevasc had a negative impact on prognosis in Pts with negative troponin I levels after admission for UA. Further studies are needed to confirm the tendency for benefit in Pts with positive troponin I levels.

P2115 Short-term prognostic significance of coagulation and inflammation markers in unstable angina

F. Passoni, B. Morelli, G. Seveso, C. Grassi, L. Lazzati, G. Beria, M. D'Urbano, F. Cafiero, S. De Servi. *U.O. Cardiologia Ospedale Civile, Legnano, Italy*

Activation of the coagulation system and inflammation are frequently associated with unstable angina (UA) presentation. The purpose of this study was to identify coagulative and inflammatory markers that would predict an unfavourable outcome in UA patients.

Methods:. Fifty-eight pts admitted to the CCU for Braunwald Class III UA had blood samples taken on admission and on day 3 to measure the following variables: interleukin-6 (IL-6), von Willebrand factor antigen (vWF), thrombomodulin (TM), prothrombin fragments (F1 + 2), thrombin-antithrombin III (TAT). At 30 days, 39 pts had an uneventful clinical course (group I) while 19 pts (group II) either died (n = 4) or had recurrent angina or myocardial infarction (n = 15).

Results:

	Group I (n = 39)		Group II (n = 19)	
	admission	day 3	admission	day 3
IL-6 (pg/ml)	7.2 ± 6.7	5.9 ± 9.1	5.2 ± 5.4	10.2 ± 11.5*
vWF (%)	112 ± 28	119 ± 17	117 ± 13	119 ± 12
TM (ng/ml)	42.5 ± 37	47.5 ± 30	41.5 ± 31	55 ± 40
F1 + 2 (nmol/l)	1.39 ± 0.78	1.46 ± 0.5	1.28 ± 0.5	1.45 ± 0.57
TAT (mg/l)	5.45 ± 8.4	4.59 ± 4.98	4.68± 2.3	5.02 ± 1.68

*$p < 0.05$ day 3 vs admission

In conclusion, no difference was found in the baseline values of coagulative and inflammatory markers between pts with or without an unfavourable 30-day outcome. Rising IL-6 values were the only prognostic indicator, suggesting that a mounting inflammatory process is associated with a worse short-term outcome.

P2116 Prognostic value of D-dimer assay in unstable angina

C. Aguiar, J. Ferreira, M. Ribeiro, I. Freire, T. Gago, R. Seabra-Gomes. *Cardiology Department, Santa Cruz Hospital, Carnaxide, Portugal*

Background and Purpose: In unstable angina (UA), risk stratification is crucial for guiding management decisions during the acute phase. High levels of cross-linked fibrin degradation products (measured as D-dimer) may reflect increased fibrin turnover suggestive of ongoing thrombosis. Therefore, we aimed to determine the prognostic value of elevated D-dimer in Pts with UA.

Methods: We prospectively studied 32 Pts (mean age 63 ± 12 years; 19% female) hospitalized for Braunwald class IIIIB UA and not presenting co-morbid conditions known to increase D-dimer. D-dimer was measured on admission using a quantitative fibrin-specific ELISA (normal < 500 ng/mL). Cardiac-specific troponin I (cTnI) was measured on admission and every 6 hours during the first day of hospitalization (negative < 0.1 μg/L). We used a composite 30 day event rate of death, non-fatal myocardial infarction (MI) or recurrent myocardial ischemia.

Results: High levels of D-dimer were present in 7 Pts (22%) and elevation of cTnI was detected in 9 Pts (28%). At 30 days follow-up, 1 Pt (3%) had died, 8 (25%) experienced non-fatal MI and 11 (34%) recurrent myocardial ischemia. In 14 Pts (44%), at least one event occurred during follow-up. The table shows the 30 day combined event rate with respect to each test used.

Test	Any Event (%)	p
D-dimer pos	85.7	<0.04
D-dimer neg	32.0	
cTnI pos	55.6	NS
cTnI neg	39.1	

Conclusion: In this population of Pts with UA, D-dimer identified Pts at higher risk for thrombotic complications and who may benefit from more aggressive therapies.

P2117 Significance of increased plasma levels of inflammatory mediators in unstable angina

S. De Servi, I. Mazzucchelli, I. Bossi, E. Ottini, M. Vezzoli, F. Meloni, M. Lotzinker, A. Mazzone. *Ist. Terapia Medica & Nefrologia, Ist. Mal. Respiratorie, Serv. Analisi biochimico-cliniche, Policlinico S. Matteo, Pavia; U.O. Cardiologia, Osp. Civile, Legnano, Italy*

Recent data have shown that an inflammatory process takes place in unstable angina (UA), resulting in the secretion of cytokines. Scanty information however is available on the relation between plasma values of inflammatory mediators, like interleukin (IL)-6, interferon-gamma (IFN-g) and the monocyte chemoattractant protein-1 (MCP-1) and the level of Troponin T, a biochemical marker of myocardial injury.

Methods: Three groups of pts were studied: 29 with UA, 28 with stable exertional angina (SA) and 19 healthy controls (C). All pts in UA and SA groups had significant CAD (>50% reduction of luminal diameter in at least 1 major vessel at coronary arteriography). Il-6 and IFN-g plasma levels were measured using the ELISA method. Data are expressed as mean + SE and ANOVA for repeat measurements was used to compare data in groups and subgroups.

Results: IL-6 was increased in the UA and SA groups as compared to the C group (UA4.68 ± 1.17; SA3.6 ± 1.6; C 1.9 ± 0.27 pg/ml, $p < 0.005$), without significant difference between SA and UA pts. IFN-g was higher in the UA group than in the the other 2 groups (UA 0.27 ± 0.09; SA 0.05 ± 0.03; C 0.02 ± 0.02 pg/ml, $p < 0.001$). Higher values of MCP-1 were also observed in UA pts (UA 1114 ± 431; SA 169 ± 34; C 101 ± 23 pg/ml, $p < 0.0001$). Among UA pts, 11 with increased Troponin T levels (>0.1 microg/L) had significantly higher IFN-g and MCP-1 values than 18 pts with undetectable Troponin T levels (IFN-g: 0.60 ± 0.04 vs 0.10 ± 0.04 pg/ml, $p < 0.001$; MCP-1: 2099 ± 906 vs 393 ± 241 pg/ml, $p < 0.01$). On the contrary, no difference was found in IL-6 values between UA pts with or without increased Troponin T (5.4 ± 1.7 vs 4.1 ± 0.9 pg/ml).

Conclusion,. IFN-g and MCP-1 plasma levels are elevated in UA pts, such increase being mostly related to myocardial cell injury and Troponin T release. IL-6 increased plasma levels are less specific for UA, as they can also be observed in SA pts. However, in UA pts they are not related to myocardial cell injury.

P2118 Troponin T release is related to a disturbed fibrinolysis in unstable angina pectoris

R. Ehlers, E. Büttcher, S. Szabo, U. Helber, M.E. Beyer, S. Kazmaier, H.M. Hoffmeister. *Medical Department III, University of Tübingen, Germany*

Detection of Troponin T is a strong prognostic marker in patients with unstable angina pectoris (UAP). We investigated molecular markers of fibrinolysis and hemostasis in 85 patients with UAP in relation to the troponin T status (TNTpos./TNTneg.). Thrombin-antithrombin complex (TAT), tissue-type plasminogen activator mass (TPA), and D-dimers (DD) were measured initially (0 d) and 2 d later vs. controls.

	TNTpos.	TNTneg.
TAT 0 d	7.25 ± 1.49	4.42 ± 0.84
(μg/l) 2 d	4.24 ± 0.49	5.96 ± 2.5
TPA 0 d	10.24 ± 0.68#	7.58 ± 0.54
(ng/ml) 2 d	12.90 ± 1.73	9.74 ± 1.05
DD 0 d	457 ± 39*	316 ± 22
(ng/ml) 2 d	451 ± 42*	275 ± 37

means ± SEM; * = $p < 0.05$, # = $p < 0.01$ for TNTpos. vs. neg..

The thrombin activation (TAT) in UAP is not related to the TNT-status, while a strong correlation between alterations of fibrinolysis and the troponin status exists.

Conclusion: The troponin status of patients with UAP is strongly associated with the alteration of fibrinolysis, while an increased thrombin activation is present independently of TNT-release in UAP. Differentiation of these pathways enables future development of targeted therapeutical approaches.

P2119 Timing of troponin T measurement to risk stratify patients admitted with chest pain in routine clinical practice

P.J. Stubbs, T.W. Greenwood, D. Moseley, P. Collinson, Avijit Lahiri. *Inst of Cardiac Research Northwick Park Hospital, Dept of Cardiology West Middlesex Hospital, Dept. of Chemical Pathology, Mayday Hospital, London, UK*

It has recently been suggested in patients presenting with chest pain that a negative Troponin measurement after six hours from chest pain onset or four hours from admission is sufficient to stratify these patients into a low risk group who can be discharged.

We studied 324 patients admitted to a single hospital with chest pain who were followed for outcome for a median of 3 years. 76/324 (23.4%) were positive for cTnT on admission cut at 0.2 mcg/l; of these 37 (48.7%) had presented more than six hours from the onset of their worst chest pain (median 12.4 hours Lower Quartile 7.4 hours, Upper Quartile 24.7 hours). In this group 28/37 had a final diagnosis of MI and 9/37 a final diagnosis of Unstable Angina.

Of the remaining 248 patients initially cTnT negative, a further 91 (37%) were positive when tested 12–24 hours following admission. Of these 28/91 (30.1%) had presented more than six hours from the onset of their worst chest pain (median 10 hours Lower Quartile 7.2 hours, Upper Quartile 13.4 hours). In this group 12/28 had a final diagnosis of MI and 16/28 a final diagnosis of Unstable Angina. Of the 91 patients who subsequently became positive for cTnT, four hour from admission samples were available for 53 patients. 38% (20/53) were still negative for cTnT at this time point.

In routine clinical practice therefore, neither sampling at either six hours from symptom onset or four hours from admission or both are sufficient to 'rule out' high risk patients.

P2120 Absence of a prognostic value of troponin I in unstable angina

F. Giraldi, A. Salvioni, M.D. Guazzi. *Institute of Cardiology of University of Milan, CNR, Centro Cardiologico "Fondazione Monzino", Milan, Italy*

Cardiac Troponin I (cTn-I) isoform has been proposed as a prognostic marker in acute coronary syndromes. Aim of the study was to investigate long-term prognostic value of cTn-I in unstable angina (UA). To this purpose 104 patients (pts) (mean age 62.3 ± 5.3 years) in Braunwald Class IIIB UA were enrolled for the study. Blood samples for cTn-I (measured by immunofluorescency, time to perform the test: 20 minutes) were obtained every 6 hours in the first two days after admission. Coronary angiography was performed in all patients within the 5th day; 93 pts (89%) underwent revascularization procedures (RP) (CABG 58 pts, PTCA 35 pts) during admission. Primary end-points were cardiac death, non-fatal AMI and repeated RP at 6 months and 1 year after hospital discharge.

Results: In the first 48 hours after admission, 65 pts (group 1, 63%) had an increase of cTn-I in at least one sample, with values of 0.6–4.2 mgL(mean 2.5 ± 1.1). In the remaining 39 (group 2) Tn-I did not exceed 0.5 mgL(cut-off value). 6-months and 1-year mortality was 2.1 and 2.2% in pts with raised Tn-I and 2.2 and 2.3% in pts with normal Tn-I, respectively (p = NS). At 6 months 4 non fatal-AMI occurred in pts of group 1 and 5 in pts of group 2 (p = NS); at 1 year 5 AMI in each group were recorded; there were no differences, between the two groups, regarding number of new RP performed during the study. On the contrary, greater incidence of death, AMI and RP was recorded in medically-treated pts (11%) and in pts in whom dissection, acute occlusion, distal embolism or peri-operative AMI occurred during revascularization.

Conclusions: In pts with unstable angina RP abolishes any prognostic value of Tn-I increase; possibility to perform full revascularization, the techniques utilized and complications following PTCA or CABG affect prognosis of these pts.

DIRECT ANGIOPLASTY

P2121 Characteristics and in-hospital outcome of patients included in the registry of the Stent PAMI trial

M.-C. Morice, W. Rutsch, L. Mattos, G. Stone, M. Eijgelshoven, D. Cox, E. Garcia, F. Kiemeney, M. Pieper, C. Grines. *On behalf of the Stent PAMI Investigators; Institut Cardiovasculaire Paris Sud, Antony, France*

The stent PAMI trial randomized 900 pts to stent or balloon at the acute phase of MI in 62 centers worldwide. 1458 pts were eligible (inclusion-exclusion criteria met, informed consent signed) and 558 pts were secondarily excluded from the main study and followed on a registry. Population. 170 pts were excluded before PTCA (lesion requiring surgery: 12.9%, culprit lesion < 70%: 3.2%) and 388 after PTCA (high likelihood of requiring stent: 20.8%, major side branch: 10%, high likelihood of requiring CABG within 6 months: 10.3%)

Demographics. The registry pts were older than the randomized pts (62.6 ± 12.7 vs 60.9 ± 12.3 years, p = NS), presented more often with diabetes (20.4% vs 15%, p = 0.01), and had more frequently multivessel disease (61.5% vs 45.0%, p < 0.001).

Treatment received. 14.3% of pts had medical treatment, 13.8% had emergency or elective CABG, 36.6% had PTCA alone and 29.6% PTCA with stent. In the 388 pts who had PTCA, procedural success was obtained in 84.3% of cases (vs 99.4% for randomized pts, p < 0.001). In-hospital recurrent ischemia occurred in 9.0% of the registry pts (vs 8.4 for randomized pts) and in-hospital mortality in 5.0% (vs 2.4% in the randomized pts, p = 0.01).

In conclusion, patients excluded from the main study of the Stent Pami trial had a more severe presentation, procedural success was lower and subsequently, mortality rate was higher.

P2122 Rescue coronary stenting improves clinical outcome in patients with acute myocardial infarction

J. Pache, J. Dirschinger, A. Kastrati, H. Schühlen, A. Schömig. *Deutsches Herzzentrum; 1. Med. Klinik, TU München, Munich, Germany*

Background: The effectiveness of intracoronary stenting as a rescue intervention in patients with acute myocardial infarction and unsuccessful thrombolysis has not been assessed. Since an extensive intimal disruption is frequently the reason for failure of thrombolytic therapy, coronary stent placement seems to be well suited in this setting. The objective of the present study is to assess the clinical outcome of patients with acute myocardial infarction, failed thrombolysis and rescue coranary stent implantation.

Methods: The analysis is referred to 167 consecutive patients, 60 ± 11 year old and 23% women. Nineteen patients were in cardiogenic shock. Patients were followed-up for 1 year after the intervention.

Results: On average 1.2 ± 0.7 stents were implanted in each patient using a mean balloon pressure of 13.3 ± 2.9 atm and a balloon-to-vessel ratio of 1.03 ± 0.10. Stent placement procedure was successful in 98.2% of the patients. Within the first 30 days after the procedure, stent vessel occlusion occurred in 1.2%; the combined endpoint of cardiac death or recurrent myocardial infarction was recorded in 1.4% of patients without shock and 47.4% of those with cardiogenic shock. At one year the probability of death or myocardial infarction was 4.7% in patients without shock and 52.6% in those with cardiogenic shock.

Conclusion: These findings suggest that in this particularly high risk cohort of patients with acute myocardial infarction and failed thrombolysis, rescue coronary stenting is associated with favorable short- and long-term clinical outcome in comparison with historical data for this subset.

P2123 Outcome of stenting in acute myocardial infarction without routine administration of abciximab

S. Peters, B. Götting, M. Trümmel, H. Rust, D. Bunke. *Academic Teaching Hospital Quedlinburg, University of Magdeburg Quedlinburg, Germany*

In the era of ticlopidine and aspirin for prevention of stent thrombosis stenting in acute myocardial infarction has become a promising approach. Despite the results of the EPISTENT trial the question remains whether the administration of Abciximab is necessary in all cases of stent implantation in acute myocardial infarction.

Methods: In order to determine the safety of stenting in myocardial infarction without routine administration of Abciximab the acute results and 30 days outcome of 100 patients treated for acute myocardial infarction from 8/97 until 11/98 were analysed retrospectively.

Results: In all cases single stent implantation (NIR, GFX, Crossflex) of different lengths (12–24 mm) were done with 10–12 atm after mechanical recanalisation and pre-dilatation of the vessel. Three patients developped acute stent thrombosis (2 × LAD, 1 × RCA) within 8 hours after the inital procedure. In one case (RCA) a lethal myocardial perforation appeared after successful recanalisation. In a fourth patient stent thrombosis appeared after rescue stent implantation for failed thrombolytic therapy. In all other cases the course was uneventfully over a period of 30 days.

In conclusion, acute stent thrombosis after stent implantation for myocardial infarction without routine administration of Abciximab is a rare event (3%) with a low mortality rate (1%). The use of bolus and infusion therapy of Abciximab over 12 hours only in high risk cases (rescue stent implantation after previous thrombolytic therapy or TIMI II flow after stent implantation) seems to be a cost saving strategy with excellent results.

P2124 Primary angioplasty and stenting in non-selected elderly patients with acute myocardial infarction: in-hospital and mid-term outcome

C. Loubeyre, T. Lefèvre, M.-C. Morice, Y. Louvard, P. Dumas, J.-F. Piéchaud, J.-F. Angellier, J.-J. Lanore, J.-F. Vaxelaire. *Institut Cardiovasculaire Paris Sud, Massy, France*

Background: Acute myocardial infarction (AMI) in elderly patients is associated with a high mortality and reinfarction rate. The risk and benefit of intracoronary stenting in this setting have not yet been assessed.

Methods: Between January 1995 and December 1997, 106 consecutive elderly patients >75 years old were admitted for AMI within 24 hours of symptom onset (mean time to admission 6.3 ± 4.8 hrs), 30.2% of whom were in cardiogenic shock. We analyzed the acute and long-term clinical outcome after primary stenting in this cohort of patients

Results: A total of 100 patients (94.3%) had percutaneous transluminal coronary angioplasty (PTCA), 80 (80%) of whom (mean age 81 ± 5, 51% female) underwent subsequent stenting. Mean time from admission to reperfusion was 38.2 ± 15 minutes. PTCA was successful in 96 patients (96.0%). No emergent coronary artery by-pass grafting or repeat MI were reported. In-hospital death occurred in 27 patients (27.0%), 62% with cardiogenic shock and 12.6% without. Vascular complications occurred in 4 patients (4%) and minor stroke in 2%. Repeat PTCA for recurrent ischemia was performed in 2 patients (2.0%). At a mean follow-up of 16 ± 10 months, 6 patients needed repeat revascularization (8.2%). Total survival was 57% (85% of in-hospital survivors).

Conclusion: Mortality in non-selected elderly patients with acute MI is high. Primary angioplasty using elective stenting in this setting seems to be associated with a very favorable short- and mid-term outcome.

P2125 Primary angioplasty in acute myocardial infarction: is there an influence of time from onset of symptoms to start of treatment on in-hospital delay and clinical course?

R. Zahn[1], S. Schneider[1], R. Schiele[1], R. Grube[2], G. Becker[3], B. Baumgärtel[4], E. Altmann[5], J. Senges[1]. *[1]Herzzentrum Ludwigshafen, Kardiologie; [2]Kreiskrankenhaus, Freiberg; [3]Städt. Krankenhaus, Kiel; [4]Städt. Krankenhaus, Freital; [5]II. Med. Klinik, Klinikum Friedrichstadt, Dresden, Germany*

Early initiation of treatment in patients (pts) with acute myocardial infarction (AMI) receiving thrombolysis is associated with lower mortality. For pts treated with primary angioplasty there are no data concerning this issue.

Methods: Out of 3 German AMI registries (MIP, MITRA, MIR; time of recruitment: 1992–1997) all AMI pts treated with primary angioplasty were analysed. 1272 pts showed a pre-hospital delay of ≤24 hours and documented in-hospital delays of ≤12 hours.

Results: Time from onset of symptoms until start of primary angioplasty (time to treatment) was ≤3 hours in 177 pts (13.9%), 3–6 hours in 649 (51%) pts and 6–24 hours in 446 (35.1%) pts..

Time to treatment (hrs)	In-hospital time (hrs)	In-hospital mortality
≤1 (n = 30)	0.33	0%
1–2 (n = 147)	0.67	5.4%
2–3 (n = 253)	1	8.3%
3–4 (n = 189)	1.67	6.4%
4–5 (n = 113)	1.67	7.1%
5–6 (n = 94)	1.33	4.3%
6–8 (n = 105)	1.42	5.7%
8–12 (n = 121)	1.75	5%
12–24 (n = 220)	2.67	5.5%
p-value	*0.001*	*0.71*

Conclusion: An increasing pre-hospital delay was associated with an increase of in-hospital time to start of primary angioplasty. In contrast to treatment with thrombolysis, time to treatment with primary angioplasty showed no association with hospital mortality, with the exception of the first hour ("golden hour").

P2126 Influence of segment location on outcome after primary angioplasty for anterior acute myocardial infarction

E. García, R. Moreno, J. Soriano, M. Abeytua, E. López de Sá, J. Elízaga, J. Botas, J.F. Portales, J.R. Rey, J. Acosta, R. Rubio, J.L. López-Sendón, J.L. Delcán. *Department of Cardiology, Hospital Gregorio Marañón, Madrid, Spain*

Patients with anterior acute myocardial infarction (AAMI) are a higher subset of patients even when treated with primary angioplasty (PTCA). The objective of this study was to evaluate the importance of the level of the occlusion of the left anterior descending coronary artery (LAD) on the outcome of patients with AAMI that are treated with PTCA.

Methods: From 1.991 to 1.998, 465 patients with AAMI were treated with PTCA within the first 12 hours after the onset of symptoms in our institution. The in-hospital outcome was compared between patients with a proximal vs. non-proximal LAD occlusion.

Results: Mean age was 64 ± 12 years and 80% were male. The in-hospital mortality was 16.6% in the entire population and 9.3% after excluding patients in cardiogenic shock. The mortality was 0%, 8.5% and 21.2% (p = 0.0004) in patients with distal (n = 7), middle (n = 233) and proximal (n = 225) occlusion, respectively. The comparison between patients with a proximal (n = 225) and non-proximal (n = 232) LAD occlusion in summarized below:

	Prox.	No prox.	p
Mortality	21.2%	8.3%	0.0001
No shock	12.3%	3.9%	0.0012
Angio. success	90.4%	91.9%	NS
LVEF < 0.40	46.7%	26.0%	0.0087
Age (years)	64 ± 9	64 ± 0	NS
Female gender	23.8%	27.9%	NS
Prior thrombolysis	5.9%	6.9%	NS
No. vessels	1.7 ± 0.8	1.6 ± 0.8	NS
Killip > 1	42.4%	20.7%	<0.0001
Diabetes	28.8%	21.6%	NS
Hypertension	44.3%	40.4%	NS
Free wall rupture	4.4%	2.3%	NS
Re-AMI	3.4%	3.7%	NS
Stent	46.2%	44.7%	NS

Conclusion: In the group of patients with AAMI that are treated with PTCA, those with a proximal LAD occlusion constitute a very high risk subset, especially due to a higher incidence of cardiogenic shock. In these patients, there should be no delay in action directed to obtain reperfusion.

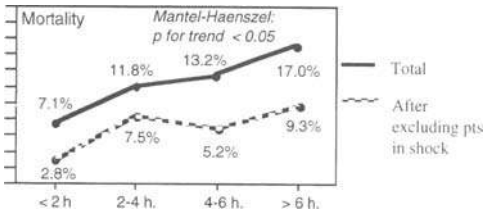
P2127 Influence of time to reperfusion on in-hospital outcome after primary angioplasty for acute myocardial infarction

E. García, R. Moreno, J. Soriano, M. Abeytua, E. López de Sá, J. Elízaga, J. Botas, J.F. Portales, J.R. Rey, J. Acosta, R. Rubio, J.L. López-Sendón, J.L. Delcán. *Department of Cardiology, Hospital Gregorio Marañón, Madrid, Spain*

It has been recently suggested that mortality is relatively constant with increasing time to reperfusion in selected patients with acute myocardial infarction (AMI) that are treated with primary angioplasty (PTCA). The purpose of this study was to evaluate the influence of time to reperfusion on the outcome in a non-selected series of patients with AMI that were treated with primary PTCA.

The study population is constituted by 713 patients (64 ± 13 yrs, 80% male) with AMI that were treated with PTCA from 1,991 to 1,998 in our institution within the first 12 hours after the onset of symptoms. The in-hospital outcome was studied in different subgroups of patients depending on the time interval from the onset of symptoms to reperfusion.

Results: Mortality in patients with <2 hours was significatively lower than in those with >2 hours: 7.1% vs. 12.9% (p = 0.0410) for the entire population, and 2.8% vs. 7.2% (p = 0.0427) after excluding patients in cardiogenic shock. The mortality was directly associated with the time to reperfusion: 7.1%, 11.8%, 13.2% and 17.0% for patients with <2, 2–4, 4–6 and >6 hours, respectively, in the whole population (Mantel-Haenszel: p for trend < 0.05).



Conclusion: In a non-selected series of patients with AMI that are treated with primary PTCA, the in-hospital mortality is directly related with the time to reperfusion.

P2128 Troponin T release during reperfusion predicts better left ventricular function recovery in patients with acute myocardial infarction treated with primary stenting than direct balloon angioplasty

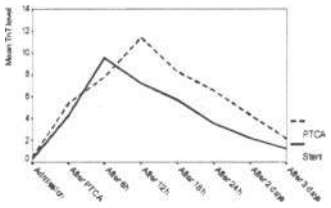
A.J. Karavidas, E.P. Matsakas, D.J. Achtipis, F.K. Panou, E. Rentoukas, N.M. Kouvousis, A.D. Vrachatis, G.D. Lianidis, S. Deftereos, A.A. Zacharoulis. *Cardiology Department, General Hospital "G. Gennimatas", Athens, Greece*

There is still lack of information regarding the recovery of left venticular (LV) function after primary stenting compared to balloon angioplasty. For this purpose we study the release kinetics of Troponin T (TnT) as a marker of reperfusion in order to determine their influence on recovery of global LV function studied by echocardiography.

Methods: Eighty patients with AMI (mean age 57.33 years, 62 men and 18 women) who underwent primary PTCA in the first 3 hours after the onset of symptoms were stratified into two groups: Group A patients (n = 40) were treated with one or more stents (for suboptimal results), while Group B patients (n = 40) were treated with balloon angioplasty. Acute angiographic success was achieved in 98% of patients in both groups. Serial venous blood samples for TnT measurement were obtained during the first 3 days, as also serial echocardiograms were obtained on 7th, 30th, 90th and 180th day after procedure and global ejection fraction (EF) was evaluated. The two groups were compared with regard to TnT kinetics and EF by Student's t-test. There were no substantial differences in sex, age, clinical or angiographic characteristics and infarct's size between the two groups.

Results: Means ± standard errors are shown in the following table and TnT kinetics is shown in the graph:

Group	Time of peak TnT level	TnT level	EF at 7th day	EF at 30th day	EF at 90th day	EF at 180th day
A	7.48 ± 0.4 h	4.22 ± 0.3	49.8 ± 0.6	52.0 ± 1.0	56.5 ± 0.9	59.7 ± 0.6
B	14.65 ± 0.8 h	5.85 ± 0.3	45.9 ± 0.6	48.6 ± 0.5	52.3 ± 0.6	55.0 ± 0.5
	p < 0.001	*p < 0.001*	*p < 0.001*	*p = 0.004*	*p < 0.001*	*p < 0.001*



In conclusion, in the stent group mean levels of TnT were lower, while TnT reached the peak level earlier (better reperfusion rate) and this predicts better LV function recovery compared to balloon angioplasty group.

P2129 Transradial approach for direct PTCA in acute myocardial infarction

Y. Louvard, C. Loubeyre, T. Lefevre, P. Dumas, J.F. Piechaud, M.C. Morice. *Institut Cardiovasculaire Paris Sud, Massy; Quincy; Antony, France*

Background: Femoral access is usually the preferred approach for direct PTCA in acute myocardial infarction (AMI). However, radial approach (Radial) may be of interest in pts with high femoral risk (thrombolytics, antiplatelet drugs, obesity, peripheral arterial disease).

Purpose of the study: To evaluate the feasibility and safety of transradial coronary angiography and PTCA in AMI.

Methods: Retrospective analysis of Radial pts included in our prospective AMI Database (AMI < 24 hours, direct admission to the cathlab for coronary angiography). The use of Radial was left to the operator's judgment.

Results: Out of 735 AMI pts, 60 (8.6%) were treated through Radial. They were 61.8 ± 14.8 years old, 80% male, Killip III 3% and IV 8%. Localization of MI was anterior in 38% and inferior in 50%. Thrombolysis was used prior to admission in 28% of cases. Onset to door time was 311 ± 262 min. The right Radial was used in 75% of cases. Technical failure occurred in 1 case (1.7%) with successful femoral access. Infarct related artery was the RCA in 45%, LAD 30% and LCX 13%. Mean ejection was 52 ± 14%. Reopro was used in 5% of cases and transfemoral IABP in 7%. Procedural success was obtained in 98.3% of cases (TIMI III flow in 90.0%) using stents in 93.3%. Door to reperfusion time was 38 ± 19, door to stent 42 ± 22 and total fluoroscopy 19.1 ± 12.2 min. During hospital stay, death occurred in 3 patients (40% in pts with shock at admission and 1.8% in pts without), SAT in 1 (1.7%), stroke in 2 (1 frontal hematoma in a thrombolysed patient, 1 TIA). No access site complication or MACE occurred. Mean hospital stay was 6.7 ± 3.3 days.

Conclusion: Transradial approach for PTCA in AMI is feasible, with a high procedural success rate. Time to reperfusion is comparable to transfemoral approach. The absence of vascular complications may be of particular interest in high risk femoral access pts.

P2130 Clinical long term outcome in a randomized trial comparing primary angioplasty vs. streptokinase

D. Berrocal, L. Grinfeld, C. Rojas Matas, G. Nogareda, G. Antonelli, A. Fernandez, J. Gabay, M.E. Halac, M. Montoya, R. Gelpi[1]. *Interventional Cardiology Dept, Hospital Italiano, Buenos Aires; [1]Cardiovascular Physiopathology Lab., Universidad de Buenos Aires, Buenos Aires, Argentina*

Primary Angioplasty (PTCA) has demonstrated to be an alternative to thrombolysis in the setting of an acute myocardial infarction (AMI). Long term benefit remains controversial. In order to evaluate this issue, we analyzed the long term outcome in the population of our "FAP" randomized trial comparing PTCA with SK.

From October 1993 to August 1995, 112 patients (p), with AMI within 12 hs. from symptoms onset, were randomized to SK 1.500.00 U (58 p) or PTCA (54 p). Mean age was 66 ± 13 years with 44.6% being > 70 years old and anterior localization in 43.4%. Primary end points were ST reduction in >50% at 120 min. from randomization and TIMI3 flow in the culprit vessel at discharge. A combination of major clinical events (death, PTCA, CABG, heart failure, re-AMI, stroke and major bleeding) were considered as a secondary end point at discharge. We considered these variables to analyze clinical outcome in long term follow-up.

ST resolution was achieved in 79.6% in PTCA group compared with 50% in SK (P: 0.002). Pre-discharge angiography was performed in 101 p (93.7%). TIMI3 flow was present in the infarct related artery in 95.6% of PTCA group and 64.5% in SK group (P: 0.001). Three year follow up (36 ± 2 months) was obtained in 98.9% of p. Survival analysis using Kaplan-Meier curve (log rank test) was made. We found a survival of 66.67% for PTCA and 60.34% for SK (P: 0.48). Event free survival was 53.7% for PTCA vs. 31.03% for SK (P: 0.008).

We conclude that in our population, PTCA achieved higher rates of ST resolution and TIMI3 flow at discharge. At three years follow-up, event free survival was better in patients treated with PTCA.

P2131 Coronary stenting in patients with acute myocardial infarction and cardiogenic shock

R. Moreno, E. García, J. Soriano, M. Abeytua, E. López de Sá, J. Elízaga, J. Botas, J.F. Portales, J.R. Rey, J. Acosta, R. Rubio, J.L. López-Sendón, J.L. Delcán. *Department of Cardiology, Hospital Gregorio Marañón, Madrid, Spain*

Coronary stenting (CS) seems to improve the outcome of patients with acute myocardial infarction (AMI). However, whether CS represents a clinical advantage in patients with cardiogenic shock remains unknown. The objective of this study was to evaluate if coronary stenting improves the outcome of patients with AMI in cardiogenic shock.

Methods: The study population is constituted by 69 patients (68 ± 12 years, 77% male) with AMI and cardiogenic shock that were treated with PTCA within the first 12 hours ofter onset of symptoms. Of them, 32 (46%) were treated with balloon alone PTCA (POBA), and 37 (54%) with CS. The in-hospital outcome of both groups was analyzed.

Results: Except for a higher incidence of prior thrombolitic therapy in patients treated with POBA (16% vs. 0%, p = 0.004), both groups of patients had a comparable risk profile. The in-hospital outcome is summarized below:

	CS (n = 37)	POBA (n = 32)	p
Angio. success	89%	71%	0.056
Death	62%	75%	NS
Re-AMI	0.0%	3.1%	NS
Death/ReAMI	62%	75%	NS
Free wall rupture	2.7%	0.0%	NS

Conclusion: There was a tendency to higher angiographic success in patients treated with CS. However, although a small beneficial effect of CS can not be ruled out in patients with AMI and cardiogenic shock, the mortality in the group of patients treated with CS was not statistically lower than in patients treated with POBA. These patients constitute a very high risk subset even with the use of CS.

P2132 Improved outcomes after gradual reperfusion angioplasty for acute anterior myocardial infarction: two-year follow-up results of a randomized trial

K. Ohsato, S. Mizuno, T. Murakami, I. Moriuchi, Y. Arai, Y. Nio, B. Kaku, Y. Takahashi, M. Ohnaka. *Internal Medicine Dept., Fukui Cardiovascular Center, Fukui, Japan*

The myocardium may be damaged by a sudden reperfusion. Primary gradual and prolonged dilatations cause less arterial trauma as compared to standard dilatations in elective angioplasty. The purpose of this study was to evaluate the impact of prolonged inflation versus standard short dilatations in patients undergoing direct angioplasty.

Methods: We performed a prospective analysis on 80 patients with acute anterior myocardial infarction. One or two prolonged (10 minute) dilatations were performed in 40 patients using a perfusion balloon catheter (Gradual reperfusion group), and the other 40 patients received two or five standard (1 minute) dilatations using a standard balloon catheter (Sudden reperfusion group).

Results: The Gradual reperfusion group had a higher success rate after the initial inflation (<50 residual stenosis) (93.5% vs. 54%; p = 0.0003), less recoil (6% vs. 31%; p = 0.011), and a lower rate of major dissections (0% vs. 14%; p = 0.036) in the acute phase. Regional wall motion improved significantly over the baseline (−2.65 SD/chord) at the time of the acute anterior myocardial infarction when seen at 1 month (−2.35, p = 0.048) and 6 months (−2.20, p = 0.047), and 2 years (−2.12, p = 0.045) after the infarction in the Gradual reperfusion group, which was not observed in the Sudden reperfusion group. Discrepancy of thallium-201 and fatty acid metabolism imagings was 33% in the Gradual reperfusion group, as compared to 11% in the Sudden reperfusion group (p = 0.038). And, cardiovascular events (sudden death, congestive heart failure, reinfarction, bypass sugery, and repeat angioplasty) followed for two years occurred less frequently in the Gradual reperfusion group (40% vs. 67%; p = 0.048).

Conclusion: These findings suggest that gradual reperfusion in primary angioplasty may prevent the initial complications and ventricular remodeling of the infarct zones in acute anterior myocardial infarction, reducing cardiovascular events for a long time.

P2133 Five-year follow-up after coronary stenting in acute myocardial infarction

A. Maimaitiming, H.-J. Rupprecht, M. Schäffer, B. Nowak, J. Meyer. *2nd Medical Clinic, Johannes Gutenberg University Mainz, Germany*

Coronary stenting has become a treatment option for acute myocardial infarction (AMI), but so far few data are available for a long-term follow-up. There is little data on long-term results and quality of life of the patient (pat.) after coronary stenting in AMI. Therefore, we examined the patients at a mean of five years after coronary stenting in AMI.

Methods: We studied 97 pat. (mean age 58 ± 11 y), in whom coronary stents were implanted after bailout PTCA in AMI between October 1993 to December 1997. 78 (80%) of them could be examined with a structured questionnaire after 5 years either by letter or phone. Major events (death, MI, CABG and RePTCA) were analyzed. Data were evaluated for a progression in angina pectoris (AP), limitation in daily activity (LA) and patient judgement of therapy (JT).

Results: See tables.

N = 97	<30 d	30 d – 5 y	during 5 y
Death	10 (10.3%)	9 (9.3%)	19 (19.6%)
MI	1 (1.0%)	0	1 (1.0%)
CABG	2 (2.1%)	4 (4.1%)	6 (6.2%)
RePTCA	3 (3.1%)	7 (7.2%)	10 (10.3%)

N = 78	during 5 y
No AP	32 (41.0%)
No LA	70 (89.7%)
Good JT	74 (94.9%)

Conclusion: The present study has demonstrated: 1. an acceptable death and revascularisation rate after coronary stenting in AMI at a mean follow-up of five years; 2. most of the patients are satisfied with the treatment of stent implantation and only 10% patients are limited in daily activity in the long-term.

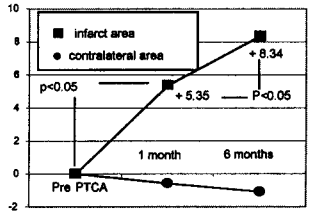
P2134 Coronary stenting within 24 hours of thrombolysis: feasibility, safety and effect on reocclusion, left ventricular function and clinical outcome

F. Fernández-Avilés, J.J. Alonso, J.M. Durán, F. Gimeno, B. Ramos, E. García-Morán, I. Garcimartin, L. de la Fuente, M. de la Torre, A. Serrador. *Hospital Universitario, Valladolid, Spain*

Reocclusion (RO) after thrombolysis (T) prevents recovery of the left ventricular function and worsens initial and long-term prognosis of AMI.

To determine the feasibility and safety of early post-T coronary stenting (CS), as well as its efficacy in preventing RO, we studied 137 consecutive pts with AMI (57 ± 10 yr, 86% male) who underwent T (accelerated rt-PA 176 ± 248 min. from onset of symptoms) followed by angiography 17 ± 7 h after T. Stenting was carried out if technically possible and flow ≥ TIMI-II existed. All pts underwent 1 and 6 months clinical and angiographic follow-up (FU).

Initial success was achieved in 99% of cases, and MLD improved from 0.89 ± 0.52 to 3.5 ± 05 mm. Hospital stay lasted 4.1 ± 2.5 days. At 30 days no adverse cardiac events occurred, all stented arteries remained patent and MLD significantly decreased to 3.1 ± 0.8 mm (p = 0.001). Over the last 5 months of FU only 1 pt had non-fatal AMI due to RO and MLD decreased to 2.4 ± 0.9 mm. Restenosis rate was 21% (≥50% criterion). Baseline LVEF (55 ± 1.6%) increased at 30 days (61.75 ± 1.6%, p < 0.01) and an additional improvement was found at 6 months (64.97 ± 1.42, p < 0.05 vs 30 days). The LVEF improvement was related to a significant and progressive increase of the infarct-area motion (figure).



Thus: 1) Unlike balloon PTCA, CS within 24 hours of T is a safe strategy that prevents RO and related events; 2) This strategy also facilitates the recovery of the infarct-area motion and the LVEF. Further studies are necessary to define the efficacy and cost-effectiveness of this strategy in comparison with the conservative approach to AMI.

P2135 Suboptimal flow after primary PTCA in acute myocardial infarction influences death rate at follow-up: results from the Stent PAMI randomized study

T. Lefèvre, M.-C. Morice, E. Garcia, F. Kiemenej, M. Pieper, C. Macaya, G.-A. Van Es, L. Mattos, M. Eijelshoven, C. Grines. *On behalf of the Stent PAMI Study Investigators; Institut Cardiovasculaire Paris Sud, Massy, France*

Results from the Gusto trial have shown that one-month mortality after acute MI treated by thrombolysis is related to TIMI flow at 90 min.

The purpose of this study was (1) to assess the incidence and predictive factors (clinical, biological, procedural) of suboptimal TIMI flow (TIMI 0–2) obtained by primary PTCA (balloon vs stent) in pts included in the Stent PAMI trial, (2) to evaluate the relationship between TIMI flow and mortality at follow-up.

Of 1,458 pts in whom informed consent was obtained, 900 were randomized, 452 to stent and 448 to balloon. Procedural success (TIMI 2 or 3 flow and residual stenosis < 50%) was obtained in 98.8% of cases (Corelab analysis) with a 15.0% cross-over to stent in the balloon group. TIMI 3 flow (Corelab analysis) was obtained in 91.0% of cases. Predictive factors of suboptimal flow were by univariate analysis: no heparin pre cath-lab (77.4 vs 84.8, p = 0.09), complication (pulmonary oedema, sustained hypotension or CPR) before PTCA (18 vs 5%, p = 0.03) and age (63.9 ± 12.3 vs 59.7 ± 12.6 years, p = 0.004). By multivariate analysis, the predictive factors of suboptimal flow were age (p = 0.0022, odds ratio 0.967) and complication before PTCA (p = 0.0038, odds ratio 0.434). Mortality at 210 days was 2.7% in the 818 pts with TIMI 3 flow, 9.1% in the 77 pts with TIMI 2 and 40.0% in the 5 pts with TIMI 0–1 (p < 0.001).

In conclusion, suboptimal flow is not unfrequent after primary PTCA in selected acute MI patients. It is reported more frequently in older patients and when complication occurs before PTCA. All efforts must be made to restore a TIMI 3 flow after primary PTCA and, therefore, decrease mortality at follow-up.

P2136 The effect of quantum therapy on fibrinolytic response and lipid profile in patients with acute myocardial infarction

N. Aliyeva-Karayeva, I. Alizade. *Department of Cardiology Hospital of Ministry of Internal Affairs, Baku, Azerbaijan*

The aim of this study was to study the effects of autotransfusion of ultraviolet-irradiated blood (AUVIB) on endothelian fibrinolytic system and lipoprotein profile in treatment of patients with acute myocardial infarction (AMI). In 54 patients with AMI we measured the fibrinolytic index (FI), before (PreA) and 10 m after anoxia (postA), variation expressed as geometric increase (FIGI) and lipid study triglycerides (TG); total cholesterol (T-C), HDL-cholesterol (HDL-C); apolipoprotein (Apo) A1; Apo B and lipoprotein index (LPI) (Apo A1/Apo B). Examination of patients was performed in 1, 3 and 6 months after discharge from the in-patients department.

The patients received 8–10 procedures of AUVIB at a 1–2-day interval. It was revealed that the levels if FI preA (p > 0.05), FI post A (p < 0.01), FIGI (0.01) raised and TG (p < 0.05), T-C (p > 0.05), HDL-C (p < 0.05), LPI (p < 0.001) lowered after treatment with AUVIB.

These results indicate that AUVIB together with clinical effect improves the fibrinolytic response of the endothelium To anoxia, and the lipid profile.

P2137 Association of non-invasive markers of coronary artery reperfusion to evaluate new therapeutic strategies and prognosis in patients with acute myocardial infarction

Ramón Corbalán, Carolina Nazzal, Francisco Cumsille, Pierre Theroux, Oscar Bazzino. *On behalf of the AMI Investigators; Cardiovascular Diseases Catholic University, Santiago, Chile*

Objectives: Non Invasive markers of coronary artery reperfusion were used to evaluate prognosis and drug efficacy in the double blind Argatroban in Myocardial Infarction Study (AMI trial) This trial compared high (3.0 meg/kg./min) and low dose of Argatroban, (Arg HD, Arg LD) a direct thrombin inhibitor, to placebo (P) in patients with acute MI < 6 hours that were treated with Streptokinase 1.5 million Units (SK).

Methods: In 612 patients we determined plasma CK levels and performed 12 lead ECGs at baseline and at 6, 12 and 24 hours after onset of treatment. We defined early reperfusion by a >50% decrease in baseline ST elevation followed by inversion of T waves within the first 12 hours in the corresponding ECG leads and peak CK rise at 6 hours. We considered late reperfusion when there was <50% reduction in pretreatment ST elevation, associated to inversion of T wave within 24 hours in the infarct related ECG leads and >60% of CK rise at 6 hours. Absence of these criteria was considered as failed reperfusion.

Results: Reperfusion rates were similar in the 3 arms of the trial. Early reperfusion was achieved in 45% of Arg HD, 46% of Arg LD and 49% of P patients. Late reperfusion occurred in 24%, 21% and 17% of patients respectively. An adverse clinical event (death, reinfarction, heart failure or shock) within the first 30 days occurred in 13.7% of reperfused patients and in 29.1% of those without reperfusion ($p < 0.001$), an odds ratio adjusted to other risk factors (Age, sex, coronary risk factors, MI location) of 0.57 (95% CI 0.39–0.84).

Conlcusions: Combination of non invasive markers of coronary artery reperfusion may be utilized systematically to evaluate new therapeutic strategies in patients acute MI and to assess post treatment prognosis.

INTRAVASCULAR ULTRASOUND AND BRACHYTHERAPY

P2138 High prevalence of angioscopically yellow plaque in angiographically mild stenosis

O. Yamaguchi, M. Asakura[1], A. Hirayama, T. Adachi, Y. Higuchi, Y. Ueda[1], K. Kodama. *Cardiovascular division, Osaka Police Hospital, Osaka; [1] 1st department of internal medicine, Osaka University Medical School, Osaka, Japan*

Background: Angioscopically-observed yellow plaques are reported to be vulnerable and likely to cause acute coronary syndrome (ACS). In addition to severe stenosis, ACS may also occur in the angiographically mild stenosis of coronary arteries. However, the prevalence of yellow plaques in angiographically mild stenosis remains to be elucidated.

Methods: We used a high-quality angioscopy with 6000 pixels. The angioscopic observation was performed in 47 angiographically mild (<50%) stenoses in 30 coronary arteries of 22 patients; 13 patients with old myocardial infarction, 4 patients with stable effort angina, 4 patients with hypercholesterolemia, and 1 patient with vasospastic angina. The lesions received coronary intervention and the culprit lesions of ACS were excluded. The diameter stenosis was determined using quantitative coronary angiographic analysis.

Results: The mean stenosis was 25.6 ± 9.6% (13–49%). The yellow plaques were observed in 44 lesions (94%). Most of the yellow plaques were focal and had smooth surface. No thrombus was detected in these lesions.

In conclusion, the angioscopic observation revealed the high prevalence of yellow plaques in the angiographically mild stenoses. Although the occurrence of ACS in such lesions remains to be investigated, the high prevalence of yellow plaque may implicate the need for the management of the mild forms of coronary artery disease.

P2139 Comparison of Electron Beam CT with intravascular ultrasound for the detection of calcified atherosclerosis: an in vitro study

H. Gschnitzer, H. Hügel, G. Friedrich, F. Weidinger, S. Schwarzacher. *Dept. of Cardiology, University of Innsbruck School of Med., Innsbruck, Austria*

Recent work suggested a high sensitivity for Electron Beam CT (EBCT) in the diagnosis of coronary atherosclerosis. This procedure is based on the detection of calcifications (Ca) being summed up in a score. Although this methodology is increasingly entering the clinical arena, scarce in vitro data are available demonstrating the true sensitivity of EBCT for Ca. This study was therefore performed to compare the EBCT with intracoronary ultrasound (ICUS), a method known to have 100% sensitivity for the diagnosis of Ca.

Methods: 16 human coronary arteries, harvested at autopsy, were mounted horizontally in a flow chamber filled with physiologic saline. An automated pullback of an ICUS-catheter was performed at a predefined speed (0.5 mm/sec) through all vessels. The vessels were then investigated with EBCT (Imatron CT, 100-ms high resolution mode) by scanning cross-sections (3 mm single slice thickness). The cross-sections were then compared in respect to the detection of calcified lesions. After the procedure, the vessels were fixed (8% formalin) and embedded with subsequent staining and cutting (according to ICUS and EBCT cross-sections).

Results: In 8 out of 10 coronary arteries with sonographic evidence of Ca, the EBCT also showed Ca, which gives a per vessel sensitivity of 80%. In a total of 243 cross-sections investigated, 67 had Ca on histology and ICUS, but only 39 had Ca on EBCT ($p < 0.01$). The specificity of EBCT to detect Ca is 100% and the cross-sectional sensitivity 59%.

Conclusion: EBCT shows a high sensitivity when Ca-scores are compared per vessel, however, the sensitivity becomes lower when cross-sections are compared.

P2140 Influence of lesion composition obtained by histology and intracoronary ultrasound on coronary arteries remodelling

O. Kovalenko[1], C. Di Mario[2], R. Albiero[2], M. Vaghetti[2], A. Colombo[2], E. Arbustini[3]. *[1] Lasnamäe polikliinik, Tallinn, Estonia; [2] Centro Cuore Columbus, Milan; [3] Pathology Department, University of Pavia, Italy*

Recent study with intravascular ultrasound (IVUS) show that coronary arteries with atherosclerotic de-novo focal plaque often develop compensatory enlargement at the lesion site (positive remodeling-PR) but may also exhibit shrinkage (negative remodeling-NR) or to be without remodeling (WR). The purpose of this study was to investigate the association of plaque composition obtained by IVUS and histology, plaque burden, eccentricity and topography with type of remodeling.

Methods: We studied 50 lesions (L) N 50 pts with CAD before directional atherectomy (DCA) using IVUS. Vessel area (VA), lumen area (LA), % plaque area [(VA − LA)/VA × 100], eccentricity index [min/max plaque thickness] were measured. PR was defined when VA at the L site was larger than that at the proximal reference site; NR, when the VA at the L site was smaller than that at the distal reference or when the ratio lesion VA/prox ref VA ≤ 0.78; lesion WR-when lesion VA was similar or intermediate with proximal and distal references VA. The specimens retrieved with DCA were examined after Movat pentachrome staining and divided based on plaque composition (prevalent (>50% plaque area) fibrous or fibrofatty) and presence of the calcium.

Results:

		PR (20 L)	NR (10 L)	WR (20 L)	P
Histology:	Fibrous	6 (30%)	8 (80%)	10 (50%)	<0.05
	Fibrofatty	14 (70%)	2 (20%)	10 (50%)	<0.05
	Microcalcium	8 (40%)	6 (60%)	4 (20%)	NS
IVUS	Macrocalcium	8 (40%)	4 (40%)	8 (40%)	NS
	General CA	16 (80%)	10 (100%)	12 (60%)	<0.05
	Arc of deep Ca	18.33 ± 9.83°*	96.66 ± 69.76°	95 ± 69.52°	
	Arc of superfic Ca	42.5 ± 32.25°	37.5 ± 10.6°	103.75 ± 36.37°#	
	Eccentricity index	0.48 ± 0.18	0.26 ± 0.20	0.43 ± 0.31	<0.05
	% plague area	81.82 ± 7.82	73.34± 16	79.2 ± 4.9	NS
Plaque	LAD prox	10 (50%)	4 (40%)	10 (50%)	NS
topography	LAD mid	4 (20%)	6 (60%)	4 (20%)	<0.05
	RCA prox	-	-	2 (10%)	NS
	RCA mid	2 (10%)	–	–	NS
	Cx prox	2 (10%)	–	2 (10%)	NS
	Cx mid	2 (10%)	–	2 (10%)	NS

*$p < 0.05$ PR vs NR and WR; #$p < 0.05$ WR vs PR and NR.

Conclusions: 1) 40% of lesions had PR, 20%-NR, 40%-were WR. 2) The prevalence of fibrotic plaque composition is significantly higher in L with NR and fibrofatty plaque composition-in L with PR. L with NR more eccentric and distributed more frequently in the mid part of LAD. Our results suggest that plaque composition, degree of superf. and deep Ca arc, plaque eccentrisity and topography influence on developing lesions with PR, NR or WR.

P2141 In vitro validation of automated plaque echogenicity quantification of intracoronary ultrasound images

W. Bocksch, M. Beck, C. Lekutat, M. Schartl. *Cardiology, Charité-CVK, HU Berlin; Deutsches Herzzentrum Berlin, Germany*

Intracoronary ultrasound (ICUS) is the gold-standard procedure for measurement of non-obstructive, lipid-rich, atherosclerotic plaque. Analysis of plaque echogenicity remains highly subjective and is dependent on the gain/compression-setting (GCS). The aim of the study was to test the reproducibility of an GCS-independent automated plaque echogenicity quantification software.

A pressure perfused, minimally diseased, coronary artery was studied with a 30 MHz mechanical ICUS-catheter (0.5 mm/s, automated pullback) at various GCS (n = 20). The video images were digitized (260 × 260 pixel, 16 shades of gray) and lumen/vessel contour was detected semi-automatically (TomTech3D-IVUS). For analysis of echogenicity of each target plaque area (n = 152), every pixel was classified as hypoechogenic or hyperechogenic with (calcified plaque) or without acoustic shadowing taking echogenicity of the adventitia as reference for the treshold. Best and worst agreement between computed areas of different GCS for total, hypo- and hyperechogenic plaque area (PA) were calculated for various gain/compression settings using linear regression analysis.

	Best	worst
Total PA	y = 0.85 + 1.1 (r = 0.80)	y = 0.89 + 1.2 (r = 0.78)
Hypoechogenic PA	y = 0.81 + 1.5 (r = 0.87)	y = 0.81 + 1.4 (r = 0.81)
Hyperechogenic PA	y = 1.0 − 0.03 (r = 0.90)	y = 1.1 + 0.16 (r = 0.86)

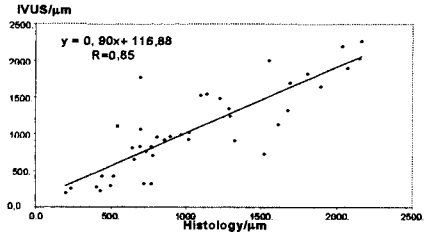
Conclusions: Reproducible automatic quantification of plaque echogenicity is possible at different GCS. This is a prerequisite for serial volumetric quantification of plaque composition in plaque regression studies.

P2142 In vitro intravascular ultrasound imaging of biocompound vein grafts: comparison to histology

W. Klimek, W. Bocksch, H.R. Zurbrügg[1], E. Frantz, R. Meyer[1], R. Hetzer[1], E. Fleck. *Cardiology., Charité-CVK, HU Berlin; Deutsches Herzzentrum Berlin; [1]Cardiothoracic and Vascular Surgery, Deutsches Herzzentrum Berlin, Germany*

Wrapping a saphenous vein with an external, ultra-thin (30 μm) metallic meshgraft (Biocompound Graft, BG) results in reduction of vessel diameter and wall stress of veins exposed to arterial pressure. The aim of the study was to evaluate the correlation between Intravascular Ultrasound (IVUS) imaging of the BG and histology.

After intraoperative preparation of the saphenous BG vein (n = 42), one segment was taken for in vitro, pressure perfused, IVUS (30 MHz Endosonics®) and consecutive histologic examination (Elastica-von-Gieson). The metallic meshgraft is visualized by IVUS as a hyperreflective ring with an average thickness of 110 ± 12 μm. Agreement between IVUS and histologic measurements of BG max. vessel wall thickness was correlated using linear regression analysis.



Conclusion: Due to excellent visualisation of the external metallic meshgraft and good correlation to histology regarding wall thickness IVUS will be the gold standard technique for follow-up studies on intimal proliferation in BG in comparison to conventional veins.

P2143 Intravascular ultrasound assessment of culotte stent deployment for the treatment of stenoses at major coronary bifurcations

N.M. Robinson, R. Balcon, C.A. Layton, P.G. Mills, A.D. Timmis, M.T. Rothman. *The London Chest Hospital, London, UK*

Purpose: The use of 2 stents in a culotte configuration is a new approach for the treatment of stenoses at major coronary bifurcations. The optimal technique for the deployment of both stents is unknown and angiographic assessment of the bifurcation is inadequate.

Methods: 11 patients with stenoses at major coronary bifurcations were treated using 2 Cordis Crossflex stents in a culotte configuration. After optimising the angiographic appearance at each marginal bifurcation, IVUS was used to evaluate both limbs of the culotte stent using a 2.9 F 30 MHz imaging catheter.

Results: IVUS images were obtained from 19 of the 22 distal limbs, in 3 cases angulation of the side branch prevented passage of the IVUS catheter. The mean lumen cross-sectional area (CSA) of the proximal reference (ref) vessel was 7.6 mm^2, the distal main reference vessel was 5.0 mm^2 and the side limb reference vessel was 4.6 mm^2. Within the culotte stent, the final mean CSA in the main limb was 6.1 mm^2 (97% of ref) and in the side limb was 5.9 mm^2 (97% of ref). However, in each case within the culotte stent, the minimum CSA and the minimum lumen diameter (MLD) of both limbs was at the bifurcation point. For all patients, the final mean CSA at the bifurcation point of the main limb was 4.3 mm^2 (70% of main stent) and of the side limb was 4.4 mm^2 (75% of side stent). The IVUS MLD at the bifurcation point of the main limb was 2.1 mm (78% of main stent) and of the side limb was 2.1 mm (84% of the side stent). This significant residual stenosis was not detectable angiographically. Quantitative coronary angiography performed off-line suggested a mean final diameter stenosis at each bifurcation point of <10%.

Conclusions: IVUS evaluation of culotte stents is feasible, allowing assessment of stent deployment and objective evaluation of the bifurcation point. The minimum IVUS CSA and MLD of both limbs of the culotte stent is at the bifurcation point. Despite an optimal angiographic appearance a significant residual stenosis was noted with IVUS at each bifurcation point. Further evaluation will be needed to assess if there is a correlation between final IVUS CSA and MLD at the bifurcation point and restenosis within the culotte stent.

P2144 Longitudinal extent and distribution pattern of transplant vasculopathy evaluated by intracoronary ultrasound imaging

W. Bocksch, E. Wellnhofer, W. Klimek, S. Dreysse, M. Musci[1], R. Hetzer[1], M. Schartl, E. Fleck. *Cardiology., Charité-CVK, HU Berlin; Deutsches Herzzentrum Berlin; [1]Cardiothoracic and Vascular Surgery, Deutsches Herzzentrum Berlin, Germany*

Transplant vasculopathy (TVP) is the major limitation of longterm prognosis after heart transplantation (HTX). The aim of the study was to describe distribution pattern and longitudinal extent of coronary lesions after HTX by means of intracoronary ultrasound (ICUS).

In 179 post-HTX patients (12–122 months) without significant stenosis by coronary angiography ICUS of the LAD was performed using a 30 MHz phased array probe (Endosonics®). 162/179 pts. (90%) had at least one coronary lesion according to the Stanford classification (I:4%, II:7%, III:6%, IV:73%). The distribution of max. plaque thickness (MPT) within the LMCA/LAD is shown in the table.

N = 179	TVP	MPT 0.3–0.5	MPT 0.5–1.0 mm	MPT > 1 mm
LMCA	93 (52%)	21 (12%)	39 (22%)	24 (13%)
Prox. LAD	148 (83%)	26 (15%)	36 (20%)	87 (49%)
Med. LAD	103 (58%)	26 (15%)	43 (24%)	31 (17%)
Dist. LAD	67 (37%)	12 (7%)	31 (17%)	12 ((7%)

In 48 pts. (30%) only one single, discrete, coronary lesion (focal disease) was found, in 27 pts (17%) more than one discrete lesion (polyfocal disease) and in 86 pts. (53%) diffuse disease throughout more than one coronary segment was found. Non-circumferential disease was associated with focal/polyfocal disease (40/48, 83%) while circumferential disease was associated with diffuse disease (79/86, 91%).

Concl.: In more than 90% of all post-HTX patients TVP is diagnosed by ICUS. The prox./med. LAD segments are affected more often than the distal one. Circumferential, diffuse disease might have a different etiology than non-circumferential focal disease.

P2145 In vivo assessment of instantaneous wall shear stress with the IVUS flow method

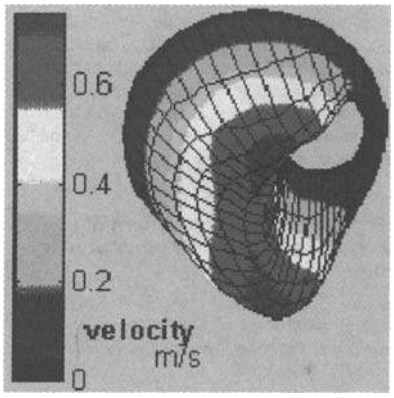
S. Carlier, G. Van Langenhove[1], F. Mastik, R. Krams, E.I. Cespedes[2], A.F.W. van der Steen, K. Bom, P.W. Serruys[1]. *Experimental Echo Lab – Ee2302, Erasmus University, Rotterdam; [1]Interventional Cardiology Dept, Thoraxcentre, Rotterdam, Netherlands; [2]EndoSonics, Rancho Cordova, USA*

Background: Wall shear stress (WSS) has been implied as the most important local influencing factor in the development of vascular remodeling and restenosis. To date, no in vivo method offers the possibility to measure true WSS in coronary arteries.

Aim: Demonstrate the feasibility to measure WSS with the IVUS flow method and compare WSS assessment with computer simulation using finite element modeling (FEM).

Method: We have previously described the principle of velocity mapping with IVUS, based on the decorrelation rate of successive radofrequency signals in small windows over the arterial lumen. Spatio-temporal integration gives volumetric blood flow. Good agreement with Doppler derived flow estimations has been demonstrated. In this study we investigated the potential to derive WSS from the velocity measurements close to the arterial wall. On the other hand, the automatically detected area and the assessment of the mean flow permit the computation of the average WSS following the the Hagen-Poiseuille formula: WSS = 4 mu Q/pi r^3, with mu being blood viscosity (0.003 N s m^{-2}), Q blood flow (m^3 s^{-1}), r radius (m). By FEM, the increase of WSS related to the presence of the catheter has been investigated.

Results: In 12 patients, pooling baseline and hyperemia measurements, true WSS ranged from 1.7 to 16.5 N m-2, and average WSS from 1.5 to 5.2, in agreement with FEM modeling showing also that WSS was decreased close to the IVUS catheter, and increased on the opposite site.



Mapping of velocities around IVUS cath.

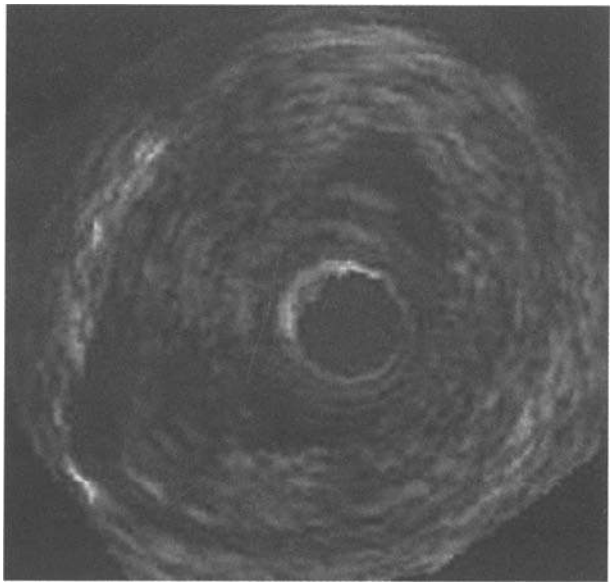
In conclusion, true WSS measurements are possible, although influenced by the catheter, and should be further investigated and related to clinical outcome.

P2146 Assessment of atherosclerotic lipid pools with high frequency intravascular ultrasound

F. Prati, E. Arbustini[1], A. Labellarte, F. Marsico[2], B. Dal Bello[1], M.T. Mallus, A. Pagano, L. Sommariva, A. Boccanelli. *Cardiology Dept., S. Giovanni Hospital, Rome; [1]Istituto di Anatomia Patologica, Pavia; [2]Cardiology Dept., S. Raffaele Hosp., Milan, Italy*

Previous intravascular ultrasound (IVUS) studies on atherosclerotic plaque characterization were limited by use of low-frequency transducers that did not define accurately soft components. The present study tested the effectiveness of high frequency IVUS transducers in identification of lipid/necrotic pools in atherosclerotic plaques. Methods. Forty MHz transducers were used for in-vitro IVUS assessment of 12 arterial segments (10 coronary arteries and 2 carotids dissected from 5 different autopsy cases). IVUS acquisition was performed at a 0.5 mm/s speed after ligature of the branching points to generate a closed system. Lipid necrotic areas were defined by IVUS as large echolucent intra-plaque areas surrounded by tissue with higher echodensity. To obtain histopathologic sections corresponding to IVUS cross-sections, vessels were divided into consecutive 3 mm-long segments using the most distal recorded IVUS image as starting reference. Then, samples were fixed with 10% buffered formalin, processed for histopathologic study, serially cut and stained with Movat penthacrome method.

Results: On histopathologic study, intra-plaque lipid pools were present in 30 of 120 cross-sections (25%). Corresponding IVUS cross-sections identified lipid lakes with a sensitivity and specificity of 70% and 94% respectively (echolucent area at 7 in the figure).



Lipid pool.

Conclusions: High frequency transducers accurately identify lipid/necrotic pools and open new perspectives on future IVUS characterization of atherosclerotic plaques.

P2147 A steerable yttrium-90 wire: development and evaluation of a novel device for intravascular radiotherapy

P. Wexberg, K. Mück[1], W. Schmidt[2], W. Görz[1], G. Maurer, M. Gottsauner-Wolf. *Clinic for Internal Medicine II, Dept. of Cardiology, University of Vienna; [1]Austrian Research Center Seibersdorf; [2]Clinic for Radiotherapy, Social Medical Center East, Vienna, Austria*

Intravascular radiotherapy (IVRT) has been shown to reduce neointimal growth after balloon injury in various animal models and in first clinical trials. Beside reducing neointimal proliferation, an ideal radiation device should be 1) leak tight, 2) flexible, and 3) low in radiation exposure of the personnel. Therefore a beta-emitting source was developed and tested in a rabbit restenosis model.

Methods: Four Yttrium-90 seeds with an activity of 800 MBq each were activated at a flux of 6×10^{13} $cm^{-2}s^{-1}$. The source was then heat shrunk into a plastic tube with an outer diameter of 0.9 mm integrated in the anterior end of a standard 0.014″ guide wire. Wipe tests were performed to detect leakage of the plastic tube. In order to test its flexibility, the source was fixed in a tube so that the distal half reached the surface of a scale, where the weight necessary to bend the wire in its center by 30° was measured. To determine radiation exposure, the staff wore thermoluminescence dosimeters (TLDs) at the procedure. The efficacy of the source was tested in 18 normolipidemic rabbits after balloon injury of the iliac artery.

Results: The device proved leak tightness both in vitro and in animal experiments. Wipe tests revealed no detectable leakage of the plastic tube surrounding the source at any time. At the procedure there was no contamination detected at the used instruments. At flexibility tests, a weight of 3580 ± 60 mg was necessary to bend the wire in the middle by 30°. This was significantly lower than for an inflated angioplasty balloon (3910 ± 62 mg). Advancement of the wire was feasible in all animals, and resulted in reduction of neointimal growth by up to 70%. Total radiation exposure as measured by TLDs was 0.41 mSv for the operator.

Conclusion: The novel IVRT device is easy to handle and warrants flexibility due to its composition of single seeds, which besides allows to adjust the active length individually by the amount of pellets in the shrink tube. Because of the diameter of the source and the inherent stiffness of the device proximal parts of coronary vessels should be preferred for IVRT.

