T.D. Wang[1], C.C. Cheng[2], W.J. Chen[3], Y.T. Lee[2]. [1]*National Taiwan University Hospital, Internal Medicine (Cardiology), Taipei, Taiwan, Province of China;* [2]*National Taiwan University Hospital, Dept. of Internal Medicine (Cardiology, Taipei, Taiwan, Province of China;* [3]*National Taiwan University Hospital, Emergency Medicine, Taipei, Taiwan, Province of China*

Objective: Hypercholesterolemia is associated with greater myocardial ischemia-reperfusion injury, in which apoptosis and inflammation-mediated necrosis both play a key role. Caspase-1 is involved in the activation of both apoptosis and inflammation, through the intermediate of interleukin-1b(IL-1b). In this study, we examined whether pharmacological inhibition of the caspase-1 cascade, using Ac-YVAD.cmk, after myocardial ischemia have greater protective effects on myocardial ischemia-reperfusion injury in diet-induced hypercholesterolemic rabbits.
Methods and results: Sixty male New Zealand White Rabbits, fed with standard chow or chow supplemented with 1% cholesterol for 8 weeks, were subjected to 30 minutes of left circumflex artery occlusion followed by 4 hours of reperfusion. An intravenous bolus of Ac-YVAD.cmk (1.6 mg/kg) or vehicle was given 20 minutes after coronary occlusion in each group. The infarct size (% of risk region) was significantly greater in cholesterol-fed rabbits than in normally fed ones (41±6% vs. 26±3%, P=0.003). Postischemic administration of Ac-YVAD.cmk markedly decreased infarct size from 26±3% to 12±2% in normally fed rabbits (P=0.005) and from 41±6% to 14±2% in cholesterol-fed rabbits ($P<0.001$). In the ischemic non-necrotic area, the percentage of TUNEL-positive cardiomyocytes was significantly greater in vehicle-treated cholesterol-fed rabbits compared with normally fed ones (39.0±2.3% vs. 15.5±0.8%, $P<0.001$), whereas treatment with Ac-YVAD.cmk markedly reduced the percentage of TUNEL-positive cardiomyocytes from 15.5±0.8% to 2.2±0.1% in normally fed rabbits ($P<0.001$) and from 39.0±2.3% to 2.2±0.1% in cholesterol-fed rabbits ($P<0.001$). Although myocardial IL-1b levels and activity of both caspase-1 and caspase-3 in the ischemic area were significantly higher in vehicle-treated cholesterol-fed rabbits compared to normally fed ones, Ac-YVAD.cmk treatment resulted in a reduction not only of IL-1b and caspase-1, but also of caspase-3 in both normally fed and cholesterol-fed rabbits. Furthermore, no differences in IL-1b levels and activity of caspase-1 and caspase-3 were observed between Ac-YVAD.cmk-treated normally fed and cholesterol-fed rabbits.
Conclusion: This study demonstrates that injection of a selective caspase-1 inhibitor after myocardial ischemia completely abolished the detrimental effect conferred by hypercholesterolemia on myocardial ischemia-reperfusion injury by attenuating both necrotic as well as apoptotic cell death pathways through inhibition of IL-1b production and activation of caspase-1 and caspase-3.

P1189 The postischaemic functional recovery of the myocardium is reduced by endogenous endothelin-1

M.E. Beyer[1], T. Hövelborn[1], M. Fischer[2], H.M. Hoffmeister[3]. [1]*Medizinische Universitaetsklinik, Abt. III, Tuebingen, Germany;* [2]*Medizinische Universitaetsklinik, Abt II, Regensburg, Germany;* [3]*Staedtisches Klinikum, Cardiology, Solingen, Germany*

Elevated plasma levels of the potent vasoconstrictor Endothelin-1 (ET-1) were observed in patients with coronary heart disease. The release of this peptide from the damaged endothelium may play a role in the initiation and maintenance of myocardial ischemia. This study examines the ETA-receptor mediated role of endogenous endothelin on postischemic myocardial function after prolonged hypoperfusion.

Methods: In an isolated rat heart model after 3h hypoperfusion (15% of preischemic coronary flow) followed by 2h reperfusion postischemic left ventricular functional recovery was determined (isovolumic steady state hemodynamics: LVP, dP/dtmax; maximal inotropic response: max LVP, max dP/dtmax). The effect of ET conversion inhibition by phosphoramidon (PHOSPH, 2 μmol/l) and of ETA-blockade by BQ 610 (0.8 μmol/l) during hypoperfusion was compared to saline controls (NaCl).

Results: 2h of reperfusion after hypoperfusion causes a partial functional recovery. This recovery is significant better after ECE-inhibition or after ETA-blockade.

	coronary flow	LVP	dP/dtmax	max LVP	max dP/dtmax
PHOSPH	57.7±4.1	58.2±2.5#	61.9±3.7#	73.3±10.3	74.1±17.0
BQ 610	54.1±5.0	56.0±2.5#	54.8±2.8¶	85.1±5.6*	84.5±6.3
NaCl	49.3±2.4	36.5±2.1	41.1±1.1	58.6±5.6	59.1±13.5

Mean ± SEM in % of preischemic values after 2h of reperfusion; *=p<0.05, ¶=p<0.01, #=p<0.001 vs. NaCl-group.

Conclusions: 2h after termination of hypoperfusion reperfused myocardium profits from ECE-inhibition or ETA-blockade during the prolonged period of hypoperfusion. This indicates that the postischemic functional recovery is reduced by endogenous ET-1 via ETA-receptors.

P1190 Low blood pressure during reperfusion reduces coronary flow and increases myocardial infarct size

E. Tsolakis, C. Charitos, K. Siafakas, A. Eleftheriou, A. Rapti, S. Drakos, A. Ntalianis, J. Nanas. *Dpt of Clinical Therapeutics, University of Athens, Athens, Greece*

Objective: The purpose of this study was to examine the effect of low blood pressure during reperfusion on the extent of myocardial infarction and on coronary blood flow (CBF) in an occlusion/reperfusion experimental model.

Methods: Twenty seven open chest pigs (22-35Kgr) underwent occlusion (O) of the middle left anterior descending coronary artery (LAD) for 1 hour followed by reperfusion for 2 hours. During reperfusion the animals were assigned to two groups; Continuous nitroglycerin infusion and fluid infusion at the appropriate rates were used to maintain mean arterial pressure (MBP) > 80mmHg in Group I (n=13) versus 60-75mmHg in Group II(n=14). The LAD coronary arterial flow was measured by transit time flowmetry and the hemodynamics and the distal to O coronary arterial pressures, were recorded before the O of the LAD and throughout the experiment. Blood pressure, heart rate, right and left atrial pressures were continuously monitored, and at the end of 3 hours, the infracted myocardium of the left ventricle was determined and expressed as the percentage of the myocardium at risk.

Results: There were no significant hemodynamic differences between the two groups before or during the LAD occlusion. During reperfusion the MBP was 89.9±3.3mmHg in Group I vs 68.7±2.5mmHg in Group II (p=0.000). In Group I the infracted myocardium was 50.3±4.3% of the myocardium at risk and in Group II 69.4±7.2% (p=0.000). During reperfusion the CBF in Group I was significantly higher than than in Group II. The CBF normalized to control level was follows: at first min 3.51±1.11 vs 2.24±1.29, p=0.097, at 5 min 2.94±0.34 vs 1.55±0.74, p=0.004, at 15 min 2.57±0.60 vs 1.24±0.74, p=0.011, at 60 min 2.01±0.69 vs 1.18±0.40, p=0.002, and at 120 min 1.41±0.88 vs 0.86±0.47, p=0.114 in Group I vs II respectively.

Conclusion: Low blood pressure during reperfusion increases the extent of myocardial infarction. This effect is most likely due to greater impairment of the coronary circulation accompanying the low blood pressure during reperfusion.

P1191 The protective effect of isosorbide dinitrate on cardiac mitochondria during ischaemia is not mediated by nitric oxide

P. Monteiro[1], S. Silva[2], J.P. Moura[2], A. Duarte[2], A. Moreno[2], L. Gonçalves[1], L.A. Providência[1]. [1]*Coimbra University Hospital, Cardiology Dept., Coimbra, Portugal;* [2]*Center for Neuroscience of Coimbra, Coimbra, Portugal*

Nitrates are one of the drugs more frequently used in the treatment of myocardial ischemia. Their anti-ischemic effect seems to be mediated by nitric oxide.

The aim of our study was to determine if the Isosorbide Dinitrate's (IDN) protective effects on the cardiac mitochondrial metabolism are also mediated by the release of nitric oxide.

We used an ex-vivo global myocardial ischemia model, with the use of a Lagendorff perfusion system. Forty Wistar rat's hearts were divided in 4 experimental groups - A (180 minutes of perfusion, with a Krebs modified solution), B (60 minutes of perfusion with the same solution, followed by 120 minutes of ischemia), C (as in B, but in the presence of IDN 1 mM) and D (as in B, but in the presence of IDN 1 mM and an nitric oxide synthase inhibitor: L-NAME 100 μM). Mitochondria were isolated and used to evaluate the activity of complexes I, II-III and IV of the mitochondrial respiratory chain (MRC), using their metabolic substrates (Glutamate/Malate, Succinate and Ascorbate/TMPD). The parameters evaluated were: Respiratory Control Ratio (RCR), O2 consumption during state 3 of mitochondrial respiration (S3), Maximal Mitochondrial Membrane's Electrical Potential (Delta Psi), Phosphorylative Lag Phase (PLP), Energetic Charges (EC) and Enzymatic Activities (EA) of each of the MRC complexes.

In the conditions studied, IDN decreased significantly S3 and was able to reduce the PLP to all the substrates considered; regarding Delta Psi, the result was globally positive, but only statistically significant when Glutamate/Malate was used. Values of EC, RCR and EA of Complexes I and IV were not significantly altered, while the EA of Complexes II-III was statistically superior to that of the ischemic group. In the group treated with L-NAME, the results were similar to those of the IDN group.

Results:

Groups/Parameters	IDN (Group B)	IDN + L-NAME (Group C)	p value (B vs. C)
Delta Psi (Glutamate/Malate)	98±1.5%	93.6±1.6%	p=n. s.
PLP (Succinate)	120.6±19.8%	111.1±18.5%	p=n. s.
EC (Glutamate/Malate)	81.9±5.2%	74.6±8.3%	p=n. s.
EA (Complexes II-III)	343.5±35.3%	369.9±26.4%	p=n. s.

Note: Values are expressed as % of control (Group A).

In conclusion, our study demonstrate that the cytoprotective effects of IDN on cardiac mitochondrial metabolism are not mediated by the release of nitric oxide.

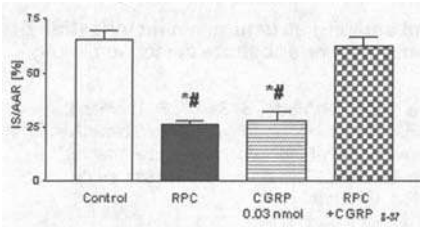
P1192 Calcitonin gene related peptide mediates cardioprotection after remote preconditioning

S. Wolfrum[1], J. Nienstedt[2], M. Heidbreder[2], K. Schneider[2], P. Dominiak[2], A. Dendorfer[2]. [1]*University of Luebeck, Medical Clinic II, Lübeck, Germany;* [2]*University of Luebeck, Institute for Pharmacology, Luebeck, Germany*

Objective: Brief ischemia-reperfusion periods of remote organs protect the heart from a pro-longed ischemic injury. Kinins and neuronal reflexes including sensory nerves contribute to the transduction of such remote preconditioning (RPC) to the heart. Because calcitonin gene related peptide (CGRP) is a well known mediator of sensory neurons we tried to delineate whether CGRP a) protects the heart from ischemic injury, b) is involved in cardioprotection after RPC, and c) leads to an activation of myocardial protein kinase C (PKC) e, a possible candidate for intracellular signal transduction of RPC.

Methods: Anesthetized rats pretreated with CGRP (0.03 nmol/kg) were subjected to 30 min of coronary artery occlusion followed by 150 min of reperfusion. Myocardial infarct size (IS) was measured by TTC staining and expressed as percentage of the area at risk (AAR). In separate experiments, RPC was achieved by brief mesenteric artery occlusion followed by reperfusion, in the presence or absence of CGRP8-37 (3 nmol/kg), a selective CGRP receptor antagonist. Rats either under-went myocardial infarction or PKCe was measured in myocardial membranes and cytosol by quantitative immunoblotting.

Results: IS/AAR% was significantly reduced in rats that received CGRP (28±4%) as compared with those receiving saline (65±5%). RPC significantly reduced infarct size (26±2%) and shifted the ratio between cytosolic and particulate PKCe, an indicator for PKC-activation, from 0.54±0.05 in controls to 0.21±0.03 (p<0.05). Infarct size reduction was abolished and PKC activation was significantly attenuated by CGRP8-37.



CGRP reduces infarct size.

Conclusions: CGRP protects the heart from ischemic injury and is involved in RPC, presumably by activating myocardial PKCe.

P1193 Remodeled myocardium: a new concept in heart failure

S.L. Moainie, T.S. Guy, J.H. Gorman III, B.M. Jackson, R.C. Gorman.
University of Pennsylvania, Division of Cardiothoracic Surgery, Philadelphia, United States of America

Introduction: Coronary artery disease is the leading cause of heart failure. Chronic ischemic syndromes (hibernating and stunned myocardium) have been identified and contribute to myocardial dysfunction. Most patients however develop heart failure insidiously after an acute MI without any further ischemic insults, suggesting that the infarct initiates a myopathic process in normally perfused myocardium.

Methods: In 6 sheep, 8 piezoelectric transducers were sutured within the myocardium of the long axis of the anterior wall of the left ventricle (LV). This allowed measurement of contraction in discrete segments of LV myocardium. Two weeks following instrumentation previously placed coronary snares were tightened, producing an antero-apical MI of 23% of the LV mass. Sonometric and hemodynamic data are collected pre-infarct and at 30 minutes, 2, 5 and 8 weeks postinfarction. Serial microsphere injections are performed at the 2, 5 and 8 week studies. Myocardial specimens are obtained using the sonometric transducers as markers thus allowing direct correlation of perfusion and functional data.

Results: Contractility in the infarct stopped immediately postinfarction and did not recover. The myocardium outside the infarct remained normally perfused throughout the study. Contractility of myocardium adjacent to the infarct decreased after the infarction. This hypocontractile region expanded and became more dysfunctional during the study period, despite unchanged perfusion. The table below presents percent change in contraction as compared to baseline in the remote, remodeled and infarcted myocardium at 30 minutes, 2 weeks, 5 weeks, and 8 weeks postinfarction.

Timepoint Post-infarction	Remote	Remodeled	Infarct
30 minutes	29.9%	46.2%	-182.6%
2 weeks	66.1%	25.2%	-158.6%
5 weeks	46.6%	-31.6%	-188.0%
8 weeks	14.9%	-96.8%	-163.5%

Conclusions: Postinfarction ventricular remodeling initiates a myopathic process in the noninfarcted myocardium that is initially localized to the region adjacent to the infarct but progressively expands to involve increasing amounts of normally perfused myocardium.

P1194 Interleukin-2 inhibition improves left ventricular function after induction of experimental myocardial infarction

C. Tschoepe[1], M. Koch[2], M. Scheeler[2], S. Dhayat[2], N. Dhayat[2], M. Noutsias[2], M. Pohl[2], H.-P. Schultheiss[2]. [1]*Benjamin Franklin Univ.-Hospital, Dept. of Cardiology, Berlin, Germany;* [2]*Benjamin Franklin Univ. Hospital, Cardiology Dept., Berlin, Germany*

Cardiac ischemia is accompanied with an increase in pro-inflammatory cytokines including interleukine-2 (IL-2).However, the role of IL-2 after induction of myocardial infarction (MI) is not known. We investigated the effect of an interleukin-2-fusion-protein (IL-2-IgG2b fusion protein) on ventricular function after induction of MI in a rat model.

Male Sprague-Dawley rats were submitted to a permanent occlusion of the left descending coronary artery or to a time-matched sham operation. Six hours before induction of MI rats were treated with a specific Il-2-fusion-protein or with vehicle and continued in a daily dose of 330µg for each animal (n=8 per group). 24h, 6 days or 3 w after operation, a Millar-tip-catheter was placed in the LV and LV pressure (LVP) and contractility (LVdp/dt max) were determined in anaesthetised and ventilated in open-chest animals. Finally, hearts were excised immediately for immunhistochemical examinations regarding IL-1β and collagen expression.

We found a decrease in LVP and contractility 24h (LVP: 56.8±2.4 vs. 80.9±4.2 mmHg; dp/dt max: 2620±158 vs. 3617±245 mmHg/sec; P=0.05) and 6d (LVP: 52.3±3.8 vs. 76.9±2.4;dp/dt max: 4423±261 vs. 2527±153 mmHg/sec; P = 0.05) after induction of MI compared to sham operated animals The impaired cardiac function was improved in animals treated with a IL-2-fusion-protein 24h post infarction (LVP: 72.8±3.6 mmHg; dp/dt max 3187±376 mmHg/sec). This improvement was also seen 6 d and 3 w after induction of MI. Improvement of LV function correlated with a reduction in cardiac IL-1β and collagen expression. No differences regarding the size of the infarcted area in the MI groups could be detected.

We present the first data for a selective blockade of Il-2 providing a significantly improvement of left ventricular function in experimental MI.

P1195 Macrophage migration inhibitory factor as a redox-sensitive cytokine in cardiomyocytes

M. Takahashi[1], Y. Ogata[2], S. Ueno[2], H. Mano[3], J. Nishihira[4], U. Ikeda[2], K. Shimada[2], E. Kobayashi[1]. [1]*Jichi Med. School, Organ Replacement Res., Minamikawachi-machi;* [2]*Cardiology*[3]*Functional Genomics, Jichi Med. School, Tochigi;* [4]*Hokkaido Univ. Sch. of Medicine, Central Res. Inst., Sapporo, Japan*

Macrophage migration inhibitory factor (MIF) plays a pivotal role in the control of inflammatory responses. Accumulating evidences indicate that inflammatory responses is associated with ischemic heart diseases. However, little is known about the MIF in the myocardium. We investigated the MIF production in patients with acute myocardial infarction (AMI), and the MIF's expression and role in the myocardium in vitro. MIF plasma levels were markedly elevated on day 1 and then decreased on days 7-21, but the levels on days 7 and 14 were still significantly higher than those in normal subjects. In contrast, although MIF levels in the supernatant of cultured peripheral blood mononuclear cells (PBMCs) from patients on day 1 after the occurrence of AMI showed no significant increase compared with those from normal subjects, the levels increased significantly on days 7-14. These findings suggest that the MIF production in patients with AMI differ between the acute and subacute stages of AMI by necrotic cardiomyocytes and activated mononuclear cells, respectively. To further investigate the MIF's expression and role in cardiomyocytes, we used cultured neonatal rat cardiac myocytes and showed that MIF production and mRNA expression were stimulated in response to hypoxia and hydrogen peroxide (H2O2), but not to angiotensinII, endothelin-1, interleukin-1, or tumor necrosis factor. H2O2-induced MIF production increased in a time- and dose-dependent manner and was completely abolished by the presence of catalase. The H2O2-induced MIF production was completely inhibited by the PKC inhibitor GF109203X, partially inhibited by the tyrosine kinase inhibitor herbimycin A, and uninhibited by calcium chelation or phorbol ester-sensitive PKC down-regulation. This suggests that H2O2-induced MIF production is mediated by an atypical PKC isoform. Furthermore, DNA microarray analysis revealed that 52 genes were preferentially expressed in response to MIF. Of these, the MIF-induced expression of glutathione S-transferase (GST), lipopolysaccharide-induced CXC chemokine (LIX), and insulin-like growth factor-binding protein (IGFBP-3) mRNAs was confirmed by RT-PCR analysis. These findings suggest that MIF is expressed by the cardiomyocytes in response to redox stress, and provide new insight into the pathological role of MIF in AMI.

P1196 T4 pretreatment and ischaemic preconditioning have additive cardioprotective effect possibly mediated by p38 MAPK attenuation during ischaemia

I. Paizis[1], C. Pantos[1], V. Malliopoulou[1], E. Karamanoli[1], P. Moraitis[1], D. Varonos[1], D.V. Cokkinos[2]. [1]*Univ. of Athens, Pharmacology, Athens;* [2]*Onassis Cardiac Surgery Center, 1st Cardiology Dept., Athens, Greece*

Introduction: Long-term thyroxine administration has been shown to protect the heart agaist ischaemic injury. This cardioprotection is associated with acceleration of ischaemic contracture (IC) and decreased activation of p38 MAPK during ischaemia and reperfusion. Ischaemic preconditioning (PC) is another cardioprotective mechanism that lowers preischaemic glycogen levels and thus accelerates IC. p38 MAPK attenuation has also been implicated in the protection conferred by PC. We investigated whether these two cardioprotective mechanisms exert an additive effect and whether this effect is associated with further decrease in activation of p38 MAPK in response to ischaemia-reperfusion (I/R) in the isolated rat heart.

Methods: Male Wistar rats were treated with L-Thyroxine (25ig/100g) subcutaneously once daily for 14 days (THYR) while normal rats treated with normal saline served as controls (NORM). The isolated hearts were perfused in the Langendorff mode and were subjected to the following protocols: 1) 20 min of stabilisation followed by 20 min of zero-flow global ischaemia (I), NORM(I), n=4 and THYR(I), n=4 2) 20 min of stabilisation followed by 20 min of I and 45 min of R, NORM(I/R), n=6 and THYR(I/R), n=6 3) 20 min of stabilisation followed by two cycles of PC (3min I, 5min R, 5min I, 5min R) and then 20 min of I, THYR-PC(I), n=4 and 4) 20 min of stabilisation followed by PC, 20 min of I and 45 min of R, THYR-PC(I/R), n=6. The postischaemic recovery of function was assessed by the recovery of left ventricular developed pressure (LVDP) expressed as % of the initial value (LVDP%). The acceleration of ischaemic contracture was assessed by the time to peak IC in min (Tmax). The levels of phosphorylated and total p38 MAPK were measured by Western blot analysis.

Results: LVDP% was 37.2(4.5) in NORM(I/R), 54.9(5.5) in THYR(I/R) and 77.9(4.5) in THYR-PC(I/R), $p<0.05$ between all groups. Tmax was 18.6(0.7) min in NORM(I/R), 12.4(0.4) min in THYR(I/R) and 6.1(0.6) min in THYR-PC(I/R), $p<0.05$ between all groups. Phosphorylated p38 MAPK was 1.9 fold higher in NORM(I) than in THYR(I), $p<0.05$ and 3.3 fold higher in THYR(I) than in THYR-PC(I), $p<0.05$. At the end of the reperfusion period phosphorylated p38 MAPK was 1.7 fold higher in NORM(I/R) than in THYR(I/R), $p<0.05$ while there was no significant difference between THYR-IR and THYR-PC-IR.

Conclusion: Thyroxine pretreatment and ischaemic preconditioning have additive cardioprotective effect. This protection might be due to profound attenuation of p38 MAPK activation during sustained ischaemia.

P1197 Myocardial protection via delta-opioid receptor activation in the isolated working rabbit heart

U. Sunderdiek[1], F. Nickel[2], B. Korbmacher[3], S. Schmitz-Spanke[3], E. Gams[3], J.D. Schipke[2]. [1]*University Duesseldorf, Thoracic and Cardiovascular Surgery, Duesseldorf, Germany;* [2]*University Hospital, Research Group Experimental Surgery, Duesseldorf, Germany;* [3]*University Hospital, Thoracic and Cardiovasc. Surgery, Duesseldorf, Germany*

Objective: Delta-opioid receptors are known to mediate natural hibernation and are involved in ischemic preconditioning. In an experimental model of ischemia and reperfusion the protective capacity of the synthetic delta-opioid receptor agonist D-Ala(2)-D-Leu(5) enkephalin (DADLE) was assessed, and it was compared with the capacity of mannitol, a potent non-specific free-radical scavenger. In addition, the protection after administration of both agents was assessed.
Methods: 28 isolated, blood-perfused working rabbit hearts were subjected to 20 min of normothermic ischemia followed by 60 min of normothermic reperfusion. Rabbit hearts were pre-treated with DADLE (D, 440 nM, n=8), mannitol (M, 8.5 mM, n=7), or a combination (D+M, n=8). The postischemic functional recovery of the hearts and troponin T (TnT) concentration were determined.
Results: Pre-treatment with DADLE alone and in combination with mannitol reduced significantly ischemic contracture by 21% and 58%, respectively. Postischemic recovery of aortic flow, when compared with non-treated hearts, was significantly improved (D 60.7% ± 11.0% and M 67.8% ± 14.3% and D+M 69.0% ± 14.2% of preischemic baseline). Myocardial oxygen consumption was also improved after pre-treatment compared with untreated hearts (D 76.7% ± 8.6% and M 80.8% ± 6.3% and D+M 79.0% ± 7.3% of preischemic baseline; $p < 0.05$), as well as an external efficiency index (stroke work/MVO2; D 76.7% ± 9.5% and M 84.8% ± 6.3% and D+M 71.0% ± 8.2% of preischemic baseline; $p < 0.05$). With DADLE pre-treatment, early postischemic TnT release was lower than M and control (0.28 ± 0.11 vs. 0.38 ± 0.09 vs. 0.48 ± 0.12 ng/ml at 60 min reperfusion; $p < 0.05$).
Conclusions: We provide experimental evidence that functional protection is effectively mediated via pharmacologic activation of delta-opioid receptors or scavenging oxygen-derived radicals (mannitol) in isolated, blood-perfused, working rabbit hearts. Since the combination of both protective agents did not provide an additional effect, we suggest that both protective measures act via a common pathway, e.g. attenuation of oxidant stress. Pre-treatment with DADLE reduces more effectively ischemic cellular injury, i.e. TnT degradation, and further adds to postischemic functional recovery.

P1198 Reduction of myocardial infact size by fluvastatin

C.P. Tiefenbacher, T. Bleeke, J. Kapitza. *Univ. of Heidelberg, Cardiology, Heidelberg, Germany*

Endothelial dysfunction with a decreased availability of NO is causatively involved in the development of reperfusion injury not only by the reduction of endothelium-dependent vasodilation but also by an increased expression of cellular adhesion molecules resulting in enhanced extravasation of activated neutrophils. Statins have been shown to improve endothelial cell function by increasing the availability of NO. We, therefore, hypothesized that statin therapy decreases myocardial infarct (MI) size and neutrophil extravasation.
Methods: In an in situ perfused rat heart model, MI was induced by ligation of the left coronary artery (LCA) for 50min, followed by 60min reperfusion. Myocardial blood flow (MBF; hydrogen clearance) and regional myocardial function (MF; pulsed doppler) were measured continuously during the experiments. MI size was determined by TTC staining and expressed as infarcted area/area at risk. Fluvastatin (fluva, 100μg/kg) was given as continuous intravenous infusion starting 20min before the ligation. Neutrophil extravasation was measured by determination of myeloperoxidase activity (MPO). The effect of fluvastatin on NO production was investigated in HUVEC.
Results: Fluva significantly attenuated the decrease of MF and reduced infarct size without influencing the reduction of MBF (control: MF 9.1%, MIsize 70.5%, MBF 1.8ml/min/g; fluva: MF 11.8%, MIsize 53.6%, MBF 1.9ml/min/g. In addition, MPO activity was significantly reduced in the fluva-treated group. In HUVEC, fluva increased cGMP production by 2fold.
Conclusion: These data indicate that exogenous substitution of fluvastatin reduces the size of myocardial infarction by attenuating neutrophil extravasation and possibly by increasing the availability of NO. We, therefore, conclude that statins may be helpful in the prevention of reperfusion injury.

P1199 Cross-talk between nitric oxide and cyclooxygenase metabolic pathways in HUVEC

C. Vassalle, V. Lubrano, C. Domenici, A. L'Abbate. *Institute of Clinical Physiology, CNR, Pisa, Italy*

Introduction: It is well known that endothelium is involved in the control of vascular integrity and function through the release of both vasodilators, such as nitric oxide (NO), prostacyclin (PGI2) and prostaglandin E2 (PGE2) and vasoconstrictors. The possibility that vessel homeostasis may be maintained through a compensatory mechanism between different metabolic pathways has been proposed. However, the existence of a cross talk between endothelial PGs and NO release has not been completely clarified. Our aim was to evaluate the interaction between NO and prostaglandins (PGs) release in HUVEC, human umbelical vein endothelial cells. Methods: Medium samples were assayed for nitrite/nitrate (NOx) assay (Griess Reaction, Cayman), endothelial NOSynthase quantification (EIA assay, R&D System) and L-citrulline (colorimetric assay based on its reaction with diacetyl monoxime), as markers for NO release. In addition prostaglandin E2 (PGE2) and 6-keto prostaglandinF1alfa (PGF1a, metabolite of PGI2) quantification (EIA assays, Cayman) were evaluated as indicator of COX activity. Six experiments were performed for each 24 hour treatment. Results: L-arginine 100 and 250 μM increased both NOx (mean±SE: from 22.8±1.6 to 28.95±2.7, 38±4cells μM/100000 cells, $p<0.01$) and 6-ketoPGF1a medium levels (from 648.8±59.5 to 1519.2±233.6 and 2291.4±293.8 pg/100000 cells, $p<0.01$). Exposure to sodium nitroprusside 25 μM induced a significant increment in 6-ketoPGF1a levels (852.5±169.3 pg/100000 cells, $p<0.05$). 6-ketoPGF1a and PGE2 medium levels were not affected by NG-monomethyl-L-arginine (L-NMMA) treatment (250, 500, 750, 1000 μM; 336.2±90.1, 583.9±59, 452.4±86.8 and 692.3±106.1 pg/100000 cells, and from 273.2±30.6 to 250.4±29, 238.5±20.1 and 244.3±48.5, 227.4±37.6 pg/100000 cells, respectively). INDO 30 and 100 μM significantly enhanced NOx (37±6.44 and 42.3±6.29 μM/100000 cells, $p<0.05$ and $p<0.01$) and citrulline levels (from 253.4±27.3 to 438±81.4, $p<0.05$ and 478.8±75.5 μM/100000 cells, $p<0.01$, respectively). In addition, eNOS production was significantly enhanced following INDO 100 μM (from 94.6±18.8 to 177.5±32.1 μM/100000 cells, $p<0.05$). Conclusion: Enhanced NO bioavailability significantly increased PGs levels, indicating that the mechanism of action of NO may be partially mediates by vasodilatatory PGs. Inhibition of PGs production with indomethacin, was compensated by the enhanced release of NO. By contrast, inhibition of NOS with L-NMMA did not affect PGs release, that fail to compensate reduced NO levels.

P1200 Atrial natriuretic peptide and NO show cyclic guanosine-monophosphate increasing and vasodilating effects in human coronary bypass grafts

A. Lercher[1], J. Fersterer[1], S. Holzmann[2], J. Bonatti[3], R. Mittermair[3], D. Höfer[3], J. Mair[4], B. Puschendorf[1]. [1]*Med. Chemistry and Biochemistry, Innsbruck, Austria;* [2]*Pharmacology and Toxicology, Graz, Austria;* [3]*Cardiac Surgery, Innsbruck, Austria;* [4]*Cardiology, Innsbruck, Austria*

Objectives: Natriuretic peptides show vasodilatory and antiproliferative effects and therefore, may be protective when applied to human coronary bypass grafts. In this study we wanted to demonstrate that bypass grafts can be stimulated by natriuretic peptides, and that there is a direct link between cyclic-guanosine-monophosphate(cGMP)-concentration and functional relaxation.
Methods: We used remnants of the internal mammary artery (IMA) and the saphenous vein (SV) of 27 patients (median: 71 years) undergoing coronary bypass grafting. 49 rings of the IMA and 29 rings of the SV were tested using the organ bath set-up (Hugo-Sachs-Electronics, Freiburg, Germany). Rings were precontracted with 30 nM U46619 (a thromboxane agonist), and relaxation in response to 300 nM atrial natriuretic peptide (ANP), 300 nM C-type natriuretic peptide (CNP), and 0.1 mM 3-morpholino-sydnonimine (sin-1, a NO liberating substance) was measured by isometric force and calculated in % changes in tension. Rings and supernatant were collected at the end of the experiment to determine intra- and extracellular cGMP concentration by a radioimmunoassay (Amersham, Vienna, Austria).
Results: Controls of the IMA showed sponaneous relaxation of 9.3% at the end of the experiment, whereas the SV remained fully contracted. However, intra- and extracellular cGMP-concentrations were similar. In the IMA, ANP and sin-1 caused significant and comparable relaxation (64% and 61%, respectively; $p<0.001$ each) compared with control rings. Furthermore, there was a significantly increased intracellular production of cGMP in these rings ($p=0.001$ each) compared with control rings. Additionally, extracellular cGMP concentration was significantly increased after ANP stimulation ($p=0.002$) of the IMA. CNP did not cause any significant relaxation or cGMP production in the IMA. In the SV, sin-1 caused significant relaxation (36%; $p<0.001$) and significantly increased intra- ($p=0.005$) and extracellular ($p=0.011$) cGMP concentration compared with controls. ANP and CNP had no significant effects on the SV. Moreover, the IMA produced significantly higher intracellular concentrations of cGMP after ANP and sin-1 stimulation compared with the SV ($p<0.01$ each).
Conclusion: ANP and NO seem to have strong vasodilating and cGMP-stimulating effects on the internal mammary artery, whereas only NO shows these effects in the saphenous vein. CNP appears to be less effective on both vessels.

THROMBOSIS – ENDOTHELIAL FUNCTION

P1201 Natriuretic factors suppress plasminogen activator inhibitor type-1 expression in human preadipocytes

A. Zirlik[1], S. von Saldern[2], C. Bode[1], T.K. Nordt[1]. [1]*University of Freiburg, Cardiology and Angiology, Freiburg, Germany;* [2]*District Hospital Offenburg, Plastic Surgery, Offenburg, Germany*

Background: Human adipose tissue and particularly its preadipocyte cell fraction produce a substantial amount of plasminogen activator inhibitor type-1 (PAI-1), known to contribute to the development of cardiovascular disease. Little is known about natural factors regulating PAI-1 expression in adipose tissue. The present study examines the effect of the atrial natriuretic factor (ANF) and the C-type natriuretic peptide (CNP) on PAI-1 expression in primary cultures of human preadipocytes.
Methods: Human preadipocytes were prepared from subcutaneous abdominal adipose tissue by collagenase digestion. The cells in primary culture were exposed to selected concentrations of ANF 1-28 and CNP 22 (10 nM, 100 nM, 1000 nM) in the presence and absence of transforming growth factor-beta (TGF-beta), a cytokine known to stimulate PAI-1 synthesis in adipose tissue.
Results: Incubation with 10 nM, 100 nM, and 1000 nM ANF reduced basal PAI-1 expression in the conditioned media by 5%, 18%, and 7%. Similarly, CNP downregulated PAI-1 protein concentration by 28%, 23%, and 18% (n=6, $p<0.05$ each). Stimulation with TGF-beta resulted in a 10-fold increase of basal PAI-1 production. Again, 10 nM, 100 nM, and 1000 nM of ANF suppressed stimulated PAI-1 levels by 20%, 22%, and 5%. The same concentrations of CNP reduced PAI-1 synthesis by 46%, 36%, and 22% (n=6, $p<0.05$ each). Expression of the PAI-1 gene as assessed by rt-PCR suggest a transcriptional regulation of PAI-1 expression by ANF and CNP.
Conclusion: ANF and CNP reduce both basal and TGF-beta stimulated PAI-1 expression in human preadipocytes. These observations suggest that both peptides are important natural regulators of PAI-1 synthesis in adipose tissue, and, thereby, are likely to be involved in vascular disease.

P1202 Platelet-leukocyte aggregation under shear stress: different involvement of selectins and integrins

H. Hu[1], D. Varon[2], S. Schulman[3], P. Hjemdahl[1], N. Li[1]. [1]*Karolinska Hospital, Division of Clinical Pharmacology, Stockholm, Sweden;* [2]*Hebrew University Medical Centers, Department of Hematology, Jerusalem, Israel;* [3]*Karolinska Hospital, Division of Hematology, Stockholm, Sweden*

Background: Platelets and leukocytes can form heterotypic aggregates in vivo, and mutually influence their functions. However, it has not been defined how shear force in the blood stream influences platelet-leukcoyte aggregation (PLA).
Methods: Hirudinized whole blood was stimulated with vehicle or agonists (10 μM ADP or 0.1 μM fMLP) under different levels of shear stress (200, 500, 1000 and 1800 S(-1)), using a cone-and-plate(let) analyzer. PLA and platelet-platelet aggregate (PPA) formation, as well as platelet P-selectin and leukocyte CD11b expression were monitored by whole blood flow cytometry.
Results: Shear stress per se increased platelet P-selectin expression, leukocyte CD11b expression, and PLA formation. More obvious effects on PLA formation were seen with lower shear stress. For example, PLAs were increased from 5.3±0.3% to 12.3±1.5% at 500 S(-1), but only to 8.2±0.7% at 1800 S(-1). Increased heterotypic aggregation was mainly seen among monocytes and neutrophils (from 12.4±2.2 to 38.8±8.3% and from 5.7±1.7 to 14.4±3.5% by 500 S(-1) shear stress, respectively), but not in lymphocytes. ADP markedly increased platelet P-selectin expression (1.8±0.3% to 32.0±3.6%) and thus PLA formation (from 5.3±0.2 to 15.5±3.9%). ADP-induced PLA was, however, reduced by >=500 S(-1) shear stress (9.6±0.6% at 500 S(-1)). fMLP markedly increased leukocyte CD11b expression (1.1±0.2 to 3.4±0.5), but did not increase PLA formation (5.3±0.3 without and 5.6±0.4% with fMLP). In fMLP-stimulated samples, PLA formation was enhanced by shear stress (18.2±4.2% at 500 S(-1)). P-selectin blockade by MAb 9E1 abolished PLA formation induced by shear stress, ADP, or fMLP. In contrast, GPIIb/IIIa blockade by c7E3 enhanced shear-, ADP-, and fMLP-induced PLA formation, presumably by blocking PPA formation and thus increasing the availability of single activated platelets for PLA formation.
Conclusions: Shear stress enhances PLA formation. P-selectin-mediated bridging is necessary to initiate PLA formation, but only supports a loose conjugation, which can be dispersed by high shear stress. GPIIb/IIIa-fibrinogen-CD11b bridging increases the stability of heterotypic conjugation.

P1203 Determinants of soluble P-selectin as a marker of platelet activation in 1316 patients with atrial fibrillation

D.S.G. Conway[1], L.A. Pearce[2], B.S.P. Chin[1], R.G. Hart[2], G.Y.H. Lip[1]. [1]*City Hospital Birmingham, University Department of Medicine, Birmingham, United Kingdom;* [2]*University of Texas at San Antonio, San Antonio, Texas, United States of America*

Introduction: Abnormal indices of platelet activation have been described in atrial fibrillation (AF), in keeping with a prothrombotic state. However, platelet activation in AF may reflect the presence of underlying atherosclerotic disease rather than increased thromboembolic risk.
Methods: We measured plasma soluble P-selectin (sP-Sel) levels by ELISA in 1315 participants enrolled in the Stroke Prevention in AF (SPAF) III trial, and related sP-sel to conventional risk factors for atherosclerosis and stroke in AF.
Results: Results from univariate analysis are shown in Table 1.

Clinical Factor	Clinical Factor Present	Clinical Factor Absent	p
Age >75 years	34 (13)	34 (13)	0.4
Male	35 (14)	31 (12)	<0.001
Hypertension	34 (14)	34 (12)	0.7
Prior Cerebral Ischaemia	32 (11)	34 (14)	<0.01
Peripheral Vascular Disease	39 (13)	34 (13)	<0.001
Diabetes	36 (15)	34 (13)	0.01
Heart Failure	34 (12)	34 (13)	0.6
Prior Myocardial Infarction	35 (11)	34 (14)	0.1
Serum Cholesterol >median (201mg/dl)	34 (13)	34 (14)	1.0
Current Smoking	38 (14)	34 (13)	<0.01
Moderate-Severe Left Ventricular Dysfunction	33 (12)	34 (11)	0.5

Univariate Associations Between Atherosclerotic and Thromboembolic Risk Factors and Plasma sP-sel Levels (values in pg/ml expressed as mean(sd))

Factors independently associated (adjusted r2 = 4%) with plasma sP-sel level following multivariate analysis were male sex (increased, $p<0.001$), current smoking (increased, p=0.01), peripheral vascular disease (increased, $p<0.001$), diabetes (increased, p=0.01) and prior cerebral ischemia (decreased, p=0.002). There was no difference in sP-sel between those at "high', "moderate" and "low" risk of stroke (SPAF III risk criteria, p=0.3) nor between different antithrombotic therapies (p=0.09).
Conclusion: Among patients with AF, plasma levels of sP-sel were higher in association with four major atherosclerotic risk factors, whereas lower or unaffected by many thromboembolic stroke risk factors. Platelet activation in AF is likely to reflect generalised atherosclerotic disease and may not play a major role in thromboembolism.

P1204 Evaluation of thrombomodulin and platelet activation products in patients undergoing PTCA. Effects of per os L-Arginine

A.S. Perpinia[1], T. Iyras[2], N.A. Michelakakis[3], A. Stergiou[3], E. Rentoukas[3], S. Hantziara[3], K. Politi[3], A.A. Zacharoulis[3]. [1]*Poliklinic Hospital, Cardiology, Athens, Greece;* [2]*O Palmos Diagnostic Center, Markopoulo- Mesogeas, Greece;* [3]*Athens General Hospital, Cardiology, Athens, Greece*

Introduction: Endothelial denudation during PTCA causes the aggregation and activation of platelets, resulting in the release of intracellular substances, which induce proliferation and migration of smooth muscle cells in the neointima of the vessel wall. This process may lead to acute or subacute thrombosis and later restenosis. Experimental data have shown that Nitric Oxide (NO) inhibits platelet aggregation and activation. The aim of our study was to evaluate the possible beneficial effects of per os L-Arginine, a precursor of NO, on plasma levels of forth Platelet Factor (PF4), b-Thromboglobulin (BTG) and Thrombomodulin (TM).

Methods: We examined 63 male pts (aged 56.5±7.6 years) undergoing elective PTCA, not treated with IIb-IIIa inhibitors. L-Arginine was given in a dose of 21 gr per day, starting 3 days before, up to 1 month after PTCA, to 37 randomly selected pts (group-1). The rest 26 pts received placebo (group-2). All pts were put on conventional treatment for PTCA. Blood samples were taken from each patient immediately before and after PTCA, after 24 h, 1 month and 6 months (samples (0), (1), (2), (3) and (4) respectively)and PF(iu/ml),BTG(iu/ml) and TM(ng/ml)were estimated.

Statistical analysis with ANOVA was performed, using STATISTICA package.

Results: There were no statistically significant differences in basic characteristics and in the values of all 3 substances before PTCA between group-1 and group-2.

Significant Differences

	PF(3)	BTG(2)	BTG(3)	BTG(4)	TM(1)	TM(2)	TM(3)
GROUP-1	86.7±21	220.4±13	218.3±22	222.9±13	27.7±5	29.3±6	29.6±6
GROUP-2	96.9±10	231.7±12	230.9±6	230.8±9	23.6±4	22.9±6	23.4
F	4.85	11.49	7.63	6.59	11.6	15.89	17.26
p	0.031	0.001	0.007	0.012	0.001	0.000	0.000

Conclusions: Oral L-Arginine favorably affects plasma levels of forth Platelet Factor, Thromboglobulin and Thrombomodulin in male pts undergoing elective PTCA, suggesting a protective role against acute or subacute thrombosis and restenosis.

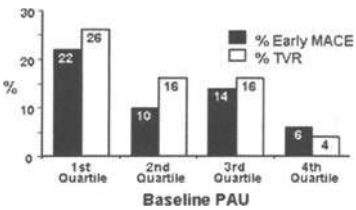
P1205 Point-of-care measurement of platelet function before angioplasty strongly predicts early MACE and late TVR

S. Steinhubl[1], J. Saucedo[2], D. Sane[3], P. Berger[4], D. Moliterno[5], J. Tcheng[6], D. Kereiakes[7]. [1]*Wilford Hall Medical Center, Cardiology, Lackland AFB, TX;* [2]*University of Arkansas, Cardiology Dept., Little Rock AR;* [3]*Wake Forest University, Cardiology Dept., Winston-Salem NC;* [4]*Mayo Clinic, Cardiology Dept., Rochester MN;* [5]*Cleveland Clinic Foundation, Cardiology Dept., Cleveland OH;* [6]*Duke University, Cardiology Dept., Durham NC;* [7]*The Lindner Center, Cardiology Dept., Cincinnati OH, United States of America*

Baseline platelet activation correlates with early thrombotic complications of PCI as well as the need for TVR but is of limited clinical utility due to the need for specialized testing. The Ultegra-RPFA is a simple, point-of-care assay approved for use in monitoring platelet function in patients treated with GPIIb/IIIa antagonists that also quantifies the patient's baseline platelet function.

Method: As part of the GOLD study, baseline Platelet Activation Units (PAU) were measured using the Ultegra-RPFA in 500 patients undergoing a percutaneous coronary intervention with the adjunctive use of a GPIIb/IIIa antagonist. Complete data out to 7 months were available in a subset of 197 abciximab-treated patients, with the incidence of early MACE (death, MI, urgent TVR) and late TVR analyzed with respect to baseline platelet function.

Results: Baseline platelet function ranged from 52 to 471 PAU (median 234). Patients with the lowest PAU values at baseline, consistent with more activated or "exhausted" platelets, had a significantly greater risk of early MACE, as well as late TVR, than those paitents with highest baseline PAU levels (figure).



Relationship of PAU to MACE and TVR.

Conclusion: These results confirm that increased levels of platelet activation prior to PCI are associated with an increased risk of both early MACE and clinical restenosis, and confirm that this can now be easily determined utilizing a simple point-of-care assay. Routine platelet function monitoring may help to optimize the future use of more expensive therapies designed to minimize MACE or prevent restenosis.

P1206 Platelet activation induced by acute coronary thrombosis and transient occlusion is related to an increased risk of early reocclusion

M. Mirabet, D. Garcia-Dorado, J.A. Barrabés, A. Massaguer, F. Padilla, L. Trobo, J. Soler-Soler. *Hospital General Vall d'Hebron, Servicio de Cardiología, Barcelona, Spain*

Platelet activation and circulating platelet-leukocyte aggregates have been described during acute coronary syndromes and may have prognostic significance. It is uncertain to what extent the increased platelet activation in these patients reflects a baseline status or is a consequence of the acute coronary event. In the present study, we investigated the changes in platelet activation induced by acute coronary thrombosis and transient occlusion, and their association with early coronary reocclusion in swine.

Methods: Twelve thiopental-anesthetized, open-chest Large-White pigs were subjected to catheter-induced coronary injury followed by a 48-min occlusion and two hours of reperfusion. Coronary blood flow was continuously monitored with a transit time flow meter. Five animals had coronary reocclusion (four during the first 30 min of reflow). Femoral venous blood was obtained at several time points of the experiment, the expression of P-selectin by platelets and granulocytes was assessed by flow cytometric analysis, and its association with the occurrence of reocclusion investigated.

Results: At baseline, the percentage of P-selectin-positive cells was low, and similar in animals with and without reocclusion. Platelet activation occurred during the experiment, and the levels were directly associated with the occurrence of reocclusion (table). The higher percentage of P-selectin-positive granulocytes in animals with reocclusion remained significant (P=0.016) after adjusting for the effect of time.

	PLA+			GR+		
	baseline	15 min R	90 min R	baseline	15 min R	90 min R
No reocclusion	2.4 (0.5)	2.6 (0.5)	2.5 (0.5)	1.7 (0.5)	3.3 (0.9)	6.0 (1.3)
Reocclusion	3.7 (0.6)	3.0 (0.4)	4.6 (0.6)*	2.2 (0.8)	10.4 (3.9)	19.9 (7.5)*

PLA+ and GR+, percentages (SE) of platelets and granulocytes, respectively, positive for P-selectin; R, reperfusion; *P<0.05 with respect to animals without reocclusion.

Thus, acute coronary thrombosis with transient occlusion promotes platelet activation. Higher levels of platelet activation are associated with early coronary reocclusion, suggesting a cause-effect relationship.

P1207 Evaluation of the role of COX-1 and COX-2 in prostacyclin production in the perfused senescent rat heart

A. Ishihata[1], T. Ogaki[2], M. Sakai[1], A. Tezuka[1], Y. Katano[2]. [1]*Physiology,* [2]*Theoretical Nursing Pathophysiology, Yamagata-shi, Yamagata University School of Medicine, Japan*

Background and Objectives: The impaired production of nitric oxide plays a pivotal role in aging-related endothelial dysfunction. In contrast, we have recently reported that the production of prostacyclin is increased in the aged rat heart. We also reported that COX-1 was increased, while prostacyclin receptor expression was not significantly changed. However, involvement of COX-2 in the increased prostacyclin production is not clarified yet. In the pathologic conditions such as inflammation and endotoxin shock, induced COX-2 may play an important role. Therefore, we tried to evaluate the role of COX-2 as well as COX-1 in the age-related changes in prostacyclin production.

Methods: Young (2-3 months old) and senescent (27-30 months old) male Fischer 344 rats were used. Hearts were isolated and Langendorff-perfused with constant pressure (75 cm H2O) at 37°C. Coronary flow, heart rate, left ventricular pressure and its first derivatives were measured. Prostacyclin was measured with the coronary effluent by enzyme-immunoassay for 6-keto PGF1alpha. Gene expressions of COX-1 and COX-2 were quantitated by real-time RT-PCR. Expressions of COX-1 and COX-2 enzymes were analyzed by Western blot. Localization of COX proteins were investigated in tissue sections immunohistochemically.

Results: Endothelin-1 induced a potent vasoconstriction and increased the prostacyclin production. The production was greater in senescent than young rat. Pretreatment with non-selective COX inhibitor diclofenac and selective COX-1 inhibitor resveratrol inhibited the response. On the other hand, selective COX-2 inhibitors (nimesulide and NS-398) did not significantly attenuate the prostacyclin production. Gene expression of COX-1 and prostacyclin synthase mRNA was significantly higher in senescent aorta, while COX-2 mRNA did not show significant change. Western blot analysis revealed that COX-1 expression was upregulated in the senescent aorta, but the level of COX-2 was not changed. Immunohistochemical analysis showed that COX-1 immunoreactivity localized in the coronary artery and aorta was stronger in the senescent rat, but COX-2 expression was faint even in the senescent rat.

Conclusion: These results suggest that COX-1 was involved in the increased production of prostacyclin in the senescent rat heart. However, COX-2 did not seem to play an regulatory role for prostacyclin production in the aging-process.

P1208 Psychological stress induces acute increases in monocyte-platelet, neutrophil-platelet and leukocyte-platelet aggregates in healthy men

A. Steptoe[1], K. Magid[1], S. Edwards[1], L. Brydon[1], Y. Hong[2], J.D. Erusalimsky[2]. [1]*University College London, Epidemiology and Public Health, London, United Kingdom;* [2]*University College London, Centre for Cardiovascular Biology, London, United Kingdom*

Background: Circulating monocyte-platelet and neutrophil-platelet aggregates have emerged as sensitive markers of in vivo platelet activation. We assessed the impact of acute psychological stress on monocyte-platelet, neutrophil-platelet. Lymphocyte-platelet and total leukocyte-platelet aggregates in healthy men.
Methods: Participants were 36 healthy nonsmoking men aged 30-59 years. Psychological stress was induced by performance of two challenging behavioural tasks (colour-word interference and mirror tracing). Blood was drawn at baseline, immediately following tasks, and at 30 and 75 minutes post-stress, and aggregates were analysed using flow cytometry. Results are expressed as the proportion of each cell type aggregated to platelets. Cardiovascular and subjective stress responses were also monitored.
Results: There were significant increases following stress in monocyte-platelet, neutrophil-platelet, lymphocyte-platelet and total leukocyte-platelet aggregates (table). Note that the leukocyte-platelet value is not equal to the sum of the aggregates of leukocyte subsets, since cell types vary in prevalence. The highest levels of aggregates were not recorded immediately post-stress, but 30 min later, and values had returned to baseline by 75 min. The increase in neutrophil-platelet and leukocyte-platelet aggregates correlated with the stress-induced increase in systolic blood pressure ($r = 0.43$ and 0.38, $P < 0.025$). The increase in monocyte-platelet and neutrophil-platelet aggregates correlated with subjective stress ratings at 30 min ($r = 0.36$ and 0.35, $P < 0.05$).

	Baseline	Post-stress	30 min	75 min
Leukocyte-platelet aggregates (%)	5.26 ± 1.3	5.45 ± 1.3	6.95 ± 2.0*	5.18 ± 1.3
Monocyte-platelet aggregates (%)	9.94 ± 3.7	10.5 ± 3.1	12.4 ± 7.5*	9.72 ± 3.8
Neutrophil-platelet aggregates (%)	4.37 ± 1.1	4.43 ± 1.3	5.10 ± 1.9*	4.79 ± 1.8
Lymphocyte-platelet aggregates (%)	3.38 ± 0.7	3.58 ± 0.9	3.59 ± 0.9*	3.49 ± 0.8

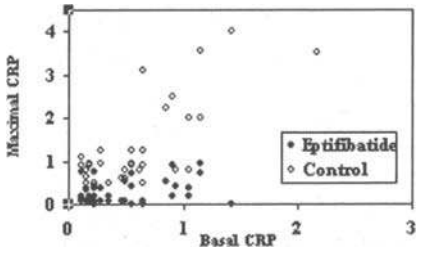
Means and standard deviations* = Different from baseline ($p < 0.05$ - 0.005)

Conclusions: Psychological stress induces platelet activation as indexed by leukocyte-platelet aggregates, with average increases of 24.7% (monocyte-platelet), 16.7% (neutrophil-platelet), 6.6% (lymphocyte-platelet) and 13.2% (total leukocyte-platelet). Platelet activation correlated with cardiovascular and subjective stress reactions, suggesting that sympathoadrenal responses may be responsible.

P1209 Degree of C-reactive protein elevation in coronary angioplasty patients

A. Merino, I. Segura, I. Alins, M. Artaiz, B. Vidal, V. Iñigo, A. Rodriguez, E. Alegría. *Palma de Mallorca, Spain*

Background: High C-reactive protein (CRP) in coronary angioplasty (CA) patients is a marker of adverse outcome. Some data pointed out that patients with high basal CRP concentration (>0.3 mg/dL) show a significant increase after CA, while patients with low basal CRP levels (<0.3 mg/dL) have no increase at all. GP IIb-IIIa inhibitors block the increase in CRP after CA probably by stabilizing arterial thrombosis. Thus, it would be of great interest to know the expected increase in CRP after CA in order to have a marker of stabilization of the thrombotic conditions.
Methods: We measured CRP levels by nephelometry in 90 patients who underwent a CA. Patients with recent myocardial infarction, recent surgery or inflammatory, metabolic or neoplastic diseases were excluded. In 48 patients Eptifibatide perfusion was initiated immediately after the procedure, and continued for 24 hours. The remaining control 42 patients received only standard heparin plus aspirin treatment. C-reactive protein was determined pre angioplasty, 24 and 48 hours after the procedure.
Results: Linear regression equation for CRP was maximal CRP = 26.45 + 1.74 * (basal CRP) for control patients, and maximal CRP = -0.77 + 1.03 * (basal CRP) for Eptifibatide patients. The figure shows the actual data.



CRP in coronary angioplasty.

Conclusions: C-reactive protein increases in a linear way after CA to almost twice the basal levels, no matter which are that basal concentrations. Eptifibatide blocked that increase, mantaining CRP at basal levels.

P1210 C-reactive protein predicts platelet reactivity and von Willebrand factor expression in patients undergoing coronary stent implantation

D.J. Angiolillo[1], A. Fernandez-Ortiz[2], E. Bernardo[1], M. Viveros[1], C.F. Barrera[1], G. Liuzzo[3], L.M. Biasucci[3], C. Macaya[4]. [1]*Hospital Clinico San Carlos, Cardiovascular Research Laboratory, Madrid, Spain;* [2]*Hospital Clinico San Carlos, Coronary Care Unit, Madrid, Spain;* [3]*Catholic University, Cardiology, Rome, Italy;* [4]*Hospital Clinico San Carlos, Invasive Cardiology Unit, Madrid, Spain*

Background: Early after PCI, thrombotic risk is the result of a complex interplay among blood components such as platelets, coagulation and inflammatory factors. The adhesion molecule P-selectin is expressed on the surface of activated platelets and mediates interaction between platelets and leucocytes. Von Willebrand Factor (vWF), a coagulation factor promoting thrombus formation, is involved in signal transduction pathways leading to platelet release reactions. C-reactive protein (CRP) has been associated with a greater risk of restenosis following PCI. Aim of the study was to assess whether CRP is associated with P-selectin expression and with vWF plasma levels in pts undergoing coronary stent implantation (STI)
Methods: We studied 32 consecutive pts undergoing STI. All pts were on treatment with aspirin (100 mg/day) and received a 300 mg loading-dose of clopidogrel at intervention time. During intervention, 100 IU/kg of heparin was administered. Pts receiving GP IIb/IIIa inhibitors were excluded. CRP levels were measured with an ultra sensitive nephelometric method at baseline. Platelet surface P-selectin (CD62-PE) was measured in non-stimulated platelets and after stimulation with 2 μM ADP and 50 μM TRAP using whole blood flow cytometry at baseline and 10 minutes, 1 hour, 4 hours, and 24 hours following STI. vWF was measured at baseline by ELISA. Pts were divided into two groups according to CRP levels: G1 (CRP<10mg/L) and G2 (CRP>10mg/L).
Results (mean±SD): G1 and G2 were composed of 24 (21 males; age:61±9y) and 8 (7 males; age:64±12y) pts, respectively. No difference in P-selectin expression in non-stimulated platelets and in platelets stimulated with ADP was observed between G1 and G2 at any time point. Following challenge with TRAP, P-selectin expression was significantly higher in G2 than in G1 at baseline (94,23±1,9% vs 91,08±6,3%; p=0.041), 10 minutes after STI (93,75±1,1% vs 86,50±14,6%; p=0.024), 1 hour after STI, (94,17±2,2% vs 86,57±16,8%; p=0,041), 4 hours after STI (94,17±3,0% vs 86,79±14,5%; p=0.027), and 24 hours after STI (93,31±2,5% vs 86,73±13,2%; p=0.029). vWF plasma levels were greater in G2 than G1 (188,64±33,8% vs 149,20±41,7%; p=0.022). No difference in platelet count was observed between the two groups.
Conclusion: Patients undergoing STI with elevated CRP levels have a greater platelet expression of P-selectin following TRAP stimuli in vitro and higher levels of vWF. A greater platelet reactivity and a greater expression of coagulation factors may be adjunctive mechanisms by which inflammation may contribute to outcome.

P1211 Age-related difference in lipid and thrombogenic factors in postinfarction patients

W. Zareba[1], A. Gudavalli[1], A.J. Moss[1], C. Sparks[2], V. Marder[3]. [1]University of Rochester, Cardiology, Rochester, United States of America; [2]University of Rochester, Pathology, Rochester, NY, United States of America; [3]UCLA School of Medicine, Vascular Medicine Center, Los Angeles, United States of America

This study aimed to determine the influence of age on levels of lipid and thrombogenic factors in patients after myocardial infarction (MI).

Methods: Blood levels of cholesterol, apolipoprotein A-1, apolipoprotein B, lipoprotein(a), triglycerides, high-density lipoprotein, low density lipoprotein cholesterol, insulin, fibrinogen, von Willebrand factor, factor VII and VIIa, plasminogen activator inhibitor 1, and D-dimer, were measured 2 months after MI in 1045 patients divided into terciles by age categories: <= 53 years (n=358), 54-64 years (n=340) and => 64 years (n=346). Nonfatal MI or cardiac death occurring during a mean 2-year follow-up were considered as an endpoint of the study.

Results: In comparison to older patients, younger patients (< 53 years) had significantly higher levels of triglycerides, cholesterol/HDL ratio, apoB/apoA ratio and insulin and lower levels of Apo-A and HDL cholesterol. Also, body mass index was significantly higher in younger than older patient (29±6, 28±5, and 27±5, respectively; p<0.001). The elderly patients (> 65) had significantly higher levels of fibrinogen, von Willebrand factor, and D-Dimer and significantly lower PAI-1 levels than younger groups. During a mean 26-month follow-up recurrent cardiac events occurred with similar frequency (7%, 8% and 8%, respectively).

Lipid and Thrombogenic Factors by Age

	Age < 53 (n=358)	Age 54-64 (n=340)	Age > 64 (n=346)	p value
Triglycerides (mg/dl)	224 (132)	199 (115)	179(97)	< 0.001
ApoA (mg/dl)	115 (24)	120 (26)	121 (26)	0.017
HDL (mg/dl)	37 (11)	39 (12)	41 (12)	<0.001
Insulin (IU/ml)	21 (36)	20 (24)	17 (24)	0.001
vWF (U/dl)	129 (60)	151 (70)	167 (72)	0.001
Fibrinogen (mg/dl)	338 (89)	354 (87)	366 (87)	0.001
PAI-1 (ng/ml)	33 (34)	27 (26)	25 (21)	<0.001
D-dimer (ng/ml)	348 (413)	450 (355)	773 (910)	<0.001

Values in parentheses are standard deviations

Conclusion: Younger post-MI patients have higher incidence of metabolic syndrome X (increased BMI, triglycerides, insulin, PAI-1 and decreased Apo-A1 and HDL cholesterol) while the older post-MI patients have higher incidence of procoagulant state (increased vVF, fibrinogen, and D-Dimer) leading to a similar risk of recurrent cardiac events.

P1212 Microvascular reactivity in patients with hypercholesterolemia: effect of atorvastatin treatment

T. Stulc, Z. Kasalova, M. Vrablik, M. Prazny, J. Skrha, R. Ceska. *1st Faculty of Medicine, 3rd Department of Internal Medicine, Prague 2, Czech Republic*

Impaired NO-dependent vasodilation of resistance vessels is an early marker of increased risk of atherosclerosis; utility of the examination of microvasculature, however, is far less established. We have therefore tested the hypothesis that hypercholesterolemia is associated with impaired microvascular reactivity and that this defect is at least partially reversible by lipid-lowering treatment. Methods: Twenty six hypercholesterolemic patients (otherwise healthy, total cholesterol >7,0 mmol/l) were examined at baseline and after 10 wks of atorvastatin treatment (20 mg/day). Skin microvascular reactivity (MR) was examined by laser-doppler flowmetry. Baseline MR values of the study group were compared to control group of healthy subjects, to patients with severe CAD and to patients with diabetes mellitus with and without diabetic retinopathy. Results: Reductions of total cholesterol and LDL-cholesterol after atorvastatin treatment were 31% and 40%, respectively. In the whole treatment group, there was no effect of atorvastatin on MR; however, marked improvement was evident in a subgroup with impaired MR at baseline (+27%, p<0,05). On-treatment changes in MR did not correlate with changes in cholesterol levels. Comparison of baseline values of our study group to those in other patient groups revealed that: 1) MR was normal in subjects with hypercholesterolemia; on the contrary, in patients with severe CAD, MR was substantially impaired (-26%, p<0,05). 2) Similarly, MR was nearly normal in diabetes patients without complications (-8%) but it was impaired in those with retinopathy (-39%, p<0,01). Conclusion: Hypercholesterolemia without symptomatic vascular disease was not associated with impairment of microvascular reactivity; marked decrease of MR was evident only in subjects with hyperlipidemia and severe CAD. Beneficial effect of atorvastatin on MR was limited to the subgroup of patients with impaired MR and this effect was independent of lipid lowering. These results indicate that microvascular reactivity reflects changes of vascular function which appear later in the process of atherogenesis. Supported by grants IGA grants NB 6134-3/200, NB 5986-3/2000 and research project J 13/98 11110000 2-1.

P1213 Preventing microinfarctions with intracoronary nicorandil during percutaneous coronary interventions

F. Airoldi[1], A. Dharmadhikari[2], C. Di Mario[1], V. Tzifos[3], M. Carlino[1], I. Sheiban[4], A. Anzuini[1], A. Colombo[5]. [1]Hospital San Raffaele, Interventional Cardiology, Milano, Italy; [2]Nashik, India; [3]Hospital Hunry Dununt, Interventional Cardiology, Athens, Greece; [4]University Hospital, Torino, Interventional Cardiology, Torino, Italy; [5]EMO Centro Cuore Columbus, Interventional Cardiology, Milano, Italy

Objective: Impact of rise in creatine phosphokinase (CPK-MB) levels by more than two times the baseline levels following percutneous coronary interventions (PCI) on long term prognosis is now well accepted. The postulate of this study was, dilation of epicardial arteries and the coronary microcirculation with local delivery of nicorandil, a potassium channel opener with vasodilatory properties, could reduce the extent of microembolizations during PCI. We studied the role of intracoronary injection of nicorandil in reducing the level of rise in CPK-MB levels following PCI.

Methods and results: Between April 2000 and September 2001, 45 patients were randomized to intracoronary nicorandil (1mg bolus, Group I), 55 patients to intracoronary nitroglycerin (1mg bolus, Group II), and 50 patients to neither of these drugs (Group III). Patients with acute myocardial infarction and unstable angina were excluded from this study. Baseline clinical characteristics were comparable in all three groups. Multivessel disease was treated in 6.7% patients in Group I, 10.9% pts in Group II and 12% pts in Group III (p=ns). Stenting was employed in 83.3% in Group I, 81.2% in Group II and 85.7% in Group III (p=ns). The incidence of rise in CPK-MB levels more than two times the baseline level in Group II and Group III was statistically more than that occurring in Group I (p=0.03 between Group I and Group II; p= 0.0002 between Group I and Group III). The difference in the mean levels of CPK-MB between Group I (Nicorandil) and Group III (none) was statistically significant (p=0.04).

Creatinephosphokinase MB levels

	CKMB<2 times baseline	CKMB>2 times baseline	Mean CK-MB rise (IU)
Group I (N=45)	43 (95.6)	2(4.4)	14±11
Group II (N=55)	45(81.8)	10(18.2)	26±14
Group III (N=50)	32(64)	18(36)	32±13

Figures in parenthesis indicate percentages

Conclusion: Intracoronary injection of nicorandil reduces the level of rise in CK-MB levels following percutaneous coronary interventions. Follow up of these cases will give us information about its impact on long term adverse effect rate.

P1214 Effective treatment of stable CAD by atorvastatin guided by noninvasive PET assessment of regional myocardial perfusion

E. Pulawski[1], D. Baller[1], P. Wielepp[2], A. Kammeier[2], R. Weise[2], W. Burchert[2], D. Horstkotte[1]. [1]Department of Cardiology, [2]Inst. Mol. Biophys., Radiopharm., Nucl. Med., Heart Center North Rhine-Westphalia, Bad Oeynhausen, Germany

Noninvasive dipyridamole (D) positron emission tomography (PET) reflects the integrated flow capacity of the coronary arterial/arteriolar system affected by diffuse atherosclerosis, often the substrate for plaque rupture. We examined the effect of atorvastatin in stable CAD on myocardial perfusion in regions with highest reduction of baseline dilator reserve. 13 patients (Pts.) with mild effort and/or atypical angina (AP) and hypercholesterolemia were studied before and after 5±1.7 months of therapy with 10-80 mg atorvastatin. Exclusion criteria were smoking, diabetes, uncontrolled hypertension, and pre-treatment with lipid lowering drugs.

Baseline data: Mean age:63.7±5.8 years; nine of the patients (9 men;4 women) had mild coronary artery disease (wall irregularities or stenosis <= 50%), four had multi-vessel disease (stenosis>70%).

Methods: Dynamic PET flow was measured quantitatively at rest (MBFR) and after D (0.56 mg/kg) (MBFD) using N-13 ammonia as flow tracer in a 3-compartment model. Pts. had restricted flow reserve (CFR) compared to normolipemic controls (n=15; 52±11 years; overall CFR: 4.0±1.3; p<0.01). Chol.: 271±25; LDL-C: 197±21; HDL: 50±9 mg/dl; CFR: 2.1±0.48; minimum coronary resistance (MR) was calculated as mean arterial pressure/MBFD; conductance as 1/MR.

Results (mean±SD): Chol:176±43; LDL-C:101±28 (-49%); HDL:51±11 mg/dl. Regional MBFD increased from 164±40 to 217±46 ml/min x 100g (p<0.05); MR decreased from 0.62±0.15 to 0.47±0.09 mmHg/ml/min x 100g (p<0.02). Regional coronary conductance ratio increased from 1.74±0.5 to 2.24±0.53 (p<0.02). Clinical improvement was reported by 12/13 (92%) and complete relief of symptoms by 7/13 (54%).

Conclusions: Even after a short treatment period, atorvastatin significantly improves regional myocardial perfusion, substantially restricted at baseline, with concomitant improvement of anginal symptoms. These data support the noninvasive management of stable CAD with statins guided by PET.

P1215 The β-blocker therapy improves the increased mortality in African-Americans with coronary heart disease treated with calcium channel blockers

E. Pittaras[1], P.F Kokkinos[2], P. Narayan[2], A.I Manolis[1], R. Fletcher[2], V. Papademetriou[2]. [1]*Mediton Medical Center, Cardiology Dept., Athens, Greece;* [2]*VA & Georgetown University Medical Cen, Cardiology Dept., Washington DC, United States of America*

Introduction: Calcium channel blockers (CCB) are widely used in African-Americans (AA) for the treatment of hypertension and coronary heart disease (CHD).This preference is mostly based on favorable antihypertensive effects. Studies in mostly caucasian patients(pts) suggest adverse effects with CCB on cardiovascular outcomes. The effects of CCB and the combination with b-blockers (BB) on outcomes in AA,have not been carefully studied.
Methods: We studied the interaction of treatment on mortality rates in 812 AA men (68±10yrs),who underwent diagnostic cardiac catheterization, echocardiogram, Holter ECG monitoring,exercise treadmill test and blood chemistry. Of these pts,309 were treated with CCB, 87 with BB,151 with both (CCB+BB) and 265 were on neither BB or CCB. Among pts treated with CCB,141 were on Nifedipine, 234 on Diltiazem, 38 on Verapamil, 41 on Amlodipine and 8 on Felodipine.
Results: Compared to pts on no CCB,pts treated with CCB had more favorale ejection fraction (58±16 vs 54±17;p<0.001).There were no other differences between pts (age,BMI,LVMI,SBP,DBP). Over a period of 10 years (120±28 months) a total 286 deaths occurred. Mortality rates were higher in pts receiving CCB (RR=1.97;CI=1.5-2.5;p=0.000). When CCB were combined with BB the risk was lower than CCB alone (p=0.0001). Subgroup analysis revealed that most of the increased mortality was due to Nifedipine (58% vs 23%;OR:4.4;p<0.000),after adjusting for confounding factors including severity of CHD. When Nifedipine was combined with BB the risk was lower than Nifedipine alone (p=0.001). There was no statistical difference in pts with Diltiazem (28.8% vs 29.1%),Verapamil and Felodipine. The combination of Diltiazem with BB had a lower risk than Diltiazem alone (p=0.03). Amlodipine had a "favorable" effect (4.8% vs 30%) in mortality rates.
Conclusion: In AA with CHD treatment with Nifedipine identifies a population in extremely high risk for cardiovascular events. Treatment with other types of CCB has no adverse effect.
The combination of BB with CCB has a beneficial effect reducing the mortality rates in this population.

MYOCARDIAL INFARCTION – INSIGHTS TO PATHOPHYSIOLOGY

P1216 Preinfarction angina may preserve the myocardial microcirculation and function after revascularization

X.H. Shu, C. Pan, H. Wang, L.L. Cheng, X. Shen. *Zhongshan Hospital, Fudan University, Department of Cardiology, Shanghai, China*

Objective: To assess the influence of preinfarction angina upon the myocardial microcirculation and cardiac function after revascularization using intravenous myocardial contrast echocardiography (MCE). Methods: Twenty-nine patients with acute myocardial infarction (AMI) were studied by means of MCE. 8.5ml of Levovist (300mg/ml) was injected intravenously 3-4ml per minute as contrast media. Harmonic power Doppler (Philips Sonos 5500) was used for myocardial imaging one week after successful revascularization. Twenty patients had PTCA plus stent, 8 had CABG, and 1 had PTCA plus stent followed by CABG within 23.6±3.6 days after the onset of AMI. All patients had TIMI grade 3 flow after PTCA plus stent. Seventeen patients (Group A) had at least one episode of angina within one week before infarction, and 12 (Group B) did not. Results: The incidence of no flow (myocardial contrast score index <0.5) was lower in Group A than in Group B patients (17.6% vs. 66.7%, p<0.05). The end-diastolic dimension (EDD) was not significantly different in Group A and Group B in the first week after revascularization (52.23±6.53mm, 55.02±9.49mm, p>0.05). It, however, decreased significantly in the fifth week after revascularization in Group A patients (47.36±5.56mm vs. 52.23±6.53mm, p<0.05), but was not changed in Group B patients (55.47±8.38mm vs. 55.02±9.49mm, p>0.05). The left ventricular ejection fraction (EF) was found to be improved in Group A patients (39.42% verse 34.61%, p<0.05), while it was not changed in Group B patients (28.33% vs. 29.22%, p>0.05). Conclusions: Preinfarction angina may preserve myocardial microcirculation and cardiac function, may help to improve the left ventricular remodeling as well.

P1217 Platelet/endothelial activation in depressed patients after acute myocardial infarction and unstable angina: evidence from clinical trials

V.L. Serebruany[1], A. Glassman[2], A. Malinin[1], R. Krishnan[3], P. Gurbel[1], C.M. O'Connor[3]. [1]*Johns Hopkins University, Sinai Hospital, Baltimore, United States of America;* [2]*Columbia University, New York, United States of America;* [3]*Duke University, Durham, United States of America*

Background: Platelets play a key role in the progression of acute cardiovascular syndromes (ACS). Clinical depression is also associated with enhanced platelet function. The purpose of this study was to assess concentrations of platelet/endothelial biomarkers in patients with acute myocardial infarction (AMI), and unstable angina (UA) enrolled in the clinical trials, dependent on the incidence of depression, and to compare these data with those of healthy controls.
Methods: Two hundred eighty one baseline plasma sample (AMI=41 (ASSENT-2); UA=126 (PRONTO); depression after ACS=64 (SADHART), and controls=50) were analyzed. Blood was drawn before applying any therapeutic strategies including interventions, thrombolytics, infusions, selective serotonin reuptake inhibitors, etc. Platelet factor 4 (PF4), beta-thromboglobulin (beta-TG), platelet/endothelial cell adhesion molecule-1 (PECAM-1), P-selectin, thromboxane (TxB2), prostacyclin (6-keto-PGF1a), vascular cell adhesion molecule–1 (VCAM-1), and E-selectin were measured by ELISA.
Results: Patients with ACS exhibited higher degree of platelet activation than controls independently of the incidence of depression. Plasma levels of P-selectin, TxB2, 6-keto-PGF1a, and VCAM-1 were higher in AMI group when compared with both depressed and non-depressed population with ACS. Surprisingly, depressed post-ACS patients exhibited the highest levels of PF4, beta-TG, and PECAM-1 when compared with the AMI and UA groups. E-selectin plasma level was constantly elevated, but did not differ among the groups. Depressed post-ACS group had higher plasma levels of all biomarkers as compared to the non-depressed UA patients.
Conclusion: Retrospective analysis of the data from several clinical trials reveals that depression indeed contributes to the hightened platelet activity in post-AMI, and/or UA patients, suggesting more aggressive anti-platelet strategy in patients with mood disorders after ACS.