P2148 Persisting coronary artery dissection after intracoronary β-radiation

I.P. Kay[1], M. Sabate[1], S. Carlier[1], A.L. Gijzel[1], M. Albertal[1], A.J. Wardeh[1], W.J. van der Giessen[1], V.L.M.A. Coen[2], P.C. Levendag[2], P.W. Serruys[1]. [1]Thoraxcenter; [2]Daniel den Hoed Cancer Center, Rotterdam, Netherlands

Intracoronary β-radiation therapy (β-rad) is a means of preventing and treating restenosis in coronary arteries after balloon angioplasty (BA). However by inhibiting restenosis, β-rad may also interfere with normal healing processes. From previous reports complete healing of coronary artery dissection appears the norm after BA, but may not occur after β-rad.

Method: To evaluate this we retrospectively analysed dissection using quantitative coronary angiography (QCA) and intravascular ultrasound (IVUS) at the time of treatment and at 6 month follow-up in patients (pts) enrolled in the Beta Energy Restenosis Trial (BERT-1.5). The calculated dose of radiation received by the dissected area in those with healed versus non-healed dissection was also compared.

Results: 31 pts were enrolled in BERT-1.5. After excluding those who underwent stent implantation, the evaluable population was 22 pts (males = 17, mean age 55.7 ± 9.0 years). QCA and IVUS-proven dissection were seen in 16 patients post intervention. Dissection classification for QCA was by the NHLBI scale (QCA type A = 5, B = 7, C = 4). IVUS proven dissection was defined as partial (P) or complete (C) (IVUS: P = 12, C = 4). The following IVUS defined characteristics of dissection were described in the affected coronary segments: length, depth, arc circumference and presence of flap. Dissection was defined as healed when all features of dissection had resolved. At 6-month follow-up, 6 (38%) and 8 (50%) unhealed dissections were seen by QCA (QCA type A = 2, B = 4) and IVUS (partial = 7, complete = 1) respectively. No correlation was made between the dose prescribed to the treated area and the presence of unhealed dissection. No change in anginal status was seen despite the presence of unhealed dissection.

Conclusion: β-rad appears to alter the normal healing process resulting in unhealed dissection in certain individuals. In view of the delayed and abnormal healing witnessed, long term follow-up may be prudent.

P2149 Dose volume histograms offer new insights into the IVUS and angiographic follow-up after coronary brachytherapy

S. Carlier, J.P.A. Marijnisen[1], M. Sabate[2], V.L.M.A. Coen[1], A. Wardeh[2], W.J. van der Giessen[2], P.C. Levendag[1], P.W. Serruys[2]. *Experimental Echo Lab – Ee2302, Erasmus University, Rotterdam; [1]Radiation Oncology, Daniel den Hoed Cancer Centre, Rotterdam; [2]Interventional Cardiology Dept, Thoraxcentre, Rotterdam, Netherlands*

Brachytherapy is a new therapeutic option to prevent restenosis. However, the use of different delivery devices, isotopes and dose prescriptions lead to a wide range of doses distribution over the arterial wall. Tools are required to analyze efficacy of radiation in function of the dose effectively absorbed by different arterial components.

Aim: Determine the absorbed doses in different volumes of irradiated coronary arteries and correlate them with the 6-month angiographic and IVUS outcome after PTCA of de-novo lesions.

Method: dose-volume histograms (DVH) were computed on 3-D ECG-triggered IVUS pull-backs, in 3 structures: (i) luminal surface volume (Vlum), defined with a 0.1 mm thickness from the automatically detected lumen contour; (ii) adventitial vol. (Vadv) defined with a 0.5 mm thickness from the EEL contour; (iii) a plaque+media vol. (Vp) encompassed by the lumen and EEL contours. DVH in 20 patients included in the BERT1.5 (beta-irradiation with 90Sr) without a stent implantation and with complete IVUS and angiographic f-up are reported.

Results: 8 were randomized to 12 Gy (at 2 mm from the source center), 4 to 14 Gy and 8 to 16 Gy. DVH demonstrated that, on average, 90% of Vlum received 8.5 ± 3.7 Gy or more (dV90lum), 90% of Vp 7.4 ± 3.0 Gy (dV90p) and 90% of Vadv 4.7 ± 2.0 Gy (dV90adv). As recently reported, at 6-m f-up with IVUS, the intraluminal volume was unchanged, but the plaque volume increased from 201 ± 61 to 241 ± 74 mm^3, accommodated by a similar increase of 39 ± 68 mm^3 of the vessel volume. DVH revealed that the plaque volume increase was inversely correlated with dV90lum (r = −0.62, p = 0.005). With angiographic f-up (diameter stenosis DS, late loss index LLI), DVH do not confirm that 8 Gy might be the minimal dose to give in the adventitia, as previously reported, but suggest a beneficial outcome when dV50p > 14 Gy (see table), but this requires confirmation in larger groups of patients.

Mean (sd) n =	dV50adv < 8 5	dV50adv > 8 15	p (Wilcoxon)	dV50 p < 14 9	dV50p > 14 11	p (Wilcoxon)
DS (%)	46 (19)	38 (19)	0.40	47 (22)	34 (13)	0.13
LLI	0.89 (1.47)	0.14 (0.63)	0.12	0.73 (1.14)	−0.01 (0.56)	0.07

In conclusion, direct assessment of vessel wall dose distribution with DVH appears useful for the understanding of IVUS and angiographic outcomes after brachytherapy.

P2150 Gallium-68 positron radiation combines biological efficacy, deep tissue penetration, generator availability and superior safety for liquid-filled balloon brachytherapy

H.P. Stoll, G.D. Hutchins, W.L. Winkle, A.T. Nguyen, C.R. Appledorn, C. Foster, K.L. March. *Indiana University, Indianapolis IN, USA*

Recent data have shown that liquid-filled balloon brachytherapy using beta-emitters can prevent restenosis. However, the use of long lived beta-emitters for this application carries significant risk for severe radiointoxication if the balloon ruptures releasing the radionuclides into the bloodstream. We hypothesized that shorter-lived beta+ emitters might overcome this risk and accordingly investigated F-18 (T1/2 = 109 min), C-11 (20 min), N-13 (10 min), O-15 (2.1 min), and Ga-68 (67 min, generator produced). To assess biological efficacy, bovine aortic smooth muscle cells (BASMC) were plated at 10 k/cm^2 and irradiated with positron doses ranging from 2.5 Gy to 30 Gy. BrdU incorporation was assessed after 24 hours and cells were counted at 4 time points ranging from 1–8 days post-irradiation. In addition, GAF-chromic film phantom studies were used to quantify the depth-dependent dose response of beta+ emitters in tissue-equivalent medium. We found a dose-dependent inhibition of BrdU incorporation (1 day), with ED50 = 1.6 Gy and ED80 = 3.2 Gy; and of BSMC growth (8 days) with ED50 = 3.4 Gy and ED80 = 7.9 Gy. Cell death rate (8 days) was <5%. Phantom measurements revealed monoexponential ($r^2 > 0.99$) dose vs depth curves with half-depth layers linearly dependent on positron energy as given by D1/2 = 0.024 + 1.04*E, $r^2 > 0.99$ (D1/2, dose half-depth; E, mean positron energy). D1/2 for F-18 was 0.29 mm, C-11: 0.42 mm, N-13: 0.54 mm, O-15: 0.70 mm, and Ga-68: 0.90 mm. Accordingly, we considered Ga-68 as the most promising isotope and calculated that 50 mCi Ga-68 inside a 3.0/30 mm balloon would deploy 25 Gy to a 1 mm deep prescription point within 3.7 min. A whole-body dose of 5 rem (in the upper range of diagnostic x-ray procedures) would result from accidental systemic delivery of this activity. Since Ga-68 combines efficacy, deep tissue penetration, availability, and superior safety, its use may significantly advance liquid filled-balloon brachytherapy.

P2151 Catheter-based endovascular irradiation with the liquid β-emitter rhenium-188 to reduce restenosis after experimental wall injury

M. Wohlfrom[1], J. Kamenz[1], J. Kotzerke[2], M. Eble[1], B. Hess[1], C. Schütte[2], C. Lenz[1], H. Hanke[1], M. Höher[1]. [1]Department of Cardiology, University of Ulm; [2]Department of Nuclear Medicine, University of Ulm, Germany

Postinterventional irradiation seems to be a promising therapy concept in the prevention of restenosis. The liquid β-emitter Rhenium-188 allows endovascular brachytherapy with a conventional balloon catheter without the problem of centring the radiation source. In an experimental model of restenosis the practicability of the method and the dose dependent effect of irradiation with Rhenium-188 on the intimal proliferation was investigated.

In 36 male New Zealand White rabbits after endothelium denudation with a Fogarty-catheter, endovascular irradiation with a Rhenium-188 filled 2.5 mm balloon catheter in different dosages (0, 7.5, 15, 30, 45 and 60 Gray [Gy]) was performed. Four weeks after intervention the vessels were excised and histologically analysed.

Intimal Area in mm^2 (median [1. quartile; 3. quartile])

Control n = 6	7.5 Gy n = 4	15 Gy n = 6	30 Gy n = 7	45 Gy n = 6	60 Gy n = 7
0.49	0.46	0.15	0.07	0	0
[0.34; 0.66]	[0.33; 0.75]	[0.04; 0.17]	[0.04; 0.10]	[0; 0.04]	0; 0.01]

Already at a dosage of 15 Gy a significant reduction of the neointimal formation was found, from a surface dosage of 45 Gy on (equivalent to a dosage of 22.5 Gy in 0.5 mm depth) almost no proliferative response to the vessel injury could be detected any more.

In summary, the catheter-based brachytherapie with Rhenium-188 seems to be an effective therapeutical concept to prevent restenosis after balloon angioplasty. Further clinical studies are planed to investigate whether in patients a reduction of the restenosis rate can be achieved as well.

P2152 β-Particle emitting radioactive stent to prevent restenosis: final results of the Rotterdam contribution to the IRIS trial

A.J. Wardeh[1], I.P. Kay[1], M. Sabaté[1], A.L. Gijzel[1], W.J. van der Giessen[1], J.M.R. Ligthart[1], V.L.M.A. Coen[2], P.C. Levendag[2], A. den Boer[1], P.W. Serruys[1]. *Thoraxcenter, [1]Heart Center Rotterdam and Department of Radiotherapy; [2]Daniel den Hoed Cancer Center Rotterdam, Netherlands*

Introduction: The Isostents for Restenosis Intervention Study (IRIS) was a multicenter feasibility and safety trial of the radioactive Palmaz-Schatz and BX Isostent in single native coronary artery disease (lesion length max. 28 mm) with 6-month quantitative angiographic (QCA) and 12-month clinical follow-up.

Methods and study population: Phosphorus-32 (^{32}P), a pure β-emitter with a half-life of 14.3 days, was directly implanted into the metal surface of the stent. Activity was 0.75–1.5 μCi at stent implantation. After balloon predilatation an Isostent was implanted with a stent delivery system with integral sheath. A lucite shield is attached to the distal end of the stent delivery system to protect personnel against radiation. On-line QCA-measurements were done pre- and post-procedure and at 6-month follow-up. Thirty-one stents were implanted in 26 pts. The pts: 18 men, 8 women, average age 60 yrs (range: 43–74) had AP CCS 2 (n = 3), 3 (n = 10) or 4 (n = 13). RCA (n = 8), LAD (n = 12) or LCX (n = 6) were treated.

Results: Thirty of the 31 stents were successfully implanted. One stent was embolized without clinical sequelae. Twenty-two pts received 1, 4 received 2 Isostents and 5 pts received additional non-radioactive stents, because of dissection or due to the lack of a 2nd radioactive stent. All results are presented as mean ± SD. Lesion length: 13 ± 4 mm. For QCA results see Table.

Table. QCA results.

	Pre	Post	FU
RD (mm)	2.93 ± 0.47	3.31 ± 0.48	2.99 ± 0.54
MLD (mm)	0.87 ± 0.28	2.84 ± 0.35	1.85 ± 0.69
DS (%)	70 ± 9	15 ± 5	38 ± 20

DS = diameter stenosis; FU = 6-month follow-up; MLD = minimal lumen diameter; Pre = pre-procedure; Post = post-procedure; RD = reference diameter.

Twenty-three (88%) pts returned for angiographic FU. Restenosis rate was 17% and target vessel revascularization 13%. Late loss index was 0.53 ± 0.35. All pts returned for 6-month clinical follow-up: 81% were angina free with no deaths or myocardial infarctions.

Conclusions: This study reports that the implantation of a radioactive stent with an activity of 0.75 to 1.5 μCi is feasible and safe. Restenosis rate was 17%, which is comparable to conventional stent trials.

P2153 "Unwrapping the candy": does the choice of the size and length of the final balloon solve the problem of edge restenosis after radioactive β-particle emitting stents implantation?

R. Albiero, M. Adamian, N. Corvaja, T. Nishida, C. Briguori, M. Sallam, M. Vaghetti, A. Amato, C. Di Mario, A. Colombo. *Columbus Hospital, Milan, Italy*

We have previously reported that restenosis after implantation of ^{32}P radioactive stents with an initial activity level between 3 and 6 μCi in patients with CAD is mainly due to an increased late loss at the stent margins associated with minimal intimal hypeplasia inside the stent. We coined the term "candy wrapper" for this pattern of restenosis. Aim of this study was to analyze the influence on restenosis of the size and length of the final balloon used to dilate the stents.

Methods: We analyzed 54 lesions in which a single 15 mm long radioactive ^{32}P β-particle-emitting stent was implanted and in which an angiographic follow-up at 4–6 months was performed. The lesions were divided in four groups based on the vessel size and on the size and length of the final balloon used to dilate the stent.

Results: The table below shows the procedural and angiographic results analyzed.

Vessel size, mm	Large > 3.0	Large > 3.0	Small ≤ 3.0	Small ≤ 3.0
Balloon length/ Stent length ratio	≤1 (Short Ball)	>1 (Long Ball)	≤1 (Short Ball)	>1 (Long Ball)
Number of lesions	19	10	11	14
Ref. diam, mm	3.40 ± 0.27	3.50 ± 0.37	2.75 ± 0.22	2.68 ± 0.23
Balloon-to-artery ratio	1.12 ± 10	1.06 ± 0.6	1.32 ± 14	1.26 ± 14
Radioactivity, μCi	6.7 ± 4.0	5.1 ± 5.2	4.6 ± 3.4	5.2 ± 4.4
Restenosis (DS ≥ 50%)	3 (*15.8%*)	4 (*40.0%*)	7 (*63.6%*)	7 (*50.0%*)

Conclusion: A lower restenosis rate was observed in large vessels, in which a less aggressive dilatation strategy with a lower balloon-to-artery ratio was used, compared with small vessels. In addition, the strategy to use a final balloon shorter than the stent length resulted in a lower restenosis rare in large vessels but not in small vessels. The findings in small vessels could be the result of the first vessel injury caused by the balloon used to preditate the lesion, which is usually longer (20 mm long) than the stent length and oversized, and to the persistent aggressive strategy with a balloon-to-artery ratio > 1.25 in small vessels.

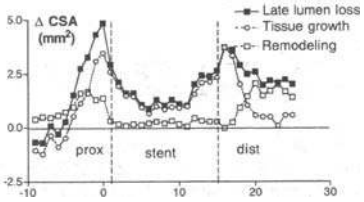
P2154 Radioactive ^{32}P β-particle emitting BX stent implantation in patients with coronary artery disease: a serial IVUS analysis of the "candy wrapper" pattern of restenosis

R. Albiero, M. Adamian, N. Corvaja, T. Nishida, C. Briguori, M. Sallam, M. Vaghetti, A. Amato, C. Di Mario, A. Colombo. *Columbus Hospital, Milan, Italy*

We have previously reported that restenosis after ^{32}P radioactive stent implantation in lesion of patients with CAD is higher than hystorical control lesions treated with non-radioactive stents due to an increased late loss at the stent margins associated with a dose related reduction in late loss inside the stent. We coined the term "candy wrapper" for this pattern of restenosis. Aim of this study was to analyze by serial IVUS measurements the mechanism of the "candy wrapper" pattern of restenosis

Methods: We studied 13 lesions with restenosis at 4–6 month FU after implantation of a single 15 mm long radioactive ^{32}P β-particle-emitting BX stent (Isostent) with an initial activity level between 3 and 12 μCi. IVUS imaging was performed using a motorized transducer pullback and quantitative IVUS analysis measuring stent/External Elastic Membrane (EEM) Cross Sectional Area (CSA), lumen CSA, and plaque CSA in slices analyzed 1 mm apart both inside the stent and in the proximal and distal reference segments. The following calculations were made: Remodeling = post-intervention (PI) EEM/stent CSA-FU EEM/stent CSA; Late lumen loss = PI lumen CSA-FU lumen CSA; Tissue growth (FU plaque CSA-PI plaque CSA).

Results: The graph below summarizes the results.



Conclusions: The Late lumen loss in the lesions with restenosis after ^{32}P radioactive stent implantation in the proximal and distal reference segments is mainly due to Tissue growth (intimal hyperplasia) in the first 2–3 mm and to Remodeling (shrinkage of the vessel) in the last 4–10 mm from the edges of the stent.

P2155 Reduced neointima formation and late lumen loss of stent-graft hybrid devices after irradiation of pig coronary arteries

S. Verheye, M.Y. Salame, N.A.F. Chronos, S.P. Mulkey, S.B. King III, K.A. Robinson. *Andreas Gruentzig Cardiovascular Center, Department of Medicine (Cardiology), Emory University School of Medicine, Atlanta GA, USA*

Background: Implantation of stent-graft hybrid devices (SG) to prevent plaque extrusion during stenting leads to neointima formation (NF) in pig coronary arteries. Endovascular irradiation (EI) prevents NF after coronary stenting. We therefore assessed the effects of EI in pig coronary arteries implanted with SG.

Methods: A SG was implanted in the LCX and RCA of pigs after overstretch balloon injury. Endovascular sites selected for SG received 30 Gy EI prior to implant. Controls were not irradiated. Quantitative coronary angiography (QCA) was done before and immediately after device implantation and at 28 days (harvest). Sections were prepared by saw-and-grinding after plastic embedding and measured by computer-assisted histomorphometry.

Results: Baseline QCA showed no difference in reference vessel diameter, balloon to artery ratio or post stent diameter between the two groups. QCA at follow-up showed that EI resulted in significantly less lumen loss in SG compared to controls.

QCA	SG	SG with EI	p-Value
Lumen Loss	2.5	0.79	<0.05

On histomorphometry, EI resulted in significantly less NF and a greater luminal area.

Histomorphometry	Luminal Area	Intimal Area	Vessel Area
Control SG	2.17 ± 0.86	6.58 ± 1.77	13.28 ± 8.84
SG with EI	5.37 ± 1.08	2.19 ± 1.00	10.87 ± 0.33
P-Value	0.003	0.008	NS

In non-irradiated SG, the neointima consisted of foreign-body response and organized thrombus close to the SG with adluminal smooth muscle cells and collagen matrix. The neointima in arteries with SG treated with EI was almost exclusively thrombus and foreign-body response.

Conclusions: The neointima in irradiated SG differs significantly both quantitatively and qualitatively compared to SG controls.

P2156 First report on safety and practicability of intracoronary radiation using a new monorail delivery system (Beta-RailTM)

S. Silber, N. Seidel, P. Rottkay, A. Schneider, A. Bauer. *Cardiology Dept., Dr. Mueller Hospital, Munich, Germany*

Beta or gamma radiation subsequent to coronary interventions is currently being applied as prophylaxis and/or therapy for (in-stent) restenosis. Possible safety risks during and shortly after administration may be a dissection, created by the 5F intracoronary catheter, longer periods of ischemia as well as inadvertent overdose. Further, delayed endothelialization can comprise an increased risk of acute/subacute stent thrombosis, which may possibly be avoided by extending administration of ticlopidine or clopidogrel. In a double-blind, placebo-controlled study, we are investigating the influence of a beta-emitting source train (ca. 42 mCi, Strontium/Yttrium-90, Novoste™) on restenosis following PTCA of de-novo lesions and restenoses. 40 patients have been thus far included with a single lesion and stable angina pectoris. Mean age was 60.5 ± 9 years, LV-EF was 61 ± 10%, reference diameter was 3.0 ± 0.6 mm; MLD before and directly after radiation was 0.6 ± 0.36 respectively 2.8 ± 0.4 mm. The dose for coronary vessels with a diameter of 2.7–3.35 mm is 14 Gy; for 3.36–4.0 mm is 18 Gy. Mean duration of radiation with 14 Gy was 173 ± 8 s (165–187 s) and 222 ± 12 s (212–240 s) with 18 Gy. The relatively bulky radiation catheter led neither to dissections nor to clinically relevant myocardial ischemia. Coronary overdose or a "getting stuck" of the radioactive pellets during passage of the inguinal region did not occur thanks to modifications required by the German authorities. In the 4-week period following radiation, coronary thromboses did not occur even after stent implantation. The added time needed for radiation after PTCA was ca. 18 ± 6 min.

Conclusions: Intracoronary brachytherapy with the new Beta-Rail™ catheter is safe. However, Ticlopidine may have to be routinely administered for 2 months after stent implantation and brachytherapy. Long-term results will be reported.

P2157 Intravascular radiotherapy with an yttrium-90 wire in a normolipidaemic rabbit restenosis model: influence on neointimal growth and vascular remodelling

Paul Wexberg, Ulrike Windberger[1], Robert Ullrich[2], Kurt Huber, Heinz Sochor, Dietmar Glogar, Peter Probst, Franz Weidinger[3], Gerald Maurer, Michael Gottsauner-Wolf. *Clinic of Internal Medicine II, Dept. of Cardiology; [1]Center for Biomedical Research; [2]Clinical Dept. of Pathology, Univ. of Vienna; [3]Clinic for Internal Medicine, Univ. of Innsbruck, Austria*

Intravascular radiotherapy (IVRT) has been shown to inhibit neointimal formation, a major mechanism of restenosis after balloon injury in various animal models. First data of clinical trials suggest also an efficacy in reducing restenosis in humans. However, the effect of radiation on vascular remodeling is still not completely elucidated. Studies on external high dose irradiation report media fibrosis and consecutive shrinkage, but recently also an increase in vessel size has been described. Therefore, the aim of this study was not only to assess the degree of neointimal formation, but also the vessel perimeter after beta-irradiation post injury.

Methods: Eighteen normolipidemic rabbits underwent balloon injury with a 3.0-mm balloon in both iliac arteries. One artery in each animal was randomly assigned for subsequent IVRT. The prescribed doses were 15 Gy (10 arteries) and 30 Gy (8 arteries) at 1 mm from the surface of the source, respectively. Four weeks later the animals were sacrificed, and the arteries were analyzed. Degree of neointimal formation was expressed as intima to media-ratio, and we measured the length of the external elastic lamina (EEL) to dermine vascular remodeling.

Results: IVRT reduced intima to media-ratio by 57.4% (p = 0.001) in the 15 Gy group and by 71.4% (p = 0.002) in the 30 Gy group. Whereas neointimal proliferation could thus be significantly reduced, EEL length (mm) did not differ between groups (15 Gy: 6.24 ± 0.94, 30 Gy: 6.34 ± 0.61, Control: 6.44 ± 0.61, p = n.s.). Similarly, arithmetically reconstructed circular vessel area (mm^2) did not alter significantly (15 Gy: 3.10 ± 0.07, 30 Gy: 3.20 ± 0.03, Control: 3.30 ± 0.03, p = n.s.). Thus, the total vessel dimensions were not affected by irradiation. There was no evidence of media or adventitia fibrosis in the irradiated arteries.

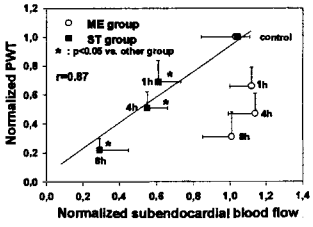
Conclusion: Our data suggest that the predominant effect of intravascular irradiation is rather inhibition of neointimal growth than a favourable influence on vascular remodeling.

CORONARY CIRCULATION: EXPERIMENTS

P2158 Loss of perfusion-contraction matching with coronary microvascular obstruction

H. Dörge, M. Behrends, T. Neumann, R. Schulz, S. Belosjorow, A. Skyschally, R. Erbel[1], G. Heusch. *[1]Departments of Pathophysiology and Cardiology; University of Essen, Germany Medical School*

A close relationship between regional myocardial blood flow and function during acute epicardial coronary inflow restriction is well established (perfusion-contraction matching). It is unclear, whether such relationship exists also with coronary microvascular obstruction. Therefore, we compared the effects of coronary microembolization (ME) to those of an epicardial coronary stenosis (ST) on the relationship between regional myocardial blood flow and function in anesthetized dogs. The left circumflex coronary artery (LCx) was cannulated and perfused from an extracorporeal circuit. Systemic hemodynamics (micromanometer), regional myocardial blood flow (colored microspheres) and posterior systolic wall thickening (PWT, sonomicrometry) were measured under control conditions and after 1, 4 and 8 h. After control measurements, 3.000/ml microspheres with a diameter of 42 μm were injected into the LCx in the ME group (n = 6). With constant systemic hemodynamics, PWT declined over time whereas subendocardial blood flow did not. In the ST group (n = 6), inflow was progressively reduced to match PWT to that of the ME group at 1, 4 and 8 h. Subendocardial blood flow in the ST group was reduced in proportion to PWT. Infarct size (TTC, histology) was not different between groups (6.4 ± 5.5% (SD) of the area at risk in ME vs. 4.6 ± 4.7% in ST) and could not account for the observed dysfunction.



Apparently, microvascular obstruction, such as occurs after spontaneous or therapeutic plaque rupture, results in greater functional impairment than an epicardial coronary stenosis.

P2159 Arterial ATP-sensitive K-channels: evidence for preferential regulation by glycolysis

H. Köppel[1], E. Kickenweiz[1], E. Pilger[1], W. Klein[1], H. Brussee[1], S. Holzmann[2], R. Gasser[1]. [1]*Dept. of Medicine;* [2]*Inst. of Pharmacology and Toxicology, University of Graz, Austria*

In earlier experiments it has been shown, that key glycolytic enzymes are associated with gating properties cardiac ATP-sensitive K-channel (J Gen Physiol 94, 911–935, 1989). In the present experiments, we use bovine and pig coronary artery strips and normal Tyrode at pH 7.4 and 27°C (for meth. details see our earlier work Arch Pharmacol 310, 129–138, 1979)

Here we show that *inhibition of oxidative phosphorylation* by *dinitrophenol* (DNP; 1 mM) led to a relaxation of pre-contracted (26.8 mM KCl) bovine coronary arteries by 58% ± 2% (± SEM; n = 16), which could be reduced to 38 ± 2% and 32% ± 2% respectively by 2 μM and 20 μM glibenclamide (± SEM; n = 8; p < 0.01). Quantitatively similar results we obtained *under hypoxic conditions* (O_2 *exchanged to* N_2 in the perfusate).

Under competitive *inhibition of glycolysis* by *iodoacetic acid* (IAA; 0.5 mM) pre-contracted bovine arteries (26.8 mM KCl) relaxed by 98% ± 1%. Relaxation could **not** be inhibited by 2 μM, 20 μM or 200 μM glibenclamide (98% ± 2%; ± SEM; n = 8). Quantitatively similar results we obtained from pig coronary arteries.

In conclusion, our results show, that glibenclamide can inhibit coronary artery dilation induced by hypoxia and blockade of oxidative phosphorylation, whereas coronary dilation secondary to inhibition of glycolysis can not be prevented by glibenclamide. This observation indicates that *key glycolytic enzymes are associated with cardiac* K_{ATP}*-channels* and under conditions in which intracellular competition for ATP is high (hypoxia/ischemia), that act as a preferential source of ATP for these channels *in arterial smooth muscle* cells.

P2160 Maintenance of coronary reactivity to adventitial cholinergic stimulation in epicardial arteries submitted to ischaemia-reperfusion

A. Rodríguez-Sinovas, J. Cinca, M. Tresànchez, J. Soler-Soler. *Cardiology Service, University Hospital Vall d'Hebron, Barcelona, Spain*

Epicardial coronary arteries submitted to ischaemia-reperfusion may develop an abnormal response to autonomic nervous discharge. However, this hypothesis has not been proven.

Methods. Left ventricular (LV) pressure, LV dP/dt, regional myocardial shortening, aortic blood flow, and coronary blood flow (CBF) at the left anterior descending (LAD) coronary artery were analyzed during pericoronary muscarinic stimulation of the LAD with topical methacholine in 11 α-chloralose anaesthetized pigs (30–40 kg). Methacholine was applied before and after a 2 h of LAD occlusion followed by 45 min of reperfusion. Changes induced by the two applications were compared by the ANOVA test.

Results. Methacholine induced a significant (p < 0.01) drop in CBF (9.6 ± 4.9 vs 2.5 ± 3.3 mL/min) followed by an hyperemic reaction (13.1 ± 8.9 mL/min). These changes were accompanied by a significant (p < 0.01) fall in LV pressure (90 ± 12 vs 79 ± 11 mmHg) and LV (+)dP/dt (1909 ± 466 vs 1388 ± 388 mmHg/s), and by a reduction (p < 0.001) in systolic segment shortening in the LAD perfused area (0.23 ± 0.05 vs 0.05 ± 0.09). Aortic blood flow was not modified during methacholine application. Application of methacholine after ischaemia-reperfusion induced a significant fall in CBF (66%) with no significant hyperemic reaction. The drop in LV pressure and LV dP/dt was comparable to baseline methacholine application.

Conclusions. Epicardial coronary arteries submitted to ischaemia and reperfusion mantain their ability to constrict under parasympathetic stimulation. Attenuation of the hyperemic reaction suggests an associated endothelial damage.

P2161 Coronary arteries from castrated rats are more sensitive to the vasodilatory action of testosterone than those from sham operated controls

K.M. English, R.D. Jones[1], R.P. Steeds, A.H. Morice[1], K.S. Channer. *Cardiology Dept, Royal Hallamshire Hospital, Sheffield;* [1]*Department of Medicine, University of Hull, Hull, UK*

Introduction: Testosterone improves angina threshold in men and acts as a potent vasodilator in animal models in-vivo and in-vitro. Purpose: This study was performed to examine the effects of androgen depletion on the vasodilatory properties of testosterone on isolated rat coronary arteries.

Methods: Male, litter mate, Wistar rats were castrated or sham operated at 4 weeks of age (pre-pubertal). These animals were killed by chloroform anaesthesia 6–8 weeks after castration (post-pubertal). Hearts were rapidly removed and left anterior descending coronary arteries dissected free from surrounding connective tissue and myocardium. Vessels were cut into 2.3 mm lengths and mounted in a wire myograph (Cambustion UK Ltd). Vessels were pre-tensioned to 100 mmHg, bathed in physiologic saline solution, bubbled with 95%O_2/5%CO_2, and active tension recordings made. Vessels were maximally pre-constricted with 100 micromolar PGF2alpha. Dose response curves were constructed to 1 micromolar-3 millimolar of testosterone (dissolved in water).

Results: Coronary arteries from castrated animals were more sensitive to the vasodilatory effects of testosterone than those from sham operated controls. This effect was more marked at lower concentrations. Castrate vs sham (n = 15 in each group), mean (SE) EC10 (dose required to produce 10% of maximal dilatation); 24.7 (7.2) micromoles vs 41.1 (6.9) micromoles, P = 0.019: EC20; 48.9 (10.3) vs 71.6 (9.4) micromoles P = 0.016: EC 50; 204.6 (30.1) vs 275.2 (36.5) micromoles, P = 0.093. (all P values by Mann Whitney U test.)

Conclusion: Androgen depletion leads to an increase in sensitivity to the vasodilatory effect of testosterone on rat coronary arteries.

P2162 Elderly rats are less sensitive to the coronary vasodilatory effects of testosterone than young animals

K.M. English, R.D. Jones[1], R.P. Steeds, A.H. Morice[1], K.S. Channer. *Cardiology Dept, Royal Hallamshire Hospital, Sheffield;* [1]*Department of Medicine, University of Hull, Hull, UK*

Introduction: Ageing may have adverse effects on coronary vascular reactivity due to atheroma development, endothelial dysfunction and changes in receptor density. Ageing is also associated with reduced levels of testosterone which acts as a potent vasodilator of rat coronary arteries in-vitro.

Purpose: This study was performed to examine the influence of ageing on the vasodilatory effects of testosterone.

Methods: A group of two year old, male, Wistar rats were compared with animals from the same breeding colony at 14 weeks of age. Animals were killed by cervical dislocation and the hearts rapidly removed. Left anterior descending coronary arteries were dissected free from surrounding connective tissue and myocardium, cut into 2.3 mm lengths, and mounted in a wire myograph. (Cambustion Ltd, UK) The vessels were bathed in physiologic saline solution, and bubbled with 95%O_2/5%CO_2. Vessels were pre-tensioned to 100 mmHg and active tension recordings made. Vessels were maximally pre-constricted with 100 μM Prostaglandin F 2 alpha, and dose response curves to 1 μM–1 mM of testosterone (dissolved in water) were constructed

Results: Mean% dilatation (SEM) elderly vs young, was lower in the vessels from elderly animals, at all doses; 1 μM; +5.4 (1.9) vs −1.1(1.9) P = 0.012, 3 μM; +6.0(1.8) vs −1.9(1.6) P = 0.007, 10 μM; +2.8(2.2) vs −7.2(2.1) P = 0.007, 30 μM; −5.2(3.4) vs −19.6(3.9) P = 0.015, 100 μM; −29.9(5.7) vs −43.6(5.5) P = 0.06, 300 μM; −64.3(10.5) vs −74.9(4.5) P = 0.016, 1 milliM; −83.5(6.2) vs −100.8(6.1) P = 0.054.

Conclusion: Coronary arteries from elderly rats are significantly less sensitive to the vasodilatory effect of testosterone than those from younger animals.

P2163 17β-Oestradiol induces vasodilation in human coronary resistance arteries in vitro

K. Takahashi, M. Ohyanagi, K. Ikeoka, S. Kobayashi, J. Tateishi, T. Iwasaki. *Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan*

Estrogen directly induces vasodilation in the human coronary circulation. However, few studies have examined the effect that estrogen has on resistance coronary arterioles (CRA), and the mechanisms responsible for estrogen-induced vasodilation are poorly understood. The present study investigated the effect of 17 β-estradiol on endothelium-dependent and independent dilation of CRA *in vitro.*

Methods and Results. CRA (diameter: 79 ± 10 μ m) were isolated from the right atrial appendages of 20 patients [13 men and 7 postmenopausal women (mean postmenopausal interval: 10.7 years)] who underwent coronary bypass surgery. CRA were double-cannulated with glass micropipets and pressurized (40 mm Hg) in a no flow state. Concentration-response curves (CRC) for acetylcholine, substance P, and calcium were obtained before and 60 minutes after 17 β-estradiol (10^{-6} M) administration. Estrogen caused vessels to relax by 13 ± 4% of the control diameter. There were no differences in the responses to the agents between arterioles from male and female patients. The CRC of acetylcholine and substance P were not affected by 17 β-estradiol, however the CRC of calcium was shifted to the right by 17 β-estradiol. Estrogen receptors were not identified by immunohistochemical staining.

Conclusions. Estrogen affects vascular smooth muscle, and arterioles dilation is not mediated by nuclear estrogen receptors in human coronary resistance arterioles.

P2164 The migration of vacular smooth muscle cells in vitro is inhibited by abciximab via the avb3 integrin: a possible explanation for the inhibition of restenosis

J.H. Baron, E.P. Moiseeva, M.A. Azrin[1], M.D. Ezekowitz[2], D.P. de Bono, A.H. Gershlick. *Division of Cardiology, University of Leicester, Leicester, UK; [1]University of Connecticut, Connecticut; [2]University of Yale, Yale, USA*

Brief i.v. administration of abciximab during angioplasty reduces revascularisation and coronary events long-term. Abciximab cross-reacts with the avb3 integrin on smooth muscle cells (SMCs). This integrin is upregulated following vascular injury, and is involved in cell migration, an important step in neointimal formation. Osteopontin (Opn) and vitronectin (Vn) are ligands for this integrin, and are present in injured vessels at increased concentrations.

Methods: Human vascular SMCs grown from primary explants were resuspended in DMEM+0.2% BSA. Their expression of avb3 was assessed by immunoprecipitation. Antibodies (c7E3, LM609 (anti-avb3) or control, 10 μg/ml) were placed in the upper chamber of a micro-Boydens chamber. The lower well contained DMEM ± Opn or Vn (20 microg/ml), or PDGF (10 ng/ml). The chambers were incubated at 6 hours at 37oC. The membrane was fixed, and cells on the upper surface were gently removed. Those on the lower surface were stained with prodidium iodide (20 microg/ml containing RNase 0.2 mg/ml). The number of cells per 5 high power fields was counted using a fluorescent microscope. The experiments were performed in triplicate.

Results: Vn and PDGF increased the migration of cells, whether they expressed avb3(avb3+) or not (avb3-). Opn only increased the migration of avb3+ cells. Migration of avb3- cells was not influenced by LM609 or c7E3. c7E3 inhibited migration of avb3+ cells to Vn by 39.2 ± 9.4% ($p < 0.0001$), to Opn by 70.9 ± 12.0% ($p < 0.001$) and to PDGF by 12.8 ± 10.7% ($p = 0.005$). LM609 also inhibited their migration, and there were no significant differences between the effects of LM609 and c7E3.

Conclusions: c7E3 and LM609 inhibit the migration of SMCs to a similar degree. The migration of SMCs not expressing avb3 was not affected by these antibodies, but these cells could still migrate to Vn and PDGF, implying other pathways are also involved.

P2165 Local delivery of antisence phosphorodiamidate compound – Restin-NG inhibits myointimal hyperplasia following balloon angioplasty

N. Kipshidze, V. Skrinska[1], E. Keane, P. Chawla, P. Iverson[2]. *Cardiovascular Medicine Dept, Medical College of Wisconsin, Milwaukee WI; [1]University of Wisconsin-Milwaukee, Milwaukee WI; [2]AVI Biopharma, Portland OR, USA*

Myointimal hyperplasia following percutaneous transluminal coronary angioplasty (PTCA) is a key component of the process of restenosis. The c-myc is a critical cell division cycle protein involved in the formation of neointima. We evaluated the long term impact of local delivery of Restin-NG upon myointimal hyperplasia following PTCA in a rabbit model. Twenty New Zealand white rabbits were anesthetized, transport catheter inserted in the iliac artery, and PTCA performed (8 atm for 30-seconds, three times; endoluminal delivery of saline (n = 10) or 500 mg. Restin-NG (n+10) to the PCTA site was at 2 atm via the outer balloon for two minutes. The diet was supplemented with 0.25% cholesterol for ten days before and sixty days after following treatment. Angiography was performed at harvest and vessels were fixed in formalin, processed and stained with Hematoxylin and Eosin, Movat's, smooth muscle cell actin and for PCNA. The area of intima and media was determined by planimetry. Data shown are mean area ± SD at sixty days.

	Control	Antisence	p value
Lumen (mm^2)	0.40 ± 0.11	1.32 ± 0.41	<0.05
Intima (mm^2)	1.43 ± 0.25	0.63 ± 0.36	<0.05

Histological analysis revealed that local delivery of antisence prevented balloon induced changes. We conclude that local delivery of Resting-NG inhibited myointimal hyperplasia following PTCA in a rabbit for up to 60 days.

P2166 Inhibition of vascular smooth muscle cell proliferation by adenovirus-mediated nitric oxide synthase gene transfer and biochemical characterization of the recombinant enzyme

W. Poller, A. Frey[1], S. Schneider-Rasp[2], J. Yu[3], M. Paul[3], H. Schmidt[1]. *Cardiology and Pneumology Dept., University Hospital Benjamin Franklin, Berlin; [1]Institute of Pharmacology & Toxicology, University of Würzburg, Würzburg[2] Institute of Biochemistry & Pathobioch, University of Würzburg Medical School, Würzburg[3] Institute of Clinical Pharmacology, University Hospital Benjamin Franklin, Berlin, Germany*

Background: Nitric oxide (NO) is synthesized in vascular endothelial cells by NO synthase isoform NOS-III. Experimental gene therapy using recombinant NOS (recNOS) has been applied to correct vascular pathology (e.g. restenosis), but full biochemical characterizations of the recombinant enzymes have not been published. However, many biochemical aspects of recNOS function and regulation are essential to assess its therapeutic potential and possible side effects. We report here a complete biochemical study of a recNOS-III expressed from an adenoviral vector.

Methods: Development of vector Ad5CMVNOS-III was done as described (PNAS 1998;95:9003). Targets were human endothelial (HUVEC) and vascular smooth (HUVSMC) cells from human umbilical veins. Biochemical NOS characterization followed published protocols.

Results: (1) Among 7 recombinant vector clones only one was fully functional, the others carried deletions. (2) The vector provided a gene transfer rate of >95% of target cells. (3) Immunoprecipitation showed a membrane-targeted recNOS-III protein of size 130 kDa with >85% of NOS activity localized in the membrane. (4) NOS activity reached a maximum on day 3, then decayed below the detection limit by day 15. (5) RecNOS-III was strongly dependent on Ca^{2+} (6.5% activity without), NADPH (inactive without), tetrahydrobiopterin (37% without), and flavins (65% without). (6) The influence of Ad5CMVNOS-III on cell proliferation is summarized in the table.

NOS-III gene transfer

Ad5CMVNOS-III	HUVEC	HUVSMC
–	100%	100%
+	−54 ± 7%	−34 ± 5%

Inhibition of human vascular cell proliferation by NOS-III gene transfer using the adenoviral vector Ad5CMVNOS-III

Conclusions: (a) The high rate of dysfunctional NOS-III vector mutants is very unusual (we have never seen it among 30 other transgenes cloned in this system) and could be a consequence of disturbance of the vector cloning procedure by recNOS expression itself, emphasizing the need for full characterization of NOS vectors. (b) Clone Ad5CMVNOS-III showed "physiological" regulation and co-factor dependency so that serious side effects are less likely. (c) Vector expression is self-limiting (<2 weeks) so that its strong antiproliferative effect should also be confined to this time interval.

P2167 Evaluation of the effect of oversizing on vascular injury, thrombogenicity and neointimal hyperplasia using the Magic Wallstent™ in a porcine coronary model

I. De Scheerder, L.H. Yanming, Q. Bei Ping, M. Szilard, Xiaoshun, E. Verbeken, F. Van de Werf. *University Hospitals Leuven, Belgium*

Oversizing of a self-expandable coronary stent results in a continuous pressure on the stented vessel wall and has been considered as a continuous stimulator for neointimal growth.

Methods: Magic Wallstents (Schneider, Bulach) with a length of 24 mm were randomly implanted with either an oversizing of ± 50% (n = 28), or an oversizing of ± 100% (n = 28) in two coronaries of 28 crossbred pigs (weight 20–25 kg). The pigs underwent a control angiogram and were subsequently sacrificed at day 3 (n = 4), day 7 (n = 4), day 14 (n = 6), day 42 (n = 10) and day 84 (n = 4). Quantitative coronary analysis before, immediately after stent implantation and before sacrifice was performed using the semi-automated Polytron 1000® system. Morphometry was performed using a computerized morphometric program.

Results: Histopathology showed significantly more perivasculitis in the high oversizing group (1.08 ± 0.17 vs. 0.92 ± 0.16, $p < 0.02$). Morphometry showed a similar lumen area at day 3 and 7. At day 14 the lumen area in the high oversizing group was significantly smaller compared to the low oversizing group (4.70 ± 0.56 vs. 5.70 ± 0.64 mm^2, $p = 0.016$). At day 42 and 84, however, this difference became insignificant.

Neointimal hyperplasia was also significantly more pronounced at day 14 in the high oversizing group (1.94 ± 0.64 vs. 1.04 ± 0.66 mm^2, $p < 0.037$). At later follow-up neointimal hyperplasia remained increased at a non-significant level in the high oversizing group.

Conclusion: This study suggests that high oversizing results in an early neointimal overresponse, most probably induced by the higher vessel stretch, resulting in more perivasculitis and subsequently more neointimal hyperplasia. At longer follow-up, however, this continuous vessel overstretching did not result in a significantly more pronounced neointimal hyperplasia.

P2168 Evaluation of continuous oral or intravenous administration of beta-cyclodextrin tetradecasulfate (CDT) for the treatment of neointimal formation after angioplasty in normocholesterolemic swine

N. Meneveau, B. Klugherz[1], B. Chaquour[1], V. Anand[1], J.E. Tomaszewski[1], M. Joullié[1], E. Macarak[1], P.E. Weisz[1], R. Wilensky[1]. *Department of Cardiology, University Hospital Saint-Jacques, Besançon, France[1] Hospital of University of Pennsylvania, Philadelphia PA, USA*

Beta-cyclodextrin tetradecasulfate (CDT), a cyclic polysaccharide capable of binding basic fibroblast growth factors, inhibits smooth muscle cell proliferation and reduces intimal hyperplasia in small animal models. We hypothesised that CDT would attenuate neointima formation after balloon overstretch injury. CDT was started 2 days before coronary injury and continued until sacrifice, 14 days after angioplasty. 38 pigs were randomized into one of 3 groups: 1) Control, 2) Oral (300 mg CDT/kg/d) or 3) IV infusion (100 mg/kg/d given continuously through a jugular venous catheter connected to a peristaltic pump). Vessels were evaluated for the maximal intimal thickness (MIT) and the intimal area (IA) which was normalised to the injury index (II). 9 additional animals (6 arteries per group) were sacrificed at 5 days to determine cellular proliferation (medial cells exhibiting the proliferating cell nuclear antigen) and the extent of mural thrombus. (Morphometric analysis: see Table)

CDT also reduced cellular proliferation (Control 55 ± 18%, Oral 35 ± 7%, p = 0.03, IV 30 ± 12%, p = 0.01) and mural thrombus formation (Control 0.84 ± 0.4 mm^2, Oral 0.44 ± 0.14 mm^2, p = 0.04, IV 0.42 ± 0.09 mm^2, p = 0.03). Factor Xa inhibition as well as the activated clotting time were increased following IV administration.

Morphometric analysis

	Control (n = 22)	Oral (n = 22)	IV (n = 22)
MIT (mm)	0.42 ± 0.11	0.34 ± 0.15	0.29 ± 0.10‡
II	0.20 ± 0.06	0.21 ± 0.11	0.26 ± 0.13
IA/II (mm^2)	3.03 ± 0.75	2.31 ± 0.83*	1.67 ± 0.73‡

Mean ± SD; *p = 0.004 vs control; †p = 0.06; #p < 10^{-5} vs control.

Conclusion: Continuous oral administration and IV infusion of CDT reduces intimal hyperplasia significantly by 24% and 48% respectively. Reduction of cellular proliferation and mural thrombus formation and/or decreased factor Xa activity may be mechanisms by which CDT inhibits intimal hyperplasia.

P2169 Gene transfer in coronary arteries of a porcine animal model: comparison of three-vector systems

U. Sendler[1], C. Valina[1], P. Sack[1], K.L. Laugwitz[1], J. Kleinschmidt[2], F.J. Neumann[1]. *[1]Deutsches Herzzentrum München, Munich; I. Med. Klinik der Technischen Universität München, Munich; [2]Inst. für Angewandte Virologie des Deutschen Krebsforschungszentrums, Heidelberg, Germany*

To establish an animal model for vascular gene therapy we compared three different vector systems with LacZ as reportergene in a porcine model. We constructed an adenovirus and an adeno-associated virus containing the LacZ gene, and compared these two viral vectors with liposomal gene transfer in their expression efficacy, onset of expression and localisation of β-galactosidase activity after local delivery.

Application was performed with a microporous balloon (3 atm) and dwell time of 2–3 min with or without prior overstretch (10 atm). Adenovirus-mediated gene transfer (10^{11} pfu/ml) resulted in protein expression in the endothelial cell layer. With the lamina elastica interna as natural barrier, we found no gene expression in the media but in theadjacent myocardium. Adeno-associated virus as vector (10^8 tp/ml) led to a very low expression in the myocardium, no protein expression could be detected in the media. Liposomal gene transfer resulted in a low gene expression in the media of the coronary arteries.

With adenoviral gene transfer and adeno-associated virus as vector high expression (>90% of transfected cells) could be obtained in cultures of endothelial cell culture and smooth muscle cells, liposomal gene transfer only led to 5% of transfected cells. Expression efficacies results in cell culture can not predict the efficacy of vascular gene transfer in the intact animal. None of the vectors investigated in this study, yielded vascular gene transfer with the microporous balloon which appears appropriate for gene therapy of restenosis in an animal model. Neither adeno-associated virus, which theoretically seems to have advantages compared to other vector systems, nor adenovirus of this generation, nor liposomal gene transfer seem to be an appropriate system for catheter-mediated gene therapy of neointimal proliferation in coronary arteries after angioplasty.

P2170 Oral matrix metalloproteinase inhibition following balloon angioplasty in a non-atherosclerotic pig model

M.J. Sierevogel, G. Pasterkamp, E. Velema, D.P.V. de Kleijn, B.J.G.L. de Smet, P.P.T. de Jaegere, C. Borst. *Experimental Cardiology Dept., Utrecht University Medical Center, Utrecht, Netherlands*

Background: Previously, we demonstrated in an atherosclerotic model that inhibition of Matrix Metalloproteinases (MMPs) by intraperitoneal injection of Batimastat significantly reduced late lumen loss by inhibition of constrictive arterial remodeling. In the present study, the effect of an orally administered, clinically applicable, MMP-inhibitor, Marimastat, was tested in a non-atherosclerotic pig model.

Methods: Balloon angioplasty was performed in 33 femoral and internal iliac arteries in 11 pigs. Pigs were randomly divided into 4 groups: 1 control group (n = 6 vessels) and 3 groups in which Marimastat was administered for 2 weeks (n = 10 vessels), 4 weeks (n = 7 vessels) and 6 weeks (n = 10 vessels) respectively. Marimastat treatment was started one day prior to the intervention. Pigs were terminated 42 days after intervention. 30 MHz intravascular ultrasound was performed at all time-points. Data of the different Marimastat groups were pooled since no significant differences were observed among the groups.

Definitions: Late lumen loss = lumen post intervention–lumen at follow up, late vessel area loss = measure of remodeling: vessel area post intervention – at follow up, intimal hyperplasia (IH) = vessel area–lumen area at follow up.

Results: See table. Values are in mm^2, mean ± sd, *p < 0.001

MMP-inhibition and late lumen loss

	Lumen control	Vessel area control	Lumen marimastat	Vessel area marimastat
Pre	11.52 ± 4.18	11.52 ± 4.18	9.60 ± 4.50	9.60 ± 4.50
Post	18.89 ± 8.04	18.89 ± 8.04	14.40 ± 5.27	14.40 ± 5.27
Follow up	9.34 ± 3.16	11.60 ± 3.73	12.70 ± 5.69	15.60 ± 6.63
Late loss	9.55 ± 5.34	7.29 ± 5.23	1.70 ± 3.24*	−1.20 ± 3.37*
IH	2.26 ± 1.52		2.90 ± 2.26	

Conclusions: 1) Oral MMP inhibition by Marimastat reduces late lumen loss after balloon angioplasty 2) The reduction in late lumen loss is the result of blocking of constrictive remodeling by the MMP- inhibitor. Intimal hyperplasia is not inhibited.

P2171 Gender differences in isoproterenol induced myocardial hypertrophy in the rat

R. Maestri, R. Pacchiana, D. Corradi, G. Graiani, N. Bertani, E. Cigola, F. Quaini, G. Olivetti. *Pathology Dept., University Medical School of Parma, Parma, Italy*

Although several investigations confirmed that isoproterenol administration induced myocardial hypertrophy and damage in rats no data are available on the existence of a gender dependent effect. We tested the hypothesis that the response of the heart to 30 mg/kg of isoproterenol may differ in magnitude between males (M) and females (F). To this purpose 20 M and 16 F 2 months old rats, were injected for 3 consecutive days with 10 mg/kg and sacrificed the following day. Age and sex matched sham-operated rats (7 M and 8 F) were injected with vehicle. Additionally, the day before sacrifice all the animals were injected ip with bromodeoxyuridine (BrdU) (50 mg/kg). To test the influences of sex hormones the same treatment was performed in 7 M and 10 F castrated rats, fifteen days after surgery. After body weight determination, hearts were arrested in diastole with cadmium chloride and the weight of the right (RV) and left ventricle (LV) inclusive of the septum separately measured. A transverse slice of the ventricles was embedded in paraffin and 5 mm thick sections were obtained and stained with trichrome to measure morphometrically the amount of myocardial damage. Monoclonal antibody to BrdU was used to document DNA synthesis and in situ terminal deoxynucleotidyl transferase assay to detect apoptotic myocyte cell death on myocardial sections. In M, isoproterenol treatment induced a 36% (p < 0.0001) cardiac growth, 40% (p < 0.0001) in the LV and 23% (p < 0.001) in the RV. In F, the same treatment induced only a 24% (p < 0.0001) cardiac hypertrophy, 25% (p < 0.0001) in the LV and 20% (p < 0.005) in the RV. Interestingly, LV growth was enhanced following removal of sexual organs. In M LV hypertrophy was 50% (p < 0.0002), whereas in F was 37% (p < 0.0001). The amount of reparative tissue was similar among all groups of treated rats averaging less than 4% in the LV and 2% in the RV (ranging from 1 to 9%). These values were always higher than in untreated controls (p < 0.001). Myocardial damage was associated with apoptotic myocyte cell death detected in 98 myocyte nuclei/1000000 nuclei in M and 47 nuclei/1000000 nuclei in F. BrdU labeling was seen in 400 nuclei/1000000 nuclei in the LV of M rats and in 900/1000000 myocyte nuclei in F. Similar values were detected in castrated rats. In conclusion, beta adrenergic stimulation causes myocardial hypertrophy and damage with DNA synthesis and apoptosis in myocyte. The growth response of M heart is enhanced with respect to F and the absence of sexual hormones increases LV hypertrophy in both sexes.

P2172 Assessment of fractal dimension of regional myocardial blood flow heterogeneity of isolated rat heart by magnetic resonance imaging under various flow conditions

P. Galuppo, J. Köpke[1], K.-H. Hiller[2], A. Haase[2], G. Ertl[3], W.R. Bauer. *II. Medizinische Universitätsklinik Mannheim, Heidelberg; [1]Institut für Klinische Radiologie Universitätsklinik Mannheim, Heidelberg; [2]Physikalishes Institut Univertisät Würzburg, Würzburg; [3]Medizinische Universitätsklinik Würzburg, Würzburg, Germany*

Fractal dimension (D) of regional myocardial blood flow heterogeneity in the heart is usually evaluated using tracer microsphere technique. The aim of our study was to develop a method for the assessment of D with a high spatial resolution in isolated rat heart. We used our previously described NMR technique which determines alterations of perfusion without contrast agent from changes of 1/T1.

Methods: Five isolated rat hearts were studied (perfusion in the Langendorff mode, constant pressure of perfusion) in a 11.75 T Bruker system. Spins of one slice (2 mm thickness, short axis view) 4–6 mm below the valvular plane were inverted by an adiabatic 180° pulse. T1 maps were gained in this slice by 16 × Snapshot FLASH images (spatial resolution 140 μm in plane, TR = 3.6 ms) under different flow conditions in the range 5.4–20.0 ml/min. Local and global 1/T1 of the slice was considered as a function of flow. Fractal analysis was performed on 1/T1 maps inside 4–7 non-overlapping squares of 16 × 16 pixels (= 256 voxels) in the left ventricular myocardium.

Results: We observed that the relative dispersion (RD) of spatial distribution of flows is well described by the power law RD (N) = RD (N = 1) N^{D-1} where N is the number of voxels, RD (N = 1) is the intercept obtained by extrapolating to one voxel. The mean correlation coefficient was 0.95. D was in the range 1.096–1.205 and regression analysis D vs. mean perfusion revealed a negative relationship (mean R = −0.763, slope = −0.005 g min/ml, $P < 0.05$).

Conclusion: High resolution analysis of myocardial blood flow heterogeneity by NM imaging is feasible. These results indicate that the fractal behaviour of myocardial blood flow holds up to very low spatial dimensions and that D exhibits only a moderate dependence on flow.

P2173 Coronary vasodilation in microvascular beds by α_2-adrenergic stimulation in dogs with pacing-induced heart failure

Kazuaki Tamagawa, Tomiyoshi Saito, Yuji Oikawa, Kazuhira Maehara, Yukio Maruyama. *First Department of Internal Medicine, Fukushima Medical University, Fukushima, Japan*

Background: It remains unknown how alpha-2 (α_2) receptor pathway in coronary microvascular beds is modulated in heart failure. We investigated the role of α_2 receptor pathway using coronary pressure-flow relationship (PF-R) during long diastole in rapid pacing-induced heart failure model.

Methods: In 18 dogs, a Doppler flow probe was placed around the left anterior descending (LAD) coronary artery, and atrio-ventricular node was completely blocked by injecting formaldehyde. PF-R was obtained by temporary cessation of ventricular pacing before and after rapid ventricular pacing at 240 bpm for 3 weeks, in which states hemodynamic study was also done. The slope of PF-R was evaluated as an index of coronary vascular resistance. Yohimbine (30 μg/kg) was administered into LAD for α_2-blockade. Propranorol (50 μg/kg), bunazosine (20 μg/kg) and norepinephrine (NE, 0.05 μg/kg) were injected to stimulate α_2-adrenergic receptor.

Results: After rapid pacing, heart failure was produced, but the slope of PF-R (1.46 ± 0.2 ml/min/100 g-LV/mm Hg) was not different from just before rapid pacing (1.23 ± 0.1, N.S.). α_2-blockade did not change the slope at both baseline state and heart failure state. On the other hand, α_2-stimulation significantly increased the slope only in failing state and this increase was abolished by N^G-nitro-L-arginine methyl ester (L-NAME, Nitric oxide synthase inhibitor) pretreatment. These slope changes corresponded coronary flow responses at given perfusion pressures tested.

slopes (before and after drug intervention): % changes

	Non-failing state		Failing state	
Resting state (n = 18)	100	to	119 ± 16	(N.S.)
α_2-blockade (n = 6)	100 to 96 ± 15	(N.S.)	100 to 104 ± 8	(N.S.)
α_2-stimulation (n = 6)	100 to 116 ± 11	(N.S.)	100 to 160 ± 17	(P < 0.05)
+ with L-NAME (n = 6)	100 to 105 ± 12	(N.S.)	100 to 105 ± 10	(N.S.)

Conclusion: These results suggest that α_2-stimulation exerts vasodilatory effect, presumably via augmentation of endothelium derived nitric oxide release in coronary microvascular beds in chronic heart failure.

P2174 Pericoronary nerves subserve a negative inotropic effect during coronary catheter balloon inflation in anaesthetized healthy pigs

A. Rodríguez-Sinovas, J. Cinca, I. Anivarro, M. Tresànchez, J. Soler-Soler. *Cardiology Service, University Hospital Vall d'Hebron, Barcelona, Spain*

Intracoronary catheter balloon inflation may stimulate coronary mechanoreceptors and this, in turn, might reflexely affect left ventricular (LV) function, in addition to the ischaemia-induced haemodynamic depression. However, this hypothesis has not been tested.

Methods. LV pressure, LV dP/dt, and ECG were analyzed during catheter balloon inflation at the left anterior descending (LAD) coronary artery in α-chloralose anaesthetized pigs (30–40 kg; n = 24). All pigs were submitted to a 1-minute ballon inflation before and after each of the following treatments: denervation of the pericoronary nerves with topical phenol (n = 7), bilateral vagotomy (n = 6), or bilateral stellectomy (n = 11). The time course of the changes induced by the two balloon inflations were compared by the ANOVA test.

Results. LAD balloon inflation induced a significant ($p < 0.01$) decay in LV systolic pressure (LVSP) (105 ± 13 vs 86 ± 12 mmHg), peak LV (+)dP/dt (2952 ± 769 vs 1770 ± 549 mmHg/s) and LV (−)dP/dt (1569 ± 362 vs 1068 ± 288 mmHg/s), together with ST segment elevation (0.03 ± 0.06 vs 0.23 ± 0.13 mV). LAD pericoronary denervation significantly attenuated the drop in LVSP (17% vs 11% at 60 s; $p < 0.001$) and in LV (+)dP/dt (34% vs 28%; $p < 0.01$). Bilateral stellectomy attenuated the effects of balloon dilation on the decay of LV (+)dP/dt (41% decay vs 33%; $p < 0.001$), whereas bilateral vagotomy had no significant effect.

Conclusions. Coronary balloon inflation elicits a negative inotropic effect subserved by sympathetic pericoronary nerves, which acts in concert with the ischaemia-induced myocardial dysfunction.

PERIPHERAL CIRCULATION: MECHANISMS, DIAGNOSIS AND TREATMENT

P2175 Aortic viscoelastic properties in patients with essential hypertension, coronary artery disease and congestive heart failure

J. Dernellis, C. Stefanadis, E. Tsiamis, C. Stratos, P. Toutouzas. *Department of Cardiology, University of Athens, Athens, Greece*

In a perfectly elastic material, the stress/strain response occurs immediately or in a negligible time. If a constant tensile stress is placed on the aortic wall, it will continue to elongate (that is, the strain will increase) for some period of time until a new equilibrium is reached; this time dependence of the stress/strain response is called viscoelasticity. To describe the viscoelasticity of the aortic wall the gradual recoil, namely stress relaxation, was used to characterize this process.

Methods: The pressure-diameter relation was determined in the descending aorta in 120 subjects. Diameter was measured with a Y-shaped intravascular catheter using sonomicrometers in the same level with intra-aortic pressure measured with a catheter tip micromanometer. Aortic distensibility was estimated by the following formula: (2 × strain/pulse pressure). In one simple model ($D = D_d \times e^{-t/\tau}$), aortic diameter was fitted an exponential decay towards the diastolic dimension (D_d), and the time course of aortic wall relaxation was estimated by an exponential decay constant (τ).

Results: The study population consisted of 32 normal subjects (NLS), 28 hypertensive patients (HYPS) with moderate and severe hypertension, 49 patients with coronary artery disease (CAD) (13 with 1, 18 with 2, and 18 with 3 vessels disease), and 11 with congestive heart failure (CHF). The mean age ± SD was 56.9 ± 11.7 and there were 98 men and 22 women. Distensibility was different between the groups (NLS: 3.4 ± 0.7, HYPS: 1.4 ± 0.2, CAD: 1.2 ± 0.2, and CHF: 1.3 ± 0.2 $dyn^{-1}cm^2 10^{-6}$, ANOVA: $p = 0.000$). The constant τ was also different between the groups (NLS: 37.6 ± 8.5, HYPS: 52.6 ± 10.7, CAD: 74.0 ± 13.9, and CHF: 55.4 ± 10.2 ms, ANOVA: $p = 0.000$). In a multiple linear regression including all demographic and hemodynamic variables, distensibility was the best predictor, of strain variability ($b = 0.0390$, $p = 0.000$) and additionally pulse pressure added to the prediction of strain ($b = 0.0027$, $p = 0.000$); for all subjects τ and heart rate were associated in the same model with strain ($b = -0.0005$, $p = 0.000$ and $b = -0.0210$, $p = 0.048$, respectively).

Conclusions: In addition to the three-dimensional and nonlinear behavior of the aorta, an important time factor must be considered in the stress/strain response, called viscoelasticity. Aortic tissue rarely behave as a perfectly elastic material both in normal and pathological conditions.

P2176 Arterial stiffness in systemic sclerosis

C. Longhini, M. Govoni[1], F. Trotta[1], P.S. Saba[2], L. Petretto[2], M. Russo, G. Gilli[3], G.F. Musacci, A. Ganau[2]. *Medicina Clinica Sperimentale, University of Ferrara, Ferrara; [1]Rheumatology Unit, Ferrara; [2]Clinical Medicine Institute, Sassari; [3]Health Physics Dept, Ferrara, Italy*

Background: Systemic sclerosis (SSc) is a generalized connective tissue disorder characterized by fibrosis and vascular changes of skin and multiple internal organs. No data are available on involvement of large arteries. Aim of the study was to evaluate anatomy and elastic properties of the great arteries in SSc.

Methods: Thirty normotensive women – 15 with SSc (disease duration: 6.4 ± 5.2 ys) and 15 healthy subjects (H) – matched for age, body mass index, clinical and 24-hour blood pressure (BP), underwent common carotid artery ultrasonography for assessing carotid intima-media thickness (IMT, mm), cross-sectional intima-media area (M-a, mm^2) and atheromatous plaques (n). As an index of arterial stiffness, pulse wave velocity (PWV, m/s) was calculated by simultaneous carotid and femoral pulse recording. Wilcoxon test, simple linear regression and binary logistic analysis were employed for statistical analysis.

Results:

	Age	24 h Sys BP	IMT	M-a	Plaque	PWV
SSc	55.8 ± 11.3	115.7 ± 9.02	0.7 ± 0.1	13.74 ± 3.1	6/15	9.2 ± 2*
H	57.9 ± 10.1	118.8 ± 7.27	0.67 ± 0.1	12.63.3 ± 2.1	4/15	7.6 ± 1.3

*$p < 0.05$

In a binary logistic analysis, PWV was the major predictor of the presence of SSc (odds ratio:5). PWV showed correlation with age, IMT, systolic, diastolic and mean BP ($p < 0.05$, $p < 0.01$, $p < 0.05$, $p < 0.05$ and $p < 0.01$, respectively).

Conclusion: Our data provide the first evidence of a peculiar involvement of large arteries in SSc, characterized by increased arterial stiffness in the absence of carotid wall thickening or plaque formation. The non invasive, easily determined evaluation of PWV may be of potential clinical and prognostic significance in SSc, predicting arterial damage and monitoring its progression.

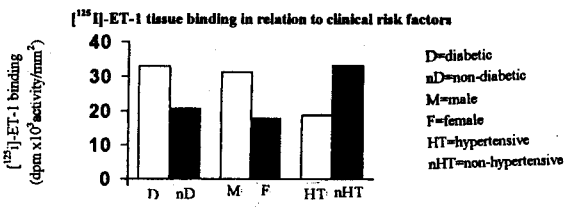
P2177 Mechanism of ischaemia and pain in peripheral vascular disease: localization of endothelin-1 binding to femoral arteries

D.A. Gorog, I.A. Jagroop[1], M.R. Dashwood[1], A. Merrigon[2], N. Standfield[2], J.P. Bagger. *Departments of Cardiology; [2]Vascular Surgery, Hammersmith Hospital, ICSM, London; [1]Molecular Pathology & Clinical Biochemistry, Royal Free Hospital, London, UK*

Raised circulating endothelin-1 (ET-1) has been found in peripheral vascular disease (PVD). ET-1 vasoconstricts by binding to ET_A and ET_B receptors on medial vascular smooth muscle cells. Binding to adventitial microvessels supplying perivascular nerves has also been described. The significance of these observations remains poorly understood.

Methods: Femoral arterial sections obtained from 9 patients undergoing aorto-femoral bypass grafting (5 men, 4 women, aged 54–77 y, 3 were diabetic and 5 hypertensive) were rinsed in saline, frozen in liquid nitrogen and stored at −70°C. ET-1 receptors were studied using *in vitro* autoradiography. Slide mounted sections were incubated in buffer containing [^{125}I]-ET-1 and receptor subtypes identified using [^{125}I]-PD131242 (ET_A selective) and [^{125}I]-BQ3020 (ET_B selective). Autoradiographs were generated on radiation sensitive film and receptor binding quantified by densitometric analysis. Microscopic localization of binding was achieved using nuclear emulsion and specific cells identified using immunomarkers.

Results: Both ET_A and ET_B binding in the tunica media was observed (ET_A 10.1 [2.8], ET_B 5.5 [2.8] mean [± SEM] dpm × 10^3 activity/mm^2). Autoradiography confirmed ET_A/ET_B binding on medial vascular smooth muscle cells and ET_B on vasa vasorum and vascular nerves. Claudication distance related to ET-1 binding ($r = 0.731$, $p < 0.05$) but not to ET_A or ET_B receptors. ET-1 and ET_B were higher in diabetics ($p < 0.05$). ET-1 and ET_A were higher in men ($p < 0.05$), ET_B receptors higher in women ($p < 0.05$). ET_A, ET_B and ET-1 concentrations were lower in hypertensives ($p < 0.05$). ET_A, ET_B and ET-1 were not inter-related.



[^{125}I]-ET-1 tissue binding in relation to clinical risk factors.

Conclusion: Medial ET_A and ET_B receptors are ideally situated to be affected by circulating ET-1. ET-1 binding to ET_A/ET_B receptors on vascular smooth muscle cells may be responsible for vasoconstriction causing ischaemia. Further, ET-1 may play a role in the mechanism of pain, by binding to ET_B receptors of microvessels supplying perivascular nerve.

P2178 Sympathetic tone and blood flow in vasovagal syncope

K.K. Naka, G. Carolan-Rees[1], D. Parthimos[2], T.M. Griffith[2], A.C. Tweddel[3]. *Department of Cardiology, Univ. of Wales College of Medicine, Cardiff; [1]Department of Medical Physics, Univ. of Wales College of Medicine, Cardiff; [2]Department of Diagnostic Radiology, Univ. of Wales College of Medicine, Cardiff; [3]Department of Cardiology, University Hospital of Wales, Cardiff, UK*

The purpose of this study was to investigate the time course and relationship between cerebrovascular, peripheral blood flow and sympathovagal interaction in patients with vasovagal syncope (VVS).

Methods: 11 subjects with well documented VVS during tilting and 10 matched volunteers were studied at baseline and during 60° head-up tilt to the onset of syncope or at 30 minutes. Spectral analysis was applied to 5-minutes continuous recordings of ECG to assess autonomic function. Low frequency (LF) variations of the RR interval reflect both sympathetic and parasympathetic activity, whereas high frequency (HF) variations are an index of vagal tone and LF/HF ratio a measure of sympathovagal balance. Transcranial Doppler of the middle cerebral artery assessed systolic (Vs) and diastolic (Vd) velocities, with derivation of pulsatility (PI) and resistance indices (RI). Subcutaneous finger flow was measured by Laser Doppler flowmetry and blood pressure by Finapres.

Results: Immediately after tilt, LF (normalised units; nu) increased from 42.3 ± 7.1 to 66.5 ± 7.8 ($p < 0.01$), LF/HF ratio from 1.1 ± 0.4 to 3.4 ± 0.8 ($p < 0.01$) and HF (nu) decreased from 57.7 ± 7.1 to 35.6 ± 7.8 ($p < 0.01$) in normals suggesting shift of sympathovagal balance towards sympathetic predominance. However, in patients with VVS, LF increased from 53.4 ± 6.3 to 72.6 ± 9.6 ($p = 0.06$), LF/HF ratio from 1.6 ± 0.4 to 5.7 ± 2 ($p = 0.05$) and HF decreased from 46.6 ± 6.3 to 27.4 ± 9.6 ($p = 0.06$). Peripheral flow (measured as flux in arbitrary units) decreased immediately after tilt in normals from 245.7 ± 41.2 to 160.9 ± 35.2 ($p < 0.01$), whereas in patients this increased from 155.3 ± 39 to 194.9 ± 92.6 ($p = 0.24$). RI increased prior to syncope, Vs and Vd decreased after tilt, most markedly before syncope suggesting cerebral vasoconstriction, out of keeping with hypotension observed at syncope.

In conclusion, patients with VVS, in constrast to normals, respond to orthostatic stress by paradoxical peripheral vasodilation and cerebral vasoconstriction preceding onset of symptoms and hypotension.

P2179 A blunted nocturnal blood pressure fall is associated with greater carotid sinus stimulation responses in patients with essential hypertension

C. Tsioufis, I. Kallikazaros, C. Stefanadis, C. Pitsavos, I. Elevsiniotis, P. Toutouzas. *Department of Cardiology, University of Athens, Hippokratio Hospital, Athens, Greece*

Ambulatory blood pressure (BP) is correlated better with indices of hypertensive cardiovascular complications than office BP. Whether the absence of the normal nocturnal BP fall is related with the extent of carotid sinus stimulation responses (CSSR) remains to be established.

Methods: Towards this end, carotid sinus stimulation (with simultaneous recordings of the ECG and the BP sphygmomanometrically at the brachial artery) was performed in 81 untreated, newly diagnosed patients (pts) with stage I–II (JNC-VI) essential hypertension (aged 54 ± 10 years, office BP 154 ± 18/97 ± 12 mmHg; without a history of any cardiac or vascular disease or syncope). Cardionhibitory type CSSR was evaluated by calculating CSSR index which is defined as the ratio of the longest R-R interval on the ECG recording during stimulation to R-R interval at rest. By ambulatory BP monitoring the pts were classified into non-dippers (defined by a reduction in the night mean systolic and diastolic BP < 10% from day) and dippers (the remaining subjects). Results: In the entire study population, LVMI was 92.9 ± 19 gr/m^2, RWT was 0.48 ± 0.06, rest R-R interval was 0.79 ± 0.05 sec, max R-R interval was 1.36 ± 0.83 sec (ranged 0.68–4.84) and CSSR index was 1.74 ± 1.03. The two groups' non-dippers (34 pts) and dippers (47 pts) were matched for age, BSA, smoking status and plasma cholesterol level. Non-dippers compared to dippers had significantly increased office systolic and diastolic BP (159 ± 19 vs 150 ± 18 and 100 ± 15 vs 94 ± 8 mmHg respectively), 24 h systolic BP (140 ± 14 vs 132 ± 9 mmHg), 24 h ambulatory pulse pressure (54 ± 7 vs 48 ± 6 mmHg), 24 h systolic load (48 ± 30% vs 28 ± 18%), LVMI (100 ± 22 vs 90 ± 16 g/m^2), RWT (0.50 ± 0.06 vs 0.46 ± 0.05), max R-R interval (1.48 vs 1.29) and CSSR index (1.72 ± 0.8 vs 1.65 ± 0.8). In the entire study population, by a multivariate model including ambulatory BP parameters, only the 24 h systolic load was identified as a significant determinant of CSSR index.

Conclusion: The absence of normal nocturnal BP fall is associated with an impairment of CSSR in the setting of moderate essential hypertension. These findings may partly be accounted for the unfavorable prognosis of non-dipper hypertensives.

P2180 Intima-media thickness of the common carotid artery is related to plasma leptin and insulin resistance in normal weight and obese subjects

M. Ciccone, G. De Pergola[1], R. Vettor[2], F. Giorgino[1], A. Minenna[1], S. Novo[3], P. Rizzon, R. Giorgino[1]. *Institute of Cardiology Univ. of Bari; [1]Institute of endocrinology Univ. of Bari; [2]Medical Semiotic Univ. of Padova, Padua; [3]Chair of patho-physiology Palermo, Italy Univ*

We sought to investigate whether intima-media thickness (IMT) of the common carotid artery (CCA) is significantly associated with leptin (L) plasma levels. L, the satiety hormone expressed almost exclusively in adipose tissue, is a marker of body fat accumulation. Moreover, the thickening of the arterial intima-media complex is the initial sign of asymptomatic atherosclerosis.

Methods. We assessed fasting plasma L levels and the IMT of the CCA in 120 healthy subjects (52 men and 68 women), aged 18–45 years, and with a wide range of BMI. L concentrations were measured by radioimmunoassay and the IMT of the CCA was quantified by high resolution B-mode ultrasound imaging. Body fat distribution (measured by waist circumference and waist-to-hip ratio), smoking habits, blood pressure, insulin sensitivity (measured by the insulin tolerance test), and fasting plasma glucose, insulin and lipid pattern (cholesterol, HDL-cholesterol, triglycerides, LDL-cholesterol) were also measured.

Results. IMT of the CCA was positively correlated with L levels ($P < 0.001$ in men and $P = 0.004$ in women) and age ($P < 0.001$ in men and $P = 0.007$ in women) and negatively associated with insulin sensitivity in both sexes ($P = 0.04$ in men and $P = 0.004$ in women). IMT was also directly correlated with cholesterol and LDL-cholesterol in men ($P = 0.03$ and $P = 0.017$ respectively), and with mean blood pressure levels in women ($P = 0.03$). When a multiple linear regression model was used, the correlation between L and IMT was maintained in both men ($P = 0.008$) and women ($P = 0.048$), independently of age, KITT, smoking habits, mean blood pressure, fasting glucose, triglycerides, cholesterol, LDL-cholesterol and HDL-cholesterol.

Conclusions. L plasma levels show an independent relationship with the IMT of the CCA, suggesting that the increase of adipose tissue mass has an independent unfavorable influence on the development of atherosclerosis.

P2181 Morphological and functional markers of peripheral atherosclerosis in obstructive coronary artery disease

I. Kranjec, A. Černe, J. Buturović-Ponikvar. *University Medical Center, Clinic of Cardiology, Slovenia, Slovenia*

Background and aim: Obstructive coronary artery disease (CAD) is a local manifestation of the advanced atherosclerotic process. Different vascular districts of patients (pts) with CAD have not been systematically evaluated for early morphological or functional markers of atherosclerosis, such as intimal-medial thickening (IMT) or endothelial dysfunction. The aim of our study was to find out to what extent the peripheral atherosclerosis is associated with these pts.

Methods: Using high-resolution 7.5 MHz linear phased-array transducer and a standard Acuson 128XP/10 system we studied IMT, as well as arterial diameter at rest and during endothelial-dependent (cold pressor test, CPT; hand-grip test, HGT; flow-mediated response, FMR) and endothelial-independent vasodilation (sublingual nitroglycerin 0.4 mg, NTG) of carotid, brachial and femoral arteries in 82 pts: in 47 pts with obstructive CAD (>50% diameter narrowing of at least one epicardial artery) and 35 control pts (angiographically smooth arteries). The mean pts age was 52 ± 14 years and female to male ratio 1:2.4.

Results (table): IMT was significantly ($p < 0.001$) increased in all target arteries in CAD pts as compared with controls. Atherosclerotic plaques were more often found in carotid (43% vs 3%) and femoral arteries (53% vs 9%) of CAD pts. Basal arterial diameters were significantly larger in carotid and brachial arteries of CAD pts but not in femoral arteries. Endothelial-dependent as well as independent vasodilation was significantly ($p < 0.05$-0.001) reduced in all target arteries of CAD pts. CAD pts with hypertension showed smaller brachial diameters ($p < 0.05$) while chronic ACE inhibition (>6 months) increased carotid diameters ($p < 0.031$). Statins improved endothelial-dependent vasodilation in brachial arteries of our CAD pts ($p < 0.05$).

Variables	Carotid artery		Brachial artery		Femoral artery	
	CAD	Controls	CAD	Controls	CAD	Controls
IMT (mm)	0.9 ± 0.2	0.6 ± 0.1*	0.6 ± 0.1	0.4 ± 0.1*	1.0 ± 0.2	0.6 ± 0.1*
Plaques (%)	20 (43%)	1 (3%)*	0 (0%)	0 (0%)	25 (53%)	3 (9%)*
Basal (mm)	6.6 ± 1.2	5.8 ± 0.7‡	4.4 ± 0.8	3.8 ± 0.7‡	8.0 ± 1.3	8.0 ± 1.3
CPT (%)	3.4 ± 3.3	8.7 ± 7.0*	4.8 ± 4.3	11.1 ± 8.5*	3.1 ± 2.7	5.6 ± 4.5‡
HGT (%)	4.6 ± 3.8	10.2 ± 5.7*	5.6 ± 4.3	13.5 ± 8.2*	3.8 ± 2.8	7.2 ± 4.0*
FMR (%)	–	–	8.1 ± 5.2	14.6 ± 5.7†-	-	
NTG (%)	7.0 ± 3.7	13.6 ± 5.7*	11.1 ± 6.4	21.2 ± 11.0*	6.7 ± 4.3	10.4 ± 4.0*

† < 0.05; ‡p < 0.01; *p < 0.001

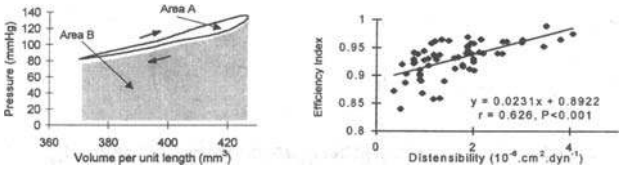
In conclusion, increased IMT and substantial endothelial dysfunction of all examined peripheral arteries was invariably present in pts with obstructive CAD while atherosclerotic plaques were found in approximately half of their carotid or femoral arteries. CPT and HGT as well as FMR seems to be equivalent in the assessment of endothelial-dependent vasodilation in these pts.

P2182 Energetics of the human aorta: association with aortic elastic properties

C. Vlachopoulos, C. Stefanadis, L. Diamantopoulos, C. Pitsavos, P. Toutouzas. *Hippokration Hospital, Athens Medical School, Athens, Greece*

The aorta (Ao), by virtue of its elastic nature, stores a considerable amount of the LV power generated during cardiac systole, which is returned by Ao recoiling during diastole. To investigate the relation between Ao energetics and Ao elastic properties, we applied a technique developed in our institution for the in-vivo determination of the pressure-volume relation (Circulation 1995; 92: 2210–9) in 62 pts (age 56 ± 10 yrs). Ao diameter and volume per unit length were measured by an intravascular dimension catheter and Ao pressure was recorded simultaneously by a Millar catheter. The area under the systolic (ascending) portion of the clockwise loop (left fig., areas A + B) represents the energy stored by the Ao, the area under the diastolic (descending) portion of the loop represents the energy forwarded by the Ao (area B), whereas the area within the loop (area A) the energy dissipated by the Ao due to its viscosity.

Results: Efficiency index of the Ao (= energy returned/stored, i.e. area B/area A + B) had a positive correlation with distensibility (= 2 × [pulsatile change in Ao diameter]/[diastolic Ao diameter] × [pulse pressure], right fig.) indicating decreased energy loss with improved elastic properties.



Conclusions. Aortic energetics are closely associated with aortic elastic properties. This new insight into the performance of the aorta may provide a better understanding of the pathophysiology of the vessel.

P2183 The morbidity of peripheral arterial disease: a powerful and consistent clinical cardiovascular ischaemic risk

A.T. Hirsch, W. Hacke[1], E.J. Topol[2], M.H. Criqui[3], W.R. Hiatt[4], M.A. Creager[5]. *Minnesota Vascular Disease Center, Univ of Minnesota Medical School, Minneapolis, USA; [1]Neurology Dept., Univ of Heidelberg Medical School, Heidelberg, Germany; [2]Cardiology Dept., The Cleveland Clinic Foundation, Cleveland OH[3]Univ of California Sch of Medicine, San Diego[4]Univ of Colorado Health Sciences Ctr, Denver[5]Brigham and Women's Hospital, Boston, USA*

Any clinical evidence of atherosclerosis identifies individuals at risk of cardiovascular ischemic events (IEs). Nevertheless, the relative predictive power of peripheral arterial disease (PAD) for such events is not widely recognized. Therefore, the CAPRIE study database was utilized to define this ischemic risk, as this trial is both the largest randomized trial of antiplatelet agents for the prevention of IEs, as well as the largest prospective evaluation of individuals with PAD.

Methods: CAPRIE prospectively evaluated 19,185 patients who presented with PAD (6452 patients), recent myocardial infarction (MI), or recent ischemic stroke (IS). Clinical evidence of PAD at study entry was recorded in all participants and included evidence of claudication, prior limb surgical revascularization, and/or amputation. Follow-up was for a mean of 1.9 years with evaluation of subsequent IEs. Multivariate analyses were performed using a reduced model of pertinent clinical factors to calculate relative risk ratios (RRs) for the event outcome cluster of MI or IS (fatal or nonfatal) in both the entire study cohort and in those presenting with PAD.

Results: All clinical markers of PAD served as potent predictors of subsequent MI or IS in the whole study cohort, including claudication (RR = 1.3, $p < 0.01$), prior surgical revascularization (RR = 2.2, $p < 0.001$), and amputation (RR = 2.2, $p < 0.005$). In those with PAD, increased risk of IEs was predicted by increasing age (RR = 1.3/10 yrs, $p < 0.001$) and diabetes (RR = 1.6, $p < 0.001$); by prior reversible ischemic neurologic deficit (RR = 2.3, $p < 0.001$) or IS (RR = 1.5, $p = 0.01$); by prior stable angina (RR = 1.7, $p < 0.001$) or MI (RR = 1.3, $p = 0.02$); or by prior surgical revascularization (RR = 2.5, $p < 0.001$). Current tobacco use or hypercholesterolemia did not predict subsequent IEs. The benefits of antiplatelet therapy with clopidogrel vs. aspirin were particularly profound in all individuals with PAD (by 22.9% [7.3%, 35.8%], $p = 0.006$).

Conclusions: PAD, whose presence is easily and inexpensively detected by medical history, examination, and the ankle–brachial index, increases the risk of IEs in patients with atherosclerotic syndromes. This risk is increased further by the presence of coronary or cerebrovascular symptoms. Ischemic event rates in PAD patients were preferentially reduced by clopidogrel compared with aspirin.

P2184 Sustained improvement in flow-mediated vasodilation after 30 minutes of submaximal constant work rate exercise in patients with chronic heart failure

R. Belardinelli, I. Paolini, A. Purcaro. *Istituto Lancisi, Ancona, Italy*

There is evidence that chronic exercise improves endothelial function (EF) in patients with chronic heart failure (CHF). However, it is not well defined whether a single bout of submaximal constant work rate exercise (SE) can improve endothelial function in the skeletal muscle vasculature. The duration of this potentially beneficial effect was also investigated.

Methods: Twenty patients with stable CHF due to ischemic heart disease were studied. A symptom-limited incremental cardiopulmonary exercise test was performed on a cycle ergometer to assess peak VO_2. Flow-mediated vasodilation in response to peak reactive hyperemia and the response to sublingual nitroglycerin (NTG) were evaluated in the right femoral artery (FA) of 20 patients with CHF. In 10 of them (group E) resting, peak hyperemic (PH) and post-NTG FA blood flow (BF) and diameter (D) were measured by a 2-dimensional and pulse Doppler ultrasonography at baseline and at 3, 24 and 72 hours after 30 min of SE on an electronically-braked cycle ergometer at an intensity of 60% of peak VO_2. Ten patients with CHF who did not exercise served as control group (C).

Results: No changes were observed in the C group. In the group E, resting BF was significantly increased after SE at 3, 24 and 72 hours (363 ± 35, 310 ± 28 and 288 ± 31 mL/min, respectively, compared with 153 ± 24 mL/min at baseline; $P < 0.01$ E vs C). Peak hyperemic BF and D were also increased at same times ($P = 0.01$ for both, E vs C), whereas no changes were induced by NTG. The changes in PHBF response after SE were correlated with peak VO_2 ($r = 0.76$; $P < 0.01$).

Conclusion: In patients with CHF, short-term SE selectively improves vascular endothelial function for at least 72 hours.

P2185 Is carotid and peripheral angiography beneficial during coronary angiography in patients with coronary artery disease?

Y.S. Yoon, W.H. Shim, D.H. Choi, W.B. Pyun, I.J. Kim, D.H. Lee, B.J. Choi, Y. Jang, S.Y. Cho. *Cardiology Division, Yonsei Cardiovascular Center, Seoul, South Korea*

It is known that carotid disease (CD) or peripheral artery disease(PAD) is frequently associated with coronary artery disease (CAD). However, the incidence of these diseases in patients (pts) with angiographically documented CAD has not been clearly documented. This study was to determine the incidence of significant CD or PAOD in pts with CAD and the strategy of routine global vascular screening during coronary angiography can benefit the pts.

Methods: Between June 1996 and Nov. 1998, for 550 consecutive pts who was diagnosed to have significant CAD (>50% stenosis) by coronary angiography, we performed digital-subtraction angiography of carotid arteries and angiography of peripheral arteries from suprarenal abdominal aorta to femoral arteries in the same setting. Average amount of dye used were 28 ml for carotid and perpheral angiography, respectively. Significant CD was diagnosed if >50% luminal narrowing was present. Significant PAD was diagnosed as having total occlusion or >50% luminal narrowing with mean pressure gradient > 10 mmHg. Abdominal aortic aneurysm was included in PAD.

Results: There were 374 males (68%) and the mean age was 59 ± 10 (24–91) yrs old. Of these, 226 (41%) had 1 vessel-disease(VD), 160 (29%) had 2 VD, 164 (30%) had 3 VD. The incidence of significant CD including internal, external and common carotid arteries was 12.2% (66 pts). The incidence of significant PAD including aortic, iliac, femoral, and renal artery disease was 28.0% (154 pts). Carotid stenting was performed in 19 pts (3.5%), renal angioplasty in 21 pts (3.8%), femoro-iliac angioplasty in 28 pts (5.1%), aortic stent-graft in 8 pts (1.5%), bypass graft of femoro-iliac arteries in 2 pts (0.4%), and surgery of aortic aneurysm in 2 pts (0.4%). Excluding duplicate procedure in a pt, 74 pts (13.5%) were undertaken angioplasty or surgery detected by routine screening.

Conclusions: Routine carotid and peripheral vascular angiography at the same setting with coronary angiography in pts with significant CAD was beneficial in detecting pts with significant CD or PAD requiring treatment.

P2186 Oestrogen, but not antioxidant, treatment improve endothelial function in women with Raynaud's phenomenon secondary to systemic sclerosis

M. Mavrikakis, J. Lekakis, C. Papamichael, A. Cimponeriu, K. Stamatelopoulos, A. Voutsas, S. Stamatelopoulos. *Alexandra University Hospital, Athens, Greece*

We have recently shown that endothelial dysfunction is present in patients with Raynaud's phenomenon secondary to systemic sclerosis. It is not known if endothelial dysfunction in this setting is due to increased oxidative or other reasons.

Methods. Nine female patients with Raynaud's phenomenon and systemic sclerosis (age 58 ± 9 years) underwent ultrasound imaging of the right brachial artery for evaluation of flow-mediated dilatation (FMD < endothelium-dependent dilatation) and nitrate-induced dilatation (NID, endothelium-independent dilatation). Ten healthy women (age 58 ± 8 years) served as controls. Subsequently patients entered a crossover study and received conjugated estrogens (1.25 mg/day Premarin) for four weeks, placebo for four weeks and 2 g of ascorbic acid orally.

Vasoreactivity studies were repeated and the end of the 4-week period of estrogens or placebo and 2 hours after the oral administration of ascorbic acid.

Results. Baselin FMD was 2.1 ± 1.6% (controls 8.2 ± 3.2%, $p < 0.001$) and NID 17.6 ± 4.8% (controls 26 ± 8%, $p = 0.01$). FMD improved after 4-week treatment with estrogens to 6.6 ± 3.5% ($p < 0.05$), while NID did not change. No significant changes were observed after placebo treatment (FMD 1.5 ± 2%, NID 18.5 ± 7.6%, ns). No significant changes were observed after administration of ascorbic acid (FMD 2.6 ± 2%, NID 16 ± 7%, ns).

Conclusions. Antioxidant treatment does not improve endothelial function in Raynaud's phenomenon secondary to systemic sclerosis, indicating that oxidative stress is not implicated in the pathogenesis of endothelial dysfunction in this setting. The improvement observed after estrogen therapy indicates a possible upregulation of NO synthase.

DIVERSE NEW DEVELOPMENTS IN EPIDEMIOLOGY

P2187 Improved one year survival after acute myocardial infarction between 1986 and 1996

J.M. Kristjansson, K. Andersen. *Dept of Medicine, Sjukrahus Reykjavikur, Reykjavik, Iceland*

During the last decade the treatment of patients with acute myocardial infarction (AMI) has changed dramatically. We set out to evaluate the effect of these changes on one-year mortality.

Methods and Results: All patients hospitalised for AMI in Reykjavik, Iceland during the calendar years of 1986 (n = 335) and 1996 (n = 351) were included in the study. Information on risk factors and medical therapy of each patient was obtained from medical records. All-cause mortality at one year after hospital admission was compared between years and related to risk factors and medical therapy at discharge and to interventional procedures within one year. Demographic characteristics did not change between 1986 and 1996. The one-year mortality decreased from 23.3% to 19.7% ($p < 0.05$). The recorded risk factors were not associated with one-year mortality. There was a significant increase in the use of aspirin (from 11% to 76%), beta blockers (from 48% to 62%) and thrombolytic agents (from 8% to 24%) between 1986 and 1996 and these drugs were associated with reduced one year mortality (table). The use of diuretics, digoxin and anti-arrhythmic agents did not change significantly but was associated with increased mortality. Calcium antagonists and ACE inhibitors had a neutral mortality effect. Although there was an increase in use of PTCA (from 7% to 23%) and CABG (from 4% to 11%) between years, these interventions were not associated with an imroved outcome.

	1986			1996		
	OR	95% CI	p	OR	95% CI	p
Aspirin	0.44	0.17–1.17	0.14	0.13	0.07–0.23	0.001
Beta blocker	0.28	0.16–0.49	0.001	0.36	0.21–0.64	0.001
Diuretic	3.18	1.89–5.36	0.001	3.55	2.01–6.27	0.001
Ca-antagonist	0.98	0.52–1.85	1.00	0.76	0.38–1.51	0.54
ACE-inhibitor	1.76	0.41–7.54	0.43	1.03	0.55–1.90	1.00
Digoxin	2.06	1.13–3.76	0.027	2.34	1.13–4.84	0.033
Anti-arrhythmic	3.61	1.18–11.1	0.025	2.92	1.27–6.73	0.017
Nitrates	0.74	0.44–1.21	0.31	0.95	0.54–1.69	0.99
Thrombolytic	0.37	0.11–1.26	0.16	0.27	0.11–0.64	0.001

Conclusions: The 6.6% mortality reduction during the last decade is mainly due to improved medical therapy.

P2188 Cancer risk and mortality in users of calcium channel blockers: cohort study

A.M. Thulstrup, H.T. Sorensen[1], J.H. Olsen[2], L. Mellemkjær[3], F.H. Steffensen[4]. *The Danish Epidemiology Science Centre, University of Aarhus, Aarhus C; [1]Department of Internal Medicine V, Aarhus University Hospital, Aarhus; [2]The Danish Cancer Society, Institute of Cancer Epidemiology, Copenhagen; [3]The Danish Cancer Society, Institute of Cancer Epidemiology, Copenhagen; [4]Department of Internal Medicine M, Aalborg Hospital, Aalborg, Denmark*

It has been suggested that calcium channel blockers may increase the risk of cancer and promote the growth of tumours. Since calcium channel blockers are used extensively in the treatment of hypertension, ischemic heart disease and supraventricular arrhythmias, even a small excess risk may have major public health implications. On this background, we report the cancer specific risk and mortality in a Danish cohort of calcium channel blocker users.

Methods: We identified calcium channel blockers users in the prescription database of the County of North Jutland, Denmark. The study cohort was then linked to the files of the Danish Cancer Registry and the Danish Registry of Death, which collect information on all cases of cancer and death in Denmark. The follow-up period for cancer occurrence began at the date of first known prescription of calcium channel blockers and ended at the date of emigration, date of death, or 31 December 1995, whichever occurred first. The standardized incidence ratio was calculated as the ratio of the observed to the expected number of cancer cases. The observed number of deaths was likewise compared with the number of expected deaths.The statistical methods assume that the observed number of cases of cancer and death in any specific category followed a Poisson distribution.

Results: We identified 23 167 who had received more than one prescription, yielding 89 295 person-years of follow-up, with a mean follow-up period of 3.16 years.

	Cancers Observed	SIR	95% CI	Deaths Observed	SMR	95% CI
All causes of death				4123	1.47	1.42–1.51
All malignant neoplasm	945	1.04	0.98–1.11	653	0.97	0.89–1.04
Colon	82	0.86	0.68–1.06	65	0.96	0.74–1.22
Rectum	53	0.97	0.73–1.27	31	1.02	0.69–1.45
Breast	84	0.96	0.76–1.19	48	1.10	0.81–1.46

Observed number of cancers and deaths and standardized incidence rate (SIR) ratio for cancer, or standardized mortality ratio (SMR), occurring in calcium channel blockers users who received more than one prescription of calcium channel blockers (N = 23167)

Conclusion: Our study provides no evidence of an association between use of calcium channel blockers and cancer risk and mortality.

P2189 Naxos arrhythmogenic right ventricular cardiomyopathy: prevalence and clinical outcome

N. Protonotarios, A. Tsatsopoulou[1], A. Anastasakis, A. Rigopoulos, E. Karvouni, A. Theopistou, E. Sevdalis, D. Markou, C. Stefanadis, P. Toutouzas. *Department of Cardiology, University of Athens, Athens; [1]"J Protonotarios" Medical Centre, Naxos, Greece*

Background: Naxos disease is a familial syndrome consisting of arrhythmogenic right ventricular cardiomyopathy, palmoplantar keratosis and curly hair. It originates from the Greek island of Naxos (population 20,000).

Methods: We traced all families with Naxos disease in the island (12 families) thanks to their stereotype phenotype (palmoplantar keratosis and curly hair). We found 25 pts (12 male/13 female, mean age 36 ± 17 years). The pts were assessed with clinical examination, 12-lead ECG, 2-D echo and 48 hour Holter monitoring and followed for a mean period of 9 ± 5 years.

Results: The prevalence of the disease in the island is about 1:800 (25:20,000). The mode of inheritance appears to be autosomal recessive. During the follow-up period, 7 pts (28%) developed heart failure and 8 pts (32%) died from cardiac causes (7 sudden, 1 right heart failure). The annual rate of sudden death was 3%. Five of 7 pts (71%) who died suddenly, as well as the patient who died of heart failure, were young (<35 years). Of all pts, 6 had a family history of sudden death (24%), 12 had syncope (48%), 7 developed sustained ventricular tachycardia (28%) and 6 developed morphological changes in both ventricles (24%).

Conclusion: Naxos disease is a progressive disease with high incidence of sudden death and heart failure. Patients who die suddenly are mainly young (<35 years).

P2190 Determinant factors of endothelial function in a Mediterranean population with a low prevalence of coronary artery disease

E. Novo, J. Balaguer, E. Jiménez, M. Chaparro, A. García-Lledó, J. García-Segovia, G. Piedrola. *Cardiology Section, General Hospital Guadalajara, University of Alcala, Spain*

Endothelial dysfunction is a key feature of atherosclerosis progression and appearance of coronary heart disease (CHD). Evidence is acumulating that coronary risk factors (CRF) differentially affect endothelium-dependent vasodilation, but its not clarify that CRF in european populations with low coronary risk affect to endothelial function (EF).

Methods: In a rural district of mediterranean population with low coronary risk (anual mortality for CHD < 70/100000 adjusted for age) 421 consecutive pts. (age 59 ± 16, 57% males) were recruited for echocardiography: 290 pts. with confirmed CHD and 131 without CHD or atherosclerosis complication (35 hipertensive patients). Flow mediated dilation (FMD%) and after nitroglicerin (endothelium-independent) were assessed in the brachial artery by high resolution ultrasound. A prognostic "score" indicanting risk of cardiovascular death or non-fatal MI was calculated according the Framingham model: age, gender, systolic blood pressure, total/HDL cholesterol, diabetes and smoking status. Others CRF were evaluated.

Results: Significant correlations were observed between FMD% and triglicerides (−0.23 p = 0.023), HDL-chol (0.41 p = 0.000), plasma glucose (−0.30 p = 0.002), fibrinogen (−0.46 p = 0.000), sistolicBP (−0.15 p = 0.046, age (−0.44 p = 0.000) and "risk score" (−0.51 p = 0.000) but not with total-chol, LDL-chol, diastolicBP. A stepwise multivariate regression incorporating laboratory data demostred HDL-chol independent predictor (β = 0.42 p = 0.004) with residual correlation (p = 0.013). After inclusion in model epidemiologic data only "risk score" influenced FMD% (β = −0.952 p = 0.000). Pts with CHD had significantly lower FMD% (0.10 ± 6.34 vs 9.29 ± 8.11 p = 0.042) and HDL-chol (46.2 ± 10.1 vs 65.1 ± 13.7 p = 0.034) and greater age (66 ± 11 vs 57 ± 15 p = 0.002) and "risk score" (2.78 ± 1.05 vs 1.47 ± 1.27 p = 0.000) without differences in others CRF or dilation endothelium-independent. Logistic regression showed "risk score" independent predictor of CHD (RR 5.45, p = 0.0183).

Conclusion: In populations with low coronary risk, the endothelial-function and appearance of CHD is associated a adverse risk factors profile depending principally of age and anormal metabolism of HDL.

P2191 Inhibition of post-injury neointima development by 17β-oestradiol and the phyto-oestrogens genistein and daidzein in non-toxic concentrations in vitro

G. Finking, M. Wolkenhauer, C. Lenz, B. Hess, H. Hanke. *University of Ulm, Department of Internal Medicine, Division Cardiology, Ulm, Germany*

Phytoestrogens like Genistein and Daidzein have a beneficial influence on haemodynamics and lipid profile in vivo. Such effects have been shown for 17β-Estradiol before. The latter has anti-proliferative properties on the vessel wall as well. The aim of this in-vitro experiment was to establish non-toxic dosages of the three estrogens which inhibit the neointima formation after endothelial balloon denudation.

Methods: In situ endothelial denudation was performed in female rabbits by a 3 F Fogarty catheter. Segments of 5 mm were randomized in groups of n = 8 and held in culture. 17β-Estradiol, Genistein and Daidzein were applicated in concentrations of 20 μM, 30 μM, and 40 μM. Groups without hormonal treatment served as controls. The segments were histologically prepared and measured after 21 days. Afterwards, 3 further groups (n = 8) were held with the lowest concentration of hormones having been evaluated to inhibit the neointimal development. After 21 days of treatment these sections were held in medium only with 20% fetal calf serum (fcs) for another week to proof whether these segments were still able to proliferate.

Results: Compared to controls, 30 μM 17β-Estradiol, 20 μM Genistein and 40 μM Daidzein significantly inhibited neointimal development over 21 days. After another week of cultivation in medium with 20% fcs the amount of neointima formation was comparable to that of untreated controls after 21 days.

In conclusion, 17β-Estradiol, Genistein and Daidzein were able to inhibit post-injury neointima formation in non-toxic concentrations. This may have therapeutical consequences as the applicated phytoestrogen concentrations were only 10 fold higher than those found in humans consuming high amounts of soy products.

P2192 The effect of osmolarity and volume of fluid intake on the risk of fatal coronary heart disease. Findings from the Adventist Health Study

J. Chan, S.F. Knutsen[1]. *Grand Terrace CA; [1]Epidemiology & Biostatistics Dept, Loma Linda University SPH, Loma Linda CA, USA*

Increased blood viscosity has been found to be directly assoicated with heart disease. Consumption of hyperosmolar fluids results in net secretion of water from the vascular system while hypo-osmolar fluids results in net absorption. We compared the effect of water, hypo- and hyper-osmolar fluid intake on the risk of fatal and non-fatal coronary heart disease (CHD) in participants of the Adventist Health Study.

Method: In 1976, 34,198 white, non-hispanic California Seventh-day Adventists enrolled in the Adventist Health Study, and were followed for 6 years. Extensive lifestyle information including diet and daily fluid intake was assessed at baseline. The risk of fatal CHD was analyzed according to self-reported daily intake of fluids among subjects without prevalent CHD, stroke or diabetes at baseline using Cox Proportional Hazards Model.

Results: Among the 26,938 persons analyzed, 124 males (1.1%) and 115 females (0.7%) experienced fatal CHD during follow-up. Fatal CHD showed an inverse dose-response relationship to daily intake of water and fluids hypo-osmolar to plasma after adjusting for age, smoking, education and BMI, fatal CHD (table).

Glasses /day	Water		Glasses /day	Hyposmolar Fluids (no coffee)	
	Male RR (95% CI)	Female RR (95% CI)		Male RR (95% CI)	Female RR (95% CI)
1 to 2	1.00	1.00	<2	1.00	1.00
3 to 4	0.61 (0.37–1.01)	0.56 (0.31–1.03	2 to <5.5	1.01 (0.49–2.10)	0.52 (0.22–1.24)
5+	0.40 (0.24–0.67)	0.60 (0.34–1.07)	>5.5	0.43 (0.20–0.092)	0.55 (0.24–1.27)
	Trend p = 0.0004	Trend p = 0.14		Trend p = 0.004	Trend p = 0.53

In females, intake of fluids hyperosmolar to plasma showed a direct relationship with risk of fatal CHD, RR (95% CI) 2.58 (1.19–5.59), Trend p = 0.01 for 4+ compared to <2 glasses/day.

Conclusion: Our data suggests that hypo-osmolar fluids are associated in a dose response fashion with reduced risk of fatal CHD in both males and females, whereas hyperosmolar fluids seem to increase the risk of heart disease in women.

P2193 Elite athletes with life-threatening arrhythmias: an update of a long term follow-up study

A. Bertoldi, F. Furlanello[1], F. Fernando[2], A. Galassi[1], M. Dallago, A. Biffi[2], G. Inama, S. Bianchi[1], C. Pappone[1]. *Cardiology Dept, S. Chiara Hospital, Trento; [1]Cardiology Dept, S. Raffaele Scientific Institute, Milan; [2]Sports medicine Dept, Sports Science Institute – I.O.C., Rome, Italy*

Over the last decade a combined effort between Sport Physicians and Cardiologists has taken place with the intent of preventing severe sports related cardiac events, by identifying athletes with life threatening cardiac arrhythmias. The aim of this study is to present our updated results, until January 1999, regarding research of life-threatening arrhythmias and cardiac abnormalities in a cohort of International elite athletes (EA) studied for arrhythmias endangering their athletic careers.

Methods and results: From 1974 to January 1999, 1952 young (>35 yrs) competitive athletes, identified with arrhythmias, underwent an individualized arrhythmological non invasive and/or invasive study based on a codified clinical and instrumental protocol, 1937 males (m) and 315 females (f), mean age 21.4 yrs. 161/1952 (139 m, 28 f, average age 24.5 yrs) were EA including Italian, European, World and Olympic Champions. Of these 161 EA, 68 (42.2%) had cardiac abnormalities: arrhythmogenic right ventricular dysplasia (ARVD) in 12 (7.5%) mitral valve prolapse in 27 (16.7%), WPW in 15 (9.3%), Dilated Cardiomyopathy (DCM) in 3 (1.9%) one with sudden deah (SD), Hypertrophic Cardiomyopathy (HCM) in 1 (0.6%), mitral valve incompetence (severe) in 1 (0.6%), Aortic valve disease in 3 (1.9%), Myocarditis in 4 (2.5%), Atherosclerotic Coronary Artery Disease (ACAD) in 1 (0.6%) with SD, unknown Cardiomyopathy 1 (1.9%), with SD. Of these 161 EA 73(45.4%)were considered non eligible to participate in competitive sport activities and 18/73 (24.6%) are under antiarrhythmic treatment, 4 had a previously documented cardiac arrest (CA) (3 on field, one (WPW) at rest). Eleven had arrhythmic syncope. One with ACAD had SD at rest as first symptom. During the follow up 2 (with ARVD) ex EA required ICD implantation for refractory fast VT and high risk of SD; 2 experienced SD during sport activity, even though they had been declared non eligible. Six EA, with WPW at risk (including an alpine skier with CA) had successful RF catheter ablation (RFCA) of the accessory pathway, 2 with refractory recurrent atrial fibrillation/flutter had successful atrial RFCA with tridimensional non fluoroscopic approach.

Conclusion: EA with arrhythmias, previously considered eligible to compete, can have several arrhythmic events, at times life-threatening that are frequently consequence of an underlying heart disease or a "primary arrhythmic disease". This long term follow-up on EA can help us to explain and try to prevent drammatic cardiac events in the so called "apparently healthy subjects".

GENETICS AND PSYCHOLOGICAL INTERACTIONS

P2194 A comparison of psychosocial adaptation and acceptance in patients with pacemakers and implantable cardioverter-defibrillators

F. Duru, S. Buchi[1], C. Buddeberg[1], T.F. Lüscher, R. Candinas. *Cardiology Dept, University Hospital Zurich, Zurich; [1]Psychiatry and Psychosocial Medicine, University Hospital Zurich, Zurich, Switzerland*

Background: Implantation of a pacemaker (PM) or an implantable cardioverter-defibrillator (ICD) in a pt, at any time in life, by itself may result in a change in the body image, bringing along problems in psychosocial adaptation and acceptance. The aim of this study was to investigate the differences and similarities between the PM and ICD pts using validated tools of health status assessment.

Methods: 210 pts, aged 40 to 70 yrs, who underwent the first implantation of a PM or an ICD between 1993 and 1997 at the University Hospital of Zurich were included. All pts were asked to complete identical questionnaires mailed to them containing the Medical Outcomes Study SF36 and Hospital Anxiety and Depression (HAD) scale, both of which have accepted validity and reliability, and a specially designed device-related questionnaire to assess different aspects of an implantation, such as perceptions of an implanted device, technical concerns and individual needs of pts.

Results: 76 pts in the PM group (59 ± 10 yrs) and 76 pts in the ICD group (58 ± 13 yrs) returned the questionnaires. Sociodemographic properties of both groups were comparable. There was no difference between the 2 groups with respect to scores on any aspect of the SF36 and HAD. However, pts in the ICD group were more frequently aware of the physical presence of an implanted device, had increased preoccupation with their diseases and needed longer time to adapt ($p < 0.05$). ICD pts perceived the device as a 'source of anxiety', but also had a higher tendency to view it as a 'source of security' and 'life-extender'. Pts in both groups had little and similar degree of anxiety for battery failure or device-related technical problems (p = NS). 20% of PM pts and 33% of ICD pts wanted involvement in a support group.

Conclusion: Despite having distinct differences with respect to underlying heart disease and type of delivered therapies, pts with PMs and ICDs had similar performance on validated tools of health status assessment.

P2195 Heart rate variability and personality traits in acute myocardial infarction

C. Carpeggiani, M. Emdin, F. Bonaguidi, C. Michelassi, P. Landi, M. Raciti, M.G. Trivella, A. L' Abbate. *Coronary Unit, CNR Institute of Clinical Physiology, Pisa, Italy*

To define the possible correlation between the autonomic tone and the personality traits during acute myocardial infarction 24-h heart rate variability (HRV) by Holter monitoring (Remco-Cardioline) and personality by 16 Personality Factor Questionnaire(16 PF)of Cattell was evaluated before discharge. A Multicenter Italian study was conducted between genuary 1990 and december 1995: 455 patients were enrolled less than 70 years of age, mean 56 ± 8, 401 males. For this study 261 pts having both good quality recordings and 16 PF were selected. Following time and frequency HRV indices were computed from the two tracings: mean 24-h RR interval, standard deviation of all normal RR (SDNN), pNN50, r-MSSD, the mean of the 3 minutes RR standard deviation (SDRR), the standard deviation of the mean of the RR for all 3-minute segments (SDANN). Moreover, RR total power, VLF, LF, HF power, as well as LF/HF ratio, were computed.

The most significant correlations between time and frequency domain indices of HRV were those between SDNN and VLF power (r = 0.63) and SDNN and RR total power (r = 0.67).With regard to psychological dimensions, factors related to Anxiety negatively correlated with both time {SDNN: r = 0.15, PNN50: r = 0.18) and frequency (Total power: r = 0.16, HF power: r = 0.12) domain indices($p < 0.05$). These results suggest a possible link between psychological dimension and autonomic nervous system.

P2196 The impact of depressed mood on quality of life in patients after successful coronary angioplasty

Dariusz Dudek, Dominika Dudek[1], Andrzej Wróbel[1], Andrzej Zięba[1], Jacek S. Dubiel. *II Department of Cardiology, [1]Department of Psychiatry, Jagiellonian University, Krakow, Poland, ul. Kopernika 17*

Background: Depressed mood is an important clinical problem in patients (pts) with coronary artery disease (CAD), present in 16–22% of cases. Previous data showed discrepancy between the morphological and functional success of coronary artery angioplasty (PTCA) and quality of life (QoL). However, data is spared on the effects of mood on QoL in pts after PTCA.

Purpose: The aim of the study was to evaluate the impact of mood on QoL in pts with CAD after successful PTCA.

Methods: 50 pts with symptomatic angina (CCS II–III) and optimal PTCA (quantitative coronary angiography (QCA) guided PTCA; residual stenosis – QCA < 30%) were included. The QoL was examined by the SF-36. Beck Depression Inventory (BDI) was used to assess depressed mood. All pts were assessed the day before and four weeks after the intervention.

Results: Four weeks after successful PTCA pts were significantly less depressed in comparison to day 1 (BDI = 8.5 vs 13.1, $p < 0.05$) and their QoL was also significantly better ($p < 0.05$). However, important differences were found between pts who were depressed (BDI > 10) the day before PTCA and those who were not (BDI < 11). In depressed pts, in contrast to non-depressed subjects, QoL did not improve after PTCA. The value of SF-36 was significantly lower in first ($p = 0.0003$) as well as in the second assessment ($p < 0.05$), in spite of optimal result of PTCA.

Conclusion: The depressed mood determinates the lack of improvement of QoL after successful PTCA.

P2197 Prevalence of dystrophin defects in male patients with dilated cardiomyopathy

E. Arbustini, P. Morbini, B. Dal Bello, N. Banchieri, A. Pilotto, M. Diegoli, M. Grasso[1], C. Campana[2], A. Gavazzi[2]. *Department of Pathology, IRCCS Policlinico S.Matteo, Pavia; [1]Transplant. Experimental Laboratory, IRCCS Policlinico S.Matteo, Pavia; [2]Division of Cardiology, IRCCS Policlinico S.Matteo, Pavia, Italy*

Dystrophin defects causing X-linked dilated cardiomyopathy (DCM) in patients (pts) with clinically dominant or exclusive cardiac involvement may be indistinguishable from other DCM, and dystrophin defects may be missed unless specifically investigated. This study was aimed at investigating dystrophin defects by screening consecutive DCM male pts

Methods: We screened dystrophin defects in 168 DCM males, aged 16 to 68, consecutively examined from 1995 to 1998; all pts underwent evaluation with invasive and non invasive methods, including endomyocardial biopsy (EMB) and biochemical investigation (muscle enzymes). Light and electron microscopy, and immunohistochemical studies of EMB samples were performed; 36 exons and muscle promoter were analyzed with 6 known multiplex polymerase chain reactions, and exon 9 and of muscle promoter-exon 1 were sequenced.

Results: Of the 168 pts, 11 (6.5%) were found to be affected by dystrophin defects; 6 were older than 20 and had performed a regular military service; 5 were younger. A mild, "myopathy" (dystrophin defects were missed) had been suspected in 3, and clinically diagnosed in 2 of the 7 older pts (2 were unsuspected), and in all 4 young pts. Family history was positive in 5 and not informative in 6. Light microscopy examination of EMB was non-informative; ultrastructural study showed multiple discontinuous membrane defects. Dystrophin immunostaining documented reduced, discontinuous or absent stain of the sarcolemma. Molecular analysis identified gene defects in 8 pts: 6 pts older than 20 (deletions of rod-domain exons) and 2 of the younger pts (deletions affecting both NH-terminus and rod-domain).

Conclusions: Although the prevalence of dystrophin defects in DCM clinical series is relatively low (6.5%), screening studies are justified by the need of subgrouping DCMs on their etiopathogenesis. Immunostain of endomyocardial biopsy and ultrastructural study of EMB allow the diagnosis; routine multiplex PCRs detect molecular defects in most cases.

P2198 The unique genetic variant in the beta 1-adrenoceptor gene and its evaluation in idiopathic dilated cardiomyopathy

F. Tesson, P. Charron, M. Peuchmaurd, V. Nicaud[1], F. Cambien[1], L. Tiret[1], O. Poirier[1], P. Amouyel[2], K. Schwartz[3], M. Komajda. *Pavillon Rambuteau, Lab. Genetique et Insuff. Card., Paris; [1]INSERM U525, Paris; [2]Service de Cardiologie, Hopitaux de Brabois, Nancy; [3]INSERM U523, Paris, France*

Genetic factors that underlie Idiopathic Dilated Cardiomyopathy (IDCM) have not yet been elucidated. Considering that beta 1-adrenoceptors are down-regulated in patients with IDCM and that beta-blocker therapy is consistently beneficial in this setting, we hypothesized that genetic variation in the beta 1-adrenoceptor might affect susceptibility to and/or severity of IDCM. As no intragenic polymorphism was available, a systematic screening of the gene was first performed. The organization and sequence of the human beta 1-adrenoceptor gene were established using polymerase chain reaction, single strand conformation polymorphism analysis and sequencing. The gene comprises 1434 bp and no intron was observed. We found a unique and frequent polymorphism (C1165G) which predicts an Arg389Gly substitution. The association of this polymorphism with IDCM was then analyzed using the PCR-restriction fragment length polymorphism method in the CARDIGENE population, a clinically homogeneous population of IDCM. Genotypic distribution was in agreement with Hardy-Weinberg equilibrium. There were no differences in the beta 1-adrenoceptor allele frequencies between IDCM (n = 426; C/G = 0.76/0.24) and age and sex-matched control subjects (n = 395; C/G = 0.78/0.22). Within the patient group, no association was observed with the severity of the disease. In conclusion, the genomic organization of beta 1-adrenoceptor is described here for the first time. We found a unique and frequent polymorphism in the coding sequence of the gene. No association was observed between IDCM and the genetic variant. Its possible involvement in other cardiac diseases related to the beta 1-adrenoceptor remains to be analyzed.

P2199 The response to short-term infusion of angiotensin II is not influenced by polymorphisms of the angiotensin AT_1- and AT_2-receptor genes in humans

C. Delles, K. Riedel[1], K.F. Hilgers, J. Jacobi, H.P. Schobel, E. Fleck[1], V. Regitz-Zagrosek[1], R.E. Schmieder. *Dept. of Medicine/Nephrology, University of Erlangen-Nuremberg; [1]Dept. of Internal Medicine/Cardiology, Charité, Campus Virchow Klinikum, Humboldt University Berlin and Deutsches Herzzentrum Berlin, Germany*

Objective: Angiotensin II (A II) is the most potent endogenous vasoconstrictor by the AT_1 subtype of angiotensin receptors (AT_1-R). The AT_2 receptor (AT_2-R) is believed to counteract some of the AT_1-R mediated effects. Polymorphisms of the AT_1R gene have been associated with arterial hypertension and left ventricular hypertrophy. This study was conducted to directly examine the influence of polymorphisms of the AT_1-R and AT_2-R gene on the immediate vascular and hormonal response to A II in humans.

Methods: We enrolled 122 male, white, young (mean age, 26 ± 3 years) subjects with normal or mildly elevated blood pressure (but never treated for that) into a cross-sectional study. Changes in mean arterial blood pressure (MAP; Dinamap, Germany), aldosterone levels (Aldo; radioimmunoassay), glomerular filtration rate (GFR; inulin clearance), and renal plasma flow (RPF; para-aminohippurate clearance) served as parameters for the response to A II (3.0 ng/kg/min over 30 minutes). The −2228 G/A polymorphism of the AT_1-R promoter and the intronic +1675 G/A polymorphism of the AT_2-R gene were determined by restriction digestion and single strand conformation polymorphism analysis after polymerase chain reaction amplification, respectively.

Results: Blood pressure, body mass index, and baseline aldosterone and A II levels were similar across the various genotypes. Infusion of A II resulted in an increase in MAP, Aldo, and GFR, and in a decrease in RPF (all $p < 0.001$). As depicted in the table, response to A II did not significantly differ across the various genotypes.

	All subjects	−2228 G/G	−2228 G/A	+1675 A	+1675 G
ΔMAP (mmHg)	+15 ± 7	+16 ± 8	+14 ± 7	+14 ± 78	+16 ± 7
ΔAldo (pg/mL)	+102 ± 70	+102 ± 73	+101 ± 64	+93 ± 69	+113 ± 70
ΔGFR (mL/min)	+4.6 ± 7.1	+4.4 ± 6.9	+5.1 ± 7.4	+5.9 ± 7.0	+3.2 ± 6.9
ΔRPF (mL/min)	−128 ± 67	−130 ± 70	−124 ± 61	−128 ± 65	−128 ± 70

Conclusion: Hormonal and vascular response to A II is not influenced by the −2228 G/A polymorphism of the AT_1-R promoter and the intronic +1675 G/A polymorphism of the AT_2-R gene. Thus, the examined polymorphisms did not influence the physiological response to A II.

P2200 Polymorphism in the high density lipoprotein paraoxonase gene M54L polymorphism and the risk of acute myocardial infarction in men: a prospective population-based cohort study

J.T. Salonen, T.-P. Tuomainen, K. Seppänen, K. Nyyssönen, T.A. Lakka, R.M. Salonen, J. Kauhanen, R. Malin[1], T. Lehtimäki[1]. *Research Institute of Public Health, University of Kuopio, Kuopio; [1]Laboratory of Atherosclerosis Genetics, University of Tampere, Tampere, Finland*

The human serum paraoxonase (PON) is an antioxidative enzyme in high density lipoproteins (HDL), which eliminates lipid soluable radicals in the circulation. The missense mutation of A-to-T in codon 54 of the PON1 gene, producing M54L substitution, is associated with PON concentration and activity. We studied whether the MM genotype which leads to reduced PON activity is associated with an increased risk of acute myocardial infarction (AMI). The study population were 1263 male participants in the KIHD study who had no prior clinical coronary disease, aged 42–60 years at baseline. PON M54L genotypes were determined by PCR and Hsp92II digestion. Of the 1263 healthy men, 146 (11.6%) were MM homozygous. These men had both reduced PON activity and increased proportion of electronegatively charged LDL of total LDL in plasma ($p < 0.05$). 117 men had, based on MONICA criteria, an AMI during up to 13 years (mean 9 years) of follow-up.

The MM homozygous men had a 2.2-fold (95% confidence interval 1.4 to 3.5, $p < 0.001$) risk of AMI in a Cox model adjusting for 11 other strongest risk factors (including blood haemoglobin, diabetes, ischaemia in exercise test, serum apolipoprotein B, cigarette pack-years and serum ferritin). This relative risk was higher in smokers (3.4, 95% CI 1.6 to 7.2, $p = 0.002$) than in non-smokers (1.7, 95% CI 1.0 to 3.1, $p = 0.060$). The association of both smoking and high hair mercury content with AMI was stronger in MM homozygous than other men.

Our findings suggest a role for PON as a protective enzyme against coronary disease and provide thus evidence supporting the role of endogenous antioxidative systems. Also, these data show that the PON1 MM homozygosity is a risk factor for AMI. PON1 M54L is a good candidate for genetic screens of persons genetically predisposed to coronary disease.

THROMBOTIC FACTORS

P2201 Effects of anticoagulant and antiplatelet therapy on outcome during long-term follow-up in 427 patients with moderate to severe heart failure

D.J. van Veldhuisen, G. Tjeerdsma, P.J. de Kam, H.J.G.M. Crijns. *Dept. of Cardiology, University Hospital Groningen, Netherlands*

Current European and American guidelines do not recommend the use of anticoagulants and antiplatelets in patients with chronic heart failure (CHF). Recent data in patients with *mild* CHF, however, suggest that both treatments may possibly be beneficial.

Methods: We studied 427 patients (pts) with moderate to severe CHF (NYHA class III–IV, mean left ventricular ejection fraction (LVEF) 23%, 77% male), who were followed for 3.4 yr (range 2.0–5.2 yr). To study the effect of anticoagulation and antiplatelets on outcome, we performed univariate and multivariate analysis.

Anticoagulants were used in 288/427 (= 67%) pts. Use vs. non-use groups were similar for NYHA class, LVEF, and etiology of CHF. However, pts who used anticoagulants more often had atrial fibrillation (80% vs. 63%), and used fewer antiplatelets.

Antiplatelets were used in 74/427 pts (= 17%). Use vs. non-use groups were similar for severity of CHF, but pts on antiplatelets more often had ischemic CHF, and used fewer anticoagulants.

During follow-up, 221 pts died. A/ 51% of pts on anticoagulants died, compared to 54% of pts not on them. B/ 42% of pts on antiplatelets died, compared to 54% not on them. On multivariate analysis, both anticoagulants ($p = 0.01$, relative risk 0.65, 95% CI 0.46–0.90), and antiplatelets ($p = 0.03$, relative risk 0.62, 95% CI 0.40–0.96) were significantly related to a reduction in all-cause mortality.

Conclusion: The use of anticoagulants and the use of antiplatelets were both independently related to a reduction in mortality in pts with advanced CHF in the present study. These findings contrast with current guidelines for CHF, which do not advocate these agents.

P2202 Soluble P-selectin in patients presenting with chest pain : evidence for endothelial origin

P.A. Gurbel, D.J. Kereiakes[1], D. Atar[2], V.L. Serebruany. *Sinai Center for Thrombosis Research, Baltimore MD; [1]Cardiovascular Research, Lindner Center, Cincinnati OH, USA; [2]Div. of Cardiology, Zurich University Hospital, Zurich, Switzerland*

It has been reported that platelet expression and plasma levels of soluble P-selectin are increased in patients with unstable coronary artery syndromes and may serve as important diagnostic markers. However, the origin of soluble P-selectin remains unknown. We sought to determine whether platelet expression of P-selectin correlates with plasma levels in a population of patients presenting to the Emergency Department with chest pain.

Methods: Simultaneous soluble and platelet P-selectin levels were determined in 338 patients presenting with chest pain to the Emergency Departments of 3 different hospitals utilizing ELISA and whole blood flow cytometry, respectively.

Results: Using regression analysis no correlation ($R^2 = 0.055$) was found between soluble and platelet-bound P-selectin for the study population, including those patients with non-cardiac chest pain ($R^2 = 0.019$), unstable angina ($R^2 = 0.007$), acute myocardial infarction ($R^2 = 0.033$), congestive heart failure ($R^2 = 0.231$), and gastrointestinal illness ($R^2 = 0.020$).

In conclusion, the platelet expression of P-selectin is unrelated to the level found in plasma in patients with acute chest pain, irrespective of the etiology of chest pain. Dissociation between platelet and soluble P-selectin suggests prominent endothelial release of this molecule in this patient population.

P2203 Complex risk analysis of left ventricular thrombi in acute myocardial infarction

C. Tóth, E. Újhelyi, L. Voith[1]. *Department of Cardiology of Ferenc Markhot County Hospital, Eger; [1]Department of Heart and Lung Diseases, University Medical School, Debrecen, Hungary*

We studied the risk factors of the development of left ventricular thrombi (LVT) detected by transthoracic echocardiography (TTE) in acute myocardial infarction (AMI).

Methods: We analysed data of 1200 non-selected patients, who had been treated during a 7-year period in our department with Q-wave AMI. TTE was performed in all cases in the acute phase of myocardial infarction (MI). We detected LVT in 118 patients (10%). The anticoagulant therapy was not different between the two groups of patients.

	AMI and LVT (n = 118)	AMI without LVT (n = 1082)	p value
Men (%)	66	63	NS
Mean age (years)	66 ± 10	64 ± 10	NS
MI in the family history (%)	3	8	0.05
Smoking (%)	24	34	0.05
Diabetes (%)	21	20	NS
Hypertension (%)	60	59	NS
Hypercholesterolemia (%)	36	45	NS
Recurrent MI (%)	16	12	NS
Anterior MI (ECG; %)	78	38	0.001
Time pbh < 24 hours (%)	17	49	0.001
Thrombolytic therapy (%)	8	19	0.01
LV dilatation (Dd > 60 mm; %)	28	18	0.05
LV aneurysm (%)	20	7	0.001
LV EF < 40% (%)	26	16	0.05

Conclusions: In cases of LVT in AMI the time passed before hospitalization (Time pbh) is often longer than 24 hours. The anterior MI, left ventricular (LV) dilatation, aneurysm and decreased ejection fraction (EF) make patients in AMI more susceptible to LVT. It's interesting that among patients who had AMI without LVT smoking and family history of MI was significantly frequent.

A seasonal fluctuation also can be observed in the incidence of LVT. We detected LVT most frequently in May (17%) and least frequently in August (5%, $p = 0.05$).

P2204 Association of fibrinogen plasma levels with lipid profile and haemostatic variables in 962 young adults

A. Doulalas, M. Kougioulis, A.D. Vasilopoulos, D. Kaipis, N. Tsolakis, T. Tselegaridis. *Department of Cardiology, 424 General Military Hospital, Thessaloniki, Greece*

Background: Several studies have shown the important role of high fibrinogen plasma levels to both plaque formation and manifestations of coronary artery disease in populations of mid and older age. However the association of high fibrinogen plasma levels with other conventional risk factors and haemostatic variables in younger age has not been investigated comprehensively.

Method: The study population consisted of 962 healthy subjects (685 males, 277 females) aged 18.5 ± 0.5 years old. For each participant, a questionnaire of medical history and life-style parameters was completed and lipid and haemostatic plasma variables were determined.

Results: The mean fibrinogen concentration was 263 ± 79 mg/dl. The study population was divided into two groups according to fibrinogen levels: Group A with fibrinogen levels ≥ 300 mg/dl (175 subjects, 18.2%) and group B with fibrinogen levels < 300 mg/dl (787 subjects, 81.8%). Comparisons between groups are shown in the table (values in mg/dl or percentage % as appropriate):

Variables	Group A	Group B	P
TC	187 ± 34	178 ± 37	0.01
LDL	114 ± 33	104 ± 45	0.005
Lp(a)	19 ± 15	15 ± 12	0.015
VII	104 ± 19	98 ± 17	<0.00005
VIII	108 ± 23	103 ± 27	0.046
X	92 ± 10	90 ± 8	0.002

Conclusion: High fibrinogen plasma levels are found rather frequently in healthy young adults. They are associated with an adverse lipid profile and high levels of haemostatic variables, suggesting existence of a tight link between atherogenesis and thrombogenesis.

DIABETES

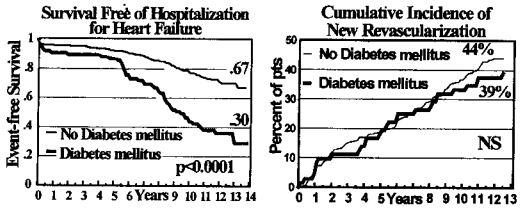
P2205 Increased late mortality and heart failure in diabetics after revascularization is not matched by more repeat interventions

D.A. Halon, M. Flugelman, A. Merdler, H.S. Rennert, G. Weisz, J. Shahla, B.S. Lewis. *Lady Davis Carmel Medical Center and Technion Israel Institute of Technology, Haifa, Israel*

Background: Following revascularization (Rev) diabetics have a higher mortality and more heart failure and a more vigorous policy of re-intervention may be required. We examined the incidence of repeat Rev in a long-term cohort study.

Methods: Cohorts of 80 diabetics and 285 non-diabetics treated by angioplasty or bypass surgery in one center in 1984–6 had structured telephone interview and records review over 12–14 yr. Analysis used Kaplan-Meier and cumulative incidence curves.

Results:



Conclusions: 1. Late mortality and heart failure were increased in diabetics vs non-diabetics after Rev. 2. There was no similar increase in late repeat Rev. 3. The data suggest that progression of CAD may be insidious or diffuse in diabetics hindering further Rev or heart failure in diabetics may have non-coronary causes.

P2206 Heart failure and prognosis in diabetic and non-diabetic patients after previous revascularisation; 8-year follow-up

P. Mitrovic, Z. Vasiljevic, B. Stefanovic, J. Perunicic, I. Mrdovic, G. Matic, T. Jozic, D. Rajic, A. Karadzic, B. Milentijevic. *Institute for Cardiovascular Diseases, University Clinical Centre, Belgrade, Yugoslavia*

Survival is poorer in diabetic than non-diabetic patients (pts) with coronary disease despite revascularization. Heart failure is a strong predictor of poor survival. We studied the need for hospitalization for heart failure (HHF) and its prognostic implications in diabetic and non-diabetic pts over 8 years after revascularisation by bypass surgery.

Methods: 380 pts revascularized by bypass surgery were studied. Survival was assessed in all pts from records and HHF from patient or family interview is available to date in 334 (87.9%). Analysis used Kaplan-Meier survival curves.

Results: Diabetics and non-diabetics were of similar age (59 ± 10 vs 57 ± 12 yrs; p = NS). Prior to revascularization a similar proportion had myocardial infarction (46/77, 60% vs 144/257, 56%; p = NS) and multivessel disease (72% vs 64%; p = NS). Diabetic had worse 8 yr survival than non-diabetics (50% vs 78%; p < 0.001), worse survival free of HHF (33% vs 60%; p < 0.001), worse subsequent survival after first HHF (38% vs 68%; p < 0.05) and worse survival free of further HHF (21% vs 58%; p < 0.05).

Conclusion: In pts with diabetes mellitus undergoing coronary revascularization long-term survival was reduced, hospitalization for heart failure was more common and hospitalization for heart failure had a more ominous prognosis, than in non-diabetic pts.

P2207 Maternally transmitted susceptibility to non-insulin-dependent diabetes mellitus and left ventricular hypertrophy

Y. Momiyama[1], Y. Suzuki, M. Ohtomo, Y. Atsumi, K. Matsuoka, M. Kimura, F. Ohsuzu[1]. *Saiseikai Central Hospital, Tokyo; [1]National Defense Medical College, Saitama, Japan*

It is suggested that non-insulin-dependent DM (NIDDM) has a strong genetic basis, and that some maternally transmitted DM is associated with mitochondrial DNA mutations, which can cause LV hypertrophy (LVH). DM is also known to be associated with LVH. Hence, LVH in NIDDM may be related to some genetic factors of DM.

Methods: We consecutively investigated the family history of DM and the prevalence of LVH using echocardiography in 324 patients (pts) with NIDDM. Pts with valvular heart disease or CAD were excluded.

Results: Of the 324 pts, 59 had diabetic mothers, 40 had diabetic fathers, and 4 had both. On the echocardiograms, LVH (wall thickness ≥ 12 mm) was found in 31 pts. The prevalence of LVH was higher in pts with diabetic mothers (17%) than in those with non-diabetic mothers (8%) (p < 0.05), whereas it was similar in pts with diabetic fathers (5%) and those with non-diabetic fathers (10%). Compared with 261 pts with non-diabetic mothers (group M–), 63 with diabetic mothers (group M+) were younger (61 ± 9 vs 64 ± 9 yrs, p < 0.05) and had the earlier onset of DM. The percentage of pts having diabetic siblings was higher in group M+ (40%) than in group M– (17%) (p < 0.001). However, there was no difference in sex, body mass index, DM duration, blood glycemic levels and blood pressures. Hypertension was present in 33% of group M+ and 47% of group M–. Group M+ had greater LV wall thickness (9.3 ± 1.4 vs 8.9 ± 1.2 mm, p < 0.02) and greater LV mass (149 ± 44 vs 139 ± 33 g, p < 0.05) than group M–. In multivariate analysis, the family history of DM in mothers, DM duration and hypertension were each significantly associated with LVH, but the family history of DM in fathers was not.

Conclusion: LVH in pts with NIDDM was associated with maternal transmission of DM. Some genetic factors of DM, such as mitochondrial DNA abnormalities, may be contributing to the development of LVH in maternally transmitted NIDDM.

P2208 Endothelium-dependent microcirculation vasomotion is not improved by lowering LDL in poorly controlled diabetes

J. Mansourati[1], C. Newton[2], L. Newman[2], A. Travis[2], S. Roman[2], M. Rafey[2], Z. Bloomgarten[2], R. Phillips[2]. [1]*Département de Cardiologie, CHU Cavale Blanche, Brest, France;* [2]*Mount Sinai School of Medicine, New York NY, USA*

Cutaneous microangiopathy is suspected to play a role in the pathogenesis of diabetic foot ulcer. Microcirculatory flow is in part regulated by the endothelium and hyperlipidemia has been shown to adversly affect endothelium-dependent relaxation in several vascular beds. We sought to determine if abnormal microcirculatory flow in the foot in patients with Type 2 diabetes and hyperlipidemia is improved by lipid lowering therapy.