P1218 Matrix metalloproteinases activity in acute myocardial infarction patients. Do their activity contributed to post-myocardial infarction dilation?

D. Papadopoulos[1], E.V Economou[2], K.I Kapetanios[2], P.K Toutouzas[2]. [1]*Laiko, Cardiology, Athens, Greece;* [2]*University of Athens, Cardiology Athens Medical School, Grecce, Greece*

Matrix Metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) are key enzymes in myocardial fibrillar collagen degradation. Do the increased activity of them as expressed by their plasma levels in patients (pts) with acute myocardial infarction (AMI) contribute to the post-MI remodeling?
Methods: Plasma levels of MMP-1, TIMP-1 and complex MMP-1/TIMP-1 (Comp) were measured in 24 AMI pts mean age (58,46+_13,9) years. Blood samples were taken on admission (0h), 3h, 6h, 9h, 12h, 18h, 24h, 36h, 48h, 3 day, 4d, 5d, 7d, 15d and 30 days there after and measured by relevant ELISA kits.Coronary arteriography, LV-venticulography and a two-D Echocardiography were done for estimation of Ejection Fraction (EF), diseased vessels, and LV-End Diastolic-Diameter (EDD). Pts (n=10) with EF <45%, EDD>47,5 mm and third Heart Sound (S3) were included in group (A) and compared to 12 pts consisting the group (B) with EF>45%, EDD <47,5 mm and without S3. Pts suffered from any other disease were excluded. ANOVA rp.m.a and unpaired t-test were used for statistical analysis. Data expressed as mean values+_ SD in ng/ml p<0,05 was consisted statistically significant.
Results: Group A pts showed higher levels of MMP-1 lower levels of TIMP-1 and Comp activity follow up by higher EDD and lower EF compared to group B pts showing lower levels of MMP-1 and TIMP-1 and higher level of Comp activity, lower EDD and higher EF. Additionally on 6h, 18h, 24h, 48h, for MMP-1 and 48h and 4 day for Comp the difference of mean values between group A and B was statistically significant from p>0,007 to p<0,025.

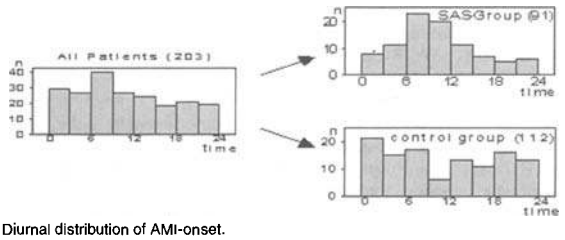
	Group A	Group B	Difference (%)
MMP-1 (ng/ml)	1,31± 0,69	1± 0,52	+ 24
TIMP-1 (ng/ml)	704,2± 899,5	697,1± 507,2	+1
Comp (ng/ml)	2,65± 2,15	3,67± 1,95	- 38
EF%	35,8±8,85	51,25±1,8	- 43
EDD (mm)	52,19±6,99	42,97±3,22	+17

Conclusions: Thus the degree of collagenolysis in AMI pts as expressed by higher MMP-1 and lower TIMP-1 and Comp activity followed by higher EDD and lower EF may be related to the post-MI dilation and to late process of LV remodeling.

P1219 The morning peak of acute myocardial infarction's onset is caused by patients with sleep apnea syndrome

A. Junker[1], J. Mehilli[2], R. Eberle[1], D. Schmohl[1], H. Szika[1], Th. von Arnim[1]. *[1]Rotkreuzkrankenhaus, Munich, Germany; [2]Deutsches Herzzentrum, Munich, Germany*

Is there a relation between the circadian rhythm of acute myocardial infarction (AMI) in the morning hours and the sleep apnea syndrome (SAS)?
Method: 203 patients after AMI (7.-14.day) were examined for sleep associated breathing disorders by means of a 5-channel recording system. Patients with congestive heart failure were excluded, all patients were mobile. The diagnostic criterion for SAS was > 10 episodes of apnea and hypopnea/h (AHI>10).
Results: SAS was diagnosed in 44,8% of all AMI patients (91/203 patients). Compared to the 112 patients without SAS there were significantly more AMI in the morning hours (6:00am-12:00am) in the SAS-group (49,5%) than in the non-SAS group (21,4%). Chi-Square-Test: p<0,0001. Patients with SAS differed from non-SAS patients only in the symptom of daytime sleepiness (29,7% vs 17,0%), age (mean 64,6years vs 60,2years) and were less likely to be smokers (33,0% vs 51,8%). There were no significant differences between SAS- and non-SAS group for BMI (mean 27,4 vs 27,1), hypertension (70,3% vs 61,6%), hyperlipoproteinemia (53,8% vs 50,9%), diabetes mellitus (19,8% vs 18,8%), family case history (20,9% vs 33,0%), history of cardiovascular disease (28,6% vs 21,4%) and the taking of sedatives (16,7% vs 21,4%).



Diurnal distribution of AMI-onset.

The strong association between SAS and morning onset of AMI could be caused by sympathetic stress reactions in consequence of the breathing disorder.

P1220 Left ventricle mechanical asynchrony in patients with acute myocardial infarction

Y. Zhang, A. Chan, M. Wang, G. Yip, P. Ho, M.K. Tse, J.E. Sanderson. *The Chinese University of Hong Kong, Medicine & Therapeutics, Shatin, NT, Hong Kong*

Background: Remodeling post myocardial infarction is an important process that leads to progressive ventricular enlargement and heart failure. It is not clear what impact an area of infarction will have on electrical synchrony of the whole ventricle. Therefore, we have assessed the degree of LV synchrony of the whole LV post myocardial infarction using tissue Doppler imaging (TDI).
Methods: Standard echocardiography and TDI were performed in 27 healthy volunteers (age 60.96±12.49) and 39 AMI patients (age59.56±11.39) within 1~7 days at the apical 2 and 4- chamber views, interrogating the following segments: septal, lateral, anterior and inferior segments at annulus, basal, mid and apical levels, and the following parameters were measured: the time to peak IVC, IVCT, the time to peak systole and systolic duration. MRI was performed in all AMI patients to assess the site and extent of the infarction.
Results: All the patient had a normal QRS duration. There was a significantly higher prevalence of prolonged time to peak systole in the whole LV in the patient group compared to normal (20.5% Vs 3.7%) (p=0.05), and it was even higher in the anterior AMI subgroup compared to normal (28.6% Vs 3.7%) (p=0.002). The ejection time was significantly prolonged in the annulus, basal, mid and most of the apical segments in patient group when compared to controls (p<0.05). Furthermore, in anterior MI subgroup the time to peak IVC was prolonged in lateral wall (p=0.01), and the time to peak systole was prolonged in anterior wall (p=0.03) compared to normal, whereas the systolic time was shortened in septum (p=0.015). In inferior MI subgroup the systolic time was shortened in septum (p=0.03) and inferior wall (p=0.029) compared to normal.
Conclusions: Myocardial infarction has a significant impact on left ventricular synchronization early after the infarction even in the absence of bundle branch block.

P1221 Baseline oxigen saturation obtained by pulse-oximetry and diagnosis of heart failure in the acute phase of myocardial infarction

J. Masip[1], F. Vecilla[1], M. Gayà[1], J. Páez[1], A.J. Betbesé[1], R. Manresa[1], J. Padró[2], R. Cañizares[1]. *[1]Hospital Creu Roja de Barcelona, Intensive Care Medicine, Barcelona, Spain; [2]Hospital Creu Roja de Barcelona, Cardiology Department, Barcelona, Spain*

The continuous monitoring of oxygen saturation (SaO2) by pulse oximetry is a current practice in many coronary care units in patients with acute myocardial infarction (AMI), but its correlation with cardiac failure (CF) has not been established.
Methods: With this objective, 206 consecutive patients with AMI were prospectively studied in the morning round for the first three days, registering simultaneous daily data from physical examination (Killip classification), chest x-ray film (Battler score evaluated by two observers) and baseline SaO2 (measured when patients were breathing room air or taking the steadiest value after a short discontinuation of oxygen therapy). The latter was also obtained at every nursing turn. Patients with cardiogenic shock (Killip IV) were excluded.
Results: 610 simultaneous registries were obtained: Killip I (66%), Killip II (21%) and Killip III (12%). There was a good correlation between baseline SaO2 and physical examination (Killip/SaO2) (mean ± SD): I/ 94 ±1.9%, II/ 91±2.6% and III/ 84±8% (R= -0.66, p<0.001) and with x-ray film (Battler/SaO2): 0/ 94±1.7%, 1/ 93±2.4%, 2/ 90±3.9%, 3/ 89±4%, 4/ 81±9% (R=-0.65, p<0.001) although a better correlation was found between Killip and Battler scores (R= 0.84). Left ventricular ejection fraction also correlated with the worst Killip, Battler and SaO2 (R=-0.56, -0.57 and -0.412; p<0.001 respectively). True CF was defined by the association of Battler >1 and Killip >1. ROC curves showed SaO2 < 93% to be the cutoff with greater area under the curve, showing a sensitivity of 76%, specificity of 86% and test accuracy of 86%.
Conclusion: Baseline SaO2 determination by pulse oximetry is a useful tool to identify cardiac failure in patients with AMI and may be an early sign of this complication if values are below 93%. Baseline SaO2 must be considered in the routine evaluation of these patients.

P1222 Hepatocyte growth factor: the advent of a unique angiogenic marker for the early detection of acute myocardial infarction patients

K.I Kapetanios[1], C.E. Pitsavos[2], S. Kastelanos[2], G.P. Vyssoulis[2], D.B. Panagiotakos[2], M.G. Toutouza[2], C.I. Stefanadis[2], P.K. Toutouzas[2]. *[1]Athens, Greece; [2]University of Athens Medical School, Cardiology Department, Athens, Greece*

Hepatocyte growth factor (HGF) is a multipotent molecule and a member of the endothelium- specific growth factors transducing a wide range of biological signals, including mitogenesis, motogenesis and morphogenesis, as well as an organotrophic factor for regeneration of various organs exhibiting a potent angiogenic and antiapoptotic activity in several cell types. In the present study we sought to elucidate any possible role of HGF in acute myocardial infarction (AMI) parients.
Methods: We measured serum HGF levels in 24 pts with first attack of AMI, admitted and thrombolysed during the acute phase,and no previous history of any other disease,and compared to those of 20 sex and age- matched normal controls (NC) with mean values: 0,32 ± 0.06 ng/ml. Serum samples were collected at the time of hospital admission (0 hours), as well as 3h, 6h, 9h, 12h, 18h, 24h, 36h, 48h, 3 days, 4d, 5d, 7d, 15d and 30d thereafter and measured by ELISA method.
Results: Data is expressed as mean values ± SEM in ng/ml. For the statistical analysis non- parametric Wilcoxon test was used, with a statistical significance of p<0,05 compared to corresponding values of: a) NC (*), b) the lowest serum value at 36h (°). HGF exhibited significantly high initial serum levels on admission (7,67 ± 2,43 *°) reaching a maximum at 3h (8,75 ± 2,67 *°). A gradual decline followed leading to a nadir at 36h (1,68 ± 0,35),which was succeeded by a steep increase up to a later peak at 4d (5,77 ± 1,84 *°). HGF gradually returned within normal range finally. Furthermore,when classified according to infarct size, pts with extensive AMI and adverse events during the early post-AMI period, exhibited a higher, more sustained initial HGF peak compared to those with minor AMI and uncomplicated clinical course (17,32 ± 4,65 vs 6,44 ± 1,67, p<0,05).
Conclusions: Thus, a statistically significant double- peak increase of HGF serum levels in AMI pts has been observed. The initially 24- fold increased HGF possibly acts as a survival factor against endothelial cell death caused by acute hypoxia due to reduced vascular perfusion, while the following progressive decrease could be attributed to thrombolytic therapy and reperfusion. The raised HGF levels, 4 days later, may be fundamental for the induction of angiogenesis implicated to the process of ventricular remodeling, thus preserving cardiac function. Therefore, HGF seems to be a useful marker for the early detection of AMI pts, as well as a prognostic indicator reflecting their clinical course.

P1223 Cardiac endothelin-1 receptors are increased in the acute phase of myocardial infarction in humans

S. Vanni, A.M. Vetere, G. Polidori, I. Cecioni, I. Bertolozzi, F. Moroni, C. Adembri, P A. Modesti. *University of Florence, Clinica Medica Generale e Cardiologia, Florence, Italy*

Plasma concentration of endothelin-1 (ET-1) are increased in the acute phase of myocardial infarction and experimental studies showed that chronic ET-1 receptor antagonist administration may improve ventricular remodelling and survival. To investigate cardiac ET-1 receptors in acute myocardial infarction we studied cardiac ET-1 receptors in the hearts of 15 patients dead 1 (n=3), 3 (n=4), 7 (n=5) and 20-30 days (n=3) after acute anterolateral myocardial infarction. Only patients who had not received thrombolysis or reperfusion were selected. The control group was formed by age-matched patients dead for noncardiac reasons. ET-1 receptors on isolated cardiac membranes were investigated using binding methods with 125I-ET-1 (2000 Ci/mmol, Amersham) as radiolabeled ligand and ET-1 (0-1μM) as cold displacer. Cardiac specimens were collected at necroscopy performed 24 hours after exitus. Receptor binding stability was preliminarly checked in hearts explanted from patients undergoing cardiac transplantation stored at 15°C for 12, 24 and 48 hours. Preliminary experiments performed on explanted hearts showed only a 21% increase in ET-1 receptor density at 48 h ($p<0.05$). In necroscopy specimens taken in post-AMI patients ET-1 receptor density was slightly decreased at day 1 (-25%, ns vs controls), increased by 82% at 3 days ($p<0.01$) and remained elevated at 30 days (+113%, $p<0.01$). In conclusion, cardiac ET-1 receptors sharply increases during the first week following myocardial infarction and remains elevated during the following month.

P1224 Oxidized low-density lipoprotein in patients with unstable coronary artery disease and a healthy control population

N. Johnston[1], B. Lagerqvist[1], A. Siegbahn[2], L. Wallentin[1]. [1]*Dept. of Cardiology,* [2]*University Hospital, Dept. of Clinical Chemistry, Uppsala, Sweden*

Background: In the clinical setting of coronary artery disease measurement of serum levels of cholesterol, LDL and HDL is common practice. Oxidatively modified low-density lipoprotein is however receiving considerable attention as evidence is mounting for its pivotal role in the initiation and progression of atherosclerosis. Measurement of oxidized LDL has not found its way into the clinical arena as many methods have been hampered by methodological drawbacks and small patient samples.
Material and methods: Using a recently developed sandwich ELISA method we evaluated the relation of oxidized LDL in 164 patients with unstable coronary artery disease (UCAD) included in the FRISC-II trial and in an equal number of age and gender matched healthy controls. 17,7% of FRISC-II patients were on treatment for hyperlipidemia.
Results: In UCAD patients oxidized LDL levels at admission were significantly higher than in controls ($p<0,001$). Total cholesterol did not differ among groups. HDL was significantly higher ($p<0,001$)and LDL significantly lower in controls ($p=0,007$).

Variable	Controls (n=164)	FRISC II (n=164)	p-value
s-cholesterol (mmol/l)	5.68±0.93	5.61±1.08	n.s.
s-HDL (mmol/l)	1.53±0.40	1.07±0.29	p<0.001
s-LDL (mmol/l)	3.37±0.83	3.62±1.03	p=0.007
s-oxLDL (U/l)	50.37±13.53	77.51±19.81	p<0.001

Conclusion: This study confirms findings in previous studies of elevated levels of oxidized LDL in patients with unstable coronary artery disease compared to healthy controls.

P1225 Tissue factor promotor polymorphisms are associated with an increased risk of myocardial infarction

I. Ott, R. de Waha, W. Koch, A. Malawaniec, N. von Beckerath, A. Schömig, A. Kastrati. *Deutsches Herzzentrum München, München, Germany*

The transmembrane glykoprotein tissue factor (TF) is the main initiator of the extrinsic coagulation cascade. TF Expression in atherosclerotic lesions plays an imporant role in local thrombus formation in acute coronary syndromes. Expression levels may be associated with different promoter polymorphisms and thereby contribute to the risk of acute myocardial infarction.
Patients with myocardial infarction (MI, n=793) and age and sex matched patients without coronary artery disease (K=340) were included. After isolation of DNA (QIAamp blood kit, Qiagen, Hilden, Germany) TF promotor polymorphisms -603 A/G and -1322 C/T were analyzed by amplification with allel specific probes (TaqMan). Both polymorphisms were concordant in 99.6% of all patients. In patients with AMI the -603 G (MI: 76%, K: 70%) allel and the -1322 T-allel (MI 76%, K: 70%) were prevalent (P=0,04). Multivariate analysis revealed an odds ratio of 1.44 (confidence intervall 1.07-1.93).
Thus,carriage ot the -603 G and the -1322 T allel is associated with an increased risk für acute myocardial infarction. The relationship between promotor polymorphism and TF Expression requires further investigations.

P1226 Intracoronary enalaprilat reduces postischaemic leukocyte-adhesion and improves coronary blood flow in patients with acute myocardial infarction

U. Schaefer[1], T. Kurz[2], R. Tölg[2], F. Hartmann[2], G. Richardt[2]. [1]*Medizinische Universität zu Lübeck, Medizinische Klinik II - Kardiologie, Lübeck, Germany;* [2]*Medizinische Universität zu Lübeck, Kardiologie Med Klin II, Lübeck, Germany*

Background: Although reopening of the infarct related artery (IRA) is the established therapy in acute myocardial infarction there is some experimental evidence that reperfusion is associated with a distinct tissue damage. This myocardial injury after ischemia and reperfusion involves postcapillary leukocyte endothelial interactions mediated by cell adhesion molecules, a phenomenon probably aggravated by endothelin-1 (ET-1). Since ACE-inhibition has been shown to be cardioprotective by decreasing leukocyte adhesion and ET-1 release, we investigated the effects of intracoronary (i.c.) enalaprilat, infused during reperfusion in acute myocardial infarction. Methods: Twenty two patients with a large acute myocardial infarction were randomized to receive (i.c.) either enalaprilat (E; 50 μg) or placebo (P) immediately after reopening of the infarct vessel by primary PCI. Plasma concentrations of soluble L-selectin, P-selectin, intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1) and ET-1 were measured before PCI and at 2, 10 and 60 min after E or P i.c. in pulmonary arterial blood. Moreover, corrected TIMI frame counts (CTFC) and 10 days follow-up LV-angiography for all patients were assessed.
Results: During reperfusion there was a significant early increase in sL-selectin (+12.7%*), sP-selectin (12,5%*) and ET-1 (+304%*) after P, which was suppressed by E. ICAM-1- and VCAM-1-levels were not affected during reperfusion in both groups. CTFC after primary PCI suggested an increase in myocardial blood flow in the infarct related artery (CTFC E vs. P: 43±7 vs. 81±30; $p=0.07$) and in the reference vessel ($p<0.01$) after E. Moreover, LV-ejection fraction tended to be improved during 10 days follow-up LV-angiography (LVEF E vs. P: +5.1% vs. -0.8%; $p= 0.06$).
Conclusion: Intracoronary enalaprilat prevents postischemic leukocyte adhesion and the release of ET-1 after primary PCI and might therefore be a promising approach to improve coronary blood flow and LV-function after acute myocardial infarction.

P1227 Prompt improvement of the endothelial function by simvastatin in the acute coronary syndrome

A. Gonta[1], G.-A. Dan[2], M. Bengus[1], R. Vasilescu[1], C. Stanescu[1], D. Sipciu[1]. [1]*Colentina University Hospital, Cardiology Dept., Bucharest, Romania;* [2]*"N.G.Lupu" Medicine Institute, Rhythmology, Bucharest, Romania*

Increasing evidence suggests that starting early statin therapy in patients who suffered an acute coronary syndrome (ACS) is associated with substantial prognostic improvement. The exact mechanism of this benefit is not yet completely understood, but it cannot be explained only on the basis of reduction of plasma cholesterol levels. Many studies indicate that treatment with statins improves the endothelial function and vasomotion.
The aim of our study was to assess the hypothesis that early therapy with Simvastatin in ACS patients (pt) is followed by a rapid improvement of endothelial function. We included 49 patients hospitalized with ACS, with cholesterol values below 200mg/dl at the time of hospitalization. They were randomly assigned to receive Simvastatin 40 mg daily (25pt), after the first 24 hours, or no hypolipemiant drug (24pt). Both groups had similar basal characteristics, including the proportion of unstable angina and acute myocardial infarction; also, the two groups were similar regarding the left ventricular ejection fraction and the treatment for ACS (which included ASA, beta-blockers and ACEI). For both groups we determined at the beginning of the study and after 6 weeks the flow-mediated vasodilatation (FMD) and the endothelium-independent Nitroglycerine vasodilatation (NMD). FMD was defined as percent change in brachial artery diameter at 1 min. after 5 min. of upper arm blood pressure cuff occlusion.
Results: Multiple determinations were made in order to assess FMD (interobserver variability < 1.2%). Basal FMD was not different in the Simvastatin treated pts. and in the not treated pts. (3.1±2.7% vs. 3.3±2.9%, p: NS). Also, basal NMD values were not different in the Simvastatin treated and the not treated pts. At 6 weeks FMD was significantly improved in the Simvastatin treated pts. compared with the not treated pts.: 11.3±0.7% versus 5.33±0.2%, $p<0.03$. NMD was not different between the Simvastatin treated and the not treated pts. (22.9±1.3% vs. 21.5±0.6%, p:NS). At 6 weeks the cholesterol values did not differ significantly vs. basal values and between the Simvastatin treated and the not treated pts.
Conclusion: Simvastatin administered on early bases in ACS normocholesterolemic patients improves promptly the endothelial function as determined by FMD. This effect may contribute to the positive long-term prognostic implications of the use of statins in ACS.

P1228 Ischaemia induces interleukin 6 and tissue factor production in patients with coronary artery disease. A dobutamine stress echocardiograhy study

I. Ikonomidis[1], G. Athanassopoulos[2], J. Lekakis[1], K. Venetsanou[1], M. Marinou[2], P. Nihoyannopoulos[3], D. Cokkinos[2], S. Stamatelopoulos[1]. *[1]Alexandra Hospital, Univ. of Athens, Dep. of Clinical Therapeutics, Athens, Greece; [2]Onassis Cardiac Surgery Center, 1st Cardiology Department, Athens, Greece; [3]Hammersmith Hosp, Cardiology Dept., London, United Kingdom*

Interleukin 6 (IL6) and macrophage colony stimulating factor (MCSF) plasma levels are elevated after acute myocardial infarction. IL6 also mediates the ischemia-reperfusion myocardial injury in experimental models. We investigated whether reversible ischemia induces cytokine production leading to increased tissue factor (TF) expression after dobutamine stress echocardiography (DSE) in patients with stable coronary artery disease (SA).

Methods: Eighty patients with SA were studied by DSE and were compared to 24 normal controls. Blood samples were obtained at rest, at peak stress and 20min after cessation of dobutamine infusion (rec) for measurement (median, 25th-75th percentile) of MCSF, IL6 and TF plasma levels (pg/ml). Patients had angiograpically documented CAD. New or worsening region wall motion abnormalities (RWMA) at stress and their duration in rec were noted.

Results.Patients had higher rest IL6, MCSF and TF than controls ($p<0.01$,Table). During DSE,45 patients presented ischemia. Patients with and without ischemia achieved similar heart-rate product at peak stress. IL6 and TF levels increased at peak stress and at rec compared to rest in ischemic but not in non-ischemic patients (Table, $p<0.05$). MCSF levels were similar at rest, at peak stress and rec in all patients. High MCSF was related with high TF only in ischemic patients in rec ($r=0.61$, $p<0.01$). Patients with RWMA lasting>5 min in rec (n=20) had higher IL6 at stress and rec than those with RWMA lasting <5 min (stress: 3.3 (2.4-4.6) vs 2.0 (1.5-2.7), rec: 2.7 (2.3-4.3) vs 1.9 (1.4-2.7), $p<0.01$).

DSE	Rest-IL6	Stress-IL6	Rec-IL6	Rest-TF	Stress-TF	Rec-TF
Ischemic (n=45)	2.1 (1.5-2.8)	2.5 (1.7-3.3)	2.4 (1.6-3.4)	266 (132-405)	371 (142-576)	385 (141-577)
Non ischemic (n=35)	2.1 (1.3-3.2)	2.1 (1.4-3.5)	2.2 (1.4-3.6)	371 (142-576)	312 (210-590)	328 (265-600)
Controls (n=24)	1.7 (0.5-1.9)			187 (120-220)		

$P<0.01$, peak stress and recovery vs rest in ischemic patients and in patients vs controls

Conclusion: Reversible ischemia induces an increase of IL-6 and TF plasma levels that is sustained in recovery after DSE. MSCF is related to TF plasma levels during the post ischemic period. Increased production of IL6 persisting throughout recovery may explain the persistent left ventricular dysfunction observed in the post-ischemic period after DSE since this cytokine has a direct negative inotropic action.

P1229 Interleukin (IL)-10 and nitric oxide in acute coronary syndromes

S. Demyanets. *Kharkov, Ukraine*

Background: Activities of cytokines with antiinflammatory properties during cardiovascular diseases bacome in the field of interest. Some studies measured IL-10 in the serum at acute myocardial infarction (AMI), stable and unstable angina (UA) patients (pts). IL-10 expression has been revealed in atherosclerotic plaques and was associated with decreased inducible nitric oxide synthase (iNOS) expression. Increased serum nitrite/nitrate were more evident in Il-10-deficient than in wild-type mice during reperfusion.

In our study we measured plasma IL-10 and total nitric oxide (NO) concentrations at the pts with different presentations of acute coronary syndromes (ACS) - UA and AMI.

Methods: 56 pts with ACS were examined - 42 pts with AMI and 14 pts with UA. Blood was taken at admission. Plasma IL-10 concentrations were measured by an enzyme immunoassay (CytElisa, Maryland; sensitivity 1,6 pg/ml). For the quantitative determination of total nitrite concentrations in plasma were used R&D Systems' Total Nitric Oxide Assay (sensitivity less that 1,35 μmol/l) wich involves the conversion of nitrate to nitrite by the enzyme nitrate reductase.

Results: AMI pts had higher IL-10 plasma levels as compared with UA pts (54,39±26,83 pg/ml vs 42,84±22,43 pg/ml; p less 0,001). In pts with Q-wave AMI (35 pts) IL-10 mean concentration were 63,17±39,51 pg/ml, which was higher than in non-Q AMI pts (21 pts) - 45,61±27,19 pg/ml; p less 0,001. Concentrations of total nitrite in plasma of UA pts were 25,37±4,26 μmol/l which statistically higher than in plasma of AMI pts - 14,74±3,28 μmol/l (p less 0,01).

Conclusions: The results suggests that during UA plasma IL-10 concentrations are associated with clinical instability and during periods of myocardial ischemia/reperfusion may be essential for cardioprotection and have a role in healing. Impaired NO production may contribute to the development of more severe presentations of acute coronary syndromes.

P1230 Angiotensin-converting enzyme Immunoreactvity is associated with macrophage-infiltration and cell proliferation in "de-novo" coronary plaques

F. Ribichini[1], F. Pugno[2], V. Ferrero[1], A. Alberti[3], E. Brscic[3], C. Di Mario[4], A. Colombo[4], E. Uslenghi[1]. *[1]Ospedale S. Croce, Cardiology Dept., Cuneo, Italy; [2]Ospedale S. Croce, Pathology, Cuneo, Italy; [3]Villa Maria Pia, Cardiology, Torino, Italy; [4]Columbus, Cardiology, Milano, Italy*

Background: Angiotensin-II contributes to the initiation and progression of atherosclerosis while its reduction following angiotensin-converting enzyme (ACE) inhibition may account for the vascular protection provided by these drugs. Therefore, ACE in the plaque is likely to be a substratum for the clinical benefits of ACE-inhibitors. The hypothesis was made that ACE in the atherosclerotic plaque could be involved with inflammation and cell proliferation. **Methods:** Histology and immunocytochemistry of "de-novo" coronary plaques retrieved with directional coronary atherectomy were analyzed in 124 patients: 74 with stable angina, 35 with sub-acute and 15 with acute unstable angina. Statistical analysis was performed on total and segmental stained plaque areas quantified by computer-aided planimetry. **Results:** Compared to stable patients, unstable patients showed more thrombotic lesions (72% versus 27% $p<0.0001$), smaller areas of fibrous type of plaque (2.3±1.2 mm^2 versus 2.8±1.1 mm^2, $p=0.03$), a higher cellular proliferative score assessed with Ki-67 immunostaining (0.78±0.9 versus 0.27±0.6, $p=0.003$), larger content of ACE-immunostained cells (25.4±23 versus 13.2±15%, $p=0.007$) and larger areas of inflammation as identified by KP-1 immunostaining (30±22 versus 21±20%, $p=0.03$). A significant linear correlation was found between KP-1 and ACE stained areas (mm^2) among unstable patients ($r=0.6$, $p=0.0001$) and was absent among stable patients ($r=0.006$, $p=0.9$). Co-localization of ACE and KP-1 was confirmed by double-immunostaining. Patients with ki-67 evidence of cell proliferation had larger contents of ACE (30.3±20% versus 14.5±19%, $p=0.004$). Proliferating cells were found to be mostly inflammatory and in part also spindled-shaped smooth muscle cells. **Conclusions:** ACE immunoactivity is associated with the process of plaque inflammation and cell proliferation in "de-novo" lesions. Both, the total content of ACE and its co-existence with areas of inflammation are significantly larger in patients with unstable angina. These observations support a role of the enzyme in the pathophysiology of plaques responsible for unstable syndromes and suggest potentially different effects of ACE-inhibitors according to clinical presentation.

P1231 Circulating vasoactive amyloid beta protein ending at 42 amino acid is elevated in severe acute myocardial infarction

E.V. Economou, C.P. Pitsavos, A. Masourou, A. Zervoudaki, M.G. Toutouza, K.I. Kapetanios, C.I. Stefanadis, P.K. Toutouzas. *Hippokration Hosp., Univ. Athens, Department of Cardiology, Athens, Greece*

Background: Circulating amyloid beta protein ending at 42 amino acid (Abeta42) can induce oxidative stress-mediated loss of vascular endothelial function, as evidenced by increased vasoconstriction and decreased endothlium-dependent vasodilation, in the periphery and the brain, that is distinct from the reporeted neurotoxic effects produced by aggregated forms of Abeta42. Vascular tissues produce Abeta42 in respose to an hypoxic/ischemic stress insult. Moreover Abeta42 is released during platelet activation and degranulation and it may have an important physiological role in events associated with clot formation. Aim of this study was to delineate whether the formation of circulating Abeta42 would be favoured by a severe acute myocardial infarction (AMI). **Methods:** In 21 patients (pts) with first attack of AMI, large infarct size, ejection fraction <45%, no evidence of any later thrombotic occlussion, extension of myocardial necrosis, or any other disease, serum levels of Abeta42 were determined on hospital admission [mean latency from the onset of chest pain: 2±1 hours (h)] before thrombolysis (0h) and after 3h, 6h, 9h, 12h, 18h, 24h, 36h, 48h, 72h, 4 days (d), 5d, 7d, 15d and 30d and compared to corresponding values of 20 age- and sex-matched healthy controls (HS). **Results:** At 0h, Abeta42 levels were noticed to be significantly higher in comparison to the respective levels of HS (26.7±1.1 vs 1.3±0.3 pg/mL, $p=0.001$). After that, a gradual drop of Abeta42 levels to their lowest values at 6h (18.2±7.8 pg/mL) was noticed and followed by a progressive elevation of them to their highest values at 30d (35.9±6.4 pg/mL), (in both cases $p<0.05$ in comparison to the respective levels at 0h). **Conclusions:** In severe AMI, serum levels of Abeta42 are elevated even at the very first 2h from the onset of chest pain, possibly due, primarly, to platelet aggregation relevant to thrombus formation. Since effective thrombolysis appears to reduce Abeta42 serum levels, not only temporally but also partially, in comparison to respective HS serum levels, other Abeta42 sources might be, in the meanwhile, implicated. This is in accordance with the following progressive elevation of Abeta42 levels, possibly due to the long-lasting action of the preceding elevated circulating Abeta42 on the vessel wall, which is well recognized to upregulate Abeta42 production. Since circulating Abeta42 has been shown to interact with and to cross blood-brain barrier, severe AMI-induced elevated circulating Abeta42 may contribute to progress not only in cardiovascular but also in cerebrovascular disorders.

P1232 Trimetazidine-mediated cardioprotection during ischaemia is mediated by mitochondrial respiratory chain's complex I activity

P. Monteiro[1], A. Moreno[2], L. Gonçalves[1], L.A. Providência[1]. [1]Coimbra University Hospital, Cardiology Dept., Coimbra, Portugal; [2]Center for Neuroscience of Coimbra, Coimbra, Portugal

Trimetazidine (TMZ) was reported to protect myocardium from ischemia. However, the mechanisms involved in this protection remain a matter of debate. To better understand this topic, we developed an animal model of global myocardial ischemia, using a Lagendorff perfusion system. Thirty Wistar rat hearts were distributed in 3 experimental groups - A - 180 minutes of perfusion with a modified Krebs solution, B - 60 minutes of perfusion with the same solution, followed by 120 minutes of ischemia, in the absence of glucose and O2 and C - as in B, but in the presence of TMZ 25 μM. Mitochondria were then isolated and used to determine the activity of complexes I, II-III and IV of the mitochondrial respiratory chain (MRC), using their metabolic substrates (Glutamate/Malate, Succinate and Ascorbate/TMPD). Parameters evaluated were: Respiratory Control Ratio (RCR), Maximum Mitochondrial Membrane's Electrical Potential (Delta Psi), Phosphorylative Lag Phase (PLP) and Enzymatic Activities (EA) of MRC's complexes.
TMZ significantly improved RCR values, near to those of controls. A significant improvement of Delta Psi values in all the MRC complexes studied was also seen after TMZ treatment, without any significant change in PLP. TMZ significantly improved the enzymatic activity of MRC's complex I, even above the values of group A (control); in the other enzymatic complexes, the impact of TMZ was reduced or none.
Results:

Parameters/groups	Ischemic (Group B)	TMZ (Group C)
RCR	56±5%	101±16% *
Delta Psi (Glutamate/Malate)	89±2%	95±1% *
EA (Complex I)	63±5%	154±11% *
EA (Complexes II-III)	60±5%	66±4%
EA (Complex IV)	71±7%	71±5%

Note: * - p<0.05 B vs C; values are expressed as % of control (Group A).

In conclusion, TMZ improved the efficiency of the oxidative system, with a better preservation of the electrochemical gradient within the inner mitochondrial membrane, without changing the phosphorylation. These mechanisms, involved in the cardioprotective effect of TMZ, are dependent on an increase in Complex I activity.

GENE DELIVERY TO CARDIAC TISSUES

P1233 Enhancement of in vitro gene transfer to smooth muscle cells by ultrasound

D. Vincentelli Djeffal, L. Pizarro, M.L. Jourdan, N. Ferrera, P. Peycher, F. Patat, P. Coursaget, L. Maillard. *TOURS, France*

Background: Gene therapy is a promising technique to prevent restenosis following percutanous coronary intervention and increase transfection efficiency is a major step before clinical applications. Ultrasounds (US) combined with agent contrast (gas bubbles) enhance mammalian cells membrane permeabilization and could increase gene transfer in smooth muscle cells (SMC). We evaluated the potential of this method to improve in vitro transfection in SMC.
Methods: SMC were obtained by outgrowth from explants of rabit thoracic aorta and cultured in DMEM containing 20% fetal veal serum. At one month growth cultured SMC were suspended in cell wells (1.10 6 cells per well) in presence of plasmid (pEGFP-N1) and exposed to US. US were performed with a 10 cm^2 surface, 1.656 MHz, piezoelectric ceramic transducer placed below cell wells on continuous mode. Transfection efficiency was optimized by varying US conditions (20 to 50 W; 30 to 60 s exposure time), plasmid concentrations (2,5 μg/ml and 5 μg/ml), adjunction of contrast agent (200 mg μparticles/ml). Cell counts, viability (uptake of 7 AAD) and transfection (GFP fluoscein) were assayed by flow cytometry.
Results: Below 50 W and 50 s US exposure, we did not observed an increase of SMC death. Optimal protein production following 30 W, 40 s exposure was no different in tested DNA concentration (2.5 μg/ml vs 5 μg/ml; p ns). Maximal gene transfection was seen with adjunction of contrast agent (1,53% with contrast agent vs 0,5% without contrast agent) without increasing mortality (8.5% vs 7.5%, p ns). US enhance significantly SMC transfection efficiency (1.53% naked DNA with US versus 0.06% with naked DNA alone; p=0.046) with 2,5 μg/ml of DNA, 100 μl/ml of contrast agent, 30 W and 40 s of US exposure. No increase of cell death was observed.
Conclusions: Ultrasounds combined with contrast agent enhance gene transfer and appears to be a safe technique to be developped for in vivo applications.

P1234 Recombinant Semliki Forest virus: perspectives for selective gene delivery in vascular lesions during stenting

A.J.M. Roks[1], R.H. Henning[1], R.A. Tio[2], A.J. van Boven[2], H.J. Haisma[3], J. Wilschut[4], W.H. van Gilst[1]. [1]Academic Hospital Groningen, Clinical Pharmacology, Groningen, Netherlands; [2]University of Groningen, Cardiology, Groningen, Netherlands; [3]University of Groningen, Therapeutic Gene Modulation, Groningen, Netherlands; [4]University of Groningen, Medical Microbiology, Lab of Virology, Groningen, Netherlands

Background: Previously, we demonstrated that recombinant Semliki Forest virus (SFV) is a more selective vector to cultured vascular smooth muscle cells (VSMC) than Adenovirus (Ad5). Here we describe the consequences for in vivo vascular gene delivery after vector administration through dwelling or a stent.
Methods: SFVLacZ or Ad5LacZ was administered through intraluminal dwelling into balloon-injured rat abdominal aorta. After 3 to 72 h the aortic segments were screened for LacZ staining. In separate experiments, especially designed coverstents (Medtronic, Maastricht, the Netherlands) were used to deliver SFVLacZ or Ad5LacZ (1e8 infectious units/stent). After 48 h and 72 h resp. LacZ expression was studied.
Results: Both SFV and Ad5 expression started after 12 h. However, SFV was more selective than Ad5 with respect to gene transfer in the media (table 1). Both vectors were successfully delivered with coverstents. However, in contrast to dwelling delivery, stent delivery led to LacZ expression to appear almost exclusively in the media.
Discussion: SFV and Ad5 have very distinct gene delivery patterns in balloon-injured vessels after dwelling delivery. However, in-stent delivery of SFV and Ad5 is feasible and leads to transgene expression to be present almost exclusively in the media.

Table 1: in vivo gene delivery

vector type	time [hrs]	positive sections [% of total # of sections]	distribution intima	media	adventitia
SFVLacZ	12	4 (2)	0	0	100
	24	31 (8)	0	90	23

SFV and Ad5 transfection into balloon-injured rat aorta. Per aortic segment 5e7 infectious virus units were delivered intraluminally to dwell for 10 minutes. LacZ expression was studied at the given time points. The gene delivery distribution per vessel layer is expressed as % of the total number of LacZ-positive sections. Standard errors are mentioned between brackets.

P1235 Lentivirus (HIV) vector system for gene delivery into cardiac myocytes

T. Sakoda[1], M. Oyanagi[1], N. Kasahara[2], K. Larry[2], T. Iwasaki[1]. [1]Kobe, Japan; [2]Genetic Medicine, Biochemistry and Molecular Biology, Los Angeles, United States of America

Human immunodeficiency virus (HIV, lentivirus) type-1 vector has a number of attractive features for gene therapy, including the ability to transduce non-dividing cells and long term transgene expression. We used a three plasmid expression system to generate pseudotyped lentivirus vector to investigate the transduction efficiency in the cardiac myocytes (CM). Both lentivirus vector and murine retrovirus vector effectively transduced into dividing cardiac fibroblasts at the same efficiency. Lentivirus vector also efficiently transduced into CM and yielded titers of 4.9x10(5) transducing units/ml (TU/ml), however murine retrovirus vector showed low transduction efficiency with titers reaching only 8.9x10(2) TU/ml. SIN (self inactivating) lentivirus vector known to be third generation lentivirus vector (a portion of 3'-LTR is deleted for reducing promoter interference) has reported to show higher levels of transgene expression than that of full length 3'-LTR lentivirus vector (1st generation of lentivirus vector). Next we investigated the transgene expression levels in CM transduced by 1st generation of lentivirus vector or SIN lentivirus vector. SIN lentivirus vector showed higher transduction efficiency into CM than that by 1st generation of lentivirus vector (6.7x10(5) vs 4.9x10(5)). Furthermore, GFP expression level (mean fluorescence) was higher in CM transduced by lentivirus vector than 1st generation of lentivirus vector (4.2x10(3) vs 1.8x10(3)). These results firstly demonstrated that lentivirus vector can efficiently transduce well-differentiated CM. This appears to be an efficient method and provide a new tool for research and therapy for cardiovascular diseases. μ

P1236 Catheter-based adenoviral overexpression of tissue factor pathway inhibitor reduces intimal hyperplasia in a rabbit injury model

C.W.K. Kopp[1], T.H. Hölzenbein[2], S. Steiner[1], H. Bergmeister[3], R. Marculescu[4], D. Seidinger[1], R. de Martin[5], E. Minar[1]. [1]*University of Vienna, General hospital, 2nd Dept. of Medicine, Vienna, Austria;* [2]*University hospital of Vienna, Department of Vascular Surgery, Vienna, Austria;* [3]*University of Vienna, Biomedical Research, Vienna, Austria;* [4]*University of Vienna, Dept.of laboratory medicine, Vienna, Austria;* [5]*University of Vienna, Inst.f.Thrombosis & vasc. Biol., Vienna, Austria*

Background: Tissue factor (TF), the major procoagulant of the atheroma and activated blood monocytes, is locally expressed at the site of balloon injury mediating a prolonged prothrombotic state. TF-pathway inhibitor (TFPI) regulates hemostasis as well as mitogenic and chemotactic effects of coagulation factors VIIa, Xa and thrombin.
Aim: To interfere with the process of restenosis by percutaneous overexpression of TFPI.
Method and Results: Myc-tagged TFPI (Ad5-TFPI-c-myc; n=10) or control virus (Ad5 lacZ, n=10) adenoviral transfection (1x109 pfu/ml) was performed in femoral arteries of atherosclerotic NZW rabbits using a drug delivery catheter. Arterial expression of the transgene was confirmed by immunohistochemistry on day 2, 5 and 21 after percutaneous overexpression in media and neointima smooth muscle cells. Restenosis as quantitated by intima to media (I/M) ratio was significantly reduced 21 days after angioplasty by 63% in Ad5-TFPI-c-myc treated arteries (0.9±0.4) compared with Ad5-lacZ (2.7±0.7) treatment ($p<0.0001$) resulting in 30% luminal gain. Reduced monocyte infiltration and vascular TF expression was observed in Ad5-TFPI-c-myc transfected vessels compared with control
Conclusion: Catheter-based adenoviral overexpression of TFPI reduces intimal hyperplasia in response to balloon injury by inhibition of TF and recruitment of monocytes in the atherosclerotic rabbit injury model.

P1237 High-level and long-term gene expression in endothelial cells transduced by lentiviral vector

T. Sakoda[1], Y. Fujioka[1], K. Tsujino[1], M. Ohyanagi[1], N. Kasahara[2], L. Kedes[2], T. Iwasaki[1]. [1]*Kobe, Japan;* [2]*Genetic Medicine, Biochemistry and Molecular Biology, Los Angeles, United States of America*

Endothelial cells (EC) are an attractive target for gene therapy. Lentivirus vector is known to infect with wide variety of cells and shows the long term transgene expression. In this study, bovine aortic endothelial cells (BAEC) were infected in vitro with lentivirus vector compared with retrovirus and adenovirus. Transduction efficiency (TE) of b-Gal gene transfer in BAEC by adenovirus, lentivirus, or retrovirus at MOI 10 (Multiplicity of infection) (determined on HeLa cells) is 69, 33, or 22% respectively. In adenovirus and lentivirus, almost 100% of BAEC were transduced at MOI 50. However, in retrovirus, TE showed only 48% at MOI 50 and no increase at MOI 100. The percentage of b-Gal positive cells was decreased rapidly at longer passage of cells after transduced by adenovirus. However, lentivirus and retrovirus showed sustained higher percentage of positive cells. SIN lentivirus vector (a portion of 3-LTR is deleted for reducing promoter interference) showed higher levels of transgene expression than that of full length 3-LTR lentivirus vector at the same MOI. Lentivirus vector showed high TE and long term expression in BAEC. Our results suggest that lentivirus can be an effective vector for the ex vivo genetically modified EC implantation and in vivo gene therapy.μ

P1238 Gene delivery method and immune status determination – Efficacy and safety of adenoviral cardiovascular gene transfer

Z. Szelid[1], P. Sinnaeve[2], P. Vermeersch[1], E. Verbeken[3], D. Collen[1], W. Flameng[4], F. Van de Werf[2], S. Janssens[2] on behalf of Center for Transgene Technology and Gene Therapy. [1]*University Hospitals Leuven, CTG, Leuven, Belgium;* [2]*University Hospitals Leuven, Cardiac Unit, Leuven, Belgium;* [3]*University Hospitals Leuven, Department of Pathology, Leuven, Belgium;* [4]*University Hospitals Leuven, Department of Cardiac Surgery, Leuven, Belgium*

Background: Adenoviruses are favored gene transfer vectors in cardiovascular applications. However, the effect of pre-existing immunity on the efficacy of different adenoviral cardiac gene transfer methods is unknown. Methods: The effect of immune status on transgene expression levels was compared following regional retrograde myocardial gene transfer and after local coronary intramural gene transfer. Adenoviral vectors expressing luciferase (5x10(10) pfu) were injected retrogradely in the cardiac vein using an occlusive balloon catheter, and locally in the LAD vessel wall using the Infiltrator catheter in naive pigs (n=12) and in pigs immunized by prior IV injection of the adenoviral vector (n=11). Neutralizing antibody (NAb) titers were assessed by the serum concentrations reducing adenovirus infectivity by 50% of control values in an in vitro infectivity assay. Titers were compared to pre-existing NAb titers in 26 patients referred for CABG. Results: Immunization with adenovirus elicited high NAb titers (1:2000) in all pigs. Myocardial luciferase expression levels [median, 25 and 75 percentiles (25p, 75p), light units, LU/mg protein], following regional gene transfer were abrogated in the left ventricular anterior wall in immunized versus naive pigs (1.26x10(3); 25p: 3.2x10(2), 75p: 5.2x10(3) vs 2.6x10(6); 25p: 9.2x10(5), 75p: 3.2x10(6) LU/mg protein, $P<0.01$). Following intramural gene transfer, however no difference in intramural transgene expression levels (1.46x10(5); 25p: 4.69x10(3), 75p: 3.1x10(5) vs 1.09x10(4); 25p: 2.57x10(3), 75p: 5.79x10(4) LU/mg protein, P=NS), nor in vascular adenoviral mRNA (0.34; 25p: 0.09, 75p: 1.9 vs 0.3; 25p: 0.03, 75p: 4.1 fg viral RNA/ ng GAPDH RNA, P=NS) was observed in immunized versus naive pigs. Transgene expression in the heart following regional gene transfer was associated with a grade I mild interstitial infiltrate (SHLT Cardiac Rejection Score) in all naive pigs, but a grade III-IV moderate to severe inflammation with myocyte necrosis and apoptosis was detected in immunized animals. In CABG patients high titer of pre-existing NAb (>1:2000) was detected in 10/26 patients. Conclusions: Pre-existing anti-adenoviral immunity abrogates cardiac transgene expression. Reduction in transgene expression levels with significant local toxicity was detected in immunized pigs following regional, but not after intramural gene transfer, and mandates screening for pre-existing anti-adenovirus immunity in patients prior to regional myocardial adenovirus gene delivery. Intramural adenoviral gene transfer, in contrast, may obviate these restrictions.

NEW INSIGHTS IN DILATIVE CARDIOMYOPATHY

P1239 Growth hormone administration as immunomodulatory treatment in patients with idiopathic dilated cardiomyopathy: a randomized crossover study

S. Adamopoulos[1], J.T. Parissis[2], M. Georgiadis[1], D. karatzas[1], C. Kroupis[1], J. Paraskevaidis[1], E. Livanis[1], D. kremastinos[1]. [1]*Onassis Cardiac Surgery Center, Dept. of Cardiac Medicine, Athens, Greece;* [2]*"Amalia Fleming" Hospital, 1st Department of Cardiology, Athens, Greece*

Background: Recent studies have shown that an abnormal proinflammatory cytokine expression and apoptotic process contribute to adverse left ventricular remodeling and progress of chronic heart failure (CHF). The present study investigates the effects of growth hormone (GH) administration on serum levels of representative proinflammatory cytokines, anti-inflammatory cytokines and soluble apoptosis mediators in patients with chronic heart failure secondary to idiopathic dilated cardiomyopathy (ICD).
Methods: Serum levels of proinflammatory cytokines tumor necrosis factor-a (TNF-a), soluble TNF receptors (sTNFRI, sTNFRII), interleukin-6 (IL-6)and soluble IL-6 receptor (sIL-6R),anti-inflammatory cytokines interleukin-10 (IL-10)and transforming growth factor-b2 (TGF-b2), and soluble apoptosis mediators soluble Fas (sFas) and soluble Fas Ligand (sFasL) were determined (ELISA method) in 10 patients with IDC (NYHA class III; EF 24±2%) before and after a 3-month subcutaneous administration of GH 4IU every other day (randomized crossover design). Peak oxygen consumption (VO2max) was also used to evaluate the functional status of IDC patients.
Results: Treatment with GH produced a significant reduction in serum levels of TNF-a (8.2±1.2 vs 5.7±1.1 pg/ml, $p<0.05$), sTNFRI (3.9±0.4 vs 3.2±0.3 ng/ml, $p<0.05$), sTNFRII (2.6±0.3 vs 2.2±0.2 ng/ml, $p<0.05$), IL-6 (5.5±0.6 vs 4.4±0.4 pg/ml, $p=0.05$), sIL-6R (32.7±3.0 vs 28.2±3.0 ng/ml, $p<0.05$), sFas (4.4±0.8 vs 3.1±0.6 ng/ml, $p<0.05$), and sFasL (34.2±11.7 vs 18.8±7.3 pg/ml, $p<0.01$)in IDC patients.No significant differences were observed in anti-inflammatory cytokines IL-10 (12.1±1.3 vs 13.6±1.7 pg/ml, p:NS) and TGF-b2 (18.8±2.2 vs 18.2±1.6 pg/ml, p:NS) after the GH treatment.However, a significant increase in ratio IL-10/TNF-a (1.8±0.3 vs 3.6±1.0, $p<0.05$) was found with GH treatment. A significant improvement was also observed in VO2max after the completion of 3 months' treatment with GH (15.0±0.8 vs 17.2±1.0 ml/kg/min, $p<0.05$). Good correlations were found between GH-induced increase in ratio IL-10/TNF-a and increase in VO2max ($r=0.76$, $p<0.01$), as well as between GH-induced reduction in sFasL and increase in VO2max ($r=-0.56$, $p=0.08$).
Conclusions: GH administration modulates beneficially circulating cytokine network and soluble Fas/FasL system in patents with IDC. These anti-inflammatory and anti-apoptotic effects may be associated with the improvement in clinical performance and exercise capacity of IDC patients.

P1240 Cardiodepressant effect on cardiomyocytes predicts acute and prolonged haemodynamic benefit during immunoadsorption

A. Staudt[1], Y. Grosse[1], J. Dahm[1], S.B. Felix[1], C. Bischoff[1], A. Hummel[1], M. Boehm[2], G. Baumann[2]. [1]*Ernst-Moritz-Arndt Universität, Innere Klinik B, Greifswald, Germany;* [2]*Charité, I. Medizinische Klinik, Berlin, Germany*

Background: Immunoadsorption (IA) represents an additional therapeutic approach in patients suffering from dilated cardiomyopathy (DCM). The present study characterizes in isolated cardiomyocytes the inotropic effects of serum antibodies in DCM patients (n = 31, EF < 30%) before IA therapy. We compared these inotropic effects in cardiomyocytes with the hemodynamic benefit of the DCM patients during IA.
Methods: Before IA from 31 DCM patients the serum antibodies were purified by anti-IgG separose and dialyzed (100 KD) against experimental buffer. We analysed the effects of the purified antibodies (300mg/L) on cell contraction (video edge detection) and on calcium-dependent fluorescence using fura-2-AM in isolated field-stimulated adult rat cardiomyocytes. Cardiodepressant effects were defined by a reduction of the calcium transient (>5%) and a simultaneous reduction of systolic cell shortening (>10%). After this in-vitro analysis, in all patients IA was performed in 4 courses, at one-month intervals until month three.
Results: Serum antibodies from 21 patients (cardiodepressant group) induced a reduction of calcium transient (-27.2 ± 2.3%) and cell shortening (-34.2 ± 2.2%) ($p<0.001$) on cardiomyocytes. In contrast, antibodies from 10 patients (non-cardiodepressant group) did not influence calcium transient or cell shortening. During the first IA course patients of the cardiodepressant group showed an acute increase in cardiac index from 2.1 ± 0.2 to 2.9 ± 0.1 l/min/m^2 ($p < 0.001$). In contrast, in the non-cardiodepressant group hemodynamics did not significantly change throughout the three months of IA therapy. The prolonged effects were also different in both groups. The cardiac index before the last IA course was 2.1 ± 0.2 l/min/m^2 in the non-cardiodepressant group and 2.9 ± 0.1 l/min/m^2 in the cardiodepressant group ($p < 0.001$). In addition, during IA therapy after three months left ventricular ejection fraction increased in the non-cardiodepressant group from 23 ± 2 to 24 ± 3% (n.s.) and in the cardiodepressant group from 23 ± 2 to 30 ± 2% ($p < 0.01$). Additional in-vitro analysis showed that the cardiodepressant effects are mediated by antibodies of the IgG-3 subclass.
Conclusions: Cardiac antibodies may play a functional role in DCM. Evidence for cardiodepressant antibodies predicts the acute and prolonged hemodynamic benefit induced by IA. The antibodies which induce the inotropic effects belonging to IgG-3.

P1241 The results of long-term idebenone therapy for myocardial involvement in Friedreich's ataxia: a strain and strain rate imaging study

G. Di Salvo[1], F. Weidemann[2], L. Mertens[3], B. Eyskens[3], G. Davidavicius[2], B. Bijnens[2], M. Gewilling[3], G.R. Sutherland[2]. [1]*Department of Cardiology, Leuven, Belgium;* [2]*Department of Cardiology,* [3]*Pediatric Cardiology, University Hospital Gasthuisberg, Leuven, Belgium*

Background: In Friedreich's Ataxia (FA) there is no standard treatment currently available for the related myocardial disorder despite causative gene and protein identification. However, 2 preliminary studies on Idebenone therapy, a coenzyme Q10 analogue and free-radical scavenger which potentially could reverse the myocardial abnormalities, have shown conflicting results on left ventricular mass regression in FA.
Study Aims: To investigate the effect of long-term Idebenone administration in FA patients with cardiac hypertrophy on a) left ventricular mass index (LVMI) (g/m^2) and b) regional myocardial function. These were evaluated by 1) standard echocardiography, 2) myocardial velocity profiles (VEL) (cm/sec) and 3) peak systolic Strain Rate (SR) (unit S^{-1}) and peak systolic Strain (S) (%).
Methods: 7 FA patients with hypertrophic cardiomyopathy (age 8.5-27 yrs) were studied at baseline (Pre) and after 12 months Idebenone (360mg/d) therapy (12M).
Results: Post-therapy there was a marked improvement in ejection fraction (%) (Pre:77±10, 12M:86±4,p=0.02) and a reduction in LVMI (Pre:126±29,12M: 101±26,p=0.03). Only 1 patient had no mesurable reduction in LVMI. In the 6 remaining patients, there were significant improvements in ultrasound-based deformitation indices in all left ventricular walls studied (septum: basal segment SR: (Pre) -0.9±0.3 vs -1.5±0.5, p=0.04; middle segment SR: (Pre)-1.1±0.3 vs -1.6±0.4, p=0.027; middle segment S: (Pre)-17±6 vs -23±8, p=0.027; average SR: (pre)-1± 0.2 vs -1.6±0.5, p= 0.04; average S: (Pre) -14±5 vs -22±9, p=0.04. Lateral wall: middle segment SR: (Pre)-0.8±0.6 vs -1.6±0.7, p=0.04; average SR: (pre)-1.0±0.3 vs -1.7±0.6, p=0.04. Posterior wall SR: (pre) 1.9±0.5 vs AT = 3.0±0.6, p=0.027).
Even in the patient with no detectable reduction in LVMI (M-mode echo) we could measure an increase in peak systolic SR in the lateral wall (from -0.2 to -0.88 unit S^{-1}), suggesting an early change in regional contractility, not detectable by M-mode echo. Interestingly, there was no change in regional peak systolic myocardial velocities in any of the 7 patients.
Conclusion: In our study, long-term Idebenone therapy significantly improved LVMI, ejection fraction and regional myocardial contractility as assessed by peak systolic SR. Moreover, SR was able to detect even subtle changes in patients where there was no LVMI reduction on standard gray scale imaging. Our findings would suggest that SR and S imaging, but not VEL, should be routinely used in the follow-up of these patients to evaluate improvement in regional myocardial function.

P1242 Interventricular and intraventricular asynchrony: contribution to functionnal and haemodynamic status in dilated cardiomyopathy

L. Fauchier[1], O. Marie[1], D. Casset-Senon[2], D. Nguyen[1], D. Babuty[1], P. Cosnay[1], J.P. Fauchier[1]. [1]*Trousseau University Hospital, Cardiology B Dept., Tours, France;* [2]*Trousseau University Hospital, Nuclear Medicine and Ultrasound Dept, Tours, France*

Left and right intraventricular asynchrony and interventricular asynchrony may all contribute to the alteration of the functionnal and the hemodynamic status in heart failure but few informations are available about the separate contribution of each dysynchrony in this degradation.
Methods: A total of 103 patients (pts) with idiopathic dilated cardiomyopathy (IDC) (WHO criteria; normal coronary angiography in all pts; mean age 51 years; range 18-70; 89 men; left ventricular ejection fraction 27 ± 11%) were studied. Left bundle branch block was present in 25% of the pts and mean QRS duration was 113 ± 32 ms. Equilibrium radionuclide angiography with Tc99m was performed and Fourier phase analysis were examined in both ventricles. Interventricular delay between the mean phase of RV and LV assessed interventricular asynchrony and standard deviations (SD) of the mean phase in each ventricle assessed intraventricular asynchrony.
Results: Among patients with LBBB, interventricular delay was more marked (51±66 vs 16± 35 ms, p=0.001) as was left intraventricular asynchrony (SD of LV mean phase 77±41 vs 50±22 ms, $p<0.0001$). Increase in SD of RV phase was related to a higher NYHA class (R=0.22, p=0.02) and a lower peak oxygen uptake(R=-0.44, p=0.0001). LV end diastolic diameter was highly correlated with SD of LV phase (R=0.59, $p<0.0001$) and to SD of RV phase (R=0.38, p=0.0001) but poorly with IV delay (R=0.2, p=0.04). LV ejection fraction did not correlate with IV delay but was inversely related to SD of LV phase (R=-0.52, $p<0.0001$) and to SD of RV phase (R=-0.41, $p<0.0001$). Cardiac index was inversely related to SD of LV and RV phase (R=-0.23, p=0.03 and R=-0.30, p=0.006) and did not correlate with IV delay. With a follow-up of 27 ± 23 months, 18 patients had a major cardiac event (7 cardiac deaths, 11 worsening of heart failure leading to heart transplantation). SD of the LV and RV mean phase were predictors of cardiac event (all $p<0.0001$) but interventricular delay was not (p=0.35).
Conclusion: The prognosis of congestive heart failure seems related to left and right intraventricular rather than to interventricular asynchrony in IDC. Moreover, all the parameters of functionnal and hemodynamic status are much better related to left and right intraventricular dysynchrony than to interventricular asynchrony.

P1243 Meta-analysis of 267 subjects with lamin mutations: are conduction disorders reliable indicators of lamin mutations?

J. van Berlo[1], J.P. van Tintelen[2], H.J.G.M. Crijns[1], Y.M. Pinto[1] on behalf of ICIN working group on hereditary cardiac disease. [1]*academic hospital Maastricht, Cardiology, Maastricht, Netherlands;* [2]*academic hospital Groningen, Clinical Genetics, Groningen, Netherlands*

Purpose: Mutations in the gene for nuclear lamin A/C can cause familial dilated cardiomyopathy (DCM), skeletal myopathy (SM) or both. Our purpose was to relate the clinical phenotype to the various known mutations.
Methods: We conducted a meta-analysis of all published patients described with a mutation in lamin A/C responsible for familial DCM and/or skeletal myopathy. Patient characteristics and localisation of gene mutation were analyzed.
Results: In total 267 patients with a lamin A/C mutation have been described. 106 pts (40%) demonstrated isolated DCM without SM. 150 pts (56%) demonstrated evidence of conduction system disease (CSD) or supraventricular arrhythmias before onset of DCM, 77 pts (29%) required a pacemaker. 95 pts (36%) demonstrated SM with arrhythmias or CSD and only a minority demonstrated isolated SM. 24 pts (9%) with isolated DCM died suddenly whereas 11 pts (4%) with SM died suddenly. No de novo mutations have been described for DCM or LGMD. Mutations occurred at various positions of the lamin gene, without clear relation to the clinical phenotype.
Conclusion: This meta-analysis is the first to provide additional insights into the clinical cardiological manifestations of lamin mutations:
1. conduction system disease invariably precedes DCM
2. 25% of patients with isolated lamin-DCM die suddenly.
Therefore, lamin A/C cardiomyopathy can be recognized in advance of clinical DCM by the combination of CSD and a positive family history.

P1244 Clonal T-cell composition, detected by family specific PCR of the T-cell receptor beta chain, is exclusively present in dilated cardiomyopathy

M. Noutsias[1], J.H.N. Blohm-Bigdeli[1], C. Assaf[2], M. Hummel[3], R. Warraich[4], M.H. Yacoub[4], H. Stein[3], H.P. Schultheiß[1]. [1]*University Hospital Benjamin Franklin, Cardiology Dept., Berlin, Germany;* [2]*UKBF, Free University, Dermatology, Berlin, Germany;* [3]*UKBF, Free University, Pathology, Berlin, Germany;* [4]*Harefield Hospital, NHLI, Middlesex, United Kingdom*

Background: Autoimmunity, resulting from molecular mimicry between viral and cryptic cardiac antigens, is postulated for the pathogenesis of dilated cardiomyopathy (DCM). Autoimmunity directed against distinct antigens evokes expansion of specific T-cell clones infiltrating the target tissue. This phenomenon leads to a clonal predominance of T-cells harboring an identical rearranged T-cell receptor gene (TCR), which can be reliably identified by family specific PCR for the Vb-N-Db-N-Jb-region of the TCR gene in combination with the GeneScan-analysis (Assaf et al., Blood 2000).
Materials and Methods: DNA extracted from explanted DCM hearts (n=17, 1 female; 49±13 years; LVEF: 18±5%) were investigated for clonality of the TCR-b-gene. Non-DCM-hearts (ischaemic cardiomyopathy: n=2, valvular heart disease: n=3, donor hearts: n=3) served as controls. The TCR-b PCR-products analyzed by high-resolution fragment analysis (GeneScan), displayed a Gaussian-like distribution profiles in polyclonal and single dominant peaks in clonal T-cell populations. Clonal TCR-b PCR-products were directly sequenced.
Results: The GeneScan analysis of the TCR-b PCR-products demonstrated a clonal T-cell population in n=9/17 (53%) of the DCM hearts. In contrast, exclusively polyclonal composition of the TCR-b PCR-products were obtained from the non-DCM hearts. Sequence analysis of the clonal TCR-b PCR-products from the n=9 DCM hearts determined Vb19.01 in n=6 cases (67%), and Vb6-1.01, Vb6-3.01 and Vb10-3.04 in each of the remaining cases.
Conclusions: Clonal T-cell composition is exclusively present in DCM, as detected by PCR and GeneScan analysis of the TCR-b rearrangement. This phenomenon indicates a clonal T-cell proliferation due to specific antigen, which confirms the autoimmune hypothesis of DCM. Our results, demonstrating a clear predominance of Vb19.01 T-cell clones in DCM, warrant the molecular analysis of the respective immunogenic sequence and eventually a TCR-based immunotherapy in DCM (e.g. with DNA vaccines).

P1245 Hematologic correlates of spontaneous echo contrast and echocardiographic parameters in patients with dilated cardiomyopathy

G. Kozdag[1], A. Vural[1], D. Ural[1], E. Ural[1], M. Ozden[2], G. Kahraman[1], A. Agacdiken[1], B. Komsuoglu[1]. [1]*Kocaeli University Medical Faculty, Department of Cardiology, Kocaeli, Turkey;* [2]*Kocaeli University Medical Faculty, Department of Biochemistry, Kocaeli, Turkey*

Objectives: Patients with dilated cardiomyopathy have a high risk for cardioembolic events. However, hematologic characteristics of these patients are not well known. The aim of our study was to investigate the relation of hematologic parameters to spontaneous echo contrast (SEC) and some echocardiographic variables in a group of patients with ischemic dilated cardiomyopathy.
Methods: The study group consisted of 45 patients (32 male, 13 female, mean age 60±11 years) with ischemic dilated cardiomyopathy. All of the study patients were in sinus rhythm and not receiving anticoagulation. Hematologic parameters were measured on the day of transthoracic and transesophageal echocardiographic examination.
Results: Patients with SEC (n=30; 67%) had an increased plasma low-molecular-weight (LMW) heparin (p=0.02), unfractionated (UF) heparin (p=0.01), fibrinogen (p=0.07), lower factor VII (p=0.09) and left atrial appendix emptying velocity (p=0.01). Multivariate analysis showed that SEC was independently related to left atrial appendix emptying velocity (p=0.004), fibrinogen (p=0.05) but not to other hematologic parameters.
Left atrial and right ventricular diameter had a significantly positive correlation to activated partial thromboplastin time (r=0.36, p=0.03 and r=0.41, p=0.01 respectively). Another positive correlation was observed between left ventricular systolic function and factor VII (EF: r=0.38, p=0.04; FS: r=0.38, p=0.04). Patients with restrictive diastolic filling had significantly higher LMW and UF heparin (p=0.03 and p=0.03). Grade of mitral regurgitation had no correlation to any hematologic parameters. Left atrial appendix emptying velocity showed a positive correlation with FVII (r=0.42, p=0.007) and a weak negative correlation with LMWH and UFH.
Conclusion: Patients with dilated cardiomyopathy and left atrial SEC have a tendency for increased coagulation and also for probable compansatory anticoagulation. The paradoxical decrease of FVII and increase of LMW and UF heparin in patients with worse left ventricular and atrial appendix function suggested an increased tendency for spontaneous intrinsic anticoagulation in patients with dilated cardiomyopathy and severely impaired left ventricular systolic and diastolic function.

P1246 From acute myocarditis to dilated cardiomyopathy: the role of myocardial catecholamines

P.M. Seferovic[1], R. Maksimovic[1], S. Stepanovic[1], A.D. Ristic[2], D. Simeunovic[1], G. Draganic[1], D. Trifunovic[1], M. Ostojic[1]. [1]*University Inst. for Cardiovasc. Dis., Klinicki Centar Srbije, Belgrade, Yugoslavia;* [2]*University Inst. for Cardiovasc. Dis., Belgrade, Yugoslavia*

Impact of the adrenergic system activation on hemodynamics in acute myocarditis and dilated cardiomyopathy is controversial.
Methods: In order to elucidate this issue, myocardial catecholamine concentration was assessed in biopsy proven acute myocarditis (BPM)(20 pts, 80% males, mean age 36.5±13.3 years) and idiopathic dilated cardiomyopathy (IDC)(32 pts, 75% males, mean age 47.3±11.9 years). The diagnosis was based on clinical data, echocardiography, cardiac catheterization, and endomyocardial biopsy findings. Myocardial norepinephrine (MNEC), epinephrine (MEC), and dopamine (MDC) concentrations were measured in EMB samples using catechol-O-methyl-transferase radioenzymatic method. The correlation between myocardial catecholamine concentration and left ventricular (LV) hemodynamics was also calculated.
Results: Comparison between the groups revealed significantly higher MNEC and MEC in BPM than in the IDC group (Table). Mean MDC values were similar in both groups (p>0.05). No significant correlation was found among myocardial catecholamine concentration and hemodynamic parameters in BPM pts. In IDC pts, both MNEC and MEC demonstrated significant positive correlation with LVdp/dt max and LVEF, and significant negative correlation with pulmonary capillary pressure and LVEDP.
Conclusions: significantly higher MNEC and MEC were found in BPM than in IDC group. Depressed LV function, decreased MNEC and MEC concentrations, as well as their good correlation in IDC group, may reflect myocardial dysfunction and indicate final stage of the disease.

P1247 Induction of activating antibodies against human β1-adrenoceptors results in progressive left ventricular dilatation and dysfunction in rats

R. Jahns[1], V. Boivin[2], S. Triebel[2], L. Hein[2], W. Voelker[3], G. Ertl[3], C.E. Angermann[1], M.J. Lohse[2]. [1]*Med. Poliklinik, Cardiology, Wuerzburg;* [2]*Institute of Pharmacology, Wuerzburg* [3]*Med. Klinik, Wuerzburg, Germany*

Purpose: A subgroup of patients with dilated cardiomyopathy (DCM) has been shown to have functionally active antibodies (Ab) against the second extracellular domain of the beta1-adrenergic receptor (b1-ECII). To investigate whether antibodies against b1-ECII (100% sequence-identity human/rat) might be involved in the pathogenesis of DCM we attempted to generate immune-cardiomyopathy in the rat.
Methods: N=35 Lewis-rats were were immunized monthly over 15 months either with fusion proteins of glutathion-S-transferase (GST) and the human b1-ECII (n=15), with GST alone (n=10), or with 0.9% NaCl (n=10). Rat-sera were screened for anti-b1-ECII Ab by ELISA, Western blotting, and immunofluorescence using Sf9- and CHW-cells expressing recombinant human b1-adrenergic receptors. In parallel, echocardiography was performed every three months (GS Vingmed, System FiVe) followed by left heart catheterization (Millar-tip-catheter) and subsequent excision of the hearts at month 15.
Results: High titers of anti-b1-ECII Ab were found throughout the study-period in all 15 immunized rats, but not in control rats. Anti-b1-ECII recognized denatured (Western blot) as well as native b1-receptors (immunofluorescence) and increased both basal and stimulated cAMP-levels in stably transfected b1-CHW-cells (functional assay). Compared with controls [C], echocardiographic follow-up revealed significant left ventricular dilatation and dysfunction in anti-b1-ECII-positive rats [b1] from the ninth month on, which progressed during the study (LVED: 8.2±0.1 [b1] vs. 7.1±0.3 mm [C]; FS: 33.7±2.9 [b1] vs. 41.1±1.1% [C]; $p<0.01$). The data obtained by cardiac catheterization (i.e. contractility dP/dt: 8113±208 [b1] vs. 10050±289 mmHg/s [C]; $p<0.001$) and the relative heart-mass (2.75±0.05 [b1] vs. 2.50±0.03 mg/g [C]; $p<0.001$) confirmed the echocardiographic results.
Conclusion: Our study shows that rats immunized against the b1-ECII-domain develop activating anti-b1-receptor antibodies and, subsequently, progressive left ventricular dilatation and dysfunction. However, to establish autoimmunity as a pathogenic principle it will be necessary to demonstrate that immune-cardiomyopathy may be induced also by transferring anti-b1-ECII to healthy animals.

P1248 LMNA defects and nuclear membrane damage in autosomal dominant dilated cardiomyopathy with atrio-ventricular block

A. Repetto[1], A. Pilotto[2], M. Grasso[2], C. Campana[1], L. Scelsi[1], A. Gavazzi[1], L. Tavazzi[1], E. Arbustini[2]. [1]*IRCCS Policlinico S. Matteo, Cardiologia, Pavia, Italy;* [2]*Institute of Pathology, Molecular Diagnostic Division, Pavia, Italy*

Familial dilated cardiomyopathy (DCM) associated with either conduction disturbances or variable myopathy has been reported to be causally linked to lamin A/C gene (LMNA) defects. LMNA gene, myocardial ultrastructural changes and protein expression were analysed in familial and sporadic DCM associated with either atrioventricular block (AVB)(n=16; 8 familial and 8 sporadic) or increased serum creatin-phosphokinase (sCPK)(n=9). Six novel LMNA mutations were identified in the 6 autosomal dominant forms with AVB (R89L, K97E, E111X, R190W, E317K, four base pair insertion at 1713 cDNA)(6/16: 37%). The immunostain with anti-lamin A/C antibodies showed reduced or absent expression of the protein in the myocyte nuclei, while endothelial and interstitial mesenchimal cells retained normal immunostain. In 3 hearts with different mutations the Western blot showed an additional 30 kDa band, suggesting degrading effect of the mutated on the wild type protein. The atrioventricular junctions of the 3 hearts excised at transplantation showed fibro-fatty changes and myocyte degeneration. Focal disruptions, bleb formation and nuclear pore clustering were documented at electron microscopy in the myocyte nuclear membranes. None of the above changes were found in controls, both disease and normal cases. The LMNA gene mutations account for 37% of the DCMs with AVB, all familial autosomal dominant. In these patients, we demonstrated decreased expression of lamin A/C, protein degradation, structural damage of the myocyte nuclear membrane, and degenerative changes of the atrioventricular junction.