Methods: We used laser Doppler techniques in conjunction with iontophoresis to measure endothelial dependent and independent microcirculation in 13 diabetic pts with LDL cholesterol > 130 mg/dL (12 F, 1 M). Patients were randomized to receive 40 mg of simvastatin (7 pts) or placebo (6 pts). Characteristics of these two groups were not statistically different at baseline (Table 1). Lipid profile and endothelial function were followed monthly. Endothelial and non-endothelial dependent vasomotion were assessed respectively by 1) response to local heating to 44°C and to iontophoresis of acetyl choline (Ach) and 2) to iontophoresis of sodium nitropruside (SNP). Although lipid profile improved significantly in the simvastatin group, endothelial function did not improve at 3 months (Table 2).

Table 1

	Age (years)	BMI (kg/m^2)	HbA1C %	TChol mg/dl	TG mg/dl	LDL mg/dl	HDL mg/dl
S	61 ± 6	33 ± 5	9.3 ± 1.7	256 ± 34	155 ± 17	177 ± 35	48 ± 10
P	60 ± 5	32 ± 5	9.1 ± 2.5	242 ± 32	137 ± 89	160 ± 24	54 ± 14

BMI: Body Mass Index, TChol: total cholesterol; TG: triglycerides

Table 2

	TChol mg/dl	TG mg/dl	LDL mg/dl	HDL mg/dl	HbA1C %	ΔHeat	ΔAch	ΔSNP
S	175 ± 29	124 ± 25	100 ± 25	51 ± 8	9.4 ± 2	1 ± 20	−0.7 ± 1.8	−9 ± 8.5
P	234 ± 35*	153 ± 125	146 ± 23*	56 ± 14	8.7 ± 1.6	0 ± 15	0.7 ± 1.4	−2.5 ± 2

ΔHeat, ΔAch and ΔSNP: Variation of normalized responses to heating, Ach and SNP between 3 months and the beginning of follow-up. *$p < 0.007$

Conclusion: In this population of patients with poorly controlled diabetes, LDL lowering by itself is not effective as a way to improve endothelial function. Further studies should assess the benefit of optimal control of diabetes, in conjuction with lipid lowering, on endothelium-dependent microcirculation vasomotion in patients with Type 2 diabetes.

P2209 Spontaneous baroreflex sensitivity in diabetic patients after pancreatic islet transplantation

Cs. Lengyel[1], Gy. Farkas[3], T. Török[4], P. Légrády[1], T.T. Várkonyi[1], A. Kardos[2], Z. Gingl[4], P. Kempler[5], L. Rudas[4], J. Lonovics[1]. [1]*1st;* [2]*2nd Depts. of Medicine;* [3]*Dept. of Surgery;* [4]*Medical Intensive Care Unit, A. Szent-Györgyi Med. Univ., Szeged;* [5]*1st Dept. of Medicine, Semmelweis Med. Univ., Budapest, Hungary*

Pancreatic islet transplantation may improve the carbohydrate metabolism and delay the development of diabetic complications. The aim of this study was to analyze the baroreflex sensitivity (BRS) in the resting supine position and after standing up in patients (pts) with insulin-dependent diabetes mellitus (IDDM) after islet cell transplantation (Tx).

Methods: 10 Tx pts (age: 43.7 ± 2.6 years, duration of IDDM: 26.4 ± 2.7 years, graft function: 9.6 ± 1.0 years; mean ± SEM), 17 non-transplanted (n-Tx) IDDM pts (age: 46.9 ± 3.8 years, duration of IDDM: 23.5 ± 3.1 years) and 15 healthy controls (age: 46.0 ± 1.7 years) were studied. The blood pressure was measured continuously with a *Finapres 2300* instrument (Ohmeda). The ECG signal was detected with a *Sirecust 730* (Siemens) electrocardiograph. The ECG and plethysmographic signals were fed through an analog-digital converter into a computer. The data were analyzed off-line. The spontaneous BRS was calculated in the supine position and after standing up.

Results: Both in the n-Tx and in the Tx group, the BRS was decreased in the supine position and also after standing up relative to the control value. In the Tx pts, the BRS values were elevated as compared with those for the n-Tx group. In the control group, the BRS was decreased after standing up in comparison with the resting position. In both the n-Tx and Tx groups, there was no significant difference between the BRS values measured in the supine and standing positions.

	Control	n-TX	TX
BRS in supine position (ms/mmHg)	8.7 ± 0.9	*3.2 ± 0.6	†*5.5 ± 0.7
BRS after standing up (ms/mmHg)	‡5.3 ± 0.5	*2.0 ± 0.4	†*3.6 ± 0.8

*$p < 0.05$ vs control, †$p < 0.05$ Tx vs n-Tx, ‡$p < 0.05$ standing vs supine position

Conclusions: 1) In long-standing IDDM, a severe impairement of the cardiovascular adaptation was found. 2) The BRS was less diminished in the transplanted patients relative to the non-transplanted group. 3) Pancreatic islet transplantation may decrease the progression of diabetic autonomic neuropathy.

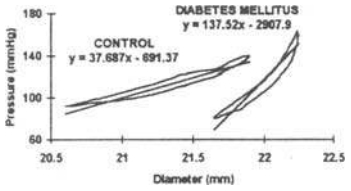
P2210 Impaired aortic elastic properties in patients with coronary artery disease: impact of non-insulin diabetes mellitus

K. Toutouzas, C. Stefanadis, E. Tsiamis, J. Dernellis, C. Vlachopoulos, P. Toutouzas. *Hippokration Hospital, University of Athens, Greece*

Deterioration of arterial elastic properties may be an early feature of vascular dysfunction. Patients (pts) with diabetes mellitus (DM) are at high risk of cardiovascular disease. This study investigated aortic elastic properties in pts with coronary artery disease with non-insulin dependent DM and matched control pts.

Methods: Fourteen patients with non-insulin dependent diabetes mellitus (DM) and 66 pts without DM were studied. All pts suffered from coronary artery disease. Instantaneous aortic diameter (D) was measured by an intravascular catheter developed in our institution and previously validated. Instantaneous aortic pressure (P) was measured simultaneously at the same aortic level with a catheter-tip micromanometer. Thus, aortic P-D loops were obtained and slope, and intercept were calculated. Also, aortic distensibility was calculated by = (Pulsatile change in aortic D)/(Diastolic D × Pulse Pressure).

Results: Age and heart rate were similar in the 2 groups. The pulse D was greater in the control group (1.27 ± 0.42 vs 0.92 ± 0.45 mmHg). The distensibility was less in DM pts (1.65 ± 0.95 vs 0.94 ± 0.48 dyn^{-1} cm^{-2} 10^{-6}, $p < 0.01$). Also, the slope (109.12 ± 118.4 vs 19.6 ± 3.3 mm^{-1}, $p < 0.004$) and the intercept was less in DM pts (−2257.39 ± 2579.7 vs −338.7 ± 93.1, $p < 0.005$).



Conclusions: In pts with non-insulin dependent DM, aortic elastic properties are deteriorated. These results may contribute to the unfavorable outcome of pts with DM suffering from coronary artery disease. Further studies in DM pts with pharmacologic agents that affect the elastic properties of the aorta are currently undergoing.

P2211 Protective effect of cicletanine on renal function in uninephrectomized diabetic spontaneously hypertensive rats

M.J. Duran[1], S. Sennoune[1], C. Arnaud[2], S. Garcia[3], M.T. Droy-Lefaix[4], J.M. Maixent[1]. [1]*Laboratoire de Biochimie, Faculté de Pharmacie;* [2]*Laboratoire de Biochimie;* [3]*Laboratoire d'Anatomopathologie, C.H.U. Hôpital Nord Marseille;* [4]*Institut IPSENParis, France*

Diabetic spontaneously hypertensive rats (SHR/D) develop renal functional alterations similar to those observed in human diabetic nephropathy associated with hypertension. Microalbuminuria is a predictive marker of renal disease in this case. Cicletanine is a new antihypertensive agent with an original structure that provides cardiovascular and renal protection and it uniquely stimulates prostacyclin production. Its effect on renal dysfunction during hypertension and diabetes is unknown. the present study was designed to assess whether the orally active cicletanine affects progressive renal dysfunction in a diabetic and hypertensive rat model of renal damage.

Methods: Uninephrectomized SHR/D (n = 18) were subdivided in three groups: SHR/D, SHR/D + 10 mg/kg body wt/day of cicletanine and SHR/D + 50 mg/kg body wt/day of cicletanine. Age-matched untreated Wistar Kyoto rats serve as control. The cicletanine treatment began one week after diabetes induction and was maintained on 6 weeks. Microalbuminuria and proteinuria have been evaluated throughout the treatment. At the end of the treatment, kidney histology and creatinine clearance were studied.

Results: Treatment with cicletanine did not affect significantly systolic blood pressure and hyperglycemia in animals. Cicletanine, at its two dosages, decreased significantly the elevated microalbuminuria of SHR/D in a dose related manner ($p < 0.01$ vs. SHR/D). These effects were similar for proteinuria and occurred after one month of cicletanine treatment. Renal histology analysis was not significantly different from Wistar Kyoto rats without signs of glomerular hypertrophy and sclerosis. Altered creatinine clearance was normalized at the higher cicletanine dose (4.2 ± 0.6 vs. 3.6 ± 0.7 ml/min./g of kidney).

Conclusion: The main finding of this study is that the orally active cicletanine has a nephroprotective effect on the progression of renal disease, probably blood pressure-independent, in a hypertensive and diabetic rat model.

P2212 Comparison of coronary stenting and coronary angioplasty in diabetic patients

O. Engin, M. Sisman, G. Ates, A. Eksik, G. Yuksel, H. Sunay, B. Ersek, T. Ulusoy, A. Cagil. *Cardiology Dept, Siyami Ersek G.K.D.C.M., Istanbul, Turkey*

Background: Most of studies have demonstrated excess morbidity and mortality in diabetic patients treated with coronary angioplasty (PTCA) and have suggested superior outcomes with coronary by-pass (CABG) surgery. Coronary stents (S) have reduced the restenosis rate compared to PTCA in the global population. But there are some questions coronary stenting in diabetic patients still unanswered.

Methods: We designed this study to compare the results of coronary stenting and PTCA in native coronary vessels with diabetic patients. We retrospectively evaluate 404 patients undergone PTCA. There were 63 (15.6%) diabetics and 341 (84.4%) non-diabetics. We prospectively evaluate 185 patients undergone coronary stenting. There were 36 (19.5%) diabetics and 149 (80.5%) non-diabetics. There were no differences in clinical and angiographic characteristics between PTCA and S groups. PTCA and S were performed to single coronary artery in all patients. We took 8 months clinical follow-up data for our study.

Results: There were no significant differences in procedural and clinical success and in-hospital major complications between PTCA and S groups. In 8 months clinical follow-up, in PTCA group incidence of untoward cardiac events was significantly higher than S group.(38% vs 13.9%, p = 0.02)Rates of mortality(3.2% vs 2.8%), nonfatal myocardial infarction(AMI)(3.2% vs 5.6%) were similar in both groups. Rates of revascularization (37.1% vs 5.6%, p = 0.005) were higher in PTCA group.

Conclusion: Diabetes is a risk factor for restenosis. Cardiac events and revascularization rates were significantly higher in patients who underwent PTCA alone at 8 months of follow-up. Coronary stenting is more suitable than PTCA in diabetic patients.

P2213 Low job-control and prevalence of diabetes: results from the Belgian "Belstress study" baseline data

F. Leynen[1], P. de Smet[1], R. Mak[2], G. De Backer[2], F. Kittel[1], M. Kornitzer[1].
[1]*Laboratory of Epidemiology and Social Medicine, Brussels Free University;*
[2]*Vakgroep Maatschappelijke Gezondheidkunde, Universiteit Ghent, Belgium*

Several epidemiological surveys have shown a positive association between stress at work and incidence of cardiovascular diseases. A current method, for measuring stress at work, consists in using "Job Stress Scales", based on the "Job Content Questionnaire", developed by R. Karasek: "Psychological Demands (PD), "Decision Latitude, or Job Control (JC)", "Job Strain" (a combination of high PD and low JC) and "Social Support at Work (SSW)". In the Belstress prospective study, we verified the association between stress at work, defined as either high PD, low JC, low SSW and Job Strain, with coronary risk factors (CRF) in 16335 male and 5084 female volunteers, aged 35–59 years old and working in 24 companies. They completed a questionnaire and underwent a clinical screening examination at the beginning of the study. Diabetes, based on a positive answer at the question "Did a physician ever told you that your blood sugar was to high?", was considered as a major CRF. The overall diabetes prevalence was 2.8% in males and 2.1% in females. After excluding the insulinodependent cases, we still found respectively 2.6% and 2.0% of subjects, having answered positively to the question. Comparison of crude means showed no differences in diabetes-prevalence between the PD-quartiles and SSW-quartiles and between Jobstrain groups, neither for males nor for females. An inverse, statistically significant, association was observed between JC and diabetes prevalence, in male as well as in female subjects. After adjustment for age, educational level (EL), Body Mass Index (BMI), SSW and Depression, we still found an Odds Ratio (OR) of 0.52 (CI: 0.38–0.71)*** between the highest JC quartile and the lowest JC quartile for the male population. An OR of 0.47 (0.26–0.85)* was found for females, independently of age, EL and BMI; after adjustment for SSW and Depression, the OR is 0.78 (0.40–1.55) (Not Significant). In females OR of diabetes between highest and lowest quartile of SSW is 0.63 (0.41–0.96), independently from age, EL and BMI.

Conclusion: A consistent inverse association is observed between JC and diabetes prevalence; we are unable to show a causality in a cross-sectional analysis; however, we have to consider the hypothesis that diabetes is one of the mediatory CRF, explaining the relationship between low JC at work and coronary heart disease as observed in several prospective studies.

P2214 Assessing diabetic autonomic neuropathy: how many tests are necessary?

O. May, H. Arildsen. *Dept. of Cardiology, Odense University Hospital, Odense; Dept. of Medicine, Horsens Hospital, Horsens, Denmark*

When diabetic autonomic neuropathy is assessed a battery of 5 tests are often used, but the number of tests required has not been investigated empirically.

Purpose: To evaluate the relative importance of 5 clinical tests using heart rate variability (HRV) as the gold standard.

Methods: In a random population based sample of 135 diabetic patients a group of 3 mainly parasympathetic tests (E/I-ratio (A), 30:15-ratio (B) and Valsalva-ratio (C)) and 2 mainly sympathetic tests (Ortostatic-BP (D) and sustained handgrip (E)) were carried out. After log-transformation of A, B and C the results of all 5 tests were standardised to units of SD. To evaluate combinations of tests the mean of the standardised readings were used. A 24-h Holter recording (Tracker) was edited manually on the Path-finder 700. Spectral analyses of the first 5 min each hour were performed in the RR-Tools programme. The mean log power of the Low Frequency band in the daytime expressed the sympathetic function and the nighttime mean log power of the High Frequency band the parasympathetic function. The mean sum of squares (Mssq) of the HRV explained by each test or combination of 2 tests in regression analysis was compared to the combination of each group of tests and to all 5 tests using an F-test (*P*, table).

	P	Mssq	*r*	*P*
Nighttime mean lnHF				
A	NS	61.9	0.57	NS
B	<0.001	40.1	0.46	0.01
C	<0.001	37.0	0.44	0.003
AB	NS	65.2	0.58	NS
AC	NS	67.9	0.60	NS
BC	NS	55.1	0.54	NS
ABC	→	71.4	0.61	NS
ABCDE		61.6	0.57	←
Daytime mean lnLF				
D	NS	46.1	0.51	<0.001
E	<0.001	9.64	0.14	<0.001
DE	→	41.5	0.48	<0.001
ABCDE		101.2	0.75	←

Results: All 5 tests were significantly associated to HRV ($p < 0.01$). The E/I-ratio had the highest correlation to HRV and no combination of the 5 tests explained a significantly larger part of the variation in HRV. The Valsalva- and 30:15-ratio were significantly poorer than their combination with E/I-ratio. The sympathetic tests were poorer than the combination with the parasympathetic tests (table).

Conclusion The E/I-ratio is the superior of the 5 tests assessed, it may be used alone or in combination with another parasympathetic test. Adding the ortostatic BP or handgrip test does not provide further information.

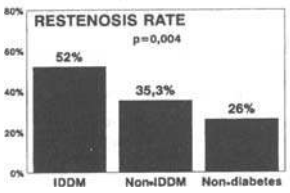
P2215 Influence of the presence and type of diabetes mellitus on the initial and long-term outcome after coronary stenting

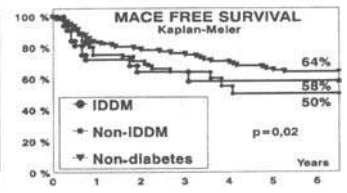
J.J. Alonso, J.M. Durán, F. Gimeno, B. Ramos, J.C. Muñoz, L. de la Fuente, A. Serrador, R. Palomino, J. Paniagua, F. Fernández-Avilés. *Hospital Universitario, Valladolid, Spain*

Data regarding the evolution after coronary stenting (CS) of insulin-dependent diabetes mellitus (IDDM) and non-IDDM patients are scant and controversial.

To assess the initial and long-term efficacy of CS in diabetics we compared the evolution of 35 IDDM patients (pts) with the outcome of 92 non-IDDM pts and a control group of 856 non-diabetic stented pts of a series of 983 consecutive pts treated with CS. Patients with IDDM were more often female (40%), and had a higher rate of previous heart failure (14%) and lower reference diameter ($p < 0.05$, compared with non-IDDM and non-diabetic pts). Hypertension was more frequent in non-IDDM pts than in the other two groups (52% vs 46% vs 37%, $p < 0.05$). No other clinical, angiographic or procedural differences between groups were found. Clinical follow-up was completed for 94% of pts (3.1 ± 1.4 years, range: 1.8–6.5).

Clinical success at one month (angiographic success without major events) was similar among the three groups (IDDM: 93%, non-IDDM: 94%, non-diabetic: 94%). Angiographic restenosis rate was significantly higher in IDDM pts. Major adverse cardiac events (death, re-PTCA, CABG or admission for myocardial infarction or unstable angina) (MACE) during follow-up were significantly higher among diabetics, without differences between IDDM and non IDDM-pts (figures)





Thus: 1) initial outcome of diabetics is similar to that of non-diabetic pts but angiographic restenosis occurs more often in IDDM pts; 2) diabetics have a worse clinical long-term evolution without differences related to the type of diabetes.

P2216 Cardiovascular autonomic neuropathy in the diabetic population: more prevalent in insulin-dependent diabetes mellitus compared to non-insulin-dependent diabetes mellitus

O. May, H. Arildsen. *Dept. of Cardiology, Odense University Hospital, Odense; Dept. of Medicine, Horsens Hospital, Horsens, Denmark*

Only a few population based studies on cardiovascular autonomic neuropathy (CAN) in diabetes is available and differences between IDDM and NIDDM has not been explored.

Purpose To estimate the prevalence of CAN in the diabetic population and compare the frequencies in IDDM and NIDDM.

Methods To delineate the diabetic population in the municipality of Horsens, Denmark, data from all prescriptions of antidiabetic medicine were registered in 8 months. A random sample of 120 users of insulin and 120 users of oral hypoglycaemic agents between 40 and 75 yrs were recruited. IDDM was registered if f-C-peptide was below 0.30 nmol/l, the remaining had NIDDM. From a standard ECG recorded at 50 mm/sec the longest RR-interval in expiration and the shortest during inspiration in each of 3 consecutive cycles of deep breathing at 6 breaths/min were measured and their mean ratio calculated (E/I-ratio). A 24-h Holter recording (Tracker) were obtained and after manual editing on the Pathfinder 700 the number of differences in successive RR intervals exceeding 50 msec ($sNN50_{24\text{-}h}$) were computed. The power in the High Frequency band (0.15–0.4 Hz) the first 5 min each hour during nighttime (HF_{night}) was calculated in the RR-Tools programme. After log-transformation the age dependent 5-percentile was established for all 3 methods in a random sample of 173 non-diabetics. CAN was registered in diabetics with values below these limits.

Prevalence of CAN, %

Method	IDDM	P	NIDDM
E/I-ratio	31.3	0.04	17.4
$sNN50_{24\text{-}h}$	34.3	0.03	19.6
HF_{night}	35.8	<0.001	7.6

Results 178 diabetics responded and readings by all 3 methods were obtained in 159. 67 had IDDM (age: 40–75 yrs, males: 63%) and 92 NIDDM (age: 43–75 yrs, males 52%). A significantly higher prevalence of CAN was found in IDDM compared to NIDDM (Table) by all 3 methods. The difference was especially pronounced when the degree of CAN was expressed by HF_{NIGHT}, which may be the more sensitive method.

Conclusion Cardiovascular autonomic neuropathy in the 40 to 75 yr old diabetic population is more prevalent in IDDM compared to NIDDM.

P2217 Improved outcome of diabetic patients with acute myocardial infarction in the thrombolytic era

S. Gottlieb[1], A. Shotan, U. Goldbourt, J. Leor, V. Boyko, L. Mandelzweig, A. Keren[1], S. Behar. *For the SPRINT and the Israeli Thrombolytic Survey Group; Jerusalem, Israel*

Several studies performed in the prethrombolytic era (PTE) consistently showed that diabetic (DM) pts with AMI have a higher in-hospital and post-discharge mortality. Data comparing the outcome of DM pts in the PTE and the thrombolytic era (TE) are scarce. We compared the incidence and short- and long-term outcome of DM pts with AMI in the TE and the PTE.

Methods: A prospective, nationwide survey of 4317 consecutive pts admitted with AMI in all CCUs in Israel during Jan.–Feb. of '92, '94, and '96 (TE), compared with a previous Israeli study of 5839 AMI pts (SPRINT Registry) in 1981–83 (PTE).

Results: DM pts in the TE (n = 1093) were older and had a worse risk profile than those without DM. DM in the TE was independently associated with increased 30-day (15.9 vs. 9.3%; OR = 1.27; 95% CI 1.00–1.61) and 1-yr (25.3 vs. 14.0%; HR = 1.42 1.42; 95% CI 1.20–1.68) mortality. The incidence of DM was higher in the TE (25 vs. 21%, p < 0001). DM pts in the TE were slightly older (65 ± 11 vs. 64 ± 9; p = 0.01) and had prior MI more often (30 vs. 25%; p = 0.01), but Q-wave MI (74 vs. 86%; p < 0.0001) and prior angina less often (39 vs. 55%; p < 0001). The crude and multivariate adjusted 30-day (15.9 vs. 22.4%; OR = 0.55; 95% CI 0.42–0.73) and 1-yr (25.3 vs. 31.4%; HR = 0.67; 95% CI 0.56–.80) mortality rates of DM pts were significantly lower in the TE than in the PTE.

Conclusions: Pts with DM in the TE had a better short- and long-term outcome than counterparts in the PTE, probably reflecting the better management of AMI pts in the TE. However, the mortality of DM pts with AMI in the TE remains high despite recent improvement in management.

EPIDEMIOLOGY: INFECTION AND INFLAMMATION

P2218 High prevalence of IgG antibody to Chlamydia pneumoniae in patients with proven coronary artery disease in a western Galilee population

Eduard Kaykov, Benyamine Abbou, Scott Friedstrom, Doron Hermoni, Uri Forschner, Nathan Roguin. *Department of Family Medicine and Department of Cardiology, Western Galilee Hospital, Nahariya; Technion Faculty of Medicine, Haifa, Israel*

Objectives. To evaluate the association between chronic infection with Chlamydia pneumoniae (C. pneumoniae), as measured by a high titer of IgG antibody, and coronary artery disease (CAD). Our study was designed to explore the relationship between seropositivity to C. pneumoniae and serious coronary events, and to assess whether or not there may be additional association between established cardiovascular factors and infection with this organism.

Background. Previous work has suggested an association between C. pneumoniae infection and CAD. The infection was demonstrated by titers of antibodies – enzyme linked immunosorbent assay (ELISA) or immunofluorescence (MIF), PCR and by the findings of C. pneumoniae in the atherosclerotic plaque.

Methods. The serum of 130 patients with proven CAD was tested for the presence of IgG antibodies to C. pneumoniae using an ELISA test (SeroCP-Savyon Diagnostics). A titer greater than or equal to 1: 64 using the MIF method, the recognized "gold standard", correlates with a positive result when using the ELISA method. The mean age was 57 (40 to 65), 82% male and 18% female. The patients had either myocardial infarction (n = 109) or unstable angina (n = 21) six months before the investigation (range 3–24 months). The serum for the control group was obtained from 98 blood donors from the same area matched for age 52 (40 to 58) and sex.

Results. In the CAD group 75% of patients were positive for C. pneumoniae. In the control group 33% were positive (P = 0.001). No increased correlation could be demonstrated between traditional risk factors and C. pneumoniae infection, except in those patients with diabetes mellitus. We found out that in diabetes subgroup there was low prevalence of IgG antibody to C. pneumoniae, comparing with other subgroups. (p < 0.006)

Conclusions. These results suggest that chronic C pneumoniae infection may be a significant risk factor for the development of coronary artery disease.

P2219 Periodontitis as a potential risk factor for coronary heart disease

S. Geerts, M. Nys, V. Legrand, E. Rompen. *Depts of Dentistry & of Cardiology, University of Liege, Belgium*

Some recent studies have suggested that an association could exist between chronic oral infections, such as periodontitis, and coronary heart diseases: the periodontal pockets could serve as reservoirs of Gram-anaerobic bacterias and their toxins, and be in relation with the development of atherosclerotic events and their acute complications.

Methods: The periodontal status of 107 heart patients (52 AMI, mean age 61.2 y; 55 CCHD, mean age 60.3 y) and of 39 controls (mean age 60.3 y) was determined. Blood samples were taken to assess various biological parameters and, in some cases, to investigate the periodontitis-associated endotoxemia: for 34 AMI and for 8 CCHD patients, 10 ml of blood were taken before and 10 ml after a gentle standardized mastication; for 28 CCHD patients, 10 ml of blood were collected without chewing. All these patients had a moderate to severe periodontitis.

Results: Both groups of heart patients exhibited an extremely high prevalence of periodontitis when compared with the controls: respectively 96%, 87% and 66% of AMI, CCHD and controls had a periodontitis, which was severe in 69% of AMI, in 60% of CCHD but only in 36% of controls. In addition, the mean number of pockets by patient was 18.5 for AMI, 16.5 for CCHD and 5.9 for controls. There were 60% of AMI patients versus 16% of CCHD patients who exhibited an levated blood level of fibrinogen. Among these AMI patients, 27.3% showed a positive and significative endotoxemia after mastication. On the other hand, 51.5% of AMI patients versus 8% of CCHD patients had an elevated blood level of CRP. 21% of these AMI patients showed a positive and significant endotoxemia after chewing. As a whole, a significant endotoxemia was found in 11.7% of AMI patients before mastication, whereas 35.3% of these patients had a post-mastication positive endotoxemia. Among CCHD patients, no one showed a positive endotoxemia before mastication when 25% of them became positive after chewing.

Conclusions. The severity, extent and prevalence of periodontitis were higher in both heart patient groups than in controls. In addition, AMI patients had more often a severe periodontal disease than CCHD patients. Our results also show that an endotoxemia can occur after a gentle mastication in periodontitis-affected heart patients. Nevertheless, wether or not periodontal disease plays an etiological role for cardiovascular diseases deserves further studies.

P2220 A role for Chlamydia pneumoniae and cytomegalovirus infections in coronary artery disease in Polish population

J. Przyłuski[1], M. Kruk[1], T.W. Deptuch[1], E. Podsiadły[2], J. Siennicka[2], W. Gut[2], Z. Dzielińska[1], J. Kądziela[1], S. Tylewska-Wierzbanowska[2], W. Rużyłło[1]. *[1]National Institute of Cardiology, Warsaw; [2]National Institute of Hygiene, Warsaw, Poland*

Background: Chlamydia pneumoniae (CP) as well as Cytomegalovirus (CMV) are common pathogens found in about 50% of healthy western population. Many studies suggest their adverse influence on development and course of coronary artery disease (CAD). So far no reports investigated relationship between infectious agents and CAD in Polish population, which has higher incidence of CAD than western European countries.

The aim of our study was to evaluate a possible role of CP and CMV infections in both CAD development and course of the disease in patients (pts) undergoing percutaneous coronary angioplasty (PTCA).

Methods: We enrolled 73 consecutive pts (mean age 54.8 years, 55 males) admitted for PTCA and 63 healthy controls (mean age 47.25 years; 31 males). The study subjects were evaluated for presence of CP specific IgG antibodies (microimmunofluorescence MIF test – Pointe Scientific; titre > = 1/8 regarded as positive) and CMV specific IgG antibodies (ELISA Eti-Cytok-G PLUS – Dia Sorin). Pts were sampled at the time of PTCA. In 68 pts available for follow up presence of CAD symptoms was assessed by angina questionnaire 7 months (mths) after the procedure.

Results: CP IgG antibodies were detected in 33 pts (45.2%) and in 14 subjects (22.2%; $p < 0.05$) from control group. In 29 out of 68 pts (42.6%) CAD symptoms were observed 7 mths after PTCA. No significant correlation was found between anti-CP IgG presence in symptomatic and non-symptomatic pts. There was no significant difference in anti-CMV IgG titre between study and control groups. Mean anti-CMV IgG titre in the symptomatic group tended to be higher than in non-symptomatic group, respectively 5.11 ± 2.67 vs 4.65 ± 3.91.

Conclusions: Our study results suggest a significant correlation between CP but not CMV infection with CAD prevalence. We did not find a positive association of CAD symptoms 7 mths after PTCA with markers of either CP or CMV infection.

P2221 Antibodies to Chlamydia pneumoniae do not predict subsequent coronary heart disease in the Scottish Heart Health and MONICA studies

R. Tavendale, D. Parratt[1], R. A'Brook, H. Tunstall-Pedoe. *Cardiovascular Epidemiology Unit, University of Dundee, Dundee; [1]Department of Medical Microbiology, University of Dundee, Dundee, UK*

Evidence associating the respiratory bacterial pathogen Chlamydia pneumoniae and coronary heart disease (CHD) is accumulating. Archived serum from participants in the Scottish Heart Health Study (1984–1987) and the MONICA risk factor surveys (1986–1995) is a valuable resource, useful for investigating new coronary risk factors. Follow-up of the study participants for both fatal and non-fatal coronary events is continuing. For this study, 252 case-control pairs with adequate stored serum were identified. Control subjects, with no evidence of coronary heart disease, were chosen from within the study populations and were matched for age, sex and locality. The average time period between the collection of blood in the original survey and the coronary event was 3.9 years.

IgG, IgA and IgM antibodies to C. pneumoniae were estimated using Savyon (Ashdod, Israel) ELISA kits. Specimens from the CHD cases and their matching controls were randomly analysed on each microtitre plate. The manufacturer's cut-off values were used to evaluate the absorbance data obtained.

Antibody	Number of positive specimens			
	Controls		Cases	
	n	%	n	%
IgG	188	75	193	77
IgA	124	49	134	53
IgM	9	4	8	3

The table shows a high prevalence of both IgG and IgA antibodies to C. pneumoniae but no case-control differences. In these subjects, antibody status is not predictive of coronary events occurring some years later. However these data do not rule out active C. pneumoniae infection having a role in the precipitation of coronary events.

P2222 Correlation of components of the metabolic syndrome with C-reactive protein: a sensitive marker of systemic inflammation

M. Fröhlich[1], A. Imhof[1], G. Berg[2], M.B. Pepys[3], H. Brenner[4], R. Muche[5], H. Boeing[6], W. Koenig[1]. *[1]Dept. of Internal Medicine II, Cardiology, University of Ulm Medical Center, Ulm; [2]Diabetes Institute, Heinrich Heine University, Düsseldorf; [4]Department of Epidemiology, University of Ulm, Ulm; [5]Department of Biostatistics University of Ulm, Ulm; [6]Dept. of Epidemiology, DIFE, Bergholz-Rehbrück, Germany; [3]Immunological Medicine Unit – Division of Medicine, Hammersmith Hospital, London, UK*

The metabolic syndrome (MS) is closely related to coronary heart disease (CHD) risk. Inflammation plays a crucial role in atheropathogenesis and features of the MS, like elevated levels of serum VLDL-cholesterol, glucose, fibrinogen and PAI-1 were linked to an ongoing acute phase response.

We correlated C-reactive protein (CRP), a sensitive marker of inflammation – with components of the MS. Total cholesterol (Chol), HDL-cholesterol (HDL), triglycerides (TG), fasting blood glucose (Gluc), uric acid (UA) and body mass index (BMI) were determined in a total of 747 men and 956 women aged 18–88 years participating in the VERA study which was carried out in 1987/88. Participants were drawn from a random sample representative for the population in West-Germany. Persons with acute and chronic diseases were excluded. Chol, HDL, TG, Gluc and UA were determined by routine laboratory methods. CRP was measured by means of a sensitive immunoradiometric assay. Prevalence of arterial hypertension (AHT) was assessed by a standardized interview.

Spearman correlation analyses yielded a statistically significant positive crude correlation between CRP and Chol ($r = 0.19$), TG ($r = 0.29$), BMI ($r = 0.32$), Gluc ($r = 0.11$) and UA ($r = 0.14$). A negative correlation was found between CRP and HDL ($r = 0.13$). After clustering subjects with 0–1, 2–3 and >4 features of the MS, age-adjusted geometric means of CRP values were calculated across groups. CRP values increased appreciably with increasing features of the MS. The values were 1.06, 1.24 and 2.0 mg/l respectively.

The MS is closely associated with a systemic inflammatory response. This may be a further pathogenetic mechanism for the increased CHD risk in those subjects.

EPIDEMIOLOGY: RISK FACTORS, PROGNOSIS AND TIME TRENDS

P2223 Longitudinal trends in cardiovascular risk factors in the Czech population

R. Cífková, Z. Škodová, Z. Hejl, V. Adámková, E. Novozámská, J. Pit'ha, M. Jozífová, D. Šraierová, G. Hauserová, A. Dušková, V. Lánská, J. Skibová, R. Poledne, P. Stávek. *Institute for Clinical and Experimental Medicine, Prague, Czech Republic*

The Czech Republic, unlike the other former East Bloc countries, has seen a decrease in total, and cardiovascular (CV) mortality in particular; still CV disease accounts for 56% of total mortality.

Methods: Three cross-sectional surveys of CV risk factors were conducted within the WHO MONICA Project in six Czech districts in 1985 (n = 2570), 1988 (n = 2768), and 1992 (n = 2342). In 1997/98, another population survey (a 1% random sample, aged 25–64, mean age 45 years) was performed in the six original districts (n = 1990) and in three other districts (n = 1219). The respondence rate was 64.4%.

Results: Over a 12-year period, there was a statistically significant decrease in the prevalence of smoking in males (from 49.2% to 36.8%, $p = 0.001$) and no change in smoking habits in females. Body mass index did not change in either sex, and obesity is still highly prevalent in the Czech population, especially aged 45+. A significant reduction, both in SBP (from 133.6 ± 20.2 to 127.8 ± 17.5 mmHg; $p < 0.001$) and DBP (from 84.1 ± 11.3 to 81.5 ± 10.1 mmHg; $p < 0.001$), was achieved. There was also a decreased prevalence and improved control of hypertension. A remarkable drop in total cholesterol was seen in both sexes (males: from 6.21 ± 1.29 to 5.65 ± 1.15 mmol/l; $p < 0.001$; females: from 6.18 ± 1.26 to 5.53 ± 1.21 mmol/l; $p < 0.001$). The 1997/98 survey showed a better lipid profile and lower diastolic blood pressure in the six original MONICA districts.

Conclusions: The remarkable improvement in CV risk factors documented in a 12-year follow-up period may contribute to the decrease in CV and total mortality, contrary to the trend in the other post-communist countries.

P2224 Standard risk factors continue to be under-recorded in patients discharged following an admission with acute coronary syndrome

M. Melville, M. Farrar, C. Gray, D. Gray. *Cardiovascular Medicine Dept., University Hospital, Nottingham, UK*

Ischaemic heart disease is multifactoral, but published reports suggest that documentation of risk factors has been poor. The European Society's Coronary Risk Chart enables easy identification of risk level but requires, as a minimum, levels of blood pressure, total cholesterol and smoking. We wanted to ascertain if increasing awareness of cholesterol had led to improvements in risk factor documentation generally.

Method: Patients admitted with symptoms suggestive of acute myocardial infarction (MI) during 6 months of 1996 and 2 months of 1998 were identified from a heart attack register. We reviewed, for those discharged with a cardiac diagnosis, the documentation of risk factors from their medical records.

Results: 2116 patients were admitted in 1996 and 1547 were discharged with a cardiac related diagnosis. For 1998 the figures were 920 and 783. For the total cohort, documentation of blood pressure increased from 70% to 96%, smoking from 76% to 90%, diabetes from 73% to 96%, family history from 48% to 94% and lipids from 23% to 41%. For discharge diagnoses of confirmed MI, suspected but unconfirmed MI and severe angina after a previous MI, similar improvements in the recording of risks other than lipids were seen. For patients with a confirmed MI, lipid recording improved from 27% to 61%, but for the largest group – those with suspected but unconfirmed MI – the improvement was less, from 22% to 37%. The ability to determine a patient's overall European risk score was only possible in 37% of all patients, due largely to the continued under-recording of lipids. Patients with a confirmed MI did slightly better- all three risks were recorded in 23% in 1996 and this had increased to 56% in 1998. Risk recording was less complete for women than for men. Women were half as likely in 1996 and still one third less likely in 1998 to have all 3 risks recorded. Patients identified as being diabetic (206 in 1996 and 114 in 1998) fared little better than the total cohort. 55% of the diabetic patients with a confirmed MI, and 46% of the entire 1998 cohort, had all 3 risk factors documented.

Conclusions: Despite recent improvements in documentation, greater efforts are still required particularly pertaining to lipids. Women remain less likely to have risks documented compared to men. Being diabetic, and so at high risk, does not mean that other risks are more likely to be recorded.

P2225 Trends in prevalence of cardiovascular disease risk factors in a working Bulgarian population, 1986-1997

V.M. Mincheva, V.G. Stoyanovsky, A.D. Stein[1], E.M. Dimitrov, D.D. Hodjeva. *Department of Cardiology, Transport Medical Institute, Sofia, Bulgaria; [1]Department of International Health, Emory University, Rollins School, Atlanta GA, USA*

Background: Bulgaria is experiencing epidemic rates of coronary heart disease and stroke mortality. Few data exist on prevalence of risk factors, and no data exist for trends in risk factors.

Methods: We compared data from two cross-sectional surveys of male transport workers ages 30–59, conducted in 1986 (n = 1146) and in 1996/7 (n = 638). The men were recruited during their annual physical examination. A structured interview was conducted and measures of anthropometry and resting blood pressure were obtained.

Results: Mean age of investigated men was 47.7 y in the 1986 study, and 43.7 y in the 1996/7 study, respectively. Hypertension prevalence (SBP > 140 mmHg and/or DBP > 90 mmHg) decreased across surveys (75% in 1986, 64% in 1996/7; age-adjusted p = 0.009). Prevalence of more severe hypertension (SBP > 160 mmHg and/or DBP > 95 mmHg) did not change (42% in both surveys). For SBP, the increase with age was steeper in 1996/7 than in 1986 (age by survey interaction, p = 0.004). Mean BMI was 27.6 kg/m^2 and 27.3 kg/m^2 (age-adjusted p = 0.16); prevalence of overweight (BMI > 25 kg/m^2) was 73% and 68% in 1986 and 1996/7, respectively. The prevalence of ever-smoking increased from 56% to 80%, reflecting increase in both current smoking (49% to 59%) and former smoking (7% to 21%). Among current smokers, the proportion smoking >15 cigarettes/day decreased from 76% to 68% (p = 0.01), probably reflecting the deteriorating economic situation. 5.9% of employees in the 1986 survey and 3.8% of employees in the 1996/97 survey reported parental history of myocardial infarction prior to age 60 y, respectively (p = 0.06).

Conclusion: Traditional risk factors were highly prevalent in 1986 and have remained widespread in this 10-year period. In the absence of major lifestyle changes, morbidity and mortality rates are unlikely to decrease in the near future.

P2226 Continuing burden of heart disease: mortality trends in Olmsted County, Minnesota

V.L. Roger, S.J. Jacobsen, S.A. Weston, K.R. Bailey, T.E. Kottke, R.L. Frye. *Mayo Foundation, Rochester MN, USA*

Age-adjusted heart disease mortality rates have declined since the 1960s. However, trends may have differed in women and the elderly. We examined age- and sex-specific heart disease mortality (ICD9 codes 390–398, 402, 404–429) in Olmsted County, MN, between 1979 and 1994. The total number of heart disease deaths was 3095, 1578 (51%) occurred in women, and 1980 (64%) in persons ≥ age 75. Most heart disease deaths (77%) were coronary disease deaths (ICD9 410–414). Age-adjusted heart disease mortality rate declined from 123 per 100,000 (95% CI 102, 144) in 1979 to 81 (67, 95) in 1994. However, Poisson regression analyses indicated that the trends differed according to sex and age. For women, the risk ratio (RR) of heart disease death in 1994 compared to 1979 was 0.69 vs 0.53 for men (P = 0.06). This equates to a decline in heart disease mortality of 2.5%/yr in women or 32% over the study period and 4.2%/yr in men or 47% over the time period. The decline in heart disease mortality was also less pronounced as age increased (P < 0.001). For 60-year-old women, the RR for 1994 compared to 1979 was 0.59, whereas for 80-year-old women, the RR for 1994 compared to 1979 was 0.77. For men, the RR for 1994 compared to 1979 was 0.61 for 80-year-old men vs 0.45 in 60-year-old men.

Thus, between 1979 and 1994, in Olmsted County, the decline in heart disease mortality was of lesser magnitude in women and in the elderly. This reflects the shift of the burden of disease towards women and older age groups and underscores the necessity to carry out age- and sex-specific analyses of heart disease mortality time trends as such trends are incompletely described by adjusted analyses.

P2227 Characteristics, resource use, and outcomes in Latin-American patients with acute coronary syndromes

M.G. Cohen[1], C.M. MacAulay[1], R. Corbalán[2], J. Isea[3], E. Silva[4], R. Diaz[5], E. Paolasso[5], D. Izasa[6], M.A. Rodas[7], R.A. Harrington[1]. *For the PURSUIT investigators; [1]Duke University, Durham NC, USA; [2]Universidad Católica, Santiago, Chile; [3]Centro Don Corro, Carcacas, Venezuela; [4]Centro Siglo XXI, Mexico City, Mexico; [5]ICR, Rosario, Argentina; [6]Clínica SHAIO, Bogotá, Colombia; [7]Clínicas Médicas, Guatemala, Guatemala*

Background: Practice patterns and resource use for managing patients (pts) with coronary disease vary in different geographic regions.

Objectives: To describe the characteristics, resource use, and outcomes in Latin-American (LA) pts treated for acute coronary syndromes in the PURSUIT trial, a randomized comparison of eptifibatide versus placebo.

	Non-LA (n = 10363)	LA (n = 585)
Median age, y	64	60
Male sex, %	65	63
Hypertension, %	55	62
Diabetes, %	23	24
Prior MI, %	32	35
Baseline MI, %	46	32
ICU admission, %	74	85
Angiography, %	61	46
Percut. intervent, %	24	18
Bypass, %	14	11
Median ICU stay, d	3	5
Total hosp stay, d	8	9
Composite rate, %	14.7	15.4

Methods: Baseline characteristics and resource and outcomes data were collected prospectively for 585 pts in 8 LA countries. The primary endpoint of PURSUIT was a composite of 30-day death or nonfatal MI.

Results: LA and other trial patients had similar baseline risk. LA pts were admitted more often to an ICU and stayed longer. The rate of the composite endpoint did not differ between groups, but mortality alone was significantly higher (6.8% for LA pts; 3.4% for other trial pts; p < 0.001).

Conclusion: LA pts had less invasive treatment and longer hospital stays for acute coronary syndromes. The death/MI composite did not differ, but mortality alone was higher. Future studies are needed to elucidate the relationship between resource use and outcome in this population.

P2228 Does heart rate predict cardiovascular mortality in a low risk population?

F. Seccareccia, F. Dima[1], C. Lo Noce[1], S. Giampaoli[1]. *Lab. Epidemiology & Biostatistics, Istituto Superiore di Sanità, Rome[1] Lab. Epidemiology & Biostatistics, Istituto Superiore di Sanità, Rome, Italy*

Elevated heart rate is considered an indicator of increased sympathetic nervous system activity, which can favour the occurrence of both severe hypertension and serious arrhythmia. Epidemiological studies demonstrated a direct association between elevated heart rate and hypertension, hypercolesterolemia and hyperglicemia, a pattern already known to be a risk factor of cardiovascular and total mortality. The purpose of this analysis is to verify the independent role of heart rate in the prediction of both cardiovascular and all-cause mortality.

Methods: Within the MATISS Project, an Italian population-based observational study, heart rate was measured from electrocardiograms in 1996 men, aged 40–69 years, screened from 1984 to 1987. Serum cholesterol, fasting blood glucose, blood pressure, pulmonary function, body mass index, smoking habits and physical activity were collected, following standardized procedures. Men were classified according to 5 groups of heart rate (= 90 beats/min). Vital status, mortality and causes of death were recorded until Dec 1997. Causes of death were coded using the WHO-ICD 9th revision.

Results: In 10 years of follow-up, 377 fatal events were recorded, 144 (38%) due to cardiovascular diseases. Age-adjusted death rates in the 5 classes of heart rate showed an increasing trend. The relative risks between the extreme classes were about threefold for both cardiovascular (3.0) and total mortality (2.7). The independent role of heart rate as predictor of cardiovascular and total mortality was investigated using the Cox proportional hazards model. Adjusting for confounders, the estimated coefficients of heart rate achieved significant level for both end-points. The adjusted relative risks for 20 beats/min heart rate increment were 1.63 (95%CI: 1.28–2.13) for cardiovascular mortality and 1.51(95%CI: 1.28–1.78) for total mortality.

Conclusions: In the free-living Italian male population, heart rate proved to be an independent predictor of mortality. These findings suggest a link of heart rate to subsequent incidence or mortality, probably, from cumulated cardiovascular conditions.

P2229 Flavonoid intake and the risk of coronary heart disease

T. Hirvonen, P. Pietinen, M.-L. Ovaskainen, M. Virtanen, S. Häkkinen[1], D. Albanes[2], J. Virtamo. *Department of Nutrition, National Public Health Institute, Helsinki; [1]Department of Clinical Nutrition, University of Kuopio, Kuopio, Finland; [2]Division of Clinical Sciences, National Cancer Institute, Bethesda, USA*

Background: Flavonoids are polyphenolic compounds found in tea, vegetables, fruits and wine. In experimental studies flavonoids have been shown to be effective free radical scavengers, metal chelators and antithrombotic agents. However, of the few epidemiologic studies only two have suggested an inverse association between flavonoid intake and the risk of cardiovascular diseases.

Methods and Results: The study population consisted of 25,372 male smokers, aged 50–69 with no previous myocardial infarction. They were participants of the Alpha-Tocopherol, Beta-Carotene Cancer Prevention Study which was a randomized, double-blind, placebo-controlled trial with daily supplementation of alpha-tocopherol and/or beta-carotene. Men completed a validated dietary questionnaire at baseline. Flavonoid intake was the sum of quercetin, myricetin, kaempherol, apigenin and luteolin intake. After 6.1 years of follow-up, there were 1,122 non-fatal myocardial infarctions and 815 coronary deaths. In the multivariate model, for men in the highest quintile of intake (median 18 mg/day) compared to men in the lowest (median 4 mg/day), the relative risk (RR) of non-fatal myocardial infarction was 0.78 (95% confidence interval (CI) 0.64–0.95, p for trend 0.02). The respective RR for coronary death was 0.99 (95% 0.79–1.26, p for trend 0.71). Wine drinkers had a lower risk of nonfatal infarction (RR 0.82, 95% CI 0.68–1.01) and coronary death (RR 0.74, 95% CI 0.57–0.98) as compared to those who did not drink wine.

Conclusions: Total flavonoid intake infarction had a modest, but statistically significant inverse association with non-fatal myocardial, whereas there was no association with coronary death.

P2230 Haptoglobin polymorphism as a risk factor for coronary heart disease mortality

D. De Bacquer, G. De Backer, J. Delanghe[1], M. Langlois[1], H. Kesteloot[2], M. Kornitzer[3]. *Department of Public Health, University of Ghent, Ghent; [1]Department of Biochemistry, University of Ghent, Ghent; [2]Department of Epidemiology, University Leuven, Leuven; [3]Department of Public Health, Free University of Brussels, Brussels, Belgium*

Background: In the biomedical literature, several reports have dealt with the haptoglobin polymorphism as a potential risk factor for cardiovascular disease. However, since these results were obtained from cross-sectional studies in clinical series of young coronary patients, no formal statement regarding the independent etiologic nature of the haptoglobin polymorphism can be made.

Methods: Within the framework of the longitudinal part of the Belgian Interuniversity Research on Nutrition and Health survey, a nested case-control study was performed with the aim of evaluating the independent role of the haptoglobin polymorphism as a risk factor for coronary heart disease (CHD) mortality. In the large cohort with baseline measurements gathered in the 80s, 107 deaths from CHD, occurring within a follow-up period of 10 years, were matched for age (mean = 64.9 yrs) and gender (36.5% women) with three controls, and in the resulting 428 subjects the haptoglobin polymorphism as well as the haptoglobin concentration was determined.

Results: The distribution of the haptoglobin polymorphism (Hptype) was found to be in Hardy-Weinberg equilibrium (Hptype 1-1: 15.0%; Hptype 2-1: 50.4%; Hptype 2-2: 34.6%). At baseline, no differences were found between the three subgroups regarding age, sex, lifestyle characteristics, cardiovascular risk factors or prevalent CHD; only the haptoglobin concentration was significantly associated with the Hptype, with highest values in the Hptype 1-1 group (1.50 g/L) and the lowest in the 2-2 individuals (1.18 g/L). Conditional logistic regression analysis for matched sets, revealed that the haptoglobin polymorphism was significantly associated with CHD death. Rather surprisingly, the finding was that 1-1 individuals were at doubled risk for CHD mortality compared to the others, the odds ratio being 2.09 (95%CI: 1.22–3.60). The association was independently from other classical CVD risk factors and the haptoglobin concentration, and of comparable size between men and women. Moreover, evaluating the interaction term in a multiplicative model, showed that the Hptype did not play a synergistic role on the prognostic value of established CVD risk factors or the haptoglobin concentration.

Conclusion: In contrast to the findings from cross-sectionally based studies, the results from this longitudinal study show that Hptype 1-1 individuals are at elevated risk for CHD mortality.

P2231 Visceral fat accumulation and conditional probabilities of coronary heart disease: a community-based study in Porto, Portugal

P. von Hafe, A.M. Pérez[1], P. Froufe[1], E. Ramos[2], H. Barros[2]. *Medicine Dept., Hospital S. João, Porto[1] Radiology Dept., Hospital S. João, Porto[2] Epidemiology Dept., Faculdade Medicina Porto, Porto, Portugal*

Background: Obesity has been one of the more inconsistent cardiovascular risk factors. Body fat distribution probably mediates the relationship between CHD and weight excess.

Methods: One hundred sixty one individuals older than 39 years (77 M, 84 F), without evidence of coronary heart disease (CHD) according to the Rose questionnaire and ECG, were selected from the community by random digit dialing, with a participation rate of 70%. Body fat distribution was assessed by computed tomography (CT) at the level of the 4th lumbar vertebra. The attenuation interval of adipose tissue was defined between −50 and −250 Hounsfield Units. Visceral fat (VF), subcutaneous fat (SF) and total fat (TF) areas were quantified. Coronary risk profile was obtained according to the updated Framingham equations, including measurements of total and HDL-cholesterol, SBP, presence of diabetes mellitus, cigarette smoking and LVH as measured by ECG.

Results: Total point score (TPS) of conditional probabilities of CHD according to Framingham equations correlated with VF ($r = 0.43$, $p < 0.0001$) and VF/SF ratio ($r = 0.42$, $p < 0.0001$) and was not related to SF ($r = 0.06$). These correlations were significant in both sexes (VF-TPS: $r = 0.44$, $p < 0.001$, VF/SF-TPS: 0.36, $p < 0.01$ in females and VF-TPS: $r = 0.42$, $p < 0.001$, VF/SF-TPS: 0.50, $p < 0.0001$, in males). When two classes of participants were considered, the first one with a total punctuation ≤ 20 and the other with > 20 points, the former group has lower VF compared to the latter (121.0 ± 62.2 cm^2 Vs 148.9 ± 73.2 cm^2, $p < 0.02$), and there were significant differences between the two classes in VF/SF and VF/TF ratios ($p = 0.04$). There were no significant differences between classes in SF ($190.7.0 \pm 90.3$ cm^2 Vs 196.3 ± 99.3 cm^2, $p = 0.81$) and TF (311.7 ± 129.7 cm^2 Vs 345.2 ± 142.5 cm^2, $p = 0.17$).

Conclusion: Visceral fat accumulation determined by CT is associated with increased conditional probabilities of CHD in asymptomatic individuals randomized from the community.

P2232 The control of multiple risk factors for coronary artery disease causes the change in the carotid arterial wall elasticity prior to the change in wall thickness

Y. Koiwa, H. Kanai[1], H. Hasegawa[1], H. Kamada, H. Chikama, K. Shirato. *The First Department of Internal Medicine, Tohoku University School of Medicine, Sendai; [1]The Department of Electrical Engineering, Graduate School of Engineering, Tohoku University, Sendai, Japan*

It has been reported that the initial change of the vascular atherosclerosis is the thickening of the vascular wall by plaque deposition with compensatory enlargement of the lumen (vascular remodeling) We tested clinically if the vascular wall elasticity (E) changed prior to the vascular wall thickning and if the correction of risk factors resulted the normalization of E even in subjects with no change in thickness.

Methods: In the population of the Tohoku Electric Company who underwent annual health examination, the subjects (n = 176) **with normal wall thickness** at the carotid arterial wall was divided into two groups; the group without any risk factors of smoking, myocardial hypertrophy, diabetes mellitus, hypercholesterolemia, lower HDL cholesterol and hypertension (normal group, n = 56), and the group with one or more risk factors (risk group, n = 120). The magnitude of the risk for myocardial infarction in each subject was quantified using 10-year probability (risk index) by the equation of multiple risk (Framingham study 1991). The vascular wall thickness (Tkn, intima-media thickness) and the instantaneous change of Tkn at the common carotid artery was measured by the recently developed high sensitivity doppler technique of phase tracking method. (IEEE. 1997, see below). The elasticity of the vascular wall is calculated as (pulse pressure of the brachial artery)/ΔTkn.

Results: There were no significant difference in blood pressure, pulse pressure, and wall thickness between two groups. However, the slope of the relationship between elasticity and age showed significant ($p < 0.01$) difference as $E = -0.9 + 0.05^*$ age ($r = 0.86$) in normal and $E = -1.5 + 0.08^*$ age ($r = 0.89$) in risk group. The risk index from the multiple risk equation and E showed linear relation as $E = 0.99^*$ risk index + 8.2, $r = 0.79$, $P < 0.01$. In eight subjects we could follow at one year interval, the change in risk index resulted no change in Tkn but change in the wall elasticity.

Conclusion: This wall elasticity changed with risk factors even in those with normal wall thickness. The demonstration of this sensitive change in E at daily clinical practice would be of use in educating such subjects with risk factors but no realistic image of the future serious disease. (Development of this novel doppler method was awarded in 1996 and 1998 by Japan Society of Ultrasonics in Medicine).

EPIDEMIOLOGY: TRIALS AND CLINICAL PRACTICE

P2233 Impact of disease history on subsequent ischaemic event rates in actual practice versus the clinical trial

J.J. Caro, K. Migliaccio-Walle, A.A. Coniglio[1], I. Thizon-de Gaulle[2]. *Caro Research, Concord MA; [1]Bristol-Myers Squibb, Princeton, USA; [2]Sanofi Pharma, Gentilly, France*

In a previous analysis, we demonstrated that patients receiving ASA after an ischaemic event in actual practice are at much higher risk of subsequent events than those randomized to the ASA arm in CAPRIE. In this paper, we examine our patients' disease history, compare it to the baseline characteristics of the trial patients and assess subsequent event rates in the actual practice patients with and without history of additional disease.

Methods: The presence of ischaemic stroke (IS), TIA, diabetes, hypertension, hypercholesterolemia, angina, MI, congestive heart failure, atrial fibrillation or PAD prior to an index diagnosis of MI, IS or PAD was evaluated using the health records of 12,931 residents of Saskatchewan, Canada. All patients were prescribed aspirin after an index diagnosis between 1990–1995 – diagnostic history was examined between 1980 and the date of index event. The distribution of baseline characteristics in actual practice was compared to those observed for patients in the aspirin arm of the CAPRIE trial. Further analysis determined the rate of subsequent MI, IS, death or combination of endpoints for patients with prior disease and those without.

Results: Health records were available for 12,881 patients in the actual practice cohort. Rates of additional disease in actual practice ranged from 7% for atrial fibrillation to 74% for hypertension versus 4% to 51% for similar histories among patients in the trial. Patients in actual practice who had any disease history were 35% more likely to experience a subsequent ischaemic event (MI, IS, vascular death) following their index diagnosis.

Conclusion: Patients in actual practice have a higher prevalence of additional disease than the patients selected for the clinical trial. In turn, this helps explain the higher risk manifested in actual practice.

P2234 Are the West of Scotland Coronary Prevention Study (WOSCOPS) results for pravastatin generalizable to other populations?

J.J. Caro, K.F. Huybrechts, G. De Backer[1], D. De Bacquer[1]. *Caro Research, Concord MA, United States; [1]Department of Public Health, University Hospital, Ghent, Belgium*

In 1996, the West of Scotland Coronary Prevention Study (WOSCOPS) demonstrated for the first time a substantial reduction in the risk of cardiovascular disease (CVD) with the use of pravastatin among hypercholesterolemic men with no previous history of CVD. Until then, direct data on the outcomes to be obtained by using statins were lacking. However, because the WOSCOPS trial population was comprised of Scottish men – which as a group demonstrate one of the highest worldwide risks for coronary heart disease – the generalizability of the results to other populations has been questioned. The legitimacy of this concern was examined, using Belgium as a case study.

Methods: Risk equations that allow prediction of the transition from health to CVD have previously been derived based on the WOSCOPS trial data. While it is unlikely that the nature of cardiovascular risk factors varies markedly between populations, the prevalence and clustering may. An epidemiologic study with information on the prevalence of these risk factors in a representative sample of the Belgian community was identified (Belgian Interuniversity Research on Nutrition and Health) and men that would have qualified for participation in WOSCOPS (i.e., 45–64 years with high total cholesterol) were selected. The probability of CVD was estimated separately for each individual by entering the corresponding risk factor data in the regression equations and then the distribution and the mean risk were derived for the cohort.

Results: In contrast to prevailing beliefs, the risk distributions were shown to be remarkably similar across populations in this study (mean 5-year risk of 14.62% in WOSCOPS versus 14.47% in Belgium). Based on two reasonable assumptions – the implications of the risk factors for baseline risk are the same in Scotland and Belgium, and no other important unmeasured factors affect the baseline risk in Belgium – our findings suggest that the pravastatin results in the WOSCOPS trial can indeed be generalized to other populations.

P2235 Practice patterns for unstable angina and MI without ST-segment elevation: UK prospective registry of acute ischaemic syndromes (PRAIS-UK)

M. Flather, J. Collinson, A. Wright, P. Dooley, I. Findlay[1], E. Rodrigues[2], K.A.A. Fox[3]. *Clinical Trials and Evaluation Unit, Royal Brompton & Harefield NHS Trust, London; [1]Royal Alexandra Hospital, Paisley; [2]Aintree Hospitals NHS Trust, Liverpool; [3]Royal Infirmary of Edinburgh, Edinburgh, UK*

Background: The acute coronary syndromes (ACS) of unstable angina (UA) or myocardial infarction (MI) without ST elevation on the admitting ECG are important and frequent causes of admission in UK hospitals. Little is known about their treatment and investigation in the UK.

Methods: We conducted a prospective cohort registry of patients with ACS in 56 UK hospitals. Twenty consecutive eligible patients were enrolled in each centre. In hospital data are available for 950 patients of a planned sample of 1000.

Results: Mean time from pain onset to admission was 8.2 hours, standard deviation 15. First admission location was 36% to a Coronary Care Unit (CCU), 48% to an acute admissions ward, 13% to a general medical ward and 3% to another location. Median length of stay in hospital was 4.5 days (inter-quartile range 2–7). Median length of stay in CCU was 2 days. On admission, 63% were on aspirin (ASA), 31% beta blocker (BB), 39% on calcium antagonists (CA), 53% on nitrates, 10% potassium channel openers (PCO). In hospital 86% received ASA, 50% BB, 53% CA, 85% any nitrate (30% IV nitrate). At discharge 85% were prescribed ASA, 47% BB, 47% CA, 69% nitrates, and 19% PCO. In hospital IV unfractionated heparin was used in 33% (median 2 days) and subcutaneous low molecular weight heparin in 43% (median 3 days). Neither treatment was used in 29% of patients. Glycoprotein GPIIb/IIIa inhibitors were used in 1%. About 40% of participating hospitals had facilities for angiography. At hospital discharge 13% of patients had undergone stress testing (1% with thallium), 10% angiography, 4% PTCA and 2% CABG. Troponin was measured in 5% of patients.

Conclusion: About 30% of patients admitted to a broad group of UK hospitals with unstable angina and MI without ST elevation are not treated with an effective heparin regimen and in those who receive heparin, the duration of treatment may be too short. Rates of investigation in-hospital appear low. Data on practice patterns for the 6 month follow-up will be available for presentation.

P2236 α-Tocopherol and β-carotene supplementation and chronic heart failure: incidence and prognosis

J.M. Rapola, J.K. Haukka, J. Virtamo. *National Public Health Institute, Helsinki, Finland*

Purpose: To study the effects of long term α-tocopherol (vitamin E) and β-carotene supplementation on incidence of chronic heart failure, and on mortality in subjects with heart failure

Methods: Subjects were participants of the ATBC Cancer Prevention Study, i.e. male smokers aged 50–69 at study entry. 27 654 men reported no heart failure at baseline evaluations, nor did they have right for refundable medication for chronic heart failure according to registers of the Social Insurance Institution. These same registers were then used for identification of new cases of chronic heart failure during follow-up.

1479 participants had either self-reported heart failure or the right for refundable medication for the disease at baseline. They were followed up through national mortality statistics for total mortality, cardiovascular and cardiac mortality.

Participants of the ATBC Study had been randomized to either 50 mg/d α-tocopherol, or 20 mg/d β-carotene, or both, or placebo, and they were followed up for a median of 6 years.

Results: There were no differences in baseline variables across supplementation groups. Of participants initially free of heart failure, 675 received the right for refundable medication for chronic heart failure during follow-up (excluding the first year). Risk for chronic heart failure did not differ across supplementation groups (RR; 95% CI): α-tocopherol 0.97 (0.78–1.20), β-carotene 1.02 (0.83–1.26), both 0.92 (0.74–1.14) compared to placebo. Multivariate adjustments had no significant effects on the results.

Among participants with heart failure at baseline, 448 died during follow-up. The risk for total, cardiovascular, or cardiac mortality did not differ significantly across the supplementation groups.

Conclusion: α-tocopherol and β-carotene supplements did not affect incidence or prognosis of chronic heart failure.

P2237 Multivariate analysis of risk factors for coronary artery disease in Jordan

Zakariya F. Daoud, Samy Z. Daoud. *Amman, Jordan*

Objectives: to describe the distribution of risk factorss and and analyse them in patients of both sexes treated at the coronary care unit, Jordan University Hospital, and compare the data produced with data in western countries.

Methods: The blood of 835 patients with documented acute myocardial infarction, 693 male (mean age 54.11 yrs) and 1142 female (mean age 62 yrs) was tested for serum cholesterol, triglycerides, low-density lipoproteins (LDL), high-density lipoproteins (HDL), fasting blood sugar, uric acid and serum creatinine. Systolic and diastolic blood pressure and cigarette smoking were included in the analysis. Student's "t" test distribution, standard method of correlation and multiple regression analysis were used.

Results:

Sex	Chol	Hdl	Ldl	Trig.	FBS
Male	205.7	37.2	135.4	152.6	145
Fem	214.8	40.1	137.1	163.8	191.9
"P"	0.09	0.03	0.738	0.267	0.0001
Male	SBP	DBP	U. acid	S. Creat	SMK/P/Y
	124.1	8.7	6.28	1.49	3.36
Fem	13.2	81.6	5.74	1.89	5.32
"P"	0.01	0.475	0.249	0.570	0.0001

Conclusion: 33% have SBP > 140; 38% have DBP > 90; 55% have Diabetes; 67% are smokers 58% have S. (Chol) > 180; 74% have Ldl > 90; 78% have hdl < 40. Classifcation of risk from s. Lipoprotins level in Jordan

	Mild	Moderate	Severe
s. chol.	140–180	181–200	200
s. trig	<100	100–150	150
ldl-c	90–120	120–150	150
Hdl		40-30	<30

SYSTEMIC ASPECTS OF HEART FAILURE

P2238 Digoxin impairs endothelium-dependent and -independent relaxations in isolated arteries

M.R. Schulze, K. Plötze, K. Matschke, C.-G. Konnerth, K. Reynen, R. Henßge. *University Dresden, Cardiovascular Institute Dresden, Germany*

Digoxin (DIG) is widely used in treatment of patients with moderate to severe heart failure (CHF). High DIG-concentrations (10^{-6} M) constrict isolated arteries. It is not known whether DIG in therapeutic concentrations ($3*10^{-9}$ M) alters endothelium-dependent or -independent relaxations in isolated arteries.

Methods: Ring preparations of pig coronary arteries (PCA) and human internal mammary arteries (IMA; obtained during surgery) were mounted into organ baths and were preconstricted with prostaglandine $F_{2\alpha}$ (10^{-6} to $3*10^{-6}$ M) or norepinephrine (10^{-6} M). Rings (n = 5–10) were subsequently exposed to endothelium-independent vasodilator nitroglycerine (NTG; 10^{-9}–10^{-6} M). In IMA we used endothelium-dependent vasodilator acetylcholine (ACh; 10^{-8}–10^{-5} M), and respectively in PCA substance P (SP; 10^{-11}–10^{-9} M). Relaxations to different substances are analysed in the abscence (–DIG) and presence (+DIG) of DIG in percentage of preconstriction.

Results: In PCA DIG impairs significantly ($p < 0.05$) relaxations to NTG and SP, in IMA only relaxations to NTG are significantly reduced. Table summarizes maximal relaxations for agonists.

	PCA		IMA	
	–DIG	+DIG	–DIG	+DIG
NTG	98.7 ± 2.3	92.0 ± 6.1*	93.1 ± 10.3	81.9 ± 19.8*
ACh			67.3 ± 19.5	66.0 ± 17.9
SP	100 ± 0	65.8 ± 26.2*		

(mean ± SEM; *$p < 0.05$)

Conclusions: 1. DIG impairs in therapeutical concentration endothelium-independent and -dependent relaxations in PCA, and endothelium-independent relaxations in IMA. 2. Further investigations are needed to evaluate whether these findings have therapeutic consequenses in treatment of patients with CHF.

P2239 Mechanical thrombectomy in patients with deep venous thrombosis : immediate and short-term results

M. Delomez, J.P. Bérégi[1], J.J. Bauchart, C. Janne d'Othee[1], S. Willoteaux[1], P. Asseman, N. Perez[1], C. Théry. *Dept des Soins Intensifs, Institut Cardiologique, Lille; [1]Department of Radiology, Hopital Cardiologique, Lille, France*

Purpose: Currently available techniques for the treatment of venous thrombosis have limitations. We report our early experience with mechanical thrombectomy in patients with deep venous thrombosis (DVT).