P1249 Familial non-X-linked dilated cardiomyopathy: progression to the disease in asymptomatic "healthy" relatives with cardiac abnormalities

A. Repetto[1], A. Fontana[1], L. Scelsi[1], A. Bertoletti[1], C. Campana[1], A. Gavazzi[2], L. Tavazzi[1], E. Arbustini[3]. [1]*Policlinico San Matteo, Cardiology, PAVIA, Italy;* [2]*Ospedali Riuniti, Cardiology, Bergamo, Italy;* [3]*Policlinico San Matteo, Molecular Diagnostic Division, Pavia, Italy*

A clinical program dedicated to familial non-X-linked dilated cardiomyopathy (DCM) was lunched in 1995 by our Centre (Eur Heart J 2001; 22:73-81). The program consisted of screening all informed and consenting relatives of patients (pts) consecutively diagnosed with DCM. Since then, we enrolled 130 index pts and 557 family members. Familial DCM was diagnosed on evidence-based data with at least two members proven as affected. Of the 557 relatives, 61 were excluded at time 0 (T0) and 3 at time 1 (T1) because of concomitant relevant disorders (hypertension, diabetes mellitus, coronary artery disease, alcohol consumption, etc.); 273 did not complete the follow-up (FU), while 220 had a 1 to 3-year clinical and instrumental FU (32.1±9.8 months). Of the 220, 18 were found to be affected at T0, leaving a study population of 202 apparently "healthy" subjects. Of the overall 202 healthy relatives, only 2,1 with LVEDD>112% + AVB and 1 with LVEDD>117% + LVFS<25%, developed DCM during the FU. Both were from DCM defined as familial at T0. Of the 20 relatives with >LVEDD, 10 had LVEDD<112% at the FU. LVFS>25% did not predict, by itself, the development of the disease.

Results in 202 healthy relatives

Instrumental Data	Time 0 (#)	Time 1 (#)	FU: from Time O to Time 1
AVB	3	4	3confirmed+1new
Left Anterior Hemiblock	2	3	2confirmed+1new
Left Bundle Brunch Block	0	0	
LVEDD>112%	14	14	3confirmed+11new,7normalized,4worsened
LVEDD>117%	6	9	3confirmed+6new,3normalized
LVFS<25%	2	9	new, 2normalized
LVEF<50%	0	2	1 from LVEDD>112%,1from LVEDD>117%

AVB atrio-ventricular block; LVEDD left ventricular end-diastolic diameter, LVFS left ventricular fractional shortening, LVEF left ventricular ejection fraction

In conclusion, only 2 of 202 healthy relatives (1%) of DCM pts developed the disease during the FU. Instrumental monitoring seems appropriate only in relatives with >LVEDD, either isolated or associated with <LVFS or AVB, especially in proven familial non-X-linked DCM.The rate of disease progression among "healthy" relatives with >LVEDD is low but imposes to continue the FU and the search for new predictive markers, given that the 2 relatives who developed the disease did not differ from the 18 who did not.

P1250 Clinical course of anthracyclines-induced versus idiopathic dilated cardiomyopathy

L. Massa[1], C. Lestuzzi[2], A. Di Lenarda[1], E. Viel[2], M. Driussi[1], N. Meneguzzo[2], G. Sabbadini[3], G. Sinagra[1]. [1]*Ospedale Maggiore, Cardiology Department, Trieste, Italy;* [2]*Centro di Riferimento Oncologico-IRCCS, Cardiology, Aviano (PN), Italy;* [3]*Institute of Geriatrics, Department of Internal Medicine, Trieste, Italy*

Background: About 5% of neoplastic patients (pts) undergoing anthracyclines therapy develop cardiomyopathy. Aim of the study was to analyse the clinical course of pts with anthracyclines-induced cardiomyopathy (AIC), as compared to those with idiopatic dilated cardiomyopathy (IDC).
Methods: Sixty-eight consecutive AIC pts (mean age 51±12 years, sex female 75%) referred to, and investigated at the Cardiology Service of Aviano (careful clinical and non-invasive assessment, including echocardiogram at baseline and at 1-year follow-up), were compared to 136 age- and sex-matched IDC pts enrolled in the Heart Muscle Diseases Registry of Trieste.
Results: AIC pts had been previously treated with adriamycin and/or epirubicin at adriamicyn equivalent-dose (EQD) of 457±152 mg/m^2, for breast cancer (n=41, 60%), lymphoma (n=18, 26%), or other tumours (n=9, 14%); 14 pts (21%) had been also treated with mitoxantrone. Eighteen pts (26%) received mediastinal or left side chest radio-therapy. Pts developed AIC 16±34 months after chemotherapy (CT). At enrollment, in comparison to IDC pts, AIC pts showed higher heart rate (HR 93±20 vs 81±17 bpm, $p<0.0001$), smaller LV end-diastolic diameter (DTD 32±5 vs 38±5 mm/m^2, $p<0.0001$), higher LV ejection fraction (EF 45±6 vs 30±10%, $p<0.0001$), and similar mild symptomatic impairment (NYHA 2.1±0.9 vs 2.0±0.8, p=NS). AIC pts were under-treated in comparison to IDC pts (ACE-inhibitors 71 vs 84%, p=0.027 (EQD enalapril 8.5 vs 21.3 mg, $p<0.0001$); beta-blockers 22 vs 64%, $p<0.0001$ (EQD metoprolol 41 vs 112 mg; $p<0.0001$); diuretics 41 vs 60%, p=0.01; digoxin 54 vs 80%, p=0.0001; anti-arrhythmic drugs 6 vs 31%; $p<0.0001$). At 12-month follow-up, AIC pts showed a less pronounced improvement in LVEF (+4±8 vs +9±11%, p=0.04) than IDC pts, while changes in LVEDD did not differ between the two groups (-1±4 vs -2±5 mm, p=NS). Survival of AIC pts was significantly worse (12, 24, 36 months: 66, 42, 29% vs 96, 94 e 91%, $p<0.0001$), while hospital admissions for cardiovascular reasons tended to be less frequent (12, 24, 36 months: 13, 13 e 13% vs 20, 23 e 27%, p=NS). Thirty-six pts died, 29 of them died for their primary disease (81%) and only 1 for heart failure progression (3%).
Conclusions: As compared to IDC pts, AIC pts are less impaired at enrolment and seem to have a more favourable evolution of cardiomyopathy, in the face of less frequent use/lower dosages of effective heart failure therapies (ACE-inhibitors and beta-blockers). High mortality rates are clearly related to the progression of neoplastic disease.

Day 3

Monday 2 September 2002

ARRHYTHMIAS MECHANISMS

1277 Autoantibodies: new upstream targets of paroxysmal atrial fibrillation in patients with congestive heart failure

A. Baba[1], T. Yoshikawa[2], M. Shimada[1], M. Akaishi[1], S. Ogawa[2]. [1]*The Kitasato Institute Hospital, cardiology, Tokyo, Japan;* [2]*Keio University School of Medicine, Cardiology, Tokyo, Japan*

Objectives: We sought to define the clinical implications of autoantibodies (Abs) as upstreams of paroxysmal atrial fibrillation (AF) in patients (pts) with congestive heart failure (CHF).
Methods and Results: Circulating Abs against myosin (M-Abs) detected by immunofluorescence, Abs against beta1-adrenergic receptors (Beta1-Abs) by ELISA, and Abs against Na-K-ATPase (NKA-Abs) by ELISA were screened in 95 CHF pts with left ventricular ejection fractions (LVEF) <45% (coronary artery disease (CAD), n=48; dilated cardiomyopathy (DCM), n=47) and 48 age-matched control pts with hypertension. All pts had no antiarrhythmics and were enrolled with ACE inhibitors at chronic stable states. Relations of the presence of paroxysmal AF to other clinical variables were assessed on 48-hour Holter monitoring. There was no Abs in control pts. However, M-Abs, Beta1-Abs, and NKA-Abs were detected in 22%, 26%, and 16% pts with CHF (CAD; 8, 10, and 4%, DCM; 36, 43, and 28%, respectively). The occurrences of paroxysmal AF were more frequent in DCM than in CAD (47% vs 15%, p<.01). A multivariate analysis suggested that NKA-Abs was an independent risk factor for the occurrence of paroxysmal AF (p<.01), although there were no differences in other clinical profiles; age, gender, NYHA functional class, concomitant medications, LVEF, left atrial diameter, severity of mitral regurgitation, serum potassium, plasma norepinephrine, and atrial natriuretic peptide concentrations.
Conclusions: This study demonstrated that autoantibodies against sarcolemmal Na-K-ATPase were closely related to the occurrence of paroxysmal AF in pts with CHF, and rose the possibility of an autoimmune process as new upstream of AF.

1278 Early atrial ultrastructural remodelling after sustained rapid atrial pacing in a canine model of induced atrial fibrillation

D. Sánchez-Quintana[1], J.A. Cabrera[2], E. García-Colis[2], F. Cabestrero[2], C. Castilla[2], J. Farré[2], P.P. Pérez[2], A. López Farré[2]. [1]*Extremadura University, Human Anatomý, Badajoz, Spain;* [2]*Fundación Jiménez Díaz, Cardiology, Madrid, Spain*

Recent studies in animal models of prolongaded sustained atrial fibrillation described that chronic sustained rapid atrial pacing lead to electrophysiological and atrial structural remodeling. Qualitative and quantitative structural changes of atrial myocardium in the early stages of pacing-induced atrial remodeling are unknown.
Methods: Fifteen halothane-anesthetized adult beagle dogs underwent insertion of a transvenous lead at the right atrial appendage (RAA). Ten dogs were continuously paced at 400 bpm for 3 days and 5 dogs in sinus rhythm served as control. Right atrial effective refractory period (ERP) was measured at either baseline and after 3 days in both groups. After 3 days structural changes of the atrial myocardium were examined and quantified in interatrial septum, lower right atrium (RA), RAA and left atrial appendage (LAA) by conventional and electron-microscopy studies.
Results: Right atrial ERP was significantly shortened after pacing from 136±15 msg to 80±30 msg. In unpaced dogs, atria appeared normal. After 3 days of continuous rapid atrial pacing, electron microscopy of atrial tissue demonstrated ultrastructural changes that were characterized by 1) loss of contractile material 2) changes in mitochondrial size and shape 3) disruption of the sarcoplasmic reticulum and 4) loss of profile of intracellular membranes. Findings correlated with the expression levels of proteins (a-actin, desmin and E-Cadherin) detected by immunohistochemical staining. No evidence of increased connective tissue content and myocyte hypertrophy was documented. Table shows the mean percentage of severely atrial affected myocytes (>25% myolysis) in paced and control dogs.

Quantification of atrial changes

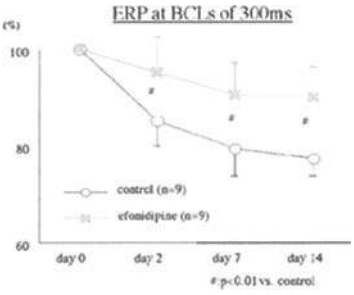
	RAA	Septum	Lower RA	LAA
Paced dogs	11±2%	6±1.5%	8±1.5%	5±1.4%
Control dogs	2±1%	3±1%	2±1%	2±1%
	p<0.001	p<0.001	p<0.001	p<0.01

Conclusions: This is the first study to demonstrate both qualitatively and quantitatively early ultrastructural changes of atrial myocardium in an animal model of pacing-induced atrial remodeling. This finding may have clinical implications for an early approach in patients with atrial fibrillation

1279 A T-type Ca channel blocker efonidipine prevents tachycardia-induced atrial remodelling in dogs

N. Ohashi, H. Mitamura, O. Kinebuchi, K. Tanimoto, Y. Kurita, S. Miyoshi, M. Hara, S. Ogawa. *Keio University Hospital, Tokyo, Japan*

Calcium overload plays a central role in inducing atrial electrical remodeling during atrial tachyarrhythmias. Since the L-type but not T-type Ca^{2+} current is downregulated in this process, a T-type Ca blocker efonidipine may potentially prevent atrial electrical remodeling.
To prove this hypothesis, we measured the atrial effective refractory period(ERP) on the day before, and 2, 7, 14 days after starting atrial pacing at 400 ppm in 9 dogs with chronic oral efonidipine (5mg/kg/day) and in another 9 dogs without drug (control). In response to rapid pacing, ERP decreased progressively in the control dogs, whereas in the efonidipine group, ERP did not change significantly and remained greater than that in the control dogs.



ERP at 300 bpm.

In conclusion, efonidipine, a T-type Ca blocker, is highly effective in preventing atrial electrical remodeling.

1280 Load mismatch at tissue discontinuities underlies progressive ventricular activation delay at long cycle lenghts

R. Derksen, R. Coronel, R.N.W. Hauer, J.M.T. de Bakker. *Heart Lung Center Utrecht, Cardiology, Utrecht, Netherlands*

Progressive ventricular activation delay (PAD) starting at long coupling intervals of premature stimulation has been shown to correlate with sudden cardiac death in patients with and without heart disease. The underlying mechanism of PAD is still unknown. Studies carried out in explanted human hearts from patients undergoing heart transplantation showed that PAD increased in areas with patchy fibrosis with long strands. The amount of delay depended on the direction of the wave front. We hypothesize that PAD may be caused by the sites of load mismatch imposed by tissue discontinuities due to fibrosis.
Methods: Load mismatch was simulated in cell cultures grown in patterns according to methods developed by Rohr and Kleber. Neonatal rat heart cells were grown in 12 star-shaped structures each with 8 arms (diameter 0.15 mm, length 2 mm). Stimulation was performed at the extremity of one arm only (n=12, group A) and 2 arms (n=6, group B). Extracellular electrograms were recorded at 24 sites, homogeneously distributed over all arms. In group A conduction curves (extrastimulus method) were determined at all recording sites. The mean increase of delay (MID) of the conduction curves was used as a measure of PAD. In group B Wenckebach periodicity (WP) was determined for both pacing sites. The shortest cycle length (CL) of pacing leading to WP was used to pace regularly both arms. Pacing was performed (1) simultaneously; (2) by a phase shift of 10, 20 and 30 ms.
Results: In group A MID was 0.81 ±0.41 ms (per 10 ms) for sites in the paced arm and 3.13 ±0.58 ms in the other arms. PAD started to increase at the transition of the paced arm and the star center. In group B summation of activation at WP-CL resulted to 1:1 conduction without increased delay. Out-of-phase pacing (up to 30 ms) increased activation delay to 31.53 ±6.83 ms. Maximum activation delay during stimulation in one arm was 25.60 ±8.80 ms.
Conclusion: Our data show: (1) Load mismatch causes PAD (2) Summation of activation facilitates conduction but may increase delay.

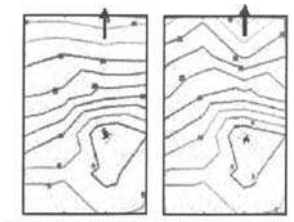
1281 Propagated conduction heterogeneity of right ventricular outflow tract in evolving canine vagal stimulation

A. suzuki[1], K. Tanaka[1], Y. Takei[1], Y. Watanabe[1], K. Kawagoe[1], N. Ejiri[2], K. Kuga[3], I. Yamaguchi[3] on behalf of I Yamaguchi. *[1]Hitachi General Hospital, Cardiovascular Medicine, Hitachi, Japan; [2]Taga General Hospital, Internal Medicine, Hitachi, Japan; [3]University of Tsukuba, Institution of Clinical Medicine, Tsukuba, Japan*

Background: Much attention has been drawn to the role of the autonomic nervous system as a trigger for Brugada and Brugada described idiopathic ventricular fibrillation. The possibility is suggested that the mechanism involved consists of a conduction disturbance existing at right ventricular outflow tract (RVOT) and that this conduction disturbance is aggravated by accelerated vagal activity. The purpose of the present study is to verify the hypothesis that vagal stimulation affects the conduction properties of RVOT.

Methods: In six anesthetized dogs, isochronal mapping at RVOT using multiple electrodes was studied with and without vagal stimulation. The right chest was opened and approximately multiple electrodes were set at RVOT. Two Teflon-coated wire electrodes were embedded in the cardiac end of each vagal nerve.

Results: Without vagal stimulation, conduction properties of RVOT was propagated upward homogeneously from breakthrough point. However, with vagal stimulation conduction properties of RVOT was propagated upward heterogeneously from breakthrough point. Especially with vagal stimulation, conduction properties of RVOT were modulated by every beats.



Isochronal mapping.

Conclusion: This study demonstrates that propagated conduction heterogeneity of right ventricular outflow tract was evolved by vagal stimulation. We propose that the mechanism involved consists of a conduction disturbance existing at the RVOT is one in which the propagated conduction heterogeneity is mainly located from the anterior wall to the RVOT but may also be modulated by every beats. Propagated conduction heterogeneity of right ventricular outflow tract by accelerated vagal activity may be important in arrhythmogenesis for Brugada and Brugada described idiopathic ventricular fibrillation.

1282 Cardiac autonomic dysfunction in patients with non-ischaemic ventricular tachyarrhythmias

T. Wichter[1], M. Schäfers[2], M. Paul[2], P. Kies[2], J. Fischer[1], L. Eckardt[1], O. Schober[2], G. Breithardt[1]. *[1]Dept. of Cardiology and Angiology, [2]Dept. of Nuclear Medicine, University Hospital of Münster, Münster, Germany*

In patients with nonischaemic ventricular tachyarrhythmias (VT/VF), the potential role of the cardiac autonomic nervous system in arrhythmogenesis is indicated by the predominance of VT/VF occurrence during either adrenergic or vagal stimulation. In arrhythmogenic right ventricular cardiomyopathy (ARVC) and idiopathic right ventricular outflow tract tachycardia (RVO-VT), VT/VF are frequently provocable by exercise and may be suppressed by antiadrenergic treatment (β-blockers). In contrast, in pts with Brugada syndrome, VT/VF mainly occur at rest or during sleep. In pts with idiopathic ventricular fibrillation (IVF) or long QT syndrome (LQTS), VT/VF may occur during exercise or resting periods.

To assess the presynaptic sympathetic myocardial innervation, 206 pts with nonischaemic VT/VF and 10 control subjects underwent 123I-MIBG SPECT scintigraphy. Quantitative analysis was performed with a 33-segment bull's eye model. 123I-MIBG (analogue to norepinephrine) uptake was defined as abnormal in case of reduction by >2 SD when compared to the same segment in the control group. Abnormal myocardial perfusion was excluded by resting and exercise ECG and coronary angiography in all pts, and by additional Tc-MIBI-SPECT in initial pts.

A regional defect of 123I-MIBG-uptake was present in 136/206 pts (66%) with nonischaemic VT/VF (table). Compared with the control group, the tracer uptake was most frequently reduced in septal and inferior LV areas.

Diseases and MIBG findings

	pts	MIBG abnormal	defect area	sign. vs control
ARVC	n=78	81%	25±14%	P< 0.01
RVO-VT	n=50	62%	25±12%	P< 0.01
IVT	n=28	64%	24±12%	P< 0.05
Brugada	n=20	50%	30±13%	P< 0.05
LQTS	n=30	47%	22±11%	n.s.

Conclusions: Cardiac autonomic dysfunction is frequent in pts with nonischaemic VT/VF as shown by the results of 123I-MIBG SPECT imaging. Autonomic dysfunction may indicate increased adrenergic release and turnover or impaired reuptake of norepinephrine. The imbalance of autonomic myocardial innervation may have significant impact on the arrhythmogenesis in pts with nonischaemic VT/VF.

STROKE IN PATIENTS WITH ATRIAL FIBRILLATION

1288 Mortality and rate of stroke or embolism in atrial fibrillation during long-term follow-up

C. Stoellberger[1], P. Chnupa[2], T. Länger[3], J. Finsterer[4], I. Klem[5], C. Wehinger[5], B. Schneider[6], E. Hartl[5]. *[1]Wien, Austria; [2]Ú;stav kardiovaskulárnych chorôb, Bratislava, Slovakia; [3]Austrian Research Centers Seibersdorf, Seibersdorf, Austria; [4]Neurologisches Krankenhaus Rosenhügel, Wien, Austria; [5]KA Rudolfstiftung, Wien, Austria; [6]University of Vienna, Institut for medical statistics and do, Wien, Austria*

Background: Patients with atrial fibrillation have a higher mortality and risk of stroke/embolism than patients with sinus rhythm. Antithrombotic therapy decreases the risk of stroke/embolism but is underused. Aim of the study was to assess the association of clinical and echocardiographic characteristics with mortality and stroke/embolism and the antithrombotic medication in the year 2000.

Methods: Included were 409 outpatients with nonrheumatic atrial fibrillation (62 ± 12 years, 36% female, 39% intermittent atrial fibrillation). Patients with thrombi received anticoagulation, patients without thrombi aspirin until the follow-up in 1995, afterwards anticoagulation according to clinical risk factors was recommended. Primary events were death. Secondary events were stroke/embolism.

Results: Follow-up was 1 to 133 months. The mortality was 4%/year. The cause of death was cardiac (84), fatal stroke (26), malignancy (23), sepsis (5) and unknown (24). Multivariate analysis identified age (risk ratio, 1.06 [CI 1.04 -1.08]; P<0.0001), heart failure (risk ratio, 2.01 [CI 1.31 - 3.0]; P = 0.0013) and good left ventricular systolic function (risk ratio, 0.69 [CI 0.49.- 0.98]; P = 0.0353) as predictors of mortality. The rate for stroke/embolism was 3%/year. Multivariate analysis identified age (risk ratio, 1.05 [CI 1.02 - 1.09]; P = 0.0006) and previous stroke (risk ratio, 2.14 [CI 1.02 - 4.51]; P = 0.0454) as predictors of stroke/embolism. In the year 2000, 51 (21%) of the 247 surviving patients received no antithrombotic medication, 88 (36%) anticoagulants, 102 (41%) aspirin and 6 (2%) low molecular heparin.

Conclusions: Therapy of heart failure and oral anticoagulation in atrial fibrillation should be taken seriously, especially in elderly patients and in those with previous stroke.

1289 Prevalence of atrial thrombi in patients with atrial fibrillation/flutter and subtherapeutic anticoagulation candidates to cardioversion

G. Corrado, L. Sormani, G. Tadeo, G. Foglia-Manzillo, M. Spata, L.M. Tagliagambe, M. Santarone. *Ospedale VALDUCE, Cardiology, COMO, Italy*

In patients with atrial fibrillation/flutter (AF) electrical cardioversion (ECV) is often used to restore sinus rhythm, but the procedure may be associated with clinical thromboembolism. The use of 3 weeks of warfarin before ECV results in a substantial reduction of thromboembolic complications. Nevertheless, in patients scheduled for ECV subtherapeutic INR values are common. An incomplete anticoagulation regimen could expose patients to the risk of post ECV thromboembolism. We retrospectively reviewed all ECV performed by the Cardiology Unit at Ospedale Valduce from June '99 to January 2002. We identified 28 patients with persistent AF in whom a transesophageal echocardiogram (TEE) was performed preliminary to ECV despite prolonged (> 3 weeks) anticoagulation with warfarin. In these patients TEE was done because of subtherapeutic INR values (i.e. < 2) in the 3 weeks preceding the scheduled ECV. A left atrial appendage (LAA) thrombus was identified in 4/28 patients (14%). In patients with LAA thrombus subtherapeutic INR values were lower (1.45±0.09 vs. 1.69±0,2 p=0.003) and LAA emptying velocities on PW Doppler were lower (13.7±4.5 vs. 25.9±12.1 cm/sec, p=0.003) with respect to patients without LLA thrombus. Male gender, presence of structural heart disease, history of hypertension, use of digoxin, presence of spontaneous echocontrast on TEE and arrhythmia type (atrial fibrillation vs. flutter) were not predictors of LAA thrombi. Furthermore, patients with and without LAA thrombi did not show difference in left ventricular (LV) ejection fraction (55.5±16.4 vs. 56.9±7.3% p=NS), LV fractional shortening (35±8.8 vs. 34.4±8.8% p=NS) and left atrial diarneter (42.8±10.4 vs. 41.9±8.4 mm. P=NS).

Concusions: subtherapeutic levels of anticoagulation before elective ECV of AF may expose patients to post-ECV thromboembolic sequelae, especially in patients with lowest INR values. Current recommendations of 3 weeks of therapeutic anticoagulation before ECV of AF > 2 days duration should be firmly observed. In patients with subtherapeutic levels of anticoagulation in the pre-ECV period a TEE-guided ECV might be helpful in reducing thromboembolic complications.

1290 Comparison of transoesophageal echocardiography findings in patients with atrial flutter and atrial fibrillation

K. Seidl, M. Vater, M. Rameken, A. Brandt, R. Zahn, C. Kilkowski, J. Senges. *Klinikum Ludwigshafen, Cardiology Dept., Ludwigshafen, Germany*

Transesophageal echocardiography (TEE) has been proposed as a method of screening patients (pts) for left atrial thrombus before direct current cardioversion(CV) of atrial fibrillation. Aim of this prospective study was to compare the incidence of left atrial thrombi and spontaneous echo contrast before planned CV in 144 pts with atrial flutter with the incidence in 845 pts with atrial fibrillation and effective anticoagulation (INR 2-3) at least 3 weeks prior to CV.

Methods: TEE studies before planned CV were performed in 144 pts with atrial flutter (77% male, mean age 62 ± 12 years, organic heart disease 56%, hypertension 54%, diabetes mellitus 15%, left atrial diameter 42 ± 6 mm, history of stroke 3.5%) and in 845 pts with atrial fibrillation (72% male, mean age 63 ± 11 years, organic heart disease 60%, atrial hypertension 57%, diabetes mellitus 13%, left atrial diameter 45 ± 6 mm, history of stroke 11%).

Results:

	Atrial Fibrillation (845 pts)	Atrial Flutter (144 pts)
Left atrial thrombus	65 pts (7.7%)	6 pts (4.2%)
Spontaneous echo contrast	374 pts (44%)	30 pts (21%)*
Mild spontaneous echo contrast	63%	70%
Moderate spontaneous echo contrast	27%	27%
Severe spontaneous echo contrast	10%	3%

* $p < 0.05$

Conclusion: Pts with atrial fibrillation had 3 times more often a history of stroke (11% vs 3.5%) compared to pts with atrial flutter. TEE revealed left atrial thrombi and spontaneous echo contrast twice as often in pts with atrial fibrillation than in pts with atrial flutter (7.7% vs 4%).

1291 Does transoesophageal echocardiography before direct current cardioversion reduce the embolic risk in patients with atrial fibrillation

K. Seidl, M. Rameken, M. Vater, H. Schwacke, A. Brandt, C. Kilkowski, R. Zahn, J. Senges. *Klinikum Ludwigshafen, Cardiology Dept., Ludwigshafen, Germany*

Transesophageal echocardiography (TEE) has been proposed as a method of screening patients (pts) for left atrial thrombus before direct current cardioversion (CV), especially in pts without long term anticoagulation (AC). Aim of this prospective single center observational study was to evaluate the usefulness of TEE to reduce acute (48 hours) and subacute (4 weeks) thromboembolic events after CV in consecutive unselected pts with atrial fibrillation (AF) and effective AC (INR 2-3). Overall 1269 pts were registered. 193 pts were excluded, because of ineffective AC. Therefore 1076 pts were included in this study. A conventional approach to CV was performed during the first 2 years of the study (control phase 357 pts) followed by TEE guided approach to CV (719 pts).

Results: TEE revealed a left atrial thrombus in 55 pts (7.7%). If a thrombus was found, no CV was performed. The embolic events are listed below. No differences were observed in pts with and without embolic event. All pts with a thromboembolic event were therapeutically anticoagulated at least 3 weeks prior to CV. None of the pts, in whom CV was not performed experienced an embolic event. CV was successful in 86% of pts in the TEE group compared to only 78% in the conventional group.

Thromboembolic events after CV

	pts	Successful CV	Acute embolic events (48h)	Embolic events (4 weeks)	Bleeding
TTE	357	78%	0 pts	3 pts (0.8%)	0 pts
TEE	719	86%	2 pts (0.3%)	4 pts (0.8%)	2 pts (0.3%)
P-Value		0.001	n.s.	n.s.	n.s.

Conclusion: 1) TEE is useful in all pts before CV despite effective AC to exclude high risk pts. 2) Despite a normal TEE before CV, 6 pts had an embolic event, suggesting that CV itself might have a thrombogenic potential.

1292 High plasma von Willebrand factor levels predict future stroke, myocardial infarction and vascular death in 994 patients with atrial fibrillation

D.S.G. Conway[1], L.A. Pearce[2], B.S.P. Chin[1], R.G. Hart[2], G.Y.H. Lip[1]. [1]*City Hospital Birmingham, University Department of Medicine, Birmingham, United Kingdom;* [2]*University of Texas at San Antonio, San Antonio, Texas, United States of America*

Introduction: Atrial fibrillation (AF) is known to be associated with an abnormal prothrombotic state, but no plasma marker has yet been found to identify individuals at greatest risk of future thrombotic events.

Method: We measured plasma von Willebrand factor (vWf, an index of endothelial damage/dysfunction) and soluble P-selectin (sP-sel, an index of platelet activation) near study entry in 994 patients (mean age 69±9 years; 75% male) treated with aspirin (alone or with low inefficacious doses of warfarin) in the 3rd Stroke Prevention in Atrial Fibrillation (SPAF III) trial, and related levels of these markers to the incidence of first subsequent stroke, myocardial infarction (MI) or vascular death during the follow-up phase of SPAF III.

Results: Median vWf and sP-sel levels in the population were 145 (IQR 124-166) iU/dl and 32 (IQR 26-41) ng/ml, respectively. The composite endpoint 'stroke, MI or vascular death' occurred in 68 (6.8%) of the 994 patients during the follow-up period. 'High' (above median) levels of vWf were predictive of an increased risk of this endpoint (hazard ratio=2.8(95%CI=1.7-4.8),p<0.001, figure 1) and remained an independent predictor after adjusting for prior stroke, heart failure, hypertension, peripheral vascular disease, diabetes and age (p=0.004). sP-sel levels were not predictive of the composite endpoint (hazard ratio=1.3(95%CI=0.8-2.1), p=0.3).

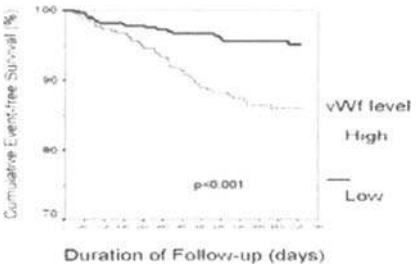


Figure 1: Kaplan-Meier survival curve.

Conclusion: Plasma vWf was an independent predictor of the combined endpoint of stroke, MI or vascular death in AF. sP-sel did not predict outcome. Endothelial damage/dysfunction appears more important than platelet activation in determining cardiovascular mortality and morbidity in AF. Plasma vWf may be a potentially useful marker for thromboembolic risk stratification in AF.

1293 Ximelagatran: a long-term oral direct thrombin inhibitor for stroke and systemic embolism prevention in nonvalvular atrial fibrillation patients

S.B. Olsson[1], P. Petersen[2] on behalf of the SPORTIF II and IV investigators. [1]*University Hospital, Department of Cardiology, Lund, Sweden;* [2]*University Hospital of Copenhagen, Division of Stroke, Hvidovre, Denmark*

Ximelagatran is a novel, oral direct thrombin inhibitor showing predictable dose-linear pharmacokinetics and no clinically significant food or drug-drug interactions. SPORTIF II was a 12-week, randomised, parallel-group study in patients with nonvalvular atrial fibrillation (NVAF) who had at least one additional risk factor for stroke (Petersen P. J Gen Intern Med 2001;16 (s1):164). Four groups of patients received either double-blind ximelagatran at doses of 20, 40 or 60 mg bid or warfarin aiming for an INR of 2.0-3.0. A total of 257 patients with a median age of 70 years (range, 39-95 years) were randomised and 254 received study drug (67 received warfarin and 187, ximelagatran). SPORTIF IV is an open-label 2-year follow-up of SPORTIF II in which eligible patients continued on ximelagatran 36 mg bid or warfarin. Since the start of SPORTIF II, ximelagatran has been given to 187 patients for the equivalent of 231 treatment years, and 67 patients have received warfarin for the equivalent of 76 treatment years. Following central adjudication, there have been two (0.9%) nonfatal ischaemic strokes in the ximelagatran group and two (2.6%) fatal haemorrhagic strokes in patients in the warfarin group. TIAs have been observed in one (0.4%) and two (2.6%) patients in the ximelagatran and warfarin groups, respectively. Major bleeds have been observed in two (0.9%) patients given ximelagatran and two (2.6%) patients treated with warfarin. No routine coagulation monitoring has been performed or required with ximelagatran. Five patients died in the trial including the two warfarin-treated patients who had strokes, while three patients died in the ximelagatran group, one from cardiac arrhythmia, one from a brain tumour and one from multiorgan failure due to old age. Asymptomatic S-alanine aminotransferase elevation was observed in a few ximelagatran-treated patients, but these levels decreased spontaneously during continued treatment or discontinuation of therapy. These preliminary data suggest that fixed-dose ximelagatran (36 mg bid) shows promise as an effective and well-tolerated oral anticoagulant for the prevention of stroke and systemic embolism, with no need for routine coagulation monitoring. Larger clinical studies to evaluate the effects of ximelagatran on the prevention of stroke in patients with NVAF are ongoing.

CARDIAC AND PERIPHERAL METABOLIC EFFECTS OF PACING

1294 Adverse effect of LBBB on regional myocardial oxygen consumption. Its reversal by electrical resynchronization evaluated by PET

G. Neri[1], P. Zanco[2], F. Zanon[3], R. Zamprogno[1], R. Buchberger[1]. [1]*Civic Hospital, Cardiology Dept., Montebelluna, Italy;* [2]*Hospital, Nuclear Medicine, Castelfranco Veneto, Italy;* [3]*Hospital, Cardiology, Rovigo, Italy*

Background: Deterioration of left ventricle function in dilated cardiomyopathy (DC) is aggravated by asynchronous contraction induced by left bundle branch block (LBBB). Biventricular pacing (BIV) induces improvement of myocardial wall function, in patients affected by DC and LBBB, but, at the moment, the secondary changes on myocardial metabolism induced by BIV are unclear. The aim of our study was to evaluate the possible changes on myocardial metabolism and perfusion induced by BIV in these patients.
Methods: To this aim 12 patients (aged 60-79 yr, mean 69) affected by DC (III NYHA functional class and ejection fraction < 40%) and QRS duration above 150 ms, were submitted to cardiac PET in basal condition and 3 weeks after the implantation of a biventricular device (3 Insync 8040 Medtronic, 8 Contak TR and 1 Contak CD Guidant). Metabolism was evaluated using F18-fluorodeoxyglucose (FDG), by the glucose load-insulin technique, and perfusion by N13-ammonia (NH3), injected at rest. A visual and a semi quantitative analysis were performed, calculating by ROIs the septum to lateral uptake ratio (SLR). The myocardial blood flow (MBF) was also calculated in ml/min/g using a dynamic acquisition and a modified Patlak method.
Results: In all the 12 patients a selective defect in FDG uptake in the septum was present in basal condition (mean SLR 0.59±0.16) with a "reverse mismatch" effect in comparison with NH3 (mean SLR 1.04±0.18, p=0.005). During BIV the distribution of FDG in the septal area improved (mean SLR 0.91±0.18 p=ns); on the contrary no significant changes were found in NH3 uptake (mean SLR 0.99±0.19). Mean ejection fraction increased from 32±6 to 41±5 (p=0.007). At the quantitative analysis the mean MBF in the septum did not show variations in basal condition and during BIV (0.81±0.32 vs 0.79±0.16; p=ns).
In conclusion, our experience suggests that, in patients affected by DC and LBBB, BIV could improve the septal glucose metabolism without significant changes in the myocardial blood flow. This phenomenon is probably due to resynchronizazion of the contraction of the septum.

1295 Biventricular pacing and blood flow in great arteries: ventricular resynchronisation alters electro-mechanical coupling of both ventricles

M. Munclinger[1], M. Wasiak[2], A S. Thornton[2], E Q. Klug[2]. [1]*Abu Dhabi, United Arab Emirates;* [2]*Johannesburg Hospital, Cardiology, Johannesburg, South Africa*

The improvement of parameters of systolic and diastolic function of left ventricle induced by biventricular pacing (BVP) is considered to be a consequence of better-coordinated and earlier left ventricular contraction. To test this assumption, the timing of ventricular outputs derived from intervals between the onset of ventricular depolarisation (surface QRS) and Doppler assessed onset (O) and peak (P) of blood flow (BF) in aorta (AO) and pulmonary artery (PA) were compared before and after BVP.
Clinical parameters and echocardiography were prospectively followed-up in 13 patients with MUSTIC indications for BVP for 6 months after implant (7 males; 58.6±10.5 year old; 7 idiopathic, 4 ischaemic, and 2 other cardiomyopathies). NYHA class, 6-minutes corridor walk, quality of life questionnaire, and echocardiographic parameters were significantly improved over the entire period of follow-up (FU).
At the baseline, O and P of BF in AO were dealyed in comparison to those in PA by 65 and 73 ms respectively. This delay was corrected with BVP to 13 and 18 ms at 1 month, 5 and 15 ms at 3 months, and 1.5 and 3 ms at 6 moths of FU. Surprisingly, this improvement resulted not only from an earlier O and P of BF in AO (by 35 and 32 ms, 30 and 20 ms, and 35 and 26 ms respectively) but also from a delayed O and P of BF in PA that were deferred by 18 and 22 ms at 1 month, 30 and 38 ms at 3 months, and 30 and 45 ms at 6 moths of FU with BVP.
In conclusion, the synchronisation of outputs of left (LV) and right (RV) ventricles due to BVP results not only from an earlier contraction of LV but also from a deferred contraction of RV. This finding suggests that the effect of BVP is derived from an alteration of inter-ventricular electro-mechanical coupling.

1296 Impact of asynchronous ventricular activation sequence on cytokine activation and oxidative stress in paced patients

M.E. Marketou[1], E.N. Simantirakis[1], D. Nikitovic[2], S.I. Chrysostomakis[1], P.G. Tzerakis[1], N.C. Klapsinos[1], P.E. Vardas[1]. [1]*Cardiology Dept.,* [2]*Clinical Chemistry - Biochemisty Dept., Heraklion University Hospital, Heraklion, Greece*

Background: Asynchronous ventricular activation due to permanent pacing through the right ventricular apex results in functional and structural changes, reduced oxygen consumption and disturbances of fatty acid metabolism. The aim of our study was to examine the uninvestigated role of abnormal ventricular activation on the oxidative stress (serum lipid peroxidation), serum levels of interleucin-6 (IL-6) and tumor necrosis factor-a (TNF-a) in paced patients.
Methods: We included 10 patients (6 men, aged 57 ± 7 years) with sick sinus syndrome, in whom a permanent dual-chamber rate-adaptive (DDDR) pacemaker was implanted. All patients had a normal echocardiogram and coronary angiogram. The pacemaker was initially programmed as AAI with a basic rate of 40 bpm. In a crossover design three months later, the patients were randomized for 15 days to either AAI or DDD pacing, with a basic rate of 60 bpm. During DDD pacing, the ventricular capture was completely paced. At the end of each 15-day randomization, blood samples were taken to evaluate lipid peroxides (measured by TBARBS assay), IL-6 and TNF-a (determined in plasma by high sensitivity immunoassays). Before randomization, the same markers were evaluated following 1 hour of AAI and 1 hour of DDD pacing, in a random order.
Results: One hour AAI and DDD pacing marker values showed no significant differences (Lipid peroxides: 254 ± 113 μmol/l, TNF-a: 2.4 ± 0.9 pg/ml, IL-6: 1.9 ± 0.5 pg/ml in AAI compared to 277 ± 107 μmol/l, 2.2 ± 0.69 pg/ml, 2.4 ± 0.8 pg/ml respectively in DDD, p:NS). However lipid peroxides and IL-6 levels were significantly lower, following the 15-day AAI pacing period compared to the DDD pacing period (Lipid peroxides: 369 ± 134 μmol/l, IL-6: 3.6 ± 1.2 pg/ml in AAI compared to 489 ± 114 μmol/l, 4.8 ± 1.6 pg/ml respectively in DDD, p<0.05). TNF-a revealed no significant change (3.1 ± 1,1 pg/ml in AAI versus 3,4 ± 0.9 pg/ml in DDD, p:NS).
Conclusions: Patients with asynchronous ventricular activation sequence caused by right ventricular apex pacing, showed increased cytokine activation and oxidative stress levels after a short-term period of continuous pacing. The clinical importance of these findings deserves further investigation.

1297 Cardiac resynchronization therapy improves myocardial perfusion and glucose metabolism in heart failure patients with left bundle branch block

A.M. Sinha[1], B. Nowak[2], W. Schaefer[2], K. Filzmaier[1], K.U. Markus[1], P. Hanrath[1], U. Buell[2], C. Stellbrink[1]. [1]*Medical Clinic I, University Hospital Aachen, Aachen, Germany;* [2]*University Hospital Aachen, Department of Nuclear Medicine, Aachen, Germany*

Patients (pts) with heart failure (HF) and left bundle branch block (LBBB) present an asynchronous left ventricular (LV) activation resulting in early contraction of the septal wall (SEP) and late contraction of the lateral wall (LAT). This might lead to a reduced glucose (GLC) metabolism and a reversed perfusion/metabolism mismatch of SEP. Cardiac resynchronization therapy (CRT) recoordinates LV activation; thus normalization of the perfusion/metabolism abnormalities associated with LBBB may be another mechanism for improved LV hemodynamics in these pts.
Methods: In 12 pts (9f, 3m, 62±12y) with LBBB (QRS 170±24ms), HF (EF 27±7%, NYHA II 2 pts, NYHA III 10pts) and dilative cardiomyopathy a pacemaker for CRT (VDD mode) was implanted. Attenuation corrected 99mTc-MIBI-SPECT (MIBI; Solus, ADAC Labs.) and gated 18-FDG-PET (FDG; ECAT EXACT 922/47, Siemens CTI) were performed before (basal) and after 14±2 days of CRT. Relative MIBI and FDG uptake [%] of SEP, LAT, anterior (ANT) and posterior (POST) left ventricular wall were quantified semiquantitatively in a total of 25 myocardial segments.
Results: Short-term effects of CRT on relative MIBI and FDG uptake are shown in the table.

Effects of CRT on MIBI and FDG uptake

		ANT (%)	POST (%)	LAT (%)	SEP (%)	LAT/SEP
MIBI	Basal	69±13	73±11	83±6	67±12	1.28
	CRT	74±15*	76±11	81±9	72±13*	1.15*
FDG	Basal	65±15	68±10	87±7	53±14	1.77
	CRT	72±12	74±10*	77+/9*	69±16*	1.16*

Mean ± SD; *p<0.05 vs basal

Conclusion: Pts with LBBB and HF have a slightly reduced ANT-SEP MIBI and a more severely reduced SEP FDG uptake (SEP reversed perfusion/metabolism mismatch). CRT leads to a normalized ANT-SEP perfusion and SEP metabolism with suspension of the septal reversed mismatch, paralleled by a relative decrease in LAT metabolism. Thus, hemodynamic benefit of short-term CRT may be partly explained by a normalized LAT/SEP perfusion and metabolism ratio with a redistribution from LAT to SEP.

1298 Myocardial perfusion and metabolic changes induced by right and biventricular pacing: evaluation by positron emission tomography

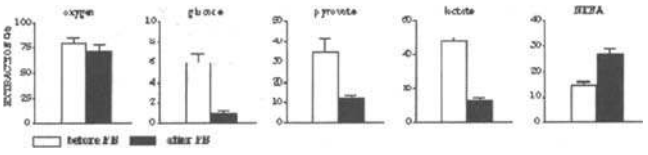
G. Neri[1], P. Zanco[2], F. Alitto[1], P. Biondi[1], M.G. Stefanini[1], R. Buchberger[1]. *[1]Civic Hospital, Cardiology Dept., Montebelluna, Italy; [2]Hospital, Nuclear Medicine, Castelfranco Veneto, Italy*

Aim of the study: Evaluate the possible changes on myocardial metabolism and perfusion induced by right ventricular pacing (VVI or DDD) and biventricular pacing (BIV) in patients affected by dilated cardiomyopathy (DC).
Methods: 28 patients (pts), age 48-79, mean 66, affected by dilated cardiomyopathy were submitted to cardiac Positron Emission Tomography (PET) for evaluation of myocardial viability. 6 pts had a VVI or DDD pacemaker implanted for conventional reasons (gr.A), 12 pts had a BIV, implanted for the presence of left bundle brach block (LBBB) and a QRS duration above 150 ms (gr.B), while the other 10 pts, without pacemaker or LBBB, were considered as controls (Gr.C). All the pts were in III NYHA class and had an EF<35%. None of them presented critical coronary stenosis. Metabolism was evaluated by PET using F18-fluorodeoxyglucose (FDG), by the glucose load-insulin technique, and perfusion by N13-ammonia (NH3), injected at rest. A visual and a semi quantitative analysis were performed, calculating by ROIs the septum to lateral uptake ratio (SLR).
Results: In Gr.A a selective defect in FDG uptake in the septum was present (mean SLR 0.67±0.15, p<0.01 in comparison with Gr.C (0.95±0.10), with a "reverse mismatch" effect in comparison with perfusion (NH3 uptake: Gr.A mean SLR 1.01±0.21; Gr.C 0.94±0.11, p=ns). Gr.B presented a homogeneous distribution of FDG and NH3 in the myocardial wall of both FDG and NH3 (respectively mean SLR 0.91±0.18 and 0.99±0.17, p=ns in respect to Gr.C).
Conclusions: Our experience could suggest that, in patients affected by dilated cardiomyopathy, conventional right pacing induce interference in the metabolism of the septum not correlated to changes in the perfusion, but probably due to asynchronous contraction of the septum. On the contrary biventricular pacing does not modify the myocardial metabolism and perfusion suggesting a better synchronized contraction of left ventricle.

1299 Alterations of cardiac metabolism induced by biventricular pacing in patients with heart failure

T. Toseli[1], N. Avigni[1], F. Regoli[1], C. Pratola[1], F. Ferrari[1], G. Guardigli[1], A. Cargnoni[2], R. Ferrari[1]. *[1]Ospedale Sant'Anna, Cardiology, Ferrara, Italy; [2]Fondazione Salvatore Maugeri, Cardiovascular Pathophysiology Centre, Gussago (BS), Italy*

Introduction: The synchronisation of ventricular contraction in CHF patients by biventricular pacing (BP) has shown to improve contractility with no increase of myocardial oxygen consumption. Alterations at energetic metabolism induced by BP were never studied previously although they constitute the essential background for the improvement of cardiac function.
Aim: We studied cardiac metabolism (in terms of percentage myocardial extraction of glucose, pyruvate, lactate and NEFA) in six patients with heart failure (age 71±12 year; EF% 26.75±2.4; VO2 peak 8.6±2.1 ml/kg/min) before and after BP (10 min of acute stimulation).
Methods: The patients were implanted with biventricular system Guidant Cont@kt TR or CD with catheter in coronary sinus Easy-Track. Two additional catheters were positioned in the coronary sinus and in aorta, respectively, in order to simultaneously draw blood for metabolic measurements.
insert image here
Results: Our data show that BP does not increase the percentage of oxygen extraction, while results in a clear redistribution of the used substrates by myocardium: it reduces the extraction of carbohydrates and increases that of NEFA, a more physiologic and convenient substrate in terms of energetic need.



Conclusions: Our preliminary data indicate that BP results in a metabolic shift in favour of NEFA without negatively affecting O2 consumption: in energetic terms, this results in a higher ATP availability that may be useful to improve cardiac function.

PREVENTION, DIAGNOSIS AND INTERVENTION: THE IMPACT OF NURSING IN PATIENT CARE

1305 Contribution of nursing to risk factor management as perceived by patients with established coronary heart disease

W.J.M Scholte op Reimer, C. Jansen, E.A.M de Swart, E. Boersma, M.L. Simoons, J.W. Deckers. *Erasmus Medical Centre Rotterdam, Thoraxcentre, Dept. of Cardiology, Rotterdam, Netherlands*

Background - Guidelines stress the importance of patient education in risk factor management in patients with coronary heart disease (CHD).
Aims - To evaluate whether guidelines on patient education in risk factor management are followed in clinical practice and to assess the contribution of nursing to risk factor management as perceived by patients with established CHD.
Methods - At 3 Dutch hospitals, 357 consecutive patients were identified after a first coronary-artery bypass graft, first percutaneous transluminal coronary angioplasty or hospital admission with acute myocardial infarction or ischaemia. Data were collected through patient interviews at least 6 months (median = 20 months; IQR = 15 - 26 months) after hospital admission. Smoking was defined as self-reported or > 10 ppm carbon monoxide in breath; overweight as Body Mass Index >= 25 kg/m^2; hypertension as >= 140/90 mmHg, high cholesterol >=5.0 mmol/L, and sedentary lifestyle as self-reported no or only light physical activity in most weeks.
Results - Among smokers (104, 29%), overweight patients (276, 78%), patients with hypertension (185, 52%), high cholesterol (151, 42%), or sedentary lifestyle (207, 58%), 75%, 36%, 65%, 61%, and 49%, respectively, reported that information on the presence or management of their risk factor(s) was provided. Chi-square test showed that patients with acute myocardial ischaemia were the most poorly informed (p=0.02) Among the informed patients, the proportion of patients informed by nurses ranged from 14% (lowering cholesterol) to 23% (increasing physical activity), while 55% (lowering cholesterol) to 71% (stop smoking) were informed by physicians, and the percentage of patients informed by an other caregiver ranged from 24% (stop smoking) to 45% (losing weight).
Conclusion - Although guidelines stress the importance of patient education in secondary prevention, many patients with established CHD and cardiovascular risk factors do not remember ever having received information about the presence or management of their risk factors. The contribution of nurses to risk factor management appeared to be small compared to the input of physicians and other caregivers. If risk factor management is considered to be a responsibility of nurses, current nursing activities in this area should reflect this concern. Identification of patients at risk and long term follow up need to be improved, which may be possible through nurse-led prevention clinics or provision of secondary prevention as part of a comprehensive cardiac rehabilitation programme.

1306 Does early percutaneous coronary intervention strategy affect patient disability and return to work after an acute coronary syndrome?

R. Yuval, M.Y. Flugelman, D.A. Halon, B.S. Lewis. *Lady Davis Carmel Medical Center, Cardiology, Haifa, Israel*

Background and aims: Current management of acute coronary syndromes (unstable angina pectoris, non-ST elevation infarction)(ACS) includes in many pts early revascularization by percutaneous coronary intervention (PCI). Little attention has been directed to the effect of an early interventional strategy on perceived pt disability, lifestyle modification and return to work after ACS.
Patients: Structured anonymous questionnaire was completed and returned by 70 of 78 consecutive pts (age 41-90 yrs; 47 males, 23 females) 6-12 mths after hospitalization for ACS. Early PCI (during index hospitalization) was performed in 21/70 pts according to symptoms and preference of treating physician.
Results: Hospitalization for ACS impacted adversely on pt perception and self-image, with more than half seeing themselves as "heart pts" thereafter. Changes in perception and self-evaluation were less marked in pts undergoing early PCI strategy. Half the pts undergoing PCI returned to work, only a third of the non-PCI group. Diagnostic angiography without PCI (N=43) had no effect on any measure of perceived disability or return to work.

Early PCI and perceived disability

	Age (yrs)	"Heart pt" perception	Increased dependency on others	Decreased self-confidence	Return to work
Early PCI (N=21)	65+13	12 (57%)	6 (29%)	8 (34%)	5/10 (50%)
No PCI (N=49)	66+10	35 (71%)	24 (49%)	33 (67%)	9/25 (36%)
p value	0.71	0.37	0.18	0.04	0.15

Conclusions: In pts with ACS who underwent early PCI (during index hospitalization): 1. There was less change in perceived pt disability and self-confidence after discharge, 2. More pts tended to return to work. 3. The advantage of PCI during index admission on pt lifestyle and return to work strongly supports an early aggressive strategy in pts hospitalized for ACS.

1307 Six minute walking test early after cardiac surgery in septuagenarian patients

A. Mazza, F. Camera, A. Maestri, S. De Feo, M. Capietti, E. Colombo, C. Opasich, R. Tramarin. *IRCCS FONDAZIONE SALVATORE MAUGERI, CARDIOLOGY, Pavia, Italy*

In quality-of-care assessment of post cardiac-surgery rehabilitation programs, measures of functional recovery have been proposed as outcome indicators. Aim of the study was to evaluate feasibility, safety and informative content of a 6-min walking test performed early after admission to an in-hospital rehabilitation unit (R) in over-70 pts.

Methods 107 consecutive elderly pts (74±4 yrs) admitted to R 12±5 days after surgery (53 CABG, 36 valve surgery, 18 combined) performed within 7 days a 6-min walking test (WT1), on telemetry monitoring; in 97 WT1 was feasible within 4 days. The recorded variables were: resting and exertional heart rate, score of fatigue (Borg Scale 1-20), symptoms, ECG alterations and arrhythmias. Other variables were: comorbidity (Charlson index), length of stay and complications in the whole surgical and R stay, disability (nursing needs: Maslow/nursing chart), functional status at discharge (WT2), left ventricular EF (LVEF), number of training sessions, self-perceived health-status (Euroqual questionnaire: Eq1 at entry, Eq2 at discharge).

Results The mean walked distance was 194±93m at WT1 and 286±106m at WT2, p<.0001; no complication and ECG alteration occurred; only isolated premature beats were recorded in 26 pts. Heart rate increased from 86±13 at rest to 95±17 bpm (p<.0001).The perceived fatigue was 12.9±1.2 Borg.
The significant differences between pts who performed WT1 within 4 days or later, and between pts who walked ≤120m (lower quartile) or more are reported in the table.

	<=4 days (n 10)	>4 days (n 97)	>120 m (n 79)	<=120 m (n 28)
Complications-n	1.7±1.5	3.7±1.4 **	1.7±1.4	2.5±1.9 *
Length of surgery stay	11.8±4.3	17±8.9 **		
Total length of stay	30.9±8.5	37.1±16 *		
Nursing needs-n	0.9±1	2.9±1.9 **	0.8±1	1.6±1.5 *
Eq1	49.9±20	34.5±23 *	52.3±18	36.7±22 **
WT2-m	297±103	182±83 **	211±93	113±98 **

* p<0.01, ** p<0.0001

LVEF, training sessions and Eq2 did not differ between the groups.

Conclusions In elderly pts after cardiac surgery a 6-min walking test performed within the first week of entry in R is feasible and safe. Simple cut-offs like timing of the test and walking performance identify more severe pts with lower susceptibility to recovery.

1308 Cardiac nurse led echocardiography – Using portable devices

A.K. Sutcliffe, D.G. Platts, K.J. Rance, M.J. Monaghan. *Kings College Hospital, Cardiology Department, London, United Kingdom*

Introduction: Echocardiography is the commonest non invasive way to assess cardiac function providing vital diagnostic and prognostic information. Cardiac technicians are unable to provide this service in the evenings and over weekends and have many requests to deal with. We assessed whether cardiac nurses with no experience of practical echocardiography could be given training and be asked to interpret left ventricular (LV) systolic function in hospital patients.

Methods: 2 cardiac nurses with no previous echocardiographic skills were given 2 half day teaching sessions in performing and interpreting cardiac ultrasound. Echocardiograms were then performed on 50 patients using portable machines. LV systolic function was to be defined as normal or as mild, moderate or severe impairment. The nurses were also asked if they would recommend a further study. An experienced cardiac technician repeated the study within 24 hours.

Results: 50 patients were studied and of these 34 (68%) were male and 16 (32%) were female. The average age of each patient studied was 64. Assessment of LV function as normal or abnormal was correct in 43 (86%) of all patients. The assessment of normal left ventricular function was correct in 33 out of 37 patients (89%) and assessment of abnormal LV function was correct in 10 out of 13 patients (77%). Quantification of impaired LV function was correct in 5 patients and incorrect in 5. A full study was recommended in 24 of these patients, because of impaired function in 14, limited views in 9, dilated LV in 2 and a pericardial effusion in 1. A full study was not recommended in 2 patients when one was required – impaired LV was called normal in both cases.

Conclusions: Cardiac nurses who provide 24 hour care for patients can perform echocardiographic assessment of left ventricular function accurately in the majority of cases, given appropriate background and training in echocardiography. Cardiac nurses recommended further studies on appropriate patients. This multi-disciplinary approach with nurse led echocardiography has the benefit of triaging requests and streamlining services.

1309 The European heart failure self-care behaviour scale: ready to use!

T. Jaarsma [1], A. Stromberg [2], J. Martensson [3], K. Dracup [4]. [1]*University Hospital Groningen, Department of Cardiology, Groningen, Netherlands;* [2]*Department of Cardiology, Linkoping, Sweden;* [3]*County Hospital Ryhov, Department of Cardiology, Jonkoping, Sweden;* [4]*University of California, School of Nursing, San Fransisco, United States of America*

Background: Improvement of self-care behaviour is an aim of several non-pharmacological nurse led management programs for patients with heart failure (HF). These programs are often evaluated on effects on readmission, costs and quality of life. It is, however, also important to know how patients changed their self-care behaviour as a result of such a program. Therefore a comprehensive, reliable and valid measure of the self-care behaviour of HF patients is needed..

Objectives: To develop a scale measuring the behaviour that HF patients perform to maintain life, healthy functioning, personal development and well being.

Method: The European Heart Failure Self-Care Behaviour Scale (EHFScBS) was developed in three phases:
1] concept analysis and first construction by literature review, by an international panel of experts and pilot testing in 179 HF patients
2] weighing and selecting items by 10 HF nurses and an international expert panel and changing scoring format from dichotomous to Likert scaling
3] testing of the new scale for validity and reliability in a sample of 442 cardiac patients from six European centres, both hospital and primary care.

Results The European Heart Failure Self-Care Behaviour Scale is a 12 item, self-administered questionnaire (Likert scale) that covers items concerning self-care behaviour of HF patients. The items covered concern for example daily weighting, fluid restriction, diet, exercise or contacting a health care provider. Face-validity and concurrent validity of the scale was established and the internal consistency of the scale was tested using pooled data of 442 patients from two centres in Sweden, three in the Netherlands and one in Italy. Cronbachs's alpha ranged in the different HF samples from 0.67 to 0.93 and was 0.81 in the total sample

Conclusion: The EHFScBS is a valid, reliable and practical scale to measure self-care behaviour of heart failure patients. It is ready to use in various studies evaluation the outcome of non-pharmacological management programs.

1310 Effects of follow-up after hospitalisation at a nurse-led heart failure clinic: a randomiced trial

A. Strömberg [1], J. Mårtensson [2], B. Fridlund [3], J-E. Karlsson [2], L-A. Levin [4], U. Dahlström [5]. [1]*Department of Cardiology, Linköping, Sweden;* [2]*County Hospital Ryhov, Department of Cardiology, Jönköping, Sweden;* [3]*Halmstad University, School of Social and Health Sciences, Halmstad, Sweden;* [4]*Linköping University, Center for Medical Technology, Linköping, Sweden;* [5]*University Hospital, Department of Cardiology, Linköping, Sweden*

Chronic heart failure is a huge public health problem with poor prognosis and frequent hospital admissions. Patients are often discharged from hospital without optimised treatment and sufficient patient education, and therefore at high risk for readmission if not optimal follow up is provided. The aim of this prospective study was to evaluate the effect of follow up at a nurse-led heart failure clinic on event-free survival,self-care behaviour and health-related quality of life for patients hospitalised due to heart failure.

Methods: A total of 106 patients were randomly assigned to either the intervention group (n=52) with follow up at a nurse-led heart failure clinic or to the control group (n=54) receiving follow up in primary health care. Mortality and morbidity were collected from medical records. Quality of life was measured through Short-Form 36 and Minnesota Living with Heart Failure Questionnaire. Self-care behaviour was measured through Heart Failure Self-Care Behaviour Scale.

Results: The majority of the patients in the intervention group paid one visit to the nurse-led heart failure clinic (n=28), 12 patients paid two visits and the rest of the patients 3-8 visits. In total the intervention group had 84 visits.
There were fewer patients with events (death or admission) after 12 months in the intervention group compared to the control group (29 versus 40, P = 0.03) and fewer deaths after 3 months (3 versus 13, P = 0.009) and 12 months (7 versus 20, P = 0.005). The intervention group also had fewer admissions (33 versus 56, P = 0.047) and days in hospital (350 versus 592, P = 0.045) during the first 3 months. After 12 months there was a trend towards fewer hospital admissions (P = 0.06) and significantly fewer days in hospital (P = 0.02)in the intervention group. The intervention group had significantly higher self-care scores at 3 and 12 months compared to the control group (P = 0.02 and P = 0.01). Both groups improved their self-care behaviour after 3 months (P < 0.001 and P = 0.01), but only the patients in the intervention group retained the improved self-care behaviour after 12 months (P < 0.001). There were no significant differences between the groups regarding quality of life. Quality of life data has not been adjusted for the large difference in mortality between the groups.

Conclusion: Follow up after hospitalisation at a nurse-led heart failure clinic can improve event-free survival and self-care behaviour in patients with heart failure as well as reduce the number of readmissions and days in hospital.

PERCUTANEOUS INTERVENTIONS IN VALVULAR HEART DISEASE

1311 Temporal trends in percutaneous mitral commissurotomy over a 15-year period from a series of 2538 patients

B. Iung, T. Haghighat, E. Brochet, O. Varenne, D. Karila Cohen, J M. Juliard, B. Cormier, A. Vahanian. *Bichat Hospital, Cardiology, Paris, France*

The analysis of a large single-center series of patients who underwent percutaneous mitral commissurotomy (PMC) for mitral stenosis provides information regarding the evolution of the indications and results of the technique over time. From 1986 to 2000, 2538 consecutive patients underwent PMC in our institution. There were 30 cases of technical failure. Initially, a single balloon was used in 30 patients, then a double-balloon in 586, and finally the Inoue stepwise technique with echo monitoring in the remaining 1892 patients, after October 1990. Patients' characteristics and results were analysed each year and globally compared using analysis of variance.

From 1986 to 2000, mean age increased from 43±15 to 51±15 yrs ($p<0.0001$) and the percentage of patients in NYHA class I or II before PMC increased from 17 to 48% ($p<0.0001$). Valve anatomy was assessed by echocardiography and classified in 3 groups: pliable valves and mild subvalvular disease (Group 1), pliable valves and severe subvalvular disease (Group 2), and calcified valves confirmed by fluoroscopy (Group 3). The percentage of patients in Group 1 decreased from 33% to 4% between 1986 and 2000, while it increased from 40 to 64% in Group 2, and from 26 to 32% in Group 3 ($p<0.0001$). There was no significant variation in mitral valve area, with a mean value of 1.03±0.23 cm^2 ($p=0.18$).

Technical failure decreased from 6% in 1986-87 to 4% in 1988 and 0.7% for following years ($p<0.0001$). The incidence of tamponade decreased from 1.4% in 1986-87 to 0.1% for following years ($p<0.001$).

The proportion of good immediate results, defined as a valve area $>=1.5cm^2$ with no regurgitation >2/4 did not differ over time, with a mean value of 87% ($p=0.20$).

In conclusion 1) Over this 15-year period, candidates for PMC were getting older and had a less favourable valve anatomy, but underwent PMC at an earlier functional stage of their disease. 2) These results confirm the importance of experience in the dramatic reduction of the frequency of technical failure and hemopericardium. 3) Despite the less favourable characteristics of the patients, the success rate remained high and stable.

1312 Immediate and short-term effects of graded dilatation for severe mitral stenosis with moderate mitral regurgitation using the inoue balloon

M. Elghany, I.G. Diab, W. Elnaggar, S. Eltobgi. *cairo university hospital, cardiology, cairo, Egypt*

Aim: To study the safety as well as the immediate and short term results of graded Inoue balloon valvotomy in patients with severe mitral stenosis associated with moderate mitral regurgitation, with special emphasis on the changes that occur in the degree of mitral regurgitation and functional class post-valvotomy.

Methods: 15 patients (60% females, 40% atrial fibrillation) with severe symptomatic mitral stenosis (mitral valve area (MVA) < 1.2 cm^2, NYHA more than or equal functional class (Fc)II, Echo score 7.4 ± 1.5) and mild to moderate mitral regurgitation (mitral regurgitant jet area (MRJA) between 3 and 7 cm^2 by Doppler colour flow mapping) were subjected to graded balloon mitral valvotomy. All patients were assessed as regards their NYHA functional class, treadmill exercise duration, and a detailed echocardiographic study before, and immediately after graded dilatation of the mitral valve as well as at 3-6 months follow-up.

Results: See table.

	Predilatation	Post dilatation	Follow-up (FU)	p-value Pre vs FU
Functional class (>Fc II, %)	73	–	13	< 0.001
Exercise duration (min)	4.7 ± 3.5	–	10.6 ± 4.1	0.0036
MVA (cm^2)	0.91 ± 0.15	1.95 ± 0.32	1.75 ± 0.22*	<0.001
MRJA (cm^2)	4.44 ± 0.65	6.74 ± 2.65	7.93 ± 3.21*	<0.001
LVEDD (cm)	5.1 ± 0.5	–	5.1 ± 0.6	NS
Left atrium (cm)	5.4 ± 0.6	–	5.2 ± 0.5	NS

* p post vs follow-up: insignificant

Conclusion: Graded dilatation of severe mitral stenosis associated with moderate mitral regurgitation is associated with a significant gain in mitral valve area which causes a marked improvement in functional class and treadmill exercise duration. However, it is associated with increase in the degree of mitral regurgitation, but this increase is well tolerated in all patients. The favorable haemodynamic effects are maintained over the short-term follow-up period. Thus, in these patients, who were routinely sent to surgery, mitral valve repair or replacement can be deferred to a later date or even indefinitely.

1313 Long-term follow-up results of mitral balloon valvuloplasty (12 years) and predictors of restenosis

M.E. Fawzy[1], J. Al-Buraiki[2], M.A. Stefadouros[2], H. Hegazy[2], M. Al-Amri[2], M. Chaudhry[2], Z. Al-Halees[2]. *[1]King Faisal Specialist Hospital, Cardiovascular Diseases (MBC-16), Riyadh 11211, Saudi Arabia; [2]King Faisal Specialist Hospita, Cardiovascular Diseases, Riyadh 11211, Saudi Arabia*

Background: The long-term results of mitral balloon valvuloplasty (MBV) are not well characterized.

Methods: We analyzed the results of 362 patients from mitral balloon database in our hospital. These patients had clinical and echocardiographic follow-up studies 1-12 (mean 5 1) year after MBV. The morphologic features of the mitral valve were graded and semiquantitated using Wilkin's mitral echo score (MES), patients were divided into 2 groups according to MES at the time of valvuloplasty, group A (MES less than or equal to 8) and group B (MES > 8). Comparison of hemodynamic variables was done using student t-test. Chi-square/Exact-test was used to study categorical variables. Logistic regression analysis was used to identify predictors of restenosis. Event free survival was plotted using the Kaplan Meier test.

Results: The procedure was successful in 98% of cases and no death was encountered. The immediate and long-term hemodynamic results are as follows (see table).

	Group A (n=274)	Group B (n=88)	P Value
Age	31 ± 10.9	34 ± 11.2	P < 0.05
MVA before cm^2	0.9 ± 0.16	0.9 ± 0.19	P = 0.2
MVA immediate cm^2	2.00 ± 0.3	1.8 ± 0.27	P < 0.0001
MVA follow-up cm^2	1.8 ± 0.36	1.5 ± 0.38	P < 0.0001
Restenosis	32 (12%)	22 (25%)	P < 0.001

Restenosis in all patients is 15%.

Logistic regression analysis identified MES and post procedure MVA < 2.0 cm as strong predictors of restenosis ($P < 0.0001$ and $P < 0.05$ respectively). The event free survival for 1, 4, 6, 8, 10, 12 years was 0.99, 0.96, 0.92, 0.82, 0.64, 0.58 for group A and 0.98, 0.8, 0.74, 0.54, 0.3, 0.15 for group B respectively.

Conclusions: Good results were observed up to 12 years after MBV and unfavorable MVM (MES > 8) and post procedure MVA < 2.0 cm are powerful independent predictor of restenosis.

1314 Long-term effect of successful mitral balloon valvotomy on severe tricuspid regurgitation

M.E. Fawzy, M. Awad, H. Hannoush, W. Hassan, M. Chaudhary, Z. Al-Halees. *King Faisal Specialist Hospital, Cardiovascular Diseases (MBC-16), Riyadh 11211, Saudi Arabia*

Background: Significant tricuspid regurgitation (TR) secondary to severe pulmonary hypertension (PH) is frequently associated with severe mitral stenosis (MS) and it has adverse impact on morbidity and mortality in pts undergoing mitral valve surgery. The effect of successful mitral balloon valvotomy (MBV) on significant TR is not fully elucidated.

Methods: 559 pts with severe MS underwent MBV over 12-year period, of these 76 pts had significant TR (2 to 4+). The TR was evaluated by Doppler echo before MBV and at follow-up 1-12 (mean 5 1) years and graded on scale 1 to 4. The pts were divided into group A (59 pts) in whom TR regressed by 3 one scale and group B (17 pts) TR did not change.

Results: In 59 pts TR regressed or disappeared due to regression of pulmonary hypertension. 12 out of 20 pts with severe TR (3 to 4+) regressed to 0 to 1 TR.

Measurement	Group A (59 pts)	Group B (17 pts)	P value
Age	29 ± 12	35 ± 12	0.13
MVA area cm^2 (B)	0.8 ± 0.16	0.8 ± 0.17	0.24
(I)	1.8 ± 0.34	1.8 ± 0.27	0.32
(F)	1.6 ± 0.45	1.5 ± 0.27	0.23
PAP mmHg (B)	62 ± 19	51 ± 14	<0.05
(F)	34 ± 15.0	41 ± 7.6	0.01
TR (B)	2.4 ± 0.55	2.1 ± 0.33	<0.05
(F)	0.86 ± 0.60	2.6 ± 0.8	<0.0001

B=before; I=immediately after MBV; F=follow-up; MVA=mitral valve area; PAP=pulmonary artery pressure; TR=tricuspid regurgitation

Conclusions: (1) Regression of significant TR after successful MBV was observed in the majority of pts who had associated severe pulmonary hypertension, and (2) MBV should be the treatment of choice even in the presence of severe TR secondary to pulmonary hypertension.

1315 Immediate and late outcome of newborn babies following balloon mitral commissurotomy during pregnancy

H. Gamra, F. Betbout, F. Maatouk, K. Ben Hamda, F. Addad, S. Khedher, R. Ben Rejeb, M. Ben Farhat. *University Hospital, Cardiology department, Monastir, Tunisia*

Balloon mitral commissurotomy (BMC) during pregnancy proved effective and safe with regard to the fetus and mother outcome up to the delivery time. However, some concern remains about potential late side effects of radiation in the newborn babies.

Methods and Results: From 06/90 to 06/2000, 58 pregnant women with severe mitral stenosis underwent a successful BMC at 26 (14-37) weeks of gestation. Mean fluoroscopy time was 16±7 min. All pts delivered at full term: 55 vaginally and 3 (5%) by caesarian section for obstetrical reasons. None of the 59 (1 twin pregnancy)newborn babies had a malformation. Mean body weight at birth was 3.04 ± 0.45 (1.8-4.4) kg. Hypotrophy (weight < - 2 SD) was observed in 4 of them. Apgar score was > 9 in all of them.

At a mean follow-up of 71 ± 35 (8-120) months, 45 (76%) babies were evaluated physically and mentally.

Physical growth was evaluated by the determination of height, weight and head circumference compared to the normal curves. Mental development was assessed by the determination of the intelligence quotient (IQ) by a pediatric psychologist.

At follow-up, a physical malformation was observed in none of the babies. Height, weight and head circumference were within ±2 SD in all of them. A normal IQ (> 0.8) was observed in 39 (87%) of them.

In the remaining 6 pts, there was no major mental retardation with an IQ between 0.52 and 0.7.

Conclusion: The immediate and late clinical outcome of newborn babies following balloon mitral commissurortomy is excellent with no evidence of radiation side effects up to six years of follow-up.

1316 Immediate results of non-surgical implantation of a balloon-expandable prosthetic valve: an experimental study in sheep

A. Cribier[1], H. Eltchaninoff[1], N. Borenstein[2], F. Laborde[2], D. Czitrom[2], M. Leon[3]. [1]*Charles Nicolle, Cardiology Dept., Rouen, France;* [2]*CERA, Paris, France;* [3]*Lenox Hill Hospital, Cardiology, New York, United States of America*

In patients with severe valvular disease and contra-indication to surgery, a balloon-expandable prosthetic valves (BEPV) might offer a new potential therapeutic option in the next future. In this study, we assessed the feasibility of non surgical implantation of an original BEPV, a three-leaflets foldable valve made of polyurethane or bovine pericardium, mounted inside a vascular tubular stainless steel stent. BEPV was crimped over a balloon catheter of 23 to 25 mm in diameter and 40 mm in length. This delivery catheter was pushed over a 0.035 stiff guide wire, through a 22 to 24-Fr sheath introduced after cut-down into the right carotid artery or the right jugular vein (according to the selected implantation site). BEPV was delivered at the desired site by high pressure balloon inflation. Implantations were performed at the following sites under general anesthesia in 48 sheep weighing 30 to 60 kg: descending aorta in 5, ascending aorta in 2, within the native aortic valve (AoV) in 19 and within the native pulmonary valve (PV) in 22. Before implantation, vascular diameters were calculated by selective angiography using the introducer sheath as a reference and by 2-D trans thoracic echocardiography in the last 20 cases. After implantation, repeat angiograms were performed near the BEPV ends to assess the antegrade and retrograde flow; the pressure gradient across BEPV was measured and the valvular function was assessed in the 25 last cases using 2D and TEE Echocardiography and Doppler. BEPV could be successfully delivered at the selected implantation site in all but 3 cases (immediate migration: AoV=2; PV=1). Early death (within 3h) occurred in 6 AoV cases, related to a wrong BEPV positioning in 3 (below the native valve, with subsequent severe mitral valve dysfunction and/or aortic regurgitation) and to pharmacological cause in 3, and in 1 PV case (ventricular fibrillation). Delayed (within 6h) BEPV migration occurred in 2 AoV and 2 PV. After successful implantation, the transvalvular gradient was minimal (< 10 mmHg) and there was no or mild regurgitation. Valvular motion was normal in the 2 AoV and 20 PV controlled by Echocardiography and Doppler. Conclusions: This BEPV can be successfully implanted in sheep in the aorta or within native valves, leading to excellent and promising acute hemodynamic results. Improvements of BEPV components and increased technical experience have markedly decreased the incidence of wrong positioning and early migration and a chronic experiment is currently ongoing.