Materials and Methods: The Amplatz Thrombectomy Device (ATD) is an 8F catheter terminating in a double inverted helix, encapsulated and rotating at 150,000 revolutions per minute. Eighteen patients (8 male and 10 female) aged 37.6 ± 16.1 (17–74) were treated. The estimated mean age of the thrombi was 11.3 ± 6.9 days (4–28); the average length of the thrombosed segment was 16.9 ± 9.1 cm (5–40) and the mean thrombus diameter was 15.9 ± 4.3 mm (8–20). The thrombi were located as follows: iliac and femoral veins (3), inferior vena cava (5), inferior vena cava and iliac vein (10). The approach used was the ipsilateral (10) or contralateral (5) femoral vein, or the popliteal vein (3). All procedures were performed under cover of a temporary caval filter.

Results: Successful recanalisation was achieved in 15/18 patients (83.3%). The percentage of thrombus removed using the ATD, estimated angiographically, was 63.9 ± 30.9%. For the 5 floating caval thrombi, 78.0 ± 22.8% of the thrombotic material was removed and 70.0 ± 31.8% for all the caval thrombi (n = 15). At the iliofemoral level, 54.6 ± 36.4% of the thrombotic material was removed. Complementary interventions were performed in 7 patients: balloon angioplasty (5), stenting (2), thrombo-aspiration (2), permanent filter (2). No serious complications occurred but 38.9% of the patients had episodes of arterial desaturation per procedure. At follow-up, obtained in 13/15 patients, 12/13 succesfully treated vena cava and 6/11 succesfully treated iliac veins were patent.

Conclusion: Thrombectomy using the ATD is a rapid and effective procedure which may be a useful therapeutic option for patients presenting with recent proximal deep venous thrombosis with iliac and/or caval clot. Further studies are needed to evaluate the effects of this technique to prevent the occurrence of complications of DVT.

P2240 Hyperinsulinaemia augments muscle lactate production during exercise in patients with chronic heart failure

W.A. Parsonage, A.J. Perry, A.J. Cowley. *Cardiovascular Medicine Dept., University Hospital, Nottingham, UK*

Introduction: Patients with chronic heart failure are resistant to the metabolic effects of insulin and develop compensatory hyperinsulinaemia. Insulin resistance correlates with exercise intolerance in patients with chronic heart failure. The mechanism of this interaction has not been explained. Exercise testing is usually performed in the fasting state when insulin levels are at a minimum and does reproduce the usual metabolic state of the patient.

Aim: To examine the effect of hyperinsulinaemia on skeletal muscle metabolism and blood flow during isometric forearm exercise.

Methods: We have employed a forearm model of muscle metabolism. 10 male patients with stable (NYHA II-III) chronic heart failure were studied on two occasions. Patients performed a series of forearm exercises at increasing workloads (5 seconds contraction, 5 seconds rest for 5 minutes at 7, 14 and 21 kg) with the right arm. The left hand was placed in a heated box for sampling of arterialised blood samples. Blood was sampled from veins draining the exercising forearm muscles for measurement of blood gases, lactate and ammonia before and after each bout of exercise. Forearm blood flow was measured in the right arm at rest and after each exercise. On one visit patients received a hyperinsulinaemic glucose clamp to maintain a steady state plasma insulin of ~250 mU/l. On the other visit the insulin was replaced with a saline placebo.

Results: Hyperinsulinaemia led to a marked increase in muscle lactate efflux during exercise (Area under the curve 2.5 ± 0.5 v 1.5 ± 0.5 p = 0.02, Peak lactate 2.18 ± 0.97 v 1.63 ± 0.75 mmol/l p = 0.01). There was no significant difference in ammonia production, oxygen extraction or blood flow during the hyperinsulinaemia.

Conclusion: Insulin infusion has a profound effect on muscle metabolism during submaximal exercise in the absence of any change in muscle blood flow or oxygen extraction. Insulin promotes glucose metabolism and inhibits utilisation of fat, which accounts for the increase in muscle lactate production during exercise. This may in part explain the relationship between insulin resistance, hyperinsulinaemia and symptoms in patients with chronic heart failure.

P2241 Apoptosis and atrophy in rat slow skeletal muscles in chronic heart failure: differences with fast muscles

Luciano Dalla Libera, Roberta Zennaro, Marco Sandri, Cristiana Leprotti[1], Giovanni Battista Ambrosio[1], Giorgio Vescovo[1]. *CNR Unit for Muscle Physiopathology, University of Padua; [1]Internal Medicine I, Venice, Italy*

Background: Congestive heart failure (CHF) is characterized by a skeletal muscle myopathy with muscle bulk loss. The mechanisms responsible for these changes are not clear at present.

Objectives: We have investigated the role of apoptosis in the rat "slow" Soleus muscle during the development of heart failure induced by monocrotaline and compared it with the "fast" Tibialis anterior.

Methods: CHF was induced in rats by injecting 30 mg/kg monocrotaline. We looked at the time course of apoptosis studying animals at day 0, 17, 24 and 30 days.

Results: We found a decreased expression of anti-apoptotic protein Bcl-2 (969 ± 10 AU 1893 ± 481 ($p < 0.002$ 0 vs 30 days)), accompanied by a rise of pro-apoptotic caspase-3 (2490 ± 36 AU 1335 ± 67 ($p < 0.001$ 0 VS 30 days)). Ubiquitin did not change (2460 ± 284 vs 2813 ± 48) while circulating TNFα was increased (5.0 ± 1.8 AU day 0, 5.16 ± 0.7 day 17, 3.5 ± 1.7 day 24 48.3 ± 30.2 day 30 $p < 0001$ ANOVA). DNA nick-end labeling showed an increased number of apoptotic nuclei both in myofibres and interstitial cells when heart failure occurs both in the soleus (0.015 ± 0.015 day 0 vs 0.062 ± 0.03 day 30 $p < 0.001$ for myofibers) and in the Tibialis Anterior (0.0025 ± 0.05 day 0 vs 0.19 ± 0.05 day 30 $p < 0.0001$ for myofibers). At 30 days, when CHF is overt, in the fast Tibialis Anterior muscle the magnitude of apoptosis is therefore significantly higher ($p < 0.05$) than in the slow Soleus. There was no appearance of muscle atrophy as measured by the muscle weight/body weight in the Soleus (0.47 ± 0.1 vs 0.48 ± 0.2 day 0 vs 30 p = NS), while in the Tibialis Anterior there was a significant decrease of this index (1.78 ± 0.02 vs 1.63 ± 0.02 $p < 0.001$ day 0 vs 30).

Conclusions: The present findings suggest that in rats with CHF TNFα induces apoptosis in skeletal muscle via activation of the caspase-3 system and that muscle bulk loss is not secondary to TNFα-ubiquitin dependent protein waste activation. Slow muscles are less prone to develop apoptosis than fast muscles. Muscle atrophy appears earlier in these latter ones.

P2242 Insulin resistance in patients with idiopathic dilated cardiomyopathy assessed by fluorodeoxyglucose positron emission tomography imaging: implications for metabolic intervention?

H.J. Siebelink, A.F.M. van den Heuvel, P.K. Blanksma, D.J. van Veldhuisen, W. Vaalburg[1], H.J.G.M. Crijns. *Thoraxcenter, Cardiology Dept., University Hospital Groningen, Groningen; [1]PET center, University Hospital Groningen, Groningen, Netherlands*

Insulin resistance may reduce glucose uptake in dysfunctional myocardium in patients with idiopathic dilated cardiomyopathy (IDC). Therefore myocardial glucose uptake might be influenced by metabolic imaging conditions.

Methods: Myocardial glucose uptake with 18-Fluorodeoxy-glucose (FDG) positron emission tomography imaging was studied in 12 consecutive IDC-patients during hyperinsulinemic euglycemic glucose clamp (clamp) and compared to 17 IDC-patients who underwent FDG imaging with oral glucose loading (load).

Results: Age (46 ± 15 vs 46 ± 14) and left ventricular ejection fraction (LVEF) (27+10% vs 34+15%) were not statistically different in both groups (load and clamp resp.). In load a positive correlation was observed between FDG-uptake and LVEF ($r = 0.37$, $p = 0.15$), while in clamp a negative correlation was demonstrated ($r = -0.38$, $p = 0.22$). Regression lines of load (FDG = 0.82 LVEF + 30.5) and clamp (FDG = −0.50 LVEF + 76) were significantly different by ANOVA ($p = 0.03$). For patients with LVEF < 30% a trend to higher myocardial glucose uptake was observed in clamp (46.7+18.7 vs 64.9+19.9 mmol/min/100 g, $p = 0.07$, load and clamp resp.).

Conclusion: In IDC-patients myocardial FDG-uptake is influenced by metabolic imaging conditions. Difference between load and clamp can be explained by insulin resistance predominantly present in IDC-patients with lower LVEF. With clamp, insulin resistance was circumvened and preserved glucose uptake was demonstrated in dysfunctional myocardium. These results suggest a basis for tailored metabolic intervention in IDC-patients.

P2243 Insulin resistance in chronic heart failure is not due to peripheral vascular dysfunction

W.A. Parsonage, A.J. Perry, A.J. Cowley. *Cardiovascular Medicine Dept., University Hospital, Nottingham, UK*

Background: Chronic heart failure is a syndrome of haemodynamic dysfunction and neurohormonal disturbance. Chronic heart failure is an insulin resistant, hyperinsulinaemic state. Insulin is a vasoactive peptide that gives rise to skeletal muscle vasodilatation. In other insulin resistant states failure of insulin mediated vasodilatation has been demonstrated, and is thought to be at least in part responsible for insulin resistance.

Aim: To explore the role of peripheral vascular dysfunction in the aetiology of insulin resistance in patients with chronic heart failure.

Methods: Ten patients with stable chronic heart failure (NYHAII-III) and nine age matched healthy controls were studied. Subjects underwent a hyperinsulinaemic euglycaemic clamp at insulin levels of ~100 and ~250 mU/l for 90 minutes each. Whole body glucose metabolism (M) was calculated during the last 30 minutes of each clamp as a measure of insulin sensitivity. Heart rate (HR), mean arterial pressure (BP), cardiac output (CO), superior mesenteric artery flow (SMAF) and forearm blood flow (FBF) were measured non-invasively at baseline and after 30 and 60 minutes at each insulin level.

Results: The patients with heart failure were insulin resistant compared to the controls (M 3.7 ± 0.7 vs. 6.1 ± 0.8 at plasma insulin ~100 mU/l; $p < 0.05$). Despite insulin resistance the insulin infusion led to a significant increase in FBF in the patients (Peak 0.73 ± 0.14 ml/dl/min; $p = 0.002$) and the controls (Peak 0.60 ± 0.21 ml/dl/min; $p = 0.037$). There was also a significant fall in SMAF in both groups but no change in cardiac output or systemic vascular resistance. There was no difference in the haemodynamic response to insulin infusion between the groups.

Conclusion: Despite insulin resistance the haemodynamic actions of insulin are preserved in patients with chronic heart failure. Insulin resistance is not due to peripheral vascular dysfunction in this population. The significance and aetiology of insulin resistance in these patients merits further study. Furthermore, insulin should be investigated as a unique skeletal muscle vasodilator in the treatment of heart failure.

P2244 Physical training in warm water – a new method to improve function in older patients with congestive heart failure

A. Cider, M. Schauffelberger, M. Hedberg[1], K. Stibrant Sunnerhagen[1], B. Andersson. *Cardiology Dept, Sahlgrenska University Hospital, Gothenburg; [1]Rehabilitation Medicine Dept, Sahlgrenska University Hospital, Gothenburg, Sweden*

Conventional physical training has been associated with improved function in patients with congestive heart failure. Rehabilitation programs using training in warm water have been used for patients with rheumatic and other disabling disorders. However, immersion in warm water in combination with physical activity has been considered potentially dangerous in patients with cardiac disorders.

Method: In order to test the applicability of water training, 14 patients with chronic heart failure (NYHA III, age 71 ± 6.4) were randomised to 8 weeks of training in warm water (33–34°C) (n = 8), or to control (n = 6). Exercise capacity and muscle strength was tested before and after the training/control period.

Results: The training program was well tolerated, and there were no adverse events. Patients in the water training group improved their maximal exercise capacity more than patients in the control group (+2.1 vs. −8.2 Watt, p = 0.03), maximal VO_2 (+0.5 vs. −2.6 ml/kg/min, p = 0.086) and the six minute walking test (+34 vs. 5.7 m, $p < 0.02$). Further, the patients in the training group improved significantly their muscle strength in shoulder flexion and abduction, as well as in performance of heel-lift. There was no significant improvement in isometric and isokinetic strength and endurance in knee extension.

Conclusion: Physical training in warm water was well tolerated and associated with significant improvement in maximal exercise capacity in patients with chronic heart failure. This new method might be useful for many elderly patients and for patients with heart failure in combination with other disorders that impede mobility.

P2245 Loss of the normal coupling between the anaerobic threshold and insulin sensitivity in chronic heart failure

F. Leyva[1,2], S.D. Anker[1], T.-P. Chua[1], I.F. Godsland[2], P.A. Poole-Wilson[1], A.J.S. Coats[1]. *[1]Department of Cardiac Medicine; [2]Wynn Department of Metabolic Medicine, ICSM, London, UK*

The anaerobic threshold (AT) is a measure of the balance between aerobic and anaerobic metabolism. Given that glucose, insulin action and oxygen are involved in this process, we considered that: a) in healthy individuals, the AT might be related to whole-body insulin sensitivity (S_I); and b) that this relationship might be altered in patients with chronic heart failure (CHF) – a condition characterised by an imbalance aerobic and anaerobic metabolism.

Methods Healthy individuals (n = 20) and patients with CHF [n = 36, aged 59.1 ± 2.0 yrs (mean ± SEM), NYHA class I–IV, AT = 11.8 ± 0.7 ml/kg/min, radionuclide LVEF = 26 ± 2%], underwent measurement of S_I (intravenous glucose tolerance test and minimal model analysis) and assessment of AT, derived from measurement of oxygen comsumption and carbon dioxide output during maximal treadmill exercise tests.

Results Whilst AT correlated positively with S_I in healthy controls [$r = 0.72$, $p < 0.001$], no such relationship was observed in patients with CHF. In stepwise multiple linear regression analyses of variables in healthy individuals, S_I emerged as the only predictor of AT (standardised coefficient = 0.72, $p < 0.001$), whilst fasting insulin, incremental insulin area and total body fat (dual photon X-ray absorptiometry) failed to enter into final models (joint $R^2 = 0.52$, $p < 0.001$).

Conclusions This is the first demonstration that, in healthy individuals, whole-body S_I is related, or 'coupled', to the AT. The absence of such metabolic coupling in patients with CHF provides further evidence of disturbed cellular metabolism in patients with this condition.

P2246 Expression of FAS in peripheral muscle biopsies from heart failure patients

G. Filippatos, C. Kanatselos[1], R. Sunga[2], S. Patsilinakos[1], B. Vougas, A. Sideris[1], D. Kardara[1], F. Kardaras[1], B. Uhal[2]. *Athens; [1]2nd Department of Cardiology, Evangelismos Hospital, Athens, Greece; [2]Cardiovascular Institute, Michael Reese Hospital, Chicago IL, USA*

It has been suggested that skeletal muscle changes may have pathophysiological significance for the progression of congestive heart failure (CHF). Apoptosis has been described in the heart of CHF patients, but is not known if apoptosis in skeletal muscles plays a role in CHF. We hypothesized that cells within the skeletal muscles might become predisposed to apoptotic cell death by expression of the "death receptor" FAS. The purpose of this study was to examine if FAS (APO1, CD95) is expressed in skeletal muscle biopsies of heart failure patients.

Biopsies from skeletal muscle (quadriceps) of 21 patients with CHF, aged 59 years, were obtained under approved protocols; all patients had ejection fraction < 35%. Paraffin blocks were obtained and sectioned at 5 microns. Immunohistochemistry with a monoclonal antibody to human FAS (clone CH11) detected highly reactive leukocytes within vessels and between fasciculi in all samples. In some biopsies, heavily immunoreactive endothelial cells also were observed within vessels interspersed throughout the fasciculi. The muscle fibers surrounding the vessels showed no reactivity with anti-FAS antibodies. These data suggest that FAS is expressed by microvascular endothelial cells and leukocytes within the skeletal muscle vascular bed in patients with CHF. They also raise the possibility that FAS-induced apoptosis in the vessels supplying skeletal muscle might contribute to the mechanism for the peripheral muscle changes observed in patients with congestive heart failure.

P2247 Apoptosis in heart failure: the link between skeletal muscle atrophy and exercise capacity limitation?

G. Vescovo, L. Dalla Libera[1], R. Zennaro, M. Sandri[1], C. Ceconi[2], R. Lorusso[2], C. Leprotti, G.B. Ambrosio, M. Volterrani[2]. *Internal Medicine I, Venice; [1]C.N.R. Unit for Muscle Physiopathology Padua; [2]IRCCS Gussago and Cardiac Surgery, Brescia, Italy*

Background In CHF exercise capacity (EC) is limited by fatigue and dyspnea. These symptoms are in part due to skeletal muscle abnormalities such as a shift from the slow fatigue resistant aerobic Myosin Heavy $Chain_1$ (MHC_1) to the fast MHC_{2a} and MHC_{2b}. The contribution of atrophy to the decreased EC is still debated, as well as the link between changes in fibers type and muscle waste. We have investigated whether apoptosis (A) plays a role in the development of the skeletal muscle myopathy in patients with CHF.

Patients and Methods We studied 9 patients with severe CHF due to ischemic heart disease (IHD) and evidence of hibernating myocardium who underwent CABG. Five subjects with no history of cardiovascular disease and normal ECG and echo represented the control group. On surgical biopsies taken from the vastus lateralis (VL) of the right leg, the electrophoretic pattern of MHCs, the fibers cross sectional area (CSA), the number of total, myocyte, and interstitial A nuclei with TUNEL method, and tissue levels of caspase-3, bcl-2 and ubiquitin were determined.

Results VL of CHF patients showed a significant increase of MHC_{2a} and MHC_{2b} ($p < 0.0001$ and $p < 0.0013$) and a significant decrease of MHC_1 ($p < 0.0001$). There was also an increased number of TUNEL positive A nuclei ($p < 0.021$ for myocyte and $p < 0.0013$ for interstitial). Tissue levels of Bcl-2 were decreased ($p < 0.0001$), while levels of Caspase-3 and ubiquitin were increased ($p < 0.0001$ and $p < 0.0001$). CHF patients showed a much higher degree of fibers atrophy as demonstrated by the decreased fibers CSA ($p < 0.0001$). We found a statistically significant correlation between the number of A nuclei and fibers CSA ($p = 0.004$ for myocyte and $p = 0.0015$ for interstitial). There was no correlation between% distribution of MHCs and number of TUNEL positive cells. The number of A cells was correlated with peak VO_2 ($p < 0.003$), but not with any of the other indices of severity of CHF. There was only a trend for peak VO_2 to correlate positively with MHC_1 and negatively with MHC_{2a} and $_{2b}$. We found a significant correlation between peak VO_2 and fibers CSA ($p = 0.0015$).

Conclusions In CHF the magnitude of myocyte A correlates with EC limitation. A causes muscle atrophy. The reduced EC in severe CHF can be explained both by the increased% of fast MHCs and by the A-related fibers atrophy.

P2248 Excessive ventilation in patients with cardiac cachexia and chronic heart failure: the role of skeletal muscle

P. Ponikowski, A.L. Clark, M. Piepoli, T.P. Chua, W. Banasiak[1], M. Rauchhaus, A.J.S. Coats, S.D. Anker. *Clinical Cardiology, NHLI, London, UK; [1]Cardiology Department, Military Hospital, Wroclaw, Poland*

Abnormal skeletal muscle may contribute to excessive ventilatory response to exercise in chronic heart failure (CHF). Patients with cardiac cachexia show major metabolic abnormalities. We hypothesised that CHF patients with cachexia, with abnormalities of muscle quantity and muscle quality (impaired strength per unit muscle) also have highly elevated ventilatory response to exercise. We investigated 114 CHF pts (age: 59 ± 9 yrs, LVEF: 23 ± 11%; NYHA: 2.7 ± 0.7; 31 cachectics [cCHF]: dry, documented weight loss > 7.5% of previous normal weight in >6 months) and 83 non-cachectics [ncCHF]), and 30 controls (age 60 ± 9 yrs). cCHF (NYHA 3.0 ± 0.6) and ncCHF (NYHA 2.6 ± 0.7) had similar age and LVEF. The regression slope relating minute ventilation to carbon dioxide (VE/VCO_2 slope) was used as an index of the ventilatory response to exercise. We also assessed muscle mass (DEXA scan) and muscle function (quadriceps isometric muscle strength and fatigue).

Results: cCHF showed higher VE/VCO_2-slope vs ncCHF and controls (47.1 ± 16.7 vs 35.1 ± 9.9. vs 26.8 ± 3.9, respectively, $p < 0.0001$ in all comparisons). Reflecting CHF severity, VE/VCO_2-slope correlated with peak VO_2 ($r = -0.51$), NYHA class ($r = 0.46$, both $p < 0.0001$), and LVEF ($r = -0.27$, $p < 0.01$). However, presence of cachexia predicted an increased VE/VCO_2-slope, independently of these clinical variables ($p < 0.01$). Neither peak VO_2 nor muscle function (maximal strength and 20-min fatigue) and muscle mass correlated with the VE/VCO_2-slope in controls. Only in cachectic patients lean leg tissue mass ($r = -0.66$, $p < 0.01$), and quadriceps strength ($r = -0.64$, $p < 0.01$) correlated with VE/VCO_2 slope. In multivariate analysis the major determinants of VE/VCO_2 were muscle mass and strength in cCHF patients and NYHA class and peak VO_2 in ncCHF patients.

Conclusions: Muscle atrophy and impaired skeletal muscle strength are the strongest predictors of an excessive ventilatory response to exercise in CHF patients who develop cachexia. The study confirms the role of skeletal musculature in the generation of symptoms in CHF patients.

P2249 Skeletal muscle biomechanical inefficiency in heart failure measured by cardiopulmonary exercise testing

W.C. Levy, B.A. Maichel[1], J.R. Stratton[1]. *Division of Cardiology, University of Washington, Seattle; [1]Veterans Affairs Puget Sound, Seattle, USA*

Background: CHF results in marked skeletal muscle changes with a decrease in efficient Type I fibers and an increase in inefficient Type IIb fibers. Reduced skeletal muscle biomechanical efficiency (BioEff) has been reported with skeletal muscle magnetic resonance spectroscopy, but has not been reported during cardiopulmonary exercise test (CPET).

Methods: We measured BioEff during peak ramp exercise (30 CHF and 15 age/sex/weight matched controls) and during 6 minutes of 35 Watt steady state exercise (15 subjects in each group) with CPET. For SS and ramp exercise, Gross (zero VO_2 baseline), Net (rest VO_2 baseline) and Work (unloaded pedaling VO_2 baseline) BioEff were calculated using the O_2 debt measured during the recovery VO_2 after exercise, rather than the estimated O_2 deficit.

$$\text{Net BioEff (\%)} = \frac{\sum(\text{Watts during exercise} \times 1435)}{\sum(VO_2 \text{ during exercise and recovery above the resting } VO_2) \times k.}$$

where k = calories/VO_2 (l/min) = 3,840 + 1,180 × RER for SS exercise and k = 5,000 calories/l of VO_2 for ramp exericse. Statistics by unpaired t-test.

Results: see table below.

CPET-CHF vs Controls

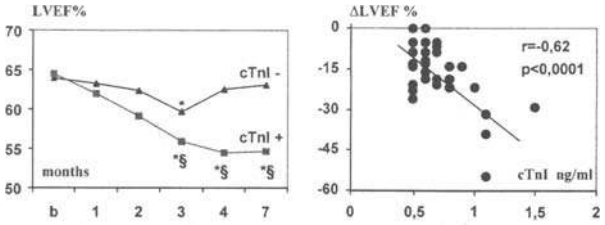
Mean ± SEM	CHF	Controls	% Change	p Value
Steady State 35 Watts				
VO_2 (ml/min)	988 ± 49	829 ± 36	+19%	0.014
Gross BioEff (%)	10.3 ± 0.5	12.6 ± 0.5	−18%	0.005
Net BioEff (%)	16.0 ± 1.0	19.3 ± 1.0	−17%	0.032
Work BioEff (%)	21.4 ± 1.5	33.2 ± 2.9	−36%	0.001
Ramp Exercise				
VO_2 at 50 Watts (ml/min)	1,027 ± 40	883 ± 34	+16%	0.024
Gross BioEff (%)	13.0 ± 0.4	17.8 ± 0.5	−27%	0.0001
Net BioEff (%)	18.7 ± 0.7	21.1 ± 0.6	−11%	0.019
Work BioEff (%)	22.9 ± 0.7	24.9 ± 0.7	−8%	0.039

Conclusions: CHF patients have an increase in VO_2 (16–19%) at matched workloads (35 Watts steady state and 50 Watts ramp exercise). This increase in VO_2 translates into a decrease in biomechanical efficiency during both steady state (−17 to −36%) and ramp (−8 to −27%) exercise. The biomechanical inefficiency in CHF measured by CPET is probably due to alterations in skeletal muscle fiber type and may relate to CHF symptoms.

P2250 Cardiac troponin I is a predictive marker of left ventricular impairment after high-dose chemotherapy

D. Cardinale, M.T. Sandri[2], A. Tricca[2], A. Martinoni, G. Lamantia, M. Civelli, G. Viale[2], F. Peccatori[1], S. Cinieri[1], G. Martinelli[1], C. Fiorentini, C.M. Cipolla. *Cardiology; [1]Ematoncology Units; [2]Laboratory Medicine, Istituto Europeo di Oncologia, University of Milan, Milan, Italy*

Patients with advanced cancer stage are often treated with high dose chemotherapy (HDCT) which efficacy is someway blunted by cardiac toxicity. As cardiac impairment may become clinically relevant weeks or months after the end of treatment, the availability of an early marker of cardiac injury, able to predict late ventricular dysfunction is an actual need. The role of serum cardiac Troponin I (cTnI) in this setting has never been investigated before. We measured cTnI value (immunoenzymometric assay, Stratus II, Dade; normal value < 0.5 ng/ml) in 109 patients (21 men, 88 women; age 45 ± 10 years, mean ± SD) affected by aggressive malignancies, before and after i.v. administration of potentially cardiotoxic HDCT [epirubicin, cumulative dose (CD) = 600 mg/mq; cyclofosfamide, CD = 12 gr/mq; etoposide, CD = 900 mg/mq; idarubicin, CD = 45 mg/mq, singly or in association]. Left ventricular ejection fraction (LVEF) was measured in all patients by echocardiography before treatment (b) and 1, 2, 3, 4 and 7 months after HDCT. In 39 cases (35%) cTnI increased after HDCT (cTnI+; 0.62 ± 0.25 ng/ml; range 0.5–1.5 ng/ml). * = $p < 0.05$ vs. baseline value. § = $p < 0.05$ vs. cTnI−.



Conclusions: 1) cTnI increased in 35% of patients treated with HDCT; 2) in cTnI+ patients a greater and more persistent LVEF reduction is observed. cTnI is an early and sensitive marker able to identify patients developing late ventricular dysfunction.

P2251 Pulse oximetry and left ventricular failure in the acute phase of myocardial infarction

J. Masip, A. Betbesé, J. Paez, F. Vecilla, G. Asensio, R. Canizares, J. Ballus, J. Padro, M. Paz, J. Otero. *Intensive Care Unit, Hospital Cruz Roja de Barcelona, Barcelona, Spain*

The continuous monitoring of oxygen saturation (SaO_2) by pulse oximetry (PO) is a current practice in coronary care units in patients with acute myocardial infarction (AMI) but its usefulness and its correlation with cardiac failure (CF) has not been established.

Methods: With this objective, 118 consecutive patients with AMI were studied prospectively during the first three days, registering daily data from physical examination (Killip classification), chest x-ray film (Battler score) evaluated by two observers and baseline SaO_2. The later parameter was measured when the patient was awake, selecting the steadiest value after discontinuing oxygen therapy for 30 minutes. Patients with cardiogenic shock (Killip IV) were excluded due to technical problems with PO.

Results: A total of 354 simultaneous registers were obtained for analysis, 74% Killip I, 18% Killip II and 8% Killip III. There was a good correlation between SaO_2 and physical examination (Killip/SaO_2): I/ 95 ± 3%, II/ 93 ± 3% and III/ 87 ± 6% (R-0.64, $p < 0.001$) and with x-ray film (Battler/SaO_2): 0/ 96 ± 2%, 1/ 95 ± 2%, 2/ 93 ± 3%, 3/ 91 ± 2%, 4/ 83 ± 3% (R-0.62, $p < 0.001$) although a better correlation was found between Killip and Battler score (R 0.78). Defining true CF by the association of Killip ≥ 2 and Battler ≥ 1, a SaO_2 < 94% correctly predicted CF with a sensitivity of 80%, specificity of 68%, and a test accuracy of 71%.

In conclusion, SaO_2 determination by pulse oximetry is a good predictor of cardiac failure in patients with AMI and may be an early sign of this complication. Pulse oximetry must be considered in the routine evaluation of these patients.

P2252 A comparison between rapid access chest pain clinics for the diagnosis and management of patients with new onset exertional angina

S.J. Sutcliffe, D.A. Wood[1], J.S.R. Gibbs[2], H. Penston, M.M. Gandhi[2], R. Roberts[2], G.C. Sutton[2]. *Cardiac Medicine Clinical Epidemiology, London; [1]Cardiac Medicine Clinical Epidemiology, National Heart and Lung Institute, London; [2]National Heart and Lung Institute, Imperial College School of Medicine, London, UK*

Introduction: Rapid and accurate diagnosis of exertional angina is important in view of the significant morbidity and mortality associated with this condition. Rapid Access Chest Pain Clinics (RACPC) have been set up to address this, and the outcomes of 4 clinics are compared.

Methods: 4 RACPC's have been opened in 4 different areas serving 4 different populations under the same research group. General Practitioners (GP) and casualty doctors were invited to refer all patients presenting for the first time with exertional chest pain considered to be angina. (At Hillingdon and Southampton hospital patients over 70 years and those from casualty were not seen). Patients were seen on the day of referral and had a history and examination, resting ECG, blood tests and exercise testing where appropriate.

Results: see table

Hospital	Southampton	Hillingdon	Bromley	Charing Cross
Study duration	21 months	18 months	18 months	3 months
Population size	192,000	155,000	295,000	157,000
No. of referrals	467	370	2137	149
Referral rate (/1000/month/pop)	0.12	0.13	0.40	0.32
Ethnic minority	2%	15%	8%	24%
Diagnoses (%)				
Non-anginal pain	58	72	67	70
Possible angina	13		7	7
Exertional angina	23	25	21	19
Unstable angina	1	1	1	0
Acute M.I.	5	2	4	4
Angiography referrals (%)	–	38	47	42

Conclusion: Different RACPC's have provided rapid diagnosis and appropriate management of new onset exertional angina in different populations. The diagnoses in all RACPC's are similar and illustrates the same extent of diagnostic misclassification in the community. When a RACPC is offered to all patients of any age there is a 3 fold increase in patients assessed for chest pain.

ASSIST DEVICES, HEART AND LUNG TRANSPLANTATION

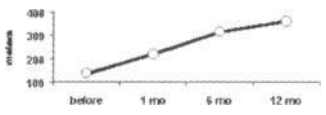
P2253 Partial left ventriculectomy improves functional capacity during long-term follow-up: relation to left ventricular shape

S. Gradinac, Z. Popovic, M. Miric, L.J. Vuk, M. Bojic, D. Berakovic, P. Otasevic, A.N. Neskovic. *Cardiovascular Research Center, Dedinje Cardiovascular Institute, Belgrade, Yugoslavia*

Several series of partial left ventriculectomy (PLV) patients have been reported recently. However, data are scarce regarding functional capacity and left ventricular function during long-term follow-up.

Methods: PLV was performed in 38 patients with end-stage idiopathic dilated cardiomyopathy enrolled in our prospective study, with mean follow-up of 19 months (range 2–28). Mean age was 52 years (range 2–71 years) and there were 6 women. In 29 patients mitral valve was repaired, while it was replaced in the remaining 9 patients. Tricuspid valve repair was done in 16 patients. Long and short axis of the left ventricle were measured by contrast ventriculography. Six-minute walking test distance was determined before, 1 month, 6 months, and 1 year after surgery.

Results: Thirty-day, 6-month, 1-, and 2-year survival were 81%, 67%, 64%, and 62%, respectively. After the initial 3-month period, patients had a stable outcome. Six-minute walking test distance increased significantly at each successive measurement (Figure). Diastolic long to short axis ratio (sphericity index) increased from 1.34 ± 0.15 before surgery to 1.66 ± 0.22 at 1 month, and 1.57 ± 0.22 after 6 months ($p < 0.05$ for both).



Changes in six-minute walking test.

Conclusion: Functional capacity improved in surviving patients during 1 year following PLV, which was paralleled with beneficial changes in left ventricular shape.

P2254 Anaesthetic strategy for partial left ventriculectomy

M. Jovic, B. Radomir, S. Gradinac, L.J. Vuk, D. Radojevic, S.D. Boskovic, L.J. Jovovic, M. Miric, M. Peric, M. Bojic. *Department of Anesthesiology, Dedinje Cardiovascular Institute, Belgrade, Yugoslavia*

Background: Surgical remodeling of the left ventricle using partial left ventriculectomy (PLV) is an attempt to reduce diameter of the left ventricle (LV) and consequently to decrease wall stress (WS). The goal is to improve LV efficiency proportionally to reduction of the afterload. Dynamic intraoperative changes in the load due to PLV and mitral valve repair (MVR) might influence left ventricular function. Therefore, haemodynamic evaluation of the patient during this procedure, as well as maintenance of anesthesia represents a challenging work and requires exceptional skill.

Methods: During two years, 38 patients (pts) (age 2–71 years) had been operated. PLV was coupled with mitral valve repair (29 pts), or valve replacement (9 pts). The modified technique for mitral valve repair and ventricular closure was used. Premedication with 0.5 mg atropine and 0.1 mg/kg midazolam was used. Induction and maintenance of anesthesia was performed with midazolam, fentanil and pancuronium. Arterial, central venous and pulmonary artery pressures were monitored continuously while transesophageal echo (TEE) was performed at the beginning and at the end of the procedure, as well as after the weaning of the bypass. Oxygen profile was measured in 20 pts after the induction, at the end of the procedure, 6 and 14 hours after operation

Results: In all pts who underwent PLV haemodynamic indexes improved at the end of the procedure. Cardiac index (CI) increased from 2.06 L/min/m^2 to 2.75 L/min/m^2, ($p < 0.05$). LVSWI was also improved (20.43 vs. 25.82 g-m/m^2). The average EF on TEE increased from 23.9% to 40.7% ($p < 0.05$). Oxygen consumption (VO_2) increased 34% (131 vs. 176 ml/min/m^2) while oxygen delivery (O_2 T) increased 10.9% (329 vs. 360 ml O_2/min). The weaning from bypass was successful using inotropic and vasodilator support which was necessary in all pts. There were no operative deaths.

Conclusion: This procedure involves reduction of left ventricular volume, correction of mitral regurgitation and eventual impairment of myocardial contractility with dynamic changes of the load intraoperatively. Continuous haemodynamic monitoring with TEE and oxygen profile provided sufficient data for proper intraoperatve treatment and maintenance of anesthesia.

P2255 Indicators of recurrent life-threatening ventricular tachyarrhythmias in cardioverter-defibrillator patients awaiting heart transplantation

Martin Stockburger[1], Christian Butter[1], Olivia Veit[1], Michael Schlegl[1], Matthias Löbe[2], Roland Hetzer[2], Eckart Fleck[1]. *[1]Department of Cardiology, Charité, Campus Virchow-Klinikum & Deutsches Herzzentrum, Berlin; [2]Department of Cardiothoracic Surgery, Deutsches Herzzentrum, Berlin, Germany*

Background: Patients with advanced heart failure awaiting heart transplantation (HTX) are threatened by ventricular tachyarrhythmias (VT). Examination of stored electrograms (EGMs) in patients awaiting HTX with documented symptomatic VT and implanted cardioverter-defibrillator (ICD) was done to improve risk stratification and to identify subgroups at increased risk for arrhythmia recurrence.

Methods: During the study period (7/1994 to 8/1998) 1484 patients have been selected for HTX in the German Heart Institute Berlin including 106 Patients with an ICD. In 64 patients only incomplete information about VT episodes was available. EGMs of 42 patients could be classified after a mean follow-up time of 9.79 ± 7.46 months. Arrhythmia detection and therapy delivery of all stored episodes have been analysed retrospectively in detail and classified individually as adequate or inadequate. Clinical, echocardiographic and hemodynamic characteristics have been examined for possible influences on time and frequency of VT episodes.

Results: During the first month of observation 14/42 patients (33%) experienced an adequately detected and terminated VT episode while 28/42 (67%) remained event-free. Groups with and without ICD therapy did not differ at this point of follow-up in baseline LVEF, LVEDP, PCW, HZV, LVEDD, LVESD, heart rate, blood pressure or NYHA-class. Patients with atrial tachyarrhythmias (AT) suffered significantly more frequent from VT episodes ($p = 0.02$). From the second to the 6th month 7/26 patients (27%) had new VT episodes. Actual values of LVEDD and LVESD did not differ significantly, but there was a strong influence of LVEDD increase during the first 6 months on new occurrence of VT episodes ($p = 0.01$). Low blood pressure at 6 months was also an indicator of VT episodes (103 ± 11 mmHg vs. 133 ± 23 mmHg, $p = 0.03$).

Conclusions: Presence of AT is correlated with more frequent early occurrence of VT episodes in patients with advanced heart failure and an implanted ICD. It is not possible to stratify the risk of recurrent VT episodes by one point hemodynamic or echocardiographic measurement, but progressive LV enlargement and hypotension are indicators of recurrent life-threatening ventricular arrhythmias.

P2256 Impact of changes between serial stress echocardiography, coronary angiography and intravascular ultrasound on clinical outcome after cardiac transplantation

C.H. Spes, V. Klauss, A.R. Tammen, J. Rieber, M. Ellinger, S.D. Schnaack, B. Reichart[1], K. Theisen, H. Mudra, C.E. Angermann. *Depts. of Cardiology (Medizinische Klinik, Klinikum Innenstadt); [1]Cardiac Surgery, University of Munich, Germany*

Coronary angiography (CA), intravascular ultrasound (IVUS) and dobutamine stress echocardiography (DSE) are used for surveillance of allograft vasculopathy after heart transplantation (HTX). In this study, the impact of changes between annual tests with these methods on the clinical outcome was compared.

Methods: 83 patients (P) were studied serially (40 ± 37 months after HTX and 12 months later) by DSE (5–40 μ/kg/min; assessment of wall motion abnormalities) (WMA) and CA. IVUS (analysis of intimal index) was done in 65 P. An increase in WMA in ≥1 segment or new WMA were regarded as deterioration by DSE. Any luminal changes by angiography and an increase of mean intimal index ≥ 5% (absolute change) were defined as deterioration. The incidence of subsequent cardiac events (infarction, heart failure, Re-HTX, revascularization, cardiac death) was compared with changes between preceeding studies.

Results: 2/50 P (4%) without and 9/31 P (29%) with DSE deterioration had an event (relative risk, 7.26; p = 0.0014); in 2/83 P, the second DSE image quality was not adequate for evaluation. 2/56 P (3.6%) with unchanged serial CA and 10/27 P (37%) with worsened CA had events (relative risk, 10.37, p < 0.0001). By combined IVUS and CA, 2/25 P (8%) without changes and 9/51 P (17.6%) with deterioration by IVUS and/or CA had an event (relative risk, 2.21, n.s.).

Conclusion: Worsening of serial DSE and of serial CA predicts subsequent events in a considerable number of patients. The chosen IVUS parameter (increase in intimal index by IVUS ≥ 5%) did not improve the prognostic value of CA. Unchanged DSE findings at serial testing, and unchanged serial CA both indicate a very low risk of subsequent events. Thus, serial DSE allows for a reliable noninvasive risk stratification after HTX and may safely help to avoid invasive procedures.

P2257 The protective effect of labetalol on myocardial function in brain-dead pigs is associated with attenuated increase in myocardial microdialysis concentrations of adenosine and lactate

E.M. Siaghy, Y. Devaux, N. Sfaksi, P. Halejcio-Delophont, F. Zannad, D. Ungureanu-Longrois, C. Burlet, J.P. Villemot, P.M. Mertes. *University of Nancy Medical School, Nancy, France*

Heart transplantation programs are partly limited by Donor hearts dysfonction of poorly understood mechanisms. Recently, altered myocardial oxygen supply/demand as a consequence of uncontrolled activation of the sympathetic nervous system (SNS) has been documented following brain death. The aim of this study was to investigate a potential protective role of pharmacological α-, β-adrenergic blockade on myocardial function, as well as its mechanisms, in brain-dead pigs.

Ten anesthetized pigs divided into two groups, GI as brain-dead animals and G2 as brain-dead animals receiving 10 mg/kg of labetalol at brain death induction, were involved in the study. Heart rate (HR), left ventricular dP/dt (LVdP/dt), coronary blood flow (Q LAD), mean aortic pressure (MAP), and cardiac output (CO) were recorded. Myocardial interstitial adenosine and lactate concentrations were assessed using microdialysis probes. Experimental brain death was obtained by an acute increase in intracranial pressure. Hemodynamic and biological parameters were recorded for 3 hours. At the 3rd hour, a volume expansion protocol was performed.

Following brain death, a transient increase in heart rate (HR: from 90 ± 11 to 158 ± 12 beats/min), left ventricular dP/dtmax (from LVdP/dt: 1700 ± 210 to 5030 ± 480 mmHg.sec^{-1}), cardiac output (CO: from 2.5 ± 0.3 to 3.4 ± 0.6 l/min), a limited increase in coronary blood flow (Q LAD: from 43 ± 6 to 70 ± 9 ml/min) was observed in G1. A significant 2 to 3 fold increase in adenosine and lactate myocardial dialysate concentration was observed, followed by a slow decline, reaching basal values after 2 hours. On the contrary, hemodynamic parameters and adenosine and lactate dialysate concentrations remained stable in G2. Following volume expansion, labetalol treated animals exhibited a significant increase in CO, dP/dt, and MAP, whereas G1 brain dead pigs exhibited decreased LVdP/dt values and only moderate increase in CO.

In conclusion, in brain-dead pigs, pharmacological α-, β-adrenergic blockade attenuates the myocardial dysfunction due to uncontrolled activation of the SNS. The protective effect of α-, β-adrenergic blockade is probably mediated by attenuation of the imbalance between myocardial oxygen supply and demand as suggested by the attenuated increase in myocardial interstitial concentrations of adenosine and lactate.

P2258 Relationship between macrovascular and microvascular changes in graft vessel disease of transplanted hearts

N. Hiemann, E. Wellnhofer[1], W. Bocksch[1], R. Meyer, M. Musci, W. Klimek[1], E. Fleck[1], R. Hetzer. *Dept. of Cardiothoracic & Vasc. Surg. DHZB; [1]Dept. of Int. Med./Cardiol., Campus Virchow, Charité, HU & DHZB Berlin, Germany*

Based on assessment of vascular function by flow-velocity measurements it has been suggested that there might be no correlation between microvascular and macrovascular graft vessel disease (GVD) in the transplanted heart. The study tests the correlation of macrovascular morphological parameters evaluated by intracoronary ultrasound (ICUS) with histological findings.

Methods: We studied 20 patients (three women, 17 men, mean age at HTx 54 ± 11 years), who underwent HTx due to terminal heart failure. All patients had cardiac catheterization including ICUS and right ventricular biopsies for diagnosis of GVD. Maximal plaque diameter, Stanford class (SC) of most severe lesion, local plaque geometry and distribution of macrovascular disease were assessed from ICUS. The paraffin-embedded biopsy samples were immunohistologically investigated with α-actin (smooth muscle cells, SMCs) and factor VIII (indicator for membrane injury of endothelial cells). Computer based quantitative morphometry and qualitative evaluation of H & E staining was performed at ×200. All data were analyzed using Mann-Whitney test.

Results: 1. Prominent endothelial cells in qualitative histologigal examination were associated with a higher amount of α-actin positive microvessels (p = 0.04) and with increased macrovascular plaque thickness (p = 0.03) as diagnosed by ICUS. 2. A higher count of α-actin positive microvessels was correlated with concentric local lesions (p = 0.04) and a diffuse distribution of macrovascular disease (p = 0.01). 3. Membrane injury of endothelial cells as indicated by an increased amount of factor VIII positive vessels in the biopsies were associated with a higher stage of macrovascular disease as assessed by the SC (p < 0.01).

Conclusion: According to our results macrovascular GVD is associated with pathologic changes in the terminal vascular system. Endothelial membrane injury and smooth muscle cell proliferation seem to be involved in the pathogenesis of this disease.

P2259 The relation of HLA-, gender- and CMV-matching to myocardial function assessed by dobutamine stress echocardiography

P.H. Jung, C.H. Spes, V. Klauss, H.U. Stempfle, J. Rieber, P. Überfuhr[1], K. Theisen, H. Mudra, C.E. Angermann. *Dept. of Cardiology, Kl. Innenstadt, University of Munich, Munich; [1]Dept. of Cardiac Surgery, University of Munich, Kl. Grosshadern, Munich, Germany*

HLA compatibility is related to survival and morphologic evidence of allograft vasculopathy in patients (pts) after heart transplantation (HTX) as shown by intravascular ultrasound measurements (IVUS) and coronary angiography in previous studies. Another method for surveillance of allograft vasculopathy is dobutamine stress echocardiography (DSE). The aim of this study was to evaluate the impact of HLA-, gender- and CMV-matching on myocardial function assessed by DSE in pts after HTX.

Methods: 104 pts (24 f, 80 m) undergoing DSE (5–40 μg/kg/min) were matched for HLA-A, -B and -DR compatibility (0–6 mismatches), donor/recipient CMV and gender status. By DSE, regional wall motion abnormalities (WMA) were assessed (16 segment model), systolic wall thickening (SWT) of septum and posterior wall was quantified and compared to previously defined normal values. A DSE score (1 = normal WMA and SWT, 2 = WMA or SWT path., 3 = WMA and SWT path.) was attributed to all pts. HLA-Typing was performed using lymphocytotoxicity technique (-A, -B) and PCR (-DR).

Results: The mean number of mismatches (MM) was 4.3. Pts were divided into a group A (<4 MM, 26% of all pts) and B (>3 MM, 74% of all pts). The mean DSE score was 1.8 in group A and 2.2 in group B with a significant difference (p = 0.038). Pts with a male donor (69.7%) had a mean DSE score of 2.3, whereas pts. with female donors (30.3%) had a mean DSE score of 1.8 (p = 0.032). A difference was also noted in recipient male/female sex (female rec. 2.0, male rec. 2.2), but did not reach statistical significance (p = 0.12). No differences in DSE score were found according to CMV-status of donor/recipient.

Conclusion: A lower number of HLA-mismatches and donor female sex is associated with fewer functional abnormalities assessed by DSE. This corresponds to previous IVUS and angiographic studies and indicates the clinical relevance of DSE.

P2260 A prospective study of changes in plasma nitrate levels following human heart transplantation: relevance to rejection and myocardial dysfunction

E.J. Birks, D. Hunt, L. Grieve, M. Burke, N.R. Banner, M.H. Yacoub. *National Heart and Lung Institute at Imperial College of Science, Technology and Medicine, London, UK*

Expression of iNOS and release of nitric oxide (NO) into the circulation has been linked to acute rejection in animal studies and NO has been shown to depress myocardial function. However its role in acute rejection in humans has not been adequately defined. We prospectively studied the relationship between plasma nitrate (breakdown product of NO), biopsy proven acute rejection and ventricular function (both systolic and diastolic) after transplantation.

Methods: Biopsies were performed weekly and then fortnightly up to 12 weeks after heart transplantation in 37 patients. On clinical indication of rejection additional studies were performed. Plasma nitrates were obtained on the morning of each biopsy (total 341). An echocardiogram was performed immediately prior to each biopsy in which the systolic parameters ejection fraction (EF) and fractional shortening (fs) and the diastolic parameters isovolumetric relaxation time (IVRT), mitral valve Pressure Half Time (MVPHT), mitral valve deceleration time (MVDT), peak a and e wave, e:a ratio and a wave duration were measured.

Results: Mean plasma nitrate rose significantly by a mean of 14.6 ± 7.4 μmol/L ($p < 0.005$) when rejection developed compared to a mean change of −2.6 ± 2.2 μmol/L between non rejecting biopsies. Plasma nitrate level showed no correlation with the systolic parameters ejection fraction EF or fs. There was a significant correlation between plasma nitrate and mitral valve peak a wave ($p < 0.001$), but no correlation with other diastolic parameters.

Conclusions: Nitrate level increases during acute rejection and could be a useful diagnostic marker. In this group of patients changes in plasma nitrate appear to be associated with diastolic but not systolic dysfunction.

P2261 Cytokine genetics and cardiac allograft vasculopathy: impact of tumour necrosis factor-α and -β gene polymorphisms

K. Pethig, A. Hoffmann, B. Heublein, Th. Wahlers, I. Kutschka, A. Haverich. *Dep. of Thoracic and Cardiovascular Surgery, Hannover, Germany Medical School*

Tumor necrosis factor (TNF) represents one of the most important pro-inflammatory cytokines, mediating immunological reactions in organ transplantation. Biological activity is influenced by several genetic polymorphisms.

To assess a possible impact of genotype on actuarial development of cardiac allograft vasculopathy (CAV) after heart transplantation (HTX), we analyzed two different TNF-gene-polymorphisms (TNF-α, position-308 and TNF-β, intron 1, NcoI-RFLP) in a large cohort of heart transplant recipients (n = 146, 1–12 years after HTX). Genotypes were correlated to the development of advanced CAV, as assessed by serial angiography (luminal obstruction $\geq$ 50%).

Allelic frequencies (TNF-α: GG = 71.2%, GC = 26.7%, CC = 2.1% and TNF-β: GG = 89%, GC = 9.6%, CC = 1.4%) were comparable to the normal population. Genotype dependent differences could be shown for the unstimulated serum activity of TNF-α (4.9 ± 1.8 pg/ml in the GG-genotype as opposed to 4.1 ± 1.7 pg/ml in carriers of the C-allel, $p = 0.05$) and were not interpretable for TNF-β (values below the detection threshold). However, freedom from CAVD was not found to differ significantly, neither between the TNF-α nor the TNF-β genotypes (TNF-α $p = 0.97$, TNF-β $p = 0.86$; kaplan meier analysis, log rank test).

It is concluded that the biological activity of TNF-α is influenced by the genotype. However, TNF-α as well as TNF-β polymorphisms fails to identify as a genetic risk marker for the development luminal obstruction in cardiac allograft vasculopathy.

P2262 Association between restoration of autonomic modulation in the native sinus node (SN) after cardiac transplantation and haemodynamic improvement

D. Ramaekers, F. Beckers, A.E. Aubert, J. Van Cleemput, W. Droogne, J. Vanhaecke, F. Van de Werf, H. Ector. *Cardiology Dept., University Hospital Gasthuisberg, Leuven, Belgium*

We recently showed that there is a clear increase in both low-frequency (LF) and respiratory-related high-frequency (HF) power in the heart rate power spectra of the native sinus node in cardiac transplant (HTX) patients from about 4–6 months onwards post-HTX, clearly exceeding pre-HTX values, suggesting a restoration of (normal) autonomic modulation post-HTX. In this study possible relations of this new technique with multiple hemodynamic and biochemical parameters were assessed.

Methods: 389 intracardiac (i) recordings (rec) were made every 1–3 mths. post-HTX in 124 HTX pts, mostly starting from an index rec 0–1 mths. post-HTX or a pre-HTX rec. i-HRV of the native SN and HRV of the donor heart were calculated in LabVIEW, as described. An expert system in SPSS, with multiple hemodynamic and biochemical parameters, obtained at the same time-points as i-HRV, was developed to validate possible correlations with these indices and with future outcome of the patients.

Results: A clear increase in the spectral content was present in the consecutive recordings from 4–6 mths. onwards for both LF ($p < 0.001$) and HF($p < 0.001$), confirming previous results. The increases of LF and HF power were highly significantly correlated (all $p < 0.001$) with right ventricular pressure (RVP; rsp = −0.51, and −0.51 resp), right a. pulmonalis pressure (APP) (rsp = −0.53, and −0.50 resp) and right atrial pressure (RAP; rsp = −0.50, and −0.59 resp), and with total bilirubin (rsp = −0.67 and 0.61 resp). There was no relation with the rejection biopsy grading of the right ventricle.

Conclusions: The restoration of autonomic modulation in the native SN seems to be associated with the improvement of cardiac hemodynamic indices such as RVP, RAP and APP. There was no relation with rejection histology. This suggests that HRV of the native SN could have an important clinical application in the routine follow-up of HTX patients.

P2263 Skin cancer in heart transplant recipients: frequency and risk factor analysis

A.L.P. Caforio, A. Belloni Fortina[1], S. Piaserico[1], L. Bombieri[1], S. Ros[1], F. Tona, A. Peserico[1], U. Livi[2]. *Cardiology, Dept Exp Clin Med, Padua University, Padua; [1]Dermatology Dept, Padua University, Padua; [2]Cardiovascular Surgery, Padua University, Padua, Italy*

The frequency of skin cancer is increased among organ transplant recipients, but the predisposing risk factors are controversial. It is also unclear whether heart transplant (HT) patients face an increased risk compared to recipients of other organs, e.g. kidney transplants (KT). We performed multivariate analysis of risk factors for skin cancer in 272 HT recipients (aged 54 ± 14 years, 233 male, mean follow-up 4.7 years, range 1 month–12 years) and in a control series of 242 KT (mean age 35 ± 15, 164 male, mean follow-up 4.5 years, range 1 month-22 years) followed up at a single Center. An extensive dermatological examination was carried out; baseline features, type of immunosuppression, number of rejection episodes requiring increased immunosuppression (3A ISHLT score), extent of sunlight exposure, skin type were recorded. Multivariate analysis (Cox multiple regression) included: age at transplant, sex, skin type, presence of warts, type of organ (heart vs. kidney), immunosuppressive regimen (double vs. triple therapy), number of Methylprednisolone I.V. boluses, sunlight exposure. During follow-up skin cancer was more common among HT patients (40, 15%) than in KT (18, 7%, $p = 0.01$). The prevalence of squamous cell carcinoma was 400 times higher than normal for Mediterranean countries. The cumulative incidence of skin cancer by life table analysis increased from 13% after 5 years to 28% after 10 years in HT patients and from 5% to 16% in KT ($p = 0.003$) (log-rank test). However, by multivariate analysis, age at transplant ($p = 0.0006$), skin type ($p = 0.03$) and sunlight exposure ($p = 0.03$), but not organ type were significant risk factors. In conclusion, age at transplant, skin type and sunlight exposure, but not organ type, are associated with increased risk of skin cancer in HT. Chronic immunosuppression may be implicated in the progressive increase of cancer frequency during follow-up. Prospective studies are warranted.

P2264 Prognostic modelling for cardiac events after heart transplantation using intravascular ultrasound in a large patient cohort

V. Klauss, K. Pethig[1], U. Siebert[2], J. Rieber, B. Heublein[1], C. Spes, H. Kalies[2], B. Reichart[3], K. Theisen, H. Mudra. *Cardiology Dept, Med. Klinik, University of Munich, Munich; [1]Dept. of Cardiac Surgery, Hannover Medical School, Hannover; [2]Institute for Medical Informatics, University of Munich, Munich; [3]Dept. of Cardiac Surgery, University of Munich, Munich, Germany*

Previous studies have shown that cardiac allograft vasculopathy (CAV) as assessed by intravascular ultrasound (IVUS) may predict cardiac events in patients after heart transplantation (HTx). These results were limited by the statistical approach and by sample size. Additionally, there is controversy about the optimal IVUS-parameter. We therefore sought to determine the prognostic impact of a suitable IVUS parameter on cardiac events in a large patient cohort.

Methods: 203 patients were studied by IVUS after HTx at two transplant centers. As potential predictors for cardiac events, we included four IVUS-parameters, the presence of angiographic CAV and various clinical characteristics. The analysis was performed in two steps. First, the IVUS-parameter with the highest predictive value was selected using deviance comparison. Second, all significant predictors were determined and relative rates (RR) with 95% confidence intervals (CI) were calculated using the Cox proportional hazards model.

Results: During a 6-year follow-up period, 37 events were observed. The maximal intimal index was found to be the most effective IVUS-predictor for cardiac events. In the bivariate analysis, various variables were significantly associated with the outcome. However, in the multivariate analysis, only the presence of angiographic CAV (RR 18.2, CI 6.5–50.7), maximal intimal index > 30% by IVUS (RR 12.0, CI 3.4–42.2) and body mass index (RR 5.6, CI 2.2–14.4) were identified.

Conclusion: We demonstrated that IVUS provides additional prognostic information to angiographic findings. This is important in patients with a normal coronary angiogram. Among all clinical parameters, body mass index has an independent prognostic impact. This may help to reduce costs and the need of invasive procedures in low-risk subgroups.

P2265 Coronary flow reserve is bi-directionally regulated by myocardial inducible nitric oxide synthase after cardiac transplantation – a longitudinal follow-up in 45 cardiac transplant recipients

S.M. Wildhirt, M. Weis[1], C. Schulze, N. Conrad, G. Rieder, C. Hopp, G. Enders[2], W. von Scheidt[1], B. Reichart. *Dept. of Cardiac Surgery, Ludwig Maximilians University, Munich; [1]Dept of Cardiology, Ludwig Maximilians University, Munich; [2]Inst for Surgical Research, Ludwig Maximilians University, Munich, Germany*

Objective: We followed 45 cardiac transplant recipients over one year and determined the potential relationship between myocardial iNOS and endothelial constitutive NOS (ecNOS) gene expression and coronary vasomotor function 1 and 12 months post-HTx.

Methods: iNOS and ecNOS gene expression was determined in endomyocardial biopsies 1, 6 and 12 months (Mo) after HTx by reverse transcriptase PCR followed by computerized densitometric analysis. Coronary flow velocity reserve (CFVR) was measured by doppler flowire in response to endothelium dependent (Acetylcholine (Ach); 30 μg/min/5 min) and independent (Adenosine (Ade); 160 μg/min/5 min) stimuli 1 and 12 months after HTx. Blood samples rom the aortic root and coronary sinus (CS) were used for measurement of nitrite (μM) and TNF-a (pg/ml) levels.

Results: iNOS and ecNOS gene expression was detected in all patients and did not differ over time (iNOS: 1 Mo: 1.9 ± 0.5 vs 6 Mo: 1.85 ± 0.6 vs 12 Mo: 1.0 ± 0.2, p = n.s.; ecNOS: 1 Mo: 15.2 ± 7 vs 6 Mo: 9.8 ± 2.1 vs 12 Mo: 8.7 ± 2.8, p = n.s.) Endothelium dependent CFVR increased in 56% over the first year (2.4 ± 0.1 vs 3.7 ± 0.17, p = 0.0001) wherea in 44% a decrease was noted (2.8 ± 0.18 vs 2.2 ± 0.22, p = 0.03). Increase in CFVR over time in response to Ach was associated with higher gene expression of iNOS (r = 0.68, p = 0.02 and with CS nitrite levels (r = 0.66, p = 0.008) at one year post HTx. In contrast, transcardiac nitric oxide production (nitrite levels in aorta: 34.7 ± 4.1 vs 40.6 ± 4.2, p = 0.0001) observed one month after HTx correlated with transcardiac production of TNF-a only in patients with impaired CFVR (r = 0.42, p = 0.02). However, this was not observed after 6 and 12 months.

Conclusions: These data in line with experimental evidence suggests a bi-directional role of iNOS activation in humans contributing to endothelial dysfunction early after HTx in association with inflammatory mediators (TNF-a) and improvement of CFVR in later stages after HTx which may delay the progression of allograft vasculopathy

P2266 Time-dependent pattern of vasular remodelling after heart transplantation: insights with intravascular ultrasound and three-dimensional vessel reconstruction

J. Rieber, V. Klauss, C. Weber, C.H. Spes, E. Regar, F. Prati[1], C.E. Angermann, B. Reichart, K. Theisen, H. Mudra. *Dpt. of Cardiology, Klinikum Innenstadt, University of Munich, Germany; [1]S. Camillo Hospital, Rome, Italy*

The progression of transplant coronary artery disease (TxCAD) remains the limiting factor after heart tranplantation (HTx). The mechanisms of coronary artery remodeling during the progression of TxCAD are not yet fully understood.

Methods: In 50 patients (pts) with angiographically normal coronary arteries (LAD = 38, LCx = 10, RCA = 2), serial intravascular ultrasound studies were performed immediately (19 pts, group I) and beyond the first year after HTx (group II, 31 pts) and 12 months thereafter in each group with a motorized pull-back system. Up to 400 precisely matched sites per patient (200 μm stepping, frame rate 5/s) were analyzed using an interactive three-dimensional analysis software package (TomTec™). Total vessel volume (VV), luminal volume (LV) and intima volume (IV) were compared between the baseline (A) and follow-up (B) study.

Results:

	Group I			Group II		
	A	B	p	A	B	p
VV (mm^3)	466.9	437.2	ns	559.8	526.5	<0.5
LV (mm^3)	426.7	390.2	ns	488.8	435.2	<0.001
IV (mm^3)	40.8	47.2	ns	71.0	91.3	<0.05

Although mean vessel volumes did not change in group I, the pattern of remodeling was very heterogeneous, revealing an enlargement remodeling in 42% and shrinkage in 58% of the vessels. In group II, 70% of the pts showed a homogeneous vessel shrinkage.

Conclusion: By serial volumetric studies, heterogeneous patterns of coronary artery remodeling were observed, depending on the time since HTx. In pts late after HTx, the ability for compensatory enlargement of coronary vessels seems to decrease. The pattern of remodeling may have an important clinical and prognostic impact.

P2267 Clinical significance of TGF-β polymorphism and the development of cardiac transplant vasculopathy

C.G. Densem, I.V. Hutchinson, A. Cooper, N. Yonan, T. Roberts, N.H. Brooks. *Cardiac Transplant Unit, Wythenshawe Hospital, Manchester, UK*

Coronary vasculopathy (CV), characterised by myointimal proliferation determines long term survival following heart transplantation. Transforming growth factor-β1 (TGF) influences neointimal formation and vascular remodeling by regulating smooth muscle cell growth, matrix production and growth factors. Polymorphism at position +915 of the TGF gene affects TGF production, individuals being high or low producers. We assessed this allelic variation on the development of CV.

Methods. CV was diagnosed by coronary angiography. Following DNA extraction sequence specific primers amplified the polymorphic TGF gene region by PCR. Electrophoresis allowed genotype identification. The results were analysed using a Kaplan-Meier actuarial curve and log rank.

Results: 129 patients and 215 angiograms were independently studied. 89.9% were high producers of TGF- β1. High producers were more likely to have CV at any time point (p = 0.0361). Low producers were protected from CV, with no patients developing disease until at least 4 years post transplant. The results were independent of pretransplant diagnosis, donor age, acute rejection episodes. sex.

Conclusions: TGF polymorphism determines susceptibility to CV and should be taken into account in future CV studies. This finding offers the prospect of preventing CV by the pharmacological inhibition of TGF.

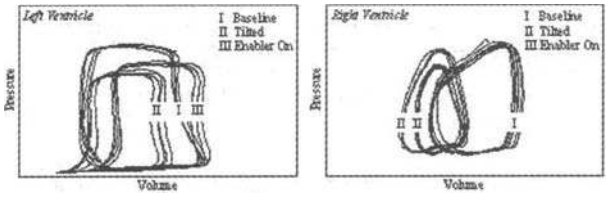
P2268 Left and right ventricular pressure-volume loops to study the effect of cardiac tilting and the enabler circulatory support system on ventricular pump function

F.H. van der Veen, A.L.A. Dekker[1], G.G. Geskes[2], K.B. Prenger[2], A.A.T. Cramers, J.W. Habets, T. van der Nagel, J.G. Maessen[2]. *Cardiology Dept, Academic Hospital Maastricht, CARIM, Maastricht; [1]Heart- & Lungfunction, Academic Hospital Maastricht, Maastricht; [2]Cardiothoracic Surgery Dept, Academic Hospital Maastricht, Maastricht, Netherlands*

Pressure-volume (PV) loops generated by a conductance catheter are used for the investigation of cardiac pump function in various experiments and treatments. Currently no other technique is available to measure beat-to-beat volume, especially if the anatomy of the heart is changed by surgery or mechanical inhibition. In this study, absolute left and right ventricular PV-loops were simultaneously obtained in the tilted heart to asses the feasibility of the Enabler circulatory support system during beating heart CABG.

Methods: In six sheep, the heart was tilted with an Octopus device to expose the inferior wall. The Enabler was placed with the inlet valve in the right atrium and outlet valve in the pulmonary artery. Absolute PV-loops were obtained with the heart I) in its normal position, II) in the tilted position and III) in the tilted position and the Enabler activated to pump 2.0 l/min.

Results: PV-loops (see fig.) showed a reduction in stroke volume and right ventricular volumes upon cardiac tilting (SV: −31 ± 9%, RVESV: −46 ± 14%, RVEDV: −40 ± 12%). Subsequent Enabler activation improved left ventricular function (SV:+13 ± 8%, LVESV:+17 ± 16%, LVEDV:+14 ± 11%). The net extra output delivered by the Enabler was limited because its activation reduced right ventricular function.



Left and right ventricular PV-loops.

In conclusion, left and right ventricular PV-loops allowed the absolute and precise assessment of cardiac pump function even with the heart in a non-anatomical, tilted position. They showed cardiac tilting has severe hemodynamic consequences and that the Enabler is able to partly correct this.

P2269 Prognostic stratification of heart failure patients with a VO_2max on the grey zone highlighted by 24-hour Holter monitoring

R. Teles, M. Mendes, P. Adragão, D. Bonhorst, R. Seabra-Gomes. *Cardiology Department, Santa Cruz Hospital, Carnaxide, Portugal*

Background: The Bethesda Consensus 1993 established that a VO_2max < 10 mL/kg is *definite* indication for heart transplantation, between 10 and 14 is a *probable* indication and over 14 is a *no indication* in heart failure patients (pts). However, there is a considerable mortality in patients on the "grey zone", eventually due to ventricular arrhythmias.

Aim: To study the additional prognostic value of 24-hour Holter monitoring in heart failure pts submitted to CPET, specially on those with a VO_2max between 10 and 14 mL/kg/min.

Methods: We performed a retrospective analysis of 53 consecutive pts submitted to their first CPET since 1992 until 1998, whose Holter-ECG was performed with less than one-year interval. Age ranged between 16 and 72 years (53 ± 13 y.o.). Most pts were in NYHA II/III functional class (86%, half in each class) and the others were in class I. Mean ejection fraction was 27 ± 8%. There was an ischemic etiology in 21 pts (40%). No cardiac transplant was performed and 2 pts were submitted to revascularization procedures. Pts were grouped according to their VO_2/kg/min: Group I- >14; Group II > 10 and ≤14; and Group III- ≤10. Ventricular tachycardia (VT) on Holter monitoring occurred in 12 pts (22.6%). Total mortality was 13.2% (7 pts) with a mean follow-up (F-U) of 22 ± 16 months.