ENDOGENOUS MECHANISM IN MYOCARDIAL PROTECTION

1340 Myocyte survival against calcium overload or simulated ischaemia is improved by overexpression of the stress and calcium-binding protein GRP94

M. Vitadello[1], D. Penzo[2], G. Michieli[2], S. Gomirato[2], R. Menabo[3], F. Di Lisa[4], L. Gorza[2]. [1]*CNR -Muscle Biol Pathophysiol Unit, Padova;* [2]*University of Padova, Biomedical Sciences, Padova;* [3]*CNR- Biomembrane Unit, Padova;* [4]*University of Padova, Biochemistry, Padova, Italy*

Increase of free intracellular calcium ions $[Ca^{2+}]_i$ plays an important role in pathogenesis of cardiomyocyte injury after ischemia-reperfusion. We investigated whether the glucose-regulated protein GRP94, a stress- and calcium-binding protein localized in cardiac sarcoplasmic reticulum, is involved in protection of myocytes exposed to calcium overload and simulated ischemia. GRP94 overexpression was achieved in skeletal C2C12 and heart H9c2 muscle cell lines by stable transfection and in neonatal rat ventricular myocytes by transient transfection with constructs expressing GRP94. Quantitative analysis revealed a 3 to 8 fold increase of GRP94 in five different GRP94 overexpressing clones with minor increase in GRP78 or calreticulin content. Calcium overload was obtained by exposing control and GRP94 overexpressing clones to 2.5μM A23187 and cell damage was evaluated by determination of LDH enzymatic activity released in culture medium and retained in cell pellets. Results show that every GRP94-overexpressing clone studied displays a significantly higher intracellular retention of LDH (from + 29.3% to +57.5%), indicating prolonged cell viability. Kynetic analysis of $[Ca^{2+}]_i$, performed in C2C12 control and GRP94 overexpressing clones, showed a significantly lower Fluo-3 fluorescence during the first 10 min after exposure to A23187 of GRP94 overexpressing clones with respect to control clones. Propidium iodide uptake was used for evaluation of GRP94 protective effect on neonatal rat cardiomyocytes transfected with a construct co-expressing GRP94 with the green fluorescent protein GFP: a lower percentage of necrotic propidium-iodide positive/GFP fluorescent myocytes expressing exogenous GRP94 was observed after exposure to the ionophore with respect to myocytes transfected with GFP alone (6.6% vs 14.0%, respectively). A comparable protective effect was detected when transfected neonatal cardiomyocytes were exposed for 4 hours to anoxia in the presence of ischemic buffer (Zhao et al. J Biol Chem 273, 23072, 1998): only 8.5% of GRP94 overexpressing/GFP positive cardiomyocytes were necrotic/propidium iodide-positive with respect to 17.7% of control/GFP positive cardiomyocytes. In conclusion, increase in GRP94 expression protects myocytes from necrosis induced by ischemia and calcium overload, where it delays the increase in $[Ca^{2+}]_i$, presumably through its involvement as a calcium-binding protein.

1341 Activation of p38 MAPK is not a trigger for ischaemic preconditioning

S. Genade[1], E. Marais[1], J. Moolman[1], A. Lochner[2]. [1]*University of Stellenbosch, Dept. of Medical Physiology, Tygerberg, South Africa;* [2]*MRC, Experimental Biology Programme, Tygerberg, South Africa*

The role of the activation of p38 MAP kinase (MAPK) as trigger of ischemic preconditioning (PC) is controversial. Bracketing the preconditioning event with the p38 MAPK inhibitor SB 203580 has been reported both to abolish or to have no effect on protection. The aim was to investigate the role of p38 MAPK activation as trigger in the mechanism of ischemic preconditioning by using the p38 MAPK inhibitor, SB203580 and anisomycin (An)as activator of p38 MAPK.

Methods: Hearts were exposed to 25 min global ischemia. A 3X5 min cycle of ischaemia was used to elicit ischemic preconditioning. The p38 MAPK inhibitor, SB203580 (10μM), was used to bracket the ischemic preconditioning triggering phase. In separate experiments p38 MAPK was activated prior to ischemia by administration of anisomycin (An)(5 μM) for 3X5 min, 1X10 min, 1X10 min plus washout(W), and 1X20 min (without washout). p38 MAPK activation was determined by Western blot (dual phosphorylation antibodies). Protection was evaluated with functional recovery (aorta output) during reperfusion (Neely-Morgan isolated working rat heart model).

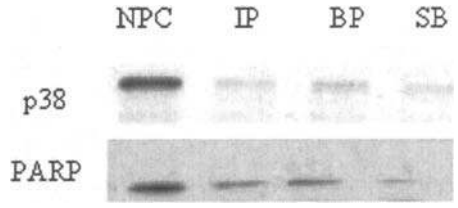
Results: Both ischemic preconditioning (3X5 min) and anisomycin (all modes of administration) significantly activated p38 MAPK. Ischemic preconditioning protected against ischemia (aorta output 16.6±1.8 ml/min vs. 3.8±1.5 ml/min in Non-PC hearts), whereas anisomycin (irrespective of protocol) failed to protect (An 3X5 min = 6.1±2.1, 1X10 min = 4.6±2.6, 1X10 min plus washout(W)= 5.3±2.8, and 1X20 min (with out washout)= 3.5±2.4. SB 203580 bracketing of the preconditioning protocol did not abolish the protective effect of preconditioning (recovery 26±0.9ml/min) but enhanced the protective effect of PC ($p<0.05$ for PC+SB vs. PC), and SB 203580 alone (3X5 min) did not have any effect on protection (aorta output 3.3±1.3 ml/min), excluding the possibility of a drug effect due to inadequate washout of drug prior to sustained ischemia.

Conclusions: Although p38 MAPK is activated during ischemic preconditioning, the protective effect of preconditioning is not dependent on activation of the stress-kinase. Inhibition of p38 MAPK during the preconditioning protocol enhances the protective effect of ischaemic preconditioning, indicating a detrimental role for p38 MAPK activation during the triggering phase.

1342 β-Adrenergic receptor stimulated preconditioning may protect against necrosis and apoptosis via inhibition of p38 MAP kinase

S. Hartley[1], S. Genade[1], B. Huisamen[2], A. Lochner[2], J. Moolman[1].
[1]University of Stellenbosch, Dept. of Medical Physiology, Tygerberg, South Africa; [2]MRC, Experimental Biology Programme, Tygerberg, South Africa

Background: The protective effect of ischaemic preconditioning (I-PC) in the rat heart is mediated by reduced activation of the stress-kinase p38 MAPK. Beta-PC (elicited by beta-adrenergic activation by isoproterenol administration) protects against ischaemia using functional recovery as end-point. The efficacy in reducing infarct size and apoptosis, and the mechanism of protection of beta-PC is unknown.
Aim: To (1) compare the effects of I-PC and beta-PC with regard to infarct size reduction and protection against apoptosis and (2) investigate the role of p38 MAPK in the mechanism of beta-PC.
Methods: Isolated perfused rat hearts were subjected to 25 minutes global ischaemia and 30 min reperfusion. Hearts were treated with I-PC (3 x 5 min ischaemia) and beta-PC (1 x 5 min 10-7 M isoproterenol) and the p38 MAPK inhibitor SB 203580 (10μM). Infarct size was determined with TTC staining, and apoptosis evaluated by determination of caspase-3 activation and PARP (Western blot). p38 MAPK activity was evaluated by Western blot (anti-dual phosphorylation antibodies).
Results: p-38 MAPK activity was equally reduced in hearts treated with I-PC, beta-PC and SB203580. This was accompanied by an equal decrease in Caspase-3 activation and PARP formation. Infarct size of hearts treated with I-PC, beta-PC and SB203580 was significantly reduced compared to non-PC hearts (24.1±2.27%, 22.53±3.3% and 23±1.8 vs. 42.5±2.3% ($p<0.05$).



P38MAPK and PARP in preconditioning.

Conclusion: I-PC and beta-PC both reduced infarct size and apoptosis, and was associated with reduced activation of p38 MAPK. The p38 MAPK inhibtor SB203580 reduced infarct size and apoptosis to the same extent. This may imply the stress kinase p38 MAPK as a mediator of protection against necrosis and apoptosis.

1343 C-Src/Bcl-xL pathway is involved in anti-apoptotic effect of endothelin-1 in H9c2 cardiomyocytes

Y. Ogata[1], M. Takahashi[2], S. Ueno[1], K. Takeuchi[3], H. Mano[4], U. Ikeda[1], K. Shimada[1], E. Kobayashi[2]. [1]Jichi Medical School, Cardiology, Tochigi, Japan; [2]Jichi Medical School, Organ Replacement Research, Tochigi, Japan; [3]Jichi Medical School, Anatomy, Tochigi, Japan; [4]Jichi Medical School, Functional Genomics, Tochigi, Japan

Apoptosis of cardiomyocytes is thought to be a feature of many pathological disorders, including congestive heart failure and ischemic heart disease. Since the loss of contractile cardiomyocytes due to apoptosis results in a furher decrease of cardiac function, the identification of the signaling pathway that mediate survival and/or apoptosis in cardiomyocytes is important. Recent investigations indicate that endothelin-1 (ET-1) plays an important role in congestive heart failure and ischemic heart disease. We therefore investigated the effect of ET-1 on cardiomyocyte apoptosis. The presence of apoptosis in rat H9c2 cardiaomyocytes was evaluated by morphological criteria, electrophoresis of DNA fragments, 4', 6'-diamidine-2'-phenylindole (DAPI) staining, and TUNEL analysis. ET-1 not angiotensinII prevented apoptosis induced by serum deprivation in a dose-dependent manner (1-100 nM). This anti-apoptotic effect of ET-1 was completely abolished by the treatment with selective ETA receptor antagonist BQ123, but not by ETB receptor antagonist BQ788. The use of specific pharmacologic inhibitors demonstrated that anti-apoptotic effect of ET-1 is mediated through a tyrosine kinase pathway (genistein and AG490) but not through PKC (calphostin C), MAP kinases (PD98059 and SB203580), or PKA (KT5270) pathways. Because c-Src family of tyrosine kinases has shown to be involved in apoptotic cell death, we next investigated the role of c-Src in the anti-apoptotic effect of ET-1. Western blotting using an antibody which recognizes the activated form of c-Src showed that activity of c-Src increased by 4.5-fold within 30 seconds in response to ET-1 stimulation. Adenoviral-mediated gene transfer of kinase inactive (KI) c-Src inhibited the anti-apoptotic effect of ET-1, whereas gene transfer of beta-galactosidase with Ad.LacZ had no effect. We further investigated whether Bcl-xL, an anti-apoptotic molecule, would be up-regulated by using a luciferase-based reporter system. ET-1 up-regulated Bcl-xL, and this up-regulation was inhibited by genistein or AG490 but not by calphostin C. The experiments using KI mutants for various tyrosine kinases revealed that c-Src (but not JAK1, Jak2, Syk, Tec, and Pyk2) is required for ET-1-induced up-regulation of Bcl-xL expression. These findings suggest that ET-1 prevents apoptosis in cardiac myocytes through the ETA receptor and the subsequent c-Src/Bcl-xL-dependent pathway, and provide a new insight into the molecular basis and therapeutic target for cardiovascular diseases including congestive heart failure and myocardial infarction.

1344 Induction of anti-apoptotic genes by ischaemic conditions

G. Taimor, B. Hofstaetter, H.M. Piper. Justus-Liebig University, Institute of Physiology, Giessen, Germany

In ischemic/reperfused myocardium nitric oxide and oxygen radicals are found increased. Both radicals induce apoptosis in normoxic cardiomyocytes. However, after simulated ischemia cardiomyocytes are transiently protected against apoptosis. To elucidate mechanisms involved in this mode of protection we now analyzed the expression of anti-apoptotic genes in cardiomyocytes exposed to ischemic conditions.
The NO-donor SNAP (100 μM) induced apoptosis in 13.2 ± 0.3% of cardiomyocytes determined by annexin/propidium iodide staining (vs. 4.0 ± 0.5% in controls, n=5, $p<0.05$). TUNEL-assay gave virtually the same results with 12.6 ± 4.9% TUNEL-positive cells vs. 5.4 ± 0.7% in controls (n=3, $p<0.05$). DNA-laddering could be detected after SNAP treatment. Release of cytochrome c from mitochondria into the cytosol increased by 103 ± 38% (n=5, $p<0.05$ vs. non-treated control) and the amount of the anti-apoptotic protein Bcl-2 associated with mitochondria decreased to 67.2 ± 13.9% within 6 h after SNAP-addition (n=8, $p<0.05$). The ability of SNAP to induce apoptosis after 3 h of simulated ischemia (anoxia in a glucose-free medium with a decreased pH) had vanished (4.6 ± 0.7% apoptotic cells). DNA-laddering was no longer found. Investigations on anti-apoptotic gene expression by RT-PCR revealed an upregulation of mcl-1 by 99 ± 62%, bcl-2 by 69 ± 26% and bcl-xl by 54 ± 26% (n=9, $p<0.05$). bcl-w expression did not change. The amount of Bcl-2 associated with mitochondria increased to 122.1 ± 6.7% (n=8, $p<0.05$ vs. normoxic controls). In the group of the IAP family (inhibitors of apoptosis), only IAP1-mRNA increased by 61 ± 32%. Survivin expression was slightly, but not significantly increased and mRNA's of XIAP and NAIP were not detected.
In conclusion, changes in cytochrome c and Bcl-2 location reveal involvement of mitochondria in NO-induced apoptosis in cardiomyocytes. Preceding ischemic conditions protect cardiomyocytes against this kind of apoptosis. The induction of anti-apoptotic genes of the bcl-2- and IAP-family under ischemic conditions may contribute to this mode of protection.

1345 The apoptosis regulator ARC prevents apoptotic and necrotic cell death in cardiomyocytes

M. Neuss[1], A.T. Chesley[2], M.T. Crow[2], E. Fleck[1]. [1]German Heart Institute, Cardiology Dept., Berlin, Germany; [2]NIA-NIH, Laboratory of Cardiovascular Science, Baltimore MD, United States of America

While apoptotic cell death of cardiomyocytes plays a role in ischemia-reperfusion, the predominant mode of cell death in myocardial infarction occurs via necrosis. Since the muscle-specific apoptosis regulator with CARD domain (ARC) was shown to prevent apoptotic cell death in the myogenic H9c2 cell line by targeting the mitochondrial apoptotic pathway we reasoned that protection from non-apoptotic cell death might occur by the same mechanism. Treatment of neonatal rat cardiomyocytes with 200μM H202 resulted predominantly in necrotic cell (>98%) death as determined by staining with ethidium-homodimer, absence of nuclear fragmentation as determined by staining with Hoechst 33342, absence of DNA-laddering and absence of immunofluorescence for cleaved caspase-3. In contrast, 24h of hypoxia resulted predominantly (>95%) in apoptotic cell death as determined by nuclear fragmentation and staining for cleaved caspase-3. Treatment with 200μM H202 caused necrotic cell death in 43.9±9.24% of cardiomyocytes after 1h and 73.7±18.23% after 12h. Infection with an ARC-adenovirus significantly reduced necrotic cell death to 26.1±21.4 after 1h and 24.98±12.1% after 12h (n=6), while neither treatment with the pan caspase-inhibitor ZVAD-fmk or an GFP-adenovirus were effective with respect to reduction of cell death. 24h of hypoxia significantly increased apoptotic cell death in comparison to control conditions (9.3±2.6 vs. 2.4±1.3, n=12). This apoptotic cell death was reduced to control-conditions by infection with an ARC-adenovirus or treatment with ZVAD-fmk but not by infection with a control virus. In the same set of experiments both hypoxia and treatment with H202 resulted in a breakdown of the mitochondrial membrane potential as determined by staining with mitotracker. Since this breakdown preceded both apoptotic and necrotic cell death we reasoned that ARC protected cardiomyocytes from both modes of cell death by preserving mitochondrial function. To directly address this question we pretreated cardiomyocytes with bongkrekic acid, an inhibitor of mitochondrial permeability transition. Bongkrekic acid prevented both apoptotic cell death in response to hypoxia and necrotic cell death in response to H202.
Conclusion: ARC protects cardiomyocytes from apoptotic and necrotic cell death by preserving mitochrondrial function. This defines ARC as a potentially important therapeutic target in the context of reperfusion injury and myocardial infarction.

CARDIAC ADAPTATION AND DYSFUNCTION IN HYPERTENSION: FROM MODELS TO PATIENTS

1346 Chronic sympathectomy improves survival and attenuates cardiac dysfunction and failure in rats with aortic banding-induced pressure-overload

S. Perlini[1], I. Ferrero[1], R. Tozzi[1], G. Palladini[1], S. Fallarini[1], G. Busca[2], R. Fogari[1], A.U. Ferrari[2]. *[1]Clinica Medica 2, IRCCS San Matteo, University of Pavia, Pavia, Italy; [2]Univ Milano Bicocca, Ctr Fisiol Clinica e Ipertensione, Milano, Italy*

The chronic sympathetic overactivity that accompanies established heart failure (CHF) represents an inappropriate response that accelerates cardiac deterioration, and it has been unquestionably shown that CHF patients benefit from beta-blocker treatment. In the earlier stages of the syndrome, however, sympathetic activation may exert favourable effects, contributing to avoid cardiac failure despite increased load or reduced contractile mass. Indeed, limited and controversial evidence exists whether interfering with sympathetic activity before the onset of overt CHF has detrimental, neutral or beneficial effects. We therefore examined the course of experimental pressure overload hypertrophy (POH) in intact and chronically sympathectomized (Sx) rats. Treatment with 6-hydroxydopamine (150 mg.kg-1 twice a week) to produce chronic chemical Sx, or with vehicle (Veh) was administered to Sprague-Dawley rats previously subjected to aortic banding (B) or sham operation (S). After monitoring survival for 10 weeks, systolic pressure (SBP, carotid catheter) and left ventricular (LV) fractional shortening (%SF), end-diastolic (EDD) and end-systolic (ESD) dimensions (M-Mode echo) were measured. Lung, LV and right (RV) weights were indexed to body weight (wti, g/100 g). In the banded groups, survival was much worse in Veh- than in Sx-treated animals, with a 10-week mortality equalling 40% and 6%, respectively ($p<0.01$). There was no mortality in the sham groups. Further results are shown in the table (means±SD; *$p<0.05$ vs. corresponding S; #$p<0.05$ vs. corresponding Vh).

	EDD (mm)	ESD (mm)	%SF	SBP (mmHg)	LV wti	RV wti	Lung wti
S-Vh (n=8)	7.1+0.3	4.3+0.2	42+2	102+12	1.87+0.11	0.53+0.13	2.89+0.64
S-Sx (n=9)	7.2+0.3	4.4+0.2	39+2	96+15	2.08+0.21	0.58+0.05	3.64+0.42
B-Vh (n=9)	9.5+0.3*	6.3+0.3*	28+4*	154+19*	2.94+0.49*	0.76+0.30*	4.31+1.21*
B-Sx (n=14)	8.6+0.3*#	5.8+0.3*	35+2#	159+18*	2.48+0.59*#	0.61+0.13#	3.70+0.61

Thus in the course of experimental POH, chronic sympathectomy had clearly favourable effects on the degree of LV hypertrophy, chamber dilation, systolic dysfunction, lung congestion and RV involvement as well as, even more importantly, on mortality. Interfering with sympathetic activity during the developmental stage of an experimental model of POH leading to LV dysfunction and failure has markedly beneficial functional and survival effects.

1347 Inhibition of left ventricular hypertrophy prevents systolic dysfunction in mice with aortic banding-induced pressure overload

G. Marano[1], F. Podo[2], S. Vergari[3], S. Palazzesi[1], G. Carpinelli[2], C. Testa[2], R. Canese[2], A.U. Ferrari[4]. *[1]Ist. Sup. Sanita, Lab. Farmacologia, Rome, Italy; [2]Istituto Superiore di Sanità, Lab Biologia Cellulare, Roma, Italy; [3]Univ Cattolica S. Cuore, Ist Anestesia e Rianimazione, Rome, Italy; [4]Centro Fisiologia Clinica Ipertensione, Dipt Med., Prev. e Biotecnol. Sanit., Milano, Italy*

Controversy exists whether the development of pressure overload-induced left ventricular hypertrophy (LVH) has beneficial, neutral or detrimental functional implications. Aim of this study was to assess the effects of preventing LVH by chronic propranolol treatment on LV systolic function and remodelling in mice with aortic banding.

Pressure overload was induced by thoracic aortic banding in 24 mice aged 3 months, 12 treated with propranolol (60 mg kg-1 d-1, Pro-Bd), 12 treated with vehicle only (Veh-Bd). Concurrent groups of sham operated mice (Sh) were studied (Pro-Sh, n=12; Veh-Sh, n=12). Four and 8 weeks after surgery, in vivo cardiac function, chamber size and LV mass (normalized to tibial length) were evaluated by cine magnetic resonance imaging (MRI) combined with intraventricular hemodynamic measurements obtained via a transcarotid, transducer-tipped catheter. LV mass figures provided by MRI strictly match with autoptic figures.

At the 4 week stage, carotid systolic pressure was similarly elevated in the two groups (Veh-Bd: 133±3 mmHg; Pro-Bd: 131±2 mmHg, p=ns), but normalized LV weight was 46% larger (145±4 mg vs 100±3 mg, $p<0.01$) in Veh-Bd compared to Pro-Bd mice, the latter being in this respect similar to the sham operated mice. Although not displaying LVH, Pro-Bd mice had significantly lower LV end-diastolic volume (61±4 ml vs 87±6 ml, $p<0.01$) and significantly higher LV ejection fraction (62±2% vs 41±2%, $p<0.01$) and LV +dp/dtmax (8454±125 mmHg.sec-1 vs 6137±135 mmHg.sec-1, $p<0.01$) compared to Veh-Bd mice. At the 8 week stage, LV weight was again larger in the Veh-Bd than in the Pro-Bd group, although in the latter LV dysfunction and remodeling started to develop. Histomorphometric analysis revealed that prevention of LVH in Pro-Bd mice pertained to the myocyte component whereas no protective effects were noted against LV fibrosis.

Thus in the pressure overloaded mouse in which the development of LVH is inhibited by propranolol administration, LV dimensions and systolic function are preserved, and LV systolic dysfunction is by no means facilitated and is rather markedly delayed. Taken together these findings indicate that i) LV hypertrophy represents a maladaptive mechanism which accelerates the progression to chamber systolic dysfunction and enlargement, and ii) the heart has the potential to cope with an increased mechanical load without increasing its contractile mass.

1348 The effect of dipping status on left atrial size in hypertension

G.P. Vyssoulis, A.G. Marinakis, E.A. Karpanou, J.D. Barbetseas, N.J. Marinakis, J.K. Rizos, D.V. Cokkinos, P.K. Toutouzas. *Athens University, Cardiology Department, Athens, Greece*

Background: It is known that left ventricular mass and left atrial size (LA) are both increased in hypertensive patients. LA enlargement is correlated with atrial fibrillation and cerebrovascular ischemic events.

It has been also shown, that non dipper hypertensive patients have increased cardiovascular risk compared to dippers. The dipping profile effect on LA dimensions has not been fully elucidated. The aim of this study was the investigation of the influence of dipping profile on LA size in hypertensive patients according to age.

Methods: The study comprised 4500 consecutive, untreated patients, (2440 men and 2060 women) with essential arterial hypertension. Twenty-four hours ambulatory blood pressure recordings were done in every patient. The patients were grouped as 2628 dippers (day systolic - night systolic mean arterial pressure>10mmHg) and 1872 non dippers. LA diameter and its indices, corrected for body surface area (LAI) or aortic root diameter (LA/AO) were calculated and the two groups (dippers and non dippers) were classified according to age decade

Results: LA increased ($p<0,0001$) with advancing age (r= 0.59) as did LAI (r=0.68) and LA/AO (r=0. 53) but had significantly higher values in non dippers (34.3 vs 32.7 mm $p<0.0001$).

The LAI had significantly higher values in non-dippers (18.4 vs 17.7 mm/m^2 $p<0.0001$), differentiating more in elderly patients (p=0.0008). Similar behavior was observed using the LA/AO ratio ($p<0.0001$).

LA correlated with daytime systolic blood pressure (r= 0.31) and pulse pressure (r= 0.37) and these relationships remained significant ($p<0.0001$) even after age correction (r=0.24 and 0.19 respectively)

Conclusion: LA enlargement is more severe in non-dipper hypertensive patients and the differentiation between dippers and non-dippers is age-related and more prominent in older patients

1349 Cardiovascular structure in patients with isolated office or ambulatory hypertension (The Vobarno study)

M. Muiesan, M. salvetti, C. Monteduro, S. Comini, B. Bonzi, S. Viola, M. Castellano, E. Agabiti-Rosei. *University of Brescia, Medical and Surgical Sciences, Brescia, Italy*

Background and Objective: Cardiac alterations have been observed in subjects with isolated office hypertension (IOH) and in subjects with isolated ambulatory hypertension (IAH). Aim of this study was to evaluate both cardiac and carotid structural changes in a large sample of general population, according to the presence of office and ambulatory normotension (NT), hypertension (HT), IOH and IAH.

Patients and Methods: In 587 subjects (40-65 yrs) of the randomized sample of population participating into the Vobarno study, left ventricular mass index (LVMI), relative wall thickness (RWT), mean-maximum intima-media thickness (meanmaxIMT) were measured by ultrasound. Never treated subjects (n = 460) were divided in 4 groups according to blood pressure (BP) values measured in the clinic and during 24 hours monitoring: NT (office BP <140/90 and 24-hrs BP <125/80 mmHg), IOH (office BP >140/90 and 24-hrs BP <125/80 mmHg), HT (office BP >140/90 and 24-hrs BP >125/80 mmHg), and IAH (office BP <140/90 and 24-hrsBP >125/80 mmHg). Results are summarized in the table

	NT n 213	IOH n 98	HT n 96	IAH n 29
Sex (M) %	37	56	68	77
Age yrs	49 (8)	53 (8)*	52 (7) *	47 (9)
Smoke (y/n/ex)	60/29/11	59/18/23	52/28/20	61/19/20
O BP/24hrs BP	94(8)/86(5)	107(6)*/88(5)*	111(7)*/102(6)*	96(4)/98(4)*
LVMI g/h2.7	34(11)	41(11)*	44(13)*	38(12)*
RWT	0.32(0.06)	0.34(0.07)	0.35(0.06)*	0.36(0.07)*
IMT meanmax mm	0.84(0.18)	0.85(0.20)	0.93(0.26)*	0.92(0.17)*

* p at least < 0.05 vs NT

Subjects with HT, IOH, and IAH have greater LVMI in respect to NT, while RWT is higher in HT and IAH. Carotid IMT, controlled for age and gender, is greater in subjects with IAH than in NT. Prevalence of carotid plaque is greater in HT and IAH than in NT.

Conclusions: Structural changes in the heart and in carotid arteries may be observed in subjects with IAH, indicating that ambulatory BP measurement may help in identifying subjects with increased cardiovascular risk, that are not adequately picked up by office BP.

1350 Microalbuminuria accompanies left ventricular geometric adaptations in untreated essential hypeertensive subjects

C. Tsioufis, D. Antoniadis, C. Stefanadis, M. Toutouza, I. Kallikazaros, C. Pitsavos, V. Papademetriou, P. Toutouzas. *Hippokration, University of Athens, Department of Cardiology, Melissia, Greece*

A slight elevated urinary albumin excretion (UAE) is well related with other target-organ damage. However the interaction between microalbuminuria (MA) and the spectrum of LV geometric pattern in essential hypertension has not been well defined.

Methods: For this purpose, MA was determined in 3 non-consecutive 24-h urine samples as UAE of 20-200mg/24h in a group of 249 untreated hypertensive subjects. Echocardiographic classification of patients into LV geometric patterns was based on relative wall thickness values and on gender specific values for LVMI.

Results: The group of patients with MA (n=119) was matched for age, sex, body mass index, smoking status and plasma cholesterol level with the group of patients without MA (n=130). Subjects with MA had significantly increased LVMI (111 vs 90 g/m^2, $p<0.0001$), relative wall thickness (0.46 vs 0.41, $p<0.001$) and office BP (161/101vs148/97 mmHg, $p<0.005$). For the pooled population, UAE was positively correlated to LVMI ($r=0.46$, $p<0.001$) and relative wall thickness ($r=0.47$, $p<0.001$). In the entire population, LV normal geometry (LV-NG), LV concentric remodeling (LV-CR), LV eccentric and concentric hypertrophy (LV-EH, LV-CH) was found in 34%, 33%, 12% and 21%, respectively. The incidence of LV-NG was significantly higher in normoalbuminuric compared to microalbumnuric subjects (55 vs 14%, $p<0.001$) while the incidence of LV-CH was significantly higher in microalbuminuric compared to normoalbuminuric subjects (32 vs 5%, $p<0.001$). Multiple regression analysis revealed that LV-CH was significantly associated with increased values of UAE and mean arterial pressure.

Conclusions: The higher prevalence of unfavorable LV geometric patterns in hypertensive subjects with MA compared to those without MA, may account for the worse cardiovascular outcomes associated with the presence of an increased UAE in hypertensive subjects.

1351 Left ventricular structure and function in sedentary and physically active subjects with left ventricular hypertrophy – The LIFE study

K. Boman[1], M. Olofsson[1], B. Dahlöf[2], M.S. Nieminen[3], V. Papademetriou[4], K. Wachtell[5], R.B. Devereux[6] on behalf of Kurt Boman. *[1]Skellefteå county hospital, Medicine, Skellefteå, Sweden; [2]Sahlgrenska University Hospital, Ostra, Clin. Exp. Research Laboratory, Gothenburg, Sweden; [3]Helsinki University Hospital, Department of Cardiology, Helsinki, Finland; [4]Veterans Administration Medical Center, Washington, United States of America; [5]Copenhagen University, Glostrup County Hospital, Copenhagen, Denmark; [6]Medical College of Cornell University, Division of Cardiology, New York, United States of America*

Background: Exercise is known to lower blood pressure and to improve cardiac function in healthy and hypertensive subjects, but little is known of the relationship between exercise status and left ventricular structure and function in hypertensive subject with left ventricular (LV) hypertrophy.

Methods: A total of 958 hypertensive patients (41% women) aged 55-80 years (mean 66) with LV hypertrophy by either Cornell voltage-duration product or Sokolow-Lyon criteria on a screening ECG, were studied by echocardiography at enrolment in the Losartan Intervention For Endpoint Reduction (LIFE) trial. At baseline exercise status was obtained from a questionnaire and categorized into 3 groups as follows; Group 1 (sedentary): Never exercise; Group 2: <=30 min twice/week; Group 3 (physically active): >30 min twice/week.

Results: Exercise status did not differ in systolic, diastolic, pulse pressures, age or between genders. Sedentary (n=212) had, compared to physically active (n= 510), higher heart rate ($p<0.001$), weight ($p<0.001$), body surface area (BSA) ($p=0.02$), body mass index ($p<0.001$), LV mass (LVM) ($p=0.04$), LVM indexed for height or BSA ($p=0.004$), thicker interventricular septum ($p=0.012$) and posterior walls ($p=0.016$) and larger left atria ($p=0.006$). Variables of systolic endocardial as well as midwall LV function did not differ and only atrial filling fraction, among diastolic filling parameters, was significantly higher ($p=0.003$) in sedentary patients. There was no difference in relative wall thickness among the groups. Multiple regression analysis showed that higher LV mass was associated with sedentary lifestyle (beta=0.059, $p<0.05$) independent of body mass index (beta=0.256), male gender (beta=-0.445) and pulse pressure (beta=0.119, all $p<0.001$). Addition of age into the model (beta=0.097, $p=0.002$), render the effect of sedentary lifestyle exceeding the level of significance (beta=-0.053, $p= 0.067$). Furthermore heart rate did not enter the regression model.

Conclusions: Sedentary hypertensive patients with LV hypertrophy had compared to physically active patients, increased heart rate, larger left atria, thicker intraventricular septum and posterior wall. LV mass was higher in sedentary patients independent of gender, blood pressure or body mass index but not of age.

NEW FEATURES OF CORONARY BYPASS SURGERY

1356 Randomised trial of on-pump versus off-pump coronary artery surgery comparing clinical outcomes, graft patency and neuropsychological function

N.E. khan[1], R. Mister[2], J.R. Pepper[1], A. De Souza[1], M.D. Flather[2], D. Wang[3], J.R. Clague[4], P.D. Collins[4]. [1]*Royal Brompton Hospital, Cardiothoracic Surgery, London, United Kingdom;* [2]*Royal Brompton and Harefield NHS Trust, Clinical Trials and Evaluation Unit, London, United Kingdom;* [3]*London School Hygiene Tropical Medicin, Department of Medical Statistics, London, United Kingdom;* [4]*Royal Brompton and Harefield NHS Trust, Department of Cardiology, London, United Kingdom*

Off-pump coronary artery bypass surgery (OPCAB) is widely believed to be associated with reduced mortality and post-operative morbidity. We conducted a study to compare graft patency, biochemical markers and neuropsychological function in patients undergoing OPCAB to those with cardiopulmonary bypass (CPB) in patients with three vessel disease.

Materials and Methods: 104 patients were recruited to a prospective, randomised study in a single institution. Exclusion criteria included single vessel disease, age > 80, recent infarct or CVA, ejection fraction <30%. One patient did not have surgery due to diagnosis of bronchogenic carcinoma. An identical standardised anaesthetic and surgical protocol was used for both groups. Patients were followed up at 3 months with quantitative coronary angiography to assess graft patency.

Results: 54 patients were randomised to OPCAB and 49 to CPB. Pre-op variables such as age (mean 63.4±8.3) and sex (85% male) were similar in both groups. The average number of grafts per patient was 3.4 in the CPB group, and 3.1 in the OPCAB group (p=0.02). 2 patients in the OPCAB group were converted to CPB intra-operatively. There were no in-hospital deaths or cerebrovascular accidents.

Post-operatively, in the OPCAB group, mean blood usage was 245 mls compared to 467mls in the CPB group (p=0.006). Times to extubation were similar in both groups, but length of post-operative stay was 7.3 days in the OPCAB group compared with 9.7 days in the CPB group (p=0.02). Adverse events at discharge were similar in both groups. Troponin T (TnT) and I (TnI), and creatinine kinase (CK-MB) levels were measured at 0, 6, 12, 24, 48 and 72hrs post-operatively. For TnT, the area under the curve was significantly higher in the CPB group, (p=0.005).

Preliminary analysis of data (n=71) at 3 months showed graft patency was 88.9% in the OPCAB group, and 95.1% in the CPB group (p=0.09). Adverse events at 3 months were similar in both groups. There were no deaths at 3 months in either group.

Conclusions: OPCAB appears to be safe and effective when compared to conventional coronary surgery. There was shorter length of stay, reduced transfusion requirement and decreased troponin release in the OPCAB group. Graft patency appears similar in both groups but larger studies will be required to determine the impact of OPCAB on long term outcomes.

1357 Coronary artery bypass grafting in multi-vessel disease on the beating heart: comparative study of 1200 patients

N.E. Mezilis[1], A.A. Pitsis[2], P.S. Dardas[2], D.D. Tsikaderis[2], A. Mpakas[2], G.D. Ioannides[3], S. Olalere[2]. [1]*Thessaloniki, Greece;* [2]*Thessaloniki Heart Institute, Cardiothoracic, Thessaloniki, Greece;* [3]*St Luke's Hospital, Intensive Care Unit, Thessaloniki, Greece*

Introduction: We present the mid-term results of coronary artery bypass grafting (CABG) for multi-vessel disease on the beating heart in comparison with the conventional surgery with the use of cardiopulmonary bypass.

Methods: We studied a total of 1200 patients undergoing isolated CABG by the same surgical team in a period of 24 months. During the first 10 months, all patients underwent operation with the use of cardiopulmonary by-pass and warm blood cardioplegia (Group A, n = 520), whereas during the next 14 months, all patients underwent CABG on the beating heart (Group B, n = 680). The following parameters were investigated: mortality, incidence of acute myocardial infarction (AMI), and stroke at day 30, intubation time, inotropic support, blood transfusions, serum kreatinine and duration of stay in Intensive Care Unit (ITU).

Results: The two groups were homogeneous with regard to clinical characteristics, such as age, sex, risk factors, angina class, ejection fraction and presence of peripheral vascular disease. Despite a trend in favour of group B, there was no statistical difference in total mortality and the incidence of AMI (2% vs. 0.4%, p=NS and 2.5% vs. 1.1%, p=NS respectively). There was significant reduction in the incidence of stroke in group B (3% vs. 0.6%, p<0.001),and less need for inotropic support and blood transfusions (62% vs. 17%, p<0.001 and 88% vs. 58%, p<0.01 respectively). Regarding the biochemical markers, serum kreatinine was less in Group B (0.9±0.3 vs. 1±0.4, p<0.009. The time spent in ITU was significantly less for the patients of Group B as compared to Group A(2.21±0.41 vs. 2±0.0, p<0.01).

Conclusions: Coronary artery bypass grafting on the beating heart is safer as compared to on- pump surgery. Off-pump surgery is associated with less post operative complications and quicker mobilization of patients as compared with conventional surgery. Long term results are awaited.

1358 Intraoperative angiography – A valuable method for quality control in off pump coronary artery surgery?

J. Bonatti[1], G. Friedrich[2], M. Danzmayr[1], L. Müller[1], S. Schwarzacher[2], O. Pachinger[2], G. Laufer[1]. [1]*University Hospital, Cardiosurgery department, Innsbruck, Austria;* [2]*Univ. Hospital Internal Medicine, Cardiology, Innsbruck, Austria*

Background: The information obtained by intraoperative graft angiography in off-pump coronary artery bypass grafting remains a matter of debate, despite the fact that anastomotic revision rates in the range of 10% after intraoperative graft angiography are reported in the literature. We present our initial experience with intraoperative angiographic evaluation of grafts placed on the beating heart.

Methods: A total of 29 coronary artery bypass grafts were investigated in 20 patients (17 female, 3 male, mean age 60). Transfemoral angiography was performed before (n=8) or after sternotomy closure (n=12) using an OEC 9800 mobile C-arm. Examination time was 24 (8-80) minutes, fluoroscopy time was 464 (211-1337) seconds. Mean contrast agent volume used was 150 (50-470) ml.

Results: No angiography-related complications occurred. Except for 3 aorto-coronary vein grafts, all bypass vessels could be visualized. Spasm of the graft or/and target vessels were present in 10 cases, 8 of them responded to intracoronary nitroglycerine application (0.25 mg). 2 grafts were severely stenosed requiring surgical revision. In addition, 2 proximal target vessel occlusions were observed and were left because of lacking evidence of intraoperative ischemia. There were no in-hospital mortality cases or perioperative ischemic events.

Conclusion: Our experience suggests that, despite being a time consuming examination technique, intraoperative angiography may reveal valuable information with possible demand for surgical revision.

1359 Coronary revascularization with free right internal thoracic artery: operative results in 1044 patients

P. Antunes, F. Oliveira, R. Lucero, M. Antunes. *Hospitais da Universidade, Cardiothoracic Surgery Dept., Coimbra, Portugal*

Objectives: This study evaluates the perioperative mortality and morbidity of patients having a free right internal thoracic artery (FRITA)-to-coronary artery graft as part of their coronary revascularization.

Methods: Between January 1992 and December 2001, 1,044 patients had a FRITA graft. Preoperative characteristics include mean age 52.8 ± 6.8 years; male sex, 1012 (96.9%); diabetes, 132 (12.6%); previous myocardial infarction, 579 (55.5%); three- vessel disease, 905 (86.7%); left main disease, 167 (16.0%); left ventricular ejection fraction < 40%, 113 (10.8%). In 3 patients (0.3%) the FRITA was the only arterial graft used, and in 1039 (99.5%) a pedicled left internal thoracic graft was also used. The mean number of grafts per patient was 3.1 ± 0.7 (2.0 internal thoracic grafts/patient), and endarterectomies were performed in 69 patients (6.6%). The FRITA was used to reach the circumflex marginal arteries in 866 patients (83.0%), the right coronary artery or its branches in 84 (8.0%), and diagonal or ramus intermedius in 92 (8.8%). The proximal anastomosis was constructed over a venous graft in 900 patients (86.2%) and directly into the aortic wall in the remainder. Cardiopulmonary bypass time was 77.6 ± 28.3 minutes.

Results: Perioperative mortality was 0.7% (7 patients). Only seventy three patients (7.0%) required inotropes, and 14(1.3%) intra-aortic counterpulsation and/or left ventricular assist device. The incidence of myocardial infarction was 4.3%. Thirty three patients (3.2%) had reintervention for hemorrhage and 42 (4.0%) for sternal complications. The incidences of respiratory failure, renal failure and cerebrovascular accident were 0.8%, 3.1% and 2.2%, respectively. The mean time of hospital stay was 8.4±8.7 days.

Conclusion: The use of the right internal thoracic artery as a free graft was associated with a low incidence of perioperative mortality and morbidity and allowed greater operative flexibility in arterial coronary revascularization.

1360 Coronary artery bypass graft using the left radial artery: early angiographic results

N. Delarche[1], J.L. Banos[1], G. Papaioanou[1], G. Estrade[1], G. Fournial[2], Y. Glock[2]. [1]*CH F. Mitterand, Cardiology, Pau University Cedex, France;* [2]*CH Rangueil, Cardiovascular Surgery, Toulouse, France*

Introduction: coronary artery bypass graft (cabg) surgery using the internal mammary artery (ima) in patients (pts) with obstructive coronary artery disease gives better long term permeability results than sapheinous vein grafts. Left radial artery (RA) can be used to perform such surgical coronary interventions.
Objectives: To evaluate the early post-operative permeability of cabg using RA.
Methods: All pts with recent surgical coronary revascularization using left RA were prospectively included and underwent selective femoral 4 French coronary grafts angiography before going out of hospital.
Results: From August 2000 to January 2002, 42 pts, (5 women, mean age 60.4 [42-78] had cabg using the left RA. Indications of revascularization were recent myocardial infarction in 6 pts, acute coronary syndrom in 11 pts (with 1 redux bypass), stable angina pectoris in 7 pts, silent ischaemia in 17 pts and valvular aortic stenosis in 1 pt. Risk factors were diabete mellitus in 15 pts, smoke in 26 pts, hypertension in 25 pts, and hypercholesterolemia in 27 pts.
Coronary status was 1 vessel disease (vd) in 2 pts, 2 vd in 5 pts, and 3 vd in 35 pts with 12 significant left main stenosis. 2 bypass grafts were performed in 22 pts, 3 grafts in 18 pts and 4 grafts in 4 pts. Left RA was used alone in 1 pt, with the left ima in 22 pts, with the 2 ima in 2 pts, with the left ima and 1 or 2 vein grafts in 16 pts, and with only 1 vein graft in 1 pt. Full revascularization was achieved in 22 pts (52%). Use of the RA concerned the left anterior descending artery in 1 pt, the first diagonal branch in 4 pts, the first or second left marginal branch in 29 pts, the right coronary artery in 8 pts. In 4 pts RA was used to revascularize 2 coronary arteries, (2 left coronary arteries in 2 pts, and 1 left and 1 right arteries in 2 pts). Local post cabg complications were radial nerve compression in 1 pt, and brachial hematoma in 1 pt. Pts didn't receive any specific antispastic treatment.
Selective RA grafts angiogramms were realized at the 13rd day [10-18]. Coronary RA bypass grafts were angiographically successfull without any abnormalities in 36 pts, (85.7%) and with focal non significant spasm or narrowing in 3 pts. There were 2 anastomotic stenosis (4.8%) between RA graft and the native coronary artery which needed RA angioplasty and stenting in 1 pt. RA graft was occluded in 1 pt, (2.4%).
Conclusion: In this prospective study cabg using RA appears to be a safe procedure with high early angiographic permeability success rate and no major local complications.

1361 Short-occlusive sutureless coronary anastomosis using adhesive

M. Buijsrogge, C. Verlaan, P. Gründeman, C. Borst. *University Medical Center Utrecht, Heart Lung Center Utrecht, Utrecht, Netherlands*

Objective: We revisited a sutureless coronary anastomosis technique by means of a preglued side-to-side ITA-LAD kissing vessel wall apposition using octyl-cyanoacrylate, which, following the arteriotomy, was converted into an end-to-side anastomosis. The feasibility, patency and vascular wall healing of this facilitated coronary anastomosis technique was studied in porcine off-pump CABG.
Methods: In 8 pigs (80 kg), 8 low flow RITA-to-LAD anastomoses (pro-thrombotic condition) and 8 high flow control LITA-LAD anastomoses (less than 15 mL/min and about 50 mL/min, respectively) were evaluated intra-operatively and at 35 days. Anastomoses were examined by flow measurement, angiography and histology.
Results: All anastomoses (but one) were hemostatic after average construction time of 5.4 minutes and coronary occlusion of 1.6 minutes. One pig died at day 19 due to saddle type pulmonary embolism unrelated to graft failure. Fourteen anastomoses were fully patent at 35 days (FitzGibbon Grade A) with angiographic classical end-to-side anastomosis configuration. Histology showed mild repair intimal hyperplasia without aneurysm formation or medial necrosis.

Table: Intra- and postoperative measurements

	Anastomosis construction time (min)	Coronary occlusion time (min)	Hyperemic response index (peak/baseline flow)		Patency	Medial necrosis
			Intra-op	35 days		
Low flow (n=7)	5.2 ± 1.2	1.5 ± 0.3	5.2 ± 1.2	5.6 ± 1.8	7/7	0/7
High flow (n=7)	5.5 ± 1.1	1.7 ± 0.2	2.7 ± 0.6	4.2 ± 1.1	7/7	0/7

Data as mean ± SD

Conclusions: On the beating porcine heart, the sutureless-adhesive coronary anastomosis technique required an average 1.6 minutes coronary occlusion and revealed a favorable healing response, even in pro-thrombotic low bypass graft flow conditions.

VARIABLES INFLUENCING CORONARY FLOW: DO WE KNOW THEM ALL?

1362 Influencing parameters on flow velocity reserve in angiographical normal coronary arteries

M. Voskuil[1], M. Meuwissen[1], S.A.J. Chamuleau[1], J.G.P. Tijssen[1], P.W. Serruys[2], J.J. Piek[1]. [1]*Academic Medical Center, Cardiology, Amsterdam, Netherlands;* [2]*Thoraxcenter, Cardiology, Rotterdam, Netherlands*

Background: Coronary flow velocity reserve (CFVR) is considered to be markedly influenced by clinical and hemodynamic parameters effecting the coronary microvascular resistance. The aim of the study was to determine variables influencing CFVR in angiographical normal arteries.
Methods: CFVR was assessed in an angiographical normal vessel in a total of 514 patients who were scheduled for PTCA of a single de novo lesion. Maximal hyperemia was induced using an i.c. bolus or i.v. infusion of adenosine. Continuous variables were dichotomized according to their mean value. Forward logistic regression analysis was performed to identify parameters that induce a low CFVR (below the mean value of 2.9; range 1.0-6.3). An independent t-test was performed for determination of clinical factors influencing predictors of CFVR.
Results: After univariate analysis of all relevant clinical and hemodynamic parameters, age >59, female gender, hypercholesterolemia, baseline APV >18 and heart rate >69 were identified as predictors of a low CFVR. Multivariate analysis revealed baseline APV >18 (odds ratio 1.9; 95% CI 1.3-2.9; p<0.01) and heart rate >69 (odds ratio 1.7; 95% CI 1.1-2.5; p=0.01) as independent predictors of low CFVR. Furthermore, diabetes (p=0.01) and hypertension (p<0.01) are positively associated with baseline APV. No clinical parameter influencing heart rate was identified.
Conclusions: Both baseline APV and heart rate are independent variables that influence CFVR. Baseline APV is positively associated with diabetes and hypertension. Although several other clinical and hemodynamic parameters were identified in a univariate way, they were no independent predictors of CFVR after multivariate analysis. Both baseline APV and heart rate should be taken into account in the interpretation of CFVR measurements for clinical decision-making.

1363 Likelihood of discordant results between fractional and coronary flow reserve: when should we measure the complementary haemodynamic parameter?

M. Meuwissen[1], M. Siebes[1], S.A.J. Chamuleau[1], J.A.E. Spaan[2], J.J. Piek[1]. [1]*Academic Medical Center, Cardiology Dept., Amsterdam, Netherlands;* [2]*Academic Medical Center, Medical Physics, Amsterdam, Netherlands*

Background: In 27% of the intermediate coronary lesions, we have observed discordant results between fractional flow reserve (FFR) and coronary flow velocity reserve (CFVR), which may be caused by a number of underlying pathological conditions that would remain undetected if only coronary flow velocity or pressure was measured. Yet, the routine measurement of both intracoronary hemodynamic signals is not cost-effective in daily clinical practice.
Aim: To determine clinical, angiographic and intracoronary hemodynamic predictors of discordant results between FFR and CFVR when either intracoronary pressure or flow velocity was measured.
Methods: In 161 patients with 1- or 2-vessel disease (201 lesions, mean diameter stenosis of 56%) we observed 55 (27%) intermediate coronary lesions with discordant results between FFR and CFVR based on cut-off values of 0.75 and 2.0, respectively. Stepwise logistic regression analysis was performed using all clinical, hemodynamic, and angiographic data to assess the likelihood of a discordant outcome between the two flow reserve parameters, when either FFR or CFVR is known.
Results: Hypertension in combination with a heart rate >70 bpm was associated with FFR >=0.75 and CFVR <2.0 (odds ratio: 4.6, 95% CI: 1.6-13.1, p=0.004, n=22). A diameter stenosis >55% (odds ratio: 4.7, 95% CI: 1.6-13.9, p=0.005), a relative CFVR <0.90 (odds ratio: 3.6, 95% CI: 1.4-9.3, p=0.01) or a combination of both (odds ratio: 5.8, 95% CI: 2.3-14.6, p=0.0001) were associated with FFR <0.75 and CFVR >=2.0 (n=33).
Conclusion: If an intermediate coronary lesion with FFR >=0.75 is present in a patient with hypertension and a high heart rate, the likelihood that CFVR <2.0 for this lesion is significantly increased. For an intermediate lesion with CFVR >=2.0, the odds for FFR <0.75 are significantly higher when the stenosis is greater than 55% diameter reduction. The additional presence of a relative CFVR <0.90 further increases the likelihood for FFR <0.75. In order to rule out the presence of otherwise undiscovered coronary disorders such as microvascular disease, measurement of the complementary flow reserve parameter is advisable in these cases.

1364 A comparison of four intracoronary physiology indices of coronary microcirculation. Validation with histomorphometry in endomyocardial biopsies

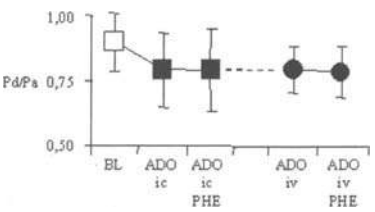
J. Garcia Gonzalez[1], J. Escaned Barbosa[1], J. Segovia Cubero[2], D. Camacho Gaxiola[1], F. Alfonso Monterola[1], M. Sabaté Tenas[1], R. Hernández Antolin[1], C. Macaya Miguel[1]. [1]*Hospital Clinico San Carlos, Interventional Cardiology, Madrid, Spain;* [2]*Hospital Puerta de Hierro, Cardiology, Madrid, Spain*

Background: Assessment of coronary microcirculation (MC) is hampered by the lack of a validated methodology. With this aim, we compared in heart transplant recipients the results of 4 intracoronary physiology indices of coronary MC status derived from intracoronary Doppler with or without concomitant measurement of pressure, with the actual structural changes in microcirculation documented in endomyocardial biopsies.
Methods: All patients (n=20) presented angiographically normal coronary arteries. Digital acquisition and storage of ECG, intracoronary Doppler flow velocity and pressure in the LAD was performed at baseline and during hyperemia (40 μgr adenosine ic) using a dedicated computerized system. Post-processing of data allowed calculation of 4 indices of MC status: coronary flow velocity reserve (CFVR), coronary resistance (CR), coronary resistance reserve (CRR), and slope of hiperemic diastolic pressure-flow relationship (DPFS). Endomyocardial biopsies were obtained simultaneously. Computerized morphometrical assessment of MC (% arteriolar obliteration and capillary density) was performed slides stained with monoclonal antibodies against endothelium. A bivariate regression analysis including both histological indices was performed with each physiological variable.
Results: A variable degree of MC disease was documented (arteriolar obliteration 75±7%, normal value 59±6%, p<0.0001; capillary density 637±216 mm^2, normal value 637±216, p=0.0001). Two physiological indices, DPFS (1.23±0.42 cm/s/mmHg) and CR (1.67±0.82 mmHg/cm/s) showed a good correlation with structural changes in MC (r=0.72, p=0.001 for DPFS; r=0.67, p=0.005 for CR). A significant, separate contribution of % arteriolar obliteration and capillary density for the values of DPFS and CR was found (beta coeff for %a arteriolar obliteration: DPFS –0.66, p=0.001; CR 0.44, p=0.02) (beta coeff for capillary density: DPFS 0.52, p=0.007; CR -0.65, p=0.002) On the contrary, neither CFR (2.06±0.59) nor CRR (2.41±0.81) showed an statistically significant relationship with structural changes of MC.
Conclusions: 1/ Significant differences were noted in the ability of 4 intracoronary physiology indices for detection of structural MC changes; 2/ absolute physiological measurements combining pressure and flow velocity (DPFS, CR) appear as the method of choice for this purpose; 3/ although a slight superiority of DPFS over CR was noted, the simplicity of the latter may justify its use for clinical or research purposes.

1365 Does alpha-blockade unmask residual myocardial resistance during adenosine in patients with coronary artery disease?

E. Barbato[1], W. Aarnoudse[2], J. Bartunek[1], M. Penicka[1], W. Wijns[1], G.R. Heyndrickx[1], N.H.J. Pijls[2], B. De Bruyne[3]. [1]*O.L.V.-Ziekenhuis, Cardiovascular Center, Aalst, Belgium;* [2]*Catharina Ziekenhuis, Cardiology Dept., Eindhoven, Netherlands;* [3]*O.L.V.-Ziekenhuis, Cardiovascular Center, Aalst, Belgium*

Adenosine (ADO), used for diagnostic purposes, is supposed to exhaust myocardial resistance. Yet, in patients (pts) with coronary artery disease (CAD), alpha vasomotor tone is enhanced and ADO might fail to reach minimal myocardial resistance.
Aim: To determine the presence of clinically relevant residual myocardial resistance after ADO administration.
Methods: Fractional flow reserve (FFR=hyperemic Pd/Pa, where Pa is mean aortic pressure and Pd mean distal coronary pressure) was assessed in 13 coronary stenoses (51±12%, diameter stenosis) of 13 pts, during IC bolus of ADO, before and 3 min after IC bolus of phentolamine (PHE, 12 μg/kg), an alpha 1-, alpha 2-adrenergic blocking agent. FFR was also measured in 10 coronary stenoses (46±10%, diameter stenosis) of 10 pts, during IV infusion of ADO, and during IV ADO plus PHE (given on top of maximal ADO hyperemia). All pts received an IC bolus of isosorbide dinitrate (ISDN, 3 mg) at the beginning of the protocols. All patients had normal left ventricular function.
Results: Since epicardial stenosis remained unchanged (ADO IC: before, MLD: 1,25±0,42; after, MLD: 1,33±0,39; n.s. - ADO IV: before, 1,48±0,22; after, MLD: 1,44±0,38, n.s.), changes in Pd/Pa ratio reflect changes in myocardial resistance. With IC ADO, FFR values were not different before and after PHE. During IV ADO, FFR remained constant before and after PHE (See graph). PHE administration did not induce any significant hemodynamic change in heart rate nor in blood pressure.
Conclusion: Myocardial resistance reached by IC and IV ADO cannot be further decreased by alpha-blockade.



1366 The effect of aortic valve replacement on coronary flow reserve in patients with significant aortic stenosis and normal coronary angiogram

A. Nemes, A. Palinkas, T. Forster, A. Varga, A. Thury, I. Ungi, M. Csanady. *University of Szeged, 2nd Department of Medicine, Szeged, Hungary*

Background: Reduced coronary flow reserve (CFR) is an important cause of myocardial ischemia in patients (pts) with hemodynamically significant aortic stenosis (AOS) and normal coronary arteries. The aim of the present study was to examine the effect of aortic valve replacement (AVR) on left ventricular mass index (LVMI), CFR and clinical symptoms after a 1-year follow-up period in pts with significant AOS, normal coronary angiogram and normal resting left ventricular function.
Patients and methods: Sixteen patients (9 women and 7 men; mean age 66±7) were enrolled into the study. All patients underwent 2 months before and 1 year after the AVR a complete transthoracic echo study and CFR measurement by transesophageal echocardiography (TEE). Coronary flow velocity was obtained by pulse Doppler during TEE in the proximal left anterior descending artery. CFR was assessed with intravenous dipyridamole (0.56 mg/kg over 4 minutes) as a vasodilator agent. CFR was calculated as the ratio of the maximal averaged peak diastolic flow velocity (APV) to the resting APV.
Results are presented in the table.

	Before AVR	After AVR	p value
LVMI (g/m^2)	180.8±55.6	128.6±31.4	0.002
CFR	1.94±0.54	2.51±0.79	0.03
Peak AOS gradient (mm Hg)	94±25	25±8	0.001
Effort angina	7/16 (44%)	1/16 (6%)	0.01

Conclusion: In patients with aortic stenosis and normal coronary arteries, the symptomatic improvement 1 year after AVR is accompanied by the rise of CFR, possibly due to the reduction of LVMI.

1367 Additive effect of hypertension and diabetes on coronary flow reserve impairment

C. Le Feuvre[1], G. Helft[1], F. Beygui[1], O. Barthélémy[1], S. Mogenet[2], J.P. Batisse[1], J. Timsit[2], J.P.H. Metzger[1]. [1]*Necker Hospital, Cardiology, Paris, France;* [2]*Necker, Immunology, paris, France*

Microangiopathy with impaired coronary flow velocity reserve (CFR) has been reported in patients with diabetes mellitus (DM) or essential hypertension (EH). It is unknown whether the combination of diabetes and hypertension may have an additive effect on CFR impairment. We measured CFR in 4 patient groups with normal left ventricular function and without significant coronary artery disease: Group 1 (n=28) were pts without DM and EH; Group 2 (n=12) were pts with DM without EH; Group 3 (n=11) were pts with EH without DM; Group 4 (n=13) were pts with DM and EH.
Average peak velocities (APV) were measured at baseline and after intracoronary administration of adenosine (12-18μg) using a Doppler-tipped flow wire. CFR was calculated by the ratio of baseline to hyperemic APV.
CFR was significantly lower in pts with DM and EH (2±0.5 in group 4 vs 2.9±0.7 in group 1, 2.5±0.4 in group 2 and 2.8±0.6 in group 3, p<.001). Similar results were found in patients with angiographic normal coronary arteries (CFR 2.3 in group 4 vs 4.1 in group 1, 2.5 in group 2 and 2.8 in group 3, $p < 0.02$) and in pts with unsignificant (<50%) coronary stenosis (CFR 1.8 in group 4 vs 2.8 in group 1, 2.6 in group 2 and 2.8 in group 3, $p < 0.002$)
Multivariate stepwise regression analysis revealed that combination of DM and EH ($p < 0.005$), left ventricular end diastolic pressure ($p < 0.004$) and heart rate ($p < 0.001$) were independently related to CFR.
Conclusions: Diabetics without hypertension have CFR similar to non-diabetics with hypertension. Diabetes and hypertension have an additive effect on impaired CFR.

RESTENOSIS RESEARCH: STILL WORTH THE EFFORT

1368 Expression of caveolin-1 in rabbit femoral and iliac arteries after balloon dilation

J. rodrigues, D.P.V. de Kleijn, M.B. Smeets, J.P.G. Sluijter, A.H. Schoneveld, E. Velema, C. Borst, G. Pasterkamp. *University Medical Center, Experimental Cardiology Laboratory, Utrecht, Netherlands*

Background: Caveolin-1 (cav-1) is the main protein component of caveolae. It has been found that cav-1 can play a role as a negative regulator in nitric oxide (NO) cellular signaling. Breakdown of collagen by matrix metalloproteases (MMP)is an essential feature in arterial remodeling. Since MMP 2 and 14 and cav-1 colocalized in caveolae, we hypothesized that cav-1 is involved in MMP activation.For this, we analyzed the localization and protein levels of cav-1 in iliac and femoral arteries at different time points after BD.
Methods: BD was performed in iliac and femoral arteries in New Zealand White rabbits (n=32). The animals were sacrified at different time points (2, 7, 14, 28 and 42 days)after BD. The contra-lateral arteries were used as a control. Expression and localization of cav-1 was performed using Western Blotting and immunohistochemistry. Arterial remodeling and intimal hyperplasia was measured by angiography and histology.
Results: Cav-1 was localized mainly in endothelial and smooth muscle cells. we determined the expression of cav-1(see table 1).The levels of cav-1 were upregulated after 14, 28 and 42days in BD arteries, but also in contralateral arteries at the same time points.Arterial remodeling and intimal hyperplasia also occurs after 7 days (see table).

	0days	2days	7days	14days	28days	42days
Iliac control	13,6± 3,3	19,4± 2,3	18,8±1,8	42,3±5,9*	47,9±3,9*	60,9±4,5*
Iliac BD	-	17,8± 4,1	18,8±4,9	33,4±7,6*	50,5±2,4*	74±5,4*
Fem control	21,6± 5,8	15,7±6,1	22,7±2,7	39,6±9,8*	61,8±6,9*	83,2±3,6*
Fem BD	-	19,4±3,3	17,7±3,1	31,7±3,5	55,3±4,6*	77,2±4,6*
DC (%)	0	3,8±2,4	-8,3±11,0	-9,0±4,6	-9,7±7,8	ND
IH(%)	0	0	1,5±0,6	5,0±1,3	16,7±2,7	ND

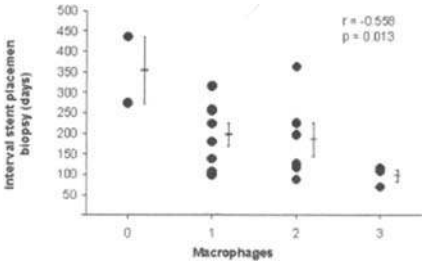
Cav-1 expression (OD*mm^2)(*=p<0.05 compared to 0 days)Fem=Femoral arteries;IH= Intimal hyperplasia fem+iliac); DC=Diameter change (remodeling,fem+iliac); ND= Not defined

Conclusions: Cav-1 expression is increased after BD and associated with remodeling and IH. Cav-1 expression is also increased in uninjured contralateral arteries. This finding suggest a systemic mechanism responsable for this up-regulation of cav-1 after balloon dilation.

1369 Time relation of the amount of macrophages in the plaque during the chronic phase of in-stent restenosis

L.J. Wagenaar[1], A.J. van Boven[1], A.C. van der Wal[2], C.M. van der Loos[2], R.A. Tio[1], A.E. Becker[2], W.H. van Gilst[1]. [1]*Academisch Ziekenhuis Groningen, Thoraxcentrum, Groningen, Netherlands;* [2]*Academic Medical Center, Dept of Cardiovascular Pathology, Amsterdam, Netherlands*

Background - Inflammation plays an important role in the acute phase of in-stent restenosis. But in the chronic phase, after approximately 30 days, the neointimal plaque consist mainly of vascular smooth muscle cells. In a previous study, we found that this neointima still contains small clusters of macrophages. In this study we investigated the relation between the amount of macrophages in the in-stent restenotic plaque and the time after the placement of the stent.
Methods - Biopsies from human coronary in-stent restenotic lesions were obtained with a pullback atherectomy catheter and immediately frozen in liquid nitrogen (n=19). The time between the placement of the stent and the biopsy varied from 69 till 465 days.
The biopsies were immunostained for smooth muscle cells, macrophages and ACE, and a semi-quantitative score was applied: 0 for no macrophages, 1 for a few or clusters of cells, 2 for <10% of cells positive, 3 for 10-50% of cells positive and 4 for >50% of the cells positive.
Results - As shown in the figure, an inverse correlation was found between the amount of macrophages and the time between the biopsy and the stent placement (p=0.013). The macrophages were mostly ACE-positive. Therefore, the amount of ACE also decreases during time (p= 0.011).



Amount of macrophages vs time-interval.

Conclusion - During the chronic phase of in-stent restenosis, the amount of macrophages in the neointima decreases, as well as the amount of ACE. This indicates that inflammatory cells play a role in the process of chronic in-stent restenosis, especially in the first phase.

1370 Inflammatory cells in post-balloon angioplasty restenosis and in-stent restenosis in relation to stable and unstable angina

B. Atasever[1], M. Meuwissen[1], A.C. van der Wal[2], C.L. van der Loos[2], K.T. Koch[1], R.J. de Winter[1], A.E. Becker[2], J.J. Piek[1]. [1]*Cardiology,* [2]*Cardiovascular Pathology, Academic Medical Center, Amsterdam, Netherlands*

Objectives: To compare the tissue composition of restenotic lesion following balloon-angioplasty (BA) and stent-implantation and its relation to clinical expression of coronary syndromes.
Methods: A total of 32 patients with stable (SA) and unstable (UA) angina underwent directional coronary atherectomy for post-BA restenosis or in-stent restenosis. Cryostat sections of atherosclerotic plaques were immunohistochemically stained with monoclonal antibodies, alfa-actin (smooth muscle cells; SMC), CD-68 (macrophages; MAC) and CD-3 (T-lymphocytes; T-cells). The extent of SMC, MAC and T-cells were analyzed semi-quantitatively: 0=none, 1=few, 2=mild, 3=heavy staining.
Results: Morphologic analysis showed in 8 (out of 16) patients with in-stent restenosis T-cell clusters, that were not observed in patients with post-BA restenosis. In addition, there was a diffuse T-cell distribution in both restenotic lesions. The table shows the result of immunohistochemical staining of restenotic tissues in relation to the type of restenosis and the clinical manifestation of angina.

	SMC	MAC	T-cells
post-BA restenosis (n=16)	2.6 ± 0.1	1.6 ± 0.1	1.3 ± 0.1
in-stent restenosis (n=16)	3.0 ± 0 *	1.3 ± 0.1	2.0 ± 0 *
SA (n=16)	2.8 ± 0.1	1.3 ± 0.1	1.6 ± 0.1
UA (n=16)	2.8 ± 0.1	1.6 ± 0.1**	1.7 ± 0.1

Values are mean±SEM, *p<0.01 compared to post-BA restenosis, **p<0.05 compared to SA

Conclusions: In-stent restenotic lesions contain significantly more T-cells as compared to post-balloon angioplasty restenotic lesions. This could relate to an stent-induced T-cell mediated immunorespons. Moreover, the presence of macrophages in restenotic tissue is positively associated with the clinical expression of angina.

1371 The effect of modulating collagen turnover on in-stent restenosis: a study in the atherosclerotic and non-atherosclerotic Yucatan minipig

M.J. Sierevogel, E. Velema, A.S. Schoneveld, D.P.V De Kleijn, C. Borst, G. Pasterkamp. *University Medical Center Utrecht, Experimental Cardiology Dept., Utrecht, Netherlands*

Background: Collagen turnover is an important feature in restenosis following balloon angioplasty and stenting. Previously, we demonstrated that inhibition of matrix metalloproteinases (MMPs) by an oral MMP inhibitor significantly reduces late lumen loss (LLL) following balloon dilation by inhibition of constrictive remodeling. In the present study, the effect of the oral MMP inhibitor BB-2983 and an oral collagen synthesis inhibitor was tested on in-stent restenosis in the Yucatan minipig.
Methods: Seventeen non-atherosclerotic and 7 atherosclerotic Yucatan minipigs underwent bilateral stenting of femoral arteries with a balloon/artery ratio of approximately 1.2. Non-atherosclerotic animals either received MMP inhibition (MMPi, n=5 pigs), prolyl4-hydroxylase inhibition (P4Hi, n=6) or served as controls (n=6 pigs). Atherosclerotic animals either received MMP inhibition (n=3 pigs) or served as controls (n=4 pigs). Pigs were terminated at 42 days follow up. Angiography was performed at all time-points to determine LLL (defined as: lumen post intervention - lumen follow up). Stents were embedded in plastic and cut for cross-sectional area measurements. In each stent, neo intima formation (IH) was quantified in a proximal and distal segment, using Sis-analysis 2.1 software.
Results: See table.

In-stent restenosis

	Non-atherosclerotic			Atherosclerotic	
	control	MMPi	P4Hi	control	MMPi
LLL (mm)	0.5±0.1 (12)	0.2±0.0 (10)*	0.8±0.2 (10)	0.9±0.1 (7)	0.5±0.1 (5)***
IH prox stent (mm^2)	2.6±0.3 (12)	1.6±0.1 (10)*	3.6±0.3 (10)**	6.2±1.7 (6)	4.2±0.6 (5)
IH distal stent (mm^2)	2.5±0.2 (12)	1.5±0.2 (10)*	3.2±0.1 (10)***	5.4±1.2 (7)	2.7±0.4 (5)

values in mean ± sem, *p<0.007, **p=0.05, ***p=0.03, (n) = number of arteries

Conclusions: MMP inhibition by BB-2983 inhibited in-stent late lumen loss in the non-atherosclerotic pig. This effect was confirmed in the atherosclerotic pig. Prolyl4-hydroxylase inhibition did not reduce neo-intima formation and thereby late lumen loss following stenting.

1372 Seeding of intracoronary stents with AC133+ endothelial progenitor cells

M. Guckenbiehl[1], S. Loges[2], M. Merten[1], U. Gehling[2], W. Ito[1], W. Fiedler[2], T. Meinertz[1], R. Köster[1]. [1]university hospital hamburg-eppendorf, cardiology, hamburg, Germany; [2]university-hospital hamburg-eppendorf, oncology-haematology, hamburg, Germany

Background: It is well established that rapid regeneration of a functional endothelium after coronary stenting contributes to reduced restenosis and diminishes the risk for sub acute and late thromboses.
Therefore we tested if seeding of coronary stents with AC133+ endothelial progenitor cells in vitro leads towards a confluent endothelial monolayer on the stent surface.
Endothelial progenitors are known for their high regenerative potential which could contribute to rapid regeneration of a functional endothelium at the site of vessel injury in vivo.
We tested several stent materials and stent coatings in order to find out the best surface for progenitor cells to become adherent and grow to confluence.
Methods: AC133+ endothelial progenitors were isolated from granulocyte colony-stimulating factor - mobilized peripheral blood. Mononuclear cells were isolated by density gradient centrifugation over Ficoll-Hypaque, incubated with AC133 conjugated magnetic micro beads and processed through a magnetic separation column to obtain purified AC133+ cells. Isolated cells were expanded under defined culture conditions in IMDM supplemented with FCS, horse serum, SCGF and VEGF for 2 weeks.
Jostent® Flex stents, coated with heparin, aluminium oxide, ceramic, different extracellular matrix proteins, as well as uncoated 316L stainless steel were incubated with a suspension of progenitor cells for 2 further weeks. Cell coverage was evaluated by REM and confocal microscopy. Afterwards cells were recovered from stents by trypsin digestion, counted and analyzed for expression of several EC-markers by immuno-fluorescence staining. Further more we evaluated cell retention after balloon expansion and exposure of the stent to pulsatile flow for 1 hour.
Results: Within 2 weeks endothelial progenitor cells became adherent and grew to confluence on heparin-, aluminium oxide- and collagen-coated stents, whereas uncoated 316 L steel turned out to be no appropriate surface for cell attachment. Morphological features as well as the expression of versatile EC-markers revealed AC133-derived cells grown to confluence as endothelium. Expansion of stent and exposure to flow resulted in retention of cells up to 65%.

1373 REGENT 1 (Restenosis Gene Therapy trial): first clinical results after local intracoronary application of iNOS-lipoplex-gene product

S. Fichtlscherer[1], A. Mügge[2], C.W. Hamm[3], H.J. Rupprecht[4], C. Hanefeld[2], M. Luz[5], H.E. von der Leyen[5], A.M. Zeiher[1]. [1]Johann W. Goethe University, Dep. of Cardiology, Frankfurt, Germany; [2]Dep. of Cardiology, Ruhr University, Bochum, Germany; [3]Kerckhoff Klinik, Dep. of Cardiology, Bad Nauheim, Germany; [4]Johannes Gutenberg University, Dep. of Cardiology, Mainz, Germany; [5]Cardion AG, Erkrath, Germany

Neointimal hyperplasia causing recurrent stenosis and reocclusion is a major limitation of the clinical utility of percutaneous transluminal coronary interventions (PCI) and, more recently, stent placement. Experimental studies suggested that local intracoronary gene therapy could be an effective therapeutical tool to prevent restenosis after PTCA. In animals,neointimal proliferation after ballon injury has been shown to be effectively reduced after application of the inducible nitric-oxide synthase (iNOS) gene. The primary objective of this first multicenter, prospective, single-blind, dose escalation study was to obtain safety and tolerability information of the iNOS-lipoplex (CAR-MP583) gene therapy for reducing restenosis following PCI. Safety is measured as the combined clinical endpoint of Major Adverse Cardiac Events(MACE), defined as death, Q wave or non-Q wave MI, emergent bypass surgery, or repeat target lesion revascularization, 30 days after treatment with CAR-MP583. Local intramural CAR-MP583 delivery was achieved using a ballon infiltrator-catheter. Until now a total of 27 patients (pts) have been included in the study (6 pts. were treated with 0.5μg, 6 pts with 2.0μg, 6 pts with 5.0μg and 9 pts with 10μg).
Results: Application of CAR-MP583 was uncomplicated in 26 of 27 pts. The target vessels were the LAD (n=13), RCX (n=6) and the RCA (n=8). In one patient, periinterventional side branch occlusion with consecutive troponin elevation occurred. No MACE were observed during follow up controls after 7,30,60 and 90 days. 6-month clinical and angiographic restenoses rates will be available 9/2002.
Summary: Local intramural application of CAR-MP 583 for reduction of restenosis after PCI is feasible and save.

SUBCELLULAR REGULATION OF MYOCARDIAL CONTRACTILITY

1374 Alterations of cross-bridge kinetics in human failing myocardium

K. Brixius[1], W. Bloch[2], R.H.G. Schwinger[1]. [1]Clinic III of Internal Medicine, Lab. of Muscle Res.& Mol. Cardiology, Cologne, Germany; [2]University of Cologne, Institute I of Anatomy, Cologne, Germany

In addition to the altered intracellular Ca^{2+}-homeostasis, changes in the recruitment of cross-bridges may result in myocardial failure, as well. Yet, evidence for alterations of isometric tension-dependent cross-bridge cycling in human myocardium is still missing. Therefore, we performed simultaneous measurements of the isometric Ca-dependent tension and actomyosin ATPase activity (MYO) in triton X-skinned fiber preparations of human non-failing (NF, n=9) and failing myocardium (dilative cardiomyopathy, DCM, n=11). The MYO/tension relation ('tension cost'), which resembles the cross-bridge detachment rate was analyzed as well.
In DCM, Ca-sensitivity of tension was significantly increased compared to NF ($EC50Ca^{2+}$: 1.39±0.14 vs. 2.22±0.41 μM). This was paralleled by a decrease in relative tension cost. Maximal Ca-activated tension (NF vs. DCM: 21.7±2.6 vs. 25.1±2.2 mN/mm^2), nHill (1.85±0.19 vs 1.87), Ca-activated MYO (+ 100±12 vs. +107±14 μM ADP/s) as well as the Ca-sensitivity of MYO ($EC50Ca^{2+}$: 1.39±0.32 vs. 1.06±0.11 μM ADP/s) were similar in both groups.
It is concluded that the increased Ca-sensitivity of tension in human failing myocardium may be attributed to an increased Ca-affinity of troponin C. This increase in the TNC/Ca-affinity may in turn induce a decline of the cross-bridge detachment rate. Although these alterations may contribute to the diastolic dysfunction observed in human heart failure, they may also represent a compensatory mechanism for the energetic situation of failing human myocardium.