Results: Six of the pts who had VT at Holter (6/12–50%) died during F-U. This death rate was significantly higher than the one on the remaining 41 pts (1/41– 2.5%, Fisher's test- p < 0.001). The results by group were the following (table):

	Group I (n = 35)	*Group II* (n = 16)	Group III (n = 2)	
Deaths	1/35 (2.8%)	5/16 (31.2%)	1/2 (50%)	p < 0.01
VT	7/35 (20.0%)	5/16 (31.2%)	0/2 (0%)	NS
Deaths with VT on Holter	1/7 (14.2%)	5/5 (100%)	0/1 (0%)	p < 0.01

Conclusions: 24 h-Holter monitoring, in cardiac failure pts submitted to CPET, conferred an additional prognostic value in the VO_2max 10–14 group, as it identified all patients that subsequently died. Those patients should be considered for ICD or Heart Transplant since they had an ominous outcome in this study.

P2270 Poor outcome following heart transplantation in the presence of diastolic dysfunction: a Doppler echocardiographic and histopathological study

T. Aziz[1], M.I. Burgess[1], S.G. Ray[1], A.K. Deiraniya[1], A.N. Rahman[1], C. Campbell[1], N. Yonan[1], P. Haselton[1], I. Hutchinson[2]. *[1]Department of Cardiac Transplantation, Wythenshawe Hospital; [2]University Department of Immunology, Manchester, UK*

Aim: To correlate structural and functional myocardial abnormalities suggesting diastolic dysfunction with subsequent clinical progress after heart transplantation.

Methods and results: In 168 heart transplant recipients (age 46 ± 10 years) who survived for at least 24 months following surgery we performed 2D and Doppler echocardiographic studies to assess left ventricular diastolic function (mitral deceleration time [MDT] and isovolumic relaxation time [IVRT]). We examined the relationship between these findings and histopathological staining of endomyocardial biopsies (H & E and antibodies for TGF-B) and clinical course. Recipients were divided into two groups based on the presence (MDT > 140 msecs; group A) or absence (MDT < 140 msecs; group B) of diastolic dysfunction. All assessments were made in the absence of rejection. There was no significant difference in donor age, recipient age, HLA mismatch or ejection fraction between the two groups. MDT and IVRT in group A (69 patients) vs group B (78 patients) were 123 ± 11 vs 168 ± 15, p = <0.001 and 56 ± 9 vs 78 ± 10, p = 0.003 respectively. Recipients in group A had higher fibrosis scores and more TGF-B staining compared to those in group B (p = 0.004 and 0.001 respectively). MDT correlated inversely with fibrosis score and TGF-B staining score (r = −0.45, p = 0.01 and r = −0.36, p = 0.01 respectively). NYHA status was 2.1 ± 0.4 in group A and 1.4 ± 0.2 in group B (p = 0.003). Post-operative survival was 1681 + 141 days in group A and 2693 ± 210 days in group B (p = 0.003).

Conclusion: Echocardiographic evidence of left ventricular diastolic dysfunction is common in cardiac allografts and is associated with increased myocardial fibrosis. Recipients with these features are a subgroup with a poor clinical outcome.

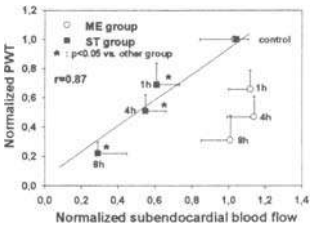
P2271 Predictor of development of severe renal dysfunction during 9 years following heart transplantation

B. Lindelöw, H. Herlitz[1], C.-H. Bergh, F. Waagstein. *Cardiology Dept, Sahlgrenska University Hospital, Gothenburg; [1]Nephrology Dept, Sahlgrenska University Hospital, Gothenburg, Sweden*

Severe renal dysfunction after heart transplantation (Htx), with high risk for dialysis or kidney transplantation, is considered to develop in approximately 20% of the patients during the first 3 years post-Htx.

Methods: In 151 Htx patients, 40 pre- and post-Htx variables in one subgroup of patients who developed severe renal dysfunction (GFR ≤20) were compared to corresponding variables in patients who did not (GFR > 20) during 9 years following Htx.

Results and conclusions: Despite a similar pre-Htx GFR (65 ± 18 vs 67 ± 16), the patients in subgroup GFR ≤20 developed severe renal dysfunction within 9 years following Htx. The recipient age (p = 0.0002) was higher and the GFR value at the first year post-Htx (p = 0.0001) was lower for patients in group GFR ≤ 20 than in group GFR > 20. Multivariate analysis showed that the recipient age together with GFR at one year post-Htx predicted the develop-ment of post-Htx severe renal dysfunction according to the Poisson model.



This results in a nomogram which predicts if and when a patient has a 50% probability of developing severe renal dysfunction within 9 years post-Htx.

P2272 Association between relocation of calcium binding S100A1 protein and severity of graft rejection in heart transplant recipients

L. Mandinov, A. Mandinova[1], U. Saunder[1], E. Oechslin, D. Atar, U. Aebi[1], C. Heizmann[2], W. Kiowski[3]. *Div of Cardiology, University Hospital, Zurich; [1]Maurice Mueller Institute, Biocenter, University of Basel, Basel; [2]Clinical Chemistry, University Children's Hospital, Zurich; [3]Internal Medicine Dept, University Hospital, Zurich, Switzerland*

Background: Immune-mediated cardiomyocyte injury occurs typically during rejection in transplanted hearts and can contribute to development of cardiac dysfunction. This process can be particularly explained by alteration in the intracellular Ca^{2+} handling. Recently, much attention has been paid to the heart specific Ca^{2+}-binding S100A1 protein, which seems to be directly involved in a variety of Ca^{2+} mediated functions of the myocytes. Thus, the aim of the present study was to investigate the ultrastructural localization of S100A1 in myocardial tissue samples of heart transplant recipients (HTR) with mild or moderate rejection.

Material and Methods: 18 HTR (15 males and 3 females, mean age 51 ± 12 years) were divided into 4 groups with respect to severity of allograft rejection according to International Society for Heart Transplantation. Five HTR had no rejection (grade 0); 5 HTR had grade 1A; 5 HTR – grade 2, and 3 HTR – grade 3A. Immunolocalization of S100A1 in myocardial biopsies was performed by confocal laser scanning microscopy. Changes in cytosolic S100A1-concntration in cardiomyocytes were studied by semiquantitative measurements of the fluorescence-intensity in different regions of tissue samples obtained by endomyocardial biopsy.

Results: There were no differences between the groups regarding gender, age, time after transplantation, medical therapy and immunosuppresion including cyclosporine level. A specific relocation of S100A1 into vesicle-like structures near the cell- membrane and in the extracellular space was observed with increasing grade of graft rejection. This relocation resulted in a significant decrease of the cytoplasmic S100A1 content in cardiomyocytes by 10% in grade 1 rejection, 34% in grade 2 and 71% in grade 3 as compared to grade O.

Conclusion: S100A1 Ca^{2+}-binding protein is directly involved in the alterations of cardiomyocytes during allograft rejection. Given its role in the structural organisation and function of the cardiomyocytes, this Ca^{2+}-binding protein could be an important link in the immune-induced injury of the heart.

P2273 Hypercoagulable state in cardiac allograft recipients

A. van de Loo[1], M.M. Koemer[3], M. Nauck[2], J. Martin[1], M. Oen[1], F. Beyersdorf[1]. *Universitätsklinik Freiburg; [1]Herz-Kreislaufzentrum; [2]Zentrallabor; [3]Herz-und Diabeteszentrum Nordrhein-Westfalen, Germany*

Rapid progressive graft vasculopathy (GVD) is a major cause of morbidity and mortality in cardiac transplant recipients (HTX). Subclinical activation of the coagulatory system has been demonstrated to be associated with progression of conventional coronary artery disease. Aim of this study was to investigate markers of the coagulatory system in HTX and compare them to consecutive control patients (C) from the centers outpatients clinic as data on this aspect are rare. In 81 consecutive HTX from 2 centers we determined Thrombin/Antithrombin-complex (TAT), Prothrombinfragment 1 + 2 (PF1 + 2) and Plasmin Antiplasmin (PAP) and Fibrinogen (F).

Results:

	HTX (mean ± SD)	C (mean ± SD)	p value
TAT (µg/l)	17 ± 35	3.3 ± 5.6	0.001
PF1 + 2 (nmol/l)	1.7 ± 0.98	1.17 ± 0.52	<0.001
PAP (ng/l)	800 ± 350	435 ± 231	<0.001
F (mg/dl)	354 ± 104	238 ± 57	<0.001

Conclusion: These results demonstrate that a hypercoagulable state characterized by increased thrombin generation and degradation exists in cardiac transplant recipients. It is relevant to possibly explain the increased risk of thrombotic comlications and progression of graft atherosclerosis in this group of patients

P2274 Clinical significance of tricuspid valve function after heart transplantation

M.I. Burgess[1], T. Aziz[2], A.N. Rahman[2], A.K. Deiraniya[2], C. Campbell[2], S.G. Ray[1], N.H. Brooks[1], N. Yonan[2]. *[1]Departments of Cardiology; [2]Cardiac Transplantation, Wythenshawe Hospital, Manchester, UK*

Aim: Tricuspid regurgitation (TR) is common following orthotopic heart transplantation (HT) but its natural history and clinical relevance are uncertain. We aimed to document clinical progress of patients after HT in relation to severity of TR.

Methods and results: We studied 208 recipients surviving for at least 6 months following HT by transthoracic echocardiography (870 examinations). TR was graded clinically and by ratio of regurgitant jet area (RJA) to right atrial area. Recipients were divided into those with no TR (group 1), subclinical TR (TR absent clinically and RJA < 25%, group 2) and clinical TR (TR clinically apparent or RJA ≥ 25%, group 3). Age, ischaemic time, pre-operative PVR or TPG, incidence of rejection episodes, ejection fraction and cyclosporin level were not significantly different between the groups. At 12 months after HT mean right atrial and pulmonary artery pressures were higher in group 3 than groups 1 or 2 (p = 0.005 and 0.03 respectively). The annual transition rate from group 1 to 2 was 13% (CI 9%–17%) and from group 2 to 3 it was 48% (CI 36%–71%). At a mean follow-up period of 72 months mean NYHA class in groups 1, 2 and 3 was 1.2, 1.7 and 3.2 respectively (p = 0.04 group 1 vs 2, p = <0.01 group 2 vs 3). The annual development of renal impairment (serum creatinine ≥ 200 micromol/l) in the three groups was 3% (CI 1%–5%), 7% (CI 3%–11%) and 61% (CI 45%–76%) respectively (p = 0.02 group 1 vs 2, p < 0.01 group 2 vs 3). Post-operative survival in days was 2017 + 198 for group 1, 1763 + 215 for group 2 and 1284 + 165 for group 3 (p = 0.03 group 1 vs 2, p < 0.01 group 2 vs 3).

Conclusion: Functional status of the tricuspid valve has significant implications for the long-term progress of HT recipients. Higher degrees of TR are associated with adverse outcome. Subclinical TR frequently progresses and assessment of tricuspid valve function should be an important part of the long-term follow-up after HT.

P2275 Plasma brain natriuretic peptide levels reflect the pattern of left ventricular filling after orthotopic heart transplantation: correlation with Doppler echocardiographic and haemodynamic findings

M.I. Burgess[1], T. Aziz[2], A. El-Gamel[2], S.G. Ray[1], B. Keevil[3], N.H. Brooks[1], A.K. Deiraniya[2], C. Campbell[2], A.N. Rahman[2], N. Yonan[2]. *[1]Departments of Cardiology; [2]Cardiopulmonary Transplantation; [3]Biochemical Medicine, Wythenshawe Hospital, Manchester, UK*

Aim: Levels of brain natriuretic peptide (BNP) are increased after orthotopic heart transplantation (HT) and this may be a reflection of abnormal diastolic filling. We studied the relationship between diastolic filling and plasma BNP in HT recipients.

Methods: Left ventricular diastolic function was evaluated at a mean of 35 months post-transplantation in 40 cardiac transplant recipients (mean age 51 years, 30% female) with normal systolic function and no significant valvular disease. All measurements were made in the absence of allograft rejection. Diastolic function was assessed by Doppler echocardiographic parameters (E:A velocity ratio, mitral deceleration time [MDT] and isovolumic ventricular relaxation time [IVRT]). Pulmonary capillary wedge pressure (PCWP) was also measured. Restrictive filling was defined as an MDT < 140 msecs. Plasma BNP levels were measured in the supine position in all patients.

Results: Doppler parameters could be measured in 35 (88%) patients. E:A ratio correlated significantly with PCWP (r = 0.316, p = 0.033). MDT and IVRT correlated inversely with PCWP (r = −0.366, p = 0.028 and r = −0.396, p = 0.019 respectively). An MDT of <140 msecs predicted an elevated PCWP (>18 mmHg) with a sensitivity of 77% and specificity of 84%. Plasma BNP level for patients with restrictive filling was 10.2 ± 2.3 pg/ml compared to 6.4 ± 1.8 pg/ml for those patients without restrictive filling; p = 0.003. There was a significant positive correlation between BNP level and E:A ratio (r = 0.61, p = 0.01). MDT and IVRT correlated inversely with BNP level (r = −0.67, p = 0.02 and r = −0.51, p = 0.03 respectively. Elevations in PCWP were related to high BNP levels (r = 0.487, p = 0.003).

Conclusion: Restrictive ventricular filling is an accurate predictor of an elevated left ventricular filling pressure in HT recipients. Even in the presence of preserved systolic function plasma BNP levels are elevated after HT and correlate with the presence of restrictive physiology in the allograft.

P2276 Enhanced basal nitric oxide production in heart transplant recipients: relation to arterial blood pressure

T. Holm, P. Aukrust[1], L. Gullestad, T. Ueland, S. Simonsen, A.K. Andreassen. *Cardiology Department, Rikshospitalet, Oslo; [1]Medical Department, Rikshospitalet, Oslo, Norway*

Total nitrite and nitrate (NO_2^- + NO_3^-) levels in plasma, considered as an index of endogenous formation of nitric oxide (NO), is reduced in patients with essential hypertension. Most heart transplant recipients (HTx pts) develop hypertension characterised by increased peripheral vascular tone and endothelial dysfunction, but it is unknown if this is due to reduced NO availability.

Methods: 63 clinically stable HTx pts (58 males, age 56 ± 1 years, mean ± SEM) 6 (range 1–13) years after HTx, treated with prednisolone, ciclosporine and azathioprine, were studied with 24 hour blood pressure (BP) monitoring. 46 received antihypertensive treatment, all were in NYHA class I, without any sign of allograft rejection or ongoing infections. Plasma NO_2^- + NO_3^- were measured by enzyme immunoassay based on Griess reaction. Blood samples were compared to 20 age- and sex- matched healthy controls.

Results: Mean (± SEM) 24 h systolic and diastolic BP for HTx pts were 130 ± 3 and 84 ± 8 mmHg, respectively. Central heamodynamics were normal (left ventricular ejection fraction 76 ± 12%, mean pulmonary artery pressure 16 ± 0.5 mmHg). Systemic vascular resistance was elevated (1714 ± 88 dynes sec cm^{-5}). Plasma concentration of NO_2^- + NO_3^- were significantly higher in HTx pts compared to the controls (56 ± 7 Vs 32 ± 3 mmol L^{-1}, $p < 0.01$), and correlated significantly with both systolic and diastolic BP ($r = 0.35$, $p < 0.01$ and $r = 0.39$, $p < 0.01$) in these patients.

Conclusion: Stable long-term HTx pts have significantly higher NO_2^- + NO_3^- levels than healthy controls. The elevated level of NO end products correlated with both systolic and diastolic BP in these patients. This finding may reflect a counter-regulatory vasodilatory mechanism to increased vascular resistance in HTx pts.

SYNCOPE AND DIAGNOSTIC TOOLS

P2277 Non-invasive and invasive studies for arrhythmia risk prediction in patients with myocardial infarction, complete bundle-branch block and syncope

B. Brembilla-Perrot, P. Houriez, O. Claudon, J.P. Preiss, H. Blangy, D. Beurrier. *CHU of Brabois, 54500 Vandoeuvre, France*

The prognosis of patients (pts) with bundle branch block (BBB) and myocardial infarction (MI) is poor, mainly in those suffering from syncope. The purpose of this study was to investigate the value of some techniques to evaluate the cause of syncope and the prognosis of these pts.

Methods: we prospectively obtained the results of clinical history, 24 hour Holter monitoring (HM), measurement of LVEF, signal-averaged ECG (SAECG) and programmed ventricular stimulation (PVS) in 124 pts with syncope, MI and BBB. 77 of them had a right (R)BBB and 47 a left (L) BBB.

Results: ventricular tachycardia (VT) was identified as the main cause of syncope: VT was induced in 68.5% of them. According to the results of PVS, pts were divided into 4 groups (gr): 1) gr IA with RBBB and VT (n = 50); 2) gr IB with RBBB but without VT (n = 27); 3) gr IIA with LBBB and VT (n = 35); 4) gr IIB with LBBB but without VT (n = 12). Sensitivity (se) and specificity (sp) of grade IV ventricular arrhythmias on HM for the detection of VT were respectively 42.5 and 47% in RBBB, 62 and 36% in LBBB; se and sp of a LVEF < 40% were 67.5% and 65% in RBBB, 85 and 9% in LBBB; se and sp of the combination of 2 of the 3 SAECG criteria, QRS duration (dur) > 155 ms, LAS dur > 30 ms and RMS 40 < 17 μV were 50 and 57% in RBBB; se and sp of the combination of 2 of the 3 criteria QRS dur > 165 ms, LAS dur > 40 ms and RMS 40 < 17 μV were 73 and 55.5% in LBBB. Cardiac mortality was 22%, 0%, 31% and 17% in grs IA, IB, IIA, IIB. The risk of cardiac mortality was not predicted by HM nor SA ECG, but was predicted by the presence of inducible VT (92% vs 10%**) and a lower LVEF (28 ± 9% vs 38 ± 15%**).

Conclusion: because of the high incidence of inducible sustained VT, the low value of HM, SA ECG, decreased LVEF for the prediction of VT and the poor prognosis of pts with VT and low LVEF, systematic PVS is indicated in pts with MI, syncope and BBB, whatever the noninvasive studies results.

P2278 Forearm blood flow during head-up tilt test and neurocardiogenic syncope: two different patterns of abnormal response

P. Flevari, E.G. Livanis, G.N. Theodorakis, E. Zarvalis, T. Mesiskli, K. Kastanioti, D.Th. Kremastinos. *2nd Dept of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

Controversial findings have been reported regarding the reduction in forearm blood flow (FBF) during the first mins of head-up tilt test in patients (pts) with neurocardiogenic syncope (NCS). The purpose of this study was to evaluate changes in FBF during the first 15 mins of 60° head-up tilt in a) control subjects and b) pts with NCS and positive tilt test response.

Methods: We studied 24 pts with typical history of NCS and subsequent positive tilt test result, 10 male/14 female, mean aged 41 ± 15 years. Pts with subsequently negative tilt test result were not included in the study. Twenty-one apparently healthy subjects, 10 male/11 female, mean aged 37 ± 16 years, were used as controls. FBF measurements, by forearm venous occlusion plethysmography, were conducted at rest (supine position) as well as during the 5th, 10th and 15th min of tilt. FBF was expressed in % limb volume change/sec. ANOVA for repeated measures with Scheffe's test were used for statistical analysis.

Results: Supine resting baseline levels of FBF were similar in NCS patients and control subjects (mean ± 1 SD: 0.035 ± 0.01 vs 0.028 ± 0.01, p: NS). During the 5th, 10th and 15th min of tilt, FBF decreased in controls ($p < 0.0002$, <0.0001 and 0.001 respectively). A mean, stable reduction in FBF values by 40% was observed in controls during the first 15 mins of tilt. In 11/24 pts with NCS, FBF values remained unchanged (<10% change from baseline values) during the 5th, 10th and 15th min of tilt ("*impaired response*"). Conversely, in the remaining 13 NCS pts, FBF values decreased during the 5th and 10th min of tilt ($p < 0.002$ and <0.0001 respectively), but returned to baseline levels during the 15th min ("*unstable response*").

Conclusion: Two different abnormal patterns may be recognized in FBF changes during a consequently positive head-up tilt test. The recognition of different pathophysiologic mechanisms in NCS may have important therapeutic implications.

P2279 Provocation of neurocardiogenic syncope with central serotonergic activation by clomipramine, during head-up tilt test

G.N. Theodorakis, E. Zarvalis, E.G. Livanis, P. Flevari, T. Mesiskli, M. Markianos, D.Th. Krematinos. *2nd Dept of Cardiology, Onassis Cardiac Surgery Center, Athens, Greece*

The aim of the study was to investigate whether the central serotonergic activation (CSA) using intravenously a serotonin re-uptake inhibitor clomipramine (clom), increase the sensitivity and the specificity of head-up tilt test. The central serotonergic system during this test was also evaluated by measuring the plasma levels of prolactin (PRL) and cortisol (CORT).

Methods: Sixty-nine subjects free of any medical treatment were studied. Forty seven patients had a positive history of recurrent neurocardiogenic syncope (NCS) (mean age 43 ± 17 years, 23 male); 22 normal subjects without history of syncope served as controls (mean age 44 ± 16 years, 12 male). All subjects were tested with two consecutive 60° head-up tilt tests with 24 hours interval. The basic tilt test (BTT) included 30 min of passive tilting and if it was negative, isoproterenol was given at the end of the test. The clom test (CTT) was performed with 5 mg clom infusion at the onset of the tilt test. Blood samples for CORT and PRL measures were taken at baseline 5, 10, and 20 min.

Results: Twenty-three subjects out of 47 of the patient group (PG) (49%) had a positive basic test and none of the controls (CG). The CTT was positive in 38 subjects (80%) of the PG and in 1 of the CG. Plasma levels of PRL and CORT increased significantly in the PG compared to CG. CORT increased in the PG from (mean ± SE) 96 ± 9 ng/ml at baseline to 133 ± 11 ng/ml, and 158 ± 11 ng/ml at 10 and 20 min, versus 84 ± 11 ng/ml to 87 ± 12 ng/ml and 107 ± 10 ng/ml respectively in the CG, $p < 0.0006$). PROL increased in the PG, from 6.6 ± 0.4 ng/ml at baseline to 19.3 ± 2 ng/ml and 19.6 ± 2 ng/ml at 10 and 20 min, versus 5.9 ± 0.6 ng/ml to 6.7 ± 0.7 ng/ml and 7.8 ± 0.9 ng/ml respectively in the CG, $p < 0.00001$.

Conclusion: CTT increase the diagnostic yield for evaluation of neurocardiogenic syncope. The CSA during the test is increased in patients with NCS.

P2280 Biochemical changes involved in the mechanism of neurocardiogenic syncope. observations during tilt table testing

K. Gatzoulis, A. Theopistou, E. Economou, S. Sideris, K. Avgeropoulou, J. Gialafos, P. Toutouzas. *Cardiology Division, University of Athens, Hippokration Hospital, Athens, Greece*

Background: Neurocardiogenic syncope (NCS) elicits one of the most powerful transient vasodilatory responses observed in human beings. The underlying biochemical mechanism for such a response has not been adequately explored. We hypothesized that various peripheral vasoactive amines and central hormonal changes may be implicated.

Methods: We studied 40 patients (pts) (age 38 ± 3 years, M/F 20/20) with probable vasovagal syncope (4 ± 1 attacks per pt) with repeat measurements of Thromboxane B_2 (TxB_2), 6 Keto-Prostagladine F1a (6 Keto PGF1a) and vasopressin (VAS) before and during a standardized tilt table testing protocol. Twenty pts (50%) developed NCS due to hypotension with (19) or without (1) bradycardia.

Results:

	Rest	15 min	peak
TxB_2 (pg/ml)	211 ± 12 (219 ± 10)	*309 ± 56 (219 ± 19)	*299 ± 32* (259 ± 29)
PGF1a (pg/ml)	258 ± 11 (290 ± 8)	262 ± 16 (306 ± 56)	287 ± 10 (304 ± 12)
vasopressin (pg/ml)	6.5 ± 1 (7.4 ± 2)	4.2 ± 3 (3.4 ± 1.5)	**105 ± 13 (6.3 ± 1.4)

*$p < 0.08$ (intragroup comparison), **$p < 0.001$ (intergroup comparison).

Within parenthsis are the measurements observed in pts with a negative tilt study. The peak values refer to the measurements obtained during either induction of NCS (positive study) or the completion of a negative study.

Conclusion: During tilting, there is a small increase in TxB^2 without any significant change in PGF1a among syncopal pts with or without a positive vagotonic reaction. On the contrary, a dramatic increase in vasopressin accompanies the vagotonic reaction of a positive tilt table testing subject.

P2281 Clinical characteristics and haemodinamic response in patients with asystole during head-up tilt test

R. García, L. Tercedor, J.F. Díaz, E. Moreno, J. Sánchez-Ramos, G. Moreno, I. Prades, J. Azpitarte. *Dept. of Cardiology, Hospital Universitario Virgen de las Nieves, Granada, Spain*

It is not clear if the type of positive response induced by the head-up tilt-table (TT) test reproduces accurately what happens during spontaneous events. If this is the case, patients (pts) presenting asystole during TT should have a different clinical pattern than those with vasodepressor or mixed responses. This study aims to assess this hypothesis by analyzing prospectively entered data from a large cohort of pts who underwent TT test.

Methods: A computerized database was used to identify 77 pts with a TT positive result. Among those, 16 had asystole > 3 sec (4–42 sec) – group A, and 61 had a vasodepressor or mixed response (group B).

Results: There was not differences between groups concerning the duration of the disease and the number of total or per year episodes of syncope. The clinical characteristics of syncope (sudden presentation, presence of triggering stimulus, incidence of seizures, incontinence or traumatism) were also similar. The number of presyncope episodes was significantly lower in group A (2.5 ± 5 vs 15.5 ± 25 in group B; $p < 0.01$). All the asystolic responses during TT appeared in the basal phase, i.e. withouth isoprenaline induction, and had a higher proportion of young patients (≥16 years) than the other kind of positive responses (38% vs 14%; $p < 0.05$). This fact could explain the higher cardiac rate, both at rest and after tilt, observed in group A (75 ± 14 bpm and 90 ± 21 bpm, respectively) with respect to group B (66 ± 12 bpm and 78 ± 17 bpm, respectively; $p < 0.05$ for both comparisons).

Conclusions: An asystolic response following tilt head-up is more frequently seen in children and can not be predicted by an apparently worse clinical profile. These patients have a higher heart rate, both at rest and after tilt; this fact could explain their higher susceptibility to simple tilt without sympathetic stimulus.

P2282 Effectiveness of fosinopril in patients with neurocardiogenic syncope not responding to β-blockade treatment

S.G. Deftereos, G.A. Lazaros, E.K. Karvouni, E.I. Rentoukas, N.M. Kouvousis, A. Theodorakis, C. Mandila, A. Tsoukas, A.S. Manolis, A.A. Zacharoulis. *Department of Cardiology, Athens General Hospital 'G. Gennimatas', Athens, Greece*

Beta-blockade (BB) is currently considered as a treatment of choice for patients (pts) suffering from neurocardiogenic syncope (NCS). However, a subset of the above pts remain symptomatic despite the BB treatment. The aim of the present study was to investigate the effectiveness of the angiotensin converting enzyme inhibitor (ACE-I) fosinopril in pts non responding to BB, given that ACE I can inhibit catecholamine release from sympathetic nerve endings.

Methods: Our study population consisted of 36 pts suffering from NCS who were found to have positive head up tilt test (TT) response with esmolol infusion (which as is it has been previously shown can accurately predict the outcome of the a head up tilt response to BB). The pts included were randomly assigned either to fosinopril 10 mg/die (9 men and 9 women aged 39 ± 5 years-group A), or to placebo (10 men and 8 women aged 41 ± 4 years-group B). TT was performed at a tilt angle of 80° for a maximum of 30 min. In pts with negative baseline TT response, isoproterenol infusion at incremental doses (up to 5 μg/min) was performed. There were not any differences between the 2 groups regarding the blood pressure, heart rate and demographic data. All pts 30 days later were re-evaluated with TT applying the same test procedure. Statistical analysis was performed with x^2 method corrected by Yates formula. P values < 0.05 were considered as statistically significant.

Results: TT resulted positive (inducing symptomatic hypotension associated or not with bradycardia) in 8 pts of group A (44%) and in in 14 pts of group B (78%)-$x^2 = 5.72$, $p < 0.05$. The drug was well tolerated in all but 2 pts who exhibited dry cough and mild hypotension respectively. Such adverse effects, however, were not severe enough to exclude the above pts from the study.

In conclusion, the ACE I fosinopril could be used as a valid alternative treatment in pts suffering from NCS non responding to BB treatment.

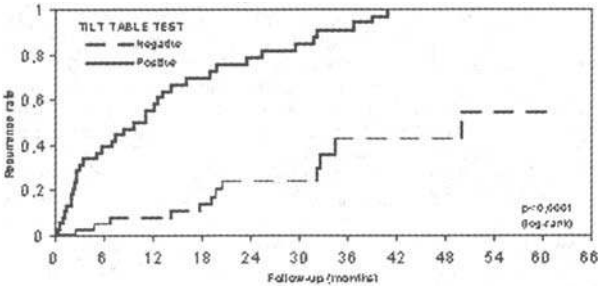
P2283 Role of tilt table test negativation in the evaluation of therapeutic efficacy of neurocardiogenic syncope

D. Hachul, M. Scanavacca, E. Sosa. *Unidade Clinica de Arritmia, Instituto do Coraçao, Sao Paulo, Brazil*

Tilt table test (TT) is a useful method to identify patients (pts) with neurocardiogenic syncope, but its role in the evaluation of therapeutic efficacy is still controversial. The aim of this study was to determine the correlation between TT negativation after therapy administration and recurrence rate and to identify other predictive variables of recurrence during follow-up.

Methods: We studied 82 pts (mean age 27 ± 19 years) with recurrent neurocardiogenic syncope (7 ± 12 episodes – median 4) and positive TT. Once empiric therapy with betablocker or fludrocortisone was initiated, all pts underwent another TT (treatment evaluation test), respecting drugs half-lives. Recurrence rate was analyzed by Kaplan-Meier method and compared by log-rank test, in pts with negative and positive treatment evaluation test. The role of gender, age, number of syncope episodes, duration of symptoms, and drug administered, were also evaluated.

Results: TT negativation after therapy was observed in 43 (52%) pts and was related to significant lower recurrence rate during follow-up ($p < 0.0001$). Significant lower recurrence rate was also observed in pts treated with betablocker and in female ($p = 0.03$ and 0.02, respectively). No other clinical variable was related to significant difference in recurrence rate.



Role of Tilt Table Test Negativation.

Conclusions: TT negativation may be considered an adequate method to determine therapeutic efficacy of neurocardiogenic syncope. Pts treated with betablocker and female presented lower recurrence rate.

P2284 Sertraline treatment for neurocardiogenic syncope

A. Pinar, M. Yesil, O. Yucel, M. Karaca, M.H. Dinckal, S. Bayata, N. Postaci. *Cardiology Dept., Izmir Ataturk Egitim Hastanesi, Izmir, Turkey*

Several methods were suggested in the treatment of neurocardiogenic syncope (NCS). Recent clinical observations have suggested a beneficial effect of sertraline, a serotonin reuptake inhibitor, in prevention of NCS. The present study was undertaken to investigate the effect of sertraline on the primary treatment of NCS.

Methods: Patients (pts) with unexplained syncope were evaluated with head-up tilt table test (HUTT). Twenty-nine subjects (14 female, mean age: 42 ± 27) who had reproducible NCS induced with HUTT were given sertraline 50 mg/day perorally and followed up for 6 months. HUTTs were performed montly, at least one positive test was considered as "HUTT positive". The patient remained in a supine position for 30 minutes and was then tilted to an angle of 80 degrees for maximum 45 minutes.

Results: Follow-up data showed that NCS during daily life disappeared ("symptomatically negative") in 26 (90%) of 29 and HUTT couldn't induce syncope ("HUTT negative") at all in 27 (93%) of 29 pts treated with sertraline (Table 1).

Table 1. Post-treatment distribution of the patients according to their symptoms and HUTT results.

	HUTT negative	HUTT positive
Symptomatically negative	25 pts	1 pt
Symptomatically positive	2 pts	1 pt

Conclusion: This study suggests that sertraline may efficiently prevent NCS, presumably through inhibition of central reflex axis.

P2285 Syncope work-up: diagnostic yield of routine neurologic evaluation in adult patients hospitalized for syncope: time for change?

J. Ganji, R. Steele, R. Jarandilla, A. ALi, R. Epp, L. Pires. *Cardiovascular Research Dept, St John Hospital, Detroit MI, USA*

Despite the pivotal role of history and physical examination in the diagnosis of syncope, syncope work-up continues to be a diagnostic dilemma. Expensive diagnostic testing is a common clinical practice.

Clinical records of all patients hospitalized for syncope at two community hospitals in 1994–1995 were reviewed. Patients were included if they had carotid duplex scanning and/or CT scanning of brain, and/or EEG as a part of syncope work-up. A total of 406 patients were admitted with an initial diagnosis of syncope. 29 (7.1%) patients with TIA or clinical stroke were excluded from the study. 377 patients, mean age 66.6, 43% males, were included in final analysis. Orthostatics were done in 80 (24%) of which 41 (51%) had orthostatic changes explaining syncope. Number of diagnostic tests performed and percent abnormal are shown in the table.

	Carotid Duplex	CT Brain	EEG
Test n (%)	140 (37%)	195 (52%)	163 (43%)
Abnormal n (%)	8 (5.7%)*	8 (4.1%)**	11 (6.7%)**

* 70% stenosis of at least one carotid artery. **Old Infarcts. ***Nonspecific

Out of 498 CT scans, duplex carotid, and EEG studies, only 27 (5.4%) were abnormal. None of these abnormalities explained the final diagnosis of syncope. Average length of stay was 5.09 ± 3.6 days. Despite this extensive work-up no definitive cause was found in 154 (38%) of patients. Evaluation of orthostatic change in blood pressure and heart rate at bedside had the highest diagnostic yield, but was only performed in a small group of patients (24%).

Our data strengthen the argument for good clinical evaluation as the most cost effective and rewarding diagnostic modality for patients presenting with syncope to the emergency centers.

P2286 Long-term follow-up and outcome of patients presenting with recurrent syncope of unknown aetiology and normal heart

K. Gatzoulis, A. Theopistou, S. Sideris, E. Sotiropoulos, K. Avgeropoulou, F. Papafanis, J. Gialafos, P. Toutouzas. *University and State Cardiac Department, Hippokration General Hospital, Athens, Greece*

Background: The purpose of this study was to assess the long term clinical course and prognosis of patients (pts) presenting with recurrent syncope (sync) of unknown etiology (SUE), namely of pts in whom the initial cardiovascular (CV) and neurological (Neuro) evaluation failed to reveal a respective disorder.

Methods: One hundred and twenty one pts (44 ± 18 years, 62 M) with 4 ± 3 SUE attacks per pt were prospectively studied over a mean follow-up period of 24 ± 7 months. All pts were initially assessed at baseline with a complete CV and Neuro examination including electrocardiography, echocardiography and a standard tilt table test protocol (TTT). The latter was at first performed without isoproterenol and only if negative, it was continued with the addition of intravenous isoproterenol. The pts were divided into Gr 1 (n = 49) and Gr 2 (n = 72) with a positive and a negative TTT response respectively. A positive TTT response, namely the reproduction of sync, was further classified into mixed (38), vasodepressor (9) or cardioinhibitory (2). B-blocker therapy was only prescribed to pts with a positive TTT, while all pts were asked to be seen at regular intervals or whenever symptoms recurred. Attention was paid to the development of new revealing cardiac or neurological manifestation during follow-up (FU).

Results. All but one pts remain alive. The Gr 1 pt who died suddenly at 18 months was found to have coronary artery disease after the mitral evaluation. Recurrent sync was observed in 6 of the 49 Gr 1 pts (14.3%) and in 11 of the 72 Gr 2 pts (15.2%). TTT stage at which sync occurred and the type of the associated vagotonic reaction observed, were not predictors of symptom recurrence among Gr 1 pts. Of the 40 Gr 1 pts asked to take long-term B-blocker therapy, only 15 pts were receiving the drug at 6 month FU. During FU, new cardiac or neurological disorder was established in 6 Gr 1 and 10 Gr 2 pts respectively.

Conclusions. Pts presenting with recurrent SUE have a favorable long-term prognosis irregardless of the TTT results. Sync recurrence is expected in a minority of these pts and cannot be predicted by the results of the baseline TTT. Although B-blockers therapy has been recommended to avoid recurrence, drug compliance is low in the setting. A persistent survey to reveal an unsuspected cardiac or neurological cause of sync is advised even if the initial evaluation is negative.

P2287 The outcome of electrophysiologic studies in non-invasively unexplained syncope can be predicted by a predefined score system

Karlheinz Seidl, Axel Drögemüller, Harald Schwacke, Monika Rameken, Gregor Siemon, Jochen Senges. *Herzzentrum Ludwigshafen, Germany*

Electrophysiologic studies (EPS) have been used to uncover the underlying arrhythmic mechanism in patients (pts) with non-invasively unexplained syncope (S). In 643 consecutive patients with S, an EPS was performed. The diagnostic yield of the EPS was 35% (223/643 pts had a positive EPS).

Aim of this study was to establish a score system which predicts best a positive electrophysiologic finding. By the use of a logistic regression model, history of injury during S ($p < 0.001$), ejection fraction $\leq 40\%$ ($p = 0.03$), and PR interval ≥ 200 ms ($p = 0.001$) were independent predictors of an abnormal EPS study. These 3 variables were entered into a score system. The max. score consisted of 3 points (injury = 1 point, EF $\leq 40\%$ = 1 point, PR interval $\geq$ 200 ms = 1 point)

Results:

Score	Sensitivity	Specificity	PPV	NPV
1	54%	75%	54%	75%
2	24%	97%	79%	70%
3	9%	99%	100%	67%

PPV/NPV = positive/negative predictive value

Conclusion 1. A predefined score using clinical and easily measurable variables is helpful in predicting a positive EPS result in pts with non-invasively unexplained syncope. 2. A score of ≥ 2 predicts a positive EPS response in more than 79% of pts with non-invasively unexplained syncope.

P2288 Risk stratification and management of patients with syncope of unknown aetiology: the role of a baseline electrocardiographic evaluation prior to electrophysiology testing

K. Gatzoulis, Th. Apostolopoulos, S. Sideris, X. Costeas, F. Papafanis, A. Theopistou, J. Gialafos, P. Toutouzas. *Cardiology Division, University of Athens, Hippokration Hospital, Athens, Greece*

Background: The electrophysiology testing (EPT) plays an important role in the risk stratification of patients (pts) with syncope of unknown etiology (SUE). However, the EPT value is limited by a non well defined diagnostic accuracy when applied indiscriminately to pts with SUE.

Methods: In this study, we examined the role of the surface 12 lead electrocardiogram (ECG) and of a 24 hour ECG recording (Holter) in the selection process of SUE pts most likely to benefit from EPT. One hundred pts (52 ± 11 years, M: 58) with SUE were divided into 3 groups according to the 12 lead ECG picture and the presence of either wide or narrow QRS complex tachycardia runs (TR) on Holter. Sixty four Gr-A pts had an abnormal ECG (conduction defects, bundle branch block, bradycardia, Q or delta wave), 16 Gr-B pts had a normal ECG with TR on Holter while the other 20 Gr-C pts had a normal ECG without TR on Holter. All pts underwent a comprehensive baseline EPT including intracardiac interval measurements, sinus and atrioventricular node function assessment as well as programmed atrial and ventricular stimulation.

Results: 51/64 (80%) Gr-A pts and 11/16 (68%) Gr-B pts had at least one abnormal EPT finding (p = NS). On the contrary, none of the 20 Gr-C pts had any abnormal finding on EPT. The most common abnormal EPT finding was the induction of sustained monomorphic ventricular tachycardia either on the basis of ischemic or dilated cardiomyopathy among 19 Gr-A pts (30%) or idiopathic among 7 Gr-B pts (43%) (p: NS). Sinus node dysfunction, serious conduction defects and rapidly conducting bypass tracts, were only observed in Gr-A pts.

Conclusions: The presence of either an abnormal ECG or TR on Holter at the non-invasive evaluation of the SUE pt, should be further studied with EPT in order to exclude important arrhythmic causes of syncope. If such an abbreviated noninvasive evaluation is non revealing, the EPT could be postponed.

P2289 Diagnostic yield of insertable loop recorder in patients with recurrent isolated syncope: International Study on Syncope of Uncertain Etiology (ISSUE)

A. Moya, M. Brignole[1], C. Menozzi[2], R. Garcia-Civera[3]. *Cardiology Dept., Hospital Vall d'Hebron, Barcelona, Spain; [1]Cardiology Dept., Ospedale Riutini, Lavagna; [2]Cardiology Dept., Ospedale S Maria Nuova, Reggio Emilia, Italy; [3]Cardiology Dept., Hospital Clínico, Valencia, Spain*

The International (Italy and Spain) Study on Syncope of Uncertain Origin (ISSUE) aims to evaluate the diagnostic yield of a manually activated insertable loop recorder (ILR) (Reveal, Medtronic Inc.) in different groups of patients (pts) with recurrent syncopes of uncertain etiology. Isolated syncope is defined as a syncope in pts with normal ECG and no other comorbidity in whom the mechanism remains unexplained after complete conventional investigations.

Since November 1997, ILR was implanted in 45 pts (23 females, 22 males, mean age 63 ± 17 years) with isolated syncope. The number of syncopes in the last 2 years was 8 ± 15 (median = 4) and the duration of symptoms was 5 ± 6 years (median = 3).

Conventional investigations which included Holter and telemetry in 98% pts, echocardiogram in 78% pts, tilt table testing in 100% pts, electrophysiological study in 78%, pts and carotid sinus massage in 100% pts, were all negative.

Results: After a mean follow-up period of 6.9 ± 4.1 months: 11 (24%) pts had at least one syncopal event, 3 (7%) pts had pre-syncope and 1 pt had angina.

Out of the 11 pts with syncope, a sinus arrest with an asystole was documented in 6 pts, normal sinus rhythm was recorded in 2 pts, and 3 pts were not able to activate the device. Out of the 3 pts with presyncope, a supraventricular tachycardia was recorded in 2 pts, and normal sinus rhythm in 1 pts. In the patient who had angina, ST-T changes were documented that were followed by an episode of ventricular fibrillation.

Conclusions: Syncopal recurrence in pts with isolated syncope during medium-term period follow-up is low. The most frequent finding in those pts was sinus arrest with asystole. Larger follow-up period is necessary.

P2290 In patients with unexplained syncope, implantable loop recorders give a greater diagnostic yeild than electrophysiological testing

A.L. Calver, V. Bulbeck, S. Allen, J.M. Morgan. *Wessex Cardiothoracic Centre, Southampton University Hospital, Southampton, UK, SO16 6YD*

Patients with unexplained syncope can be difficult to evaluate. Between December 1997 and November 1998 29 patients were fitted with implantable subcutaneous loop recorders (ILRs) {Reveal™, Medtronic, Minneapolis, Mn}. The patients were aged 15–77 years (mean age 46 yrs), 20 were female. The time from first syncope to implant was 2–27 years, median 3 yrs. All patients presented with witnessed recurrent syncope (2–18 events, median 5 events). Before implantation all patients were investigated for arrhythmias with ambulatory ECG monitoring or a patient-activated ECG recorder, electrophysiology study, and tilt-table testing/carotid sinus massage. No abnormality was identified in any of the patients. Other cardiac investigations were echocardiography (29), cardiac catheterisation (6), cardiac MRI (2). 17 patients had no structural heart disease identified and 1 patient was known to have corrected Tetralogy of Fallot; 5 patients had trivial aortic valve disease or coronary disease and 3 patients had impaired LV function (EF 39%, 44% and 50% on LV angiography). Neurological investigations were negative (CT scan 3, EEG 6).

Results: All post implant syncopal episodes were documented by ILRs. To date 15 patients (52%) have activated their ILR during a syncopal episode to determine cardiac rhythm and rate during the episode. Activation of the ILR has occurred between 0.25 and 4 (median 1) months after implant (ILR life is approximately 16 months). The ILR recording has facilitated appropriate patient management in all these patients. Syncope has been correlated with cardiac arrhythmia in 8 patients (28%).

Conclusion: In this patient group, the diagnostic yield of an ILR is greater than that of electrophysiological study. In addition, documentation of normal sinus rhythm during syncope also aids patient management. ILRs should be used in place of electrophysiological study in the investigation of syncope of unknown cause in patients with no or trivial structural heart disease.

VENTRICULAR ARRHYTHMIAS AND SUDDEN DEATH

P2291 Predicting effect of d,l-sotalol on ventricular tachycardia inducibility from the response of RR variability to drug

B. Brembilla-Perrot, P. Houriez, O. Claudon, D. Beurrier, J.P. Preiss. *CHU de Brabois, Vandoeuvre, France*

D, l-sotalol is an effective antiarrhythmic drug in the prevention of ventricular tachycardia (VT), but less effective than defibrillator for the prevention of sudden death. The purpose of the study was to report a rapid means for the identification of non-responders to d, l-sotalol in patients (pts) with spotaneous and inducible VT.

Methods: programmed ventricular stimulation and RR variability were studied in the control state (CS) and 10 days after treatment with 160 to 320 mg of d, l-sotalol in 36 pts, with VT.

Results: in 14 patients (group I) d, l-sotalol suppressed the VT inducibility. In 22 pts (group II) sustained VT remained inducible during d, l-sotalol treatment. The VT rate was slowed in 8 pts and unchanged or accelerated in 14 pts. At baseline, HRV was similar in both groups. During treatment with d, l-sotalol, the parameters reflecting the parasympathetic activity pNN50, rMSSD and HF increased in both groups: HF increased from 75 ± 68 to 146 ± 134 in group I ($p < 0.05$) and from 60 ± 49 to 125 ± 79 in group II ($p < 0.05$). Other parameters were unchanged in group I. In group II, the parameters associated with sympathetic activity (CV, LF/HF) decreased significantly: CV decreased from 13 ± 4 to 9 ± 2 ($p < 0.001$) and LF/HF from 4.7 ± 3 to 3 ± 2.02 ($p < 0.05$).

Conclusion: the betablocking effect of d, l-sotalol produced a significant improvement over control values in indices of parasympathetic tone in all the treated patients. But, only in non-responders to sotalol, the drug decreased the HRV parameters associated with sympathetic activity. Therefore, the effects of d, l-sotalol on heart rate variability could help to detect the non-responders to the drug and to avoid an electrophysiologic study.

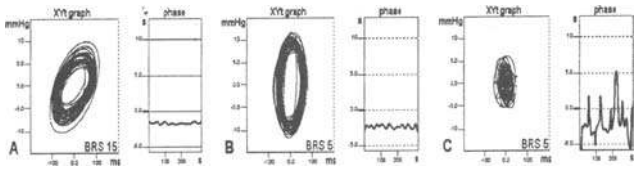
P2292 Time delay stability of baroreflex feedback system and autonomic nervous system dysfunction

T. Kára, P. Jurák[1], M. Souček, M. Novák, Z. Nováková[2], J. Halámek[1], J. Šumbera, J. Toman, M. Štejfa, I. Řiháček. *Department of Cardiology, Faculty Hospital "Sv. Anna"; [1]Institute of Scientific Instruments, Academy of Science; [2]Institute of Physiology, Medical Faculty of Masaryk University; Brno, Czech Republic*

Dysfunction of the baroreflex feedback system (BFS) play important role in pathophysiology of sudden cardiac death (SCD). The aim of the study was the development of new methods enabling the analysis of BFS function in time. The BFS stability is analyzed especially in the graphic form: a) XYt graph (X axis for R-R intervals variability [ms], Y axis for SBP variability [in mm Hg] and t axis for time [s]); b) immediate phase between systolic blood pressure (SBP) and heart rate (HR).

Methods: 25 healthy volunteers, 15 patients with essential hypertension (EH), 23 patients with defibrillator (ICD) for documented ventricular tachycardia/fibrilation. Methodology: continual recording of blood pressure (Finapres), ECG, frequency and depth of breathing (original system ANNA1) for 5 minutes at rest and during the managed breathing frequency 6 × min.$^{-1}$ (deep breathing) and 20 × min.$^{-1}$ (shallow breathing).

Results: The best results were achieved at deep breathing (6 × mill.$^{-1}$). Typical findings of individual groups are shown in the Figures



A) Healthy individuals: a very stable value of the phase shift (approx. −1.7 s) and a symmetrical XYt graph represent very good characteristics of the BFS; B) patients with EH: higher phase shift (approx. −2.5 s), but still good BFS characteristics, which may have a connection with the so called re-setting of BFS.; C) patients with ICD, as far as their BRS can ever be evaluated (it was not possible in 13 patients: 6 exhibited an extremely low heart rate variability and 7 suffered numerous dysrythmias): total chaos in BFS (system unstable). The findings shown in Figure C did not occur in groups A and B. Patients in B and C exhibit the same baroreflex sensitivity (BRS) value of 5 ms × mm. Hg.$^{-1}$ However, although the BRS values of groups B and C are similar, their characteristics and prognosis vary widely.

Conclusion: The detection of the phase shift and XYt graph create a new technique of individual evaluation of autonomic nervous system dysfunction, especially in patients exhibiting the same values of decreased BRS.

P2293 Age and sudden cardiovascular death following myocardial infarction

S.Z. Abildstrom, C. Rask-Madsen, M. Ottesen, C. Torp-Pedersen, L. Kober. *Dept. of Cardiology, Gentofte University Hospital, Copenhagen, Denmark*

Sudden cardiac death (SCD) accounts for approximately 50% of all cardiovascular deaths after acute myocardial infarction (AMI). The aim of the present study was to assess the incidence and relative incidence of SCD following AMI in different groups of age.

Methods: We analyzed data from 6676 consecutive patients with AMI screened for the Trandolapril Cardiac Evaluation (TRACE) study. The screening period was 2 years and the follow-up 2–4 years. A central mortality committee classified the deaths of the randomized patients with respect to mode and cause of death. Deaths of non-randomized patients were classified applying similar criteria to information from the death certificate and the patient file. SCD was defined as cardiovascular death within one hour of onset of symptoms.

Results: Of the 5983 patients alive at discharge 1659 died during follow-up. Of these deaths 535 were classified as SCD and 726 as non-sudden cardiovascular. The patients were divided into 4 age groups (<56 y, 56–65 y, 66–75 y, >75 y). Cardiovascular death comprised 75–77% of all deaths in the four age groups. The 3-year mortality due to SCD was found to increase significantly with increasing age group; 4%, 7%, 11% and 16% respectively. However the incidence of SCD relative to death of all cause and to cardio- vascular death decreased significantly with increasing age group (44%, 40%, 33% and 27%) and (58%, 52%, 43% and 35%) respectively. No upper age-limit could be detected for SCD.

Conclusion: Increasing age is associated with increased risk of SCD following AMI, but decreased risk of SCD relative to all-cause and cardiovascular mortality, even if cardiovascular death comprises the same proportion of deaths in all age groups. Studies aiming at reducing SCD following AMI should consider this distribution of SCD in different groups of age in order to achieve the best relation between sensitivity and specificity.

P2294 Pause-dependent torsades de pointes in acquired long QT interval: long-term clinical outcome

A. Da Costa, T. Chalvidan[1], A. Belounas, M. Viallet, J.C. Deharo[1], H. Mansour[2], D. Lamaison[2], A. Cerisier, P. Djiane[1], K. Isaaz. *[1]University of Saint-Etienne, Marseille; [2]Clermont-Ferrand, France*

Long term prognostic of pause-dependent torsades de pointes (PD TDP) due to acquired long QT syndrome, a disorder that may lead to sudden death (SD), have not been fully investigated.

Methods. 93 pts (age 74.7 ± 9.5, 73 females) were included based on the association of 4 criteria: (1) ECG documented PD TDP; (2) prolonged QT interval and corrected QT using Bazett's formula (QTc); (3) long-short initiation sequence; (4) baseline bradycardia or drug or metabolite disturbance known to induce PDTP. After correction of all precipitating factors, absolute dispersions of QT and QTc were measured, as QTmax-QTmin, and QTc max-QTc min, respectively, before discharge. Long term clinical outcome was evaluated based on the occurrence of the following adverse events (AE): syncope (S), TDP recurrence (TDPR) and (SD). Pts were categorized according to presence or absence of AE (AE+, AE−).

Results. No difference was found between AE+ and AE− regarding age (72 ± 12 vs 75 ± 8), gender (78% vs 79% female), kaliemia (3.6 ± 0.9 vs 3.6 ± 0.6), heart rate (52 ± 12 vs 56 ± 15). During a mean follow-up of 27 ± 26 months (range 1–123 months) 49 events occurred in 27 pts: 18 S, 15 TDPR and 16 SD. Univariate analysis and multivariate analysis were performed on 6 variables using Cox model with two combined end points defined as following:

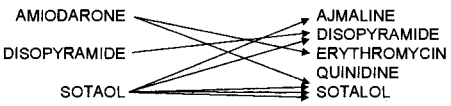
n = 93	AE		SD and/or TDPR	
	Uni.	Multi	Uni.	Multi
History of MI	0.11	–	0.18	–
Echo LVEF (%)	0.10	–	0.065	–
Mean QT (ms)	0.016	0.128	0.014	0.09
Mean QTc (ms)	0.26	–	0.12	–
QT max–QT min (ms)	0.018	0.12	0.037	0.1
QTc max–QTc min (ms)	0.0075	0.04	0.017	0.04

Conclusions: High rates of arrhythmic events are found in a population of PD TDP due to acquired long QT syndrome despite correction of initial precipating factors. QTc dispersion appears to be the only independent predictor of arrhythmic events at a long term follow-up.

P2295 Drug-induced torsade de pointes: the problem of cross-sensitivity

J. Mergenthaler, G. Mönnig, L. Eckardt, H. Wedekind, E. Schulze-Bahr, P. Kirchhof, M. Borggrefe, G. Breithardt, W. Haverkamp. *Univ.-Hospital Münster, Department of Cardiology and Institute for Arteriosclerosis Research at the University of Münster, Germany*

Torsade de pointes (TDP) is a form of potentially life-threatening ventricular tachyarrhythmia. It may occur in setting of a congenital long QT syndrome, however, most often it develops secondary to treatment with drugs prolonging repolarization, i.e. drugs which lengthen the cardiac action potential. Between 1989 and 1997, we have collected data from 91 patients (pts.) who developed drug-induced TDP. We could identify eight pts (9%) (8 females, mean age 58 ± 10 yrs.), who developed at least 2 episodes of TDP while being treated with different drugs. Time interval between the TDP episodes ranged from 7 days to 5 years. The QTc was measured 420 ± 59 ms$^{1/2}$ prior to drug treatment and increased to 540 ± 70 ms$^{1/2}$ at the time of TDP. There was no evidence for a congenital long QT syndrome in any of the pts. The type of cross-sensitivity (drugs on which pts. developed their TDP) is shown on the graph:



Conclusions: Thus, a potential cross-reactivity of proarrhythmic potential should be considered if another repolarization prolonging drug is to be administered to a patient who has already experienced drug-induced TDP. Therefor repolarization prolonging drugs should be completely avoided in these pts.

P2296 The central role of QT dispersion and left ventricular function as predictive factors of ventricular fibrillation in pause-dependent torsades de pointes associated with acquired long QT interval

A. Da Costa, T. Chalvidan[1], A. Belounas, J.C. Deharo[1], M. Viallet, H. Mansour[2], D. Lamaison[2], A. Cerisier, P. Djiane[1], K. Isaaz. *[1]University of Saint-Etienne, Marseille; [2]Clermont-Ferrand, France*

Predictive factors of ventricular fibrillation (VF) in pause-dependent torsades de pointes (PDTP) due to acquired long QT syndrome remain unknown.

Methods. 91 pts were included based on the association of 4 criteria: (1) ECG documented PTDP; (2) prolonged QT interval and corrected QT using Bazett's formula (QTc); (3) long-short initiation sequence; (4) baseline bradycardia or drug or metabolite disturbance known to induce PDTP. Pts were divided into 2 groups: PDTP with documented VF responsible of cardiac arrest treated by cardioversion (**GI**) and PDTP without cardiac arrest (**GII**) before admission or during the hospital staying with continuous monitoring. Absolute and relative dispersions of QT and QTc were measured as QTmax-QTmin, standard deviation (SD) of QT/QTmean, QTc max-QTc min, SD of QTc/QTc mean, respectively in the 12 lead standard ECG at admission.

Results. No difference was found between **GI** and **GII** regarding age (74.8 ± 8 vs 73.7 ± 9), gender (71.1 vs 77.3 female), kaliemia (3.6 ± 8 vs 3.5 ± 7), baseline heart rate (56.6 ± 15 vs 54.7 ± 15).

Univariate analysis	GI (n = 38)	GII (n = 53)	p
History of MI	12/38 (32%)	7/53 (13.2%)	p = 0.035
Echo LVEF (%)	43.9 ± 14	65 ± 9	p < 0.0001*
QT mean (ms)	591 ± 73	514 ± 78	p < 0.0001
QTc mean (ms)	563 ± 76	508 ± 9	p = 0.002
QT max-QT min (ms)	166 ± 56	84 ± 49	p < 0.0001
SD QT/QT mean (%)	9.9 ± 3.5	6.3 ± 3.2	p < 0.0001
QTc max-QTc min (ms)	158. ± 57	81 ± 44	p < 0.0001
SD QTc/QTc mean (%)	9.9 ± 3.6	6.2 ± 3.0	p < 0.0001*

*Stepwise regression analysis showed that LVEF and relative dispersion of QTc were the only independent factors predictive of VF.

Conclusions In pts with acquired conditions susceptible of inducing torsades de pointe, LV function and QTc relative dispersion should be carefully measured due to their peculiar value as risk factors of VF.

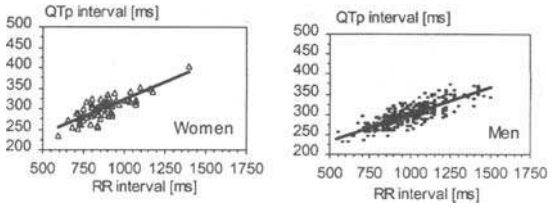
P2297 Gender-defined pattern of ventricular repolarisation: a possible explanation of predisposing to drug-induced torsades de pointes in women?

I. Savelieva, K. Hnatkova, A. John Camm, M. Malik. *St George's Hospital Medical School, London, UK*

Gender-specific difference in ventricular repolarization duration and relation to cardiac cycle length may explain a higher frequency of drug-induced torsades de pointes in women. The characteristics of QT interval components have been suggested to be as important as the QT interval itself.

Methods: QT_{peak} (QT_p) and T_{peak}-T_{end} (T_pT_e) intervals and T_pT_e/QT_p ratio were evaluated in 1100 healthy volunteers (910 men, age 32 ± 11; 190 women, age 35 ± 15) by QT Guard software (Marquette Medical Systems). To assess gender-dependent relation between QT interval components and cardiac cycle length, the slopes of linear regressions of QT_p and T_pT_e intervals plotted against the corresponding RR interveal were compared.

Results: A significant gender-specific difference was observed in the duration of the early and late phases of repolarization. The QT_p interval was significantly longer in women than in men (300 ± 27 vs 291 ± 27 ms, p < 0.0003), whereas men had a significantly prolonged T_pT_e interval (93 ± 6 vs 89 ± 6 ms, p < 0.0001). Respectively, the T_pT_e/QT_p ratio was lower in women than in men (0.30 ± 0.03 vs 0.32 ± 0.03, p < 0.0001). In all subjects, QT_p/RR slopes were significantly steeper in women compared to men (0.1504 vs 0.1292; 0.1430 vs 0.1281; p < 0.05). Women had more labile relation between ventricular repolarisation and cycle length, i.e. increase in steepness of QT_p/RR and decrease in T_pT_e/RR with age, while the same relation in men remained stable.



Conclusion: A significant difference in QT interval components indicates gender-specific shapes of the ascending and descending T wave. Prolonged early phase of repolarization and a progressive increase in the QT_p interval at slower heart rate may facilitate drug-induced arrhythmias in women.

P2298 Verapamil suppresses early afterdepolarizations and torsade de pointes in an isolated rabbit heart model of LQT1 and LQT3

L. Eckardt, R. Johna, P. Kirchhof, L. Naim, G. Mönnig, G. Breithardt, M. Borggrefe, W. Haverkamp. *Dept. of Cardiology and Inst. of Arteriosclerosis Research, University of Münster, Germany*

Background: Torsade de pointes (TDP) is a potentially life-threatening arrhythmia typically seen in acquired QT-prolongation and the long QT-syndrome (LQTS). Early afterdepolarisations (EAD) and triggered activity are discussed as the underlying mechanism of TDP. As there is evidence that calcium channel blockers can suppress EAD we studied the effects of verapamil on a recently developed model for LQT1 (KCNQ1) and a new model for LQT3 (SCN5A).

Methods: In this model, the potassium channel blocker sotalol (S, 10 μM), and erythromycin (E, 150 μM) simulate LQT1, whereas veratradine (V, 0.5 μM) by inhibition of sodium channel inactivation mimics LQT3. The induction of TDP was studied in the presence of bradycardia and hypokalemia [n = 18].

Results: S, E, and V lead to a significant increase in QT-interval. During sinus rhythm no arryhthmias occurred irrespective of drug dose and potassium concentration. During bradycardia (AV block) and hypokalemia (1.5 μM) TDP and EAD reproducibly occurred. Monophasic action potentials demonstrated EAD in endocardial and only rarely in epicardial recordings. Although verapamil had no effect on QT-prolongation none of the S and E treated hearts demonstrated TPD in the presence of verapamil. EAD were also nearly completely suppressed. In V treated hearts verapamil also diminished the occurrence of TDP (only 2 out of 6 hearts showed TDP and EAD after administration of V).

Conclusion: Verapamil suppresses TDP and EAD in an experimental model for LQT3 and LQT1 without changing QT intervals. Thus, verapamil preserves the antiarrhythmic effect of action potential prolongation of class III agents so that it might be a valuable additional therapeutic option in patients with abnormal QT-prolongation at risk for TDP.

P2299 Does sports activity enhance the risk of sudden death in young people?

D. Corrado, C. Basso[1], G. Thiene[1]. *Depts. Cardiology; [1]Pathology, University of Padua, Italy*

Methods: We prospectively studied the incidence and the cause of sudden death (SD) in both competitive athletes and nonathletes (≤35 years) in the Veneto Region of Italy from January 1979 to June 1998 according to a specific clinico-pathologic protocol of investigation. During the study period the young population of the Veneto Region averaged 2,009,600 persons with a rate of participation in competitive athletics of 9.6%.

Results: There were 300 sudden deaths (0.85 per 100,000 persons per year): 55 among competitive athletes (1.6 per 100.000 per years) and 245 among nonathletes (0.77 per 100,000 per year). The estimated relative risk of SD among athletes as compared with nonathletes was 2.1 (95% confidence interval, 1.5 to 2.8; p < 0.0001). The Table shows the main causes of SD in young athletes vs nonathletes:

Cause	Total (N = 300)	Athletes (N = 55)	Nonathletes (N = 245)
Obstructive coronary artery disease	54 (18%)	10 (18%)	44 (18%)
Right ventricular cardiomyopathy	35 (12%)	13 (24%)*	22 (9.0%)
Myocarditis	32 (11%)	5 (9.0%)	27 (11%)
Mitral valve prolapse	27 (9.0%)	6 (11%)	21 (8.6%)
Disease of conduction system	24 (8.0%)	4 (7.2%)	20 (8.2%)
Hypertrophic cardiomyopathy	18 (6.0%)	1 (1.8%)	17 (6.9%)
Anomalous coronary artery origin	7 (2.3%)	6 (11%)**	1 (0.4%)
Other	103 (34%)	10 (18%)	93 (38%)

*$p = 0.005$; **$p < 0.001$ for the comparison with nonathletes*

Conclusions: The incidence of SD was increased 2.1 times in young competitive athletes as compared with nonathletes. Arrhythmogenic right ventricular cardiomyopathy and anomalous coronary artery origin were the only cardiovascular conditions significantly associated with SD during sports.

P2300 Idiopathic ventricular arrythmias or concealed cardiomyopathy?

B. Turkia[1], L. Bokeria[2], T. Artiuchina[2], B. Bogonatov[2]. [1]Institute of Cardiology, Tbilisi, Georgia; [2]V.I. Burakovski Institute of Cardiovascular Surgery, Moscow, Russian Federation

We compared clinical and electrophysiological features of idiopathic ventricular arrythmias (IVA) with myocardial histology in IVA of different QRS morphologies to define whether these arrhythmias represent the expression of specific myocardial diseases.

Methods: study involves 24 pts with monomorphic idiopathic ventricular tachycardia (VT) and ventricular extrasystoles (VE), in which echocardiography and heart catheterization failed to detect structural abnormalities of the heart. All patients underwent direct surgery during cardiopulmonary bypass for refractory IVA. Catheter electrophysiologic study with mapping and intraoperative epi- and endocardial mappings and intraoperative myocardial biopsy were performed in all cases. Biopsy specimens were obtained by direct excision of subendocardial and intramural layers of myocardium in arrhythmogenic sites and in distant areas of ventricles.

Results: 16 pts had VT or VE of left bundle branch block morphology (LBBB) and right axis deviation (RAD) and 8 pts had paroxysmal VT of right bundle branch block (RBBB) and left axis deviation (LAD). VTs with RBBB and LAD were inducible with programmed stimulation and sensitive to verapamil, His-deflection on VT was identifiable in 6 patients during 15–20 ms in QRS complex and arrhythmogenic sites were localised in the left ventricle in posteroapical part of interventricular septum (IVS). In patients with LBBB morphology and RAD different responses to electrical stimulation were observed and arrythmogenic sites were localised on IVS in right ventricular outflow. Biopsies of patients with LBBB and RAD showed histological features compatible with arrhythmogenic right ventricular displasia (ARVD) – interstitial adipose infiltration with fibrosis and myocyte hypertrophy, which were confined to the outflow part of IVS. In patients with VT of RBBB and LAD changes consistent with dilated cardiomyopathy were involving both ventricles.

In conclusion, we suggest that concealed arrythmogenic cardiomyopathy is an aetiologic basis for refractory IVA. Concealed localized myopathic process of ARVD is the most common cause for IVA with LBBB and RAD and latent diffuse myopathic process (possibly initial stage of dilated cardiomyopathy) – for IVA with RBBB and LAD.

P2301 A 10 year follow-up study of elite athletes with frequent and complex ventricular arrhythmias

A. Biffi, L. Verdile, F. Fernando, A. Spataro, A. Pelliccia, P. Piovano, G. Caselli. Sports Medicine Dept, Sport Science Institute, Rome, Italy

Few long term follow-up studies are conducted in subjects with frequent and complex ventricular arrhythmias with apparently "normal" hearts, these studies usually show a benign prognosis. Up to date no studies of this kind have been conducted in athletes. Nevertheless in some cases sudden death can be the only dramatic sign of an underlying silent cardiomyopathy and frequently occurs during exercise. Therefore, early identification of myocardial diseases in athletes with ventricular arrhythmias is the main goal of a pre-participation cardiovascular screening.

Methods: From 1988 to 1998 we studied a group of 250 athletes referred to our Institute for ventricular arrhythmias. From this group we selected a subgroup of 82 elite athletes with frequent and complex ventricular arrhythmias (Group A – mean age 25.2 yr.) The inclusion criterium was a 24-hour Holter monitoring showing the presence of >2000 ventricular ectopic beats and >15 ventricular couplets. These athletes were compared to a control group of 70 athletes (mean age 23.8 yr.), with < 10 VEB's in the 24 Hours (Group B). All athletes underwent a cardiovascular screening including physical examination, routine blood test, chest X-rays, resting and stress-test ecg, color-Doppler echocardiogram, 24-hour Holter monitoring and time-domain signal-averaged ECG. Furthermore, 28 athletes (Group A) underwent a cardiac magnetic resonance imaging, 21 a cardionuclear scintigraphy, 9 transesophageal echocardiography, 5 a myocardial biopsy and 19 an endocavitary electrophysiologic study.

Results: Twenty-eight athletes of Group A had an underlying heart disease (34.1%) versus 1/70 (1.4%) of the control athletes (Group B – $p < 0.0001$). In particular, 4 had right ventricular arrhythmogenic dysplasia, 5 myocarditis, 9 abnormal dilatation of the left ventricle, 8 mitral valve prolapse, 1 atrial septum defect and 1 bicuspid aortic valve. Our ten years follow-up period shows until now a favourable outcome and no cases of sudden death.

Conclusion: This study shows the usefulness of an extensive cardiovascular pre-participation screening in identifying subclinical heart diseases in athletes with frequent and complex ventricular arrhythmias and the necessity of a prolonged follow-up period to monitor the arrhythmia and eventual evolution of the underlying cardiopathy. However up to date these arrhythmic athletes have a similar prognosis to those without ventricular arrhythmias

P2302 Clinical profile of congenital coronary artery anomalies with origin from the wrong aortic sinus leading to sudden death in young competitive athletes

C. Basso, B.J. Maron[1], D. Corrado[2], G. Thiene. Dept. Pathology; [2]Cardiology, University of Padua, Italy; [1]Minneapolis Heart Institute Foundation, Minneapolis MN, USA

Congenital coronary artery anomalies with origin from the wrong aortic sinus are not uncommonly associated with sudden death (SD) in young athletes, with these catastrophic events probably provoked by myocardial ischemia. Such coronary anomalies are rarely identified during life, often because of insufficient clinical suspicion. However, they are amenable to surgical treatment, emphasizing the importance of timely clinical identification.

Because there is a paucity of data available characterizing the clinical profile of these coronary malformations, we reviewed 2 large registries of SDs in young competitive athletes, recorded consecutively in the US and Italy. We assembled 27 SDs in young athletes, identified solely at autopsy as due to either left main coronary artery from the right aortic sinus (n = 23) or right coronary artery from the left sinus (n = 4). All athletes died during (n = 25) or immediately after (n = 2) intense exertion on the athletic field. Of the 27 athletes, 15 (55%) had no clinical manifestations or testing during life. In the remaining 12 (45%) certain clinical data were available. Ages were 11–32 years (mean 16 ± 7). Premonitory symptoms had occurred in 10, including syncope in 4 (exertional in 3, recurrent in 2; occurring 3–24 months prior to SD) and chest pain in 5 (exertional in 3, all single episodes; occurring ≤ 24 months prior to SD). All cardiovascular testing was within normal limits, including basal 12-lead ECG (in 9/9), stress ECG with maximal exercise (in 6/6) and left ventricular wall motion and cardiac dimensions by echocardiography (in 2/2).

In conclusion: 1) standard testing with ECG under resting or exercise conditions is unlikely to provide clinical evidence of myocardial ischemia and would not be reliable screening tests in large athletic populations; 2) premonitory cardiac symptoms not uncommonly occurred shortly before SD, suggesting that a history of exertional syncope or chest pain requires exclusion of this anomaly; 3) a high index of clinical suspicion is crucial for the in vivo identification of these anomalies in physically active individuals.

P2303 Does the acceleration of ventricular fibrillation imply an increase in the complexity of arrhythmia?

F.J. Chorro, L. Mainar, J. Cánoves, J. Sanchis, E. Llavador, L.M. Such, V. López-Merino, L. Such[1]. Service of Cardiology, University Clinic Hospital, Valencia; [1]Departament of Physiology, Valencia University, Valencia, Spain

With the purpose of determining whether the acceleration of ventricle fibrillation (VF) implies an increase in the complexity of the arrhythmia, 12 Langendorff-perfused rabbit hearts were used to analyze the epicardial activation maps obtained during VF using a multiple electrode (121 unipolar electrodes, interelectrode distance = 1 mm) under control conditions, following myocardial stretching (intraventricular balloon), after administering verapamil (Vp, 0.2–0.8 μmol), and upon adding myocardial stretch to Vp perfusion.

Thirty seconds after VF induction by overdriving, and maintaining myocardial perfusion, activation maps were obtained at 100-ms intervals over a 2-s period, classifying the results from lesser to greater complexity (I = one wavelet without block lines, II = two simultaneous wavelets with block lines, III = three or more wavelets with multiple block lines).

Both stretching and Vp accelerate the fibrillatory process (median VV interval: control = 68 ± 6 ms, stretch = 49 ± 14 ms, $p < 0.001$; Vp = 51 ± 5 ms, $p < 0.001$ vs control). Stretch-induced acceleration causes a significant variation in the types of maps, with type III increments and type I and II decrements (control: I = 19%, II = 49%, III = 32%; stretch: I = 8%, II = 33%. III = 59%, $p < 0.001$), whereas Vp-induced acceleration is accompanied by type III decrements and type I and II increments (Vp: I = 24%, II = 58%, III = 18%, $p < 0.001$). On applying stretch during Vp perfusion, the fibrillatory process is not accelerated to a greater degree than with Vp alone (stretch + Vp: median of the VV intervals = 47 ± 6 ms); however, type I and II decrements and type III increments are recorded, but with percentages similar to control.

Conclusions: VF acceleration does not always imply an increase in the complexity of arrhythmia. Myocardial stretching and Vp accelerate the fibrillatory process; however, while stretching increases the complexity of arrhythmia, Vp reduces it. The effects upon arrhythmia complexity are in turn countered when stretching is applied under the action of Vp.

P2304 The cardioselective ATP-sensitive potassium channel antagonist HMR 1883 attentuates T wave changes and prevents ventricular fibrillation induced by myocardial ischaemia

G.E. Billman, H.C. Englert[1], B.A. Schoelkens[1]. *Dept. of Physiology, The Ohio State University, Columbus OH, USA; [1]Hoechst Marion Roussel Institute, Frankfurt, Germany*

The activation of ATP-sensitive potassium channels during myocardial ischemia leads to potassium efflux, reductions in action potential duration, dispersion of repolarization and ventricular fibrillation. Drugs that inactivate these channels should attenuate these ischemic changes and thereby prevent ventriclar fibrillation. However, non-selective ATP-sensitve potassium channel antagonists have been reported to reduce coronary blood flow and to depress cardiac function. Furthermore, these agents can also alter pancreatic channels promoting insulin release and hypoglycemia. A cardioselective ATP-sensitive potassium channel antagonist, HMR 1883, 1-[[5-[2-(5-chloro-o-ansamido)ethyl]-2-methoxyphenyl]sulfonyl]-3-methylthiourea, may offer cardioprotection without the untoward actions of existing drugs. To test this hypothesis, ventricular fibrillation was induced in 13 dogs with healed myocardial infarctions by a 2 minute coronary occlusion during the last minute of exercise. On subsequent days, the exercise plus ischemia test was repeated after either HMR 1883 (3.0 mg/kg i.v.) or glibenclamide (1.0 mg/kg i.v., n = 7). Ischemia elicited several significant (ANOVA $p < 0.01$) changes including: reductions in refractory period (control 121 ± 2, occlusion 115 ± 2 ms), ST-segment depression (−3.3 ± 0.7 mm), dispersion of repolarization as measured by the descending portion of the T wave (Tpeak-Tend, control 34 ± 3, occlusion 40 ± 6 ms) and T wave oscillations (n = 9). HMR 1883 pretreatment prevented the reduction in refractory period (HMR 122 ± 2, occlusion 121 ± 3 ms), the increase in repolarization (Tpeak-Tend, HMR 35 ± 2, occlusion 29 ± 3 ms), attentuated the ST-depression (−1.8 ± 0.4 mm) and suppressed T wave oscillations (n = 6). This drug also prevented VF in 11 of 13 animals ($p < 0.001$). Interestingly, HMR 1883 did not alter the ischemic T wave changes in the 2 animals that were not protected. In a similar manner, glibenclamide also reduced these ischemic changes and protected 6 of 7 animals ($p < 0.01$). However, in contrast to HMR 1883, this drug also reduced blood glucose, coronary blood flow and left ventricular dp/dt maximum. These data suggest that the cardioselective ATP-sensitive potassium channel antagonist HMR 1883 can reduce ischemic changes in refractory period and repolarization, thereby protecting against ventricular fibrillation without major hemodynamic actions or altering blood glucose.

P2305 Nuclear morphometry of the myocardial cells as a diagnostic tool in cases of sudden death due to acute myocardial infarction

G.A. Lazaros[1], V.A. Papapanagiotou[2], I.G. Panayiotides[1], K.S. Stefanaki[1], M.N. Tzardi[1], I.G. Vlachonikolis[3], A.A. Zacharoulis[2], G.S. Delides[1]. *[1]Pathology Department, University of Crete Medical School, Heraklion; [2]Department of Cardiology, Athens General Hospital, Athens; [3]Department of Biostatistics, University of Crete Medical School, Heraklion, Greece*

Sudden cardiac death (SCD) due to acute myocardial infarction (AMI) is one of the leading causes of death. However, in a significant percentage of individuals who die suddenly, no indication of AMI is found during post-mortem examination, especially when the time interval between symptoms appearance and death is short. In the present study, we have examined whether nuclear morphometry (NM) could differentiate individuals dying of AMI within 1 our from symptoms onset, from those dying of other non-cardiac causes.

Methods: Our study population consisted of 20 individuals (group A), who died suddenly, within 1 hour (mean time 35 ± 13 min.), of a clinically recognized (by means of the symptoms and the presence of ST segment elevation) AMI, before death. In addition, in the post mortem examination, acute coronary thrombosis was identified in all cases as the cause of death. In all individuals, in not fewer than 10 paraffin embedded and sectioned tissue blocks of full thickness left ventricular wall (sampled from areas supplied by the occluded coronary artery), 100 nuclei were studied. In the above nuclei, we have evaluated certain morphometric parameters, such as, minimum, maximum, mean and standard deviation perimeter and area. The aforementioned nuclear parameters were compared with those of a control population (group B), in which 20 individuals whose sudden death was caused by traffic accidents, were included. All individuals of group B were found to have coronary arteries free of significant stenosis and their left ventricular samples were obtained in a spiral stepwise manner from the apex to the base. All measurements were performed at a ×600 magnification, using a microscope connected to an IBM compatible PC and to a high-resolution monitor. The program used was the commercially available Image Pro II processing system. Statistical analysis was done using Student's t-test, Mann-Whitney nonparametric method and multivariate analysis by means of the discriminant analysis method, both in a linear and a stepwise approach. Statistical significance of the mean nuclear perimeter (MNP) cut-off point was calculated by means of x^2.

Results: Except for the minimum area, we have found a statistically significant difference of all parameters between the two groups, with the values of group A exceeding the corresponding values of group B. With stepwise discriminant analysis method, the MNP was selected as the best predictor of cardiac death. MNP achieved a correct reclassification percentage (based on Fisher's linear discriminant function) of 92.5% (85% and 100% for groups A and B respectively). Moreover, by applying the cutoff of 172 μm between the 2 groups for the MNP, we could identify the individuals who died suddenly of AMI with a specificity of 100% and sensitivity 85%, ($p < 0.001$).

In conclusion, (MNP) could be applied in cases of sudden death when AMI is suspected but cannot be proved with the available methods. In the above cases, when MNP of the myocardial cells exceeds 172 μm, AMI should be considered as the most probable cause of death.

P2306 Is there an electrogram pattern predictive of successful application during transthoracic RF epicardial catheter ablation to treat ventricular tachycardia?

E.A. Sosa, F. Oliveira, A. d'Avila, M. Scanavacca. *Unidade Clínica de Arritmia, Instituto do Coração, São PAulo, Brazil*

Transthoracic epicardial RF catheter ablation is being utilized to treat post-MI and Chagasic VT. However, entrainment maneuvers can not be performed to define whether a site is part of the circuit since the epicardial stimulation threshold is too high in most patients. The aim of this study was to define whether there are epicardial electrograms patterns predictive of ablation success.

Methods: A regular ablation catheter was introduced into the pericardial space by transthoracic puncture during 21 procedures in 19 consecutive patients. The electrograms obtained from 239 sites were analyzed and defined as mid-diastolic potentials, continuous activity and early signal. A 60° C pulse was delivered for 10 seconds at each site. Electrogram duration and precocity were determined for each application.

Results: VT was interrupted at 47 of 239 sites (19%). At 57 sites, electrograms were defined as mid-diastolic signals (24%). VT interruption occurred in 5 sites (9%) whereas 52 applications did not interrupt VT. Duration and precocity did not differ between successful and not successful applications. Electrograms were defined as continuous electrical activity at 27 sites (11%) and interruption occurred in 8 of them (30%). An early electrogram was found in 155 sites (65%). RF interrupted VT in 34 sites (22%) but electrogram duration (181 ± 72 ms versus 177 ± 68 ms) and precocity (107 ± 47 ms versus 94 ± 44 ms) did not differ among these sites.

Conclusion: Electrogram pattern is not helpful in defining a site for a successful epicardial RF application. Although safe, epicardial catheter ablation based on "burning-mapping" is not ideal because this approach is only effective in 20% of the sites.

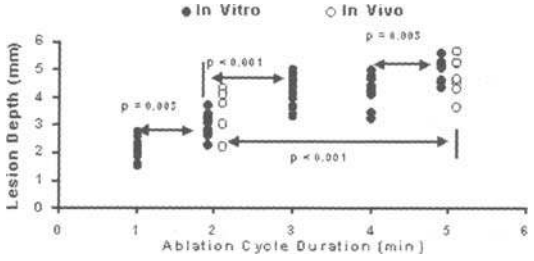
P2307 Long ablation cycles result in increased depth of multi-electrode ablation lesions using pulsed radiofrequency energy

I. McRury, S. Diamond, A. Schlichting, C. Wilson. *Electrophysiology Division, C.R. Bard, Inc., Billerica MA, USA*

Ablation cycles of 60–120 seconds are typically used during RF ablation with a single distal tip electrode. It has been assumed that similar ablation durations would suffice for multiple electrode RF ablation. However, multiple electrode RF ablation creates a larger heat pool in the tissue than distal tip ablation, and may require longer ablation cycles to achieve the maximum steady-state tissue damage.

Methods: A RF controller (Bard) that rapidly distributes sequential pulses of RF energy in 5 ms "packets" to up to 4 electrodes under temperature (T) control was used to create linear lesions in vitro and in vivo. A quad-polar ablation catheter (Bard)with four 4 mm electrodes, 3 mm spacing, and T monitoring and control of each electrode was used for the ablation of approximately 4 cm^3 peices of bovine myocardium in bovine blood at a target T of 60°C with 50 W of power. The electrode T, energy delivered to electrodes (E), lesion length (LL), and depth (LD) were measured during ablations at five ablation cycle durations (AC) of 1, 2, 3, 4 and 5 minutes. A two and 5-minute ablation were performed in the left ventricle of 10 goats. Paired comparisons of the in vivo lesions were performed.

Results: All lesions were continuous. In vitro, all electrodes maintained 60°C for the full AC. LD increased with AC (chart) and was directly proportional to E during the ablation ($R = 0.89$, $p < 0.01$). LL was approximately 28 mm in all cases. In vivo, 2 min vs. 5 min AC LD was 3.5 ± 0.7 mm vs. 4.8 ± 0.7 mm ($p < 0.01$), with similar LL (20 ± 8 vs. 24 ± 8 mm) and T (46 ± 5 vs. 47 ± 4°C). The E increased from 9.6 ± 2.6 to 18.9 ± 7.2 kJ ($p < 0.03$).



Lesion Depth vs. Ablation Cycle Duration.

Conclusion: Lesion depth of ablations from multiple electrodes using rapid sequential pulsed RF energy increases with increasing ablation duration up to 5 min.

P2308 Therapy of slow ventricular tachycardias: a substantial and increasing problem in patients with implantable cardioverter-defibrillator

C. Unterberg, A. Wieckhorst[1], A.B. Buchwald. *[1]Dep. of Cardiology, University of Göttingen; Dept. of Cardiology, University Clinic of Kiel, Germany*

The therapy of slow ventricular tachycardias (SLVT) ≤ 160 beats per minute (bpm) in patients (pts) with implantable cardioverter-defibrillator (ICD) is an increasing problem in the follow-up (FU) of these pts. The aim of this study was to evaluate the frequency, development and therapy of these SLVT.

Results: In 294 pts with ICDs of the third generation, 56 pts (8 pts DCM, 48 pts CAD, LVEF 37 ± 14%, echocardiographic LVED 67 ± 8 mm) were with SLVT (138 ± 17 (110–175) bpm). At the time of implantation SLVT was known in 48 pts (48/294 16%) and 8 pts (3%) developed unknown SLVT after 19 ± 7 (6–41) months. In 23 of the 48 pts SLVT were detected during FU (mean 7 ± 7; 1–29 months), 15 pts received antiarrhythmic agents (AA): 9 amiodarone, 2 d, 1-sotalol, 2 mexiletine, 1 flecainide. VT-frequency decreased about 18 ± 7 bpm in 13 of these 23 pts (56%), possibly due to a newly started AA-therapy in 7 pts (3 amiodarone, 2 d, 1-sotalol, 1 mexilitine, 1 flecainide). Unknown SLVTs that were not detected by the ICD occurred in 8 pts, 4 of these pts were on AA-therapy since the implantation, 4 had no AA. Detected SLVT (cycle length 400–600 msec, duration 75 ± 20 sec, onset and stability programmed) were effectively terminated by antitachycardia pacing in 87% of episodes (90% pts), and in 13% by shock. Inadaquate therapy was started in 4 pts due to sinus tachycardia. Neither the slowing of VT-cycle length nor the appearance of new SLVT correlated with worsening of the LV-function.

Conclusion: The incidence of inadequate therapy, in pts with SLVT (12%) equales to the whole ICD collective (11%) with Vts > 160 bpm, if detection-duration is sufficiently long with simultanous programming of onset and stability. In 56% of the pts, the frequency of known SLVT decreases during FU, this is accompanied by a new AA-therapy in 54%, but occurs spontaneously in 46% without a change of LV-function. These features of SLVTS should be taken into account during the initial programming of ICDs.

P2309 Open-chest radiofrequency ablation with the "showerhead" catheter: experimental experience with a new, limited surgical approach to the treatment of ventricular tachycardia

C. Stellbrink, F.A. Schöndube[1], J. v. Rango, D. Baumgartner[2], A.M. Sinha, M. Zarse, R. Seipelt[1], L. Adams[3], B.J. Messmer[1], P. Hanrath. *Medical Clinic I; [1]Dept. of Thoracic & Cardiovascular Surgery, RWTH Aachen; [2]Dr. Osypka GmbH Grenzach; [3]CWA Aachen, Germany*

Conventional closed-chest radiofrequency current ablation (RFCA) of ventricular tachycardia (VT) has met limited success due to insufficient mapping and lesion size (LS). VT surgery is associated with high morbidity and mortality due to ventriculotomy and cardiopulmonary bypass (CPB). We developed a mapping and ablation tool (AT) with a steerable shaft (5.2 mm diameter (D)) and an electrode (E) head (14.3 mm D, Figure) carrying 16 mapping/ablation E's (3 mm D each) for open-chest RFCA of VT. Saline irrigation was provided via 5 channels between the E's. A customized software allowed on-line color-coded visualization of the endocardial activation sequence. In 6 pigs (German landrace) we investigated the feasibility of the AT for left ventricular (LV) mapping and RFCA using transmitral LV access after left atrial incision without CPB. Mapping was performed under echocardiographic (echo) guidance and with arterial/left atrial pressure recording. The origin of 2 focal LV discharge sites (posterior and anterior wall) achieved by epicardial pacing was mapped and L's created by consecutive RFCAs. LS was macroscopically assessed after tetrazolium blue staining.

Results: There were no signs of hemodynamic compromise in any animal and only mild mitral regurgitation in echo. Mean L size was: length 6.7 ± 1.8, width 5.1 ± 2.5, depth 2.6 ± 0.9 mm and volume 48.2 ± 37.3 mm^3. All lesions were within 5 mm radius of the pacing E.

Conclusion: LV mapping with this new "shower-head" AT is feasible and large LS may be achieved. Further studies are needed to evaluate this approach in RFCA of macroreentrant VT.

P2310 QT parameters do not predict recurrences of ventricular arrhythmias after defibrillator implantation in patients with coronary artery disease and life-threatening ventricular arrhythmias

J. De Sutter, R. Tavernier, J. Kazmierckzak, L. Jordaens. *Department of Cardiology, University Hospital, Ghent, Belgium*

QT dispersion (Qtd, the difference between the maximum and the minimum QT duration of the surface ECG) is believed to reflect regional differences in repolarisation, and has been proposed as a risk factor for the development of ventricular arrhythmias (VA) after acute myocardial infarction (AMI). We evaluated the prognostic value of QT parameters for recurrences of VA after defibrillator (ICD) implantation in patients with coronary artery disease (CAD) and VA.

Methods: At the moment of ICD implantation, we studied QT parameters QTmax, QTcmax and QTd) derived from a simultaneous 12 lead ECG (50 mm/sec) in 57 patients (55 men, age 66 ± 9 years) with CAD (mean vessel disease score 2.3 ± 0.7 and a mean ejection fraction 34 ± 13%) and life-threatening VA. Patients were followed during 582 ± 301 days for recurrences of VA treated by ICD antitachycardia pacing and/or shock.

Results: During follow-up 28 patients (49%, group I) had recurrences of VA requiring ICD treatment and 29 patients (51%, group II) had no recurrences. Mean values ± SD for the QT parameters are given in the table for the whole group and groups I and II. No significant differences were noted between groups I and II.

	Total group	Group I	Group II	P-value
QTmax (ms)	439 ± 50	437 ± 65	441 ± 39	NS
QTcmax (ms)	475 ± 46	472 ± 51	477 ± 43	NS
QTd (ms)	45 ± 19	45 ± 23	45 ± 15	NS

Conclusions: QT parameters (including QTmax, QTcmax and QTd) do not predict recurrences of VA in patients with CAD and ICD implants.

P2311 A new approach to elucidate the mechanism of wide QRS complex tachycardia through the analysis of the first postpacing interval following entrainment by right ventricular apex stimulation

J.L. Merino, R. Peinado, I.F. Lozano, A. Sanchez-Recalde, J.A. Sobrino. *Lab. Electrofisiologia Cardiaca, Hospital Universitario "La Paz", Madrid, Spain*

Background: Definitive criteria – based on the recording of a His or bundle-branch electrogram- have been established for the diagnosis of bundle-branch reentry (BBR) ventricular tachycardia (BBR-VT). However, the use of these criteria is limited because catheter instability, concealment by the perihisian ventricular activation, or severe His-Purkinje disease, may make difficult and time consuming the recording of the His or right bundle branch electrogram during tachycardia. Since the first postpacing interval after entrainment (FPI) has been correlated with the distance from the pacing site to the reentrant circuit, we postulated that BBR-VT entrainment by pacing from the right ventricular apex (RVa) – the normal area of insertion of the right bundle branch- should result in an FPI close to the tachycardia cycle length (TCL) and that this may differentiate BBR-VT from other mechanisms of wide QRS complex tachycardia with VA dissociation, such as myocardial reentrant ventricular tachycardia (MR-VT) or AV nodal reentrant tachycardia (AVNR-T).

Methods: Transient entrainment by pacing from the RVa was attempted in 9 consecutive patients with 13 BBR-VT, 24 consecutive patients with 26 MR-VT and 34 consecutive patients with 34AVNR-T. Pacing cycle length was 10–30 ms shorter than the TCL. Measurements were done at 200 mm/sec with electronic callipers.

Results:

	BBR-VT	MR-VT	AVNR-TV
TCL (ms)	286 ± 36	289 ± 50	341 ± 58*
FPI – TCL (ms)	5 ± 15**	88 ± 44**	149 ± 34**
FPI – TCL range (ms)	−21/+26	+36/+178	+100/+228

Anova, *p < 0.02, **p < 0.0001

Conclusions: An FPI less than 30 ms longer than the TCL, following entrainment by RVa stimulation, makes unlikely MR-VT or AVNR-T and suggests a BBR mechanism. This finding should lead to further investigation to establish or rule out the BBR-VT diagnosis using standard criteria. On the other hand, an FPI more than 30 ms longer than the TCL suggests tachycardia mechanisms other than BBR.

P2312 Relation between genetic CTG expansion and development of sustained ventricular arrhythmias in myotonic dystrophy

J.L. Merino, J. Molano, R. Peinado, I.F. Lozano, J.R. Carmona, A. Sanchez-Recalde, J.A. Sobrino. *Lab. Electrofisiologia Cardiaca, Hospital Universitario "La Paz", Madrid, Spain*

Background: Sustained ventricular arrhythmias (SVA) have been documented and linked to the high incidence of sudden death seen in patients with myotonic dystrophy (MD). A significant relationship has been demonstrated between an abnormally high number of repetitions of the cytosine-thymine-guanine (CTG) sequence in locus 19q13.3 and a high density of ventricular ectopy. This finding suggests that the size of the expansion is a predictor for the development of SVA in MD. However, no studies have been reported addressing the size of the expansion in patients with both MD and SVA.

Methods: 5 patients (39 ± 7 years, 4 male) with MD, non-significant structural heart disease, and SVA, underwent quantification of the CTG expansion. All patients had at least one sustained monomorphic ventricular tachycardia, both clinically documented and induced by programmed stimulation. All underwent blood DNA amplification by PCR and CTG expansion analysis by Southern electrophoresis. The results were compared with those obtained from a control group of 25 consecutive patients (40 ± 11 years, 13 male) with MD and non-clinically documented or suspected SVA. There were no significant clinical differences between the two groups.

Results:

	n	CTG repeats
SVA	5	1,120 ± 698
No SVA	25	559 ± 324
p		<0.01

Conclusions: The size of CTG expansion in locus 19q13.3 is a predictor for the development of SVA in patients with MD.

P2313 Prediction of pre-discharge cognitive deficits in cardiac arrest survivors using serum protein s-100 and neuron specific enolase

N. Grubb, C. Simpson, R. O'Carroll[1], I. Deary[2], R. Sherwood[3], H. Abraha[3], K. Fox[4]. *Cardiology Dept, Royal Infirmary, Edinburgh; [1]Psychology Dept, University of Stirling, Stirling; [2]Psychology Dept, University of Edinburgh, Edinburgh; [3]Clinical Biochemistry Dept, Kings College Hospital, London; [4]Cardiovascular Research, University of Edinburgh, Edinburgh, UK*

Background: Over 30% of out-of-hospital cardiac arrest (OHCA) survivors suffer significant memory deficit, mediated by hypoxic brain injury during cardiac arrest. Brain enzyme assays can predict survival after stroke but have not been evaluated as predictors of functional deficits in OHCA survivors. This study evaluates serum protein S-100 and neuron specific enolase (NSE) as markers of brain injury after OHCA.

Methods: Of 66 consecutive early OHCA survivors, 34 survived to discharge. 32 were assessed with the Rivermead Behavioural Memory Test (RBMT), a test of episodic long term memory (maximum score 24 points). Serum was obtained from OHCA survivors on admission, at 24 and 72 hours. We compared NSE and S-100 levels at each time in those with severe memory impairment (Group A, RBMT < 16) and without (Group B, RBMT≥16). We calculated correlation coefficients for enzyme levels versus RBMT scores.

Results: S-100 level at 24 hours was the best predictor of memory impairment at discharge, mean (95%CI) Group A: 0.24 (0.15–0.33). Group B: 0.08 (0.05–0.11), p = 0.004. Admission and 72 hour S-100, and all NSE estimates, were poorer predictors. Correlation values are shown in table.

S100 and NSE levels vs RBMT scores

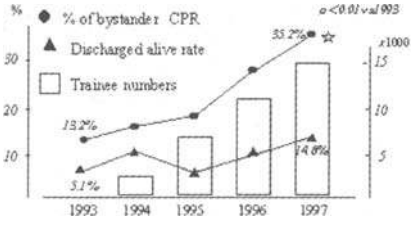
Correlations vs RBMT	r	r^2	p value
S100 24 hours (μg/l)	−0.52	0.27	0.009
NSE 24 hours (ng/ml)	−0.36	0.13	0.05

Conclusions: Estimation of serum levels NSE and S-100 24 hours after resuscitation predict memory function after OHCA. A 24 hour S100 value >0.15 μg/l was highly predictive of memory impairment, and may be a useful index for planning rehabilitation.

P2314 Public cardiopulmonary resuscitation training program and its effect in a country area of Japan: Iwate CPR propagating Committee

Y. Mizunuma, H. Mukaida, T. Suzuki, H. Niinuma, K. Hiramori. *Second Department of Internal Medicine, Iwate Medical University, Morioka, Japan*

Incidence of cardiac arrest due to ischemic heart disease in Japan was less than that in USA or Europe. In Iwate prefecture, a country area of Japan, 300 km north-east from Tokyo, 1.4 million population, 300 nontraumatic out-of-hospital cardiac arrests are occurring every year. EMS system responded for the victims within seven minutes, but survivor from nontraumatic out-of-hospital cardiac arrest was 5 percents. Iwate CPR Committee has founded on from 1993, including Iwate Medical Association, Iwate Red Cross, Iwate Fire Department, Iwate Commercial Association etc. First Action: CPR instructor were cultivated with the same skill and teaching method. Second Action: Pamphlets and videotapes were made for giving lessons in CPR technique and importance of early bystander CPR. Third Action: On-TV campaign for gathering people to the training program was performed. By 1997, 2,000 CPR instructors were nurtured, 150,000 persons (10 percents of Iwate prefectual population) were trained on the CPR program during these four years. In a year, about 80 victims of out-of-hospital cardiac arrest had been transported to our Iwate Emergency Medical Center, and only 11 (13.2%)of them underwent bystander CPR in 1993. In 1997, the ratio of bystander CPR improved significantly up to 35.2% (p < 0.01, vs.1993).



Effect of CPR Spreading.

This ratio was more than twice average in Japan. The ratio of patients who were discharged alive from hospital increased from 5.1% to 14.6%, but it was not statistically significant. This CPR propagating program should be continued.

P2315 Evaluation of serum protein S-100 and neuron specific enolase as predictors of death after resuscitated cardiac arrest

N. Grubb, C. Simpson, R. O'Carroll[1], I. Deary[2], R. Sherwood[3], H. Abraha[3], K. Fox[4]. *Cardiology Dept, Royal Infirmary, Edinburgh; [1]Psychology Dept, University of Stirling, Stirling; [2]Psychology Dept, University of Edinburgh, Edinburgh; [3]Clinical Biochemistry Dept, Kings College Hospital, London; [4]Cardiovascular Research, University of Edinburgh, Edinburgh, UK*

Background: Prediction of outcome after resuscitated out-of-hospital cardiac arrest (OHCA) is difficult. This study evaluates the prognostic value of protein S100 and neuron specific enolase (NSE) after OHCA.

Methods: Serum was obtained from 66 early OHCA survivors on admission (adm) and at 24 and 72 hours. NSE and S100 were measured using radioimmunoassay. We compared median (range) enzyme levels at each time point in the survivors (n = 34) and in those who died in hospital (n = 32). Receiver operating characteristic plots were derived and optimal cut-off values obtained for predicting in-hospital death.

Results: summarised in table.

NSE and S-100 levels

	Survived	Died	p value
S100 adm (μg/l)	0.67 [0.01–6.70]	2.02 [0.06–12.30]	p<0.001
S100 24 hrs (μg/l)	0.19 [0.00–0.58]	1.11 [0.05–9.20]	p<0.001
S100 72 hrs (μg/l)	0.11 [0.00–0.44]	0.81 [0.02–3.00]	p<0.001
NSE adm (ng/ml)	16.6 [6.7–40.7]	24.1 [7.4–56.1]	p<0.001
NSE 24 hrs (ng/ml)	17.5 [9.2–70.9]	49.9 [12.9–170.0]	p<0.001
NSE 72 hrs (ng/ml)	13.8 [6.5–59.9]	53.8 [11.5–116.5]	p = 0.03

Conclusions: Estimation of serum NSE and S100 24 hours after resuscitation helps predict outcome after OHCA. Although no cut off values for either enzyme at any time point gave good combined sensitivity and specificity, 24 hour cut-off values of 0.6 μg/l (S100) and 35 ng/ml (NSE) had 100% and 95% specificity respectively for in-hospital death and are likely to be clinically useful indices for planning management and counselling patients' relatives.

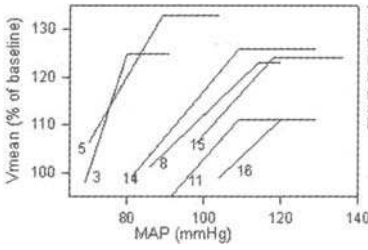
P2316 Cardiac arrest and cerebral blood flow autoregulation

C. Sundgreen, F.S. Larsen[1], T.M. Herzog, G.M. Knudsen[2], S. Boesgaard, J. Aldershvile. *Dept. of Medicine B, Rigshospitalet, Copenhagen; [1]Dept. of Medicine A, Rigshospitalet, Copenhagen; [2]Dept. of Neurology N, Rigshospitalet, Copenhagen, Denmark*

Introduction: Normally cerebral blood flow(CBF) is kept constant within wide limits of mean arterial pressure(MAP; 60–150 mmHg) due to autoregulation. We determined the lower limit of cerebral autoregulation within 12 hours after cardiac resuscitation.

Methods: Six healthy males (median age 30 yrs., range 21–61) and 18 patients (3 females, age 69 yrs. (42–81)) were included. Changes in CBF as determined by transcranial Doppler mean flow velocity (Vmean) in the middle cerebral artery was measured during a stepwise rise in MAP induced by infusion of norepinephrine. MAP was plotted against the Vmean and a lower limit of autoregulation was identified by double regression analysis based on least square measurements. $PaCO_2$ was kept at 36 mmHg (22–60) during the study.

Results: MAP was increased from 80 (72–90) to 112 mmHg (110–124) in the volunteers and from 78 (46–118) to 106 mmHg (60–149) in the patients. The lower limit of cerebral autoregulation was 76 mmHg (41–79) in the volunteers, and 109 mmHg (80–120) in seven (figure) of twelve patients with preserved autoregulation ($p < 0.01$), in whom a lower limit of autoregulation could be identified. The remaining 6 patients had impaired autoregulation i.e. a linear correlation between Vmean and MAP. There was no difference in baseline MAP, Vmean, $PaCO_2$ or duration of cardiac arrest between the two groups of patients or between the two subgroups of patients with preserved autoregulation.



The lower limit of cerebral autoregulation calculated by transcranial Doppler ultrasonography mean flow velocity (Vmean) in the middle cerebral artery in the seven patients with right-shifted autoregulation curve. Numbers indicate patients.

Conclusion: In the acute phase after cardiac arrest cerebral autoregulation is impaired or right-shifted in a majority of patients. Our finding indicates that MAP should be kept at a higher level than commonly accepted in patients resuscitated from cardiac arrest in order to secure cerebral perfusion.

P2317 Immediate coronay intervention and mild hypothermia in comatose survivors of out-of-hospital ventricular fibrillation improve patient outcome

K. Nagao, N. Hayashi, K. Kanmatsuse[1], K. Arima, J. Ohtsuki, M. Kikuchi[1], H. Kawamata[1], K. Satou[1], I. Watanabe[1], M. Yamashita[1], H. Hao[1], S. Ohguchi[1]. *Department of Emergency and Critical Care Medicine; [1]Department of Cardiology, Nihon University, Tokyo, Japan*

A good recovery rate of patients with out-of-hospital cardiac arrest is still low. There is evidence that coronary reperfusion therapy for acute myocardial infarction (MI) reduce the mortality and hypothermia therapy for traumatic brain injury improve the neurologic outcome. Consequently, we performed immediate coronary angiography plus intervention and mild hypothermia when indicated in comatose survivors of out-of-hospital ventricular fibrillation (Vf).

Methods: This study was performed in sixteen consecutive patients who had cardiac cause of Vf and met the indication criteria of mild hypothermia. Immediate coronary angiography was performed in patients who had return of spontaneous circulation (ROSC) by standard advanced cardiac life support and coronary intervention was attempted in patients who had acute coronary-artery occlusion. Subsequently in patients systolic blood pressure above 90 mmHg and Glasgow coma score (GCS) of 3 to 5, hypothermia was induced by 34°C coil cooling and continued for at least two days Furthermore fluid-nutrition-anticoagulation manegement by complete parenteral nutrition and continous hemodialysis-filtration. Outcome was assessed both in terms of survival rate and good recoveny rate.

Results: The cardiac cause of Vf was acute coronary syndrome in 14 patients hypertrophic myopathy in 1 and other cause in 1. The mean time from Vf to start of CPR was 9.2 ± 7.6 min; the mean time until ROSC, 39.6 ± 22.6 min; the successful reperfusion rate, 88.9% the mean GCS before hypothermia, 3.6 ± 0.6; the mean core temperature and duration at cooling stage, 34.3 ± 0.5°C and 83 ± 39 hr. Of these 16 patients, 81.2% (n = 13) survived at hospital discharge and 68.6% (n = 11) exhibited a good recovery rate.

Conclusions: The strategy of immediate coronary angiography plus intervention and mild hypothermia for cardiopulmonary cerebral resuscitation resulted in a 69% good recovery rate in comatose suvivors with out-of-hospital Vf. To confirm this result, larger, randomized, prospective, controlled studies using this strategy should be conducted.

P2318 Is electrophysiologically guided amiodarone therapy still indicated in patients with sustained ventricular tachyarrhythmias?

J. Schläpfer, F. Rapp, C. Chételat, L. Kappenberger, M. Fromer. *Division of Cardiology, University Hospital, Lausanne, Switzerland*

We analyzed the outcome of 98 consecutive patients (pts) with sustained ventricular tachyarrhythmias (VT) treated with electrophysiologically guided (EP) amiodarone (amio).

Methods: 88 men, 10 women, mean age: 59 ± 11 year, mean ejection fraction: 36 ± 11% with VT were treated with EP guided amio. The underlying cardiopathy was ischemic in 87 pts, dilated in 9 pts and hypertrophic in 2 pts. According to the results of the EP study after a mean amio charging dose of 13.1 ± 1.3 g, pts were classified as "responders" (group 1 = 48 pts) or "non responders" (group 2 = 50 pts): Group 1 pts continued amio whereas group 2 pts were treated as follows: defibrillator (ICD) = 40 pts; surgery = 3 pts; RF ablation = 2 pts; 4 pts in Group 2 were excluded for follow-up because the scheduled ICD implantation could not be performed.

Results: During a mean follow-up of more than 5 years, total mortality and sudden cardiac death were significantly lower in Group 2 pts compared with group 1 pts (p: < 0.03 and 0.009, respectively). Furthermore, 6 pts in group 1 switched to an ICD.

In conclusion, EP guided amio "responders" have an impaired suvival compared with "non responders" treated with an ICD; therefore even EP guided amio therapy is obsolete for these pts.

P2319 Randomized comparison of 150 J biphasic and 200-360 J monophasic waveform automatic external defibrillators in out-of-hospital cardiac arrest victims

T. Schneider, P. Martens[1], H. Paschen[2], M. Kuisma[3], B. Wolcke, B. Gliner[4], W.D. Weaver[5], L. Bossaert[6], D. Chamberlain[7]. *Johannes Gutenberg Universität, Mainz, Germany[1] St. Jan Hospital, Brugge, Belgium[2] Freie Und Hansestadt Inst, Hamburg, Germany[3] Helsinki City EMS, Helsinki, Finland[4] HP Heartstream, Seattle WA[5] Henry Ford Hospital, Detroit MI, United States; [6] University Hospital, Antwerp, Belgium[7] University of Wales, Cardiff, UK*

Background: Since the 1960s, external defibrillators have traditionally relied on high-energy monophasic shocks. In 1996, a biphasic waveform automatic external defibrillator (AED) was introduced that delivers 150 J shocks. This study compared 200–360 J monophasic waveform AEDs to a 150 J impedance-compensating biphasic waveform AED.

Methods: The AEDs were randomly selected in response to 338 out-of-hospital cardiac arrests in four emergency medical service (EMS) systems. Of these arrests, 113 had a cardiac etiology with ventricular fibrillation as the first monitored rhythm and was shocked by an AED. Time from emergency call to first shock was 8.9 ± 3.0 minutes; collapse to first shock was 12.3 ± 4.2 minutes. The primary endpoint was successful defibrillation with 3 shocks or fewer. Secondary endpoints included first shock defibrillation efficacy, return of spontaneous circulation (ROSC), and survival to hospital admission and discharge.

Results: Study results are provided in the table below. *Survival to hospital discharge not yet known for four admitted patients.

	200–3060 J	150 J	P-value
Defibrillation, ≤3 shoks	40/60 (67%)	53/54 (98%)	<0.0001
Defibrillation, 1st shock only	35/60 (58%)	51/54 (94%)	<0.0001
ROSC	33/60 (55%)	41/54 (76%)	0.02
Survival, admission	31/60 (52%)	33/54 (61%)	0.3
Survival, discharge	16/58 (28%)	14/52 (27%)	0.9

Conclusions: The 150 J impedance-compensating biphasic waveform defibrillated at higher rates than 200–360 J monophasic shocks, resulting in significantly more patients achieving ROSC. EMS system outcomes of survival to hospital admission and discharge were not statistically different.

P2320 Re-entrant activity during ventricular fibrillation: an experimental study of the modifications in circuit size produced by antiarrhythmic drugs

J. Cánoves, F.J. Chorro, L. Mainar, J. Sanchis, L.M. Such, E. Llavador, V. López-Merino, L. Such[1]. *Service of Cardiology, University Clinic Hospital, Valencia; [1] Departament of Physiology, Valencia University, Valencia, Spain*

With the purpose of analyzing the characteristics of reentrant activity during ventricular fibrillation (VF) and its modifications following the administration of antiarrhythmic drugs, 32 Langendorff-perfused rabbit hearts were used to record fibrillatory activity induced by overdriving with an epicardial multiple electrode (121 unipolar electrodes, interelectrode distance = 1 mm) positioned on the free wall of the left ventricle. While coronary perfusion was maintained under both control conditions and following Flecainide (Fl, 1 μmol, n = 10), D-sotalol (Sot, 20 μmol, n = 10) or Verapamil (Vp, 0.2–0.8 μmol, n = 12), activation maps were obtained at 100-ms intervals over a 2-s period. In those maps reflecting closed loop reentry, the number of consecutive loops were quantified, along with the dimensions of the central line of the rotation (LG) and the area (AR) encompassed by it plus two electrodes surrounding the central zone – to record reentrant activity.

Closed loop reentry is observed in between 4.5% and 9% of the maps analyzed in each group. The number of consecutive loops does not differ significantly during Fl (control = 1.4 ± 0.6, Fl = 1.3 ± 0.5 loops) and Sot perfusion (control = 1.2 ± 0.3, Sot = 1.0 ± 0.1), though it increases with Vp (control = 1.3 ± 0.4, Vp = 2.1 ± 1.1, $p < 0.02$). The length of the central zone and the area encompassed by it plus two electrodes increases significantly during perfusion of Fl (control LG = 5 ± 1, Fl LG = 7 ± 1 mm, $p < 0.001$; control AR = 45 ± 6, Fl AR = 64 ± 6 mm^2, $p < 0.001$) and Sot (control LG = 5 ± 1, Sot LG = 7 ± 1 mm, $p < 0.001$; control AR = 43 ± 6, Sot AR = 57 ± 7 mm^2, $p < 0.001$), and decreases under the influence of Vp (control LG = 5 ± 1, Vp LG = 4 ± 1 mm, $p < 0.02$; control AR = 49 ± 4, Vp AR = 37 ± 5 mm^2, $p < 0.001$).

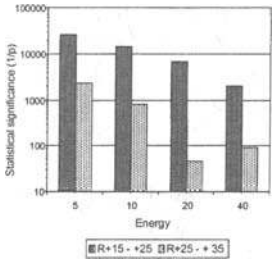
Conclusions: Reentrant activity can be recorded by epicardial mapping during VF. The dimensions of the LG and AR increase under the influence of F1 and Sot, and decrease with Vp.

P2321 Wedensky cardiac modulation: dose-related separation of patients with ventricular tachycardia from healthy controls

Katerina Hnatkova, Marshall S. Stanton, Stephen J. Ryan, Marek Malik, Thomas M. Munger, Nemer Samniah, Jorn Bathen, Mark W. Kroll, David G. Benditt, Ole Rossvoll, Harold H. Hoium. *Harbinger Medical Inc., Minneapolis MN; Univ. of Minnesota Hospital, Minneapolis MN; St. Jude Medical/Daig, Minnetonka MN; Mayo Clinic, Rochester MN, USA; Regional Hospital, Trondheim, Norway; St. George's Hospital Medical School, London, UK*

Wedensky phenomenon is the effect of a subthreshold stimulation without capture that reduces the stimulation threshold and changes the action potential of a subsequent suprathreshold stimulation with capture.

Patients with EP documented ventricular tachycardia (n = 47, mean age 63 ± 13 years, 83% male) and healthy controls (n = 30, 44 ± 16 years, 60% male) were subjected to a subthreshold external stimulation between precordial and left subscapular patches. Stimuli of 5, 10, 20, and 40 mA were delivered for 2 ms after a 20 ms delay following a real-time R wave detection. 60 to 200 subthreshold stimulated QRS complexes were averaged and compared with the same number of non-stimulated complexes. Vector magnitude wavelet decompositions (53 scales of central frequencies 40–250 Hz) were obtained for both stimulated and non-stimulated complexes and their difference characterised the Wedensky phenomenon numerically. The surface area of the 3D envelope of the wavelet residuum was measured in a window 20 ± 5 ms after the R peak (a window centred around the stimulation moment) and the subsequent 10 ms windows (30 ± 5 ms after the R peak). The areas of the residuum spectral 3D envelope in these windows were statistically compared in the VT patients and healthy controls.



All differences were highly significant (up to $p < 0.00005$ – figure) the manifestation being more pronounced in the control group. The separation of the groups was more significant in the window around the stimulation moment. The significance decreased with increasing subthreshold stimulation energy. Thus, (a) Wedensky phenomenon in the late QRS part is brief, (b) VT pts are less sensitive to the phenomenon, especially at very low subthreshold energies.

P2322 Validation of a semiautomatic external defibrillator for narrow and wide QRS tachycardia

H. Tanner, R. Leuenberger, A. Kruse, J. Fuhrer. *Cardiology, University Hospital, Berne, Switzerland*

Background: Semiautomatic external defibrillators (SAED) are widely used to treat life-threatening ventricular arrhythmias. However, neither sensitivity nor specificity of their advice to give a shock are well established.

Methods: Therefore, we studied sensitivity and specificity of the advices of the SAED ForeRunner™ (Heartstream, Inc. Seattle, USA) to shock spontaneously occurring and induced narrow and wide QRS tachycardias during routine electrophysiological studies. Moreover, right ventricular stimulation at cycle lengths of 380, 370, 360, ... up to 300 ms was performed. In every patient each paced cycle length was analysed.

Results: In 50 consecutive patients (26 males, 24 females) we analysed 274 tachycardias with the SAED (58 spontaneous or induced tachycardias, 216 right ventricular stimulations). In all 29 narrow QRS tachycardias (median heart rate 185/min, range 140–250/min) no electric countershock was advised, specificity of 100%. In 22 of 29 (76%) spontaneous or induced wide QRS tachycardias (median heart rate 180/min, range 130–270/min) no electric countershock was advised. In 158 of 216 (73%) right ventricular stimulations no electric countershock was advised. Admitting the SAED should shock a wide QRS tachycardia at a certain heart rate, we found the following sensitivities at different rates in all wide QRS tachycardias:

Heart rates (≥/min):	160	170	180	190	200	210	220	230	240	250	260
Sensitivities (%):	29	34	41	47	50	43	50	60	67	50	100
Tachycardias (n):	217	165	111	60	34	7	6	5	3	2	1

Conclusions: The specificity of the SAED ForeRunner™ to recognize narrow QRS tachycardias is excellent. However, the sensitivity of the SAED to detect a potentially harmful wide QRS tachycardia seems to be limited.

PACING AND ICD-RELATED PROBLEMS

P2323 Safety and performance of a new dual-chamber implantable cardioverter-defibrillator: results from a European multicentre study

Burkhard Hügl[1], Volker Kühlkamp, Erhard Helmling, Herwig Schmidinger, Giriam Grönefeld, Bernd Lemke, B. Waldecker, Reinhard Höltgen, Alexander Schirdewan, Carlo Pappone. *On behalf of the Multicenter European GEM-DR-Investigators; [1]Heart Center, University of Leipzig, Germany*

The purpose of this prospective multicenter (36 European centers) study was to evaluate the safety and performance of a new dual-chamber ICD (Medtronic Model 7271 GEM DR). Between 11/97 and 5/98 a total of 216 patients (pts) were implanted. Indications (non-exclusive) for ICD implant were survival of sudden cardiac death (56%), recurrent poorly tolerated sustained VT (75%) or MADIT (3%). The typical pt was a 61 years old male (79%) suffering from coronary artery disease (64%) and/or dilated cardiomyopathy (22%), with an ejection fraction of 39%. During a follow up (FU) period of 2.9 ± 1.4 months 70 pts experienced 1108 ventricular tachyarrhythmia episo-des and 48 pts experienced 486 supraventricular tachycardia (SVT) episodes, of which EGM was stored by the device. All VT/VF (of which 99.6% were treated successfully) and the majority (71%) of the SVT episodes (untreated) were appropriately detected. During the FU period 110 pts experienced 187 adverse events (AE). Inappropriate VT/VF detection occurred in only 26 pts (12%). AEs resulting in death (6), requiring surgical intervention (37) or hospitalization (52) were classified as severe and occurred in 66 pts (31%). Four pts died of heart failure and two pts died of electromechanical dissociation. None of the deaths were considered to be device relat-ed. Severe Device Related AEs, including 10 lead dislodge-ments and 10 inappropriate VT/VF detections, occurred in 29 pts (13%).

Conclusion: The new Dual-Chamber ICD proved to be safe and effective with a low rate of adverse events. The new PR-Logic algorithm seems to be very useful for the correct discrimination of supraventricular from ventricular arrhythmias.

P2324 Rate characteristics and circadian variation of atrial tachyarrhythmia recurrences: first lessons from patients with a dual-chamber defibrillator with atrial tiered therapies

C. Wolpert, W. Jung, S. Spehl, R. Schimpf, B. Schumacher, C. Schneider[1], B. Esmailzadeh[1], A. Welz[1], B. Lüderitz. *Depts. of Cardiology; [1]Cardiovascular Surgery, University of Bonn, Bonn, Germany*

A new dual-chamber implantable cardioverter-defibrillator (ICD) provides additional atrial therapies. Moreover, the activation of the atrial therapies can be freely programmed to any time of the day. there is no systematic data, yet, about the incidence and duration of paroxysmal atrial tachyarrhythmias (AT) in patients with an ICD. Since activation of atrial therapies does not only influence the rhythm, but also quality of life, the aim of this prospective study was, to assess the clinical characteristics as atrial rate, duration and circadian variation of AT episodes in ICD-patients to guide appropriate programming of atrial therapies.

Patients and Methods: 225 episodes from 19/34 patients with a dual-chamber ICD Medtronic Jewel AF 7250 were included in the analysis. Duration of the episodes and circadian distribution of the AT episodes (E) were assessed using the device data log. Furthermore, the atrial rate measured as the median PP-interval of each episode was determined.

Results: The mean atrial cycle length was >220 ms in 78% of the E. In all these E the device classified the activation pattern as regular. The duration of the AT episode was <1 min in 64 E, 1–5 min 107 E, 5 min–24 h in 52 E and >24 h in 4 E. The mean duration was 11 min. The circadian variation of AT episodes exhibited a significant peak between noon and 6 p.m. (0–6 a.m 11 E, 6 a.m–noon 25 E, noon-6 p.m. 63 E and 6 p.m.–12 p.m. 23 E) ($p < 0.05$).

Conclusions: 1. 78% of the AT reveal a regular atrial activity with a median cycle length > 220 ms. Thus, atrial antitachycardia pacing therapies should be extensively programmed in all patients. **2.** 98.3% of the episodes terminate spontaneously within 24 hrs. Empiric atrial shock programming should therefore be avoided, because the vast majority is non-sustained and terminates spontaneously **3.** Shock therapy should be programmed in patients with persistent AT during the sleep hours to reduce pain perception.

P2325 Re-used pacemakers – an alternative in elderly patients

S. Pescariu, B. Dodinot[1], D. Cozma, M. Stiubei, A. Ionac, D. Gaita, H. Branea, C.T. Luca, C. Luca, S.T.I. Dragulescu. *Centrul de Cardiologie, Timisoara, Romania; [1]University Hospital, Nancy-Brabois, France*

Aim: The aim of this study was to investigate the safety and the cost-benefit ratio of re-used pacemakers (PM) in elderly patients in a retrospective case-controlled study in an area with poor health care services.

Methods: 131 patients (gr. I) with an age > 70 years (mean age 79 ± 5 years) who received a re-used PM were matched for date of implantation and mode (AAI, VVI, DDD) to 140 patients (mean age 79 ± 9 years) (gr. II) who received new PM. Criteria for re-use were PM implanted <1 year and no sign of damage at examination and interrogation. The majority of PM was provided by the Bank of PM "Stimubank" Nancy, France. All patients were observed for a mean of 35 ± 21 month for complications defined as infections and signs of PM malfunction and PM replacement earlier than anticipated due to battery depletion. A cost-benefit analysis was performed for survival and time to PM replacement.

Results: The number of complications did not differ significantly between the group implanted with re-used PM (infections 4, malfunctions 5) and the group implanted with new PM (infections 3, malfunctions 6). There was no early replacement due to battery depletion in either of the two groups.

76 of 131 patients (57%) died after an average implantation time of 3.3 years and before needing PM replacement. 78 patients of group II (55%) died after an average implantation time of 3.2 years. The cost-benefit analysis revealed a substantial economical advantage for the group implanted with re-used PM.

Conclusion: The re-use of PM can be performed without increased risk to the patients provided that a proper routine for technical control and sterilization is followed. Reuse of PM makes it possible to implant advanced pacing systems with a very good cost-benefit ratio in patients in whom life expectancy is lower than that of the PM.

P2326 Cardiac resynchronization for heart failure: do patients with prior indications for pacing benefit?

P. Holt[1], C. Bucknall[1], R. Chatoor[1], D. Gras[2], P. Mabo[3], T. Tang[4], H. Oude Luttikhuis[5], A. Kirstein-Pedersen[6]. *For the InSync Investigators; [1]St. Thomas Hospital, London, UK; [2]Clinique du Val d'Or, Paris; [3]Dep. de Cardiologie et Maladies, Rennes, France; [4]Ottawa Heart Institute, Ottawa ON, Canada; [5]St. Sophia Ziekenhuis, Zwolle, Netherlands; [6]Skejby Sygehus, Aarhus, Denmark*

The InSync™ study is a prospective, multicenter, non-randomized trial evaluating Cardiac Resynchronization (CR) therapy in patients (pts.) with advanced heart failure (NYHA Class III/IV), dilated cardiomyopathy (EF < = 35%, LVEDD = > 60 mm) and ventricular conduction delays (QRS = > 150 ms). Pts. with prior pacing systems were also included in this evaluation. Clinical effects of cardiac resynchronization were compared between these pts. and pts. without a prior pacing system.

Methods: 53 pts. implanted with the InSync system, including a transvenous left ventricular lead via the coronary sinus, were included in this analysis. From this group, 17 had a previous pacing system and 36 had no prior pacing system. We have excluded 7 pts. who did not have a previous pacing system yet were indicated for pacing at the time of InSync implantation. Measured parameters included QRS duration, NYHA classification, 6 min hall walk, and Quality of Life (Minnesota Living with HF)

Analysis: 1) *within* each group, statistically significant changes in clinical endpoints at one and three months were observed compared to baseline. 2) *Between* group comparisons, with p-values, are shown in the table below.

Clinical Endpoint	Δ Pts with prev. pacing system	Δ Pts without prev. pacing system	p-value
QRS duration (msec)	47.4 ± 30 (N = 16)	18.9 ± 32.2 (N = 33)	0.005
NYHA classification	0.9 ± 0.7 (N = 17)	1.1 ± 0.9 (N = 36)	0.305
6 minute hallwalk (m)	46.3 ± 67.4 (N = 11)	66.8 ± 95.2 (N = 28)	0.519
Quality of Life score	14.9 ± 23.1 (N = 16)	18.1 ± 26.1 (N = 35)	0.672

Conclusions: These data from the InSync trial demonstrate increased patient benefit from CR at 3 months in both groups, those with prior pacing systems in place, and those not previously indicated for pacing. The data also suggest a trend toward greater improvement in pts. receiving a system for the first time. Longer term studies will be required to evaluate the benefit of CR in both patient groups.

P2327 Long-term outcome of patients with multiple (≥3) non-infected transvenous leads

Carel C. de Cock, Linda M.C. van Campen, Patrick M.J. Verhorst, Otto Kamp, Cees A. Visser. *Medical Center VU, Amsterdam, Netherlands*

Lead extraction is associated with a relatively high number of complications. However, the presence of multiple (≥3) leads have been related to thromboembolic manifestations. We studied 48 consecutive patients (pts) with ≥3 non-infected leads. No additional care was provided except for aspirin 80 mg bid and annually performed echo Doppler studies. Clinical follow-up included signs of right heart failure, subclavian and/or axillary vein thrombosis, hospital admissions and cumulative mortality. Echo Doppler studies assessed the presence of right atrial or right ventricular spontaneous contrast and tricuspid regurgitation. Pts were compared with age-matched controls with dual chamber stimulation. In the study group 24 pts had two ventricular leads, 14 had two atrial leads and 10 had two atrial and two ventricular leads. Median follow-up was 7.4 ± 2.2 years.

	Multiple leads (n = 48)	Controls (n = 48)	p-value n
RHF	15%	13%	–
Vthr	13%	10%	–
HA	1.1 ± 0.27	1.3 ± 0.30	–
SPEC	4%	4%	–
TR	23%	4%	p < 0.05
MORT	13%	15%	–

RHF = right heart failure; Vthr = vein thrombosis; HA = hospital admissions/year; SPEC = spontaneous echo contrast; TR = tricuspid regurgitation; MORT = mortality.

Conclusion: patients with multiple ≥3 leads experience no clinical adverse outcome during long term follow-up despite a significant higher incidence of echocardiographic assessed tricuspid regurgitation.

P2328 Impact of chronic ddd pacing on sympathovagal balance in patients with hypertrophic obstructive cardiomyopathy

E.N. Simantirakis, G.E. Kochiadakis, M.K. Kanakaraki, E.M. Kanoupakis, M.E. Marketou, P.E. Vardas. *Cardiology Department, Heraklion University Hospital, Heraklion, Crete, Greece*

Autonomic dysfunction has been reported in patients with hypertrophic obstructive cardiomyopathy (HOCM). Although DDD pacing has been proved useful for the relief of symptoms, it has not been investigated whether it has any impact on autonomic nervous system activity in HOCM patients. The aim of this study was to examine if DDD pacing changes sympathovagal balance, as assessed by heart rate variability (HRV), in such patients.

Methods: We studied 11 pts (7 men, age 52 ± 8 years) with HOCM refractory to drugs. In all pts a DDD pacemaker was implanted and the AV delay was programmed to ensure a full ventricular activation sequence. Time domain indexes of HRV (mean NN, SDANN, SDNN, SD, rMSSD, pNN50) were determined from 24-hour Holter recordings 1 week before and 1 year after pacemaker implantation. The pacemaker was turned off during the second recordings. The same indexes were determined in 10 healthy controls at the same time points.

Results: The controls showed no significant differences in any of the measured parameters between the 2 time points. The HOCM pts showed an increase in SD (from 27 ± 13 to 41 ± 13 ms, $p < 0.001$), rMSSD (from 18 ± 5 to 32 ± 8 ms, $p < 0.001$) and pNN50 (from 1.03 ± 1.06 to 8.52 ± 4.84%, $p < 0.0001$). As a result, the values of these 3 parameters in the HOCM pts, which were lower than in the controls before pacing, were restored to normal levels by the end of the study.

Conclusions: Our findings indicate that long term pacing in HOCM pts restores the sympathovagal balance in the heart by increasing vagal activity. Thus, DDD pacing may have a beneficial impact on the prognosis of such patients.

P2329 Atrial pacing reduces mode switching episodes in patients with paroxysmal atrial fibrillation

G. Stabile, A. De Simone, D. Franco Vitale[1], G. Senatore[2], P. Turco, V. Larocca, R. Rotunno[3], T. Di Napoli[3]. *Electrophysiology Laboratory, San Michele Hospital, Maddaloni (CE); Department of [1]Cardiology; [2]Geriatrics, Federico II University of Naples, Naples; [3]Civil Hospital Polla (SA), Italy*

Atrial pacing (AP) has been reported to be effective in reducing atrial fibrillation (AF) recurrences. However, the efficacy of AP has been demonstrated only by the reduction of patients' symptoms, a parameter that represents a potential bias. Recently it has been demonstrated that the pace-makers' mode-switching (MS) algorithms are reliable in detecting paroxysmal episodes of atrial tachyarrhythmias. The aim of our study was to prospectively analyze the effect of AP on MS episodes in patients with AF undergoing pace-maker (PM) implant because of coexisting sick sinus syndrome or atrioventricular block.

Methods. Twenty-three patients underwent PM implantation. Before hospital discharge, the PM were programmed in the DDD mode with bipolar atrial and ventricular sensing and pacing. The lower and the upper atrial rate were, respectively, programmed to 50 bpm and 220 minus patient age bpm. All the patients received the same antiarrhythmic medications used before PM implantation. At a follow-up of 4 months (follow-up period I), PM were reprogrammed in DDDR mode, with a lower rate of 75 bpm, and followed-up for the next 4 months (follow-up period II).

Results. During the 4 months of follow-up period I 19/23 (82.6%) patients had at least one symptomatic AF episode, and 21/23 (91.3%) patients had at least one MS episode. The overall mean number of AF episodes/patient was 3.1 ± 3.8 and was reduced to 0.7 ± 1 ($p = 0.005$) in the follow-up period II. In the follow-up period II a lower number of MS episodes/patient were observed than follow-up period II (5.9 ± 7.8 vs 49.9 ± 87, $p = 0.05$). This was associated with an higher percentage of AP time (85.4 ± 15.9 vs 39.6 ± 22.5, $p < 0.001$). An inverse correlation was found between the logarithm number of MS episodes and the percentage of AP time ($r = -0.53$). A direct correlation was found between the AF episodes and the MS episodes ($r = 0.7$).

Conclusions. The results of this study show that AP reduces MS episodes in patients with paroxysmal AF. Its efficacy is correlated with the percentage time of AP. These data seems to confirm, in an objective way, the efficacy of AP in reducing AF recurrences.

P2330 The importance of electrode placement in the right atrium for sensing of early onset of atrial intrinsic activity

W.A. Hartung, D. Hartung[1], R. Willems[2], D. Mahnkopf[3], A. Mittag[3], J.Ch. Geller, H.D. Esperer, A. Goette, S. Reek, H.U. Klein. *Division of Cardiology; [1]Division of Nuclear Medicine, University, Magdeburg; [3]Institute of Medicine Technology Magdeburg, Germany; [2]Guidant/CPI Research, Zaventem, Belgium*

Background: Multisite atrial pacing algorithms are new pacing concepts for the prevention of onset of atrial arrhythmias. A central roll in these prevention concepts plays the early sensing of the onset of atrial activity. The aim of this study was to investigate the importance of the placement of the atrial electrodes for sensing of early onset of atrial intrinsic activity.

Methods: In 11 female merino sheep (4.6 ± 1.3 years; 66.3 ± 6.1 kg) EP-catheters were placed fluoroscopically at the high right atrium (HRA) and at the coronary sinus ostium (Cs-Os). A modified single-VDD-lead was placed with the atrial ring electrodes floating in the high and mid right atrium. The P-wave onset to floating electrodes, to the HRA, and to the Cs-Os position were measured during intrinsic rhythm (1000 Hz sampling rate; unfiltered signal).

Results: In 10 of 11 experiments, the earliest sensing of onset of atrial intrinsic activity was observed over the atrial floating ring electrodes. The onset of the atrial signal sensing was recorded 18.4 ± 16.6 ms earlier using floating electrodes compared to wall contact electrodes in the HRA position ($p < 0.05$), and 40.0 + 16.9 ms earlier compared to the Cs-Os position ($p < 0.05$). The difference of onset sensing between HRA and Cs-Os position was also significant ($p < 0.05$). The onset of atrial intrinsic activity was sensed 19.9 ± 8.1 ms earlier using floating ring electrodes compared to the onset of the P-wave in the surface ECG ($p < 0.05$).

Conclusion: The intra-individual comparison of the onset sensing of atrial intrinsic activity is significantly dependent on the location of atrial wall contact electrodes. Sensing of the onset of atrial intrinsic activity can be done significantly earlier using floating ring electrodes in the mid right atrium compared to wall contact electrodes. Therefore, atrial sensing using floating ring electrodes may be helpful in early detection of atrial arrhythmias.

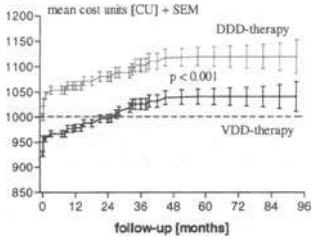
P2331 Does implantation of single-lead VDD-pacemakers reduce the costs of pacing therapy in patients with isolated AV block?

Uwe K.H. Wiegand, Werner Peters, Frank Bode, Raphael Schreiber[1], Hendrik Bonnemeier, Hugo A. Katus, Jürgen Potratz. *Medical University of Lübeck, Departments of Internal Medicine II; [1]Finances, Lübeck, Germany*

Implantation of single-lead VDD-pacemakers is an established alternative to DDD-pacing in patients with AV-block and normal sinus node function. This study compares long-term cost-efficacy of both systems.

360 patients with isolated AV-block received single-lead VDD-pacemaker (VDD, n = 180) and DDD-systems (DDD, n = 180) in alternating order and were followed over a period of 42 ± 15 months. Costs of implantation included: Costs of devices, leads and operation material, of surgeon, nurse and medical technician and of hospitalisation. Follow-up costs included routine pacemaker controls as well as costs of pacemaker-related complications. Costs were converted into virtual cost units (CU): mean costs of uncomplicated DDD-pacemaker implantation defined 1000 CU. Endpoints of the study were death, any operative revision and complete loss of AV-synchrony.

Costs of devices were not different (721 ± 65 CU in VDD vs. 722 ± 76 CU in DDD). However, due to lower cost of leads and shorter implantation times (44.3 ± 5.1 min in VDD vs. 74.4 ± 13.5 min in DDD, p < 0.001) overall costs of an uncomplicated pacemaker implantation were significantly lower in the VDD-group (fig). Furthermore, a tendency to less re-operations in the VDD-group (3.3 vs. 6.1%, p = 0.15) led to reduced follow-up costs per year (14 ± 22 CU in VDD vs. 22 ± 30 CU in DDD, p = 0.002). Study endpoint was reached in 12.8% of patients with VDD and 14.4% with DDD (n.s.).



Assuming a mean battery lifetime of 6 years, about 10% cost reduction compared to DDD-devices can be achieved by VDD-pacemaker implantation without reducing the efficacy of pacemaker therapy in patients with isolated AV-block.