1375 The essential role of mitochondrial ATP-sensitive potassium channel in cardiac inotropy

P. Dos Santos[1], M. Laclau[2], P. Diolez[3], J.B. Thambo[1], L. Tariosse[2], K. Garlid[4]. [1]Hopital Haut Lévêque, pessac, France; [2]Inserm U. 441, 33604 Pessac, France; [3]CNRS-Bordeaux 2 Victor Ségalen, UMR 55-36, Bordeaux, France; [4]Oregon Graduate Institute, Department of Biochemestry, Beaverton (OR), United States of America

This study investigates the role of mitochondrial ATP-sensitive potassium channel (mitoKATP) during the response to positive inotropic stress in Langendorff perfused rat hearts.
6 groups of 6 hearts were studied. The first 3 groups were initially perfused with modified Krebs-Heneseleit buffer containing 1.75 mM [CaCl2] and switched to a buffer containing 4 mM [CaCl2], 0,5 μM dobutamine, or 80 μM ouabain respectively. The last 3 groups were initially perfused with modified Krebs-Heneseleit buffer containing 1.75 mM [CaCl2] before inhibition of mitochondrial ATP-sensitive potassium channel by 5 hydroxydecanoate, a mitoKATP inhibitor. They were then switched to a buffer containing 4 mM [CaCl2], 0,5 μM dobutamine or 80 μM ouabain respectively, without 5 hydroxydecanoate. Two additional series of 6 hearts, challenged by high calcium in presence or absence of 5 hydroxydecanoate, were studied by 31P NMR spectroscopy. Inotropic challenged induced a 60 to 75% increase in rate pressure product. Perfusion of 5 hydroxydecanoate did not induce any change in left ventricular function in control conditions. However, it significantly decreased the stress-induced increase in rate pressure product to 15 to 45% ($p < 0.001$ vs without 5 hydroxydecanoate)and increased the rate of the initial stress-induced increase in ADP and decrease in phosphocreatine ($p < 0.005$ vs without 5 hydroxydecanoate).
This study provides for the first time a physiological role for mitoKATP. Opening of heart mitochondrial ATP-sensitive channel is essential for an adequate response to positive inotropic stress. We hypothesize that maintenance of mitochondrial volume during the stress requires the opening of mitoKATP and that the preservation of the architecture of the inter mitochondrial membrane space maintains the efficiency of energy transfer processes at the time they are most needed.Beside its role in cardioprotection against ischemia-reperfusion injury, mitoKATP could also be implicated in heart failure.

1376 Subcellular mechanisms of delayed stretch-induced inotropy in rabbit myocardium

D. Von Lewinski[1], B. Stumme[1], C. Luers[1], L.S. Maier[2], B. Pieske[1].
[1]*Universitätsklinik Göttingen, Kardiologie und Pneumologie, Göttingen, Germany;* [2]*Loyola University, Department of Physiology, Chicago, United States of America*

Mammalian myocardium is characterized by a biphasic inotropic response to stretch with an initial rapid, followed by a delayed increase in force. The first phase is believed to result from increased myofilament sensitivity to Ca^{2+}. In rat myocardium, the second phase was attributed to a stretch-dependent paracrine release of endothelin-1.

Methods: Rabbit right ventricular papillary muscles, electrical stimulation, isometric contractions (1 Hz; 37°C). Stretching to lmax, relaxing to 88%lmax for 30 min, again stretching to 98%lmax. Repetition of the same protocol with the same muscle after blocking the Na^+/H^+-exchanger NHE-1 (HOE 642 10μM; n=16), the Na^+/Ca^{2+}-exchanger NCX (KB-R7943 5μM; n=8), stretch activated channels, SAC (Gd2+ 10μM; n=11) or the ETA-receptors (BQ123 0.1μM; n=9). Action potential duration was recorded in 7 trabeculae at room temperature (floating electrode method).

Results: Stretching rabbit papillary muscles from 88% to 98%lmax resulted in a biphasic response. During the initial, rapid phase force increased by 144±9% ($p<0.05$). During phase 2, force increased further by 61±4%. Neither HOE642, KB-R7943, Gd2+ nor BQ123 pretreatment affected the force increase in phase 1. Inotropic response in phase 2 was unaffected by pretreatment with Gd2+ and BQ123. In contrast, HOE642 and KB-R7943 significantly blunted the inotropic response to stretch during phase 2 by 31±5% and 61±7%, respectively. (both $p<0.05$). Action potential duration was not significantly altered by stretch.

Conclusions: Rabbit myocardium is characterized by a biphasic inotropic response to stretch. The initial, larger phase is not dependent on recruitment of stretch-activated ion channels, ETA-receptor, NCX or NHE-1 activation. NHE-1 and NCX activation largely contribute to the inotropic response in phase 2, possibly via intracellular alkalinisation and $[Na^+]_i$ accumulation with "reverse mode" Na^+/Ca^{2+}-exchanger dependent Ca^{2+}-influx. APD-increase does not contribute to the NCX reverse-mode activation.

1377 Dose-dependent effect of SERCA1-expression in rabbit isolated ventricular cardiomyocytes

N. Teucher[1], J. Prestle[1], T. Seidler[1], G.L. Smith[2], G. Inesi[3], H. Kogler[1], G. Hasenfuss[1]. [1]*Georg August Universität Göttingen, Cardiology and Respiratory Care, Göttingen, Germany;* [2]*University of Glasgow, Institute of Biomedical Life Science, Glasgow, United Kingdom;* [3]*University of Maryland, Biochemistry and Molecular Biology, Baltimore, United States of America*

Due to its kinetics, the SR-Calcium-ATPase of the fast-twitch skeletal muscle (SERCA1) is an interesting target for gene therapy of heart failure. We analysed the contractility of rabbit isolated ventricular cardiomyocytes after adenovirus-mediated gene transfer of the SERCA1-gene.

Isotonic shortening was measured in cells transfected at different multiplicity of infection (MOI) either with SERCA1-virus (Ad-SERCA1) or β-Galaktosidase (Ad-LacZ) as control.

Analysis of mRNA and protein expression levels exhibited an increase in transgene-expression which depends on viral concentration. In the functional measurements, the SERCA1-group showed a decrease in the time peak shortening (TTP) by 10.29% at MOI10 ($p<0.05$) and by 22.48% at MOI50 ($p<0.05$). The time from minimum cell length to 50%-relengthening (RT50) was reduced in SERCA1-group by 11.05% ($p=0.053$) at MOI10 and by 28.92% at MOI50 ($p<0.05$) (MOI10: n=11 isolations; MOI50: n=7 isolations). Fractional shortening was increased at MOI10 by 12.44% in the SERCA1-group compared with Ad-LacZ ($p<0.05$). At MOI50, however, we found a decrease by 21.85% in fractional shortening of Ad-SERCA1 ($p<0.05$).

These data show progressively faster twitch kinetics in relation to SERCA1 expression levels. At MOI10 we found a positive inotropic effect of SERCA1-expression, but we found a negative inotropic effect at MOI50.

The negative inotropic effect at high SERCA1 expression levels is most likely due to excessive activation of Calcium removal resulting in smaller Calcium transients. Therefore, dose of SERCA overexpression is critical for improvement of myocardial function.

1378 Depressed spark amplitude and decreased spark frequency in cardiomyocytes of transgenic mice with cardiac overexpression of Phospholamban

I. Hirsch[1], M.C. Brandt[2], M. Lindner[2], H. Sauer[3], J. Hescheler[3], D.J. Beuckelmann[2], E.G. Kranias[4], R.H.G. Schwinger[1]. [1]*Lab. of Muscle Res.and Mol.Cardiology, Clinic III of Internal Medicine, Cologne, Germany;* [2]*University of Cologne, Clinic III of Internal Medicine, Cologne, Germany;* [3]*University of Cologne, Department of Neurophysiology, Cologne, Germany;* [4]*University of Cincinnati, Depart. of Pharm. & Cell. Biophysics, Cincinnati, United States of America*

Phospholamban (PLB), a phosphoprotein of the sarcoplasmatic reticulum (SR), regulates the Ca^{2+}-affinity of SERCA 2a. To investigate, the effects of different expression-levels of PLB on the Ca^{2+}-release from the SR and on the expression of other Ca^{2+}-handling proteins we measured: 1) whole-cell Ca^{2+}-transients (Fura-2 method) and resting Ca^{2+}-sparks in isolated cardiomyocytes of transgenic mice either 2-fold overexpressing (PLBOE) or lacking (PLBKO) phospholamban in comparison to their controls (CON) 2) the protein-levels of the ryanodine receptor type 2 (RYA2), triadin and FKBP12.6. in homogenates (Westernblots).

In cardiomyocytes from PLBKO, peak fura-2 ratio amplitudes were significantly increased (CON: 0.27±0.02, PLBKO: 0.36±0.03).This was accompanied by an elevated spark frequency [sparks/100μm*sec] (CON:1.51±0.08, PLBKO:4.59±0.18) and higher spark amplitudes (CON:1.54±0.01, PLBKO: 1.92±0.01). The protein expression of RYA2 (CON: 161.0±22.2 DU, PLBKO: 67.9±16.DU), triadin (CON: 265.3±30.0 DU, PLBKO: 72.8±13.6 DU) and FKBP12.6 (CON: 26.0±5.0 DU, PLBKO: 7.6±2.0 DU) was significantly decreased. Cardiomyocytes from PLBOE mice demonstrated significantly decreased Fura-2 ratio- (CON: 0.4±0.04, PLBOE:0.26±0.02) and Ca^{2+}-spark amplitudes (CON: 1.60±0.03),PLBOE: 1.37±0.01), as well as a lower spark frequency (CON: 1.78 ±0.13,??PLBOE: 1.33 ±0.11). The protein levels of the RYA2 (CON: 48.7±23.6 DU, PLBOE: 114.05±5.1 DU), triadin (CON: 57.4±20.3 DU, PLBOE: 170.9±6.2DU) and FKBP12.6 (CON: 5.7±4.0 DU, PLBOE: 11.7±3.0 DU) were significantly increased.

These data indicate that Ca^{2+}-release from SR correlates with the expression of phospholamban, despite adaptive alterations in the protein-levels of ryanodine receptor type 2 (RYA2), triadin and FKBP12.6.

1379 β3-Adrenoceptor mediated eNOS-activation reduces cardiac contractility by stimulation of the AKT-kinase

K. Brixius[1], W. Bloch[2], C. Pott[1], A. Krahwinkel[2], U. Mehlhorn[3], R.H.G. Schwinger[1]. [1]*Clinic III of Internal Medicine, Lab. of Muscle Res.& Mol. Cardiology, Cologne, Germany;* [2]*University of Cologne, Institute I of Anatomy, Cologne, Germany;* [3]*University of Cologne, Cardiothoracic Surgery, Cologne, Germany*

The signal transduction pathway and the (patho)physiological implication of β3-adrenergic stimulation in human myocardium remains unclear. Therefore, we investigated isometric force of contraction (electrically stimulated, isometric contracting trabeculae), eNOS-activation (immunfluorescence studies) and Ser-1177 phosphorylation (western blot) as well as phosphorylation of the AKT-kinase (immunfluorescence studies, western blot) in human right atrial (RA, Bypass OP), left ventricular nonfailing (NF, donor hearts) and failing (DCM, dilated cardiomyopathy) myocardium after application of BRL 37344 (BRL), a preferential β3-agonist.

Application of BRL (10 μM) increased force of contraction in RA (+56%, n=8, $p<0.05$) and reduced contractility in left ventricular myocardium. The decrease in force of contraction was significantly increased in DCM (-27%, n=8, $p<0.05$) compared to NF (-9%, n=4). In RA, NF and DCM, BRL induced an activation of eNOS. To investigate whether this eNOS-activation is mediated by a stimulation of the phospholipase C/IP3/AKT-kinase signaltransduction pathway, the phosphorylation of AKT-kinase and eNOS (Ser 1177) was measured. Application of BRL (10 μM) resulted in a time-dependent phosphorylation of AKT kinase (max. 2 min.), which correlated with a Ser 1177-phosphorylation of eNOS.

Conclusions: 1) β3-adrenergic stimulation leads to a phosphorylation-dependent eNOS activation via the phospholipase C/IP3/AKT-kinase signal transduction pathway in human cardiomyocytes. 2) There are regional differences in the inotropic effects of β3-adrenergic stimulation in human myocardium. 3) The negative inotropic effect of β3-adrenergic stimulation is increased in human heart failure.

MOLECULAR MECHANISMS OF ATHEROSCLEROSIS FROM MOUSE TO MAN

1380 Reducing the gap junction protein connexin43 substantially protects against atherosclerosis in LDL receptor-knockout mice

B.R. Kwak[1], G. Pelli[1], N.R. Veillard[1], F. Mulhaupt[1], R.W. James[2], F. Mach[1].
[1]*Cardiology Division,* [2]*Endocrinology and Diabetes, University Hospital Geneva, Geneva, Switzerland*

Intercellular channels present in gap junctions allow the direct exchange of ions and small metabolites between cells in contact thus coordinating physiological processes such as cell growth and differentiation. We have recently demonstrated increased expression of the gap junction protein connexin43 (Cx43) in specific subsets of cells in atherosclerotic lesions. Because the development of atherosclerosis critically depends on paracrine cell-to-cell interactions, we hypothesized that direct intercellular communication via gap junctions may be another key regulator of atherogenesis. Atherosclerosis-susceptible LDL receptor-deficient mice were intercrossed with mice heterozygous for a Cx43 null mutation (Cx43+/- mice). Male LDL receptor-deficient mice with normal (Cx43+/+LDLR-/-) or reduced (Cx43+/-LDLR-/-) levels of Cx43 of 8 weeks old (n=7 per group) were fed a cholesterol-rich diet (1.25%) for 14 weeks. Atherosclerotic lesions were measured by computer image analysis measuring the extent of sudanophilic lesions within the thoraco-abdominal aorta and aortic root. The composition of the atherosclerotic plaques was analyzed using immunostainings with cell specific antibodies. Increase in serum lipid profiles (total cholesterol, triglycerides) and body weight did not differ between both groups. We confirmed the reduced levels of Cx43 in Cx43+/-LDLR-/- mice by Western blots on total protein extracted from hearts. The progression of atherosclerosis was reduced by 50% in the thoraco-abdominal aorta of in Cx43+/-LDLR-/- mice; lipid deposition being for Cx43+/-LDLR-/- and Cx43+/+LDLR-/- mice 7.1±0.9% and 15.4±1.5%, respectively (mean±SEM, $p<0.05$). These results were confirmed in aortic root analysis. Interestingly, atheroma in Cx43+/-LDLR-/- mice contain less inflammatory cells and exhibit thicker fibrous caps with more collagen and smooth muscle cells, features associated, in human, with stable atherosclerotic lesions.
Taken together, these data indicate a critical role for Cx43-mediated gap junctional communication in atherogenesis, and may open up towards therapeutic strategies not only affecting paracrine cell-cell interactions but also gap junctional intercellular communication to reduce the evolution of this common disease.

1381 Intervention studies utilizing an apolipoprotein E knockout mouse model of plaque rupture

K. Carson[1], A. Luttun[2], P. Carmeliet[2], C. Jackson[1]. [1]*Bristol Royal Infirmary, Bristol Heart Institute, Bristol, United Kingdom;* [2]*University of Leuven, Center for transgene technology, Leuven, Belgium*

The brachiocephalic artery of the apoE knockout mouse (apoE-/-) has been established as a site of predilection for plaque rupture. The aims of this study were twofold: 1) to test the hypothesis that the plasminogen activator system may be involved in the process of plaque destabilization and 2) to assess the plaque stabilizing effects of pravastatin. Double knockout mice, deficient in the genes for apoE and Plasminogen Activator Inhibitor-1 (apoE-/-:PAI-1-/-) were created. Eleven of these apoE-/-:PAI-1-/- mice and twelve apoE-/- controls were fed a high fat diet for 25 weeks. Serial sections were taken through the brachiocephalic artery and were examined for plaque ruptures. The thickness of the fibrous cap, the proportion of the plaque occupied by the lipid core, and the number of fibrous layers within the plaque were also determined. Additionally, 40 apoE-/- mice were given pravastatin 40 mg/kg/day in their drinking water whilst on the high fat diet. Controls comprised 60 apoE-/- mice drinking plain tap water. This study was planned to continue for 9 months, with assessment of the incidence of sudden death using survival curves, in addition to the histological examination as above. There were significantly more plaque ruptures in the apoE-/-:PAI-1-/- mice than in the apoE-/- controls (6 of 11 compared to 1 of 12, $p = 0.03$, Fisher's exact test). Furthermore, in those that had plaque ruptures, the lipid core occupied a significantly greater proportion of the plaque than in those without (44 ± 3% compared to 33 ± 3%, $p = 0.01$, unpaired t-test), and there were significantly more fibrous layers within the plaque (4.9 ± 0.3 compared to 3.4 ± 0.5, $p = 0.02$, unpaired t-test).
Preliminary results from the pravastatin study show a clear reduction in the incidence of sudden death in the treatment group (3 of 40 compared to 15 of 60, $p = 0.03$) at 4 months, however this study is ongoing and full results, including incidence of plaque rupture and plaque morphometery, are awaited.
These results suggest that the plasminogen activator system plays an important role in the process of plaque destabilization and rupture. They also demonstrate that this model has important correlates with human lesions, in that the proportion of the plaque occupied by lipid and the presence of previous healed ruptures both act as markers of instability. The preliminary data from the pravastatin study are encouraging, and the full results from this study will be very interesting, in that they may confirm that pravastatin does indeed reduce the incidence of plaque rupture and promote plaque stability.

1382 Adenovirus-mediated overexpression of tissue inhibitor of metalloproteinase-2 attenuates atherosclerosis in apolipoprotein E-deficient mice

J.L. Johnson[1], C.L. Jackson[1], A.H. Baker[2], A.C. Newby[1], S.J. George[1].
[1]*University of Bristol, Bristol Heart Institute, Bristol;* [2]*University of Glasgow, Dept. of Medicine and Therapeutic, Glasgow, United Kingdom*

Atherosclerotic plaque rupture and subsequent occlusive thrombosis remain the underlying cause of sudden cardiac death. Matrix metalloproteinases (MMPs) and associated excessive matrix degradation is thought to mediate the progression of stable atherosclerotic lesions to an unstable phenotype prone to rupture. We hypothesised that overexpression of human tissue inhibitor of metalloproteinases-2 (TIMP-2), a natural inhibitor of MMPs, could inhibit atherosclerotic plaque development in atherosclerosis prone apolipoprotein E-deficient (ApoE-/-) mice, resulting in smaller more stable lesions.
Male ApoE-/- mice on a C57Bl/6 x Sv129 mixed background were fed a high-fat cholesterol-rich diet for 6 weeks to enable the onset of early atherosclerosis. All mice were then predosed via tail vein injection with empty virus RAd66 (1.5 x 10*9 pfu/mouse). After 4 hours mice were infected with either human RAd.TIMP-2 (0.2 x 10*9 pfu/mouse) or RAd66 (0.2 x 10*9 pfu/mouse) and returned to the high-fat diet. Serologic, histological and immunological analyses were carried out 4 weeks after adenoviral delivery.
Infection with RAd.TIMP-2 resulted in elevated plasma levels of TIMP-2 and resulted in a marked reduction (51%; $P=0.039$) in mean lesion area (0.66 ± 0.24 mm^2; $n=4$) as compared with RAd66 infected mice (1.34 ± 0.22 mm^2; $n=6$). Similarly, a significant reduction (45%; $P=0.034$) in lumenal occlusion was observed (25.20 ± 8.69%) compared to RAd66 mice (45.51 ± 5.43%). In addition, there was a marked loss in macrophage numbers, apoptotic cells as well as MMP proteins. Conversely, an increase in smooth muscle cells, collagen deposition and fibrous cap thickness was seen in RAd.TIMP-2 infected mice compared to controls. Finally, evidence of intra-plaque haemorrhage was observed in RAd.66 infected mice but was not apparent in RAd.TIMP-2 infected mice.
These findings indicate that elevated circulating levels of TIMP-2 attenuates the progression of early atherosclerotic lesions to more established or vulnerable lipid-rich plaques. Therefore adenovirus-mediated overexpression of human TIMP-2 in ApoE-/- mice demonstrates its role in promoting atherosclerotic plaque stability.

1383 Isolation and transduction of rabbit monocytes – Promising vehicles for local delivery of arteriogenic gene products

J. Herold[1], R.C. Braun-Dullaeus[1], B. Fernandez[2], M. Heil[2], Z. Xing[3], W. Schaper[2]. [1]*Giessen University, Internal Medicine/Cardiology, Giessen, Germany;* [2]*Max Planck Institute, Dpt. of Experimental Cardiology, Bad Nauheim, Germany;* [3]*Mc Master University, Dpt. of Pathology, Hamilton, Ontario, Canada*

Monocytes/macrophages (Mo) represent intriguing vehicles for genetherapeutic approaches to augment collateral growth (arteriogenesis) in ischemic diseases. After ex vivo transduction and re-injection they would home to sites of arteriogenesis and secrete a gene product of interest. An accepted model of arteriogenesis is the rabbit model of hind limb ischemia. However, isolation of rabbit monocytes is problematic and ex vivo transduction techniques have not been established. This study was designed to establish rabbit Mo isolation and to explore different methods of in vitro transduction. Rabbit blood (40 ml) was taken from the ear vein and a modified Ficoll-Paque centrifugation protocoll was elaborated. The leukocyte fraction was plated into culture wells containing macrophage medium. Adherent cells were cultivated for up to 7 days. We were able to isolate 530.000 cells/ml blood and FACS analysis confirmed a 90% purity of the Mo-culture. Following transduction techniques were systematically examined using a reporter gene coding for LacZ: adenovirus (av), liposomes (lp), and electroporation (ep). We determined both the transduction efficiency (TE) with in vitro X-Gal staining and quantified the activity of beta-galactosidase (gal) by spectrometry. As little as 25 plaque forming units (pfu) av resulted in a TE of 98±1% of Mo when infeced 24 h after isolation. gal activity rose from 3.2±0.1 (control) to 50.9±0.3 mU/Mio cells. av concentrations up to 250 pfu as well as GM-CSF activation (200 U/ml) of cultivated Mo for up to 7 days were not able to further increase gal activity (50.9±0.1 mU/Mio cells). Neither lp (different lipid formulations) nor EP were able to significantly transduce Mo despite systematic change of DNA/lipid ratio (lp), day of transduction (lp, ep), and voltage (ep). The homing of ex vivo av-LacZ-transduced Mo was impressively demonstrated by their intravenous injection into rabbits one day after femoral artery ligation and visualization in proximity to collateral vessels through X-Gal staining of histologic sections. We demonstrate that isolation of rabbit Mo is feasible but only viral transduction is effective. Their homing to sites of arteriogenesis has intriguing potential for genetherapeutic approaches.

1384 Introducing a new model for studying macrophage homing into atherosclerotic plaque in apoE-deficient mice

S. Litovsky[1], P.R. Wyde[2], M. Madjid[1], A. Akhtar[1], W. Casscells[1], M. Naghavi[1]. [1]*Center for Vulnerable Plaque Research, Univ. of Tex-Houston & Tex Heart Inst, Houston;* [2]*Baylor College of Medicine, Dept. of Mol. Virology & Microbiology, Houston, United States of America*

Background: Previous work from our laboratory has shown that the influenza virus exerts prominent effects on the atherosclerotic plaques of apo E-deficient mice. Specifically, a marked increase in subendothelial inflammatory cells (macrophages and T-cells) and smooth muscle cells were noted and a case of plaque erosion with superimposed fibrin-rich thrombus was seen. Since cytokines could be a mechanism by which the virus exerts its effect on the plaque, we decided to test this hypothesis with administration of TNF-á and IL-1â. In order to visualize plaque homing of macrophages, and because we have experience with SPIO (superparamagnetic iron oxide) in MRI studies, we decided to combine the administration of cytokines with SPIO.
Methods: Eight apo E k/o retired breeders, approximately 11-month old were divided into 2 groups. Five received mouse recombinant TNF-á and IL-1â IP 0.2 ìg each; apo E k/o controls received 0.5 mL saline contaning 1% BSA. In addition, three wild-type, age matched mice received the same dose of cytokines. Three hours later, all animals were injected with I.V. SPIO (Feridex) (1mMol/kg of iron). Six days later, the recipients were euthanized and the aorta was perfused with PBS. The entire aorta was formalin-fixed and processed for light microscopy.
Results: In apoE k/o without cytokines little to no iron was deposited in the plaques. In apo E-k/o mice pre-treated with cytokines, prominent superficial mononuclear, iron-containing infiltrate was present. In multiple superficial areas, dense cell clustering was seen. Immunohistochemistry demonstrated that although most of the cells were iron-containing macrophages, some T-cells and smooth muscle cells were also present. Wild-type mice showed no iron uptake into their aortas.
Conclusion: Administration of a single dose of TNF-á and IL-1â induced a striking homing of macrophages and to a lesser extent of T lymphocytes and smooth muscle cells to the subedothelium of apo E k/o mice. This effect was not seen in age-matched apo E k/o mice not treated with cytokines and neither in wild-type mice. This study strongly suggests that, the influenza virus exerts its effects on the plaques (at least partially) through cytokine-mediated mechanisms. In addition, SPIO was shown to be a good marker for recent macrophage homing into the plaque.

1385 The cellular immune response to oxidized LDL aggravates atherosclerosis. Evidence from adoptive transfer studies in immunodeficient mice

X. Zhou, C. Tenger, A-K. Robertsson, G. Hansson. *Karolinska Institutet, Medicine, Stockholm, Sweden*

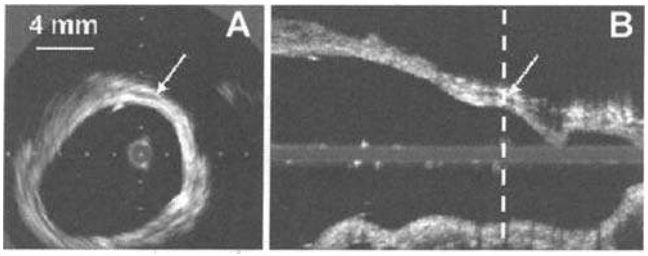
Atherosclerosis is associated with immune responses to oxidized low density lipoprotein (LDL) and certain microorganisms. The expression of HLA-DR by activated macrophages and activated T cells adjacent to these macrophages in the lesions strongly suggests that a cell mediated immune reaction is taking place in the process of atherosclerosis. However, the role of specific immune responses has remained unclear. We have previously shown that transfer of CD4+ T cells into immunodeficient SCID x apoE knockout (KO) mice accelerates disease (Zhou et al Circulation 2000, 102:2919). To further explore if this effect is dependent on specific disease-associated antigen, we have now transferred CD4+ T cells specific for oxLDL into SCID x apoE KO mice. As controls, we used CD4+ T cells specific for a non-relevant antigen (KLH) and naïve CD4+ T cells. After 12 weeks, all the mice that had received T cells had significantly aggravated lesion development. However, mice receiving CD4+ T cells specific for oxLDL had a substantially increased lesion progression compared to those receiving naive or KLH specific T cells. Circulating levels of the Th1 cytokine, interferon-gamma was increased in proportion to the acceleration of atherosclerosis. These data show, for the first time, that adoptive transfer of oxLDL antigen-specific T cells accelerates atherosclerosis. They support the notion that Th1 cellular immunity is proatherogenic and identify oxLDL as a culprit autoantigen.

PULMONARY VEINS IN ATRIAL FIBRILLATION: FROM ANATOMY TO ABLATION

1386 Three-dimensional intravascular ultrasound architecture of the pulmonary venous wall: implications for radiofrequency ablation

J.A. Cabrera[1], D. Sánchez-Quintana[2], F. Cabestrero[1], S.Y. Ho[3], M. Orejas[1], F. Navarro[1], J.M. Rubio[1], J. Farré[1]. [1]*Fundación Jiménez Díaz, Cardiology, Madrid, Spain;* [2]*Extremadura University, Human Anatomy, Badajoz, Spain;* [3]*Imperial College, Paediatric Cardiac Morpholigy, London, United Kingdom*

Recent basic and clinical electrophysiologic studies have documented the critical role of the wall of the pulmonary vein (PV) in the pathophysiology of paroxysmal atrial fibrillation.
Methods: Cross-sectional (figure A) and longitudinal (figure B) high-frequency (3.2F,30MHz) intravascular ultrasound (IVUS) images were examined in 32 PVs from 12 normal human autopsied hearts. The entire lengths of the PV from venoatrial junction to 2 cm distally were imaged using a motorized pullback at 0.5 mm/s to obtain a three-dimensional (3D) ultrasound reconstruction of each PV. Histological sections at the intervals allowed comparison to be made with ultrasound images.
Results: The cross-sectional ultrasound characteristic of the PV wall had a three-layerd pattern. The inner layer was an echogenic ring representing both endothelium and connective tissue of the media (mean thickness 1.4±0.2 mm). The middle layer was an hypoechogenic layer corresponding the sleeves of the left atrial myocardium surrounding the external aspect of the venous media (figure). This layer was thicker at the venoatrial junction (2.7±0.6 mm) and decreased toward the lung hilium. The outer layer was echodense, corresponding to fibro-fatty adventitial tissue (mean thickness 2.1±0.3 mm). A significant correlation ($p<0.001$) was found between longitudinal ultrasound and histological measurements of the myocardial content over the PV.



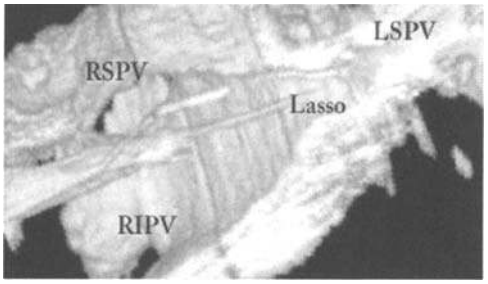
3D-ultrasound of the PV wall.

Conclusion: This study demonstrates the ability of 3D high-frequency IVUS to visualize the architecture and structure of the PV. Cross-sectional and longitudinal IVUS images can provide information on the thickness and distal limits of the myocardial sleeves and can be a valuable tool to help accurate targeting during ablation procedures.

1387 Three-dimensional intracardiac echocardiography (ICE) of pulmonary vein anatomy and location of circular mapping catheter in ablation of atrial fibrillation

T. Vogtmann, S. Ernst, F. Ouyang, M. Goya, M. Antz, K-H. Kuck. *AK St. Georg Hamburg, Cardiology Dept., Hamburg, Germany*

Background: The visualisation of pulmonary vein (PV) anatomy by angiography is limited, but crucial for identifying the ablation target for PV isolation. We investigated 3-D-ICE as an adjunctive imaging technique, to visualise PV anatomy and control positioning of circular mapping catheters (Lasso, Biosense Webster) in the PVs.
Methods: We performed 3-D ICE studies with a non-steerable 9 F-9 MHz ICE-catheter (Boston Scientific) with an ECG- and respiration triggered pull-back (TomTec workstation) starting 2-3 cm inside the PV pre and after PV isolation. PV ostium size, localisation and wall contact of Lasso (placed guided by fluoroscopy and electrical potentials) and lesion formation were studied.
Results: We report on 22 pull-backs in 5 pts (2f, 54±8 y) with an acquisition time of 318± 115 sec. 3-D reconstruction for left superior PV (LSPV) was possible in 5/5, left inferior (LIPV) in 4/5, right superior (RSPV) in 3/5 and right inferior (RIPV) in 0/5 cases. Averaged ostium size before ablation was (median/range) 14/12-18 mm (LSPV), 16,5/13-18 (LIPV), 21/19-22 (RSPV) in ICE compared to 14/12-18 (LSPV), 16,5/13-18 (LIPV) and 19/17-21 (RSPV) in angiography. First branching was visualised 13,6 ± 7,6 (2-22) mm distal of the PV-os. Position of Lasso was clearly identified in 11/12 veins with a distance of 9,3±4,2 (4-17) mm to the ostium. Post ablation thickening of the PV wall was detected in 6 PVs with no relevant stenosis. During the study 1 pt developed ST-elevation with no abnormality in coronary angiography suggesting ischemia due to air embolism.



Lasso in LSPV.

Conclusion: 3-D ICE of pulmonary veins provides detailed anatomical information of the proximal PV's and the position of circular mapping catheters. RF induced tissue changes in the PV wall can be visualised by ICE.

1388 Utility of intracardiac ultrasound imaging in guiding circumferential pulmonary vein ablation with the laser balloon catheter

L. Leite, W. Su, S. Johnson, D.L. Packer. *Mayo Clinic, Cardiac Electrophysiology, Rochester, United States of America*

Background: Pulmonary vein (PV) isolation has been used as the endpoint for (AF) ablation in laser balloon ablation (LBA). Whether catheter tip-tissue contact is required in achieving successful electrical isolation of these veins has been unclear.
Method: To determine the role of intracardiac ultrasound (ICUS) in guiding PV ablation with LBA, and to assess the role of direct tissue contact, 59 PVs were ablated in 27 mongrel dogs. LBA was performed next to the PV orifice via a transseptal approach under fluoroscopic and ICUS guidance. Laser energy was delivered at 3.5 to 5.5 W/cm for 120 to 720 sec. Before laser application, ICUS color Doppler was used to assess for the presence of a blood flow leak between the targeted PV and the LBA catheter. After laser energy was delivered, PV isolation was established during normal sinus rhythm and distal coronary sinus and PV pacing with a 20-pole catheter positioned into the PV. Multivariate logistic regression analysis of the contribution of PV ablated, power delivered, time of application, presence of leak identified by ICUS, and balloon diameter and length to successful ablation isolation was undertaken.
Result: A total of 59 PV were ablated (23 RSPV, 27 LSPV, 8 LIPV, and 1 RIPV). Mean burn time was 279±177 sec, mean balloon diameter was 23±3 mm, and mean balloon length was 25±4 mm. Complete isolation was achieved in 38/59 (64%) PVs, and was significantly more common in the absence of blood flow leak: 30/38 (83%) versus 8/23 (35%) when a leak was documented ($p<0.05$, OR: 2.4, 95% CI: 1.4; 4.7). This was independent of time of application (302±223 sec vs. 266±148 sec, p=ns), power (3.5 W/cm, 4.5 W/cm, and 5.5 W/cm), PV ablated [8/23 (78%) RSPV, 18/27 (67%) LSPV, 2/8 (14%) LIPV, and 1/1 (100%) RIPV, $p<0.05$)], balloon diameter (24±3 mm vs. 22±3 mm, p=ns) and length (27±4 mm vs. 24±4mm, p=ns). The positive predictive value of leak was 65% and the negative predictive value was 83%.
Conclusion: An identifiable leak between PV and the LBA device seen by ICUS is predictive of lower PV isolation rates. ICUS may be useful for leak detection to avoid ineffective energy application during circumferential PV ablation.±

1389 Ostial pulmonary vein isolation in patients with atrial fibrillation utilizing a multipolar basket catheter and a new navigation system

T. Arentz[1], J. von Rosenthal[1], T. Blum[1], K. Peters[2], G. Bürkle[1], D. Kalusche[1]. [1]*Herzzentrum, Abt. Interventionelle Kardiologie 2, Bad Krozingen, Germany;* [2]*Herzzentrum, Interventionelle Kardiologie1, Bad Krozingen, Germany*

Atrial fibrillation (AF) is frequently induced by triggers originating from pulmonary veins (PV). Ostial PV isolation utilizing catheter ablation technique is a potential for cure. However, utilizing current ablation and mapping techniques a long procedure duration, prolonged fluoroscopy time and a high risk of recurrence are encountered.
Method: We studied 38 patients (mean age 52±12 years, 29 male) with refractory AF (paroxysmal n=29 persistent n=9). A 64-pole basket catheter (CONSTELLATION, EPT diameter=31 mm) was placed into the PV to identify the earliest PV activation during sinus rhythm (SR) or coronary sinus pacing. The ablation catheter was placed next to the electrodes showing earliest PV activation utilizing a novel navigation system (ASTRONOMER, EPT). The radiofrequency energy was delivered with a maximum temperature of 50° and a maximum power of 30 watt. Endpoint was complete elimination of all distal PV potentials during sinus rhythm.
Results: The mean number of procedures per patients were 1.4, mean procedure duration 238±94 minutes, mean fluoroscopy time 36±19 minutes. A total of 81 out of 84 mapped PVs were successfully isolated at the ostium utilizing a mean of 6.8 radiofrequency energy pulses. Complications: one pericardial tamponade, 10X carbonization observed on the splines/electrodes of the basket catheter (no clinical sequelae). The mean follow up is 8.4 ± 4.8 months and 32 out of 38 patients (84%) are were free of AF or had at least a significant improvement in symptoms.
Conclusion: The use of a multipolar basket catheter for mapping of the PV ostium facilitates identification of conduction paths from the left atrium into the PVs. The ASTRONOMER navigation system allows precise steering of the ablation catheter to areas identified as left atrial to PV conduction pathways.

1390 Pulmonary vein isolation by radiofrequency ablation using an irrigated multipolar ablation catheter in the ostium

C. Weiss[1], S. Willems[1], O. Franzen[1], T. Rostock[1], J.R. Skarda[2], M.T. Stewart[2]. [1]*Univ. Hospital Eppendorf, Cardiology, Hamburg, Germany;* [2]*Medtronic, EP Systems, Minneapolis, MN, United States of America*

Background: Isolation of arrhythmogenic pulmonary veins (PV's) by radiofrequency current ablation (RF) has been introduced as a curative treatment of atrial fibrillation (AF). The use of conventional RF catheters is time consuming and carries the risk of thrombembolic complications. The aim of the present in vivo study was to evaluate a novel multipolar irrigated ablation catheter designed to create contiguous lesions encircling the PV ostium in a single ablation position. Methods: In 9 sheep, transseptal puncture and RF ablations were guided using intracardiac echo (ICE, Acuson, USA). The 6F RF catheter, formed with super-elastic helical elements with maximal radii of 9 or 10mm, was intended to position the distal portion of the helix within the PV. The proximal ablation section (tripolar, 22m coiled electrode length, Medtronic, MN, USA) at the PV ostium. A porous membrane covering the entire surface of the ablation electrodes achieved irrigation (10 ml/min, 0.9% saline). Additional to RF applications at the PV ostium RF was applied at both appendages and in the orifices of the coronary sinus (CS) and the vena cava (VC). Following RF ablation, the animals were sacrificed and macroscopical and histological analyses of the lesions were performed. Results: Positioning of the catheter could be achieved in 16 PV ostia. ICE showed an adequate wall contact of the RF electrodes. During 84 irrigated RF deliveries no impedance rise (>300 W) occurred and no coagulum formation at the electrode has been observed with the ICE. PV isolation or reduction of local electrograms (>50%) were observed following all RF applications in the PV ostia. A total of 28 lesions created in the PV, CS and VC ostia and atrial appendages showed no charring or crater formation at the endocardial surface. RF lesions were contiguous between 2 adjacent electrodes (depth 4 ±3 mm, width 5 ±3 mm).
Conclusions: Isolation of PV by the irrigated, helical RF is feasible without the risk of coagulum formation. Due to a single ablation position stabilized in the PV this RF catheter might simplify the procedure.

1391 Transcatheter cryothermal ablation for pulmonary veins isolation in patients with atrial fibrillation

C. Tondo[1], G. Fassini[1], G. De Martino[2], S. Riva[1], F. Giraldi[1], M. Berti[1], N. Trevisi[1], P. Della Bella[1]. [1]*Centro Cardiologico, Arrhythmia Department, Milan, Italy;* [2]*Catholic University, Arrhythmia Department, Rome, Italy*

Cryothermal tissue injury is distinguished from hyperthermic lesions by the preservation of basic underlying tissue architecture and minimal thrombus formation. Such differences can be potentially significant in settings requiring extensive lesion formation, such as catheter-based procedure for the treatment of atrial fibrillation (AF). Safety and efficacy of cryoenergy were tested by attempting pulmonary veins (PV)isolation in 15 consecutive patients (pts)(13 males, mean age 57±8 years)with drug-refractory paroxysmal (12pts)/persistent (3pts)AF. Four pts had had prior right sided ablation and 3 prior conventional focal PVs RF ablation. A steerable 7F cryocatheter (Freezor, Cryocath)with 4 mm tip electrode using nitrous oxide as a refrigerant was used to produce cryolesions at the PVs ostia. Simultaneous circumferential PV activation obtained by a loop-shaped catheter guided cryothermal applications in each pt.Acute results are reported in Table 1. In the first two pts, conventional radiofrequency current was used after left upper (LUPV), right upper (RUPV)or left inferior (LIPV)PVs cryoisolation; in 2 pts RIPV was not targeted and in 2 pts RIPV isolation failed. Freezing resulted in painless ablation; no procedure relate complications occurred. At a mean follow up of 6±2 months, 10 pts (66%) were syptoms-free, 2 pts had chronic AF and 3 pts have sporadic AF episodes on drug. Conclusions: Cryoisolation of PVs is safe and may provide a potential alternative to radiofrequency current in clinical settings requiring extensive tissue destruction, such as the catheter-based approach for the treatment of AF.

MYOCARDIAL DISEASES

1392 Assessment of the significance of electrocardiogram abnormalities in junior elite athletes

S. Firoozi, S. Sharma, G. Whyte, R. Thaman, M.S. Hamid, P.M. Elliott, W.J. McKenna. *St George's Hospital Medical School, Cardiological Sciences, London, United Kingdom*

Background A significant proportion of athletes have Sokolow voltage criteria for LVH. A few have minor T wave inversion (TWI; < -0.2mV) in the inferior and right ventricular (RV) leads. The significance of these findings in unclear and poorly studied. The aims of this study were to correlate voltage criteria for LVH on ECG with LVH on echocardiography, and to evaluate the significance of minor T wave inversions in the inferior and RV leads.

Methods Between 1996 and 2001, 1350 junior (age 14-18) elite athletes and 200 healthy adolescent controls underwent ECG and echocardiography. Voltage criteria for LVH were correlated with LV wall thickness (LVWT) where LVH was defined as a LVWT > 2 SD of the predicted mean derived from the controls. In patients with TWI we looked for cardiomyopathy and anomalous coronary arteries on echocardiography.

Results Sokolow criteria for LVH were present in 45% of athletes and 23% of controls. On echocardiography, LVH was seen in 63 (12%) athletes but in no controls. The Sokolow criteria for LVH were positive in all individuals with LVH at echo (sensitivity = 100%) but with a high false positive rate (33% in athletes and 25% in controls; specificity = 67%). In contrast, the Romhilt-Estes criteria for LVH were specific (100%) and sensitive (92%).

Inferior TWI was seen in 0.6% of athletes but no controls. It was also present in RV leads in 20 athletes and 3 controls. TWI was absent in other territories. Echo was normal in these subjects and no anomalous coronary arteries were identified.

No athlete with LVH had q waves, LBBB, ST depression, deep T wave inversion. Also, no athlete with RV TWI exhibited epsilon waves or RV ectopics.

Conclusion Sokolow voltage criteria are a common finding in junior elite athletes. They are a sensitive, but non-specific marker for LVH. The Romhilt-Estes criteria offer a more specific, and thus better marker for true LVH. Furthermore, junior athletes with true LVH don't have additional ECG changes seen in cases of pathological LVH such as HCM. The presence of these changes should deter a diagnosis of athlete's heart.

Minor TWI in the inferior and RV leads is seen in a minority of junior elite athletes. These ECG changes were isolated and not accompanied by other findings indicative of a cardiomyopathic process. They most likely represent part of the normal paediatric ECG.

1393 Cardiac condition in myotonic dystrophy

D. Babuty[1], T. Farrokhi[1], D. Casset-Senon[1], L. Fauchier[1], M. Raynaud[2], G. Dupassage[3], P. Cosnay[1]. [1]*Hôpital Trousseau, cardiologie B, Tours Cedex, France;* [2]*Faculté de Médecine, Département de génétique, Tours, France;* [3]*Faculté de médecine, Neurologie, Tours, France*

Myotonic dystrophy (MD) is a common form of adult muscular dystrophy frequently associated with cardiac complications. However the cardiac condition of these patients is always unclear as is the incidence of cardiac events.

Since 1994 we, consecutively, enrolled 55 patients with MD diagnosis on the basis of electromyography and molecular genetic. Each patients underwent physical examination, ECG, 24 hours ambulatory ECG, electrophysiological study and determination of systolic and diastolic function of left ventricle (LV) by radionuclear angiography. All patients were consulted once a year.

At time of enrollement, no patient had heart failure; abnormalities of atrioventricular (AV) conduction were present in 58% of patients and 50% of patients had a lengthening of HV interval during electrophysiological study justifying implantation of a prophylactic pace maker. Atrial arrhythmias were recorded in 8 patients. LV diastolic function was altered in 72% of patients with minor alteration of LVEF in only 16% of patients.

During the follow up (40.5 * 30 months), 24 pts (43%) developed 36 cardiac events: one sudden death, 15 complete AV block, 15 sustained atrial arrhythmias, and 5 non sustained ventricular tachycardia. No patients developed heart failure. Three patients died of respiratory insufficiency. Complete AV block occurred only in the group of patients with lengthening of HV interval at baseline evaluation.

In MD cardiac abnormalities are frequent especially in term of AV conduction, atrial and ventricular arrhythmias. Whereas LV diastolic dysfunction is frequent, patients rarely developed clinical heart failure. That cardiac condition justifies a regular cardiac control and implantation of prophylactic pacemeker in patients with lengthening of HV interval.

1394 Characteristic yearly progression of electrocardiographic abnormalities in cardiac Fabry disease

T. Takenaka, H. Teraguchi, T. Yoshitama, S. Hamasaki, S. Minagoe, C. Tei. *Kagoshima University, The First Dept. of Internal Medicine, Kagoshima, Japan*

Background: We reported that we had detected cardiac Fabry disease, an atypical variant of Fabry disease with manifestations limited to the heart, in 3% of unselected male patients with left ventricular hypertrophy (LVH) of unknown cause. Since Fabry disease results from a deficiency of alpha-galactosidase A (alpha-gal A) and enzyme replacement is now a treatment option for the disease, we sought to establish cardiac parameters over time to evaluate the effect of therapy. We report here the first characteristic serial electrocardiographic changes in patients with cardiac Fabry disease. Methods: The diagnostic criteria for cardiac Fabry disease included the presence of LVH, low plasma alpha-gal A activity, and the absence of other typical symptoms of Fabry disease such as angiokeratoma, acroparesthesias, hypohidrosis, and corneal opacities. We performed serial electrocardiograms (ECGs) in 10 consecutive male patients with cardiac Fabry disease over periods ranging from 3 to 14 years (mean, 7.4±4.0), assessing rhythm, PR interval, QRS width, and QRS voltage. Arryhthmias were evaluated by 24-hour Holter monitoring. Results: The first ECGs were obtained at 60±8 years of age and the latest at 68±8 years. In the first ECGs, one patient had a first degree atrioventricular (AV) block. Over 3 years his PR interval elongated significantly. The remaining 9 patients showed normal sinus rhythms initially. Among these 9 patients, one developed a complete AV block and 4 developed first degree AV blocks over time. Mean PR intervals from 9 patients with sinus rhythms increased from 0.19±0.03 to 0.22±0.04 seconds ($p<0.05$). Intraventricular conduction delays, present in 6 patients on the first ECGs, were present in 9 patients on the latest ECGs. Mean QRS width from all 10 patients increased from 0.13±0.04 to 0.17±0.04 seconds ($p<0.01$). In the initial ECGs, 8 patients had left ventricular (LV) high voltage. However, none of the patients had LV high voltage on the latest ECGs, even though all still had LVH on echocardiogram. By Holter monitoring, ventricular premature contractions (VPCs) were detected in all 10 patients. In 7 patients evaluated with serial Holter monitoring, ventricular tachycardia appeared. Conclusion: In patients with cardiac Fabry disease, conduction delays and VPCs worsened and LV high voltage attenuated despite the presence of LVH with the duration of the disease process.

1395 Left ventricular hypertrabeculation/noncompaction in 62 patients: Prevalence and association with other cardiac and neuromuscular disorders

C. Stoellberger[1], J. Finsterer[2], G. Blazek[3]. [1]Wien, Austria; [2]Neurologisches Krankenhaus Rosenhügel, Wien, Austria; [3]Hanusch-Krankenhaus, Wien, Austria

Background and Objectives: Few data are available about the prevalence of left ventricular hypertrabeculation/noncompaction (LVHT), the number of investigations necessary to diagnose LVHT and the rate of associated cardiac and neuromuscular disorders (NMD). Aim of the study was thus to assess 1. the prevalence of LVHT, 2. the number of echocardiographic examinations necessary to diagnose LVHT, 3. cardiac abnormalities are associated with LVHT and 4. the rate of NMD in patients with LVHT.
Methods: LVHT was diagnosed if in one plane >3 trabeculations apically to the papillary muscles were seen and Doppler imaging visualized intertrabecular spaces perfused from the ventricular cavity. All patients in whom LVHT was diagnosed between June 1995 to December 2001 underwent a clinical cardiological examination. It was noted, after how many examinations LVHT was diagnosed. All LVHT-patients were invited for a neurological examination.
Results: LVHT was diagnosed in 62 (12 female) patients with a mean age of 50 (18-75) years. The prevalence of LVHT was 0.24%/year. In 47% of the patients LVHT was diagnosed at the first echocardiographic examination, in 25% more than 3 examinations were necessary. In 97% of the patients LVHT was associated with echocardiographic abnormalities, ECG abnormalities in 92%, cardiac symptoms in 89%, heart failure in 73% and arrhythmias in 65%. Among the 49 LVHT-patients who underwent a neurologic examination, 82% had a NMD and 18% were neurologically normal.
Conclusions: LVHT is a heterogeneous echocardiographic finding which is often overlooked, more prevalent than previously believed and associated with NMD in the majority of patients.

1396 Impact of disease activity on left ventricular performance in patients with acromegaly

C. Bruch[1], B. Herrmann[2], A. Schmermund[3], K. Mann[2], R. Erbel[3]. [1]WWU Muenster, Innere Medizin C, Muenster, Germany; [2]University Essen, Dept. of Endocrinology, Essen, Germany; [3]University Essen, Dept. of Cardiology, Essen, Germany

Background: In patients with acromegaly, abnormalities of systolic and diastolic left ventricular (LV) performance, mostly associated with hypertension and/or LV hypertrophy, have been reported. We used two-dimensional/Doppler echo methods and tissue Doppler imaging (TDI) to elucidate the impact of disease activity on LV function in patients with acromegaly.
Patients & Methods: In a prospective study design, echocardiographic measurements were performed in 15 patients with active acromegaly (mean age-adjusted serum insuline-like growth factor-I (IGF-I) level 420± 170 ng/ml, mean growth hormone (GH) nadir during a 75-g oral glucose load 12.3± 30.1 μg/L, AA group), in 18 patients with cured (mean IGF-I level 205± 115 ng/ml, mean GH nadir during glucose load 0.72± 0.34 μg/L, n=14) or well controlled acromegaly ((normal age-adjusted ranges of IGF-1 levels under medication with somatostatin analogues: 354± 88 ng/ml, n=4), CA group) and in 24 control subjects (CON group). Acromegalic subjects with systemic hypertension, diabetes mellitus, coronary artery disease or valvular lesions were excluded. All study subjects underwent conventional 2-D/Doppler echo measurements including mitral and pulmonary venous flow velocities and assessment of ejection fraction (EF) and 'Tei-Index' (isovolumic contraction time and isovolumic relaxation time divided by ejection time). Systolic and diastolic mitral annular velocities (S', E', A', E'/A'-ratio) were derived from pulsed TDI.
Results:

Group	EF (%)	mitral E/A-Ratio	S'	E'	A'	E'/A'-Ratio	Tei-Index
CON	60±9	1.12±0.33	8.3±1.3	10.0±1.7	10.0±1.7	0.98±0.16	0.40±0.06
AA	58±9	0.78±0.22*	7.8±1.7	6.8±1.7*	10.3±1.8	0.68±0.22**	0.54±0.13**
CA	58±9	1.11±0.36	8.2±1.5	9.1±3.0	11.1±2.7	0.90±0.32	0.44±0.07

* p<0.05, ** p<0.01 AA vs. CON/CA

Conclusion: Disease activity has a significant impact on LV performance in patients with acromegaly. In subjects with active disease, diastolic dysfunction and beginning impairment of 'overall' LV performance are present. TDI analysis of mitral annulus velocity and assessment of the Tei-Index complement the evaluation of LV performance and might be a useful addition in the diagnostic work-up of acromegalic patients.

1397 Cardiac amyloidosis: electron and immuno-electron microscopy of abdominal fat allows identification and characterization of amyloid fibrils

L. Verga[1], M. Concardi[1], V. Fidanza[1], G. Palladini[2], L. Obici[2], G. Merlini[2], E. Arbustini[1]. [1]IRCCS University Hospital San Matteo, Molecular Diagnostic Division, Pavia, Italy; [2]IRCCS University Hospital San matteo, Internal Medicine and Medical Oncology, Pavia, Italy

The diagnosis of cardiac amyloidosis, suspected on the basis of clinical and echocardiographic findings, is usually made by means of endomyocardial biopsy (BEM).
Given that fat tissue is a favorite site of fibril deposition in several systemic amyloidoses, we tested that hypothesis that patients presenting with the clinical phenotype of restrictive cardiomyopathy suspected to be due to myocardial deposits of amyloid also have fat tissue deposits. To this aim, we evaluated the role of electron microscopy and immuno-electron microscopy studies on abdominal fat fine-needle biopsy samples in diagnosis and characterization of cardiac amyloidosis. We investigated 17 patients with restrictive cardiomyopathy suspected to be due to amyloidosis. Patients underwent physical examination, electrocardiography, 2-D and Doppler ecocardiography, immunofixation of serum and urine to detect monoclonal immunoglobulins and abdominal fat (AF) biopsy. Of the 17 patients, 15 had a corresponding myocardial tissue study, either endomyocardial biopsy or autopsy study. AF was investigated with polarized light (Congo red), electron and immuno-electron microscopy using specific antibodies to kappa and lambda light chains, apolipoprotein A1, serum amyloid A (SAA) and transthyretin (TTR). The ultrastructural study of fat tissue samples identified amyloid deposits in 17/17 cases, and in the corresponding myocardial tisuue in 15/15 cases. Immuno-electron microscopy specifically stained amyloid fibrils with antibodies anti-lambda (n = 9), -kappa (n = 2), -apolipoprotein A1 (n = 2) and -TTR (n = 4). Immuno-electron microscopy revealed TTR immuno-labelling in 3 patients with accidental monoclonal components. TTR and apolipoprotein A1 positive cases carried missense mutations in the corrisponding genes. Our results demonstrate that amyloid deposits are present in the abdominal fat of patients suspected to have cardiac amyloidosis and that immuno-electron microscopy characterizes amyloid protein in all cases.

PSYCHOSOCIAL CONSEQUENCES OF CARDIOVASCULAR DISEASE

1398 Quality of life in patients with symptomatic multivessel coronary disease

D. Favarato[1], W.A. Hueb[2], D. Carrara[3], S.B. Hiscok[4], C.J. Cleonice Jacintho[5], L.A.M. Cesar[2], S.A. Oliveira[2], J.A.F. Ramires[2]. [1]InCor, Clinical Unit of Atherosclerosis, sao paulo, Brazil; [2]hear t Institute (INCOR)- USP, Clincial Unit od Coronary Disease, Sao Paulo, Brazil; [3]Heart Institute (INCLOR) USP, Nursigng Departement, Sao Paulo, Brazil; [4]Heart Institute (INCOR) USP, Psicology Department, Sao Paulo, Brazil; [5]Heart Institute (INCOR) USP, Nursing Departement, Sao Paulo, Brazil

Background: although coronary angioplasty (PTCA) and coronary bypass surgery (CABG) are routinely used, there is no conclusive evidence that these interventional methods offer greater benefit than medical therapy (MT) alone as far as quality of life (QOL).
Objective: This study sought to evaluate the QOL of three possible therapeutic strategies for patients with symptomatic multivessel coronary disease and preserved ventricular function.
Methods: a total of 7783 elegible patients with multivessel disease were screened in a single institution and 611 7.8% patients were randomly assigned to undergo CABG, 203 to PTCA 205 and 203 to MT. QOL was evaluated by SF-36 questionnaire by interviews, in the pre treatment phase and 6 and 12 months of follow up.
Results: although all treatments offered improvement in QOL, such amelioration was greater in surgical group (table, *p<.0001).

Quality of life first year MASSII

Treatment	ptca		medical		cabg	
period	pre	12m	pre	12m	pre	12m
physical functioning	59.2	72.8*	50.2	66.2*	46.6	73.5*
role physical	34	52.6*	23.4	39.8*	20.7	48.2*
general health	64.5	63.8	63.4	60.8	62.5	64.4*
mental health	65.9	74.6*	63.4	70.4*	64.4	74*
vitality	64	72.2*	55.6	61.6*	56.1	73.8*
role emotional	51.9	67.1*	49.8	64.9*	45.5	68.9*
social functioning	57.5	70*	57.4	62.7*	52.7	66.9*
bodly pain	63.1	75.4*	61.7	70.1*	56.8	76.8*

*p <.0001

Conclusion: In conclusion surgical treatment offers better QOL among patients with extensive CAD than PCTA or MT.

1399 Quality of life and coping strategies in patients undergoing coronary angioplasty

D. Husser, A. Bollmann, C. Kuehne, H.U. Klein, J. Molling. *University Hospital, Cardiology, Magdeburg, Germany*

Background: In patients (pts) with coronary artery disease (CAD) both a reduced quality of life (QOL) and pathologic coping strategies (Cop) are described. There is, however, a lack of systematic studies comparing QOL and Cop in stable vs. unstable angina.
Methods and Results: This pilot study assessed QOL and Cop in 60 patients (mean age 60±11 years, 47 male) undergoing coronary angioplasty (Group I: urgent, n=30, Group II: scheduled, n=30). There were no significant differences in pts clinical characteristics with respect to age, gender, extend of CAD, and concomitant disease between the two groups. Patients completed the Seattle Angina Questionnaire (SAQ), the Medical Outcomes Study Short-Form Survey (SF-36) and the Trierer Coping Scales (TSK) in order to determine QOL and Cop, respectively. All but the SAQ treatment satisfaction (Sat) subscale were similar between groups. Sat was higher in Group I (89±12 vs. 79±16, p=.013 vs. Group II) with higher values indicating more Sat. Among the Cop scales Group I pts exhibited more rumination (Rum, 46±11 vs. 52±8, p=.05 vs. Group II) with higher values indicating pathologic tendencies. All other Cop subscales were similar between groups. Mental health was reduced in Group II (72±16 vs. 63±17, p=.041 vs. Group I) with both Sat (Beta=0.364, p=.041) and Rum (Beta=-0.246, p=.046) being independent predictors.
Conclusion: Early angioplasty may improve patients treatment satisfaction and prevent pathologic coping strategies.

1400 Hormone replacement therapy, ethnicity and psychological health in women: results from the NHLBI-sponsored WISE study

M. Olson[1], S. Kelsey[1], L. Shaw[2], S. Mankad[3], C. Cornell[4], K. Matthews[1], S. McGorray[5], C.N. Bairey Merz[6] on behalf of Women's Ischemia Syndrome Evaluation Study Investigators. *[1]University of Pittsburgh, Dept. of Epidemiology, Pittsburgh, United States of America; [2]Atlanta Cardiovascular Research, Atlanta, United States of America; [3]Allegheny General Hospital, Pittsburgh, United States of America; [4]University of Alabama at Birmingham, Birmingham, United States of America; [5]University of Florida, Gainesville, United States of America; [6]Cedar-Sinai Medical Center, United States of America*

Background: Prior observational studies demonstrate that white compared to black women are more likely to use hormone replacement therapy (HRT). Little information exists regarding use and psychological factors associated with HRT use among black women.
Methods: WISE is a four center study of women who undergo coronary angiography for suspected ischemia. In this cohort, 38% have significant CAD(>=50% stenosis in one or more epicardial arteries). At the baseline visit, 226 (48%) of 469 postmenopausal women indicated that they were on HRT during the previous three months. Women also reported psychological state with the Beck Depression Inventory (BDI)and the Cook Medley Scales. Higher scores on the BDI indicate more symptoms of depression, while higher scores on the Cook Medley indicate more hostility.
Results: Users of HRT were younger than non-users (60 yrs. vs. 64 yrs. respectively, p<0.001)and were more educated (55% vs.45%> high school). While among white women HRT use was associated with better psychological health, this effect was not apparent among black HRT users. BDI scores for white HRT users were 9.4 ± 7.8 vs. 10.6 ± 8.2 for non-users,(p=0.006, ajdusted for both age and education). Among black women, BDI scores were 13.0 ±8.2 for HRT users and 11.7 ± 8.0 for non-users, p=NS). Similar trends were noted for the Cook Medley Scores. Cook Medley Aggression scores were higher for non-users 2.9 ± 1.7 vs. 2.6 ±1.7 among white women (p< 0.001), but not black women. The Cook Medley scores for black women who used HRT were 3.2 ± 1.9 vs. 3.0 ± 1.7 for non-users (p=NS). Further adjustment of differences by angiographic findings (e.g. significant CAD)did not affect these associations.
Conclusion: In this cohort of women undergoing angiography for suspected ischemia, there are ethnic differences in the relationship between HRT use and psychological state. Within the white but not the black HRT users, there are fewer symptoms of depression and lower aggression scores than among the non-users.

1401 Sleep complaints increase the risk for recurrent events in middle-aged women with coronary disease. The Stockholm female coronary risk study

C. Leineweber, K. Orth-Gomer. *Karolinska Institute, Public Health Sciences, Stockholm, Sweden*

Objective: Sleep disturbances have been found to increase coronary risk. Female coronary patients below the age of 70 have poorer prognosis compared to their male counterparts and women in general have more sleep problems than men. We examined the impact of sleep complaints on prognosis, taking into account both standard risk factors and depressive symptoms.
Methods: All female patients aged 65 or under who were admitted with an acute coronary syndrome between 1991 and 1994 in Stockholm, were followed for five years for recurrent coronary events (n=292). Sleep complaints and depression were measured at baseline using standardized questionnaires. The sleep questionnaire, which was answered by 283 women, assessed quality of sleep, restorative function of sleep and snoring.
Results: Poor sleep quality was associated with recurrent events including cardiovascular mortality, acute myocardial infarction and revascularization procedures. Adjusting for age, hypertension, diagnosis at index event, diabetes, body mass index, symptoms of heart failure, HDL-cholesterol, triglycerides, smoking and education, the hazard ratio for women with poor (upper quartile) as compared to good (lower quartile) sleep quality was 2.5 (95% CI: 1.2-5.2). Women who did not wake up refreshed, had a significantly higher multivariable risk of a recurrent events (HR=2.4; 95% CI: 1.2-4.6). We previously found a poorer prognosis in women with depressive symptoms (HR=1.9; 1.1-3,6). Women with both depression and poor sleep quality had 66% (95% CI: 59%-73%) event free survival compared to 83% (95% CI: 69%-97%) in women without any of these complaints (HR=2.7; 95% CI 1.1-7.1). Heavy snoring was not related to depression or to prognosis.
Conclusions: Our results indicate that poor sleep and not waking up refreshed predict poor prognosis in female coronary patients. The prediction was somewhat further strengthened by depressive symptoms.

1402 The impact of an implantable cardioverter defibrillator: the Leiden follow-up study of ICD patients and their partners

N.M.S de Groot, L. van Erven, M.J. Schalij, E.E. van der Wall. *Leiden University Medical Center, Cardiology, Leiden, Netherlands*

Being a recipient of an implantable cardioverter defibrillator (ICD) might have considerable psychosocial consequences. This study therefore evaluated 1) the presence of psychosocial problems in ICD pts and 2) the relation between psychosocial problems and various clinical variables.
Methods Standardised questionnaires (also containing specific ICD related questions) were sent to 220 ICD pts. Chi-square tests were used for data analysis.
Results Sixty-eight percent of the ICD patients (123 male (81%), 59±12 yr.) and 62% of the partners (28 male (21%), 58±11 yr.) returned the questionnaires. Anxiety, depression or nervousness was reported by respectively 49%, 30% and 52% of the patients and by 36%, 24% and 66% of the partners. In patients, mental health problems were strongly associated with a lower left ventricular ejection fraction (p=0.006), younger age (p=0.029), employment (p=0.011), experience of ICD discharges (p=0.032), previous myocardial infarction (p=0.019) and a higher NYHA functional class (p=0.05). Use of psychiatric medication was related with female gender (p=0.014), experience of ICD discharges (p=0.044), older age (p=0.02), marital status (p=0.024) and co-morbidity (p=0.019).
In partners, nervousness was associated with previous myocardial infarction of ICD patients (p=0.049); the use of sedatives was associated with older age (p=0.017). Sixty percent of the partners had a need for counseling or support groups.
Conclusion: Psychosocial problems are present in ICD patients and their partners and are associated with a number of clinical variables. A specific ICD-rehabilitation program should therefore be available for both ICD patients and their partners.

1403 Working status after CABG and stented angioplasty: results from the ARTS study

W.K. Lindeboom[1], B.A. van Hout[2], P.W.S Serruys[3], F. Unger[4], Y. Taeymans[5], G. van Nooten[5], M. Pieper[6], D. Maass[6]. [1]Cardialysis, Statistical Department, Rotterdam, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands; [3]Academic Hospital Dijkzigt, Thoraxcentre, Rotterdam, Netherlands; [4]Klinik für Herzchirurgie, Salzburg, Austria; [5]University Hospital Gent, Gent, Belgium; [6]Herzzentrum Bodensee, Leipzig, Switzerland

Background: The ARTS trial was a randomized clinical trial comparing bypass surgery with stented angioplasty. The results indicate that there are no differences in the incidence of death, MI and stroke but that stenting is associated with more repeat re-vascularizations. Despite these additional re-vascularizations stenting may still be associated with less medical costs. This present study aims to analyze the indirect non-medical costs associated with these different treatment strategies.
Method: To assess the working status of the patients, we reviewed information from the CRF for those patients below the age of 62 who were economically active at the time of procedure. A 'working' status variable was constructed, containing 5 levels; working, at home, in hospital, stopped working and dead. For each patient included the number of days spent in each 'status-value' was calculated. Analysis of variance for repeated measurements was used to assess the differences by treatment arm over time.
Results: Due to the difference in type of treatments, time spent in hospital and time at home are significantly higher in the CABG arm of the trial. The differences maybe translated into a cost of EUR 10,000 when valuing the days missed from work at a per diem of EUR 200 per day. All differences are concentrated during the first 6 months. The additional working days missed during follow-up in relationship to repeat procedures do not outweigh the differences in the first months.

	Mean days Stenting	Mean days Bypass	P-value
Death	15	26	0.393
Permanently stopped working	201	200	0.962
Time in hospital	8	12	0.0007
At home (temporarily not working)	95	140	0.0014
Working	780	722	0.169

Conclusion: The difference in working status, especially in terms of days worked, manifests itself in the first 6 months after the procedure. After 6 months, no significant differences are found and potential differences due to more repeat re-vascularizations do not outweigh the savings from the first six months.

MODULATION OF ATHEROSCLEROTIC PLAQUE INFLAMMATION

1412 The effects of azithromycin on soluble cell adhesion molecules and markers of inflammation: A randomized double blind placebo controlled study

G.S. Hillis[1], C. Pearson[2], P. Dawson[3], D. Stirling[3], C.A. Ludlam[3], K.A.A. Fox[4], A.D. Flapan[2]. [1]Mayo Clinic, Division of Cardiovascular Diseases, Rochester, United States of America; [2]Royal Infirmary of Edinburgh, Department of Cardiology, Edinburgh; [3]Department of Haematology, [4]Department of Cardiovascular Medicine, University of Edinburgh, Edinburgh, United Kingdom

Background: Chlamydia pneumoniae (CP) infection has been implicated in the pathogenesis of atherosclerosis and the acute coronary syndromes (ACS). Macrolide antibiotics may reduce adverse events in survivors of an ACS, but the data are conflicting and the mechanisms unclear. One potential explanation is that macrolides reduce CP mediated activation of vascular endothelium, thereby reducing plaque instability. To test this hypothesis, the current study assessed the effects of azithromycin (AZ) on markers of endothelial cell activation (soluble cell adhesion molecules; sCAMs) and other inflammatory markers, in survivors of an ACS.
Methods: One hundred and forty one consecutive survivors of an ACS were studied 8 months after their index event. All had stable cardiac symptoms for at least 3 months prior to commencing the study. Patients were excluded if they had conditions known to affect levels of sCAMs +/or markers of inflammation. They were randomized to receive AZ 500mg daily for 5 days (n = 72) or matched placebo (n = 69). Neither patients nor investigators were aware of their treatment. Levels of soluble intercellular adhesion molecule-1 (sICAM-1), soluble vascular cell adhesion molecule-1, soluble E-selectin, high-sensitivity C-reactive protein and interleukin-6 were assayed at baseline and 3 months later, along with CP titres (IgA and G). Baseline levels of sCAMs and inflammatory markers were correlated with clinical risk factors, CP titres and each other. Temporal changes in levels in active and placebo treated groups were compared using analysis of co-variance.
Results: Levels of sCAMs and inflammatory markers were significantly correlated with each other and with conventional risk factors but were unrelated to baseline CP titres. Mean levels of sICAM-1 fell in both placebo (baseline 304±10ng/ml, 3 month 290±9ng/ml) and AZ treated (baseline 307±11ng/ml, 3 month 277±10ng/ml) patients during the study period, but this was more marked in the group who received active treatment (adjusted difference in means 19.4; 95% CI 3.9 - 34.9: P = 0.01). AZ treatment had no significant effect on levels of other sCAMs and inflammatory markers.
Conclusion: Among survivors of an ACS, CP seropositivity is not associated with higher levels of sCAMs or other inflammatory markers. AZ reduces sICAM-1 levels but not other sCAMs or inflammatory markers. It is not, however, clear that the modest effect demonstrated would be of clinical relevance. Further study is required to explain these data, to determine the effects of prolonged therapy and to assess any impact of AZ on leukocyte activation

1413 Interleukin-10 production is decreased in activated monocytes from patients with acute coronary syndromes

P.L. van Haelst[1], B. Langeveld[1], J. Bijzet[2], C. Balje-Volkers[1], J.F. May[1], J.W. Cohen Tervaert[3], R.O. Gans[4]. [1]Cardiology Dept., [2]Clinical Immunology, University Hospital Groningen, Groningen, Netherlands; [3]University Hospital Maastricht, Clinical Immunology, Maastricht, Netherlands; [4]University Hospital Groningen, Internal Medicine, Groningen, Netherlands

Objectives To investigate if activated monocytes in acute coronary syndromes (ACS) produce different amounts of cytokines that are known to affect the Th1/Th2 balance.
Background ACS are associated with enhanced monocyte activation. Monocyte activation in ACS is supposedly the result of the action of pro-inflammatory (Th1-type) cytokines. However, not much is known about the role of anti-inflammatory (Th2-type) cytokines.
Methods C-reactive protein (CRP) and neopterin levels were measured in 22 patients with acute coronary syndromes, 50 patients with stable vascular disease and 22 healthy controls. In addition, levels of TNF-alpha and Il-10 were determined after repectively 6 hours and 24 hours of incubation of full blood with lipopolysaccharide (LPS, 50 μg/mL).
Results As expected, CRP (median, interquartile range (IQR)) (1.5 mg/L(0.8-4.5) vs. 2.1(0.9-3.6) vs. 0.4(0.3-1.2)) ($p<0.001$) and neopterin (7.4 nmol/L(6.0-8.7) vs. 7.1(6.0-8.9) vs. 6.4(5.6-7.3)) (p=0.07) were higher in patients with atherosclerosis than in controls. IL-10 production after LPS stimulation was greatly reduced in patients with acute coronary syndromes (16,175 pg/ml, 7,559-28,470 pg/ml) as opposed to patients with stable atherosclerosis (28,379 pg/ml, 12,601-73,968 pg/ml) and healthy controls (63,830 pg/ml, 22,040-168,000 pg/ml) (p=0.003). Levels of TNF-alpha were not different (7,313 pg/ml(4,740-12,615) versus 11,002(5,913-14,190) versus 8,229(5,225-11,364) (p=0.24).
Conclusions Inflammation in unstable atherosclerosis is associated with monocyte activation and a reduced production of IL-10. We hypothesize that, in unstable coronary syndromes, the production of Th1 cytokines that are responsible for the activation of monocytes/macrophages is not counterbalanced by anti-inflammatory cytokines such as IL-10, thus favoring inflammation and thrombosis.

1414 Cytokine mRNA expression is significantly increased in diseased vein grafts specimen compared to native veins or coronary artery disease

J.F. Christiansen[1], D. Hartwig[2], F.M. Bechtel[1], H. Klueter[3], H.H. Sievers[1], C. Bartels[1]. [1]Cardiac Surgery, [2]Institute of Immunology, University of Lübeck, Lübeck, Germany; [3]Institute of Immunology, University of Mannheim, Mannheim, Germany

Background: Elevated cytokines levels in atherosclerotic lesions may contribute to plaque vulnerability with unstable plaque syndromes and subsequent vessel occlusion. To what extent inflammation contributes to vein graft disease is widely unknown. Therefore, the mRNA expression of various cytokines (IL -1, IL -6, IL -8, TNF-a, INF-?) were quantified in diseased vein graft specimen and compared to cytokine mRNA levels in native saphenous veins and atherosclerotic coronary arteries.
Methods and Results: Cytokine mRNA expression was quantified using a real time RT-PCR in the following tissue samples immediately snap frozen during cardiac surgery: native saphenous veins (nSV), coronary arteries with atherosclerotic changes (CAD) and diseased vein grafts (VG).
Diseased vein grafts expressed significantly higher cytokine m RNA levels compared to nSV resp. CAD specimen (Il-1: p= 0.003 resp. p=0.012; IL-6: p=0.009 resp. p=0.0004; IL-8: p= 0.001 resp. p= 0.001; TNF-a: p= 0.017 resp. p= 0.023) No differences regarding INF-? mRNA expression could be detected between the studied tissue specimen.
Conclusion: Cytokine mRNA expression of IL-1, -6, - 8 and TNF-a was significantly increased in diseased vein grafts compared to native saphenous veins and coronary artery disease. Thus vein graft disease seems to have a pronounced inflammatory activity. This finding may implicate new therapeutic strategies for the prevention of the unresolved problem of vein graft disease.

1415 Human Toll like receptor 2 activation results in expression of pro-inflammatory factors associated with plaque vulnerability

A. H. Schoneveld, D.P.V de Kleijn, C. Borst, G. Pasterkamp. *University Medical Center, Cardiology, Utrecht, Netherlands*

Toll Like Receptor-2 (TLR-2) is a member of the Toll like receptor family which is an essential part of the innate immune system. TLR-2 is the specific receptor for the Gram + bacterial cell wall component peptidoglycan (PG). We recently detected PG in human atherosclerotic plaques and observed an association between its presence and plaque vulnerability. We hypothesize that arterial wall cells can be activated by PG through TLR-2 leading to the production of pro-inflammatory factors, favoring plaque instability. Human coronary arteries as well as human vascular smooth muscle cells (VSMC) and primary adventitial fibroblasts (PAF) were analyzed for the expression of TLR-2 and stimulated with PG to study the expression of pro-inflammatory cytokines and chemokines.

Methods: TLR-2 was detected by Western-blot in human coronary arteries and cells. Cultured VSMC (cell-line) and PAF (isolated from fresh human aorta) were stimulated for 6 hours with 15 μg/ml PG. Expression of pro-inflammatory cytokines were detected on mRNA and protein level using a RNAse protection assay and ELISA technique.

Results: Western-blot analyses revealed the presence of TLR-2 in human coronary artery tissue and in cell-lysates from PAF and VSMC. TLR-2 expression did not increase in cells after PG stimulation. Cytokine and chemokine production did increase following PG stimulation, as is depicted in the table.

	VSMC mRNA (OD*mm²)		PAF mRNA (OD*mm²)		PAF protein (ng/ml)	
	PG	control	PG	control	PG	control
IL-1 beta	0,5±0,1	0,4±0,1	12,6±4,5*	2,4±0,4	3,3±0,3 *	1,5±0,1
IL-1 Ra	70,9±19,4*	13,3±9,6	51,0±10,2*	0,13±0,6	0,3±0,1 *	ND
IL-6	50,8±9,8*	12,5±7,8	70,6±9,1*	9,1±2,7		
IL-8	6,7±1,7*	2,2±0,4	21,0±3,6*	0,4±0,3		
MCP-1	1,1±0,1	1,3±0,1	91,6±12,6	4,9±0,9		

Cytokine and chemokine expression in cultured cells after PG stimulation. ND=non detectible; *=P< 0,05 compared with control; n=3

Conclusion: We report, for the first time, the presence of TLR-2 in human coronary arteries and in cells originating from the vascular wall. Our data show that cells in the arterial wall can be activated through TLR-2 to produce pro-inflammatory cytokines/chemokines. Therefore, TLR-2 may be an important mediator in the inflammatory process, leading to plaque vulnerability.

1416 Oestrogen's protective effect against atherogenesis may be mediated by an up-regulation of interleukin-10 production

D. Rachon[1], J. Wieckiewicz[1], L. Hak[1], K. Suchecka-Rachon[2], J. Mysliwska[1]. *[1]Medical University of Gdansk, Department of Histology and Immunology, Gdansk, Poland; [2]Medical University of Gdansk, Dep. of Hypertension and Diabetology, Gdansk, Poland*

The protective role of oestrogen against early development and progression of atherosclerosis is well documented, but the mechanisms responsible for this effect are not well understood. Atherosclerosis has recently been recognized as an inflammatory process and interleukin-10 (IL-10) is a potent anti-inflammatory cytokine with a number of potential effects that could dampen inflammation at sites of vascular wall damage. Thus, we studied the effects of 17beta-oestradiol on IL-10 production by peripheral blood mononuclear cells (PBMC) of postmenopausal women. Forty healthy postmenopausal women, age range 50-65 years, with clinical symptoms of oestrogen deficiency were enrolled in the study. The control group consisted of twenty healthy young women, age range 22-31 years, with regular menses and who were not taking oral contraceptives. The levels of IL-10 in the sera and PBMC culture supernatants were measured using commercially available immunoassay. The effect of 17beta-oestradiol on the spontaneous IL-10 production by PBMC of postmenopausal women was also studied in vitro and in vivo. Thirty out of forty postmenopausal women were given hormonal replacement therapy of 50μg 17beta-oestradiol/day transdermally (Estraderm 50MX, Novartis) and the spontaneous production of IL-10 by the PBMC was analysed after 6 and 12 months of treatment. The postmenopausal women had significantly lower serum levels of IL-10 than the young controls. The spontaneous production of IL-10 by non-stimulated PBMC into the culture supernatants was also significantly lower in the postmenopausal women compared with the young. Our in vitro experiments showed that 17beta-oestradiol at the concentrations of 10-8M up-regulated the spontaneous IL-10 production by PBMC of postmenopausal women. In vivo treatment with 17beta-oestradiol transdermally also enhanced spontaneous IL-10 production by PBMC of postmenopausal women after 12 months of the therapy. Our results indicate that 17beta-oestradiol may enhance IL-10 production by the PBMC of postmenopausal women. We suspect that one of the mechanisms of oestrogen's protective effect against atherogenesis may be mediated by an up-regulation of IL-10 production - a potent anti-inflamatory cytokine with anti-atherogenic properties.

YOUNG INVESTIGATORS' AWARD SESSION (THROMBOSIS)

1432 NFkB and IkB kinase-2 regulate tissue factor and cytokine production in human atherosclerotic plaques: an analysis via adenoviral gene transfer

C. Monaco[1], E. Paleolog[1], N. Cheshire[2], M. Feldmann[1]. *[1]Kennedy Institute of Rheumatology, Imperial College, London, United Kingdom; [2]ST Mary's Hospital, Vascular Surgery, London, United Kingdom*

Background Nuclear translocation of nuclear factor kappa B (NFkB) subunit p65 has been observed in human atherosclerotic plaques. However it is difficult to test in vivo if NFkB activation is necessary for tissue factor (TF) and cytokine production in atherosclerotic plaques, due to the lethality of p65 and I kappa B alpha (IkBa, the inhibitor of NFkB nuclear translocation) knock-out mice. Adenoviral gene transfer can be used to overcome these limitations and dissect intracellular signalling pathways. The aim of our study was to achieve direct evidence of a functional requirement for NFkB and IkB kinase-2 (IKK-2), the main kinase responsible for IkB phosphorylation and degradation, in the regulation of cytokine and TF production in human atherosclerotic plaques.

Methods Atherosclerotic tissue, obtained from aorta, carotid, iliac, femoral and popliteal arteries from patients undergoing revascularisation/repair surgery, was dissociated via enzymatic digestion in order to obtain a single cell suspension, cultured and infected with adenoviral vectors encoding for beta-Galactosidase (Adv-bGal), for IkBa, for the dominant negative (DN) form of IKK-2, or without insert as control. TF antigen was assessed by ELISA on cell lysates. IL-6 and TNFalpha production was assessed via ELISA in culture supernatants.

Results Enzymatic dissociation yielded a viable population of cells, containing lymphocytes (CD3+, range 6-17%), macrophages (CD68+, 40-50%) and smooth muscle cells. Cells remained viable in culture until at least day 5, and showed a constitutive production of TF (2100pg/mL±995 at 24 hours), IL-6 (6049pg/mL±7000) and TNFalpha (800pg/mL±623). Successful infection with Adv-bGal of >90% of cells was achieved at a multiplicity of infection as low as 100:1, as evaluated by FACS analysis. Overexpression of IkBa (as assessed by Western Blot) abolished spontaneous expression of TF, and significantly reduced constitutive production of TNFalpha by 90±16% and IL-6 by 75±17% ($p<0.001$). Similar results were obtained by overexpression of DN IKK-2.

Conclusions Cells freshly isolated from atherosclerotic plaque in culture constitutively produce TF and pro-inflammatory cytokines such as TNFalpha and IL-6. We have established a method of adenoviral gene transfer into these cells resulting in high infectibility rates. Constitutive production of TF and cytokines could be strongly inhibited by adenovirally-mediated NFkB and IKK-2 blockade. Thus, NFkB and IKK-2 appear to be interesting potential therapeutic targets for treatment and prevention of atherosclerosis and its thrombotic complications.

1433 Synthetic peptide-analogues of the GPIIb subunit inhibit fibrinogen binding to the GPIIb/IIIa receptor and platelet activation

J. Mitsios[1], M. Abatzis[1], J.A. Goudevenos[2], M. Sakarellos-Daitsiotis[1], C. Sakarellos[1], D. Tsoukatos[1], V. Tsikaris[1], A.D. Tselepis[1]. [1]*University of Ioannina, Department of Chemistry, Ioannina, Greece;* [2]*University of Ioannina, Department of Cardiology, Ioannina, Greece*

Background and Aim: Upon platelet activation the integrin receptor GPIIb/IIIa, undergoes conformational changes and binds to soluble adhesive ligands, mainly fibrinogen (Fg), leading to platelet aggregation. The GPIIb/IIIa ligands contain the recognition sequence, Arg-Gly-Asp (RGD). RGD containing peptides and non-peptide mimetics are potent inhibitors of GPIIb/IIIa-Fg interactions, however, they maintain the receptor in its high affinity state, enhancing platelet activation, through an outside-in signaling pathway. An alternative approach for inhibiting Fg binding to GPIIb/IIIa, platelet aggregation and further enhancement of platelet activation, is to use peptide analogues of the GPIIb/IIIa binding sites for Fg that could interact with Fg, and inhibit its binding to the receptor.
Methods and Results: Five 20-peptides, overlapping by eight residues, covering the extracellular sequence 289-356 of the GPIIb subunit were synthesized. Their effect on ADP-induced platelet aggregation and ATP secretion was studied. The effect of these peptides on the binding of FITC-labeled Fg (FITC-Fg) to ADP-activated platelets, as well as on the binding of the specific antibody PAC-1 against the activated receptor was also determined by flow cytometry. Among them, the 20-peptide 313-332 (YMESRADRKLAEVGRVYLFL) exhibited the most potent inhibitory effect on platelet aggregation (56% inhibition) and ATP secretion (100% inhibition). Furthermore, the peptide completely inhibited the binding of FITC-Fg on ADP activated platelets, whereas it did not affect the binding of PAC-1. To further investigate the amino acid sequence responsible for this effect, we synthesized several 8-peptide analogues of the above sequence. Our results showed that peptides containing the ESRAD sequence maintained the inhibitory properties exhibited by the original 20-peptide. The RGDS peptide that is known to bind to the receptor inhibited platelet aggregation and ATP secretion, as well as the binding of FITC-Fg and PAC-1.
Conclusions: The 20-peptide analogue 313-332 of the GPIIb subunit inhibits platelet aggregation and secretion possibly interacting with fibrinogen rather than the receptor itself in contrast to RGDS, which inhibits platelet aggregation, interacting with the receptor. This effect is possibly due to the amino acid sequence ESRAD. Such peptides may be useful tools in the further understanding of the interactions between GPIIb/IIIa and Fg, which lead to platelet aggregation and activation, or may be used as potent inhibitors of platelet activation.

1434 The PPAR-gamma agonist rosiglitazone reduces circulating platelet activity in non-diabetic coronary artery disease patients

J S. Sidhu, D. Cowan, J A. Tooze, J C. Kaski on behalf of Cardiological Sciences, St. George's Hospital Medical School. *London, United Kingdom*

Background: Platelet activation plays a key role in atherogenesis, the genesis of atherothrombotic events and the pathogenesis of restenosis after coronary artery stenting. Rosiglitazone, a Peroxisome Proliferator-Activated Receptor-gamma (PPAR-gamma) agonist, is an insulin-sensitising agent and is used in the treatment of type 2 diabetes mellitus. Recent studies suggest that PPAR-gamma agonists may have direct anti-inflammatory and anti-platelet effects, independent of their insulin-sensitising effect. The aim of this study was to assess the effect of rosiglitazone on circulating platelet activity in non-diabetic coronary artery disease patients.
Methods: Ninety-two subjects with stable, documented coronary artery disease and without previously diagnosed type 2 diabetes mellitus were selected. Maintaining their current therapies, patients were randomised in a double-blind manner to placebo (n=46) or rosiglitazone (n=46, 4 mg/day for 8 weeks followed by 8mg/day for 4 weeks) for 12 weeks. Circulating platelet activity was measured at baseline and after 12 weeks using whole blood flow cytometry to quantify the percentage of platelets expressing P-selectin (CD62P). Fasting insulin and glucose were also measured at baseline and at study end. The homeostasis model of insulin resistance index (HOMA-R) was used as a measure of insulin resistance where HOMA-R is calculated as fasting serum insulin * fasting plasma glucose/22.5. One way ANOVA for repeated measurements was used to assess the effect of treatment on measured parameters.
Results: Eighty-four subjects completed the study. The % of P-selectin positive platelets was significantly reduced by rosiglitazone treatment compared with placebo (P = 0.04). In the rosiglitazone group the % of P-selectin positive platelets (median [interquartile range]) decreased from 0.1% [0.05-0.24] to 0.05% [0.01-0.15]. Rosiglitazone treatment also significantly reduced insulin resistance (HOMA-R) compared to placebo (P = 0.023). No significant correlation was observed between change in platelet activity and change in HOMA-R or fasting glucose.
Conclusions: We have shown for the first time that rosiglitazone significantly reduces circulating platelet activity in coronary artery disease patients without diabetes mellitus. This effect appears to be independent of any insulin-sensitising or glucose lowering effect. Further studies are warranted to determine whether this anti-platelet effect translates into clinical benefit, namely a reduction in the risk of atherothrombotic events, in both diabetics and non-diabetics.

1435 Intravenous infusion of a nitric oxide donor inhibits thrombosis triggered by damaged vessel wall at flow conditions of coronary arteries

G. Vilahur, M.I. Baldellou, L. Casani, L. Badimon. *Cardiovascular Research Center, IIBB/CSIC-HSCSP-UAB, Barcelona, Spain*

Background: Impairment of nitric oxide (NO) dependent pathways have deleterious effects in the cardiovascular system because of the multiple processes that are regulated by NO. Compounds that release NO are useful candidates to restore NO-functions in specific pathological situations.
Objective: To study whether donation of NO with a novel platelet-selective NO-donor (LA-810) at a systemic level can inhibit thrombosis elicited by damaged vessel wall (eroded and disrupted vessel wall) at hemodynamic conditions typical of patent and stenotic (60 to 70%) coronary arteries.
Methods: Thrombogenicity was measured at baseline and after intravenous injection of a NO-donor in the porcine experimental model and assesed as platelet-thrombus formation in the ex vivo Badimon perfusion chamber. Animals were anesthetized, heparinized, catheterized and the perfusion chamber was placed in an extracorporeal shunt (carotid artery-jugular vein). After baseline perfusions, pigs were given the iv-infusion of NO donor (6.6 nmols/Kg/min at an infusion rate of 1.25 ml/min) during 2 hours. Platelet deposition was quantified by radioisotopic measurement of deposited platelets. Blood pressure, heart rate and in vitro platelet aggregation were measured during all the experiments.
Results: Platelet deposition was significantly inhibited ($p<0.0005$) on both disrupted and eroded vessels and at shear rates typical both of patent and stenotic coronaries, without significant modifications of blood pressure or heart rates.Platelet aggregation in vitro was also inhibited. Platelet deposition on severely damaged vessels was reduced from $98x10^6$ to $47x10^6$ PTL/cm^2 ($p<0.0001$) at stenotic shear rate and from $54x10^6$ to $28x10^6$ PTL/cm^2 ($p<0.0001$) at patent artery shear rate. Platelet deposition on eroded vessels (mild injury) was reduced from $11x10^6$ to $6x10^6$ PTL/cm^2 ($p<0.0001$)at stenotic shear rate and from $3x10^6$ to $1x10^6$ PTL/cm^2 ($p<0.0001$) at patent artery shear rate.
Conclusions: Donation of NO with a novel NO-donor,that without modifying blood pressure inhibits platelet function, is a highly efficacious antithrombotic strategy at all shear rates and degrees of vascular damage. Therefore, it seems a highly promising strategy to reduce acute thrombosis triggered by coronary artery disease.

1436 Proteolysis of tissue factor pathway Inhibitor-1 by thrombolysis in acute myocardial infarction

B. Steppich[1], V. Malcouvier[1], D. Zieglgänsberger[1], S. Geith[1], F.J. Neumann[2], I. Ott[1]. [1]*Deutsches Herzzentrum München, München, Germany;* [2]*Herzzentrum Bad Grozingen, Kardiologie, Bad Grozingen, Germany*

In acute myocardial infarction (AMI), surface-bound TFPI-1 inhibits an increased monocyte procoagulant activity. In addition, TFPI-1 is released from microvascular endothelial cells after treatment with heparin and thereby contributes to its antithrombotic properties.
We examined 19 patients of a randomized study comparing intravenous fibrinolysis with atleptase (n=9) and revascularization by stent placement (n=10). Before and after therapy we obtained blood samples for analysis of monocytic TFPI-1 surface expression by flow cytometry and plasma TFPI-1 concentrations by immunoassay.
We found a significant decrease in surface TFPI-1 on circulating monocytes 24 hours after thrombolysis (P=0.006) that was not observed after stenting. Systemic plasma TFPI-1 concentrations increased immediately after stenting by 71±14% (P=0.008) whereas after thrombolysis, a decrease in TFPI-1 plasma concentrations by 21±11% was observed (P=0.075). In vitro experiments confirmed that plasmin decreased TFPI-1 surface expression dose-dependently.
Activation of the fibrinolytic system by atleptase in AMI decreases surface-associated TFPI-1 on circulating monocytes and plasma TFPI-1. Reduced TFPI-1 may contribute to thrombotic complications after fibrinolysis in AMI.

CORONARY REVASCULARISATION: NEEDLE OR KNIFE?

1446 Arterial revascularization therapy study: a randomized trial of stenting in multivessel coronary disease versus bypass surgery. 3 year results

V. Legrand[1], P.W.S Serruys[2], F. Unger[3], L. Bilodeau[4], M. Carrier[4], O. Mendiz[5], W.K. Lindeboom[6], P.C. Otto-Terlouw[6] on behalf of the ARTS.
[1]CHU Sart Tilman, Cardiology Department, Liege, Belgium; [2]Academic hospital Dijkzigt, Thoraxcentre, Rotterdam, Netherlands; [3]Klinik für Herzchirurgie, Salzburg, Austria; [4]Montreal Heart Institute, Montreal, Canada; [5]Fundacion Favaloro, Buenos Aires, Argentina; [6]Cardialysis, Rotterdam, Netherlands

Background: The ARTS study showed that, after 1 year, CABG was 14% more effective but also EUR 3,000 per patient more costly, suggesting that stenting may be preferred over CABG in patients for whom both treatments seem appropriate.
Methods: Twelve hundred and five patients were randomly assigned to bypass surgery or stent implantation when there was consensus between the cardiac surgeon and interventional cardiologist on equivalent 'treatability'. The primary clinical endpoint was freedom from major adverse cardiac and cerebrovascular events at one year. Major adverse cardiac and cerebrovascular events at 3 years constitute a secondary endpoint. Cost is expressed as resource use multiplied by unit costs. Effectiveness is expressed as freedom of Major Adverse Cardiac and Cerebrovascular events. Cost effectiveness is the ratio of both parameters, the difference in cost and effect were evaluated.
Results: At three years 95.5% of the surgical group and 96.3% of the stented patients were alive (p=0.56). Eighty eight (88.8) % of the surgical and 87.0% of the stented patients were free of death, stroke and myocardial infarction (P=0.38). Among patients who survived without stroke or myocardial infarction, 21.3% underwent a second revascularization in the stent group, as compared with 5.1% in the surgical group. At three years 83.6% of the surgical and 65.7% of the stented patients were event-free survivors (P <0.001). At three years 87.0% in the surgical cohort and 81.6% in the stent group were angina free. In patients with diabetes 81.3% in the surgical group and 52.7% in the stented patients were free of any events after three years (P <0.001). The ARTS study showed that, after 3 years, CABG was 18% more effective but also EUR 2,268 per patient more costly, resulting in an incremental cost effectiveness ratio of EUR 9,996.
Conclusion: The difference in the rate of revascularization between the two groups was 15% at 2 years and is 18% at 3 years. At three years the percutaneous treatment is no longer more cost effective than the surgical treatment.

1447 De novo proximal–mid-LAD lesions: a comparison of minimal invasive direct coronary artery bypass (MIDCAB) with coronary artery stenting

G. Dangas[1], F. Kuepper[2], I. Iakovou[2], D.T. Ashby[2], G.W. Stone[1], S. Stamou[3], M.B. Leon[1], R. Mehran[1]. *[1]Lenox Hill Hospital, Interventional Cardiology, New York, NY, United States of America; [2]Cardiovascular Research Foundation, New York, NY, United States of America; [3]Washigton Hospital Center, Cardiac Surgery, Washington, DC, United States of America*

Background: MIDCAB and coronary artery stenting are established methods of treatment for isolated lesions of the left anterior descending artery (LAD). We compared the two methods in a matched patient population in a single center setting.
Methods: We evaluated the in-hospital and one-year results in 119 consecutive patients who underwent MIDCAB to 441 consecutive patients undergoing coronary stenting in isolated proximal and mid LAD lesions. We excluded patients with acute MI, shock, and severe heart failure.
Results: In-hospital complications were similar between MIDCAB and stenting; but surgery had longer length of hospital stay. At one-year follow-up, MACE and target vessel revascularization (TVR) were higher in the stent group, whereas 1-year mortality was similar in both groups.

In-hospital and 1-year clinical outcome

	MIDCAB	Stent	P value
IH-death	0.0%	0.9%	0.6
IH QWMI	0.0%	0.5%	1.0
IH non-QWMI	9.2%	10.7%	0.7
IH MACE	0.8%	1.4%	1.0
IH stroke	0%	0.5	1.0
Hospital length of stay (days)	8.8 ± 3.3	3.0 ± 3.7	0.06
ICU length of stay (days)	1.1 ± 0.7	0.2 ± 1	<0.0001
1-year death	3.1%	3.4%	1.0
1-year MI	0.0%	2.3%	0.21
1-year TVR	7.2%	16.8%	0.01
1-year MACE	3.1%	18.4%	0.0005

Conclusions: MIDCAB and coronary artery stenting have very similar in-hospital and death and MI rates. MIDCAB requires longer hospitalization, but has less TVR and MACE at 1-year than the current stent designs. However, 1-year mortality of stenting is similar to MIDCAB.

1448 Primary stenting or ACAB? Early results of comparison the two methods of treatment of single LAD disease

A. Gerber[1], J. Drzewiecki[2], M. Cisowski[3], A. Bochenek[3]. *[1]Katowice, Poland; [2]Silesian University School of Medicine, Ist Department of Cardiology, Katowice, Poland; [3]Silesian University Medical School, Ist Department of Cardiosurgery, Katowice, Poland*

100 patients aged 25-76(mean age 52),with anginal symptoms of at least CCS II, and angiographically proved critical stenosis of proximal segment of LAD, were randomised to primary, direct stenting (DS, 50 patients, group I), or atraumatic, coronary artery bypass grafting, by the use of thoracoscopic harvested left internal mammary artery (ACAB, 50 patients, group II).
Coronary artery risk factors, mean age, left ventricle ejection fraction, type of lesion and degree of LAD stenosis were comparable in both groups.
Optimal angiographic and clinical result was obtained in group I, with no in-hospital complications, and no adverse events in one month follow-up period. 6-months follow-up comprised 40 patients, whose anginal and angiographic status was evaluated, resulting in 15% rate (6 patients) of restenosis, that was treated with PTCA.
In group II, we achieved a very good effect, with no relevant complications during in-hospital and 1-month follow-up period. From 40 patients, whose clinical status was assesed in 6-months follow-up, non symptomatic critical stenosis of LIMA-LAD anastamosis was observed only in 1 case (2,5%) –PTCA of the graft was performed.
One-year clinical follow-up included 22 patients of group I, mean anginal status was CCI I, stress test was negative in 19 patients, positive in 3 patients (13,6%), who required target vessel revascularisation procedures. One death was noted due to disseminated neoplasmatic disease. During one –year follow-up of 22 patients from group II, only one patient (4,7%) had aggraviation of anginal status, a control angiography revealed coronary artery disease progression, (PTCA of RCA was performed). Other patients from group II had no angina in one-year follow-up.
Conclusions: early results show a definitive prevalence of cardiosurgical treatment (ACAB), upon direct primary stenting of LAD critical stenosis, with only slightly higher cost of surgical procedure.

1449 Assessment of left ventricular function in patients 1 year after randomisation to coronary artery bypass graft surgery or stent percutaneous coronary intervention in the SoS trial

G. Koutroulis[1], M. Ritsou[2], J. Booth[3], T. Clayton[4], R. Stables[5], F. Nugara[3], P. Nihoyannopoulos[2]. *[1]Hammersmith Hospital, Cardiology Dept., London, United Kingdom; [2]Hammersmith Hospital, NHLI, ICSM, Department of Cardiology, London, United Kingdom; [3]Royal Brompton & Harefield NHS Trust, Clinical Trials & Evaluation Unit, London, United Kingdom; [4]LSHTM, Medical Statistics Unit, London, United Kingdom; [5]Royal Liverpool University Hospital, Cardiothoracic Centre and, Liverpool, United Kingdom*

Background In the Stent or Surgery study (SoS), patients were prospectively randomised to CABG (500) and PCI (488) with stent implantation aiming for optimal revascularisation. We hypothesised that LV function at 1 year post - procedure will be the same, regardless the initial treatment allocation.
Methods: Global LV function was assessed by ejection fraction (EF) (modified Simpson's rule), and regional LV function by the wall motion score Index (WMSI) (ASE), using echocardiography. Echocardiographic studies were analysed blindly at a core laboratory. Primary outcome was a comparison of WMSI and EF at one year between the two groups.
Results Of the 988 patients randomised, 972 (98.4%) were alive at one year. In the surviving patients 764 (79%) had available WMSI calculations and 515 (53%) had EF measured at one year. The WMSI in the CABG group (n=383) was 1.3 (SE 0.2), compared with 1.2 (SE 0.2) in PCI group (n=381), P=0.48). The EF in the CABG group (n=245) was 54.8 (SE 0.6), compared with 55.3 (SE 0.6) in PCI group (n=270), difference =0.5, 95% CI -1.1 to 2.1, P=0.55. Compared with the pre procedural values both groups showed a similar change in WMSI and EF. The WMSI was greater at 12 months: CABG group 1.19 versus 1.27, (mean difference 0.08, 95% CI 0.04 to 0.11, p<0.001), PCI group 1.19 versus 1.26 (mean difference 0.07, 95% CI 0.03 to 0.10). EF was lower in both groups: CABG group 57.5 versus 54.9, (mean difference -2.7, 95% CI -4.0 to -1.4, p<0.001), in the PCI group 56.7 versus 54.9 (mean difference -1.9, 95% CI -2.9 to -0.8, p=0.001).
Conclusions In the SoS study at one year there was no difference in LV function in patients treated with PCI or CABG. At one year there has been a minor decline in global and regional function which may be attributable to the occurrence of myocardial infarction and other factors affecting cardiac function.

1450 Fractional flow reserve to select optimum treatment in multivessel disease: beyond ARTS

N. Pijls. *Catharina Hospital, Cardiology, Eindhoven, Netherlands*

Background: In multivessel disease, it is controversial if complete revascularization by bypass surgery (CABG) is superior to PTCA of the culprit lesion(s) only. Fractional flow reserve (FFR, calculated from coronary pressure measurement) is a reliable index to identify whether a stenosis is culprit (i.e. functionally significant). Aim of the present study was to compare selective PTCA of culprit lesions only (FFR less than 0.75) to CABG of all stenoses.
Methods: In 150 patients with ARTS-like characteristics, referred for CABG, FFR was determined in 378 coronary arteries considered for bypass grafting. If FFR was less than 0.75 in 3 or more stenoses or in 2 type C lesions, CABG was performed (CABG-group). If only 1 or 2 lesions (not both type C) were culprit, PTCA and stenting of those lesions was performed (PTCA-group).
Results: Out of 150 patients, 86 classified for CABG-group and 64 for PTCA. Both groups had complete similar angiographic and other baseline characteristics. At 2-year follow-up, no differences were seen in adverse events (event free survival 74% in CABG-group and 72% in PTCA-group) and a similar number of patents were free from angina (76% in the CABG-group and 77% in the PTCA-group). Importantly, the results in both groups were as good as the surgery group in the ARTS-study.
Conclusion: In patients with multivessel disease, PTCA of culprit lesion(s)only, as identified by FFR below 0.75, yields a similar 2-year outcome as bypass surgery.

1451 Minimally invasive CABG versus PTCA with stenting in isolated high-grade stenosis of the proximal LAD

J. Winter[1], D.J. Drenth[2], N.J.G.M. Veeger[3], S.H.J. Monnink[3], A.J. Van Boven[3], J.G. Grandjean[2], M.A. Mariani[2]. *[1]University Hospital Groningen, Cardiology, Groningen, Netherlands; [2]Thoraxcentre, Cardiothoracic Surgery, Groningen, Netherlands; [3]Thoraxcentre, Cardiology, Groningen, Netherlands*

Purpose: To compare minimallly invasive direct coronary artery bypass grafting (surgery) with percutateous transluminal coronary angioplasty with primary stenting (stenting) in patients with an isolated high grade stenosis (ACC/AHA classification type B2 or C) of the proximal left anterior descending artery (LAD). At 6 months both procedures are compared in a single centre prospective, randomized study with angiographic and clinical follow-up.
Methods: Patients with stable angina pectoris due to an isolated high grade stenosis of the proximal LAD were randomly assigned to surgery (n=51) or stenting (n=51).
Results: Periprocedural events did not significantly differ between surgery and stenting. At 6 months quantitative coronary angiography showed a patency rate of 96% after surgery and 71% after stenting ($p<0.001$). After 6 months no significant difference was found for major adverse cardiac or cerebral events (MACCE) and need for repeat target revascularisation between surgery and stenting. After 6 months return of angina pectoris and physical work capacity did not significantly differ between both procedures. However, use of antianginal drugs was significantly higher after stenting (<0.01).
Conclusion: This is the first prospective, randomized study that shows that in patients with a high grade stenosis of the proximal LAD, minimally invasive direct coronary artery bypass grafting (MID-CABG) has a significantly better patency rate and a lower need for antianginal medication, than percutaneous transluminal angioplasty (PTCA) with stenting after 6 months follow-up.

DRUG ELUTING STENTS: ARE THEY STILL HOLDING THEIR PROMISE?

1452 365-day follow-up of the RAVEL study: a randomized study with the sirolimus-eluting bx velocityTM balloon-expandable stent

A. Colombo[1], J. Fajadet[2], G. Schuler[3], P. Barragan[4], C. Bode[5], J.E. Sousa[6], M.C. Morice[7], P.W. Serruys[8] on behalf of the RAVEL Investigators. *[1]Centro Cuore Columbus, Cardiology, Milan, Italy; [2]Clinique Pasteur, Toulose, France; [3]Herzzentrum GmbH, Liepzig, Germany; [4]Clinique Beauregard, Mareseille, France; [5]Albert-Ludwigs Universitatskliniken, Freiburg, Germany; [6]Institute Dante Pazzanese of Cardiology, San Paolo, Brazil; [7]Institut Cardiovasculaire Paris Sud, Massy, France; [8]Torax Center, Rotterdam, The Netherlands*

Background: The RAVEL is a multicenter, double-blind, randomized study with a two-arm design assessing safety and effectiveness of the Sirolimus-eluting Bx VelocityTM stent versus the uncoated metal Bx VelocityTM stent (18 mm).
Methods: The primary endpoint was angiographic late loss at 6 months. The secondary endpoints were major adverse cardiac events (MACE), target vessel revascularization, target lesion (TL) revascularization, restenosis rate. Inclusion criteria: patients with stable or unstable angina with single treatment of de novo lesions, < 18 mm in length, 2.5-3.5 mm in diameter.
Results: Between August 2000 and December 2000, 238 patients were included in 19 sites in Europe and South America. Baseline demographics and lesion characteristics were equally distributed. After a loading dose, Clopidogrel or Ticlopidine was continued up to 8 weeks. No acute, subacute or late thrombosis occurred. During a follow-up to 1 year, the overall rates of rank-ordered MACE were 5.8 percent in the actively treated group versus 28.8 percent in the control group ($p<0.001$) (table).

	Sirolimus		Control	
	210 days	365 days	210 days	365 days
Death	0	2 (1.67%)	2 (1.69%)	2 (1.69%)
Q-wave MI	2 (1.67%)	2 (1.67%)	0	0
Non Q MI	1 (0.83%)	2 (1.67%)	3 (2.54%)	4 (3.39%)
TL CABG	1 (0.83%)	1 (0.83%)	1 (0.85%)	1 (0.85%)
TL PTCA	0	0	26 (0.85%)	27 (22.88%)
Any MACE	4 (3.33%)	7 (5.83%)	32 (27.2%)	34 (28.8%)

Conclusions: The cumulative event-free survival is 94.0% in the Sirolimus group versus 70.7% in the control group ($p<0.001$).

1453 The U.S. multicenter, randomized, double-blind study of the sirolimus-eluting stent in coronary lesions: safety outcomes at 9 months

J.W. Moses[1], C. O'Shaughnessy[2], R. Caputo[3], D. Kereiakes[4], C. Brown[5], D. Williams[6], R.E. Kuntz[7], M.B. Leon[8] on behalf of The SIRIUS Investigators. *[1]Heart and Vascular Institute, Lenox Hill, New York City, New York, United States of America; [2]North Ohio Heart Center, Elryia, Ohio, United States of America; [3]St. Joseph's Hospital, Syracuse, New York, United States of America; [4]The Christ Hospital, Cincinnati, Ohio, United States of America; [5]Fuqua Heart Center, Atlanta, Georgia, United States of America; [6]Rhode Island Hospital, Providence, Rhode Island, United States of America; [7]Harvard Clinical Research Institute, Boston, Massachussets, United States of America; [8]Lenox Hill Heart & Vascular Institute, Cardiovascular Research Foundation, New York City, United States of America*

SIRIUS is the U.S. multicenter (53 investigational sites), randomized, double-blind study examining the safety and efficacy of the Sirolimus-eluting coronary CYPHER stent (140mcg sirolimus/cm^2, slow-release) vs. placebo (conventional, bare metal VelocityTM coronary stent) in 1,101 patients (550 pts per arm) in de novo native coronary lesions. Single vessel treatment of "higher risk" lesions – 2.5-3.5mm diameter and 15-30mm length – is required. Antiplatelet regimen consists of ASA + Plavix (for 12 weeks). The primary endpoint is target vessel failure at 9 months (cardiac death, MI, or target vessel revascularization). Repeat angiography at 8 months (first 850 pts) and intravascular ultrasound substudy are secondary endpoints. Patients enrollment was complete in August 2001.
There were no differences in baseline demographic characteristics between the 2 groups. Diabetic patients contributed to 26.5% of all randomized patients. Patient demographics, lesion characteristics, and acute procedural angiographic and clinical results were similar between the two groups. Major adverse cardiac events, (MACE: Death, MI, Target vessel revascularization) at 30-days are presented in the table. No cases of acute stent thrombosis were reported at 180 days of follow-up. There were 2 cases of subacute stent thrombosis and one late thrombosis in all randomized patients.

MACE at 30-days

	Group A (n=522)	Group B (n=535)
Death (%)	0	0.2
CABG (%)	0	0
Q-wave MI (%)	0	0.4
Non-Q wave MI (%)	2.1	2.1
Repeat PCI (%)	0	0
30-days MACE (%)	2.1	2.8

CABG = coronary artery bypass grafting; PCI = percutaneous coronary interventions

Conclusion: The SIRIUS study represents a higher risk study cohort than RAVEL. The incidence of stent thrombosis seems to be low at 180-days of follow-up. Fully adjudicated rates of stent thrombosis (acute, subacute and late), death and MI at 9 months for the entire study cohort will be available for presentation.

1454 A European multi-centre, randomised, double-blind study of the sirolimus-eluting stent in patients with de novo coronary artery lesions

J. Schofer[1], G. Breithardt[2], R.E. Kuntz[3], J.J. Popma[3] on behalf of the E-SIRIUS investigators. [1]*Center for Cardiology, Hamburg, Germany;* [2]*University Hospital, Dept. Clin. Cardiology and Angiology, Münster, Germany;* [3]*Brigham & Women's Hospital, Boston, United States of America*

Background: Long-term results after coronary stenting are limited by excessive neointimal hyperplasia resulting in restenosis and repeat revascularization. Sirolimus (rapamycin), a macrolytic immunosuppressant with cytostatic and anti-inflammatory actions, incorporated within a non-reactive polymer coating has been shown to reduce neointimal hyperplasia in pre-clinical and clinical research.
Methods: The E-SIRIUS study is a multi-centre (35 investigational sites in Europe) randomised, double-blind trial examining the safety and efficacy of the sirolimus-eluting stent vs. a control (uncoated) stent in 350 patients (175 patients per study arm) with de novo native coronary artery lesions >= 15 and <= 32 mm in length and >= 2.50 mm to <= 3.0 mm in diameter (by visual estimate). Antiplatelet regimen is 60 days of clopidogrel with long term ASA. The primary endpoint is in-stent minimum lumen diameter (MLD) at 8-month follow-up. Secondary endpoints will be assessed as composite Major Adverse Cardiac Events at 30 days, 6, 9, and 12 months, and 2, 3, 4 and 5 years post-procedure. Other secondary endpoints include angiographic binary restenosis (>= 50% diameter stenosis) at 8 months post-procedure. The secondary objective is to assess cost-effectiveness expressed in incremental cost/life years gained or cost/quality adjusted life year gained at different time points (8 months, 1 year, 3 and 5 years).
Results: Thus far (as of February 1, 2002), 339 patients have been enrolled in the study as per protocol.
Conclusions: A multi-centre, European, randomised, double-blind trial to determine the safety and effectiveness of the sirolimus-eluting stent in de novo native coronary artery lesions (E-SIRIUS) is underway. Thirty-day results from the enrolled patient cohort focusing on safety issues will be available for presentation.

1455 Study of anti-restenosis with the biodivysio dexamethasone eluting stent (STRIDE) – a multicenter trial

X.S Liu[1], C. Hanet[2], M. Vandormael[3], V. Legrand[4], Y.M Huang[1], I. De Scheerder[1] on behalf of On behalf of the STRIDE investigators. [1]*University Hospitals Leuven, Cardiology, Leuven, Belgium;* [2]*Cliniques Universitaires St Luc, Cardiology, Bruxelles, Belgium;* [3]*Clinique St Jean, Cardiologie, Bruxelles, Belgium;* [4]*CHU Sart Tilman, Cardiology, Liege, Belgium*

Background: Drug eluting stents have been proposed as an alternative approach to prevent in-stent restenosis. Pre-clinical work showed a reduced intimal hyperplasia in a porcine model using the Biodivysio Drug Delivery Phosphorylcholine coated stent loaded with a high dose dexamethasone (DEX). The aim of this study is to evaluate the acute safety and efficacy of the Biodivysio DEX eluting stent implanted in patients with de novo single vessel disease.
Methods: In this multicenter trial, 71 patients, 79% were male, average age 61.9 (range 42 - 82) from 8 study sites were included. Risk facters: 63% had hypercholesterolaemia, 56% had hypertension, 42% had a previous MI, 46% had two or more than two vessel diseases, 31% had lesion type B2 or C, 28% had unstable angina pectoris. One 11 mm, 15mm or 18mm long Biodivysio DD PC stent was immersed in a 15 mg/ml DEX solution, yielding a total DEX dose of 45 μg per mm stent before implantation. Minimal lumen diameter (MLD) and % diameter stenosis (DS) were measured before, immediately after stenting and at 6-month (m) follow-up (f-up). The primary endpoint of the study is 6m angiographic restenosis rate. The secondary endpoints are 30 days and 6m major adverse cardiac events (MACE) defined as death, MI, CABG & target vessel revascularization.
Results: All the stent implantations were successful. Five pts were excluded from further analysis because of obvious protocol violations. Per protocol MACE at 6m: 2 pts had recurrence of symptoms, due to a study stent related restenoses (2.8%). QCA: mean reference diameter: 2.95±0.52 mm, MLD-pre: 1.03±0.35 mm, % DS-pre: 64.75±11.81% and MLD and % DS after stent implantation was 2.47±0.46 mm and 15.47±7.17% respectively. MLD at 6M follow-up: 1.99±0.61, % DS stenosis: 32.39±15%, Late Loss: 0.48mm. Late loss was lower in the unstable angina pectoris group compared to the stable patients
Conclusion: These results show that implantation of a Biodivysio Dexamethasone eluting stent is feasible and safe. Compared to other studies, using a non drug loaded Biodivysio PC coated stent, the late loss was significantly lower, suggesting a beneficial effect on in-stent neointimal hyperplasia. This beneficial effect on late loss was more pronounced in the unstable patient group.

1456 Heparin-coated stents in small coronary arteries – Results of the COAST trial

M. Haude[1], T. Konorza[1], U. Kalnins[2], D. Glogar[3], E. Grube[4], R. Gil[5], A. Serra[6], R. Erbel[1] on behalf of the COAST investigators. [1]*University Essen, Cardiology Department, Essen, Germany;* [2]*P. Stradins Hospital, Latvian Center of Cardiology, Riga, Latvia;* [3]*AKH Wien, Cardiology Department, Vienna, Austria;* [4]*Siegburg Hospital, Cardiolgy department, Siegburg, Germany;* [5]*Pomorskiej Akademii Medycznej, Szczecin, Poland;* [6]*University of Barcelona, Servicio Hemodinamica Cardiaca, Barcelona, Spain*

Background: The role of stenting compared to balloon angioplasty (PTCA) for the treatment of symptomatic coronary artery stenoses in small vessels is still unclear. In addition, the benefit of heparin-coated stents in this scenario has not been documented.
Methods: 600 patients (pts) in 21 centers with native coronary stenoses in vessels <2.6 mm were randomly assigned to one of 3 treatment arms: PTCA or non-coated JOSTENT FLEX (ST) or heparin-coated JOSTENT FLEX (H-ST) implantation. The primary endpoint was minimal lumen diameter (MLD) at 6 months. Secondary endpoints included technical success rate and eventfree survival.
Results: Based on intention to treat, 588 pts could be analyzed with a reangiography rate of 81%. Baseline parameters were similar between the 3 groups.

	PTCA	ST	H-ST	P
MLD post intervention [mm]	2.05±0.41	2.17±0.42	2.19±0.40	0.001
acute gain [mm]	1.23±0.47	1.41±0.47	1.42+/0.48	0.0001
MLD at follow-up [mm]	1.34±0.48	1.47±0.48	1.45±0.54	0.049
late loss [mm]	0.73±0.49	0.69±0.60	0.76±0.58	n. s.
net gain [mm]	0.55+/0.51	0.72±0.51	0.69+/0.59	0.047
technical success	75%	98%	98%	0.0001
restenosis rate	31%	24%	30%	n. s.
eventfree survival at 6 months	85%	89%	89%	0.189

In the PTCA group 25% of pts required cross-over to stenting because of recoil or flow limiting dissections or threatening closure, which resulted in a postinterventional "stent-like" residual diameter stenosis of 12±16%.
Conclusion: A larger postinterventional MLD and acute gain were found in the two stent groups. At follow-up, there is a borderline statistically significant MLD and net gain difference in favor of the stent groups with surprisingly similar late loss compared to PTCA. These data did not convert into statistically different restenosis rates between the three groups. Finally, the H-ST did not provide any angiographic or clinically relevant benefit over the ST in the treatment of stenoses in small native coronary arteries.

THROMBOLYSIS

1458 How does ST-segment resolution one-hour after fibrinolysis for acute myocardial infarction predict final infarct size? Insights from ASSENT 3

G. Wagner[1], Y. Fu[2], S.G. Goodman[3], C.B. Granger[1], L. Wallentin[4], F. Van de Werf[5], P. Armstrong[2] on behalf of the ASSENT III Investigators. *[1]Duke Clinical Research Institute, Division of Cardiology, Durham, United States of America; [2]University of Alberta, Medicine Dept., Edmonton, Canada; [3]University of Toronto, Division of Cardiology, Toronto, Canada; [4]University Hospital, Cardiology, Uppsala, Sweden; [5]University Hospital Gasthuisberg, Department of Cardiology, Leuven, Belgium*

Background: Little information exists regarding the relationship between early resolution of ST segment elevation and infarct size after fibrinolysis. Moreover, the relationship between early i.e. 60 minute ST resolution after initiation of TNK reperfusion and myocardial infarct size assessed by QRS score at discharge remains uncertain.
Methods: Accordingly we analyzed a subset of hospital survivors in ASSENT 3 (n=3296) who had three sequential ECGs (baseline, 60 min and discharge) free of confounders. ST segment resolution (Schroder's method) and QRS score (Selvester) were analyzed in a core ECG laboratory.
Results: The results are shown in the table - Anterior MI (n=1150) versus Non-anterior MI (n=2146). The sum of ST shift at baseline ECG are 16.4±9.0 mm for anterior MI and 10.7±6.6 mm for inferior MI (p<0.001).
Conclusion: These data demonstrate a good relationship between ST resolution at 60 minutes and QRS infarct size at hospital discharge further corroborated by the % of patients with >5x peak CK. Patients treated within two hours versus those treated >2 hours had a lower infarct size (QRS score 4.9±3.7 versus 5.3±3.8, p=0.005) further emphasizing the value of shortening time from symptom onset to reperfusion.

1459 Randomized trial comparing stenting within 24 hours of thrombolysis versus ischaemia-guided approach to thrombolysed acute myocardial infarction with ST-segment elevation

F. Fernández-Avilés[1], J.J. Alonso[1], J.M. Duran[1], A. Castro[2], J. Blanco[3], J. Alonso-Briales[4], J. Lopez[5], F. Fernandez-Vazquez[6] on behalf of GRACIA group. *[1]University Hospital of Valladolid, Institute of Heart Science (ICICOR), Valladolid, Spain; [2]H. Juan Canalejo, A Coruña, Spain; [3]H. Río Hortega, Valladolid, Spain; [4]H. Virgen de la Victoria, Malaga, Spain; [5]H. Rio Carrion, Palencia, Spain; [6]H. Leon, Leon, Spain*

Background: In pts with AMI and ST elevation, routine balloon angioplasty hours after thrombolysis has been strongly discouraged because of its association with a higher incidence of adverse cardiac and non-cardiac events. The GRACIA trial was designed to re-evaluate the potential benefit of an early posthrombolysis interventional approach in the era of stent and GP IIb/IIIa inhibitors.
Methods: A total of 500 patients with AMI with ST elevation were randomly assigned to 2 posthrombolysis strategies: a) angiography within 24 hours of thrombolysis (rt-PA) followed by adequate coronary revascularization with stenting or surgery, or b) a conservative approach guided by the presence of ischemia either spontaneous or provoked by non-invasive stress tests. The primary clinical end-point was the incidence of the combined event: death, AMI or the need for coronary revascularization at one- and 12-months. Revascularization of conservative patients during hospital stay was not considered as an event. This abstract summarises the evolution at 30 days
Results: Thirty percent of conservative patients underwent cardiac angiography due to recurrent ischemia or positive stress test, and 47 of them (19%) underwent revascularization before discharge. According to angiographic findings, the final treatment of interventional patients included: stenting of the culprit artery in 79%; bypass surgery in 3% and medical treatment in 16% (no significant stenosis or unsuitable anatomy). Following the protocol, abcximab was used in 27% of invasive patients. The overall mortality at 30 days was similar in both groups (conservative 2%, invasive 2.5%). The incidence of the primary endpoint at 30 days was also similar (conservative: 6%; invasive: 4.8%, p= 0.55). During hospital stay the incidence of the combined endpoint was similar in both groups (conservative: 2.4%, invasive: 4%, p= 0.31). However, the incidence of events after discharge was higher in the conservative group (3.7% vs 0.8%, p= 0.03). No differences were found in major bleeding or vascular complications (conservative 1.6%, invasive 1.6%, p= 0.73). Hospital stay was significantly shorter in the invasive group (7.6±6.4 vs 11.2±6.8 days, p= 0.0001).
Conclusions: Early posthrombolysis catheterisation and appropriate intervention (stenting or surgery) is a safe strategy that: 1) does not increase events (cardiac, vascular or bleeding complications); 2) reduces hospital stay and; 3) reduces post-discharge incidence of events.

1460 Biochemical predictors of thrombolysis effectiveness early in the course of ST-segment elevation myocardial infarction

M. Zairis[1], O. Papadaki[2], A. Liras[2], M. Dimou[3], J. Hatzissavas[2], A. Papantonakos[2], M. Papanikolaou[3], S. Foussas[2]. *[1]Piraeus, Greece; [2]Tzanio Hospital, Cardiology Dept., Piraeus, Greece; [3]Tzanio Hospital, Department of Immunology, Piraeus, Greece*

Background: Rapid and adequate reperfusion of the jeopardized myocardium is the only effective treatment in the patients with ST-segment elevation myocardial infarction (STEMI). Whilst the benefit of thrombolysis is unequivocal, reperfusion fails in many patients. The aim of this prospective study was to evaluate the role of the plasma levels of either high sensitivity C-reactive protein (hs-CRP), cardiac troponin I (cTnI), or fibrinogen on the thrombolysis effectiveness estimating by continuous 12-lead electrocardiographic analysis (12L-ECG).
Methods: To examine the time course of ST segment recovery during the administration of intravenous thrombolysis a total of 157 consecutive patients with STEMI were studied. All pts had presented in the first 6 hours from onset of index pain. The course of higher ST-segment elevation was evaluated by continuous 12L-ECG monitoring. Successful thrombolysis was considered as the abrupt 50% ST-segment stable recovery in the first 90 minutes after thrombolysis initiation. Plasma levels of the studied markers were estimated upon admission.
Results: Seventy-nine patients had positive (>0.1ng/Lt) cTnI. There was a significant relationship between plasma cTnI values and prehospital delay (time interval from index pain to admission)(Spearman R=0.51; p<0.001). Patients with or without positive cTnI didn't differ significantly concerning the mean values of either hs-CRP (0.58mg/dl vs.0.54mg/dl respectively; p=0.65) or fibrinogen (3.4g/Lt vs.3.3g/Lt respectively; p=0.85). In the first 90 min 85 (85/157; 54.1%) patients had attained 50% ST-segment recovery. By univariate logistic regression analysis cTnI (RR=0.44; p=0.001), time interval from index pain to thrombolysis initiation (RR=0.68; p<0.001), hs-CRP (RR=0.74; p<0.001), and diabetes mellitus (RR=0.27; p=0.001) were related to thrombolysis effectiveness. Fibrinogen was not related to thrombolysis effectiveness (RR=0.93; p=0.54). However, by multivariate analysis time interval from index pain to thrombolysis initiation (RR=0.54; p<0.001), hs-CRP (RR=0.66; p=0.01), and diabetes mellitus (RR=0.30; p=0.009) were the only independent predictors of thrombolysis outcome.
Conclusions: The present study implies that hs-CRP is a strong predictors of thrombolysis effectiveness whilst elevated plasma cTnI values may reflect the preceding myocardial necrosis (strong association with prehospital delay). Fibrinogen is not associated with thrombolysis outcome. Acute inflammatory reaction at the culprit artery may be responsible for the fail of thrombolysis in patients with high CRP values.

Abstract 1458 – Table: Anterior MI versus Non-anterior MI

ST resolution at 60 min	Anterior MI >70%	Anterior MI 30-70%	Anterior MI <30%	Non-ant MI >70%	Non-ant MI 30-70%	Non-ant MI <30%
No of pts	299	401	450	829	663	654
Peak CK >5 uln	54.9	75.2	82.4*	48.8	(68.8)	(71.5)*
QRS score at D/C	4.7±3.3	6.2±3.5	6.8±3.5*	4.2±3.5	4.8±3.8	5.4±3.9*
Treated <2hr	3.8±2.9	5.8±3.5	6.9±3.5*	(3.9±3.4)	(4.4±3.7)	5.2±3.9*
Treated >2hr	5.2±3.4	(6.4±3.6)	(6.8±3.5)*	4.3±3.6	4.9±3.8	5.4±3.9*

*p<=0.031 for all pair-wise comparisons across 3 categories of ST resolution except pairs in brackets

1461 Effect of tenecteplase versus alteplase on platelets in patients during the first three hours after acute myocardial infarction

V.L. Serebruany[1], A. Malinin[1], K.P. Callahan[1], A.S. Binbrek[2], F. Van de Werf[3], J.H. Alexander[4], C.B. Granger[4], P. Gurbel[5]. *[1]Johns Hopkins University, Sinai Hospital, Baltimore, United States of America; [2]Rashid Hospital, Dubai, United Arab Emirates; [3]University of Leuven, Leuven, Belgium; [4]Duke University, Durham, United States of America; [5]Sinai Hospital, Thrombosis Research Center, Baltimore, United States of America*

Background: Platelets play a pivotal role in the pathogenesis of acute myocardial infarction (AMI), as well as in coronary artery reocclusion and occurrence of bleeding events. Ultimately, the success of certain fibrinolytic agents is highly dependable on their direct effects on platelets. We sought to determine how tenecteplase (TNK) and alteplase (t-PA) affect platelets in vitro as in a setting of an ASSENT-2 clinical trial.
Methods: For the in vitro study, whole blood of donors was incubated with 30 mg TNK and 60 mg t-PA. Platelet aggregation, bedside analyzers, and flow cytometry measuring 9 major receptors and platelet-monocyte microparticles were utilized. Forty-one patients (21-TNK, and 20-t-PA) from a single ASSENT-2 site underwent 7 serial sampling of plasma every 30 minutes for 3 hours. Levels of PECAM-1, VCAM-1, P-selectin, beta-thromboglobulin, platelet factor 4, thromboxane, and prostacyclin were measured by ELISA.
Results: Significant inhibition of conventional and whole blood platelet aggregation, decreased platelet activation by Ultegra, and prolonged closure time with the PFA-100 device were observed in the TNK treated samples. Flow cytometry reveals decreased expression of GP IIb/IIIa, PECAM-1, vitronectin receptor, CD151, and formation of the platelet-monocyte microparticles after incubation with TNK. Assessment of serial samples in the ASSENT-2 trial showed a significant decrease of soluble platelet-endothelial biomarkers in the TNK group. There was a trend toward decreased platelet function with t-PA; however, these differences were much smaller than those observed with TNK.
Conclusion: Both in vitro and ex vivo studies show that t-PA and TNK affect platelet function in human volunteers and in patients with AMI early after thrombolysis. Comparison between agents revealed that anti-platelet properties of TNK are much stronger than those of t-PA. These data challenge simultaneous use of fibrinolytic agents and platelet GPIIb/IIIa inhibitors.

1462 Bolus intravenous heparin as reperfusion therapy for acute myocardial infarction

T. Onodera, A. Takizawa, A. Shimane, K. Murata, R. Takeuchi, Y. Kawaguchi, H. Otani. *Shizuoka City Hospital, Cardiology, Shizuoka, Japan*

Introduction: Early reperfusion of infarct related coronary artery has been reported to be associated with improved prognosis in acute myocardial infarction (AMI). We sought the effect of early administration of bolus intravenous heparin on reperfusion in AMI.
Methods: Eighty-nine patients with AMI presenting within 6 hours after onset were randomized to 3 groups (150U/kg heparin bolus at arrival at emergency department, 75U/kg heparin at arrival, or 75U/kg heparin at the beginning of emergent coronary angiography). No other thrombolytic agents were given. Patients with cardiogenic shock were excluded. Patency of infarct related artery was assessed by emergent coronary angiography with TIMI grade. After TIMI flow grade evaluation, coronary angioplasty or stenting was performed on indication.
Results: There were no differences in age, sex, time from onset of AMI to arrival, or Killip functional class among the 3 groups. Time from administration of heparin to initial angiography was 44±11 minutes in patients with heparin at arrival and 3±2 minutes in patients with heparin at angiography. TIMI 2 or 3 flow was more often seen in patients with 150U/kg heparin at arrival (13 of 29 patients: 45%) or 75U/kg heparin at arrival (12 of 30 patients: 40%) than in patients with 75U/kg heparin at angiography (5 of 30 patients: 17%)($p<0.05$). In each group, 1 patient showed ventricular fibrillation between arrival and angiography. There were no in-hospital deaths. One patient with 75U/kg heparin at arrival showed massive gastric bleeding. No other serious bleeding was seen.

Number of patients with each TIMI grade

	Heparin 150U/kg at arrival (n=29)	Heparin 75U/kg at arrival (n=30)	Heparin 75U/kg at angiography (n=30)
TIMI 0	12	16	22
TIMI 1	4	2	3
TIMI 2	8	6	3
TIMI 3	5	6	2

Conclusions: Bolus heparin given at arrival at hospital showed increased rate of coronary reperfusion without increasing serious complications. Utilization of this inexpensive and easily applicable therapy should be considered in AMI.

1463 Pre-hospital thrombolysis reduces incidence of ischaemic heart failure after acute myocardial infarction

J. Roncalli, M. Galinier, F. Brunelle, D. Carrie, J. Fourcade, M. Elbaz, J. Puel, J.M. Fauvel. *CHU Rangueil, Cardiologie Dept., Toulouse, France*

Background: Randomized trials comparing primary angioplasty and in-hospital thrombolysis in acute myocardial infarction (AMI) have shown an advantage for primary angioplasty on left ventricular ejection fraction (LVEF). The pre-hospital thrombolysis with a mean gain of one hour compared with in-hospital thrombolysis could improve LVEF as well as primary angioplasty for AMI. This study compares the benefits on LVEF and in-hospital outcome after pre-hospital thrombolysis versus primary angioplasty in patients with acute myocardial infarction (AMI).
Methods: We conducted a study including 318 patients with AMI hospitalized in a single center from 1995 to 1999. Patients underwent primary angioplasty (primary PTCA group: n = 157) or received pre-hospital thrombolysis with accelerated rtPA (pre-hospital thrombolysis group: n = 161) within 6 hours after the onset of chest pain. We noted the LVEF and looked at the in-hospital outcome focusing on global mortality and major adverse cardiac events (MACE).
Results: The two groups were similar in their baseline characteristics. No difference was noted between the 2 groups for LVEF (52.3 ± 9.7% for primary PTCA group versus 51.8 ± 11.4% for pre-hospital thrombolysis group; p = 0.98) at the hospital discharge. No difference was noted for in-hospital mortality (primary PTCA group: 2.48%, pre-hospital thrombolysis group: 2.54%) with no increased risk of major bleeding event (primary PTCA group 1.91% versus pre-hospital thrombolysis group: 2.48%; p = 0.72). Regarding MACE (primary PTCA group: 10.8% vs. pre-hospital thrombolysis group: 7.45%; p = 0.29), the groups were statistically not different.
Conclusion: Pre-hospital thrombolysis prevent ischaemic heart failure after AMI as well as primary angioplasty. We could reduce the incidence of ischaemic heart failure after acute myocardial infarction by early initiation of reperfusion therapy with pre-hospital thrombolysis. Consequently our results in the real-life world encourage more frequent use of thrombolytic therapy in the pre-hospital stage.

NEW DEVICES FOR INTERVENTIONS IN ACUTE MYOCARDIAL INFARCTION

1464 Thrombo-aspiration with the "Rescue" system in acute myocardial infarction. Comparison of immediate results between rescue use and primary use

P. Legalery, F. Schiele, M.F. Seronde, N. Meneveau, J.P. Bassand. *Department of Cardiology, Besancon, France*

Purpose: Thromboaspiration (TA) with the "RESCUE" system (Boston Scientific) seems to be a logical treatment in Acute Myocardial Infarction (AMI) in case of thrombotic occlusion. It can be used as a primary therapy (primary TA) or after failure of reperfusion post angioplasty (rescue TA). We compared the immediate angiographic and ECG results between the two strategies.
Methods: Non randomized, single center registry. Immediate results were assessed by the TIMI flow, ST elevation changes and absolute value, Creatine Kinase (CK) and troponin TI release at 24 hours. All patients were pre treated by enoxaparin (1mg/kg), 2b/3a inhibitors and aspirin (250 mg).
Results: Of the 30 consecutive patients (64±13 years) entered in the registry, AMI was anterior in 9, lateral in 5 and inferior in 16. TA was used as rescue in 15 (50%) and as primary in 15(50%), without additional angioplasty in 8(27%). TIMI flow was 0 in all patients before procedure and afterwards was 3 in 19 patients (63%), 2 in 7 (23%); while 4 had no successful reperfusion (13%). The comparison of the results between primary and rescue strategy is presented in the table.

	TIMI3 flow post	ST elevation pre (mm)	ST elevation post (mm)	Changes in ST elevation	CK at 24h (U/l)	Troponin at 24h
Primary TA	10/15	4.1±2.0	1.2±1.5	2.9±0.6	1023±662	27±32
Rescue TA	9/15	4.9±1.7	2.2±1.7	2.7±0.5	2241±1102	54±33
P value	0.70	0.13	0.12	0.75	0.002	0.045

Conclusions: TA using the "RESCUE" system can be used as a primary therapy as well after failure of reperfusion with balloon angioplasty. Enzyme release seems lower when used as primary choice.

1465 Use of a porous filter protection system during direct angioplasty on native coronary arteries

U. Iimbruno, C. Palagi, A.S. Petronio, A. Micheli, G. Amoroso, M. De Carlo, V. Di Bello, M. Mariani. *Cardiothoracic Dpt, Univ of Pisa, Pisa, Italy*

The benefits of vessel recanalization induced by primary percutaneous coronary intervention (PCI) in patients with acute myocardial infarction (AMI) are limited by the possibility to induce distal embolization of the fresh thrombus or plaque which in turn may be related to the appearance of the no-reflow phenomenon. Aim of this study was to evaluate the safety and feasibility of the use of the "Filter-wire Ex" (FW), a distal embolic protection device, during primary PCI on native coronary vessels. Methods: 23 consecutive patients (18M,5F, age 62±9 yrs) admitted < 6 hours after AMI onset and with TIMI grade flow 0 or 1 in the infarct native coronary vessel were treated by primary PCI in association with FW to prevent distal embolism. Hospital outcome of these patients (group PCI+FW) was compared to 23 patients with AMI treated by primary PCI alone (group PCI) matched for age, sex and infarct location. Patients with cardiogenic shock, left main coronary artery disease or infarct vessel size < 3.0 mm were excluded. Results: successful positioning of the FW device was obtained in 22 out of 23 patients while visible emboli in its basket were recovered in 7 patients. Demographic and baseline clinical characteristics were similar in the two groups with the exception of the arterial puncture-to-vessel recanalization time, slightly longer in the PCI+FW group (24±6 vs 21±5 min, p<0.05). The prevalence of persistent ST-segment elevation (pSTe) and TIMI grade flow 0-2 at the end of PCI as well as a composite end-point (CEP) at 4 weeks including death, heart failure, recurrent angina or AMI were higher in the PCI group with respect to the PCI+FW group (see table). Improvement of the 2D-echo left ventricular regional wall motion index (delta-RWMI) 4 weeks after AMI was significantly greater in the PCI+FW group (see table).

	TIMI 0-2 after PCI	pSTe	CEP	delta-RWMI
PCI	22%	35%	39%	-0.25±0.26
PCI + FW	4%	9% *	13%*	-0.41±0.21*

*: p<0.05

Conclusions: the use of the FW device during primary PCI in patients with AMI is safe and technically feasible in native coronary arteries. In this clinical setting, FW seems to prevent the no/slow-reflow phenomenon improving the recovery of the left ventricular wall motion.

1466 Primary angioplasty with thrombectomy devices. Experience at one centre

E. Pinar, R. López-Palop, I. Lozano, R. Cortés, P. Carrillo, D. Saura, F. Picó, M. Valdés. *Hospital Virgen de la Arrixaca, Cardiology Department, Murcia, Spain*

As Primary Angioplasty (PA) is performed in lesions with large thrombus burden, it is associated with an increased risk of acute occlusion, distal embolization and no-reflow. Thrombectomy devices (TD) may avoid this complications and lead to a better procedure outcome. Our aim was to analyse the efficacy of thrombus extraction with TD during PA.

Methods: Retrospective analysis of PA performed with TD to patients with AMI at our hospital. Two devices were used: XSizer 4.5 and 6 F (Endicor Medical) and Rescue (Scimed).

Results: Twenty-three patients were treated with PA and TD (age 63±11.2, 66% male), 17.3% of them in cardiogenic shock. XSizer was used in 7 (30.4%) and Rescue in 16 (69.6%), with an 8 (21.8%) or 7 French (78.2%) guiding catheter. All patients received stent and abciximab was administered in 69.5%. Culprit vessel was RCA in 16 (69.5%), LDA in 6 (26.1%) and saphenous vein graft in one case. The artery was occluded in 20 patients (87%) and TIMI flow during different stages of the procedure is shown in the table.

	Initial	After guidewire	After Thrombectomy device	Final Result
TIMI 0	20 (87%)	1 (4.3%)	1 (4.3%)	1 (4.3%)
TIMI I	3 (13%)	15 (66.2%)	0	0
TIMI II	0	6 (26.2%)	8 (34.8%)	0
TIMI III	0	1 (4.3%)	14 (60.9%)	22 (95.7%)

TIMI flow during the procedure.

Once the guidewire crossed the stenosis, intracoronary thrombus was seen in all cases; after TD usage, thrombus image disappeared in 8 cases (36.4%), improved clearly in 6 (27.3%) and slightly in 3 (13.6%), with no changes in one (4.5%).

After PA, final flow was TIMI III in 22 patients, myocardial perfusion was blush grade 3 in 12 (54.6%), 2 in 9 (39.1%) and 1 in one patient (4.5%).One patient with shock at admission died during the procedure.

Conclusion: Thrombectomy devices during primary PTCA are associated with efficient thrombus extraction, achieving a good angiographic result and leading to high procedural success.

1467 More rapid ST-segment resolution and improved epicardial flow using the embolisation protection device GuardWire in percutaneous coronary intervention for acute myocardial infarction

G. Sütsch[1], C. Metzler[1], S. Murphy[2], M. Gibson[2], F.W. Amann[1]. [1]*University Hospital, Zurich, Switzerland;* [2]*Harvard Clinical Research Institute, Boston, United States of America*

Background: Percutaneous coronary interventions (PCI) in acute myocardial infarction (AMI) are associated with high success rates. However, high epicardial flow grades alone do not indicate adequate myocardial reperfusion as demonstrated by delayed or absent ST-segment resolution (ST-RES) and/or low tissue level (re-)perfusion (TIMI myocardial perfusion grade =TMPG) in a substantial proportion of patients (pts). Possibly, embolic debris liberated in excess during PCI are responsible for this observation. We speculated that the embolisation protection device GuardWire (GW) might reduce the embolic burden during PCI and thus improve these reperfusion parameters.

Methods: A total of 55 pts with complete occlusion of the infarct related artery and ST-elevation underwent PCI for AMI (<12 hours from symptom onset) using either conventional (n=30 pts) or GW-assisted (n=25 pts) PCI. Pre/post-PCI core lab analysis compared TIMI flow grades (TFG), corrected TIMI frame counts (CTFC), TMPG and ST-RES between the groups.

Results: Clinical and baseline angiographic data in GW and non-GW pts were identical (except for a lower number of LAD in the GW group). Post-PCI, GW pts had much better TFG 3 (100% vs. 75%, p<.008), CTFC (20.0±5.4 vs. 44.0±30.3, p<.009) and ST-RES (77.4±17.3% vs. 50.0±26.2%, p<.0001) while TMPG 3 improved alike in both groups (40% vs. 50%, p=.50).

Conclusions: In this first comparative study, reperfusion seems improved with distal embolisation protection in PCI for AMI. Larger trial are needed to confirm these preliminary observations and to assess its clinical benefits.

1468 Postinfarct VSD closure with amplatzer atrial septal occluders

J. Bialkowski, M. Szkutnik, L. Polonski, M. Gasior, P. Chodor, A. Lekston, M. Zembala. *Silesian Center for Heart Diseases, Department of Paedriatric Cardiology, Zabrze, Poland*

Background: Amplatzer Atrial Septal Occluders (ASO) were applied rutinely in our center to close ASD II The unique construction of ASO also permits to close others undesirable shunts, which is sometimes a life saving procedure. Experience in transcatheter treatment of postinfarct VSD with ASO is presented.

Patients & methods: Five patiens (pts) with mean age 61 (from 51 to 71) years were included. The procedure was performed between 1.5 and 12 months (mean 4.5 m) after myocardial infarction. One pt had double VSD (residual post 2 months earlier surgery) and another coexisting critical stenosis of right coronary artery. All pts were in III/IV NYHA class. In all venous jugular approach was applied to close VSD.

Results: All procedures, but one were finished successfully. In one pt cannulation of VSD appeared impossible both from venous and arterial side, because of its oblique intraseptal trajectory (which was confirmed during subsequent operation). In 4 pts post infarct VSD's were closed with 5 ASO (in postsurgical pt 2 ASO were apllied) and immediate significant clinical improvement was achieved. In one pt prior to VSD closure, PTCA and stent implantation of RCA was performed. The stretched diameter of VSD ranged from 15 to 19 (mean 17) mm.and the size of implanted devices from 16 to 20 (mean 18) mm. Fluoroscopy time was 45 (18-87) min. During procedure ventricular fibrillation requiring defibrillation was frequent. One pt died one week after procedure because of multiorgan failure and increasing mitral incompetence.

Conclusions: Implantation of Amplatzer occluders, despite some technical problems, is an atrractive option of tratment for patients with postinfatct VSD.

1469 Thrombectomy prior to stenting is a novel strategy to obtain optimal reperfusion in acute myocardial infarction patients

N. Ito, M. Nakamura, H. Nuruki, S. Yajima, R. Nakajima, M. Yamamoto, H. Hara, T. Yamaguchi. *Ohashi Hospital, Toho University, Third Department of Internal Medicine, Tokyo, Japan*

Background: A goal of reperfusion therapy is to obtain TIMI 3 flow at both epicardial and myocardial perfusion. The purpose of this study was to evaluate the efficacy of thrombectomy prior to stenting for the myocardial optimal perfusion. Objects and Method: A consecutive 92 acute myocardial infarction patients underwent primary angioplasty were studied. Subjects were divided into 2 groups by means of the use of RescueTM thrombectomy catheter (Rescue group: 40 cases, non Rescue group: 52 cases). To evaluate epicardial and myocardial reperfusion after primary angioplasty, ST-segment elevation were measured from twelve-lead electrocardiograms before angioplasty and 1hr after reperfusion, and the sum of the ST-segment elevation and ST-segment resolution was calculated. ST-segment resolution was classified into 3 groups: complete (>70%), partial (30% to 70%), non (<30%), and we evaluated the percentages of ST-segment resolution 1hr after angioplasty.
Results: There is no difference in the baseline characteristics of both groups, including elapsed time, using tPA and TIMI grade before PTCA. The data of electrocardiographic analysis was as follows.

The data of ST-segment resolution

	Rescue (n=40)	non Rescue (n=52)	p value
Sum of ST-segment elevation before angioplasty(mV)	0.97±0.85	0.93±0.98	NS
ST-segment resolution 1hr after angioplasty(%)	62.1±22.9	29.6±29.4	<0.0001
complete, n(%)	19 (47.5)	6 (11.5)	0.001
partial, n(%)	20 (50)	18 (34.6)	NS
non, n(%)	1 (2.5)	28 (53.9)	<0.0001

Conclusions: Thrombectomy with RescueTM prior to stenting is associated with early and greater ST-segment resolution. These findings may suggest that thrombectomy before PTCA is a useful strategy for obtaining sufficient epicardial and myocardial reperfusion.

BNP IN HEART FAILURE: PREDICTORS OF OUTCOME

1470 The prognostic significance of NT-proBNP in severe chronic heart failure is independent of aetiology: a substudy of the COPERNICUS trial

F. Hartmann[1], M. Packer[2], A.J. Coats[3], P. Mohacsi[4], M. Tendera[5], I. Amann-Zalan[6], M. Baumann[6], H.A. Katus[1] on behalf of The COPERNICUS Study Group. *[1]Universitaetsklinik Luebeck, Medizinische Klinik II, Luebeck, Germany; [2]Columbia University, College of Physicians and Surgeons, New York, United States of America; [3]Royal Brompton Hospital, London, United Kingdom; [4]University Hospital, Abt. f. Kardiologie, Bern, Switzerland; [5]Silesian School of Medicine, Katowice, Poland; [6]Hoffmann-La Roche AG, Basel, Switzerland*

Background: Recently, prognostic significance of the new cardiac marker N-terminal proBNP (NT-proBNP) was documented in ischemic cardiomyopathy (CMP). The COPERNICUS study offered the unique possibility to evaluate the value of NT-proBNP to predict the occurrence of death and hospitalisation in patients with severe congestive heart failure of different aetiology.
Methods and Results: Baseline plasma concentrations of NT-proBNP were measured using a newly developed sandwich ELISA in a subgroup of 695 patients with ischemic and 353 patients with non-ischemic CMP having symptoms at rest or on minimal exertion who were enrolled in the European part of the COPERNICUS study and were randomised to placebo (n=524) or carvedilol (n=524) for up to 29 months. NT-proBNP concentrations were markedly increased (mean ± SD = 579 ± 822 pmol/L), with significantly higher levels in the ischemic CMP patients (624 ± 862 vs. 491 ± 732 pmol/L). By univariate and multivariate Cox regression, NT-proBNP (analysed as a continuous or categorical variable) was found to be a powerful predictor of all cause mortality (see table) and other major clinical events, all p < 0.0001. Predictive value of NT-proBNP was similar when both patients with ischemic and non-ischemic CMP were analysed separately, no statistically significant interaction was detected between NT-proBNP and aetiology (p=0.5 for NT-proBNP classification by median).

One-year mortality rates

	NT-proBNP		Risk Ratio	95% CI
	< median	> median		
All patients (n=1048)	6.2%	22.4%	3.13	1.94 - 5.07
Ischemic CMP (n=695)	8.6%	25.0%	2.70	1.56 - 4.70
Non-ischemic CMP (n=353)	3.1%	18.2%	4.60	1.70 - 12.49

Conclusion: Circulating levels of NT-proBNP predict all cause mortality and major clinical events in patients with severe heart failure, independent of aetiology of CMP.

1471 Association between N-terminal pro brain natriuretic peptide and left ventricular function in mild to moderate heart failure

B.A. Groenning[1], G.A. Riegger[2], P.R. Hildebrandt[1], M. Baumann[3], L. Ryden[4], M. Komajda[5] on behalf of the CARMEN Steering Committee and Investigators. *[1]Copenhagen Univ. Hosp. Frederiksberg, Dept. of Cardiology and Endocrinology, Frederiksberg, Denmark; [2]University of Regensburg, Dept. of Internal Medicine II, Regensburg, Germany; [3]F. Hoffmann-La Roche Ltd, IHCS Dept., Basel, Switzerland; [4]Karolinska Sjukhuset, Department of Cardiology, Stockholm, Sweden; [5]Hopital Pitie Salpetriere, Department of Cardiology, Paris, France*

Background: N-terminal pro brain natriuretic peptide (NT-proBNP) has been reported to be a useful marker in the diagnosis of chronic heart failure (CHF). However, the diagnostic value of the marker in patients with mild to moderate CHF has not been well characterized, and even more importantly, only little is known about possible confounders for interpretation of a given NT-proBNP concentration in the individual patient. The aims of the present analysis from the Carvedilol and ACE-Inhibitor Remodelling Mild Heart Failure Evaluation (CARMEN) trial were (I) to evaluate NT-proBNP as a marker for left-ventricular (LV) dimensions and systolic function, and (II) to identify variables of independent significance for the plasma level of NT-proBNP in a large group of patients with mild to moderate CHF.
Methods: At baseline, 504 patients (406 men, 98 women) (mean (SD) age=62.4 (11.4) years) with LV systolic CHF (LV ejection fraction (LVEF) < 39%; mean (SD)=29.2 (6.48)%) in NYHA classes I - III (I:28 (6%), II:332 (66%), III:144 (29%)) were examined clinically, and echocardiograms (n=408, by central core-lab) and blood samples (NT-proBNP by non-extracted, enzyme-linked, sandwich immunoassay) were obtained.
Results: (log) NT-proBNP (geometric mean (95% CI)=150 (136-165) pmol/l) was significantly associated with LVEF (r=-0.49, p<0.0001), and LV end-diastolic (mean (SD)=87.8 (25.5) ml/m^2; r=0.40, p<0.0001) and end-systolic (mean (SD)=63.2 (22.9) ml/m^2; r=0.45, p<0.0001) volume indices. By multiple linear regression analysis, low LVEF (standardized parameter estimate (SPE)=0.44, p=0.002), high age (SPE=0.26, p<0.0001), high NYHA class (SPE=0.17, p=0.0001), high heart rate (mean (SD)=77.7 (11.3) bpm; SPE=0.15, p=0.0003), high serum creatinine (mean (SD)=105 (23.9) μmol/l; SPE=0.15, p=0.0009) and low diastolic blood pressure (mean (SD)=80.8 (10.1) mmHg; SPE=0.13, p=0.02) were all independently associated with a high plasma level of NT-proBNP.
Conclusion: NT-proBNP is strongly associated with LV dimensions and systolic function in patients with mild to moderate CHF. When interpreting a given value of NT-proBNP, it may be necessary to adjust for the independent effects of age and renal function.