P2332 Clinical response to pacemaker therapy: carotid sinus hypersensitivity versus vasovagal syncope

W.K. Shen, D. Beinborn, A. Jahangir, D.O. Hodge, S.S. Hammill, D.L. Hayes. *Mayo Clinic, Rochester MN, USA*

Vasodepression and cardioinbibition are two components of the efferent pathways underlying neurocardiogenic syndromes (NCS), including carotid sinus hypersensitivity (CSH) and vasovagal syncope (VVS). It has been suggested that the relative contribution of the two efferent components is likely different in CSH and VVS; therefore, conjectured that response to pacemaker (PM) therapy is expected to be different. In this retrospective study, clinical responses (improved, asymptomatic) were assessed by a prospective survey in 230 pts with CSH (age 69 ± 12 yrs, F/M = 44/186) and 24 pts with VVS (age 57 ± 23 yrs, F/M = 10/14) following PM implantation between 1984-1996. f/u was completed in 166/230 pts (72%, mean f/u 2.5 ± 2.9 yrs) with CSH and in 24/24 pts (100%, mean f/u 2.0 ± 1.6 yrs) with VVS. Survival free from recurrent symptoms was assessed by the Kaplan-Meier method:

Clinical Response	NCS	F/U (probability)			
		1 yr	2 yr	3 yr	P
Asymptomatic	CSH	0.82	0.76	0.71	0.001
	VVS	0.65	0.42	0.31	
Improve or	CSH	0.96	0.96	0.94	0.01
Asymptomatic	VVS	0.90	0.82	0.68	

CSH pts are older (p = 0.02), male predominant (p = 0.01), and with longer pauses (p = 0.01). Multivariate analysis showed older age (p = 0.05) in VVS pts and presence of prodromes (p = 0.05) in CSH pts were predictors for recurrent symptoms. Mode of pacing was not an independent predictor for recurrent symptoms in either group (p > 0.05).

Conclusion: 1) Long-term response to conventional PM therapy is significantly more favorable in pts with CSH when compared to pts with VVS; 2) Significant differences in clinical characteristics are present between these two NCS; 3) Careful evaluation of mode of pacing in pts with VVS is warranted.

P2333 Does the ventricular activation sequence affect myocardial contractility during exercise?

S.K. Leung[1], C.P. Lau, C. Lam[1], P.C. Ho, C.M. Yu, K. Lee, F. Renesto[2], M.D. Torres. *[1]Kwong Wah Hospital & Queen Mary Hospital, Hong Kong, China; [2]Sorin Biomedica Cardio, Saluggia, Italy*

Background: Right ventricular (RV) pacing result in delay between right and left ventricular contraction, hence unfavorable haemodynamics effects. Peak endocardial acceleration (PEA) measured by an implantable acceleration sensor at the tip of the pacing lead reflects myocardial contractility. Thus, it can be used to assess ventricular performance with native ventricular activation and RV pacing during submaximal and maximal treadmill exercises.

Methods: PEA sensing DDDR pacemakers (Best-Living, Sorin Biomedics) were implanted in 15 patients (age 71 ± 8 year) with sick sinus syndrome, with the ventricular leads implanted into the RV apex in all patients. The sensor was tailored to a rate of 90 to 100 bpm using a 2-minute walking test. The patients were subjected to submaximal treadmill exercise test at 2 mph 0% gradient and maximal exercise test using the CAEP protocol. During exercise, the pacemakers were randomly programmed to DDDR with: 1) RV pacing using an atrioventricular delay (AVD) optimized non-invasively by echo-Doppler to obtain highest cardiac output and longest diastolic filling time (paced AVD); 2) normal ventricular activation by programmed an AVD long enough to allowed intrinsic AV conduction (native AVD). PEA values were recorded beat by beat by pacemaker telemetry both at rest and during exercise. The maximum changes in PEA (ΔPEA) during exercise with the 2 ventricular activation sequences were compared using t-tests.

Results: The mean paced AVD and native AVD were 142 ± 42 ms and 208 ± 20 ms respectively.

	2 mph, 0%	CAEP		
	ΔPEA (G)	ΔPEA (G)	Exercise duration (s)	Exercise workload (METS)
Paced AVD	0.53 ± 0.04	1.1 ± 0.15	496 ± 35 s	4.0 ± 0.27
Native AVD	1.0 ± 0.17	1.1 ± 0.17	479 ± 51	3.8 ± 0.33
P value	<0.01	NS	NS	NS

Conclusion: The ventricular contractility was significantly better with native AVD than paced AVD during submaximal exercise tests. During maximal treadmill exercise, PEA was a less sensitive indicator for ventricular performance.

P2334 A prospective, randomized comparison of QRS duration and QT interval between right ventricular apical and high septal lead placement in patients with dual-chamber pacemakers implanted for high-degree block

Z.I. Harris, H.J. Marshall, M.D. Gammage. *Cardiovascular Sciences Group, Division of Medicine, University of Birmingham, Birmingham, UK*

Background: Pacing from the right ventricular apex produces a wide and bizarre QRS complex, reflecting abnormal activation of the myocardium. Right ventricular high septal pacing produces more normal depolarisation and repolarisation patterns and should, therefore, produce a narrower QRS complex and shorter QT interval. Current data suggests that QRS prolongation can predict deterioration in systolic function with time.

Methods: We studied 24 patients receiving first implant dual chamber pacemakers for high degree AV block]. Patients were randomised to active fixation lead on the septum (n = 11) or a passive fixation lead in the apex (n = 13). ECGs were recorded pre implant, at 24 hours, and at 1 and 4 months post implant. All traces were recorded at 50 mm/sec and measurements were taken manually from the start of the bipolar pacing spike. Mean QRS duration and QT interval were calculated from the mean of 3 consecutive complexes per lead (36 complexes per ECG)

Results: The septal group QRS duration was significantly shorter at 24 hours and 4 months, and QT shorter at 4 months. Data are shown as mean ± standard deviation

	QRS (millisec)		QT (millisec)	
	Apical	Septal	Apical	Septal
Pre	107.5 ± 27.1	96.9 ± 28.5	493.8 ± 69.6	464.9 ± 127.0
24 hrs	160.8 ± 15.7	145.4 ± 15.4*	440.9 ± 26.6	422.3 ± 28.8
1 m	160.7 ± 14.8	150.0 ± 9.2	433.6 ± 22.0	395.7 ± 46.5
4 m	161.7 ± 7.4	145.9 ± 11.7*	426.7 ± 27.7	385.3 ± 14.9*

*p < 0.01

Conclusion: Septal pacing results in narrower QRS complexes and shorter QT intervals than apical pacing in the medium to long-term. These data suggest the potential for preserved cardiac function with septal lead placement over time; this observation will require further investigation.

P2335 Should single-lead VDD pacemakers be implanted in young patients?

Uwe K.H. Wiegand, Jürgen Potratz, Frank Bode, Hendrik Bonnemeier, Hugo A. Katus, Werner Peters. *Medical University of Lübeck, Department of Internal Medicine II, Lübeck, Germany*

Implantation of single-lead VDD-pacemakers is established in patients with AV-block and normal sinus node function. However, there is concern whether these devices should be implanted in physically active young patients in whom development of sinus node disease and atrial undersensing are of particular interest.

232 consecutive patients with isolated AV-block and VDD-pacemakers were investigated. This population was subdivided into 2 groups according to age at time of implantation: age $\leq$ 60 years (group A, n = 62) and age > 60 years (group B, n = 170). Follow-up visits included pacemaker telemetry, Holter monitoring and exercise testing 2 and 12 weeks after implantation followed by 6-months intervals. Minimal intraoperative ($MPOT_{IOP}$) and telemetered atrial potentials 2 weeks after implantation ($MPOT_{TEL}$), incidence of atrial undersensing (US), sinus node dysfunction (SND) and atrial arrhythmias (AA) as well as the maintenance of AV-synchronous pacing mode (AVS) were investigated.

	Age $\leq$ 60 years (A)	Age > 60 years (B)	p-value
$MPOT_{IOP}$ [mV]	1.61 ± 0.47	1.21 ± 0.57	<0.001
$MPOT_{Tel}$ [mV]	1.20 ± 0.55	0.65 ± 0.51	<0.001
US [%]	6.5	22.9	0.004
SND [%]	0.0	2.9	0.17
AA [%]	1.6	10.6	0.03
AVS [%]	1.6	93.5	0.048
Follow-up [months]	36 ± 11	33 ± 17	n.s.

Due to higher intraoperative atrial potential amplitudes and a less marked postoperative decrease of potential, $MPOT_{Tel}$ was higher in group A. In correspondence, incidence of US was markedly lower compared to group B. Showing a low overall incidence, SND was only observed in group B. Furthermore, incidence of AA was lower in group A. After a mean follow-up of 36 months, 98.4% of group A patients remained in the VDD-pacing mode.

Our data show a very low incidence of sinus node dysfunction and atrial arrhythmias in young patients with AV-block. Atrial sensing is improved compared to older patients. Thus, youth of patient should not be a reason to avoid VDD-pacemaker implantation.

P2336 Left ventricle coronary vein accessibility for implantation of a defibrillating ICD and/or pacing lead system

E. Meisel[1], D. Pfeiffer[2], Ch. Butter[3], M. Eldar[4], L. Engelmann[2], S. Hahn[5], B. Schubert[5], U. Michel[5]. *[1]Heart & Circulation Center, Dresden; [2]University Hospital, Leipzig; [3]Virchow Clinic & Berlin Heart Center, Berlin, Germany; [4]Sheba Medical Center, Tel Hashomer, Israel; [5]Guidant, St. Paul MN, USA; Brussels, Belgium*

Background: Pacing and ICD lead systems that incorporate an electrode inserted transvenously into coronary veins residing on the left ventricle have been proposed.

Methods: A study was conducted in twenty-four patients (Pts) receiving an ICD system to evaluate the ease of placing a lead into two different preselected coronary target veins on the left ventricle. The prototype lead emulated a left venous access (LVA) defibrillation and/or pacing lead and consisted of a modified 0.018″ guidewire. The LVA lead was inserted from the left subclavian vein into the coronary sinus via a guide catheter. Pts were randomized to attempt LVA lead insertion into either the anterior interventricular (AIV) or posterior vein (PV). Positioning was guided by a venogram. A crossover to the other vein location was allowed only if the initially randomized vein was not accessible.

Results: The LVA lead was successfully positioned in either the AIV or PV in all Pts (100%). The LVA lead was successfully inserted into the AIV in 12/13 Pts attempted (92%). In one patient the AIV was very narrow and therefore the LVA lead could not be passed. Mean time for insertion into the AIV was 16.0 ± 13.6 min (median = 10 min, range = 3–38 min). The LVA lead was successfully inserted into the PV in 12/14 Pts attempted (86%). In two Pts, the PV was too tortuous for placement of the LVA lead. Mean time insertion into the PV was 16.3 ± 14.6 min (median = 11 min, range = 1–50 min).

Conclusion: This is the first major study of the accessibility of coronary veins located on the left ventricle as potential sites for pacing or ICD lead system implantation. Results showed these sites can be accessed with a high degree of success. Pacing or ICD systems, particularly for patients with congestive heart failure, utilizing a lead placed deep into a coronary vein residing on the left ventricle are feasible.

P2337 Validation of the basis of paced activation sequence mapping

N. Pérez-Castellano, J. Almendral, J. Villacastín, A. Arenal, S. González, M. Ortiz, J. García, E. Pérez-David, J.L. Delcán. *Gregorio Marañón General Hospital, Madrid, Spain*

Paced activation sequence mapping (PASM) has been used for the ablation of atrial tachycardias. PASM attempts to locate the tachycardia origin by reproducing during pacing the activation sequence obtained during tachycardia. Our objective was to test the strength of the basic principles of this technique by studying the paced intra-atrial conduction, the reproducibility of time measurements and the resolution.

Methods and results: In 20 patients undergoing an electrophysiologic study, a decapolar catheter was stably set at the lateral right atrium describing a figure-of-9 in 45° LAO view. Three consecutive 10 mm-spaced electrode pairs were selected. Bipolar pacing was consecutively performed from each of them and bipolar electrograms were recorded from the others. Pacing protocol consisted of a train of 7 impulses at 2 drive cycle lengths (300 and 350 ms) and 2 pacing outputs (twice and tenfold the threshold amplitude at 2 ms pulse width). Local activation time was considered as the point when the largest rapid deflection crosses the baseline. We analyzed 240 pacing sequences. Cycle length and activation direction did not influence conduction time. The change in pacing output from twice to tenfold the threshold value shortened the conduction time by 1.9 ms [95% confidence interval (CI) 1.5–2.2 ms, p < 001]. Two observers measured twice a random sample of 48 recording (20%). The 95% limits of intraobserver and interobserver agreement were ± 2.6 ms and ± 2.9 ms respectively. The resolution was estimated by measuring the successive time changes in the relative activation of 2 appropriately placed references produced when pacing site is switched to each contiguous 3 mm-spaced electrode pair of a 20-pole catheter set into the coronary sinus. The median shift was 7.5 (range 2.5–20) ms per 3 mm.

Conclusions: The low intra and interobserver variability and high temporal-spatial resolution support PASM as an alternative to conventional activation mapping to localize focal tachycardias. The small impact of a tenfold increase in pacing output suggests that formal threshold measurements may not be necessary.

P2338 Evaluation of the left ventricular contractile function in irregular heart beat created by different pacing mode

T. Tabata, R.A. Grimm, T.N. Mazgalev, N.L. Greenberg, D.A. Agler, D.W. Walliack, Y. Yamanouchi, J.D. Thomas. *Department of Cardiology/F15, Cleveland Clinic Foundation, Cleveland OH, USA*

Backgrond: The assessment of the left ventricular (LV) contractile function during atrial fibrilation is problematic due to beat to beat variability. Purpose: We evaluated LV systolic function during varying RR intervals produced by different pacing conditions using a canine atrial fibrillation (AF) model.

Methods: Epicardial echocardiography, LV pressure recording and aortic flow measurement were performed simultaneously in 8 healthy mongrel dogs during triggered AF and right ventricular (RV) pacing. AF was induced by programmed random rapid right atrial pacing. Heart rate was slowed during AF by vagus nerve stimulation (VNS). The AV junction was subsequently ablated by radiofrequency energy and random slow rate RV pacing was performed. The LV stroke volume (SV) was calculated using LV outflow Doppler velocity profile. The maximum value of the first derivative of LV pressure curve (+dP/dt) and aortic peak flow rate (AOF) by transonic flow meter were also recorded. The ratio of the preceding RR interval to the pre-preceding RR interval (RR1/RR2) was evaluated during all conditions.

Results: 1) All the variables showed significant positive correlation with RR1/RR2 in each pacing mode. 2) The value at RR1/RR2 = 1 in the linear regression line showed similar change by different pacing mode for all variables (table).

	Base(sinus)	Rapid AF	AF+vNS	Ablation+Rvpace
SV (ml)	18.2	10.7	15,2	14.9
AOF (l/min)	1.02	0.48	0.76	0.64
+dP/dt (mmHg)	2727	2406	2838	2421

The value at RR1/RR2 = 1 in the linear regression line for each indeces in different pacing modes.

Conclusions: 1) Indices of LV contractile function during periods of variable RR intervals closely correlated to the ratio of the preceding RR interval to the pre-preceding RR interval. 2) The value at RR1/RR2 = 1 can allow us to estimate LV contractile function during atrial fibrillation.

P2339 Detection of atrial arrhythmias in DDD pacemaker by automatic interpretation of data analysis – a new tool for follow-up

S. Sack, N. Dagres, J. Herrmann, A. Golles, P. Defaye[1], E. Mouton[2]. *Dept. of Cardiology, Medical School, University of Essen, Essen, Germany; [1]Dept. of Cardiology, CHU Michallon, Grenoble; [2]Le Plessis Robinson, Ela Medical, Paris, France*

Arrhythmias and pacemaker (PM) dysfunction are difficult to document even during follow-up. In the new generation of PMs, a variety of diagnostic tools are available, which makes rhythm control possible. Analysis is time consuming and requires experience.

Methods: With a recently introduced software (AIDA), Holter data of the PM are automatically analysed and results are shown in a comprehensive way. In the AIDA multicenter trial, 836 patients (pts) were included in 12 countries. Chorus II PM, equipped with an automatic fall back mode switching algorithm, was implanted in 232 pts. PM Holter data were compared with surface Holter electrocardiogram after 1 day (D1) and with clinical symptomatology after 28 days (D28). Bipolar atrial lead was mandatory to adjust high sensitivity (0.4 mV).

Results: Study group consisted of 151 males (65%) and 81 females (35%) with a mean age of 69 ± 12 years. After D1, 35 pts (15%) developed at least one episode of supraventricular tachycardia (SVT) (26 pts atrial fibrillation, 9 pts atrial tachycardia). Sensitivity and specificity was 97.2% and 96.4% for AIDA compared to Holter. Lead fixation type (tined 43%, screw-in 57%) did not effect SVT incidence. Pts with SVT were older (73 ± 10 vs. 68 ± 12 years, $p < 0.01$). After D28, 100 pts (47%) developed SVT, of whom 51% were asymptomatic. Thirty six pts (36%) were asymptomatic and with no history of SVT. Arrhythmias (AA) detected at D1 are shown in the table.

Arrhythmias detected at D1:

	Sensitivity	Specificity
Atrial sensing failure	80%	98%
Atrial sensing failure during AA	95%	100%
Endless loop tachycardia	100%	100%
Ventricular ectopic beats	93%	99%
Atrioventricular crosstalk	83%	99%

In conclusion, the new AIDA software in the Chorus II PM seems to be a useful tool in detecting SVT, delivering reliable results as compared to surface Holter, the "golden standard" so far.

P2340 Paradoxical undersensing of high atrial rates with increasing sensitivity in dual-chamber pacemakers

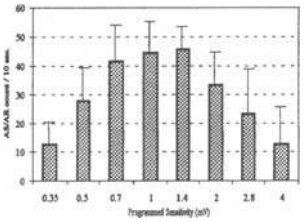
Rik Willems, Patricia Holemans, Hugo Ector, Frans Van de Werf, Hein Heidbüchel. *Cardiology, University of Leuven, Leuven, Belgium*

Dual chamber pacemaker therapy in patients with supraventricular arrhythmias depends critically on an accurate detection of the atrial rate.

Background: We developed a sheep model of atrial fibrillation (AF) based on rapid atrial pacing. We used bipolar atrial leads in all animals to assure appropriate atrial sensing. In a subgroup, Thera D(R) (Medtronic®) pacemakers, programmed to deliver a burst of 42 Hz on detection of sinus rhythm (SR), were implanted. In 5 sheep that developed chronic AF, we noticed during the arrhythmia a significantly higher frequency of inappropriate bursts at higher sensitivity levels, indicating that the pacemaker misjudged the atrial tachycardia.

Methods: We assessed the atrial detection by counting the atrial sensed events (AS/AR) reported by Thera D(R) and Marathon (Intermedics®) DDD(R) pacemakers in sheep with AF and using a waveform generator.

Results: We demonstrated that paradoxically during AF the pacemaker recognized fewer atrial events at a higher sensitivity (cf. graph. for Thera D(R)). Using the waveform generator we saw that at rates above 6 Hz (cycle length < 166 ms) there was a critical sensitivity above which the pacemaker failed to report appropriately the atrial activity. This cut-off value was a function of the amplitude and waveform of the signal used. It was possible to mislead the Thera's mode switch feature.



Conclusion: This paradoxical undersensing can not be explained by a programmable software defined setting, but is hardware dependent and based on saturation of the atrial amplifier. Knowledge of this behavior is important for cardiologists using dual chamber pacemakers in patients with paroxysmal AF. There is an optimal sensitivity level dependent on the amplitude of the atrial sensed signal. It may therefore not be appropriate to program the sensitivity as high as possible.

P2341 The SYDIT (Syncope: Diagnosis and Treatment) study: preliminary data

Ammirati, F. Colivicchi, S. Toscano, R. Ricci, M. Pepe[1], S. Cavaglia'[1], F. De Seta[1], M. Santini. *[1]Dipartimento delle Malattie del Cuore, Ospedale S. Filippo Neri, Rome, Italy; Medtronic Italia*

Background: Cardiac pacing has proven a valuable therapeutic option in the treatment of recurrent cardioinhibitory vasovagal syncope. However, an empirical tilt-guided pharmacological therapy has been considered the first step in a correct approach to recurrent vasovagal syncope so far.

Methods: Aim of the present open randomized clinical trial is to compare the effectiveness and safety of pharmacological therapy (Atenolol or Etilephrine) versus cardiac pacing (DDD with rate drop response function, RDR) in the long-term treatment of recurrent vasovagal syncope. Patients are included in the investigation if they fulfill the following criteria: 1) no cardiac disease, 2) age > 35 yrs, 3) at least 3 syncopal spells in the preceding 2 yrs, 4) positive head -up tilt testing with an heart rate drop of more than 30% and a lower heart rate less than 50 bpm. Eligible patients are randomized to pharmacological therapy (initially Atenolol 100 mg die, with a switch to Etilephrine 50 mg die in case of syncope recurrence despite treatment) or cardiac DDD with RDR pacing (pacemaker Medtronic Thera DR). Pacemaker programming is made according to the heart rate behavior during head-up tilt testing. Patients are followed for syncope recurrence (main end-point).

Results: To date 24 patients have been included and randomized (15 females and 9 males, mean age 59.1 yrs); 11 patients have received a pacemaker while 13 patients are on drug treatment. During the follow-up (mean duration 5.8 months) 3 patients on pharmacological treatment have experienced a syncopal episode, while no such event has been noted in any pacemaker patient.

P2342 Spontaneous sarcoplasmic reticulum Ca^{2+} release occurs at lower luminal Ca^{2+} content in heart failure

Paul Neary, Godfrey L. Smith, Stuart M. Cobbe. *Clinical Research Initiative in Heart Failure, Glasgow University, Glasgow, UK*

Ventricular arrhythmias are common in heart failure (HF). One postulated mechanism for the generation of ventricular arrhythmias is spontaneous sarcoplasmic reticulum (SR) Ca^{2+} release which may generate early after depolarisations via activation of the Na^+-Ca^{2+} exchanger. There is evidence, however, that SR Ca^{2+} uptake and therefore SR Ca^{2+} content is reduced in HF, which would be expected to reduce the likelihood of spontaneous SR Ca^{2+} release. We measured frequency and amplitude of spontaneous SR Ca^{2+} release in permeabilised ventricular myocytes from a rabbit model of HF.

Methods: Single ventricular myocytes were isolated from the hearts of New Zealand White rabbits with HF induced by coronary artery ligation and from sham operated rabbits. Myocytes were permeabilised using β-escin, allowing perfusion of the cytosol with a mock intracellular solution containing 100–250 nM $CaCl_2$. SR Ca^{2+} release was measured by inclusion of Fura-2. The frequency of spontaneous release was measured at 100–250 nM cytosolic [Ca^{2+}]. Amplitude of spontaneous Ca^{2+} release reflected SR Ca^{2+} content.

Results: The table shows that SR Ca^{2+} content was lower in HF cells. Spontaneous Ca^{2+} release is less frequent at low cytosolic [Ca^{2+}], but above 150 nM Ca^{2+}, this difference disappears.

Cytosolic [Ca]	100 nm	150 nm	200 nm	250 nm
HF amp. (nM)	27.2 ± 7.2	37.5 ± 4.3	48.7 ± 4.1	65.6 ± 6.3
Sham amp. (nM)	49.4 ± 7.4	68.4 ± 9.2	73.4 ± 10.4	106.7 ± 14.1
p =	>0.05	<0.05	<0.05	<0.01
HF freq. (Hz)	0.01 ± 0.01	0.03 ± 0.01	0.08 ± 0.01	0.14 ± 0.02
Sham freq. (Hz)	0.03 ± 0.01	0.05 ± 0.01	0.09 ± 0.01	0.14 ± 0.02
p =	>0.05	<0.05	>0.05	>0.05

Conclusion: In situations of increased cytosolic Ca^{2+} levels, spontaneous SR Ca^{2+} release remains a potential arrhythmogenic mechanism despite a reduction in SR Ca^{2+} content.

P2343 Ventricular arrhythmias in rabbits with overload induced heart failure are related to calcium aftertransients

J.T. Vermeulen, A. Baartscheer, C.A. Schumacher, C.N.W. Belterman, F.J.G. Wilms-Schopman, J.W.T. Fiolet, R. Coronel, T. Opthof, M.J. Janse. *Department of Clinical and Experimental Cardiology, University of Amsterdam, Netherlands*

Background: Ventricular arrhythmias are common in patients with heart failure. Calcium handling is abnormal in failing myocardium. We studied the relation between arrhythmias *in vivo* and calcium handling *in vitro* in a combined volume and pressure overload model of heart failure in the rabbit.

Methods: In control rabbits and rabbits with heart failure (HF rabbits) 24 hour Holter recordings were made. Myocytes were isolated from the same hearts and loaded with Indo-1 to measure intracellular calcium in isolated myocytes. Rapid cooling was performed to estimate sarcoplasmic reticular calcium content (SRCC). Burstpacing during exposure to norepinephrine (50 nMol/L) was used to elicit aftertransients (elevations in calcium following a stimulated calcium transient).

Results: Arrhythmias were not observed in control rabbits (n = 5). In 4 of 6 HF rabbits ventricular couplets and/or short runs of ventricular tachycardia (VT) were detected. In 9 of 13 cells isolated from HF rabbits hearts with couplets or VT, calcium aftertransients could be induced, but only in one out of 18 cells from hearts from control rabbits or HF rabbits without couplets or VT ($p < 0.05$). Both diastolic and systolic calcium were elevated in HF rabbits compared with control rabbits (26 HF rabbit cells vs 17 control rabbit cells: diastolic calcium 125.5 ± 12.0 vs 75.5 ± 5.9 and systolic calcium 285.3 ± 29.7 vs 187.7 ± 16.5, $p < 0.05$). SRCC tends to be higher in myocytes from HF rabbits (23 HF rabbit cells 375.1 ± 46.9 vs 17 control rabbit cells 270.2 ± 17.6 nMol/L).

Conclusion: In rabbits with overload induced heart failure, ventricular arrhythmias are related to calcium aftertransients. The occurrence of aftertransients may be related to altered calcium release from the sarcoplasmic reticulum.

P2344 Transvenous techniques for pacing and ICD leads removal: a long-term single centre experience

M.G. Bongiorni, E. Soldati, G. Arena, G. Gherarducci, M. Favaro, C. Giannessi, M. Mariani. *Cardiovascular and Pulmonary Dept, University of Pisa, Pisa, Italy*

Transvenous removal of pacing and ICD leads has today an high success rate and a low incidence of serious complications. This has changed the management of infected leads as well as of most abandoned leads. However, the procedures are often complex and the experience of the operators seems to affect both results and complications.

Materials and Methods: From December 1989, 582 leads in 365 pts (261 men, 104 women, mean age 65.2 years, range 17–93) were managed. In total, 551 pacing leads, 354 ventricular and 197 atrial leads, and 31 defibrillating leads, among which 21 ventricular, 3 atrial and 7 SVC leads, required removal; their mean implantation period was 66.2 months (range 0.5–276). We used the Cook Vascular extraction kit and, when necessary, other intravascular tools (Catchers and Lassos, Sulzer Osypka).

Results: Among the 582 leads, the technique was judged to be not applicable in 14 (2.4%) leads. Removal was attempted in 568 leads; 534 leads (503 pacing leads and all the 31 ICD leads) were removed (94%). Globally, 91.8% of the leads submitted to our attention were successfully extracted. The success rate has increased over time. In the first 3 years (63 leads) it was 73%, while in the period 1993–95 (160 leads) it was 88.1%; in the last 3 years (345 leads) 97.7% of the leads were removed. Serious complications occurred in 6 cases (1.01%); we observed 3 cases of cardiac tamponade, 2 pulmonary embolisms, 1 undesired dislodgement of a chronic pacing lead.

Conclusions: Our experience shows that the success rate and the complications are highly affected by the experience of the staff. The transvenous removal techniques are very effective in well trained and experienced Centres; the possibility of life-treathening complications requires the availability of cardiosurgical stand-by.

P2345 Ancillary tools in pacemaker and defibrillator lead extraction using the vascoextor lead removal system

Antonis S. Manolis, Themos Maounis, John Chiladakis, Vassilis Vassilikos, Eleni Manolis, Dennis V. Cokkinos. *Patras University, Patras; Onassis Cardiac Surgery Center, Athens, Greece*

A new pacing lead removal system (VascoExtor, VascoMed, D) with 3 types of locking stylets (S, L or K) and recently 1 type (Magic) was used over 25 months to extract 40 pacemaker leads in 24 pts and 3 defibrillator (ICD) leads in 3 pts (19 men & 8 women, aged 66 ± 14 yrs). Indication was pacer infection (n = 19), pacer (n = 4) or ICD (n = 3) lead dysfunction or prior to ICD implant (n = 1). Leads were in place for 3.7 ± 3.9 yrs. Infections involved both pocket & lead(s) and were due to S. epidermidis (12), S. aureus (5), S. aureus plus E. coli (1) or fungi (n = 1). Skin erosion was present in 14 pts. Of the 40 pacing leads, 10 were unipolar ventricular, 14 bipolar ventricular, 4 unipolar atrial, 8 bipolar atrial, 2 unipolar VDD, all tined, and 2 bipolar active fixation atrial leads. The ICD leads were 2 two-coil leads (Endotak, CPI) and 1 one-coil lead (EnGuard, Telectronics). Using the S (11 pts) or K (7 pts) or Magic (2 pts) stylets, all pacing leads & 2 ICD leads were removed in 20 pts from a right (n = 15) or left (n = 4) or right & left (n = 1) subclavian approach by traction (6 atrial leads) or sole use of VascoExtor stylets (25 pacing leads/2 ICD leads). However, in 7 pts (26%) ancillary tools were required. In 3 pts fragments of atrial and ventricular leads were captured and removed with a noose catheter or a pigtail catheter or a bioptome. In another pt, locking could not be effected and a noose catheter from a right femoral (RF) approach was used and aided by pigtail & Amplatz catheters plus a bioptome to finally remove 2 leads. In a pt with ICD lead, a combined left subclavian (stylet S) and RF approach (using a noose catheter) was required due to lead separation. In a pt with a dysfunctional unipolar ventricular lead implanted 12 years earlier, to facilitate exchange of locking stylets, a motor drive unit was used, but extraction failed. VascoExtor sheaths were helpful only in 1 pt. Finally, lead removal was successful in 26/27 pts (96%) or 42/43 leads (98%) without complications.

Conclusion: to enhance the success of pacing or defibrillator lead extraction with use of the VascoExtor locking stylet system, an array of ancillary tools are required in 26% of pts.

P2346 Usefulness of intracardiac echocardiography during transvenous leads removal procedures. An early experience

M.G. Bongiorni, R. Baglini, G. Arena, E. Soldati, G. Gherarducci, S. Fiorilla[1], H. Schwaier[1], M. Mariani. *Cardiovascular and Pulmonary Dept, University of Pisa, Pisa, Italy; [1]Boston Scientific Corporation, EPT Europe, Paris, France*

Although transvenous lead removal is today an effective and safe technique, possible life-treathening complications must be considered, which require careful monitoring and fast diagnosis. In addition, the availability of information about 1) the condition of the intravascular part of the leads to remove, 2) the presence and extension of adhaerences to the venous wall, 3) the dimension of endocarditis vegetations and their relation with the cardiac structures, is very helpful for planning and performing removal procedures. The aim of our study was to evaluate the usefulness of Intracardiac Echocardiography (ICE) during transvenous lead removal procedures.

Materials and Methods: ICE was performed in 6 patients (4 men, mean age 74.6 years) who underwent removal of 10 pacing leads due to infection of the pacing system. The procedures were performed using the Cook Extraction kit (Cook Vascular Inc., Leechburg, PA, USA). ICE was performed using a 9 French 9 Mhz catheter, ICE Ultra, connected to Clear View Ultra EC 1003 ultrasound console (Boston Scientific Corp., S. José, CA, USA). The ICE catheter was inserted through the femoral (5 pts) and right internal jugular vein (1 pt).

Results: In all the patients, the ICE catheter allowed clear visualization of the leads and their course. The adhaerences to the venous wall were easily detected in all cases. During dilation by sheath, ICE allowed monitoring the dilation, and the relation between the sheath and the anatomical structures. In 1 patient, ICE allowed detection of small vegetation on the lead, which was not identified by TEE. During the removal procedure, the position of the vegetation and its relation with the dilating sheath were easily monitored. No complication related to the use of ICE was observed.

Conclusions: Transvenous lead removal represents another field for possible application of ICE. Our initial experience confirmed the usefulness of this imaging technique in guiding the procedure and monitoring the possible complications.

P2347 Laser-assisted endocardial lead extraction: a venographic study

S.S. Mushahwar, H.A. Fewins, R.G. Charles, D.T. Connelly. *The Cardiothoracic Centre, Liverpool, UK*

Excimer laser assisted endocardial lead extraction is described as a safe and efficacious procedure. Although the laser energy used has a limited adsorption depth (0.06 mm), it is not clear whether or not local tissue damage can unexpectedly occur, and cause unwanted complications.

We retrospectively assessed the effects of laser-assisted lead extraction on related venous structures.

Fourteen patients (pts) (12 male) required complete explantation of pacing systems for infection (7), erosion (6), and intractable discomfort (1). Mean age (+SD) was 64.4 +16.2 years. Mean duration (+SD) of lead implant was 91.9 +23.3 months. Total leads removed were 36 leads (2.6/patient). Laser assisted extraction was required for 28 leads, whereas countertraction using a locking stylet was sufficient for the remaining eight leads. No acute complications occurred. One pt developed superior vena caval obstruction within 4 weeks.

Venography was performed in this cohort of pts. Mean duration to venography (post-procedure) was 18 weeks (14.8). Venography in 6 (43%) of the pts demonstrated abnormalities of the implantation vein. Four pts had complete occlusion of the implant subclavian vein, of which three were asymptomatic. The other two had narrowing of the subclavian vein. The remaining eight venograms were normal.

Conclusion: Despite the reported safety of laser-assisted endocardial lead extraction, venography demonstrates that damage to associated venous structures is common. This may be of no clinical consequence, but further long-term follow-up is necessary.

P2348 Injury of the tricuspid valve resulting from laser sheath extraction of chronically implanted pacemaker and ICD leads

F.A.L.E. Bracke, C.J. Botman, L.M. van Gelder, C.H. Peels, A. Meijer. *Department of Cardiology, Catharina Hospital, Eindhoven, Netherlands*

Introduction: The laser sheath is successful for extracting chronically implanted pacemaker and ICD leads. However, there are no data on the risk of injuring the tricuspid valve with application of the laser during extraction of ventricular leads. Therefore, transesopagheal echocardiography was performed before and after laser sheath extraction.

Methods: In 12 consecutive patients (pts) 9 ventricular pacing leads and 3 ICD leads were extracted with an Excimer laser sheath. Mean age 61.5 years (range 33 to 85 years). A 12 F laser sheath was used in 7 leads, a 14 F in 2 leads, a 16 F in 2 ICD leads and a 12 F and 16 F in one ICD lead. Indication for extraction was infection in 5 pts and lead malfunction in 7 pts.

Results: Before extraction, 9 pts had mild, 3 pts moderate tricuspid valve regurgitation. After extraction, regurgitation remained unchanged in 9 pts but increased from mild to moderate in 3 pts, including an ICD patient. In all 3 pts a new regurgitation jet through the leaflet was apparent with colorflow. A new tear in a leaflet was visible on 2-D echocardiography in 2 pts. The laser sheath used in these pts was 12 F in 2 pts, 12 F/16 F in 1 pt. (ICD lead).

Conclusion: Laser sheath extraction of ventricular pacemaker and ICD leads resulted in direct injury to the leaflets of the tricuspid valve in 25% of pts, with significant echocardiographic increase in valve regurgitation. Although the clinical consequences need further evaluation, these results caution against indiscriminate extraction of multiple superfluous leads in asymptomatic patients.

P2349 Prevention of pacemaker and defibrillator infections: safety and efficacy of perioperative H_2O_2 use in 990 patients

Eckhard U. Alt, Andreas Plewan, Francesca Leipold. *I. Med. Klinik, Klinikum rechts der Isar; German Heart Center, Technische Universität München, Munich, Germany*

Background: Infections of biomaterials are of concern following implantation. Despite the preventive use of antibiotics, there is an infection rate of 2–5% associated with implantation of pacemakers and defibrillators.

Methods: In collaboration with the institute for microbiology we tested the possible benefit of 3% H_2O_2 in treating polyurethane and silicone electrodes and found a significant reduction of the number of bacteria after a single wiping and rinsing and of the polymere structures. Additional in vitro tests also showed that 3% H_2O_2 had no effect on the structural integrity of the silicone and polyurethane material determined by SEM and by mechanical testing. Based on these experimental results, all patients (pts) were prospectively treated with the adjunctive use of 3% H_2O_2 during implantation. A single dose of a standard cephalosporine was given before implantation to all pts.

Results: From 1993 to 1997, 990 pts were operated by the same implanting cardiologist. 721 operations were new implantations, 269 replacements. Among those were 150 defibrillator, 435 DDD, 139 AAI, and 266 VVI pacemaker implantations. The mean age for pacemaker pts was 73.2 ± 12.5, for defibrillators 56 ± 11.6 years. The mean operation time for pacemakers was 42.4 ± 22.7, for defibrillators 51.3 ± 25.6 minutes. Among those 990 pts, one infection of a defibrillator and one infection of a pacemaker occurred in the perioperative setting, both with staphylococcus epidermidis (0.2%). The infection rate for the same center and implanting physician with no significant difference as far as the type of pacemaker, age or other patient related factors were concerned, showed an infection rate of 1.83% for the years prior to the use of H_2O_2 ($p < 0.01$).

Conclusions: The perioperative use of H_2O_2 in 990 pts reveals this method to be highly effective and safe in the prevention of perioperative infections of pacemakers and defibrillators. Its use is simple, fast and highly cost-effective.

P2350 Myocardial perfusion abnormalities in permanent paced patients without coronary artery disease

A. Le Helloco, J.L. Alberini, A. Devillers, M. Bedossa, P. Bourguet, C. Almange. *Department of Cardiology, University Hospital, Rennes, France*

The aim of this study was to evaluate the frequency and the topography of myocardial defects (M.D.) assessed by Thallium tomography (SPECT) in patients (pts) with permanent cardiac pacing. 28 pts implanted with dual chamber pacing for AV block (18 pts) and sinus node disease (10 pts) with normal coronary arteries were included in this prospective study and were divided in group 1 (16 pts) with normal myocardial perfusion and group 2 (12 pts) with reversible or not myocardial defect. All pts underwent exercise test, dipyridamole SPECT, echocardiography with analysis of septal movement (S.M.) radionuclide angiography with left ventricular ejection fraction (LVEF) and coronary angiography. Thallium images were divided in 16 segments and the severity of reduction in Thallium uptake was scored using a four point grading system in each patient (1 = normal uptake to 4 = severe reduction).

Results:

	Group 1	Group 2	
Age	66.3 ± 5.5	64.1 ± 11.6	NS
Angina	11	9	NS
Permanent pacing (mths)	54 ± 22.8	48.4 ± 21.8	NS
LVEF (%)	63.7 ± 3.7	53.1 ± 5.6	$p < 0.0005$
Paradoxal S.M.	5	10	$p < 0.01$

In 9 pts. reversible or irreversible defect was present in infero-apical (75%) or septo-apical territory (25%). A good correlation was noticed between the severity of defect and altered LVEF in paced pts.

Conclusion: Moderate M.D. can be induced by permanent cardiac pacing in pts without CAD (42.9%). Apical permanent pacing can deteriorate LVEF in some pts with myocardial perfusion abnormalities.

P2351 A new algorithm to optimize the AV delay based on the QT interval: for which patients?

P. Defaye[1], L. Belle[2], P. Chavernac[3], S. Guérin[4]. [1]*University Hospital, Grenoble;* [2]*Hospital, Annecy;* [3]*Hospital, Castres;* [4]*Vitatron, Issy les Moulineaux, France*

Optimal programming of AV delay (AVD) in dual chamber pacemaker is essential to allow a good mechanical synchronization of the atrium and ventricle, and an adequate ventricular filling time. Our previous studies showed an apparent relation between the optimal AVD and the longest QT interval (Qti). The aim of the study was to evaluate accurately the variations of QTi versus the AVD. The study was conducted in 11 patients (pts), 70 ± 18 years old, presented with a 2/1 (4 pts) or a complete AV block (7 pts) and implanted with a Vitatron Diamond I or Diamond II device. Ejection fraction (EF) was normal (>60%: EFN) for 7 pts and low (<45%: EFL) for 4 pts.

Methods: Pacing rate was fixed at 80 bpm to capture the atrium. The pacing mode was set on DDDR mode and the AVD varied from 90 to 300 ms by step of 30 ms. External ECG associated with device event markers was recorded continuously during all the measurements at a paper speed of 200 mm/sec to measure accurately QTi.

Results (*: $p < 0.005$):

(ms)	EFN	EFL	p
Optimal AVD	130 ± 50	168 ± 62	0.16
Longer QTi	334 ± 16	374 ± 19	0.003*
Non adequate AVD	186 ± 45	214 ± 70	0.24
Shorter QTi	331 ± 16	367 ± 20	0.007*
p (AVD)	0.23	0.21	
p (QTi)	0.0014*	0.0011*	

Conclusion: The new results confirmed the existing relation between QTi and optimal AVD. The most significant variation was found for patients with low EF. A new study has been set up to measure automatically QTi for different AVD.

P2352 Three-year follow-up of VDD therapy: results of the ELVIS study

M.J. Jakob[1], N. Treese[2], A. Schuchert[3], A. Schöpfel[4], W.A. Stertmann[5], J. Kreuzer[6], G.F. Rettig-Stürmer[1]. *[1]On behalf of the ELVIS-study group, Hospital Sulzbach; [2]Marienhospital Osnabrück; [3]UKE, Hamburg; [4]Hospital Kitzingen; [5]Justus-Liebig University, Centre of surgery; [6]CCB Bethanien, Germany*

The aim of the study was to evaluate the role of VDD-pacing in pacemaker-therapy.

Methods: From 19. Jan 94 to 26 July 96 176 patients (p) in 10 German investigational centers recieved the VDD-pacer Unity™ (Intermedics, Angleton TX, USA) for symptomatic AV block. All p were chronotropically competent. 36 months post implant data from 99 p were analyzed.

Results: Of these 99 p 28 died, of which in 22 cases the underlying cause was heart disease. No significant changes concerning sinus node function could be observed over time. AV-sequential stimulation reached 98.1%, mode survival was 92% at 36 month follow-up.

Follow-Up	1 month	12 months	36 months
Patients (n)	102	153	71
Sinus rate (min^{-1})	76.8 ± 14.7	75.2 ± 13.6	80.7 ± 15.4
AV-synchronisation (%)	96.5 ± 6.6	98.0 ± 4.9	98.1 ± 15.4
VVI-stimulation (%)	2.2 ± 5.9	1.1 ± 4.8	0.8 ± 2.6
Mode-survival (%)	100	93.4	92.0
Permanent Afib (%)	0	3.2	8
Paroxysmal Afib (%)	n.i.*	n.i.	9%
Revisions (n)	3	0	0
Atrial signal (mV)	1.1 ± 0.5	1.2 ± 0.5	1.2 ± 0.4
Deaths (n)	0	8	28

*not investigated

The incidence of permanent atrial fibrillation (pAfib) reached 3.2% within the first year and 8% at the end of the 36 months period. Paroxysmal Afib was recorded in 9%. 4 of the p with pAfib had CAD, one had hypertonus. No significant difference regarding sinus rate and p-amplitude at 1 month follow-up could be observed in comparison to those p, in whom no Afib evolved over time. P with sinus rates between 50 and 60 min^{-1} did not develop Afib. Need for revision was very low with a rate of 1.7%.

Conclusions: 1. VDD-pacing is physiologic and efficient. 2. Incidence of pAfib is associated with the underlying heart desease and not with the VDD-mode. 3. Need for revision is low.

P2353 One-year follow-up multicentre study using the Olbi stimulation technique with an implantable single-lead pacing system

J.F. Stockinger. *On behalf of the OLBI Multicenter Study Group; Müritz Klinik, Klink, Germany*

Purpose: In a multicenter study the clinical practicability of single lead dual chamber stimulation was investigated. During the 12 months follow-up the feasibility of the atrial stimulation with biphasic pulses, the chronaxy rheobase relation during floating stimulation and the technical integrity of the lead were proven.

Methods: In 42 pts (mean age: 75 ± 10 years), indication AV-block II–III without sinus node dysfunction, a single lead VDD system (DROMOS SL M7, BIOTRONIK) was implanted, which is able to stimulate the atrium with two overlapping biphasic pulses (OLBI-Stimulation). We determined the atrial and diaphragmatic pacing threshold at 4 different pulse durations in different positions up to 12 months after implantation.

Results: For the chronaxy rheobase relation only the examinations with successful atrial stimulation at 0.25 ms, 0.5 ms, 0.75 ms and 1.0 ms pulse duration were used. For discharge the pulse duration threshold relation is shown in the following table:

Pulse duration (ms):	0.25	0.50	0.75	1.00
Atrial threshold (V):	2.94 ± 0.99	2.23 ± 0.67	1.99 ± 0.61	1.85 ± 0.47

The atrial stimulation was successful in 27 of 42 patients at discharge, in 22 of 33 patients at 6–8 weeks follow-up, in 15 of 30 patients at 6 months follow-up, and 13 of 22 patients 12 months post implantation. The atrial pacing threshold at 0.25 ms pulse duration increased from 2.7 V at discharge to 3.1 V at 6 months to 3.3 V at 12 months follow-up. The P-wave amplitude decreased from 1.7 mV at discharge to 1.5 mV at 6 months follow-up and to 1.4 mV at 12 months follow-up.

The development of the ventricular sensing and pacing threshold is shown in the following table:

	Discharge	6–8 weeks	6 months	12 months
R wave (mV):	9.7 ± 3.9	12.3 ± 4.8	13.1 ± 5.0	12.6 ± 6.5
Pacing threshold (V):	1.5 ± 0.7	1.6 ± 0.7	1.5 ± 1.3	1.3 ± 0.4

Conclusion: With the use of OLBI stimulation the successful stimulation of the atrium is possible. The lead shows a high reliability concerning the atrial and ventricular sensing threshold, and the ventricular pacing threshold. It could be demonstrated that there exists a well defined chronaxy rheobase relation for atrial pacing using the OLBI stimulation. For the clinical application further technical developments are necessary.

P2354 Clinical validation of new pacing-sensing configurations for automatic atrial capture verification in pacemakers

C. Butter, W. Hartung[1], M. Stockburger, R. Willems[2], G. Zhang[3], D. Lang[3], E. Fleck. *Deutsches Herzzentrum Berlin; Charité, Campus Virchow-Klinikum, Berlin; [1]Otto von Guericke University, Magdeburg, Germany; [2]Guidant/CPI, Brussels, Belgium; [3]Guidant/CPI, St. Paul MN, USA*

Introduction: Automatic Capture Verification (ACV) may guarantee maximal patient safety; it may also increase device longevity and save time during follow-ups. A major obstacle for ACV by evoked response detection is pacing induced afterpotential (AP). It is more problematic in atrial than in ventricular ACV, because atrial evoked response (AER) is smaller and occurs earlier after pacing. The aim of this study is to perform atrial ACV by analyzing AER signals using a conventional monophasic waveform to pace atrium between A-tip and Can. To reduce AP, small coupling capacitors (CC), and independent pairs of electrodes between A-ring and V-tip (AV) or between A-ring and an electrically isolated indifferent electrode (AI) were used for AER sensing.

Method: Patients (pts), indicated for DDD pacemaker, were included in the acute study. After lead implantation and routine measurements, a custom made external pacing system (Guidant/CPI, St. Paul, MN) with multi-channel data acquisition capability was connected to the leads. An automatic protocol with step-up and stepdown pacing (0.1 to 7.1 V at 0.5 ms, steps of 0.1 V) was performed. Different CC (2 μF and 15 μF) were used. AI and AV signals were independently analyzed both real-time and off-line to detect AER. Every pacing beat was also visually inspected and compared with surface ECG to verify capture. With the intracardiac signals properly filtered, the detection was based on the signal within a window of 12–60 ms after the pacing spike.

Result: Data from 17 acute pts, age 66.0 ± 13.0 yr., were analyzed. Bipolar atrial lead measurements, using a standard PSA, were (mean ± SD) impedance 736 ± 240Ω, P-wave amplitude 4.7 ± 2.5 mV, slew-rate 1.7 ± 1.3 $V.s^{-1}$ and pacing threshold at 0.5 ms 0.9 ± 0.4 V. The results with CC = 2□F showed that out of 3225 collected atrial pacing beats, correct capture verification was 99.91% for sensing in the AI and 99.44% in the AV channel. Although smaller CC is preferable for shorter and smaller AP, the results showed that larger CC worked well too (99.91% and 99.41%, respectively).

Conclusion: The new independent pacing-sensing configurations can greatly reduce and shorten after-potentials. Therefore, they provide AER signals that can be used for atrial ACV.

P2355 Correlation between sensor signal and sinus rhythm in patients implanted with a rate responsive pacemaker driven by contractility: long-term evaluation

J. Clémenty[1]. *On behalf of the European PEA Clinical Investigation Group; [1]Hôpital du Haut-Lévêque, CHU de Bordeaux, 33604 Pessac, France*

Background: From December 95 to October 97, 100 patients (pts) were implanted with the dual chamber Rate Responsive (RR) system (SORIN Living 1 – BEST) for a multicentric European clinical evaluation. The first study assessed the good correlation between Peak Endocardial Acceleration (PEA) and sinus atrial rate and demonstrated that PEA is a significant parameter for driving RR.

Aim of the study: From January 97 to October 97 a group of 70 pts enrolled in the clinical study (mean age 67 ± 11.8 yrs, 42 male, 28 female) were evaluated at 1 year. Sixty-one pts out of 70 underwent stress test, and in 42 pts 24 h Holter monitoring, including continuous recording of the PEA signal, was performed. PEA signal values at rest and during stress test were analysed and compared with 1 month data.

Results: The PEA and HR data at 1 year vs 1 month are summarised in the following table:

	Basal conditions		Maximum	
(1 g = 9.8 m/sec^2)	PEA (g)	HR (ppm)	PEA (g)	HR (ppm)
1 month	0.41 ± 0.26	73 ± 9	1.63 ± 0.77 ± 123 ± 20	
1 year	0.45 ± 0.29	71 ± 11	1.72 ± 0.83	127 ± 15

The PEA vs HR correlation during stress test at 1 month was R = 0.63 ± 0.16 ($p < 0.005$) while at 1 year was R = 0.71 ± 0.18 ($p < 0.005$). During the 24 h Holter monitoring the PEA signal followed very closely the spontaneous heart rate (data at rest: PEA = 0.41 ± 0.3, HR = 65 ± 10; during activity: PEA = 1.4 ± 0.7, HR = 104 ± 18).

Conclusions: The 1 year follow-up data confirmed a good correlation between PEA and spontaneous heart rate in patients with normal sinus function. The PEA signal demonstrated to be a stable parameter in long term conditions and reliable to be used as physiological sensor in driving RR pacemakers and monitoring heart rate changes. The long term experience also demonstrated the absence of any adverse effect and the reliability of the sensor mounted on the tip of a standard lead.

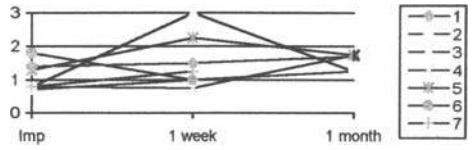
P2356 Threshold values in biventricular pacing for congestive heart failure

Ali Oto, Aylin Yildirir, Mustafa Kemal Batur, Elif Sade, Serdar Aksöyek. *Hacettepe University Dept. of Cardiology, Ankara, Turkey*

Synchronous biventricular pacing with the electrodes implanted in the right ventricule (RV) and the coronary sinus (CS) has been evolved as a new modality for intractable congestive heart failure. Pacing threshold (T) in CS has been a major limitation for left ventricular (LV) pacing. However with the new CS leads and new lead technology it has been possible to achieve lower T values. We evaluated the T values in biventricular pacing during implantation and follow-up up to 1 month.

Methods and Results: Seven patients (5 M, 2 F; mean age 61.6 ± 8.5, range 52–73), 5 ischaemic and 2 idiopathic dilated cardiomyopathy were included in the study. Mean efor capacity was 3.0 ± 2.7 METS with Naughton protocol and mean EF was 27.9 ± 10.8%. All patients had intraventricular conduction defect and 2 had atrial fibrillation. RV and CS leads (Medtronics 2188 CS lead) and an additional atrial lead for the patients in sinus rhythm were implanted with a mean implantation time of 93.0 ± 12.8 min and a mean scopy time of 28.8 ± 5.1 min. T values for atrium, RV and CS could be measured separately as the QRS axis changed at the point of CS T with the output gradually decreased. T values are given below.

	Baseline			First Week
	Threshold (V)	P or R wave (mV)	Impedance (Ω)	Threshold (V)
Atrium	0.8 ± 0.2	11.6 ± 8.2	507 ± 130	0.6 ± 0.3
RV	0.4 ± 0.1	19.9 ± 6.6	606 ± 110	0.7 ± 0.3
CS	1.1 ± 0.4	19.2 ± 9.5	629 ± 136	1.5 ± 0.9
Biventricular	0.8 ± 0.3	22.1 ± 7.2	836 ± 199	1.5 ± 0.9



Conclusion: Therefore we conclude that pacing from the CS with the new electrodes may solve the T problem for LV pacing.

P2357 Feature of the clinical manifestation of myocardial infarction in females in Kyrgyzstan

N. Tsoy, M. Mirrakhimov. *National Centre of Cardiology and Internal Medicine, Bishkek, Kyrgyzstan*

The aim of the investigation was to evaluate feature of the clinical course of myocardial infarction (MI) in females. Case histories of 387 patients with MI who were admitted to the coronary care unit were studied. Risk factors, clinical manifestation, complications and in hospital mortality were evaluated. There were 262 males and 125 females. The mean age of males and females was 55.8 ± 3.0 and 62.9 ± 3.1, respectively ($p > 0.05$). White females had more frequently MI than Kyrgyz females (80.8% vs 7.2%, $p < 0.001$). Majority females (93.6%) had menopausal period. Females as compared to males more frequently had prior history of arterial hypertention (43.2% vs 16.8%, $p < 0.01$), type I and II diabetes (15.2% vs 5.7%, $p < 0.01$), obesity (16.0% vs 6.9%, $p < 0.01$). Females less frequently had previous MI (13.6% vs 24.8%, $p < 0.01$), smoking (8.0% vs 52.0%, $p < 0.001$). There were no significant difference in the size, localization and incidence of necrosis by ECG between the groups. Females had a somewhat higher incidence of heart failure (Killip) during the in hospital period than males but the difference was not statistically significant (35.9% vs 28.6%, $p > 0.05$). Recurrent MI occurred more often in females compared to males (18.4% vs 9.5%, $p < 0.05$). In hospital mortality rate was of 12% in females vs 5.7% in males ($p < 0.05$).

Thus, the incidence of MI is lower in females than in males. MI more frequently develops in white females with more comorbid condition: hypertention, diabetes, obesity. The incidence of recurrent ischemia, in hospital mortality occurs more frequently in females.

P2358 Silent myocardial ischaemia and diabetes mellitus in Mexican patients with coronary heart disease

A. Unzueta, J. Escobedo[1], A. Torres, R. Moreno, A. Unzueta, Jr., J.M. Hurtado[1], J.J. Rivera, G. Medina, H. Hernández. *Hospital of Cardiology, National Medical Center Siglo XXI, Mexico; [1]Division of Epidemiology, Coordination of Comunity Health, Mexican Institute of the Social Security, Mexico City, Mexico*

Patients with diabetes are at increased risk for coronary heart disease and perhaps also for silent ischemia. We conducted a cross-sectional study to assess the effect of diabetes on the occurrence of silent ischemia.

Methods: A total of 249 patients with coronary heart disease was screened with a 24-hour Holter electrocardiogram. Silent myocardial ischemia was diagnosed according to the American Heart Association criteria. All recordings were blinded analyzed by two independent physicians and one of the authors. Diabetes was diagnosed according to the American Diabetes Association criteria. Continuos variables were analyzed using ANOVA or the Kruskal-Wallis (KW) test. To evaluate the independent effect of diabetes on the occurrence of silent ischemia, a logistic regression analysis was conducted. Odds ratios (OR) were calculated to assess association, with 95% confidence intervals ($CI_{95\%}$).

Results: There were 165 non-diabetics and 84 diabetics. Silent ischemia was more frequent in diabetics (52% vs. 44%), but there was no difference on the mean number of ischemic events. Total ischemic time per 24 hours was similar, but the median duration of ischemia in 24 hours was greater in diabetics (66 minutes vs. 40.5 min.; KW = 4.8, p = 0.03), as was the median ischemic time per episode (41.3 vs. 27.6; KW 5.31, p = 0.02). Duration of diabetes was related to silent ischemia and there was a 3.5% increased risk for each year of diabetes history (OR 1.03, $CI_{95\%}$ 1.0–1.08).

In conclusion, diabetes may increase the risk of silent myocardial ischemia. Diabetic autonomic neuropathy involving the cardiac afferent sympathetic system may be its cause. Silent ischemia seems to be more severe in diabetics, mainly as the evolution of the disease is longer.

Day 4

Tuesday, August 31, 1999

OPTIMIZED CARDIAC PACING

2440 Haemodynamic effects of adjunct DDD-pacing in patients with high-grade atrioventricular block after transcoronary ablation of septum hypertrophy for hypertrophic obstructive cardiomyopathy

F.H. Gietzen, Ch.J. Leuner, J. Hegselmann, C. Strunk-Muelier, H.J. Kuhn.
Dept. of Cardiology, Bielefeld Hospital, Bielefeld, Germany

Transcoronary ablation of septum hypertrophy (TASH) is an effective catheter interventional therapy for HOCM. However, beside reduction of septal thickness, elimination of outflow obstruction and improvement of symptoms, the injection of 96% ethanol into a first septal branch leads to intermittent or permanent high-grade AV block in up to 28% of the pts..

To evaluate the relative merits of isolated TASH compared with those of a combined therapy, the symptomatic and hemodynamic benefits of adjunct DDD-pacing were estimated by serial invasive measurements 2 weeks and 7 months after intervention. 32 out of 119 pts. (27%) treated catheter-interventionally were provided with a dual-chamber pacemaker because of high-grade AV block 48 hours after TASH, and 9 additional pts. (8%) had preexisting pacemaker therapy of HOCM. During follow-up pacemaker dependence was observed in 14 pts. (12%) because of a persistent high-grade AV block. With regard to baseline characteristics – like age, gender, septal thickness, gradients, NYHA functional class, exercise tolerance and PA-mean pressure at workload – no significant differences were found between the 78 pts. (65%) with an isolated TASH-procedure and the 41 pts. (35%) with a concomitant DDD-pacemaker therapy.

In the "pacemaker provided group" the decrease in resting gradient (-38 ± 40 versus -45 ± 37 mmHg, n.s), postextrasystolic gradient (-109 ± 60 versus -108 ± 48 mmHg, n.s.), NYHA functional class (-1.4 ± 0.7 versus -1.3 ± 0.6, n.s.) and pulmonary artery mean pressure at workload (-8 ± 9 versus -8 ± 8 mmHg, n.s.) did not exceed the effects documented in the "isolated TASH group". However, pts. with an isolated TASH procedure demonstrated a more pronounced improvement of the exercise tolerance ($+28 \pm 23$ versus $+15 \pm 21$ watts, $p = 0.044$), a more complete preservation of the left ventricular ejection fraction (-1% versus -5%) and were treated by a lower amount of ethanol injected (3.2 ± 1.9 versus 4.1 ± 2.6 ml).

Conclusion: The necessity of adjunct DDD-pacing seems to be a result of a more aggressive ablation procedure and does not improve the symptomatic and hemodynamic benefits of TASH in HOCM.

2441 Effect of atrioventricular delay on left ventricular diastolic function in patients with DDD-pacing for complete atrioventricular block

N.I. Gouzoumas, I.H. Styliadis, H.I. Karvounis, I.G. Nouskas, G.E. Parharidis, G.E. Louridas. *Ist Department of Cardiology, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece*

Dual Chamber (DDD) pacing with a short atrioventricular (A-V) delay may improve cardiac function in patients (pts) with heart failure and compromised systolic left ventricular (LV) function, as suggested by preliminary observations. However, comprehensive data on how permanent DDD-pacing affects hearts with abnormal LV-diastolic parameters and preserved systolic LV-function are currently incomplete. This study was designed to evaluate how A-V delay affects already impaired Doppler-derived LV-diastolic indexes in pts with normal systolic LV-function.

Methods: Eleven pts [5 males/6 females aged 65.4 ± 14.2 years (range 25–78)] were enrolled. Pts had a DDD pacemaker implanted for complete A-V block, were asymptomatic (NYHA Class I, LV-ejection fraction > 57%) and were examined 1 year after implantation. Pts underwent Doppler assessment of transmitral flow during pacing at A-V delay values of 100, 150 and 200 ms in a randomized fashion. The following Doppler indices were measured: peak E wave velocity (PVE), peak A wave velocity (PVA), E/A ratio, E wave deceleration time (DTE), mitral filling time (MFT) and isovolumic relaxation time (IVRT). Calculations were done at a constant heart rate of 80 bpm in all pts.

Results: Comparisons between measurements at different A-V delay values are depicted in the table. DTE could not be measured at 200 ms because of E and A wave fusion. "p" denotes overall significance for repeated measures ANOVA test.

Variables	Atrioventricular delay values (ms)			p
	100	150	200	
PVE (m/s)	0.50 ± 0.11	0.48 ± 0.13	0.45 ± 0.12	<0.0005
PVA (m/s)	0.82 ± 0.19	0.88 ± 0.14	0.94 ± 0.15	<0.001
E/A ratio	0.63 ± 0.23	0.56 ± 0.14	0.50 ± 0.12	<0.037
MFT (s)	0.39 ± 0.05	0.36 ± 0.04	0.31 ± 0.04	<0.0005
IVRT (s)	0.10 ± 0.02	0.11 ± 0.02	0.10 ± 0.01	<0.352
DTE (s)	0.12 ± 0.02	0.10 ± 0.01	–	–

Paired comparisons between the various A-V delay values investigated showed significant differences in all variables studied except IVRT (the highest significance [$p < 0.0005$] was found comparing A-V delay values of 100 and 200 ms).

Conclusion: During permanent DDD-pacing for complete A-V block, Doppler indices of diastolic LV-function improved significantly at the shortest A-V delay value investigated (optimal measurements at 100 ms).

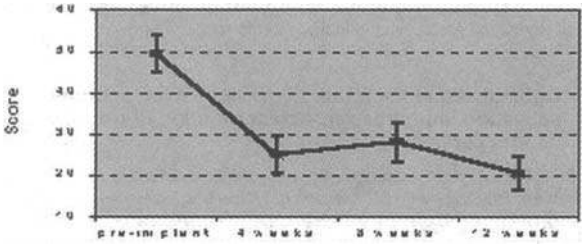
2442 Optimized atrioventricular pacing on right, left or biventricular sites impressively improves quality of life

S. Sack, U. Wolfhard[1], N. Dagres, A. Golles, A. Aurrichio[2], W. Hoersch[3], T. Pochet[3], R. Erbel. *Dept. of Cardiology, Medical School, University of Essen, Essen; [1]Dep of Thoracic and Cardiovasc Surgery, University of Essen, Essen; [2]Dept. of Cardiology, University of Magdeburg, Magdeburg, Germany; [3]Guidant Europe, Brussels, Belgium*

Atrioventricular (AV) pacing has recently been introduced as a promising method to improve clinical outcome in patients (pts.) with end-stage congestive heart failure (CHF).

Methods: In 42 pts. (21 males, 21 females, 60 ± 6 years) with CHF (EF $21 \pm 7\%$), permanent pacemaker systems for right (RV), left ventricular (LV) or biventricular (BIV) stimulation were implanted. Best unichamber (RV or LV) and BIV modes at different AV intervals were evaluated in terms of pulse pressure and first derivative of LV pressure (dP/dt). For long term follow-up, pts. were stimulated at best unichamber or BIV mode for 4 weeks (w) in a randomized fashion. After a wash-out period with no pacing for another 4 w, permanent pacing in the remaining mode was tested. Quality of life was evaluated by the Minnesota Living with Heart Failure Questionnaire (LHFQ), designed for CHF patients. LHFQ contains 21 items addressing physical and emotional dimension.

Results: Improvement in quality of life observed by reduction of LHFQ Score could be demonstrated impressively after 4 weeks ($p < 0.001$). After a wash-out period (8 weeks) with no benefit, further improvement occurred at 12 weeks ($p < 0.05$ vs. 8 weeks). Interestingly, gender analysis showed much more benefit for males than for females ($p < 0.05$).



LHFQ Score.

In conclusion, permanent AV sequential pacing at best unichamber or biventricular mode impressively improves quality of life. Available data encourage this new therapeutic option in CHF patients.

2443 Effects of lead position on cardiac function in de novo dual-chamber implants: a randomised, prospective study of high septal versus apical lead positioning within the normal heart

Z.I. Harris, H.J. Marshall, M.D. Gammage. *Cardiovascular Sciences Group, Division of Medicine, University of Birmingham, Birmingham, UK*

Background: Right ventricular apical pacing is known to produce localised areas of left ventricular (LV) hypertrophy due to abnormal contraction patterns. This produces dyskinetic wall motion resulting in systolic and diastolic dysfunction. A more physiological approach may be to position the lead on the interventricular septum in order to more closely mimic normal activation sequences. Whilst alternative pacing sites are becoming more readily accepted as an option for lead placement, little is known of the consequences of septal pacing in the normal heart, or more importantly whether this method can preserve cardiac function.

Methods: We studied 24 patients receiving first implant dual chamber pacemakers for high degree AV block with normal ventricles [Fractional Shortening (FS) > 30% determined by echocardiogram, no regional wall motion abnormality and no history of cardiac disease]. Patients were randomised to septal (n = 11) or apical pacing (n = 13). Echocardiograms were performed at 24 hours, 1 and 4 months post implant to measure LV systolic (LVIDs) and diastolic (LVIDd) internal dimensions and FS. All patients were ventricular pacing dependant.

Results: LVIDd was significantly lower in the septal group at 24 hours, 1 and 4 months poat implant, and LVIDs at 24 hours and 1 month. Data are shown as mean ± standard deviation (SD)

	LVId (mm)		LVIDs (mm)		FS (%)	
	Apical	Septal	Apical	Septal	Apical	Septal
24 hr	49 ± 4.3	44 ± 6.9*	36 ± 5.9	31 ± 4.6*	36.6 ± 9.9	38.5 ± 6.9
1 M	52 ± 5.1	43 ± 4.0*	36 ± 4.9	31 ± 4.2*	35.9 ± 7.8	37.8 ± 8.9
4 M	53 ± 5.9	43 ± 6.6*	37 ± 5.8	31 ± 5.9	36.2 ± 7.8	38.5 ± 7.8

*$p < 0.05$

Conclusion: These data suggest preserved systolic function in patients with septal leads as compared to the apically paced group. These data suggest that septal pacing in the previously normal heart preserves left ventricular function better than traditional apical pacing in the short to medium term.

2444 Optimal sequence rather than minimal asynchrony of activation improves ventricular function during ventricular pacing

F.W. Prinzen, M.F.M. van Oosterhout, W.Y.R. Vanagt, C. Storm[1], R.S. Reneman. *Physiology Dept., Maastricht University, Maastricht; [1]Cardiology Dept., Zuiderziekenhuis, Rotterdam, Netherlands*

Abnormal electrical activation, as occurring during ventricular pacing and left bundle branch block (LBBB), reduces LV pump function. We compared two approaches to optimize LV function using ventricular pacing: minimal asynchrony and optimal sequence of electrical activation.

Methods: ECG and hemodynamics (aortic flowprobe, LV pressure and its 1st derivative LVdP/dt) were measured in anesthetized open-chest dogs during pacing (DDD AV interval 25 ms) from various sites. Experimental LBBB was induced by RF-ablation.