1472 Changes in plasma brain natriuretic peptide and norepinephrine over time and subsequent mortality and morbidity in Val-HeFT

I.S. Anand[1], L. Fisher[2], T. Chiang[3], R. Glazer[3], N. De Angelis[4], S. Masson[4], G. Tognoni[4], J.N. Cohn[5] on behalf of the Val-HeFT Investigators. *[1]VA Medical Center, Special Cardiology, 111C-1, Minneapolis, MN, United States of America; [2]University of Washington, Department of Biostatistics, Seattle, United States of America; [3]Novartis Pharmaceuticals Corporation, East Hanover, United States of America; [4]Istituto Mario Negri, Milano, Italy; [5]University of Minnesota, Department of Cardiology, Minneapolis, United States of America*

Background: Plasma brain natriuretic peptide (BNP) and norepinephrine (NE) are important determinants of the progression of heart failure (HF) and predict long-term mortality and morbidity (M&M). Whether changes in BNP and NE over time correspond to subsequent changes in M&M has not been studied. The Val-HeFT trial that evaluated the efficacy of valsartan in 5010 patients with NYHA class II to IV HF, and measured BNP and NE at baseline and sequentially during follow-up provided an opportunity to examine this relationship. Methods: Baseline (BL), and the % change from BL to 4 months in BNP (n=3740) and NE (n=3746) were analysed by quartiles (Q) for subsequent mortality (Mort), and first morbid event (Morb: death, sudden death with resuscitation, IV inotropic therapy, and hospitalisation for HF), using a Cox proportional hazard model with baseline values as a covariate. The hazard risk ratio (RR) and 95% CI for changes between quartiles, using first Q as control was calculated for mortality and first morbid event, in all patients irrespective of treatment group. P-values were computed using log-rank test.

Table

Quartiles		% Mort	RR vs Q1	95% CI	Log Rank P-value	% Morb.	RR vs Q1	95% CI	Log Rank P-value
	% Change in BNP								
Q1	<-45	13.6	1.00			21.5	1.0		
Q2	-45 to -13	15.5	1.30	1.03-1.66	0.165	25.5	1.37	1.33-1.65	0.027
Q3	-13 to +30	15.1	1.36	1.07-1.74	0.321	28.1	1.65	1.37-2.00	0.0009
Q4	≥ +30	19.1	1.92	1.52-2.43	0.0006	33.0	2.24	1.86-2.69	<0.0001
	% Change in NE								
Q1	<-24	14.4	1.00			25.9	1.00		
Q2	-24 to+4.5	16.0	1.23	0.97-1.55	0.30	26.3	1.12	0.93-1.33	0.82
Q3	+4.5 to+41	15.7	1.28	1.01-1.62	0.30	27.4	1.24	1.04-1.48	0.27
Q4	≥ +41	17.5	1.48	1.17-1.87	0.066	29.2	1.41	1.18-1.68	0.05

Results: Baseline BNP and NE in quartiles showed a significant quartile-dependent increase in M&M. Patients with the greatest decrease in BNP at 4 months (Q1) had the lowest subsequent M&M. RR for subsequent M&M increased significantly in patients with smaller decreases or increases in BNP (Q2 to Q4) over time (table). Similar findings were seen for NE, although the results did not reach a level of significance. Conclusions: Both BL and % changes in BNP over time are related to subsequent events.

1473 NT-pro BNP predicts toleration of beta-blocker therapy in patients with chronic heart failure

N. Johnston, M. Green, S. Robb, I. Morton, H. Dargie. *Western Infirmary, Cardiology, Glasgow, United Kingdom*

Recently, the results of several studies have provided convincing evidence that beta-blockers (BB) decrease mortality in patients with symptomatic chronic heart failure (CHF). However, extensive surveys carried out in Europe indicate the use of BB in clinical practice is still very low (between 9% and 52%) and only 21% in the UK. This is partly due to difficulties in implementation of this treatment and reluctance to commence therapy in the community. The aim of this study was to examine implementation of BB therapy in a dedicated CHF clinic and to assess the possible use of NT-pro BNP to predict toleration of beta-blocker therapy.

All patients (86) referred from the CHF clinic for commencement of BB therapy from 01/10/1999 to 01/10/2001 were included. Data was collected detailing aetiology of CHF, co-morbidity and concurrent drug therapy as well as LV function from the initial echocardiogram. At the first visit the lowest licensed dose of BB was started and doubled every 2 weeks until maximum dose was achieved. Patients were observed for 3 hours each visit, and pulse and blood pressure were recorded every 30 minutes. Side-effect profile was recorded, as well as follow up data on drug compliance. NT-pro BNP was measured at initial visit to the clinic and on average every 3 months thereafter during uptitration of BB.

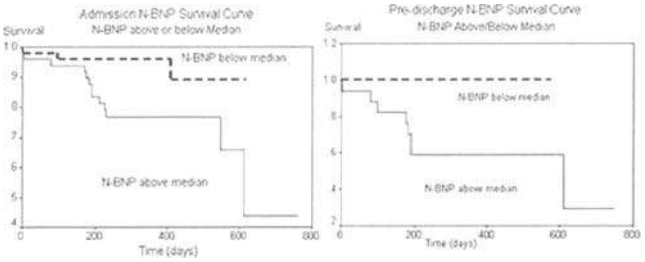
Data was available on 86 patients. Average age was 67 (range 23-86 years of age). Of the patients referred 48.7% had severe LVD, 48.7% moderate LVD and 6.3% mild LVD. NYHA was also graded; 17.9% were grade I, 46.4% grade II, 28.6% grade III and 7.1% grade IV. 89.5% patients tolerated BB therapy with 41.9% established on full dose therapy. Average time taken to establish the patient on their maximum tolerated dose was 10 weeks (range 8-44 weeks). Multivariate analysis was performed using multiple linear regression. The only significant, independent, predictors of toleration of BB therapy were NT-pro BNP level before commencement of BB and during uptitration of BB. The higher the NT-pro BNP level, the less likely the patient was to tolerate BB therapy. A history of COPD or PVD did not predict toleration of BB and nor did NYHA class or echocardiographic findings of severe LVD.

BB therapy can be safely and effectively commenced in the majority of patients with CHF. NT-pro BNP predicts which patients will tolerate full dose BB therapy and could therefore be of use in the future to determine which patients with CHF could safely be commenced and uptitrated on BB in the community rather than attending hospital supervised programmes.

1474 Pre-discharge but not admission levels of NT-proBNP independently predict death and heart failure after admission with acute heart failure

R J. O'Brien, B. Demme, I B. Squire, J E. Davies, L L. Ng. *University of Leicester, Dept of Medicine &Therapeutics, Leicester, United Kingdom*

Plasma N-terminal pro B-type natriuretic peptide (N-BNP) reflects LV function and prognosis in heart failure. We studied its correlation with measures of LV function during admission with LVF ± unstable angina (UA), and its utility in predicting death, further LVF and other endpoints. Admission plasma N-BNP was measured in 96 unselected patients (mean age 74, range 46-93) with acute LVF (LVF alone=61, LVF with UA =35) and before discharge in 36. Median N-BNP was 2944 pM on admission (14-29368) and 1944 pM (14-8155) pre-discharge. It rose proportionally to degree of LV dysfunction on echo (p=0.001). N-BNP correlated with age (p=0.0005), 1/Creatinine (p=0.0005) and rose with increasing peak Killip class (p=0.0005). There was no correlation of N-BNP with history of previous MI, hypertension, diabetes, hyperlipidaemia, or angina. During median follow-up of 350 days (range 2-762) 15 (16.7%) patients died, 21 (21.8%) were readmitted with LVF, and 15(15.7%) were hospitalised with UA. A further 17 (17.7%) had clinical LVF at outpatient visit. No episode of non-fatal MI was recorded. N-BNP was higher in those who died (5663.7 v 1631.9 pM, p=0.013), were readmitted with LVF (p=0.04), had outpatient LVF (p=0.049), or a composite of these (p<0.001). N-BNP on admission or discharge above the median was associated with reduced survival (Fig 1,log ranks p=0.015 and p=0.003 respectively).



However, only pre-discharge N-BNP was independently predictive of a composite of mortality and heart failure in multivariate analysis (odds ratio 15.30 [1.4-168.9],p=0.026).No deaths occurred in patients with pre-discharge N-BNP below median. N-BNP is dramatically raised in acute LVF.Pre-discharge rather than admission levels may be more representative of long-term prognosis.

1475 N-terminal BNP in the community diagnosis of suspected heart failure: what is an appropriate diagnostic threshold?

S.P. Wright[1], R.N. Doughty[1], G.D. Gamble[1], A. Pearl[2], J. Pomfret[1], S.A. Muncaster[1], T. Yandle[3], S. Fisher[3], A.M. Richards[3], N. Sharpe[1].
[1]*University of Auckland, Division of Medicine, Auckland, New Zealand;*
[2]*University of Auckland, Division of General Practice, Auckland, New Zealand;*
[3]*University of Otago, Dept of Medicine, Christchurch, New Zealand*

Background: Brain natriuretic peptide (BNP) is potentially useful for the diagnosis of suspected heart failure (HF) presenting in the community. However, patients with suspected HF are often elderly with other medical conditions that can elevate BNP, causing false positives. Normal ranges for BNP are often established in populations of healthy subjects considerably younger than symptomatic patients presenting in primary care.
Methods: Patients with dyspnoea and/or oedema presenting to their general practitioners (GPs) were entered into a randomised, controlled effectiveness trial of BNP (the Natriuretic Peptides in the Community Study). Each patient underwent full clinical assessment including ECG, chest x-ray, echocardiography and N-terminal BNP measurement (normal range of 0 to 50 pmol/l) by an independent study investigator. An independent expert panel decided whether or not HF was present using ESC criteria.
Results: 304 patients were included, mean age 72 yrs (SD 11.4), 65% female. 77 patients (25%) met the case definition for HF; these patients had a significantly higher N-terminal BNP than those without HF, 286 (SD 319) vs 61 (SD 67) pmol/l, p=0.0001. The frequentist parameters for BNP in the diagnosis of HF are shown in the table.

Frequentist parameters for BNP

Nt-BNP, pmol/l	Sens, %	Spec, %	PPV, %	NPV, %
>50	89	62	49	94
>100	59	91	75	82
>150	56	93	78	84

From the receiver operating characteristic curve (ROC) for BNP, the diagnostic threshold providing optimal sensitivity and specificity for the diagnosis of HF was 125 pmol/l. The area under the ROC curve for BNP was 0.82.
Conclusion: For a cohort of elderly patients presenting to GPs with symptoms suggestive of heart failure, the diagnostic threshold for N-terminal BNP with optimal sensitivity and specificity was 125 pmol/l. For clinical use in the community, a recommended BNP diagnostic threshold between 100 and 150 pmol/l is appropriate in terms of a high specificity and negative predictive value. The diagnostic threshold for BNP should be carefully considered in the population in which the test is utilised, and may be very different from the upper range of normal.

DETERMINANTS OF LONG-TERM PROGNOSIS IN HEART FAILURE

1476 The efficacy of new interventional programmes depends on the stage of heart failure, evaluated by BNP plasma concentration

R. Pacher[1], K. Schenk[2], D. Sponer[1], R. Berger[1], P. Moser[2], M. Huelsmann[1].
[1]*University of Vienna, General Hospital, Dpt of Cardiology, Vienna, Austria;*
[2]*Ludwig Boltzmann Institute, Cardiovascular Research, Vienna, Austria*

Background: Interventional programmes, including heart failure (HF) outpatient clinics and HF nurse specialists improve life quality, reduce readmission rates and decrease costs.Little is known in which stage of disease such interventions are most effective. Therefore we evaluated the impact of severity of HF, determined by BNP plasma levels, on the efficacy of special outpatient care ("SOPC") in comparison with conventional outpatient care ("COPC"). Methods:112 HF patients (mean age: 68±12 years, 63% males) who were hospitalized 3 months prior to study entrance were randomized to SOPC (n=48) or COPC (n=64). In all patients an individual prescription of RAAS antagonists and additional betablockade including an uptitration schedule according to the ESC guidelines was performed by a cardiologist at the first visit in the HF outpatient clinic. Diuretic regimens and additional therapies (digitalis, anticoagulants, antiarrhythmics) were prescribed as clinical appropriate. In the SOPC group regular home visits by a nurse specialist were arranged after 3,6 and 12 months as well as in case of worsening HF to controll the precribed therapeutic regimen, body weight, heart rate, blood pressure and signs and symptoms of HF.Results: In the SOPC group a significant reduction of the event rate (readmission rate and all cause mortality) was achieved (17% vs. 33%; p=0.04). BNP plasma levels were comparable in both groups (314±272 vs. 369±369 pg/ml; p=n.s.). Patients with BNP values <260 pg/ml had a comparable 1 year event-rate, with and without SOPC (0% vs. 3%; p=n.s.). Patients with BNP values >260 pg/ml, treated with SOPC had more events compared to patients with BNP values <260 pg/ml treated with COPC (32% vs. 3%; p=0.002). Patients with BNP values >260 pg/ml had fever events with SOPC than with COPC (32% vs. 75%; p=0.003). Conclusion: The efficacy of SOPC depends on the severity of disease evaluated by BNP levels. BNP determination might be helpful in selecting patients for novel care programmes, especially when resources are limited.

1477 Prognosis and heart failure: role of C-reactive protein?

H. Tanner, G. Moschovitis, R. Hullin, D. Pfiffner, P. Mohacsi, O.M. Hess.
University Hospital, Swiss Cardiovascular Center, Bern, Switzerland

Background: Clinical studies suggest that inflammation with activation of the cytokine pathway is important in chronic heart failure (CHF) and may be responsible for an adverse outcome in these patients (pts). Thus, the present study evaluates C-reactive protein (CRP) values in CHF pts with regard to severity of the disease and mortality.
Patients and methods: Laboratory evaluation including CRP (norm < 5 mg/l) echocardiography and/or cardiac catheterization were carried out in 126 pts (84% males) with CHF. NYHA-classification was assessed in all pts. Secondary reasons for CRP elevation (infections, tumors, chronic inflammatory diseases) were excluded. Mean age was 54 ± 12 years. 44% pts had coronary artery disease, 51% dilated cardiomyopathy, and 5% valvular heart disease. Mean follow-up was 2.3 ± 1.8 years. Independent predictors for mortality were determined in a stepwise logistic regression model. For mortality analysis, transplanted pts were excluded.
Results: 8% of all pts were in NYHA-class I, 29% in NYHA II, 46% in NYHA III, and 17% in NYHA IV. During follow-up 15 pts (12%) died and 52 pts (41%) were transplanted. CRP values (mean ± SEM, mg/l) in the 4 NYHA-classes were as follows: NYHA I = 2.5 ± 0.4, NYHA II = 3.9 ± 0.6[1], NYHA III = 8.8 ± 1.5[2], and NYHA IV = 9.3 ± 3.3[2], [1]p<0.05 vs. NYHA I,[2]p<0.001 vs. NYHA I. Survivors had a mean CRP level of 3.9 mg/l, pts who were subsequently transplanted 6.2 mg/l, and pts who died during follow-up 21.6 mg/l (p<0.001). 93% of all survivors had a CRP < 7.5 mg/l, whereas 74% of all pts who died had a CRP > 7.5 mg/l. The predictive value of a CRP > 7.5 mg to die during follow-up was 75%. CRP, age and left ventricular ejection fraction were independent predictors for mortality (p<0.01), but not NYHA-class and gender (p>0.5).
Conclusions: CRP is an independent predictor for mortality and is significantly related to the severity of CHF. Furthermore, it allows to identify pts with an increased mortality. Thus, CRP is an simple and reliable parameter for assessing clinical outcome in pts with CHF.

1478 Comparative prognostic significance of plasma aldosterone, BNP, norepinephrine and renin in 4305 patients with heart failure in Val-HeFT

R. Latini[1], S. Masson[1], I. Anand[2], D. Judd[2], M. Salio[1], P. Cardano[1], G. Tognoni[1], J.N. Cohn[2] on behalf of the Val-HeFT Investigators. [1]*Institute Mario Negri, Cardiovascular Research Dept., Milan, Italy;* [2]*University of Minnesota, Minneapolis, United States of America*

Background: Elevated plasma concentrations of several neurohormones (NH) are related to increased mortality/morbidity in patients with heart failure (HF). In most previous studies, the size of the sample has been insufficient to compare the predictive value of different NHs. Val-HeFT evaluated the efficacy of valsartan in 5010 patients with NYHA class II to IV HF, and measured several NHs at baseline, providing an opportunity to examine this relationship.
Methods: Plasma aldosterone (Aldo), brain natriuretic peptide (BNP), norepinephrine (NE) and renin activity (PRA) were measured prior to randomization. The risk ratio (RR) for mortality and non-fatal morbid events(i.e. cardiac arrest resuscitated, hospitalization for HF, IV inotropes or vasodilators for at least 4 hours) was calculated for patients with baseline values >= vs < the median, using a Cox proportional hazard model with baseline NH category as a covariate. Data was analyzed for all patients independent of study group.
Results: Plasma concentrations of individual NHs were available for 4305 patients, with mean (±SD) age 63±11y, 38% in NYHA class III-IV, and mean ejection fraction 27±7%. The risk ratios (RR) for individual NHs (>=median vs. <median) are reported in the table. Patients with baseline NH concentrations above the median had significantly higher risk of dying or having a non-fatal morbid event over a mean follow-up of 23.0 months, when compared to patients with NH below the median. BNP had the highest values for RR and patients with baseline BNP >=97 pg/mL had a greater than 2-fold increase in mortality and non-fatal morbid event.

		RR (95% confidence intervals)	
NH	baseline median	mortality	non-fatal morbid events
Aldo	101 pg/mL	1.13 (0.98-1.30)	1.40 (1.21-1.63)
BNP	97 pg/mL	2.47 (2.12-2.87)	2.97 (2.53-3.49)
NE	394 pg/mL	1.74 (1.51-2.01)	1.59 (1.37-1.84)
PRA	5.3 ng/mL/h	1.44 (1.25-1.65)	1.27 (1.09-1.46)

Conclusions: Whereas all 4 NH are significant prognostic markers in HF, plasma BNP provides the greatest distinction between high and low risk for morbidity and mortality.

1479 Prolonged survival and fewer readmissions: the long-term effects of a home-based intervention in chronic heart failure

S. Stewart, J.D. Horowitz. *The Queen Elizabeth Hospital, Cardiology Dept., Adelaide, Australia*

Background: Although post-discharge programs of care for patients with chronic congestive heart failure (CHF) prolong event-free survival, reduce readmissions and lower costs in the short-term, it is not known to what extent initially observed benefits persist in the longer-term, nor whether such programs positively influence survival.
Methods: We prospectively studied the longer-term effects of a multidisciplinary home-based intervention (HBI) in a composite cohort of typically older CHF patients randomly allocated to either HBI (n = 149) or usual care (n = 148) as part of two closely related randomized studies. As before, we used a primary end-point of time to unplanned readmission or death (event-free survival) on an "intention-to-treat" basis. Other study endpoints included the total number of unplanned readmissions and associated stay, health care costs and all-cause mortality.
Results: During a median of 4.2 years of follow-up, the primary endpoint occurred in 130 (87%) HBI vs 135 (91%) usual care patients. Median event-free survival was more prolonged in the HBI group compared to usual care (7 versus 3 months: $P < 0.01$). Fewer HBI patients died during follow-up (56% vs 65%: $P = 0.06$) and had more prolonged survival (median survival 40 vs 22 months: $P < 0.05$) compared to usual care. Assignment to HBI was both an independent predictor of event-free survival (RR 0.70: $P < 0.01$) and survival alone (RR 0.72: $P < 0.05$). Overall, HBI patients had 78 fewer unplanned readmissions compared to usual care patients (397 vs 475 - a mean of 0.17 vs 0.29 readmissions/month: $P < 0.05$). HBI patients also had a shorter average length of stay and were admitted to less expensives units. Despite more prolonged survival, therefore, HBI patients had 1003 fewer days of readmission (3,123 vs 4,126 - a mean of 1.2 vs 2.3 days/patient/month: $P < 0.001$) and the median total cost of these readmissions per HBI and usual care patient, respectively, was $A325 vs $A660/month ($P < 0.01$).
As such, the cost of initially providing greater levels of health care to HBI patients (about $A600/patient) proved to be less than 10% of total cost-savings in the longer-term ($A7000/HBI patient).
Conclusions: This is the first study to show that the beneficial effects of HBI in reducing frequency of unplanned readmissions in CHF persist in the longer term and are associated with prolongation of survival. These data provide further compelling evidence for the application of this type program as part of the gold-standard post-discharge management of CHF.

1480 Prevalence and prognostic role of anemia in patients with heart failure in the IN-CHF Registry and the Val-HeFT trial

A.P. Maggioni[1], R. Latini[2], I. Anand[3], S. Barlera[2], L. Gonzini[1], C. Opasich[4], L. Tavazzi[5], J.N. Cohn[6] on behalf of Val-HeFT and IN-CHF Investigators.
[1]ANMCO Research Center, Florence, Italy; [2]Mario Negri Institute, Milan, Italy; [3]VA Medical Center, Minneapolis, United States of America; [4]Fondazione S. Maugeri, Pavia, Italy; [5]San Matteo Hospital, Pavia, Italy; [6]University of Minnesota, Minneapolis, MN, United States of America

Background: In the Framingham Study, anemia was an independent risk factor for the development of heart failure (HF), and in SOLVD it was an important predictor of mortality. Moreover, correction of mild to moderate anemia has recently been shown to improve HF. In the present study we assessed the prevalence and prognostic role of anemia in two separate populations: (a) relatively unselected patients in clinical practice (IN-CHF), and (b) a more selected population randomized to Val-HeFT.
Methods: There were 2411 ambulatory patients with HF that were monitored prospectively in a community setting (IN-CHF), and 5010 patients randomized in Val-HeFT. Anemia was defined as a hemoglobin (Hb) level < 11 g/dl in women, < 12 g/dl in men. Univariate and multivariate analyses were performed separately in Val-HeFT and IN-CHF databases to evaluate the prognostic role of anemia.
Results: In the IN-CHF registry there were 15.5% of patients with anemia as compared with 9.9% in Val-HeFT. In both databases patients with anemia were older, had more severe functional impairment, higher ischemic etiology of HF, greater serum creatinine and lower body mass index than patients without anemia. In the IN CHF registry the one-year all-cause mortality was significantly higher in anemic (25.8%) as compared to non-anemic (13.2%) patients ($p<0.0001$), and anemia was an independent risk factor for 1 year mortality in a multivariate analysis (RR 1.59, 95%CI 1.19-2.13).
In Val-HeFT the all cause mortality during the follow-up period of 23.0 months was significantly higher in anemic patients (29.6%) as compared to patients without anemia (18.5%, $p<0.0001$). Even after adjustment for other factors, anemia remained an independent predictor of mortality (26% higher than that of non anemic subjects, RR 1.26, 95%CI 1.04-1.52).
Conclusions: These data confirm that anemia is common in HF patients in the community. Lower incidence of anemia in clinical trials of HF is probably because of exclusion criteria. In both populations, anemia remains an independent predictor of mortality.

1481 Prevalence, characteristics and prognostic signficance of anaemia in heart failure

S. Stewart[1], C. Berry[2], J.D. Horowitz[1], J.J.V. McMurray[2]. *[1]The Queen Elizabeth Hospital, Cardiology Dept., Adelaide, Australia; [2]University of Glasgow, CRI in Heart Failure, Glasgow, United Kingdom*

Background: There are few data examining the clinical and prognostic significance of anaemia in patients with chronic heart failure (CHF).
Methods: Using the unique Scottish Morbidity Record linkage scheme, we examined the prevalence, characteristics and prognostic significance of anaemia in all patients with a first-ever admission for CHF (principal diagnosis) in Scotland during 1990-1995. We also specifically examined the relationship between renal dysfunction and anaemia in a cohort of 291 CHF patients from Australia and Scotland.
Results: During the period 1990-95 a total of 20,049 men and 22,664 women were discharged for the first-time with a principal diagnosis of CHF in Scotland. A secondary diagnosis of anaemia was recorded in 2.8% (0.9% iron deficient) of male and 4.5% (1.3% iron deficient) of female discharges. Non-specific anaemia was the most common form of anaemia recorded. The strongest independent correlate of non-specific anaemia was a concurrent diagnosis of renal disease – the adjusted OR (95% CI) being 2.9 (2.1, 3.9: $P < 0.001$) in men and 3.2 (2.5, 4.2: $P < 0.001$) in women. In the short term, a concurrent coding of both iron deficient anaemia and non-specific anaemia was associated with a significantly better prognosis ($P < 0.001$ for all comparisons). The adjusted risk of death within 30-days of admission associated with iron deficient anaemia was 0.31 (0.18-0.53) in men and 0.39 (0.26-0.59) in women. The equivalent adjusted risk for non-specific anaemia being 0.59 (0.44-0.79) and 0.65 (0.52-0.79). Conversely, whilst the risk of death within 30 days to 2 years was equivalent for those patients with iron deficient anaemia, compared to the rest, non-specific anaemia was associated with an adjusted increased risk of death in both men (OR 1.36; $P < 0.01$) and women (OR 1.21; $P < 0.05$). In the cohort of 291 CHF patients subject to greater scrutiny, we identified a significant, inverse correlation between serum creatinine and haemoglobin levels:in men the R squared was 0.05 ($P < 0.001$) for these two parameters and in women 0.23 ($P < 0.001$) with higher creatinine levels being associated with lower haemoglobin levels in this cohort.
Conclusions: Anaemia is prevalent in CHF patients presenting to hospital for the first time. Non-specific anaemia is commonly associated with renal disease with a strong correlation between higher creatinine and lower haemoglobin levels. Whilst iron-deficient anaemia is associated with better survival rates, non-specific anaemia is independently associated with higher mortality rates in the medium-term.

ASSESSMENT OF LEFT VENTRICULAR FUNCTION BY TISSUE DOPPLER

1505 Local myocardial contraction characteristics in mitral valve prolapse detected by colour tissue Doppler, strain rate and strain imaging

N. Ozdemir[1], C. Kaymaz[2], M. Akçay[2], C. Çevik[2], O. Karakaya[2], O. Yncedere[2], M. BilaloÕlu[2], M. Özkan[2]. [1]*Kosuyolu Heart & Research Hospital, Cardiology Clinic, Istanbul, Turkey;* [2]*Kosuyolu Heart & Research Hospital, Cardiology Clinic, Ystanbul, Turkey*

In patients with mitral valve prolapse (MVP) whether a local heterogeneity in the systolic contraction related to papillary muscle (PM) tracking is controversial. We aimed to assess local longitudinal contraction of LV and PM in MVP using the individual curves of tissue Doppler velocity (TV) and velocity time integral (TVTI), strain rate (SR), strain (epsilon), the time from R-wave to the occurrence of compression/expansion cross-over (TCEC),and tissue density(TD). Study population comprised 25 patients with classical MVP(mean age 40±12).Curved M-mode data were obtained from apical views, and TCEC was measured.Individual longitudinal curves of TV,TVTI, SR, epsilon and TD data were extracted. Peak TV and TVTI were significantly higher for basal lateral and septal LV segments compared with other segments and PM ($p<0.01$). Moreover, both TV and TVTI curves revealed a significant midsystolic peak in the mid lateral and medial LV segments, and a late systolic peak within the PM ($p<0.05$). Late systolic TV peak (up to 10 times compared with baseline, $p<0.001$) within the PM was found to be increased from PM base to chordal insertion points ($p<0.05$). Distinctive mid and late systolic peaks related to mid LV segments and PM were also evident in the SR and epsilon curves. Curves extracted from mid and basal LV,and PM showed that SR was the highest at late systole ($p<0.001$) and increased up to 8-10 times compared with baseline ($p<0.001$).Epsilon curves revealed a distinct and late systolic peak lower than initial peak values ($p<0.05$). Individual TD density curves also disclosed a second late systolic decrease related to PM,mid and basal LV segments ($p<0.05$). However, longitudinal TCEC curves from LV segments, and PM showed no local difference ($p>0.05$).

In conclusion, individual TV,TVTI, SR, epsilon,and TD curves suggest that systolic contraction may offer spatial and temporal difference within the LV wall and PM in patients with MVP. Results seem to be consistent with mid and late systolic increase in local deformation related to papillary muscle tracking by prolapsed mitral leaflets.

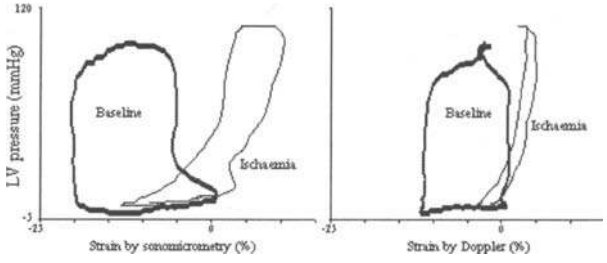
1506 Regional myocardial work index by strain Doppler echocardiography and left ventricular pressure – a new method for quantifying myocardial function

S. Urheim[1], S.I. Rabben[2], E. Lyseggen[2], H. Skulstad[3], H. Ihlen[3], O.A. Smiseth[1]. [1]*Rikshospitalet, Inst.Surg.Research/Dept.of Cardiology, Oslo, Norway;* [2]*Rikshospitalet, Inst.Surg.Research, Oslo, Norway;* [3]*Rikshospitalet, Department of Cardiology, Oslo, Norway*

Background: There is need for better methods to quantify regional myocardial function. In the present study we investigate the feasibility of quantifying regional function in terms of a segmental myocardial work index as derived from strain Doppler echocardiography (SDE) and invasive pressure.

Methods: In 6 anaesthetized dogs we measured LV pressure by micromanometer and myocardial longitudinal strains by SDE and by sonomicrometry. The regional work index was calculated as the area of the pressure-strain loop. Measurements were done during baseline, during intravenous volume loading and during myocardial ischaemia. The figure shows representative pressure-strain loops by the two methods. The area of the LV pressure-strain loop using sonomicrometry was used as reference method.

Results: LV end-diastolic pressures at baseline, during volume loading and LAD occlusion were 6.3 ± 1.1 (± SEM), 20.0 ± 2.1 ($P<0.01$) and 6.4 ± 1.4 mmHg (NS), respectively. Volume loading increased the pressure-strain area from 1.3 ± 0.2 to 2.4 ± 0.2 kJ/m^3 using SDE and from 1.5 ± 0.3 to 2.7 ± 0.3 kJ/m^3 using sonomicrometry, and ischaemia caused a decrease to 0.4 ± 0.1 and 0.6 ± 0.2 kJ/m^3, respectively. The regional work index by SDE correlated well with sonomicrometry ($y=0.70x + 158$, $r=0.80$, $P<0.01$).



Conclusions: A regional myocardial work index can be estimated by SDE in combination with LV pressure. This approach should be tested clinically, and could represent a new method for on-line assessment of myocardial tissue viability during invasive studies.

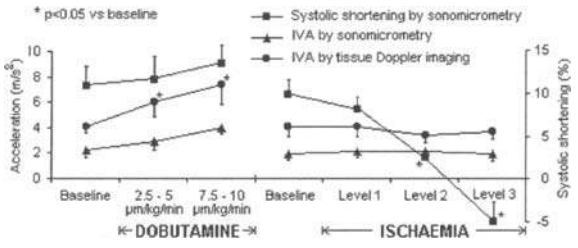
1507 Myocardial acceleration during isovolumic contraction – Is it really a sensitive index of myocardial function?

E. Lyseggen[1], S.I. Rabben[1], H. Skulstad[2], S. Urheim[1], C. Risøe[1], H. Ihlen[2], O.A. Smiseth[1]. [1]*Rikshospitalet, Institute for Surgical Research, Oslo, Norway;* [2]*Rikshospitalet, Department of Cardiology, Oslo, Norway*

Introduction: Myocardial acceleration during isovolumic contraction (IVA), as measured by tissue Doppler imaging (TDI), has been introduced as an index of myocardial contractility. The present study investigates the ability of IVA to reflect changes in regional myocardial function during global enhancement of contractility and during regional myocardial dysfunction.

Methods: In 6 anaesthetized dogs we measured pressures, myocardial long axis velocities by TDI (133-184 Hz), and segment lengths by sonomicrometry (200 Hz). Peak IVA was calculated from the TDI data and the sonomicrometric dimension data (from the positive IVC velocity spike). Measurements were done during baseline, IV dobutamine, and at 3 levels of regional myocardial ischemia (reductions in LAD flow).

Results: Dobutamine infusions increased LV dP/dt max by 121 ± 33% (± SEM, $p<0.05$) and Doppler IVA by 3.3 ± 1.2 m/s2 ($p<0.05$). At ischaemia level 2 there was a marked reduction in systolic shortening by 80 ± 15% ($p<0.05$). At ischaemia level 3 the segments became dyskinetic. (Figure). Doppler IVA, and LV dP/dt max were unchanged at all levels of ischemia. Doppler IVA correlated with IVA by sonomicrometry ($r = 0.67$, $p<0.01$). IVA by sonomicrometry occurred 26 ± 2 ms after start of IVC and at a LV pressure of 13.9 ± 0.8 mmHg.



Relation of QRS- and IVD-Shortening

Conclusions: Consistent with previous reports, myocardial acceleration during isovolumic contraction reflected global changes in LV inotropy. However, IVA did not reflect regional myocardial dysfunction during ischaemia. IVA occurred near end-diastole, and one should consider if IVA may reflect LV end-diastolic wall oscillations rather than intrinsic myocardial contractility.

1508 Patients with a hypertensive response to exercise have impaired systolic and diastolic function

P.M. Mottram, S. Yuda, R. Leano, T.H. Marwick. *Princess Alexandra Hospital, University Department of Medicine, Brisbane, Australia*

Background: A hypertensive (HT) response to exercise predicts the development of chronic hypertension and may represent an early sub-clinical stage of the disorder. We sought whether subtle abnormalities of myocardial function could be detected in these pts with sensitive new echo techniques.
Methods: The study included 52 subjects: 37 pts (age 55±10yrs) with a HT exercise response (BP >210/105mmHg in males; >190/105mmHg in females), normal LV ejection fraction and a negative stress ECG or stress echo and 15 age-matched controls with a normotensive exercise response. Assessment of diastolic function utilized transmitral and pulmonary vein Doppler, flow propagation velocity (color M-mode) and mitral annular velocities. Mean values for cyclic variation (CV) of integrated backscatter (IB), strain rate (SR) and peak systolic strain were averaged from individual segments using Color tissue Doppler imaging (Vingmed System Five) in 3 standard apical views.
Results: Pts with a HT exercise response had mildly reduced exercise performance compared with controls (Bruce protocol duration 8.5±2.7 vs. 10.2±2.2 min, p=0.04). LV mass index was similar, but resting BP was higher and some, but not all, parameters of diastolic function were impaired in HT exercise response pts (table). Peak systolic strain, SR, and CV, were significantly lower in pts compared with controls indicating systolic dysfunction (table).

	Controls	HT Exercise Response	p
Mean resting BP (mmHg)	86±6	104±16	0.0002
LV Mass Index (g/m^2)	81.0±14.4	88.9±19.0	0.16
E wave Deceleration Time (msec)	201±24	223±34	0.028
Flow Propagation Velocity (cm/s)	79±17	64±22	0.024
CV (dB)	7.63±1.04	6.37±0.96	0.0001
SR (1/s)	-1.97±0.25	-1.47±0.22	<0.00001
Peak Systolic Strain (%)	-30.6±3.6	-25.7±3.4	0.00002

This difference in reduction of IB and strain parameters was equally apparent in pts with and without a history of resting HT.
Conclusions: A HT response to exercise is associated with abnormalities of myocardial function, even in the absence of a clinical history of hypertension. Such abnormalities may represent early changes of hypertensive heart disease.

1509 "Pure" diastolic dysfunction: does it ever exist?

D. Vinereanu[1], N. Florescu[2], A. Tweddel[3], M.R. Stephens[3], M. Cinteza[2], A.G. Fraser[1]. [1]*Welsh Heart Research Institute, Cardiff, United Kingdom;* [2]*University Hospital of Bucharest, Cardiology Dept., Bucharest 5, Romania;* [3]*University Hospital of Wales, Department of Cardiology, Cardiff, United Kingdom*

"Pure" diastolic dysfunction is usually diagnosed when Doppler assessment of transmitral flow is abnormal but the left ventricular (LV) ejection fraction (EF) is normal. Transmitral flow reflects global filling, and it becomes abnormal once >50% of LV segments have impaired relaxation. EF may be measured accurately by planimetry, or it may be inferred from fractional shortening which measures only radial function. Longitudinal function, governed by subendocardial fibres, is more sensitive as a marker of early changes in systolic function with age or disease.
Aim: To investigate the correlation between global diastolic dysfunction and regional (radial and longitudinal) systolic function.
Methods: Fifty subjects (15 with hypertrophic cardiomyopathy, 15 with hypertension, and 20 normal subjects, of similar age, 38±10, 44±7, 39±12 years, and EF, 65±8, 64±7, 66±6%) were studied by conventional and tissue Doppler echocardiography. Global diastolic dysfunction was assessed from the flow propagation velocity into the LV by colour M-mode (FPV), from the mean early diastolic velocity of the mitral annulus (Etde), and from its ratio with the transmitral E wave velocity (E/Etde); and global systolic function by measurement of EF (Simpson's rule). Radial and longitudinal function were assessed separately from the posterior wall (PLAX view) and from mitral annular velocities (mean of 4 sites - Stde, apical views).
Results: Global diastolic function correlates (r) with longitudinal systolic function (*p<0.01), but not with radial or global systolic function (table). From 25 patients with isolated diastolic dysfunction (FPV<45 cm/s or Etde<8 cm/s), 23 (92%) also had longitudinal systolic dysfunction (Stde<9 cm/s).

Systolic vs. diastolic LV function

Systolic function	FPV	Etde	E/Etde
Longitudinal	0.41*	0.65*	0.60*
Radial	0.09	0.04	-0.11
Global (EF)	0.04	0.12	0.05

Conclusion: Global "diastolic dysfunction" is strongly associated with a progressive decline in longitudinal systolic function. This suggests that "pure" diastolic dysfunction is diagnosed erroneously when systolic function is assessed by old echocardiographic techniques. Tissue Doppler longitudinal velocities reveal more subtle changes of systolic function.

1510 Early diastolic mitral annulus velocity is superior to flow propagation velocity in assessment of left ventricular diastolic function

T. Paleèek, A. Linhart, J. Bultas, M. Aschermann. *General teaching hospital, IInd department of internal medicine, Prague, Czech Republic*

Background: Pulsed wave tissue Doppler echocardiography (PW-TDE) and color M-mode are novel Doppler methods used for left ventricular (LV) diastolic function assessment. Until now only few studies compared accuracy of these methods in the same series of patients.
Objectives: To determine the utility of PW-TDE and color M-mode parameters in distinguishing abnormal LV diastolic function in patients with various cardiovascular diseases and to compare their discriminating power.
Methods: Early diastolic mitral annulus velocity (Em) determined by PW-TDE and color M-mode flow propagation velocity (Vp) were measured in 86 male patients with clearly defined LV filling pattern type by using standard Doppler indices. Values of Em < 0,08 m.s-1 and Vp < 0,5 m.s-1 were considered to detect abnormal LV diastolic function. Receiver operating characteristics (ROC) curves of Em < 0,08 m.s-1 and Vp < 0,5 m.s-1 were compared by assessing the areas under the curve (AUC), the sensitivity and the specificity were calculated by using standard formula.
Results: A value of Em < 0,08 m.s-1 distinguished abnormal LV diastolic function with higher sensitivity and specificity than Vp < 0,5 m.s-1 (96% and 87% vs. 73% and 84%, respectively). Comparison of ROC curves showed significant difference between AUC on behalf of Em (p < 0,01). In stepwise multiple logistic regression analysis, pseudonormal filling pattern and EF > 60% were identified as significant predictors of Vp false negative results (p < 0,05).
Conclusions: Em appears to be superior to Vp in detection of LV diastolic dysfunction. Vp fails to detect abnormal LV filling in particular in patients with preserved LV systolic function and pseudonormal filling pattern type.

EUROPEAN SOCIETY OF CARDIOLOGY LECTURE ON CLINICAL CARDIOLOGY

1512 Long-term biventricular pacing reduces pulmonary capillary filtration pressures. A study using carbon-11 acetate positron emission tomography

F. Braunschweig[1], J. Sörensen[2], A. Olsson[3], H. von Bibra[1], C. Linde[1]. [1]*Karolinska Hospital, Dept of Cardiology, Stockholm, Sweden;* [2]*Uppsala University, PET Centre, Uppsala, Sweden;* [3]*Karolinska Hospital, Dept of Physiology, Stockholm, Sweden*

Background: Biventricular pacing (BiV) improves symptoms in patients with severe heart failure and intraventricular conduction delay and has been shown to acutely reduce ventricular filling pressures. Whether long term BiV reduces the extent of pulmonary congestion is unknown. To investigate this, we studied the first pass net lung retention rate of 11C-acetate as an index of the pulmonary capillary filtration pressure.
Methods: Six patients (56±10y, EF 22±9%) with severe CHF due to ischemic heart disease (n=3) or dilated cardiomyopathy (n=3), successfully treated with BiV for at least six months, were assessed by 11C-Acetate-PET first at baseline (BiV "on") and after a 2 weeks treatment cessation (BiV "off"). Patients were also evaluated by two-dimensional echocardiography, Brain Natriuretic Peptide (BNP), the six minute walk test and a quality of life questionnaire (Minnesota).
Results: The rate of fist pass acetate-retention in lung tissue was significantly increased when BiV was "off" as compared to "on" (0.039 ± 0.015 and 0.023 ± 0.013 ml/min/ml respectively; p<0.05), indicating an increased pulmonary congestion. In parallel, BNP (+69%, p<0.05) and the left ventricular enddiastolic diameter (+3 mm, p< 0.05) increased between "on" and "off". There was a trend towards a decreased walking distance and QoL.

	11-acetate lung retention (ml/min/ml)	BNP (ng/l)	LVEDD (mm)	6'walk (m)	QoL (score)
BiV "on"	0.023±0.013	110±100	69.0±13.3	517±349	16±8
BiV "off"	0.039±0.015	186±143	71.8±12.9	487±333	22±8
p-value	p<0.05	< 0.05	< 0.05	ns	. ns

Conclusions: This study shows for the first time, that pulmonary capillary filtration pressures and, thus, the extent of pulmonary congestion can be reduced by long term biventricular pacing. This finding is in agreement with recent reports on increased exercise capacity, quality of life and functional class by BiV.

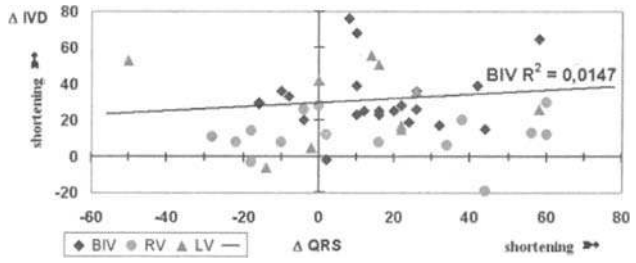
1513 QRS-complex shortening as predictor for electromechanical restoration in heart failure patients with cardiac resynchronization therapy (Cardiac Resynchronization Therapy)

C. Butter, M. Schlegl, M. Schurr, E. Wellnhofer, E. Fleck. *Deutsches Herzzentrum Berlin, Cardiology, Berlin, Germany*

So far there is diverging information about the value of QRS shortening to optimize left ventricular (LV) pacing site and AV delay in patients with congestive heart failure and left bundle branch block undergoing electrical resynchronization therapy.The aim of the investigation was to evaluate the correlation between QRS change and the change in the interventricular electromechanical delay (IVD) measured by Doppler echocardiography.

Methods: 25 patients (QRS 180ms; EF 27%) were implanted with a CRT device suitable for either LV or biventricular pacing (BIV). Optimal AV delay was determined invasively by the maximum increase of pulse pressure during the implant procedure and/or confirmed by Doppler echocardiography according to Ritter's method.The IVD's were assessed by the onset of pulmonary and aortal flow either under sinus rhythm with intrinsic conduction or under different pacing conditions (RV; LV; BIV). 12-lead-ECG was reported parallel and QRS width averaged in II, V1 and V6 three times.

Results: The IVD under sinus rhythm with intrinsic conduction was 65±18.6ms. It was significantly reduced by LV pacing (-65%; $p<0.001$) and BIV pacing (-45%; $p<0.001$), whereas RV stimulation does not change the IVD (-8%;p=0.24). In contrast BIV stimulation showed the largest reduction in QRS width (-8%;p=0.02). Neither LV (-3%; p=0.22) nor RV-pacing (-1,3%; p=0.41)caused a significant change of QRS width. Only in a minority (n=3) was QRS width reduced below 140 ms.



Relation of QRS- and IVD-Shortening

Conclusion: The largest reduction of IVD was achieved by LV pacing, whereas the greatest reduction in QRS width was observed under BIV. No correlation exists between QRS shortening and electromechanical restoration.
Therefore QRS shortening seems not to be a helpful tool to optimize cardiac resynchronization.

1514 PATH-CHF II: Cardiac Resynchronization Therapy using haemodynamically optimized univentricular pacing in heart failure patients stratified by severity of ventricular conduction delay

A. Auricchio[1], C. Stellbrink[2], C. Butter[3], S. Sack[4], J. Vogt[5], A. Ramdat Misier[6], D. Böcker[7], T. Pochet[8] on behalf of the PATH-CHF II investigators. *[1]Univ Hosp, Magdeburg, Germany; [2]Univ Hosp RWTH, Aachen, Germany; [3]German Heart Inst, Berlin, Germany; [4]Univ Hosp, Essen, Germany; [5]Heart Ctr, Bad Oeynhausen, Germany; [6]Isala Klinieken, Zwolle, Netherlands; [7]Univ Hosp, Münster, Germany; [8]Guidant CRM, Diegem (Brussels), Belgium*

The PATH-CHF II multi-center trial assessed clinical efficacy of cardiac resynchronization therapy (CRT) using hemodynamically optimized univentricular pacing in patients (pts) with mild to severe heart failure, with or without ICD indication, who were prospectively stratified by severity of ventricular conduction delay.

Method: The design was a randomized controlled crossover (3 months CRT on and 3 months off) with equal distribution of pts having QRS duration > 150 ms (Group I) or between 120 and 150 ms (Group II). 89 pts were implanted with hemodynamically optimized univentricular VDD pacing (LV pacing: 86, RV pacing: 3). Mean age: 60 ± 9 years, 59 males, mean LVEF 22 ± 8%, mean QRS interval 156 ± 21 ms, NYHA class II/III/IV: 29/59/1. Primary endpoints were peak oxygen uptake (VO2p), oxygen uptake at anaerobic threshold (VO2at) and 6-minute walk distance. Secondary endpoints included quality of life (QOL) score assessed by the Minnesota Living with Heart Failure questionnaire.

Results: The effect of CRT was significant for all endpoints for the whole population, as well as for Group I ($p<0.05$). Significance was not reached in Group II for any endpoint.

Conclusions: The PATH-CHF II trial demonstrates significant clinical improvement in mild to severe heart failure pts. Benefit associated with 3 months of CRT depends on magnitude of baseline QRS interval. However, longer term data are required to confirm these findings. Further analyses are also needed to identify other parameters predictive of CRT benefit, especially in narrow QRS patients.

Results of Groups I and II

Endpoints	Sequence	Group I CRT	Group I No treatment	Group II CRT	Group II No treatment
VO2p (ml/kg/min)	A	15.6 ± 3.6	13.0 ± 3.5	14.5 ± 2.5	14.1 ± 2.4
	B	15.6 ± 2.8	13.6 ± 3.1	15.3 ± 3.4	15.0 ± 3.4
VO2at (ml/kg/min)	A	10.5 ± 2.5	8.9 ± 2.0	10.4 ± 2.0	9.9 ± 2.0
	B	10.8 ± 1.4	9.4 ± 1.4	10.0 ± 2.5	10.0 ± 2.4
6 min walk (m)	A	462 ± 79	407 ± 117	413 ± 81	411 ± 60
	B	448 ± 69	411 ± 61	488 ± 93	479 ± 68
QOL (score)	A	24 ± 19	32 ± 27	22 ± 18	23 ± 23
	B	17 ± 13	24 ± 15	23 ± 21	24 ± 14

Sequence A: pts with active CRT during the first 3 month period. Sequence B: pts with active CRT during the second 3 month period.

COMPUTER DEMONSTRATION

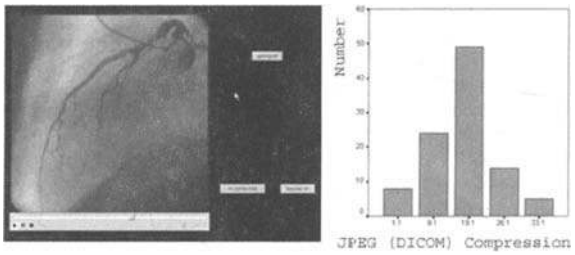
1525 Comparison of different video compression algorithms for angiographic data: a web based approach

W. Vocke[1], T. Warns[2], K. Kronberg[1], J. Riesmeier[2], M. Eichelberg[2], M S. Claus[2], G-H. Reil[1]. *[1]Klinikum Oldenburg, Kardiologie, Oldenburg, Germany; [2]Health Information Systems OFFIS, Oldenburg, Germany*

Background: A compression of angiographic data is obligatory for Internet based applications, e. g. telemedicine, due to the limited network bandwidth. We developed a web based user interface to rate the image quality of different compression algorithms.

Methods: The angiographic data set used for comparison consists of 10 coronary angiograms each of them compressed with 8 different algorithms and 6 different compression ratios. In addition, each set contains the uncompressed data as a reference. Compression algorithms used are JPEG (Joint Photographic Experts Group), JPEG 2000, 2 different MPEG (Motion Picture Experts Group) implementations and 3 proprietary video streaming formats.
We designed a web based user interface to simultaneously display and rate the individual angiographic cases (see table). The rater selects the minimum quality required for diagnostic purposes by switching backwards and forwards through the quality steps (resulting from the different compression ratios). The results are stored in a database which allows for a graphical presentation and additional statistical analyses.

Results: 10 physicians rated 490 films
– none of them had problems using the interface
– the rating took 43 min. on average (from 25 to 75 min.)
– rapid display of statistics, e.g. number of adequate JPEG films (see table, 8x 1:1, 24x 9:1, 48x 19:1, 14x 26:1, 4x 33:1)
– high volume raters (>2500 coronary angiographies) selected significantly more high compressed images as adequate 55,8% vs 35,7%.



User interface and database result.

Conclusion: Our web based approach enables experts to compare different compression algorithms, independently from where they reside. Therefore, it is predestined for multicenter studies on medical image compression over the Internet.

1526 Quantitative three-dimensional intravascular ultrasound: improvements towards (semi-) automated border detection including the stent border

J. Dijkstra[1], G. Koning[1], J.C. Tuinenburg[1], P.V. Oemrawsingh[2], J.H.C Reiber[1]. [1]*Leiden University Medical Center, Radiology, Leiden, Netherlands;* [2]*Leiden University Medical Center, Cardiology Dept., Leiden, Netherlands*

Background: IntraVascular UltraSound (IVUS) is a catheter-based technique, which provides real-time high-resolution images of the arterial wall. The technique is used very often for clinical research studies to measure in-stent restenosis. The technique is used often to monitor the stent placement or to visualize in-stent restenosis. Automation of the boundary detection of the stent, lumen, and vessel reduces the required analysis time and the subjectivity of the manual tracing procedure. The three-dimensional reconstruction permits an advanced assessment of the morphology.
Methods: The user is able to define the distal, proximal and main segment in which the boundaries are detected. If a stent is present, the procedure starts with the automated detection of the stent boundary. The detection method is able to correct itself based on the expected location of the stent struts and uses a three-dimensional model and the approximately circular appearance of the stent. By on-line presenting the area data graphically, the user immediately gets feedback about the quantitative results. Next the vessel and lumen detection is performed, based on a combination of transversal and longitudinal contour detection techniques using a model of the vessel and knowledge about the morphologic structures. The possible errors easily can be corrected by minimal user-interaction.
Results: In a set of 200 slices from different pullback series (acquired with Boston Scientific and EndoSonics equipment) the automatically detected stent boundaries were compared to manually drawn stent boundaries. The comparison of the cross-sectional stent areas for the manually traced and automatically detected boundaries resulted in an r-value of 0.99. In a set of 50 pullback runs (acquired with Endosonics equipment) the entire stented segment was analyzed automatically and the most distal and the most proximal slice in a continuous series of slices containing stent struts was selected to assess the stent length. The comparison of these distances with the original stent lengths resulted in an average overestimation of 0.35 ± 1.42 mm by IVUS. The start and end point of a stent are not well defined because the catheter moves in and out the stent, due to cardiac motion.
Conclusion: Due to the flexible use of more than two longitudinal cutplanes and the advanced knowledge-guided contour detection approach, the new IVUS analysis system has proven to be suitable for clinical research studies. The inclusion of the stent boundary will be very useful for in-stent restenosis studies, e.g. the effect of drug-coated stents.

POSTER DISPLAY III

MODERATED POSTER SESSION III

P1527 Noncompaction of the ventricular myocardium in a paediatric population: study up-date and developmental considerations

C. Lilje[1], V. Rázek[1], A. Müller[1], C. Habermann[2], F. Weiss[2], J. Weil[1]. [1]*Univ.-Klinikum Hamburg-Eppendorf, Kinderkardiologie, Hamburg, Germany;* [2]*Univ.-Klinikum Hamburg-Eppendorf, Diagnostic Radiology, Hamburg, Germany*

Background: Noncompaction of the ventricular myocardium (NCVM) is a rare developmental disorder defined by morphological criteria. The reported morbidity and mortality is considerable.
Purpose: To evaluate the prevalence, associated cardiac features, and implications of NCVM in a pediatric population.
Methods: All patients consecutively examined by echocardiography at our institution between 9/1999 through 12/2001 were evaluated.
Results: 64 of 4.913 patients (1.3%) aged 3days-21years were diagnosed. The gender ratio was 0.83 (f:m). There was consistent affection of the left ventricular apex (100%). Besides NCVM, 21 patients (33%) had a normal cardiac anatomy while 43 patients (67%) suffered from congenital heart defects (CHD). Patients with isolated NCVM were younger than CHD patients. In the first group, 12 patients (57%) had a dilated hypocontractile left ventricle. 2 patients died (4.7%). In the CHD group, 4 patients (9.3%) had a compromised left ventricular function with dilatation. Morphologically, 37 patients (86%) had some kind of left sided, 12 patients (30%) some kind of right sided obstruction. In all 8 patients with VSDs there was affection of the muscular septum (100%). No atrioventricular septal defect, transposition of the great arteries, or truncus arteriosus communis was seen along with NCVM. Neither was NCVM seen in dilated cardiomyopathy following myocarditis. Arrhythmia was found in 3 patients (4.7%), thrombi and embolization in one each (3.1%).
Conclusion: NCVM appears to be more frequent than suspected. Congestive heart failure is common, particularly along with isolated NCVM, while other complications are rare. The coincidence of selected CHD associated with NCVM is striking. Potential developmental implications are discussed. Fetal, histo-pathological, and follow-up studies are sought.

P1528 Targeted disruption of the annexin 6 gene improves resistance to hypoxia injury in the adult mice cardiaomyocyte

G. Song[1], T. Hawkins[2], S. Moss[3]. [1]*University College London, Centre for Cardiovascular Biology, London, United Kingdom;* [2]*University College London, LMCR MRC, London, United Kingdom;* [3]*University College London, Cell Biology, I.O.O., London, United Kingdom*

Annexin 6 is one of a family of Ca^{2+}-dependent phospholipid-binding proteins. The function of annexin 6 is poorly understood, although it has been known that annexin 6 acts as a regulator of intracellular Ca^{2+} and other ion channels, and potentially as an ion channel of the cell. Annexin 6 has been shown in vitro to have a modulatory effect on the SR calcium-release channel, cardiac L-type calcium channel and Na^{+}/Ca^{2+} exchanger. To investigate the possible cardio-toxic and/or cardio-protective effects of annexin 6 in hypoxic conditions, we examined lactate dehydrogenase (LDH) levels in myocytes isolated from mice with targeted disruption of the annexin 6 gene (knockout, KO, n=6, age=12 weeks) and wild type mice (WT, n=6, same age), as well as myocyte live percentage. After isolation then eight hours hypoxia, LDH released by myocytes from annexin 6 KO mice was significantly lower than that from WT animals (0.442±0.031 vs 0.531±0.057, LDH injury index, KO vs WT, mean±SD, $P<0.01$). Eight hours of reoxygenation after eight hours hypoxia further increased LDH levels in both experimental groups, but the significant difference between KO and WT mice remained (0.547±0.073 vs 0.633±0.024, $P<0.05$). In the end of reoxygenation, percentage of live cells was markedly higher in annexin 6 KO group compared to that in WT group (based on a 400-cell count, 44.75±2.99% vs 28.50±2.87%, $P<0.01$). These data indicate that the absence of annexin 6 in the mice may improve myocyte viability and increases cell resistance to hypoxic stress.
It has been reported that human end-stage heart failure is associated with depressed annexin 6 in mRNA and protein levels. We have demonstrated that mechanical properties and Ca^{2+} extrusion and uptake are increased in myocytes from the annexin 6 gene knockout mice. Taken together, these findings suggest that the annexin 6 may play an important role as a negative regulator, not only in intracellular Ca^{2+} cycling and myocyte mechanics, but also in protection of cardiomyocyte. The inhibition of annexin 6 may benefit cardiac functions.

P1529 In vitro culture of muscle derived stem cells for application in human cardiac regenerative therapy by means of cellular cardiomyoplasty

J. Cosin-Sales[1], A. Perez[2], S. Inogés[2], G. Rábago[3], E. Alegria[1], J. Barba[1], J.J. Gavira[1], J. Herreros[3]. [1]*Clinica Universitaria de Navarra, Cardiology Dept., Pamplona, Spain;* [2]*Clinica Universitaria de Navarra, Cellular therapy area, Pamplona, Spain;* [3]*Clínica Universitaria De Navarra, Cardiovascular Surgery, Pamplona, Spain*

Animal studies as well as some preliminary clinical data suggest that transplantation of autologous myoblast (cellular cardiomyoplasty) may result in improvement of cardiac function after myocardial infarction. The purpose of our study was to optimize and upgrade the in vitro culture of autologous myoblast for clinical application. Muscle biopsies from 15 patients undergoing cardiac surgery were obtained. Satellite cells were isolated by enzymatic digestion, culture in Ham F12 media supplemented with human serum and without growth factors. Cells underwent a preplating step on day +6 to deplete fibroblast from the culture. Muscle progenitor cells (myoblast) were identified by their expression of NCAM (CD56), lack of expression of CD45 and the presence of desmin in the cytoplasm by flow cytometry and immunohistochemistry. After preplating, the percentage of CD56+/CD45- cells was 44.12% ± 1.44 (mean ± SEM) while the percentage of desmin positive cells was (40% ± 1.1) (mean ± SEM, correlation > 90%). Samples in which myoblast purity was below 30% were subjected to a positive CD56 cell selection using magnetic immunobeads (MILTENYI). After selection myoblast purity was always greater than 90%. Culture was continued after cell selection. We assessed the effect of serum or plasma concentration, degree of confluence and the number of days in culture. We compare the yield between samples with (group 1) and without (group 2) selection. Cell yield (number of CD56 cells/gram of muscle) was not significantly different between group 1 and 2 (53.1 x 106 ± 2.7 and 49.5 x 106 ± 4.3, respectively), but there were significant differences in percentage of CD56 cells (85.9 ± 2.1 and 36.3 ± 7.6; $p < 0.05$). However, serum concentration below 10% resulted in a significantly reduce cell yield. In conclusion, we demonstrate that enough muscle progenitor cells can be obtained from a 5 grams muscle biopsy for cellular cardiomyoplasty provided there is more than 10% of human serum. Cell selection based on expression of CD56 antigen is a potential way to increase myoblast purity and deplete unwanted fibroblast. The culture system has been scale up for clinical purposes.

P1530 Comparative effects of candesartan and enalapril on left ventricular hypertrophy in patients with essential hypertension: the CATCH study

C. Cuspidi[1], M.L. Muiesan[2], L. Valagussa[1], M. Salvetti[2], C. Di Biagio[3], E. Agabiti-Rosei[2], B. Magnani[4], A. Zanchetti[1] on behalf of CATCH investigators. [1]*Ospedale Maggiore, Clinica Medica e Terapia Medica, Milano, Italy;* [2]*Clinica di Medicina Interna, Scienze Mediche e Chirurgiche, Brescia, Italy;* [3]*Takeda, Rome, Italy;* [4]*Università di Bologna, Istituto di Cardiologia, Bologna, Italy*

Background: A limited number of studies evaluated the effect of angiotensin II receptor antagonists (AIIAs) on left ventricular hypertrophy (LVH) in comparison with other antihypertensive drugs,and no large study has compared AIIAs with angiotensin converting enzyme inhibitors (ACEIs).
Methods and Results: The CATCH (Candesartan Assessment in the Treatment of Cardiac Hypertrophy) study was a multicenter prospective randomized double-blind trial comparing the effects of candesartan cilexetil (8-16 mg o.d.) and enalapril (10-20 mg o.d.) with possible addition of hydrochlorothiazide (12.5-25 mg o.d.) on echocardiographic left ventricular mass index (LVMI), in 239 hypertensives with LVH (LV mass index, LVMI > 120 g/m^2 in men and >100 g/m^2 in women). Two dimensionally guided M-mode echocardiograms were carried out at screening (recruiting scan) randomization (baseline scan) and after 24 and 48 weeks of treatment.Baseline and treatment echocardiograms were read at two central labs without knowledge of the scan time sequence.In intention to treat (ITT) analyses (196 patients), systolic and diastolic blood pressures (SBP,DBP) were significantly and equally reduced by two treatments. Candesartan and enalapril reduced LVMI to the same extent,i.e. by 15.0, and 13.1 g/m^2 (-10.9 and -8.4%), ($p<0.001$ for both). The proportion of patients achieving normalization of LVMI was non-significantly higher with candesartan (36.3 vs 28.6%). Similar results were obtained in per protocol (PP) analyses.Cough incidence was lower with candesartan ($p<0.03$).
Conclusions: CATCH is the first large study comparing the effects of an AIIA and an ACEI on LVMI. Candesartan cilexetil was found equally effective as enalapril in reducing SBP,DBP and LVMI in hypertensives with LVH, according to both ITT and PP analyses.

P1531 Peroxisome proliferator-activated receptor gamma activators inhibit mechanically-induced hypertrophy in cardiac myocytes

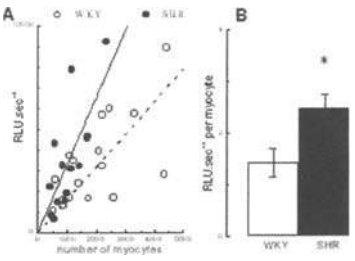
K. Yamamoto, R. Ohki, U. Ikeda, K. Shimada. *Jichi Medical School, Cardiology, Tochigi, Japan*

Background: Peroxisome proliferator-activated receptors (PPARs) are transcription factors belonging to the nuclear receptor superfamily. PPAR gamma, one of three members of PPARs, inhibits growth and migration in vascular smooth muscle cells. The natural prostaglandin D2 metabolite, 15-deoxy-delta12,14-prostaglandin J2 (15d-PGJ2) and synthetic antidiabetic thiazolidinedione (troglitazone) are ligands for PPAR gamma. PPAR gamma mRNA is present in cardiac myocytes; however, whether PPAR gamma affects cardiac hypertrophy remains unknown.
Methods and Results: We investigated the effects of PPAR gamma activators on cardiac hypertrophy in cultured neonatal rat cardiac myocytes. Cyclic 4% biaxial mechanical strain caused enlargement of the cardiac myocytes (1.3 ± 0.1 fold versus control, $P<0.0001$), but the PPAR gamma activators troglitazone and 15d-PGJ2 (10 μM) inhibited this effect (troglitazone, -72%, $P<0.0005$; 15d-PGJ2, -88%, $P<0.0002$). [^{3}H]Leucine uptake was increased by 4% mechanical strain (1.9 ± 0.2 fold versus control, $P<0.002$), and this increase was inhibited by troglitazone and 15d-PGJ2 in a concentration-dependent manner (troglitazone, -52% at 10 μM, $P<0.01$; 15d-PGJ2, -70% at 10 μM, $P<0.005$). Total cell protein was also increased by 4% mechanical strain (control, 164.3 ± 11.9 mg/dish; strain, 265.5 ± 18.0, $P<0.0002$), and this effect was inhibited by troglitazone and 15d-PGJ2 (troglitazone, -61%, $P<0.005$; 15d-PGJ2, -72%, $P<0.001$). In addition, mechanical strain induced mRNA expression for brain natriuretic peptide, but both PPAR gamma activators inhibited this effect. Furthermore, both PPAR gamma activators inhibited the activation of nuclear factor-kB (NF-kB) induced by mechanical strain. Pyrrolidine dithiocarbamate, an inhibitor of NF-kB activation, inhibited strain-induced [^{3}H]leucine uptake (-50% at 100 μM, $P<0.05$).
Conclusions: These results demonstrate that PPAR gamma activators inhibit mechanically-induced cardiac hypertrophy in cardiac myocytes and suggest that PPAR gamma activators may regulate cardiomyocyte hypertrophy via the NF-kB pathway.

P1532 Superoxide production by left ventricular myocytes in control and hypertrophied hearts

S.M. Bryant, C. Sears, Y.M. Kim, K. Channon, B. Casadei. *University of Oxford, Cardiovascular Medicine, Oxford, United Kingdom*

Oxidative stress induced by an increase in vascular superoxide anion (O2-) production has been implicated in the pathogeneses of cardiac hypertrophy and failure. However it is unknown whether O2- is generated from within ventricular myocytes themselves and whether an increase in its production is an early feature of myocardial pathology. In this study we have measured NADPH-stimulate O2- production in left ventricular myocytes isolated from age matched (8 week) Wistar (WKY) and spontaneously hypertensive rats (SHR) rats, using lucigenin-enhanced chemiluminescence (5μM lucigenin), at 37°C. Data are presented as mean±sem (n). NADPH elicited O2- production in a dose-dependent manner (EC50; 53±1 μM). NADPH-stimulated O2- production was not attenuated in myocytes pre-incubated with oxypurinol (100μM) or rotenone (100μM) but was abolished by the flavoprotein-oxidase inhibitor diphenyleneiodonium (100μM) and was quenched by tiron. Fig.1A shows that the relationship between NADPH-stimulated O2- production and myocyte number is steeper in hypertrophied (SHR) than in control (WKY) myocytes ($P < 0.05$). Mean data for the slope (calculated for each experiment) shows that NADPH-stimulated O2- production is increased by ~58% in hypertrophy from 1.43±0.27 in WKY to 2.46±0.28 RLU sec^{-1} per myocyte in SHR ($P < 0.05$, Fig 1B). Qualitatively similar data were obtained in a murine model of isoprenaline induced-hypertrophy.



Superoxide production in hypertrophy.

Conclusion: These data show for the first time that superoxide is released from within rat ventricular myocytes. NADPH-stimulated O2- production is mediated via a flavoprotein-containing oxidase (presumably NAD(P)H-oxidase) and is increased in hypertrophy. These findings suggest a putative autocrine role for superoxide in the control of cardiac function.

P1533 FKBP12 overexpression in isolated rabbit cardiomyocytes enhances intracellular Ca^{2+} transients, SR Ca^{2+} content and contractility

T. Seidler[1], D. Zibrova[1], D. Reynolds[2], C.M. Loughrey[2], A. Kania[1], H. Kögler[1], G.L. Smith[2], G. Hasenfuß[1]. [1]*Georg-August University Goettingen, Dept. Cardiology and Pneumology, Goettingen, Germany;* [2]*University of Glasgow, Inst. of Biomedical and Life Sciences, Glasgow, United Kingdom*

In heart failure, Ca^{2+} release from the sarcoplasmic reticulum (SR) is disturbed. The FK506 binding proteins FKBP12 and FKBP12.6 coordinate function of SR Ca^{2+}-release channels (RyR) in striated muscle. FKBP12.6 binds to the cardiac RyR isoform (RyR2) and over-expression of FKBP12.6 in cardiac myocytes diminishes Ca^{2+} leak via RyR2, increases SR Ca^{2+} content and contractility. Expression levels of FKBP12 in heart are considerably higher than FKBP12.6, yet previous work suggested that FKBP12 does not associate significantly with RyR2. To investigate this further, we have enhanced FKBP12 expression in isolated rabbit cardiomyocytes using adenoviral gene transfer.
Successful overexpression was demonstrated by increased FKBP12 RNA, and -protein levels using RT-PCR and Western blots. Contractility of isolated rabbit cardiomyocytes was measured by video edge detection 48h post adenoviral transfection. When compared to lacZ transfected myocytes (beta-galactosidase control), FKBP12 over-expressing cardiomyocytes showed significantly increased fractional shortening (FS) (by 12%) at a multiplicity of viral infection (MOI) of 100 (2.1±0.2% vs 2.4±0.3%, respectively, n=12, p=0.04). In separate experiments, intracellular Ca^{2+} transients were monitored in Fura-2 loaded cardiomyocytes stimulated at 1Hz. No change in diastolic [Ca^{2+}] was observed in the two experimental groups, but peak systolic [Ca^{2+}] was significantly higher in FKBP12 over-expressing cardiomyocytes (587±25nM) compared to the lacZ control (482±28nM) group. Furthermore, the amplitude of the Ca^{2+} transient in response to 10mM caffeine was enhanced to a similar extent (peak value 1181±44nM vs 1003±50nM) indicating the increased contractility is a result of enhanced SR Ca^{2+} content.
Additional experiments were carried out on beta-escin permeabilised cardiomyocytes perfused with 160nM Ca^{2+} in a mock intracellular solution. Under these conditions caffeine-induced Ca^{2+} release was significantly greater in FKBP12 over-expressing cardiomyocytes when compared to lacZ transfected cells (caffeine integral = 0.7±0.1 μMs vs 1.6±0.1 μMs). This suggests that increased SR content in response to FKBP12 over-expression is a result of direct effects on cardiac SR function and challenges the current view, that FKBP12.6 is the isoform that exclusively modulates RyR2.

P1534 Mutations in the human muscle LIM protein gene in families with hypertrophic cardiomyopathy

C. Geier[1], A. Perrot[1], C. Oezcelik[1], P. Binner[2], T. Scheffold[2], K. Hoffmann[3], P. Nuernberg[3], K.J. Osterziel[1]. [1]Charité/Campus Buch & Virchow-Klinikum, Kardiologie, Berlin, Germany; [2]Herz-Kreislaufforschung, Institut f. Mol. & Klin., Wuppertal, Germany; [3]Max-Delbrück-Centrum, Gene Mapping Center, Berlin, Germany

Introduction: Muscle LIM protein (MLP) is an essential nuclear regulator of myogenic differentiation. Additionally, it may act as an integrator of protein assembly of the actin-based cytoskeleton. MLP-knockout mice develop a marked cardiac hypertrophy reaction and dilated cardiomyopathy. MLP is therefore a candidate gene for heritable forms of hypertrophic (HCM) and dilated cardiomyopathy (DCM) in humans.
Methods: We evaluated 600 unrelated individuals (400 patients with DCM, 200 patients with HCM) using physical examination, ECG, echocardiography/TDI, and heart catheterization. DNA was extracted from blood. The samples were analyzed for mutations in the human CRP3 gene encoding MLP by polymerase chain reaction, single strand conformation polymorphism analysis, and sequencing.
Results: We found 3 different missense mutations in 3 unrelated patients with familial HCM, but detected no mutation in the DCM group and a control group (n=200). All mutations predict an amino acid exchange. They affect highly conserved residues in the functionally important LIM 1 domain which is responsible for interaction with alpha-actinin and with certain muscle specific transcription factors. Family studies revealed cosegregation of clinically affected individuals with the respective mutations in MLP.
Conclusion: Our study provides evidence that mutations in the CRP3/MLP gene can cause HCM.

P1535 Novel mutations in the beta myosin heavy chain (β-MHC) and myosin binding protein C (MYBPC3) gene are associated with dilated cardiomyopathy

J. Erdmann[1], S. Dähmlow[2], T. Knüppel[2], C. Frömmel[3], C. Gille[3], A. Elsner[2], R. Hetzer[2], V. Regitz-Zagrosek[2]. [1]University Hospital Regensburg, Cardiology, Regensburg, Germany; [2]Deutsches Herzzentrum Berlin, Cardiac and Thoracic Surgery, Berlin, Germany; [3]Charite, Institute of Biochemistry, Berlin, Germany

Mutations in the β-MHC and MYBPC3 gene have been reported to cause hypertrophic cardiomyopathy (HCM). Recently, mutations in the β-MHC gene and in the troponin T gene have been reported to cause dilated cardiomyopathy (DCM). In order to detect novel mutations in sarcomeric genes that are linked with DCM we screened the βMHC and the MYBPC gene in 46 consecutive patients with DCM.
Mutation screening was done with SSCP at 2 different temperatures. Comparison with the wave procedure in 1000 PCR fragments yielded >95% sensitivity for this approach. Mutations were confirmed by repeated sequencing of independent PCR products. The effect on proteins structure was determined with the STRAP: Editor for Structural Alignment of Proteins (Bioinformatics 2001:377) program.
In the β-MHC gene, the two mutations Ala 223 Thr and Ser 642 Leu were found in two young patients with severe DCM. They affect two highly conserved amino acids. Nonpolar side chains are exchanged against uncharged polar groups. The mutations are localized in the globular part (head) of the myosin molecule situated near the surface but not on the solvent accessible surface. Considering the effects of the mutants on the protein structure in comparison to all known 3-D-structures of myosin, including given sequence information, we conclude that both amino acid exchanges will influence the local structure.
In the MYBPC3 gene, Asn 948 Thr occurs in a DCM patient and exchanges a conserved AA. All three mutations were not found in 88 controls and not in 136 patients with HCM.
Thus, mutations in sarcomeric genes that are expected to modify protein structure and that have not been linked with HCM so far, are associated with DCM. Causal relations must be established by family studies.

P1536 The human AT2 (+1675G/A) polymorphism influences left ventricular structure in hypertensive males, but not in females

M. Fischer[1], C. Hengstenberg[1], S. Holmer[1], V. Regitz-Zagrosek[2], G.A.J. Riegger[1], H. Schunkert[1], J. Erdmann[1]. [1]University of Regensburg, Medical Department II, Regensburg, Germany; [2]Deutsches Herzzentrum, Cardiac and Thoracic Surgery, Berlin, Germany

A polymorphism of the x-chromosomal human angiotensin II subtype 2 receptor (AT2-R) gene (+1675G/A) was recently associated with LV hypertrophy in young men with arterial hypertension, while in individuals without hypertension no such relationship was documented.
The aim of this study was to reinvestigate the implications of the AT2 +1675G/A polymorphism on LV structure in an independent population.
We used real-time PCR and melting curves on a LightCycler (Roche Molecular Biochemicals) to genotype the +1675G/A polymorphism of the human angiotensin II receptor subtype 2 in a total of 1534 participants of an age-stratified general population. LV hypertrophy was defined as a LV mass index (LVMI) of >=131 g/m^2 in men and >=100 g/m^2 in women and hypertension as a blood pressure >=160/100 mmHg. The overall frequency of the A and G allele was 57% and 43%, respectively. The slopes of the regression lines correlating systolic or diastolic blood pressure levels with septal thickness, posterior wall thickness and LVMI were significantly steeper in male individuals carrying the A-allele compared to the slopes in individuals with the G-allele ($p<0.01$). Moreover, septal wall thickness, posterior wall thickness and LVMI were significantly higher in hypertensive men carrying the A-allele as compared to those with the G-allele ($p<0.01$). In male hypertensive carriers of the A-allele prevalence of LV hypertrophy was substantially higher than in carriers of the G-allele (27.1% vs. 2.4%, $p<0.01$). In normotensive men and in women there was no association between LV hypertrophy and AT2 +1675G/A-polymorphism. Multivariate analysis confirmed the polymorphism as an independent predictor of cardiac hypertrophy related to pressure overload.
This study confirms the relation between the x-chromosomal AT2 +1675G/A-polymorphism and LV hypertrophy in hypertensive men. No such association could be demonstrated in women suggesting additional hormonal influences.

ATRIAL FIBRILLATION – ABLATION, MECHANISMS

P1537 Transveneous cryoablation of supraventricular tachycardia including atrial fibrillation

L. Rodriguez[1], C. Geller[2], H. Tse[3], C. Timmermans[1], S. Reek[4], K. Lee[3]. [1]Academic Hospital Maastricht, Department of Cardiology, Maastricht, Netherlands; [2]Otto-von-Guericke University, Department of Cardiology, Magdeburg, Germany; [3]Queen Mary Hospital, Department of Cardiology, Hong Kong, China; [4]Otto-von-Guericke University, of Cardiology, Magdeburg, Germany

Background: Radiofrequency (RF) catheter ablation is currently used in the treatment of cardiac arrhythmias. Although the success rate is high for almost all supraventricular tachycardias (SVT), this technique has some limitations in safety and effectiveness for treating more complex arrhythmias. The aim of this study is to report the acute safety and efficacy of a new cryoablation system when used for the treatment of SVT, including the treatment of atrial fibrillation (AF).
Methods: Forty-nine patients with SVT (age: 48 years; [23-76], male=38) were enrolled in this study. Five patients dropped out of the study prior cryoablation. The remaining 44 patients were treated with cryoablation (AF [n=22], atrial flutter [n=15], accessory pathway [n=3], AV nodal reentrant tachycardia [n=2], AV junction ablation for permanent AF [n=1], atrial tachycardia [n=1]). Cryoablation was performed with the CryoCor cryoablation system that uses a 10 Fr catheter, a pre-coolong system and N2O as the refrigerant. Acute success was defined as electrical block across the ablation site or line.
Results: The number of freezes applied varied according to the index arrhythmia treated (1-34 freezes/patient). Acute success was 100% (23/23) for right-sided procedures and 96% (20/21) for pulmonary vein isolation. Fifty-three out of fifty-five PV(s) were isolated (2.5 PV/patient). The case of failed PV isolation was complicated by persistent AF. The average and nadir catheter tip temperature for right and left-sided procedures were similar and stable -75±1.63°C and -80°C and -75±5.89°C and -78°C respectively. Procedure related complications included stroke (n=1), transient ST-T segment changes (n=1) and AV fistula (n=1). There were no serious cryoablation related complications or acute PV(s) stenosis.
Conclusions: This novel cryoablation system can safely and successfully treat various types of SVT including AF. Despite of the high blood flow in the right atrial isthmus and PVs, conduction block can be obtained at these sites with cryoablation.

P1538 Microwave isthmus ablation with a novel catheter

L. Karolyi[1], S.G. Spitzer[1], B. Merkely[2], L. Geller[2], O. Kiss[2], A. Laszik[3], P. Sotonyi[3]. [1]*Institute of Cardiovascular Research, Electrophysiology, Dresden, Germany;* [2]*Semmelweis Medical University, Cardiovascular Surgery, Budapest, Hungary;* [3]*Semmelweis Medical University, Forensic Medicine, Budapest, Hungary*

Application of microwave energy, using different prototypes of generators and catheters (microwave antennas), has been considered more effective for the creation of transmural lesions than radiofrequency energy. The aim of the study was to test the safety and feasibility of creating linear lesions in the right atrial isthmus using a new microwave catheter. Also, the dose-response correlation of different energy settings on histopathological changes was studied. Ablation was performed in eight open chest mongrel dogs (weight: 29 ± 8 kg) using a 2.450 MHz microwave generator with 35-50 Watts and a recently designed 9 F deflectable catheter with a 25 mm antenna. Linear lesions were created at a mean maximum antenna temperature of 49 ± 3 °C. The catheter was placed first in the cavotricuspid isthmus and than withdrawn to the inferior vena cava until bidirectional block occurred. Bidirectional isthmus block was achieved in five dogs delivering 1.8 ± 0.8 (min: 1, max: 3) ablations. A total of eleven isthmus lesions were created, with a mean length of 12.9 ± 6.3 mm and width of 5.9 ± 2.4 mm. The histological examination of the lesions are characterized by haemorrhage, development of oedema, presence of focal fibrin thrombi in small vessels, focal myocytolysis or hypercontraction necrosis. None of the 4 lesions created by 35 watts were transmural, however 6 of the 7 lesions created by energy settings of 40-45-50 watts were transmural. Ventricular arrhythmias during energy delivery were not observed. Coronary artery thrombosis or significant catheter thrombosis were also not observed.

Conclusion: The lowest energy setting in this study (35 watts) was also able to produce acute bidirectional block, but the lesion was not transmural and characterized by oedema. This may be associated with a high recurrence rate. Low energy and insufficient tissue contact were probably responsible for the unsuccessful ablations. Based on these data, energy settings up to 40 watts (maximum 50 watts) and application duration of approx. 90 seconds are recommended.

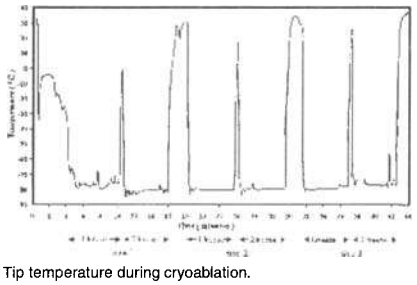
P1539 The addition of a pre-cooler allows a novel catheter-based cryoablation system to obtain low and stable temperatures

C. Timmermans[1], K. Scharnberger[2], G.M. Ayers[2], H.J.G.M. Crijns[1], L.M. Rodriguez[1]. [1]*Academic Hospital Maastricht, Cardiology, Maastricht, Netherlands;* [2]*CryoCor Inc., San Diego, United States of America*

Background: Studies using cryothermia (Cryo) to create myocardial lesions have shown promising results. However, these earlier systems, when used for tranvenous ablation in regions of increased blood flow, may be underpowered to produce sufficient low and stable temperatures (T) needed to create permanent lesions. The study purpose was to evaluate a new cryoablation system that uses a pre-cooler to increase efficiency of catheter tip refrigeration.

Methods: The cryoablation system (CryoCor) consists of a 10-Fr catheter with a 6.5 mm tip electrode and a console. It uses a gas primary refrigerant that is pre-cooled (-35°C) to a liquid state by a secondary refrigerant. The primary refrigerant then expands through a small orifice at the catheter tip to produce the cooling effect. In 5 dogs right atrial isthmus (RAI) ablation was performed with Cryo to test the ability of the system to achieve and maintain adequate catheter tip T.

Results: All RAI were successfully ablated with 6 (see graphic) to 10 freezes at 3 to 5 sites. Nadir T was between -68 and -83°C (mean -75±1.6°C). T of -65°C was reached 3±0.2 sec and nadir T 9±0.5 sec after onset of Cryo. Mean T fluctuation during a freeze was 2.6±0.6°C.



Tip temperature during cryoablation.

Conclusion: The addition of a pre-cooler appears to overcome the issues associated with transvenous Cryo, namely the ability to achieve rapid, low and stable catheter tip T.

P1540 Atrial natriuretic peptide before and after cardioversion therapy in patients with chronic atrial fibrillation

B. Wozakowska-Kaplon[1], G. Opolski[2], M. Janion[1]. [1]*Wojewodzki Szpital Zespolony, Oddzial Kardiologii, Kielce, Poland;* [2]*Medical University of Warsaw, Internal Medicine & Cardiology Dept., Warsaw, Poland*

The treatment of patients (pts) with atrial fibrillation (AF) has improved significantly during the past decade, but most pts remain limited by symptoms and recurrence of arrhythmia. The studies on neurohormonal remodeling in pts with AF are becoming increasingly important. The results could possibly enhance treatment of these pts.

The aim of this study was to determine plasma atrial natriuretic peptide (ANP) concentrations in pts with chronic AF, one day before, the day after and 30 days after electrical cardioversion (CV) therapy.

Methods: We attempted CV in 42 consecutive pts (30 men and 12 women), aged 57±8 years, with chronic nonvalvular AF of duration 7±6 months. The underlying heart disease was diagnosed as systemic hypertension in 20, ischaemic heart disease in 17, dilated cardiomyopathy in 3 and arrhythmia alone in 2 pts. All these pts had good left ventricular function, with ejection fraction of >50%. They were in controlled AF and with normalized blood pressure. Plasma samples of ANP were obtained at rest: one day before, the day after and 30 days after CV therapy, and were prepared by refrigerated centrifugation and stored until radioimmunoassay.

Results: CV was successful in 35 pts. However in 6 of the 35 pts, AF reappeared within 1 month. The control group comprised 11 pts, matched with age, sex and concomitant diseases, and without AF. There were not statistical differences before CV in pt's characteristics between the group with successful CV and unsuccessful CV or with recurrence of AF. The mean baseline ANP level was 58,5±15,7 pg/ml in the study group and 34,3±10,2 pg/ml in the control group ($p<0,01$). The successful therapy reduced significantly the pretreatment mean plasma ANP concentration from 58,5±15,7 to 31,4±15,0 pg/ml; $p<0,01$, the day after CV, in the group of 35 pts. It remained stable for the next 30 days (36,9±15,2pg/ml) in the group of 29 pts who remained in sinus rhythm, and increased to 53,4±16,4pg/ml in the group of six pts who had recurrence of AF. Plasma ANP did not change in the group of 7 pts with unsuccessful CV, one day before, the day, and 30 days after CV: 60,2±10,7; 59,4±10,4; and 56,6±10,6 pg/ml, ns, respectively.

Conclusions: The plasma ANP concentration in pts with AF was significantly reduced after successful CV and remained stable for a period of 30 days.

P1541 Evaluation of atrial propagation by electroanatomic mapping in patients with idiopathic paroxysmal atrial fibrillation versus control patients

R. De Ponti[1], M. Tritto[1], G. Spadacini[1], M. Lanzotti[1], R. Marazzi[1], P. Abello[1], F. Caravati[2], J A. Salerno-Uriarte[2]. [1]*University of Insubria, Dept. Cardiol "Mater Domini", Castellanza, Italy;* [2]*Fond. Macchi - University of Insubria, Dept. Cardiovasc. Sci., H Circolo, Varese, Italy*

The aim of this study is to evaluate atrial conduction in pts with idiopathic paroxysmal atrial fibrillation (IPAF) by comparing electroanatomic propagation maps on sinus rhythm of IPAF pts vs control (C) pts. After informed consent, 15 pts were included in the study; 8 (8 M, mean age 40±11 yrs) in the IPAF group and 7 (5M, 37±11 yrs) in the C group. In the IPAF group, pts had no frequent ectopies triggering AF episodes, no organic heart disease and they were on stable sinus rhythm and off drug at the time of evaluation. In the C group, pts had no history of atrial arrhythmias, no organic heart disease and underwent an off drug electrophysiologic procedure for ablation of a left-sided accessory pathway. Mapping was performed on stable sinus rhythm, in both atria, by an electroanatomic mapping system (CARTO, Biosense-Webster, Inc.). Qualitative and quantitative analyses of propagation maps were performed. A mean of 110±22 and 87±20 mapping sites were acquired in the right (RA) and left atrium (LA), respectively. The propagation duration was longer both in the RA (106±8 vs 92±10 ms) and in the LA (103±18 vs 81±10 ms) in IPAF pts as compared to C pts. Accordingly, also the atrial systolic time interval was longer in the IPAF group than in the C group (136±20 vs 105±9 ms, respectively). Particularly, a marked prolongation (mean value in the C group + 2 standard deviations) of propagation was observed in the RA in 3 pts and in the LA in 4 pts. In addition, 4 pts showed a marked prolongation of the interatrial propagation over the Bachmann's bundle. No prolonged propagation was observed in the C group.

In conclusion: these preliminary data show that a subset of pts with AF, even in the absence of an organic heart disease, have an altered atrial conduction on sinus rhythm, as compared to C pts. Electroanatomic mapping seems to be able to identify different pattern of altered propagation.

P1542 C-reactive protein and atrial fibrillation: evidence of an inflammatory process in the initiation and perpetuation of the arrhythmia

M. Acevedo[1], R. Corbalan[1], L.A. Perez[1], S. Braun[1], D. Springmuller[1], J. Pereira[2], M.T. Lira[1], C. Navarrete[3]. *[1]Catholic University Hospital, Cardiovascular Diseases, Santiago, Chile; [2]Catholic University Hospital, Thrombosis and Hemostasis, Santiago, Chile; [3]Catholic University Hospital, Public Health, Santiago, Chile*

Atrial Fibrillation (AF) is the most common sustained arrhythmia.The mechanisms that contribute to the triggering and perpetuation of AF are still not fully understood. We hypothesized that an inflammatory process can be involved in the genesis and maintenance of AF. We determined C-reactive protein (CRP), a marker of systemic inflammation, in patients with paroxysmal and chronic AF.
Methods and Results: We prospectively determined CRP plasma levels (immunoturbidimetric method) in 104 patients: 88 with non-valvular AF (50 with paroxysmal and 30 with chronic AF) and 16 patients with valvular heart disease, and compared them with 20 normal subjects in sinus rythm matched by age and sex. Mean age of the group was 66 ± 14 years old, 55 males. Forty-six percent of the patients were > 70 years old, 51% were hypertensives, 14% diabetics and 34% had associated CAD and/or dilated cardiomyophaty. Seven patients reported previous embolic events. Transesophageal echocardiography showed 56% of patients with an enlarged left atrium (>45 mm), 54% with left atrial echo contrast and/or presence of thrombus, and 12% with evidence of systolic left ventricular dysfunction. CRP levels at entry were 1.1 ± 1.9 mg/dL in the entire cohort, 0.6 ± 0.9 mg/dL in patients with paroxysmal AF, 1.7 ± 3.4 mg/dL in patients with chronic AF and 1.7 ± 2.1 mg/dL in patients with valvular AF. CRP levels were significantly higher in all groups when compared to a control group of 20 patients in sinus rythm (p = 0.001 entire AF, p = 0.01 paroxysmal AF, p =0.01 chronic AF and p = 0.03 valvular AF versus controls). Overall, there was a trend for reduction in CRP levels after 30 days (p = 0.06). The reduction was significant and more pronounced in patients with chronic AF than paroxysmal AF (p = 0.03) and it was not related to use of antiplatelet and/or oral anticoagulants agents after discharge or during the 30-day follow up. CRP levels were significantly related to history of hypertension (p = 0.03) and left atrial enlargement (p = 0.04) but not to age (p = 0.98).
Conclusions: This study provides evidence of the presence of an inflammatory process that may be involved in the genesis and perpetuation of AF.

P1543 Characterization of paroxysmal and persistent atrial fibrillation in the human left atrium

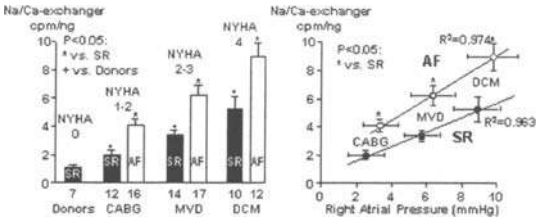
M. R. Karch, G. Ndrepepa, M.A.E Schneider, J. Dong, B. Zrenner. *Deutsches Herzzentrum Muenchen, Cardiology, Munich, Germany*

Atrial fibrillation (AF) in the left atrium (LA) is poorly defined in terms of regional differences in the degree of organization.
Methods and Results: The study population consisted of 21 patients (15 men and 6 women; mean age 58 ± 9.4 years) with paroxysmal (10 patients) and persistent (11 patients) AF. Mapping of the LA during AF was performed with a 64-electrode basket catheter (Constellation® Boston Scientific) equipped with a software to perform quantitative analysis of AF characteristics. Patients with paroxysmal AF had longer AF cycle lengths (CL) and more pronounced regional differences as compared with the patients with persistent AF. A septal-to-lateral gradient in the distribution of the AF CL, with the septal region showing the shortest CL was observed. In total, AF CL in the LA in patients with persistent AF were 20% shorter than in patients with paroxysmal AF. AF CL in the coronary sinus (CS) were 21% shorter in patients with persistent as compared with patients with paroxysmal AF.
Compared with CL in the posterior wall of the LA, the CS CL were 26% and 29% longer in patients with paroxysmal and persistent AF, respectively. Type I AF was dominant pattern in the anterior wall of the LA. In all other regions of the LA in the paroxysmal and persistent AF groups the type III AF was the most dominant pattern in the activation of the LA. The CS activation displayed a higher degree of organization as compared to the posterior wall of the LA.
Conclusions: AF in the LA displays substantial regional differences in terms of AF cycle lengths and the degree of organization (types of AF). Patients with persistent AF have shorter cycle lengths and a higher degree of disorganized activity than patients with paroxysmal AF. Due to substantial differences in terms of AF cycle lengths and the activation patterns, the CS does not reflect the LA activity.

P1544 Upregulation of the atrial Na/Ca-exchanger in patients with atrial fibrillation: correlation with atrial pressure and the degree of heart failure

U. Schotten[1], M. Greiser[2], D. Benke[2], C. Stellbrink[2], J.F. Vazques-Jiminez[2], P. Hanrath[2]. *[1]Maastricht University, Dept. of Physiology (CARIM), Maastricht, Netherlands; [2]University Hospital Aachen, Dept. of Cardiology, Aachen, Germany*

Background: Altered Ca^{2+} homeostasis has been hypothesized to contribute to the proarrhythmogenic substrate in atria of patients with atrial fibrillation (AF). Increased likelihood of delayed after-depolarisations (DADs) mediated by the Na^{+}/Ca^{2+}-exchanger (NCX) might contribute to this phenomenon. We studied the NCX protein expression in right atria of patients with and without AF.
Methods: Using Western blot analysis we determined the protein expression of the NCX in right atrial appendages of 88 patients. 7 Appendages were obtained from organ donors, the other patients underwent: coronary artery bypass graft surgery (CABG, n=28), mitral valve surgery (MVD, n= 31), or cardiac transplantation due to dilated cardiomyopathy (DCM, n=22). The atrial NCX content was related to the atrial rhythm and to the hemodynamic and clinical state of the patients.
Results: In all underlying heart diseases the NCX was significantly upregulated in patients with AF. In addition, a higher NYHA class and an increased atrial pressure were associated with an upregulation of the NCX.



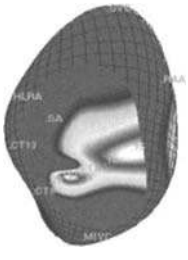
NCX protein expression in right atria.

Conclusion: The high prevalence of AF in patients with a higher NYHA-class suggests that an increased probability for DADs due to the upregulation of the NCX might contribute to the proarrhythmogenic substrate in AF.

P1545 Right and left atrial initiation of atrial fibrillation: three-dimensional atrial activation analysis

A. Filipecki[1], S. Saksena[2], A. Prakash[2]. *[1]Electrophysiology Research Foundation, Passaic, United States of America; [2]Atlantic Health System, Cardiovascular Institute, Passaic, United States of America*

The origin of atrial premature beats (APBs) and onset of spontaneous AF was studied with 3-D non-contact and biatrial catheter mapping in 36 pts with recurrent, drug-resistant AF: Gp.1 - 16 pts had focal pulmonary vein (PV) or left atrial (LA) triggers and Gp.2 - 20 pts had right atrial (RA) triggers. In all pts RA or LA AF was initiated by a single beat-to-beat changing wavefront. In Gp.1 the mean AF cycle length (CL) was 211±34 ms. In 10 Gp. 1 pts, a single LA wavefront emerged into the RA in the high (n=4) or mid septum (n=6) and divided into superior and septal RA wavelets (Fig.1). The superior wavelet activated the lateral RA and the septal wavelet propagated craniocaudally and transversely to fuse with the superior wavelet. In 6 Gp.1 pts, inferior septal breakthrough was followed by caudocranial activation with a single RA wavefront. Mean RA activation time in Gp.1 was 171±40 ms, with electrical quiescence present between successive AF cycles. In Gp.2 the mean AF CL was 239±41 ms, (p=.11 vs Gp.1). APBs initiated a single macroreentrant wavefront without electrical quiescence between AF cycles, resulting in 2 or 3 daughter wavelets in 13 pts (p=.10 vs Gp.1).



Conclusions: 1. Dynamic macroreentrant tachyarrhythmia initiated by focal trigger precedes sustained AF in both atria. 2. Single septal breakthrough wavefront and up to 2 daughters RA wavelets activates RA in LA onset of AF. 3. Continuous RA activation due to a single dynamic macroreentrant wavefront often resulting in 2 or 3 daughter wavelets features RA onset of AF.

P1546 Induction of apoptosis in atrial and Bcl-2 upregulation in ventricular myocytes is a transient phenomenon in persistent atrial fibrillation

R. Ammer[1], T. Aretz[2], D. Keane[3], J.N. Ruskin[3]. [1]*Universitätsklinikum Muenster, Cardiology Dept., Muenster, Germany;* [2]*Massachusetts General Hospital, Pathology Dept., Boston MA, United States of America;* [3]*Massachusetts General Hospital, Cardiology Dept., Boston MA, United States of America*

Background: The cellular changes from electrical to structural remodeling in persistent atrial fibrillation (AF) are not all known.
Methods: Myocardial samples were obtained from the hearts of 44 goats which had undergone cardiac pacemaker (660ppm) implantation to induce AF in 31 goats for 2 to 430 days. Cardiac samples from the other 13 goats in sinus rhythm (SR) were used as controls. Apoptosis was evaluated histo- and biochemically.
Results: Persistent AF for 3 months was characterized morphologically by an up to 9-fold increase in atrial myocyte apoptosis (TUNEL staining, 0.27 ± 0.05% vs. 0.03% ± 0.01%, $p<0.001$) and biochemically by agarose gel electrophoresis and Western blots for Bax, Bcl2, Cytochrome C, activated Caspase-3(p20); the percentage of ventricular myocytes labeled with Bcl2 was 5-times higher for goats in AF than in SR ($p<0.005$). The percentage of apoptotic atrial myocytes, but not fibrocytes, correlated with the duration of AF ($p<0.05$). After peaks of apoptotic myocytes, atrial volume increased. Patchy fibrosis in the atrial wall (13±2% after 430 days) correlated with the duration of AF ($p<0.05$). Glycogen accumulated in atrial myocytes over time. Goats in AF for 430 days revealed apoptosis in atrial and Bcl2 expression in ventricular myocytes comparable to baseline levels (ns.).
Conclusions: In this model, programmed death of myocytes increases within 60 to 180 days of AF, despite enhanced Bcl2 expression and prior to atrial stretch and fibrosis. After 230 to 430 days the extent of apoptotic myocytes in goats with AF is indifferent to SR. This transient phenomenon may contribute to the progression of electrical and structural remodeling associated with AF.

P1547 Intraoperative radiofrequency ablation of atrial fibrillation (IRAAF) study stopped after 386 pts. treated because of significant complications

G. Hindricks[1], F.W. Mohr[2], N. Doll[2], U. Wetzel[1], J. Gummert[2], E. Grebe[1], P. Schirdewahn[1], H. Kottkamp[1]. [1]*University Leipzig Heart Center, Electrophysiology, Leipzig, Germany;* [2]*University Leipzig Heart Center, Cardiac surgery, Leipzig, Germany*

Since July 1997 intraoperative radiofrequency ablation (IRAAF) of atrial fibrillation (AF) was performed in 387 patients (pts.; 237 men, 150 women, mean age 61 ± 10 yrs.) with paroxysmal (26%) or permanent (74%) AF. In all pts., contiguous left atrial (LA) lesion lines between the mitral annulus and the pulomonary veins were induced temperature-guided (60°C, unipolar energy application) with a hand-held ablation probe (Osypka). 129 pts. underwent the procedure exclusively for the treatment of AF while in the other pts. IRAAF was performed in combination with mitral valve surgery (163 pts.) or various other types of heart surgery (95 pts.). Damage of the oesophagus following the procedure was observed in 4 pts. (1%). The first pt. (no. 56) with this type of complication developed fever and recurrent neurological symptoms 5 days after surgery. Re-operation revealed perforation of the oesophagus and an fistula to the left atrium resulting in air embolism. Initially, it was believed that the complication was due to mechanical perforation of the oesophagus by a transoesophageal echo probe. However, the intraoperative treatment concept was also slightly changed: The lesion line between the left upper and right upper PV was deployed more superior along the roof of the LA instead of posterior. However, damage of the oesophagus occurred in 2 additional pts. (nos. 239 and 241). Histological analysis of the oesophageal lesion showed thermal damage of the tissue thus proving direct effects of radiofrequency ablation. Prevention of thermal damage of the oesophagus was then attempted by careful intraoperative surgical separation of the oesophagus from the left atrium and by placement of a isolation scrub into the Sinus obliquus pericardii. However, although all preventive efforts were made, perforation of the oesophagus occurred in an additional patient (no. 382). This pt. also had to undergo surgical repair of the oesophagus.
Conclusions: Intraoperative induction of linear lesions to the left atrium bears the risk of severe damage of the oesophagus. Although this complication occurred rarely (1%), the IRAAF program was stopped because no effective prevention seems to be possible when radiofrequency is applied to the endocardium in unipolar fashion. This type of complications may also occur following percutaneous left atrial ablation.

P1548 Safety and efficacy of antiarrhythmic surgery using cooled-tip radiofrequency ablation in patiens with chronic atrial fibrillation

T. Deneke[1], K. Karghi[2], P.H. Grewe[1], T. Lawo[1], F. Kuschkowitz[2], A. Laczkovics[2], B. Lemke[1]. [1]*Bergmannsheil Bochum, Department of Cardiology, Bochum, Germany;* [2]*Bergmannsheil Bochum, Cardio-Thoracic clinic, Bochum, Germany*

The original Cox-Maze procedure is a highly effective method to restore Sinusrhythm (SR) even in patients with chronic atrial fibrillation (AF). Is a method applying intraoperatively linear lesions using cooled-tip radiofrequency (RF) ablation effective and safe in treating chronic permanent AF in patients undergoing open heart surgery?
Method: 93 patients (mean age 67 years, mean ejection fraction 61%, left atrium 53mm diameter)) with chronic permanent AF (mean duration 54 months) underwent open heart surgery (mitral valve replacement in 35, mitral valve plasty in 12, coronary artery bypass in 22, aortic valve replacement in 10 and combined procedures in 14) plus an additional modified maze procedure using intraoperatively cooled tip RF ablation.
Results: The mean extracorporal circulation duration was 168 minutes and the cross-clamp time was 101 minutes. The 30-day mortality was 2.1% (2/93). After a mean follow-up duration of 15 months a cumulative rate of SR of 0.77 was documented. Mode of conversion to SR was spontaneous in all but 1 patient usually within the first 6 months after the procedure. Doppler-echocardiography 6 months after the procedure revealed (43 patients) biatrial contraction in 85%, right atrial contraction in 13% and no atrial contraction in 2% of patients in SR. Conclsions: Antiarrhythmic surgery using intraoperatively cooled-tip RF ablation is a safe and effective method to treat chronic permanent AF in patients undergoing open heart surgery. SR can be restored in 77% of patients with variable indication for cardiac surgery and biatrial contraction can be documented in 85% of these patients.

P1549 Tissue temperature controlled radiofrequency ablation

D. Bierbaum, O. Eick. *Medtronic Bakken Research Center, Maastricht, Netherlands*

Background: During radiofrequency energy delivery catheter tip temperature can be significantly lower than tissue temperature. We performed tissue temperature controlled radiofrequency ablation in vitro and evaluated the effects of cooling, electrode-tissue contact and target tissue temperature on lesion size.
Methods: Pieces of porcine ventricle were immersed in a bath of isotonic saline solution at 37° C. Radiofrequency energy was controlled by the tissue temperature as measured with a thermocouple needle placed 2 mm beneath the ablation electrode. Radiofrequency power was delivered for 30 seconds and limited to 50 W. A total of 81 radiofrequency ablations was performed with different electrode-tissue contact forces (0.04 N, 0.36 N and 0.67 N) and target tissue temperatures (50°C, 60°C and 70°C) using either an irrigated (27 ablations, 20ml/min irrigation flow rate) or a non-irrigated ablation catheter. Twenty-seven non-irrigated applications were performed with fluid flow maintained by the pump of the thermostat and another 27 applications without flow. Every combination was applied 3 times and the average values were used for evaluation.
Results: For tissue target temperatures of 50° C, 60° C and 70° C the lesion volume for non-irrigated ablations was on average 21 ± 8 mm^3, 45 ± 23 mm^3 and 109 ± 45 mm^3, respectively, requiring an average power of 6 ± 2 W, 10 ± 5 W and 20 ± 9 W, respectively, to reach target tissue temperature. For irrigated ablations the respective values for lesion volume were 12 ± 7 mm^3, 37 ± 20 mm^3 and 92 ± 30 mm^3, respectively, with an average power of 8 ± 2 W, 10 ± 3 W and 19 ± 9 W, respectively. The lesion size was in both application groups not correlated to the electrode-tissue contact force. In the non-irrigated ablation group the catheter tip temperature was on average 66 ± 13° C in the group with fluid flow and 83 ± 13° C in the group without flow whereas the tip temperature in the irrigated group was 33 ± 1° C on average. There was no difference in lesion size between the group with fluid flow and those without.
Conclusion: Lesion size during tissue temperature controlled radiofrequency delivery increases with increasing target tissue temperature and becomes independent of flow and electrode-tissue contact. Irrigation of the catheter tip electrode does not increase lesion size but avoids excessive heating of the ablation electrode. Our data suggests that a cooled tip ablation catheter with an extractable needle allowing for tissue temperature controlled ablation may yield reproducible and predictable lesions.

ATRIAL ARRHYTHMIAS

P1550 Origin of electrical activation within the right atrial wall: differentiation by electrogram characteristics using non-conact mapping

T. Paul[1], M. Kroll[2], T. Kriebel[2], B. Windhagen-Mahnert[2], B. Franzbach[2], M. Zutz[2], J. Tebbenjohanns[3]. [1]*Medical University of South Carolina, Pediatric Cardiology, Charleston, United States of America;* [2]*Hannover Medical School, Pediatric Cardiology, Hannover, Germany;* [3]*Hannover Medical School, Cardiology, Hannover, Germany*

Background: Clinical data using the non-contact mapping system (Ensite 3000) in mapping and ablation of atrial ectopic tachycardia suggest that characteristics of reconstructed unipolar electrograms may predict the origin of electrical activation within the atrial wall (endocardial vs. myocardial vs. epicardial origin).
Animals and Methods: In ten pigs (mean body weight 62 kg) pacing (600 msec, 2 msec, double diastolic threshold) was performed at the lateral high right atrium, at the mid-posterior right atrium and at the lateral inferior right atrium from the endocardium, the myocardium and the epicardium, respectively. Activation was recorded using the non-contact mapping system. Reconstructed unipolar electrograms at the location of earliest endocardial activation assessed by isopotential maps were analysed systematically for differences in morphology.
Results: see table.

Pacing site	max. V	dV/dt	Initial R-wave
Endocardial	-1.95±1.03 mV	377.5±250.7 mV/ms	5%
Myocardial	-3.04±1.84 mV	798.22±860.4 mV/ms	56%
Epicardial	-2.08±0.67 mV	440.8±401.6 mV/ms	58.3%
p	<0.01	<0.01	<0.001

Presence of initial R-wave had a positive predictive value of a subendocardial origin of electrical activation of 0.96. In addition, unipolar electrograms during myocardial stimulation exhibited significantly higher max. voltage and a more rapid dV/dt.
Conclusions: Morphology characteristics of unipolar electrograms generated by non-contact mapping allow for discrimination of an endocardial versus an subendocardial origin of atrial activation. Findings may be helpful in selecting the appropriate mode of energy delivery during ablation procedures.

P1551 Upstream stimulation versus downstream stimulation: arrhythmogenesis based on repolarization dispersion in the human heart

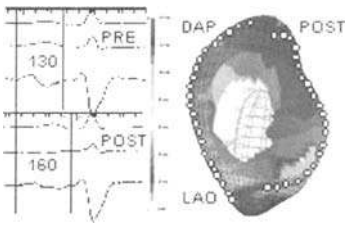
F. Bode[1], P. Karasik[2], H.A. Katus[1], M.R. Franz[2]. [1]*Universitaetsklinikum Luebeck, Medizinische Klinik II, Lübeck, Germany;* [2]*VA and Georgetown Medical Center, Cardiology, Washington DC, United States of America*

Background: Induction of sustained ventricular tachycardia (VT) is often feasible at one stimulation site while application of an identical pacing protocol to another site fails to provoke VT. We tested the hypothesis that a dominant VT induction site has shorter action potential duration (APD) and effective refractory period (ERP) than a non-inducing site, resulting in collision against longer ERP ("upstream") as opposed to shorter ERP ("downstream", no collision).
Methods: Sixty-nine patients undergoing programmed stimulation for VT inducibility had monophasic action potential recording/pacing catheters placed in the right ventricular outflow tract (RVOT) and apex (RVA) simultaneously. At basic cycle lengths of 600ms and 400ms, up to 3 extrastimuli were introduced in 5-10ms decrements until ERP was reached. Upon completion of a drive cycle at one stimulation site, it was repeated at the other site. A drive train that induced VT was compared to a corresponding train at the other stimulation site.
Results: Thirty-eight patients had inducible VT, 9 exclusively by RVA pacing and 9 exclusively by RVOT pacing. APD and ERP at the induction site were significantly shorter (12±15ms, $p<0.05$ and 22±14ms, $p<0.01$, respectively, at 600ms BCL) than at the non-induction site. The dispersion of repolarization between corresponding action potentials at the two sites was 58±41ms during baseline stimulation (S1) at the inducing site but only 37±23ms at the non-inducing site ($p<0.05$). Extrastimulus application increased the dispersion of repolarization at both sites ($p<0.05$). Dispersion reached a maximum of 75±45ms during VT induction, but only 53±33ms during extrastimulation at the non-induction site ($p<0.05$ for intersite difference).
Conclusions: Site specificity of VT induction underscores the role of dispersion of repolarization and refractoriness in facilitating reentry arrhythmias. Upstream stimulation at a site with short repolarization produces larger dispersion and facilitates VT induction.

P1552 Resynchronization of atrial compartments after catheter maze with dual-site right atrial pacing

A. Filipecki[1], S. Saksena[2], A. Prakash[2]. [1]*Electrophysiology Research Foundation, Passaic, United States of America;* [2]*Atlantic Health System, Cardiovascular Institute, Passaic, United States of America*

Catheter right atrial (RA) maze procedure may be more effective in combination with dual site RA pacing (DAP). We analyzed P wave duration before and after RA maze in 30 pts with refractory AF and in a subgroup (n=20) undergoing DAP after RA maze. 3-D non-contact mapping (NCM) was employed to analyze RA activation patterns. Results: 30 pts, mean age 69±10 yrs, mean LA size 42±9 mm, mean LVEF 43±12%, with cardiac disease (n=25) were studied. NCM showed effectiveness of RA maze in all pts with distinct lines of intraatrial block with anterior and posterior RA compartments. Prolonged atrial activation in individual RA compartments was noted in all pts immediately after the procedure. Mean P wave duration was 139±19 ms before RA maze and increased to 161±24 ms after it ($p<.001$). P wave amplitude was also significantly reduced. Intraatrial reentrant tachycardias circulating around the linear lesions or within a RA compartment were seen in 7 pts (23%). DAP produced two distinct, simultaneous wavefronts in each RA compartment resynchronizing them and reducing P wave duration to 136±16 ms ($p<.001$). Global atrial activation time was reduced by 10-30% (mean 18%).



ECG pre/post & isochrones of DAP post.

Conclusions: 1. RA maze significantly prolongs global biatrial activation time and can promote macroreentrant arrhythmias in the atrium. 2. Antiarrhythmic benefit of DAP after RA maze can be due to resynchronization of atrial compartments, as well as collision of simultaneously paced wavefronts on both sides of linear lesions.

P1553 Radiofrequency ablation of atrial arrhythmias after a remote open-heart surgery: role of conventional and CARTO mapping

A. Nabar[1], C. Timmermans[2], A. Medeiros[2], K. Polymeropoulos[2], S. Philippens[2], H.J.G.M. Crijns[2], L.M. Rodriguez[2]. [1]*Academic Hospital Maastricht, Cardiology Dept., Maastricht, Netherlands;* [2]*Academic Hospital Maastricht, Cardiology Dept., Maastricht, Netherlands*

Background: Considering the complex nature of the substrate after open-heart surgery, conventional mapping for radiofrequency (RF) ablation of atrial arrhythmias (AA) could be supplemented by CARTO electroanatomical mapping.
Methods: Mapping and RF ablation was performed in 19 patients (50±11 years, 11 women) having symptomatic AAs after a remote open-heart surgery: valvular (n=8), atrial septal defect (n=9), Ebstein's(n=1) and Rastelli's (n=1) repair. Only conventional mapping [peri-tricuspid (PT) Halo, His and coronary sinus catheters] was performed in 11 patients. CARTO was done, de novo (n=4) or for the same (n=2)/a new (n=2) recurrent AA after previous RF ablation, in the remaining 8 patients and as supplementary to conventional mapping.
Results: Linear ablation of the low right atrial (RA) isthmus for PT atrial flutter (AFL): counterclockwise (n=7), clockwise (n=2), and previously documented (n=1), was successful after conventional mapping alone in 10 patients (91%). Conventional mapping failed to localize the AA and ablation was unsuccessful in the remaining 1 patient. Activation maps generated using the CARTO system showed, a clockwise PT (n=2), septal (n=2) and a double-loop (n=1) reentry in 5 patients. The AA cycle length was mapped almost completely (92%±11%). A voltage (scar) map alone could be obtained during sinus rhythm in 2 other patients. Conventional mapping had shown PT-AFL in these patients. An unconventional isthmus, between the scar and an anatomical barrier (superior/inferior vena cava or tricuspid annulus), was ablated more often (n=5) then the low RA isthmus (n=2). The ablated isthmus was anatomically the most convenient (2.7±1 cm), but not the slowest conducting zone. Two focal atrial tachycardias were seen in the remaining 1 patient. Ablation was successful in all 8 patients (100%), although after a second CARTO procedure in 1 patient. After a follow-up of 12±11 months, 2/18 patients (11%) ablated successfully had a same (1) or a new (1) AA recurrence.
Conclusions: AAs after a remote open-heart surgery can be ablated successfully (>90%) with a low recurrence rate (11%). Despite an underlying scarred substrate, PT-flutter circuits were frequent (72%). These could be mapped and ablated successfully using conventional techniques. CARTO mapping helps to uncover peri-scar reentry and guide ablation of unconventional isthmi.

P1554 Use of CARTO to identify the critical isthmus in left atrial macroreentrant tachycardia and to guide successful ablation

M. Antz[1], F. Ouyang[2], M. Goya[2], T. Vogtmann[2], A. Schaumann[2], D. Bänsch[2], K.H. Kuck[2]. [1]*St. Georg Hospital, Cardiology Dept., Hamburg, Germany;* [2]*St. Georg Hospital, Cardiology, Hamburg, Germany*

Right atrial macroreentrant tachycardia can be ablated with high success rates. However, left atrial macroreentrant tachycardia (LAMRT) are less well understood and ablation success is limited. We therefore investigated 19 pts (6 with normal hearts and 13 with structural heart disease but none with left atriotomy) with permanent left atrial macroreentrant tachycardia (LAMRT; cycle length 325±89 msec; range 205 to 510 msec).

Methods and Results: CARTO maps of the LA were performed during LAMRT in all pts (223±50 points/map; range 115 to 345) and identified 1-4 electrical silent areas or lines of double potentials per patient. In 16 pts 25 LAMRT circuits (CL>=240 msec) were identified as single loops (n=6) or dual loops (n=19) with the reentry propagating through an isthmus located between a PV and a posterior electrical silent area/ line of double potentials (n= 6), anterior electrical silent area/ line of double potentials (n=4) or roof line of double potentials (n=1), between the mitral anulus and an anterior electrical silent area/ line of double potentials (n=5), between two distinct anterior electrical silent areas/ lines of double potentials (n=6), between two roof electrical silent areas (n=2), or between a posterior and a roof electrical silent area (n=1). Ablation targeted an isthmus-width of 10.8±4.6 mm (range 4.0-21.6 mm) and maximal bipolar atrial amplitude of 0.04-1.22 mV. A mean of 3.3±1.8 radiofrequency (RF) applications resulted in termination of the LAMRT and conduction block across the identified isthmus in 16/16 pts. In contrast, the LAMRT circuit could not be identified in the remaining 3 pts with faster LAMRT (CL<=230 msec) due to multiple electrical silent areas/ lines of double potentials or inability to identify >90% of the reentry cycle length. During a mean follow-up of 1-31 months (median 15 months) LAMRT recurred only in 2/3 pts with failed ablation, while atrial fibrillation occurred in 3/16 pts in the successfully treated group and in 1/3 pts in the failed ablation group.

Conclusions: High density mapping using CARTO can identify the reentrant circuit in LAMRT. The location of the critical isthmus is variable, but usually narrow and of low amplitude. Conduction block across the left atrial critical isthmus can be achieved with few conventional RF applications resulting in high success and low recurrence rates.

P1555 Feasibility of catheter cryoablation for ablation of atrioventricular nodal reentrant tachycardia and complete atrioventricular junction ablation

T. Neumann, N. Guettler, K. Kurzidim, J. Sperzel, H.-F. Pitschner. *Kerckhoff-Clinic, Department of Cardiology, Bad Nauheim, Germany*

Background: Nowadays radiofrequency ablation is the standard procedure for the ablation of tachycardias. In this study experiences with the recently developed catheter cryoablation are reported in patients with AV nodal reentrant tachycardia (AVNRT) and for the complete AV junction ablation.

Methods: Cryoablation was applied to 26 patients, 20 with AVNRT. In 6 patients with atrial fibrillation a complete AV junction ablation was carried out. The CCT.2 CryoConsole by CryoCath® and the Cardiac CryoAblation Catheters Freezor® 3 and Freezor® 5 by the same company were used for ablation. In all cases a cryomapping with a temperature of - 30°C preceded the cryoablation with the temperature of - 75°C. During the cryoablation each application lasted 240 seconds.

Results: Acute success could be obtained in 18/20 patients with AVNRT. In two patients the effect on the slow pathway was only temporary, so that the ablation had to be finished with radiofrequency energy. In another patient a reversible third degree AV block was observed. In one of the 6 patients with complete AV junction ablation a complete AV block could not be achieved, so that the ablation had to be continued with radiofrequency energy. In another patient a second procedure with radiofrequency energy had to be carried out because of a recovery of AV nodal conduction. Especially in patients with AVNRT and running tachycardia cryomapping was useful for confirmation of a successful ablation site. Another advantage of cryoablation is the stability of the catheter position due to freezing of the tip.

Conclussion: Cryoablation is a promising alternative to radiofrequency energy in the ablation of tachycardias, which so far has been applied in patients with AVNRT and for complete AV junction ablation in our institution. A cryomapping is useful to find a successful ablation site. Another advantage is the stable catheter position due to freezing of the catheter tip.

P1556 Percutaneous cryoablation of antero-septal and mid-septal accessory pathways: a step-by-step method

R. De Ponti[1], M. Tritto[1], G. Spadacini[1], M. Lanzotti[1], R. Marazzi[1], P. Moretti[1], N. Agostini[1], J A. Salerno-Uriarte[2]. [1]*University of Insubria, Dept. Cardiol "Mater Domini", Castellanza, Italy;* [2]*Fond. Macchi - University of Insubria, Dept. Cardiovasc. Sci., H Circolo, Varese, Italy*

Recently, percutaneous cryoablation (Cryo) has become available for ablation of cardiac arrhythmias. This study describes a method for Cryo of accessory pathways (APs) close to the normal atrioventricular conduction system, such as antero-septal and mid-septal APs. To this aim, 7 pts (6 M, mean age 29±8 yrs) were considered: 3 had a para-hissian, 2 an anterior para-septal and 2 a mid-septal AP. In all pts a novel catheter for Cryo (Freezor 3, Cryocath Technologies, Inc.) was used, in which the cooling effect of the tip electrode is obtained by expansion of fluid N2O. Ablation was performed in sinus rhythm (4 pts) or AV reentrant tachycardia (3 pts), according to the following protocol: 1) the most suitable site was selected during mapping in sinus rhythm and/or tachycardia; 2) the firmest tissue/electrode contact was obtained by switching from the inferior to the superior vena cava approach, if necessary; 3) test applications were performed for 30 s with a progressive step-by-step decrease in the tip electrode temperature from -30 to -75°C until AP conduction interruption was observed; then, after further check for 20 s at the effective temperature, Cryo application was performed at -75°C up to 120-240 s (para-hissian and mid-septal APs) or 240-480 s (anterior para-septal APs). At any moment during cooling, if any sign of initial modification of conduction over the normal pathway (minimal A-H interval prolongation, appearance of right bundle branch block, termination of orthodromic AV reentrant tachycardia in the antegrade limb) occurred, cryo had to be immediately interrupted. The test application interrupted AP conduction at -33±28°C (range 0 to -75°C) and Cryo was then continued according to the protocol for 251±167 s (range 40-480 s). Due to cryoadherence effect, the catheter never displaced during cooling, even when sudden changes in heart rhythm occurred. In 2 pts, an initial modification of the conduction over the normal pathway (15% A-H interval prolongation in one case and right bundle branch block in another) was observed after 170 and 40 s and at -75 and -40° C, respectively; these modifications rapidly reverted upon Cryo discontinuation. In all pts the procedure was successful with no complication; no pt had recurrence in a 115±42 day (range 210-90 days) follow-up.

In conclusion: a step-by-step method for Cryo of antero-septal and mid-septal APs is permanently effective and safe; initial modifications over the normal condution pathway are reversible, if Cryo is timely interrupted; cryoadherence contributes to safety in this critical area.

P1557 Unusual variants of accessory pathways with wide-ranging atrial and ventricular insertions: successful linear ablation within the coronary sinus

P. Schirdewahn, G. Hindricks, U. Wetzel, A. Dorszewski, C.H. Elsner, H. Kottkamp. *University Leipzig Heart Center, Electrophysiology, Leipzig, Germany*

Accessory atrioventricular (AV) pathways are usually described electrophysiologically and histologically as discrete cable-like muscle fibers with some degree of terminal ramification. In many cases, singular energy applications are sufficient for successful ablation.

In 3 young patients (pts) (age; 4, 14, and 18 years, respectively) with recurrent atrioventricular reentrant tachycardia (AVRT), invasive electrophysiologic testing was performed. In all cases, exclusively retrograde conduction over the accessory pathways was present. Coronary sinus mapping during AVRT revealed earliest retrograde atrial activation at the left inferior mitral annulus in all pts. However, in one case, spontaneously changing activation sequences were observed left inferior, and in the other 2 cases, earliest retrograde atrial activation was recorded over a range of coronary sinus electrodes. Repetitive energy applications to the presumed atrial and ventricular insertion sites were unsuccessful in all cases. The recording of unusually big accessory pathway activation potentials within the coronary sinus then led to ablation within the coronary sinus. Step by step ablation within the coronary sinus, thereby placing a linear lesion, allowed successful ablation in all cases. Coronary sinus ablation was started left inferior, and in 2 cases, the final energy applications were done in the coronary sinus ostium. In the remaining case, the accessory pathway network extended to the right side and ablation was continued to the right inferior area at the tricuspid annulus. Coronary sinus angiography revealed normal findings in all pts. No complications were observed.

In rare cases of young pts with accessory pathways, wide-ranging ventricular insertions can be observed extending from the left inferior mitral annulus to the coronary sinus ostium or even to the right inferior tricuspid annulus. Placement of linear lesions within the coronary sinus allows successful ablation of these unusual accessory pathways along their left sided course extending towards the coronary sinus ostium.

P1558 Transcutaneous epicardial radiofrequency ablation for treatment of posteroseptal accessory pathways not achievable via the middle cardiac vein

L. Leite[1], E. Arfelli[2], V. Lima[2], A.A.V. de Paola[2], *[1]Mayo Clinic, Cardiac Electrophysiology, Rochester, United States of America; [2]Federal University of Sao Paulo, Clinical Electrophysiology, Sao Paulo, Brazil*

Although radiofrequency ablation (RFA) provides complete cure for nearly all patients with accessory pathways (APs), epicardial course has been clearly recognized as a possible cause of the prolonged or failed attempts.
Methods: A 57-year-old man presented with palpitations followed by syncope and sudden cardiac death. His first ECG showed a pre-excited atrial fibrillation (AFib), with shortest RR interval of 210 msec. Clinic evaluation was unremarkable. After 3-failed endocardial ablation procedures was attempted, and being refractory to medical therapy, he underwent to epicardial ablation. Transthoracic puncture was performed in the subxyphoid area under fluoroscopy guidance. A 7 Fr quadripolar catheter was inserted in the epicardial space through an 8 Fr sheath for mapping and ablation. An endocardial catheter was positioned in the middle cardiac vein (MCV) for simultaneous endocardial-epicardial mapping. A ventricular electrogram (20 msec) and AP potential (30 msec) earlier than the delta wave were recorded in the epicardial space. During the first RF energy delivered in the epicardial space to the distal ablation catheter resulted in loss of preexcitation in the third brat. After 45 minutes, coronary artery angiography was repeated which showed no injuries. No complication was observed in the procedure. After 8 months of follow-up the patient presented no further supraventricular tachycardia and no recurrence of preexcitation.
Conclusion: Epicardial ablation of accessory pathways is feasible and may be a useful alternative for AP with epicardial course not achievable via MCV.

P1559 The risk factors of atrial fibrillation in patients with Wolff-Parkinson-White syndrome

L. Szumowski, F. Walczak, E. Kozluk, E. Szufladowicz, R. Kepski, Z. Jedynak, A. Piatkowska, E. Bujnowska. *Institute of Cardiology, Electrophysiology Lab., Warsaw, Poland*

AF is observed more often in patients (pts) with WPW than in the general population. The aim of this research was to compare the differences between risk factors of AF in pts with WPW and AF vs pts without AF.
Group and method: We analyzed 239 pts with WPW. Gr.1-81 pts with AF (23F, age 43±15), gr.2-158 pts without AF (91F, age 34±15) We analyzed risk factors such as: sex, age, syncope, atrioventricular tachycardia (AVT) rate, other arrhythmia, CHD, HT, small and moderate mitral valve insufficiency (IM), other diseases, echocardiography findings, number of accessory pathways (AP) and its localization, effective refractory periods (ERP) of the atrium, ventricle, atrioventricular node and AP.
Results: In multifactoral analysis only sex, age and syncope were AF risk factors. In logistic regresion age, sex, syncope, CHD, HT and IM increased AF occurrence. Also in AF patients VF and AFl occurred more often and concealed AP occurred seldom. In patients with WPW and AF there was a trend of more left free wall (LFW) and right postero-septal (RPS) AP location. We did not observe significant differences in AVT rate, other diseases, echocardiography findings and refractory periods.

	Sex	Age	Syncope	VF	CHD	HT	IM	LFW	AP retro	Multiple AP	AVT rate
AF-81 pts	23F	34±15	35	11	13	21	40	67	9	19	210
No AF-158 pts	91F	43±15	36	3	12	24	46	102	51	26	217
P	0,0001	0,001	0,001	0,002	0,04	0,04	0,01	0,04	0,002	NS	NS

AP-accessory pathway, AVT rate-maximal rate of atrio-ventricular tachycardia, CHD-coronary heart disease, F-female, HT-hypertension, IM - small or moderate mitral valve insufficiency, LFW-left free wall AP localisation, pts-patients, retro-retrograde conduction only

Conclusions: 1. In pts with WPW age, sex (more AF in men), and syncope are independent risk factors of AF.
2. There was significantly more VF in pts with WPW and AF than in the group without AF.

SYNCOPE

P1560 Prevalence and triggers of syncope in young adults: a questionnaire

K. Ganzeboom[1], N. Colman[2], J.B. Reitsma[3], W. Shen[4], W. Wieling[1] on behalf of The Dutch FAST group. *[1]Internal Medicine, [2]Cardiology, [3]Clinical Epidemiology & Biostatistics, Academic Medical Centre, Amsterdam, Netherlands; [4]Mayo Clinic, Department of Internal Medicine, Rochester, United States of America*

Background: To learn more about the true prevalence of syncope in a young healthy population we performed a descriptive study among the medical students in the Academic Medical Centre. Our first study objective was to determine the prevalence of syncope in a young population, including the recurrence rate. Other study objectives included the evaluation of the gender difference in syncope and the evaluation of the triggers provoking syncope in young adults. The main part of the questionnaire we developed consisted of questions about the history of syncope, the frequency of syncope and triggers of syncope.
Results: The questionnaire was handed out to 395 students. Seventeen students did not fill in their gender. The remaining group consisted of 254 (64%) women and 124 (31%) men. The gender distribution is in accordance with the overall ratio of female and male students in our curriculum. The median age for female and male students was 21 years.
Of all 395 students 154 (39%;95%CI 34-44) reported that they had experienced at least one (episode of) syncope. The prevalence of syncope was almost twice as high in women compared to men (47% vs. 24%; RR 1.9, 95%CI 1,4-2,7). The mean age at which the first syncope occurred was not significantly different between women and men (14.3 and 14.8 years respectively). Female as well as male students mentioned a diverse range of triggers. Being in a warm environment and prolonged standing was mentioned by respectively 47 (12%) and 41 (10%) students. Other frequently named triggers were pain, illness, alcohol and drugs, emotion, seeing blood, standing up, insufficient food intake and tiredness. Many students marked a combination of triggers as the cause of an episode of syncope.
Conclusions: Syncope is common in young adults. The majority of triggers involved in syncope in young adults are mostly common daily activities and circumstances.

P1561 Efficacy of correction of subclavian stenosis/occlusion in patients with subclavian steal and previous by pass internal mammary-IVA

S. Novo[1], F. Ferrara[2], C. Amato[2], F. Meli[2], V. Cospite[2]. *[1]Università di Palermo, Chair of Cardiovascular diseases, Palermo, Italy; [2]University, Cardiovascular diseases, Palermo, Italy*

Background: Steal syndrome and subclavian steal syndrome are a complication of atherosclerotic disease.Such syndrome have numerous anatomic and clinical variations whose common haemodynamic characteristic is the presence of haematic vertebral-subclavian.In such conditions, a considerable amount of blood is diverted from the cerebral area to re-occupy the upper limb,and the quantity of blood used depends on both the stenosis level of the subclavian artery in prevertebral area and the activity of upper limb.In the last few years,episodes of subclavian steal had left internal mammary artery-interventricular anterior artery (LIMA-IVA)bypass graft.The aim of this report is the evaluate the efficacy of subclavian steno-occlusion corrective treatment in surgical patients with a vertebral-subclavian haematic steal syndrome.
Methods: We observed 207 patients aged between 48 and 77 years who had the LIMA-IVA bypass graft,through ecocolordoppler.Of these,31 patients turned out to be affected by steno-occlusion of the homolateral subclavian artery.10 patients(group 1)had less than 30% of subclavian stenosis and showed latent vertebral-subclavian steals;they were treated with acetylsalicylic acid and ticlopidine. 7 patients (group 2) had 50% to 70% subclavian stenosis and presented an intermittent vertebral-subclavian steal;only 4 of these patients were treated with angioplasty and stent application to the subclavian artery and 3 were treated with acetylsalicylic acid and ticlopidine.14 patients(group 3)had more than 70% stenosis(11 patients)or total occlusion(3 patients)of the subclavian artery and were treated with angioplasty and stent application or carotid-subclavian bypass graft.All the patients were checked every three months for a period of 5 years after the diagnosis.
Results: Ther first group of patients showed no angina and no sign of subclavian restenosis.In the second group only two patients, affected by angina,showed subclavian restenosis at angiography and were again treated with angioplasty and stent.In the third group only one patient underwent further angioplasty with stent for restenosis.
Conclusion: The results of this study showed that the subclavian steal syndrome may be adverse event in patients subjected to LIMA-IVA bypass graft.The identification of the haematic kind of steal is essential in an appropriate therapeutic approach.The study also indicated that steal syndrome can cause the development of more serious symptoms which cannot be medically treated.

P1562 Diagnostic yield of supine and upright carotid sinus massage in patients with unexplained syncope

D. Graf[1], J. Schlaepfer[1], M. Fromer[1], J. Metzger[1], A. Berger[1], E. Gollut[1], L. Kappenberger[1], E. Pruvot[2]. [1]*CHUV, Cardiology, Lausanne, Switzerland;* [2]*Case Western Reserve University, Heart and Vascular Research Center, Cleaveland, United States of America*

Carotid sinus hypersensitivity (CSH) as a cause of syncope (Sy) is frequently underdiagnosed, and its prevalence in patients (pts) with unexplained syncope (un-Sy) is unknown. The aim of the present study is to establish prospectively the diagnostic value of supine and upright carotid sinus massage (CSM) in pts with un-Sy referred to a syncope clinic.

Method: 317 patients (age: 53±20 y, female 46%) with 6 un-Sy on average (range 1-200) have been consecutively included in a targeted work-up (WU). Our WU started with a 20 min detailed interview, followed by a head-up tilt test, and an upright and supine CSM. A CSM was considered positive when both following criteria were met: 1) a pause ^{3}3 s (cardioinhibitory form, CI), a drop in systolic blood pressure (SBP) ^{3}50mmHg (vasodepressive form, VD), or both together (mixed form), and 2) if the positive CSM appeared reasonably as the cause for the spontaneous episodes of un-Sy.

Results: A CSM was performed in 89% (283/317)of the pts, and was considered diagnostic in 35% (99/283). The following CSH forms were observed: VD in 61%, CI in 17% and mixed in 22%. 77% (76/99) of the pts with a positive CSM were tested in both positions: the supine position alone was positive in 5%, the upright position alone in 61%, while both positions together were positive in 34% of the pts. 51% (39/76) of the positive CSM tested in both positions reported symptoms, during the upright position in 75% or in both positions in25%, but never during supine CSM. Among the 39 symptomatic pts, a vertigo was reported in 50%, a dizziness/pre-syncope in 48%, and a syncope in 20%. One transient neurological complication (hemiparesia) was reported in the 601 CSM (prevalence 0.17%) performed or in the 283 pts (prevalence 0.35%) tested. In the 99 pts with a diagnostic CSM, the decline in SBP was significantly higher (42 vs 29 mmHg, $p<0.01$) and the increase in the RR interval significantly smaller (1185 vs 1610ms, $p<0.01$) in the upright as compared to the supine position. No difference was observed between the symptomatic and asymptomatic pts with a diagnostic CSM.

Conclusion: In pts with un-Sy, the prevalence of CSH after a negative WU is as high as 35%, with nearly 2/3 of VD form. Because symptoms were only reported in the upright position, a negative supine CSM should be followed by a supine test, especially if one considers to use the so-called "method of symptoms". Because of the low prevalence of complications, CSM can be safely performed in both positions.

P1563 Recurrency of neurocardiogenic syncope is independent of treatment

L. Cano[1], A. Madrid[1], A. Berruezo[2], P. Cabeza[2], J.M.G. Rebollo[1], E. Benitez Rodriguez[2], C. Piñero[2], C. Moro[3]. [1]*Ramon y Cajal, Arrhythmia, Madrid;* [2]*Hospital Puerta del Mar, Cardiology, Cadiz;* [3]*Alcala Univ., Medicine, Alcala, Spain*

Clinical predictors of recurrence in patients with neurocardiogenic syncope are poorly defined and at the present time there is no optimal treatment that could favorably influence the natural course of this common and threatening condition. We have completed a retrospective analysis of the 417 subjects with unexplained syncope that underwent a tilt table test (TT) from March 1994 till June 2001. The mean follow-up period from the TT to the last interview was 47 ± 25 months and the mean age of the population under study was 38 ± 20 years, with a sligthly more frequent incidence of women (214, 51.3%) over men (203, 48.7%). The TT was considered positive in 136 patients (32.6%), negative in 279 patients (66. 9%) and indeterminate in 2 patients (0.5%). Of the 136 positive TT, 19 (13.97%) showed a cardioinhibitor response, 56 (41.17%) a vasodepressor response and 61 (44.85%) a mixed response. During the the follow-up 275 (65.9%) patients had no recurrent events while 125 (29.9%) patients showed one or more fainting episodes and 17 (4.07%) patients were lost to followup. The incidence of recurrent events was 0.9 ± 2.03 per patient - year. Recurrence of syncope could not be predicted from the type of positive TT response; it was recorded in 7 of the 19 patients with an inhibitory response (58.33%), 11 of the 56 patients with a vasodepressor response (19.6%) and 22 of 61 patients with a mixed response (36.06%), P= 0.095. Recurrent syncope was more frequent in patients with a mixed than in patients with a vasodepressor response (P= 0.04), but there was no significant difference when we compare the patients with the mixed response and the patients with the cardioinhibitory response (P= 1.00), or this latter group and the patients with the vasodepressor response (P=0.21). The records of 402 patients (96%) were available for post-TT treatment analysis and we found that treatment had no influence on recurrence of syncope. Thus, recurrent events were as frequent in the 265 (65.9%) patients that received no treatment as in the 137 (34.07%) patients that received treatment as a result of a positive TT (P= 0.06).

Conclusions: The TT seems to have a therapeutic effect itself. Our findings suggest that the type of TT has no predictive power for the recurrence of neurocardiogenic syncope. However, patients showing a mixed response on the TT are more prone to suffer recurrent neurocardiogenic syncope. Finally, no treatment seems to offer any significant protection against recurrent neurocardiogenic syncope.

P1564 Supraventricular tachycardias are a frequent cause of dizziness and syncope

B. Brembilla-Perrot, M. Nippert, A.C. Vançon, D. Beurrier, P. Houriez, M. Andronache, O. Claudon. *CHU Brabois, Cardiologie, Vandoeuvre, France*

Dizziness/syncope is a frequent event in population without heart disease and their causes remain difficult to elucidate. The objectives of the study were to determine the diagnosis value of esophageal electrophysiological study for the evaluation of sino-atrial and AV nodal conduction, for the induction of supraventricular tachycardia and for the assessment of the mechanism of dizziness/syncope in patients with normal ECG and without heart disease.

Population and methods: 145 patients aged from 20 to 87 years, without heart disease, with a normal ECG in sinus rhythm complained of dizziness and syncope; 56 patients had also a feeling of palpitations or tachycardia associated with syncope; the patients had no significant arrhythmia on the 24 hour Holter monitoring. Electrophysiologic study was performed during a consultation by transesophageal route: rate of occurrence of 2nd degree AV block during atrial pacing and sinus node recovery time were measured; programmed atrial stimulation using 1, 2 atrial extrastimuli were performed in basal state and after infusion of 20-50 μg of isoproterenol; arterial blood pressure was monitored.

Results: 1) study was negative in 43 patients (30%); 2) sinus node dysfunction was noted in 10 patients (7%); 3) vasovagal reaction reproducing spontaneous symptoms was provoked by isoproterenol infusion in 15 patients (10%); 4) sustained atrial fibrillation was induced in 22 patients (15%); 5) paroxysmal junctional tachycardia was induced in 55 patients (38%). Patients with negative study were more frequently females (64%)than males (36%) and were younger than those with sinus node dysfonction or atrial fibrillation (respectively 44±21 years and 71±9, 63±14). Patients with vasovagal reaction were more frequently males (59%) than females (33%)and were significantly younger than all the other subgroups (36±21 years). The treatment was guided by these data: advices, pace-maker,beta-blockers, antiarrhythmic drugs or radiofrequency ablation of reentrant circuit were indicated according to the diagnosis and suppressed syncope in all patients but 2.

Conclusion: esophageal electrophysiologic study performed during a consultation was a safe, rapid and economic means to detect an arrhythmia in 60% of patients complaining syncope, especially those with palpitations. Supraventricular tachycardia clearly was an underestimated cause of dizziness and syncope.

P1565 Comparison between the postural blood pressure test and the head-up tilt test in patients with recurrent syncope of unexplained origin

A. Schuchert, M.A. Aydin, C. Kretzschmar, G. Frost, T. Meinertz. *University Hospital Hamburg-Eppendorf, Department of Cardiology, Hamburg, Germany*

The postural blood pressure test identifies patients with an orthostatic hypotension and the head-up tilt test is used to detect the neurocardiogenic reflex-mediated origin of syncope. The aim of the investigation was to compare the two tests in patients with recurrent syncope of unexplained origin.

Methods: The study included 48 out-clinic patients who were referred for a head-up tilt test. All patients underwent a postural blood pressure test and separately a head-up tilt test. For the postural blood pressure test the patients stood up for 5 minutes. A positive postural blood pressure test was defined by more than 10 mmHg decrease of systolic blood pressure, by more than 5 mmHg decrease of diastolic blood pressure or by a drop of more than 5 bpm of the heart rate. The head-up tilt test consisted of a drug-free stage with a 60-degree angle of tilt for 45 minutes and a provocation stage with nitroglycerin.

Results: There were 25 patients with a positive (54 ± 17 years, male n = 11; 44%) and 23 patients (65 ± 4 years, male n = 13; 65%) with a negative postural blood pressure test. The demographic data of the two groups were not significantly different. Patients with a positive test had a history of 22 ± 69 syncope and patients with a negative test of 11 ± 13 syncope (negative) syncope (not significant (ns). The patients had during the last 6 months 3.7 ± 5.7 (positive) and 2.1 ± 3.9 (negative) syncope (ns). A positive head-up tilt test had 13 (52%) patients with a positive and 11 (48%) with a negative postural blood pressure test (ns). The head-up tilt test became positive during the drug-free state in 6 (positive) and 8 (negative) and during the provocation stage in the 7 (positive) and 3 (negative) pts (ns). The time until the head-up tilt test became positive was 18 ± 22 min (positive) and 12 ± 18 min (negative), respectively (ns). During 28 ± 10 months follow-up recurrent syncope had 8 (32%) patients with a positive and 7 (30%) patients with a negative test (ns).

Conclusions: The postural blood pressure test had in patients with recurrent syncope of unexplained origin no predictive value for a positive head-up tilt test. The findings indicate that there is no close association between orthostatic hypotension and vasovagal syncope.

P1566 Results of shortened head-up tilt testing potenciated with sublingual nitroglycerin in a large cohort of patients with unexplained syncope

M. Pérez-Paredes[1], G. Barón-Esquivias[2], J.A. Ruiz Ros[1], A. Pedrote[2], D.M. Gimenez[1], J.I. Valle[2], A. Carnero[1], M. Gonzálvez[1]. [1]*Hospital Univ. "Morales Meseguer", Cardiology, Murcia, Spain;* [2]*Hospital "virgen del Rocío", Cardiology, Sevilla, Spain*

Background: In spite of its clinical acceptance as a test to diagnose vasovagal syncope, head-up tilt test (HUT) continues to be limited in use partly because of the lack of a standardized test protocol and the lengthy duration of a complete study. Recently, a new simplified and time-saving protocol, including the sublingual administration of nitrogyicerin (NG) ("the Italian Protocol"), has been proposed as standard method of HUT. In the present study we evaluated the diagnostic value of HUT potenciated with NG on a large cohort of patients with recurrent syncope of unknown origin.
Methods: 426 patients (230 men and 196 woman, mean age 44.6 ± 19.4 years) with recurrent syncope (mean 5.4 ± 7.2 events), no structural heart disease and normal baseline ECG were studied. We also studied 15 healthy volunteers 8 men and 7 women, mean age of 43 ± 20 years. HUT was performed at 60° for 20 minutes; if negative, 400 ìg sublingual NG spray was given and the test continued for a further 15 minutes. Blood pressure and cardiac rhythm were continuously monitored.
Results: Sixty-one (14.3%) patients had a positive response during the initial unmedicated phase; 365 (85.7%) had no symptoms and underwent NG test. The mean time to syncope was 10.5 ± 5.7 min. After administration of sublingual NG spray, another 194 patients (53.2%) had a positive HUT. The mean tilt time for the NG positive patients was 4.7 ± 2.1 min. An exaggerated response was ilicited in 27 patients (7.4%). Patients with positive baseline HUT were younger (35.5 ± 19.4 vs 46.5 ± 19.3; $p < 0.001$) and suffered more syncopal events (10.5 ± 5.7 vs 4.7 ± 2.1; $p < 0.001$) that those with positive NG HUT. No control subject had a positive reponse during the unmedicated phase. Two (13.3%) subjects (mean age 43 ± 18 years, 1 man and 1 woman) had a positive reponse to the NG test, 11 (73.3%) a negative response and 2 (13.3%) an exaggerated response (mean age 46 ± 19 years, 1 man and 1 woman). The total positivity rate was 60% with a specificity rate of 85.7%.
Conclusions: In patients with syncope of unknown origin, shortened HUT potentiated with sublingual NG was found to be fairly sensitive and highly specific in inducing vasovagal responses.

P1567 Situational syncope: prevalence, response to head-up tilt testing and follow-up

D. Leftheriotis, E.G. Livanis, P. Flevari, G.N. Theodorakis, E. Zarvalis, F. Kolokathis, D.T.H. Kremastinos. *Onassis Cardiac Surgery Center, B' Cardiology, Athens, Greece*

The prevalence of situational syncope (SS) among patients (pts) with neurally-mediated syncope (NMS) is not fully investigated. Additionally, the rate of positive response to head-up tilt testing (HUT) in pts with SS and their follow-up (FU) have not been studied in detail. The aim of this study is to further elucidate these issues.
Methods: We prospectively studied 121 pts (mean age 42±17 yrs, 51 men and 70 women) with history of recurrent NMS. They had normal electrophysiological study and they were free of structural heart disease. Before study inclusion, they underwent a HUT (60° tilting for 30 min and if negative, isoproterenol infusion) and then, they were followed-up for 6 months. Pts with VVS were treated with propranolol, while pts with SS were advised to avoid the trigger event. The prevalence of SS among the study population was assessed. For each pt we compared the number of syncopal spells (sync) during the last 6 months before study inclusion with that during FU.
Results: In a total of 121 pts with NMS, 28% had SS. Their syncopal attacks were associated with meal (15 pts, 44%), micturition (14 pts, 41%), defecation (3 pts, 9%), cough (1 pt, 3%) and swallowing (1 pt, 3%). The remaining pts (72%) had VVS. The response to HUT and the number of sync before and during FU were similar in pts with SS and VVS (p:NS). Ten out of the 34 pts with SS (29%) had also experienced occasional episodes of VVS. They had similar response to HUT and prognosis to those without VVS attacks (p: NS).

	number of pts	positive HUT	sync last 6 months	sync during FU
VVS	87 (72%)	37 (43%)	2.2±0.4	0.2±0.3
SS	34 (28%)	16 (47%)	2.1±0.4	0.1±0.3

(mean values ± SD).

Conclusions: In our study, pts with SS constituted a considerable proportion of pts with NMS. Although SS and VVS may differ in the mechanism of sync, they had similar response to HUT and similarly benign prognosis. Furthermore, the coexistence of occasional VVS episodes in pts with SS was not associated with a higher rate of positive response to HUT or worse natural history.

P1568 Clomipramine infusion during tilt to imply the neurocardiogenic origin of syncopes and presyncopes of unknown etiology

R. Carlioz, J. Deroche, E. Perrier, P.A. Leduc, G. Quiniou, P. Graux, G. Lambert, J.P. Burlaton. *Hopital percy, Cardiology, Clamart cedex, France*

Clomipramine (CP) was recently proposed as a new drug challenge during tilt test (T) for the diagnosis of neurocardiogenic syncope (NCS). The aim of this study was to prospectively evaluate the diagnostic accuracy for NCS of two T strategies in 477 consecutive patients (pts) [mean age (m.a): 47.8 ± 23.5 years; male: 288 (60.4%)] with syncopes (S)/presyncopes (PS) of unknown etiology after negative clinical and non invasive investigations.
Methods: Group A: the first 319 patients (pts) [192 (60.2%) male; m.a = 49.7 ± 23 years] were tilted at 60° for 30 minutes (min), then for 15 min with 2 μg/min isoproterenol infusion rate. Group B: the following 158 pts [95 (60.1%) male; m.a = 43.1 ± 24.6 years] were tilted at 60° for 20 min with 5 mg CP infused during the first 5 min of T. S/PS with bradycardia/asystole and concomitant fall in blood pressure were considered as positive (+) response for NCS.
Results: There was no significant difference between group A/B in age, sex-ratio, S [239 (74.9%) versus (vs) 112 (70.9%) pts], mean number of events per pt (5.7 ± 10.3 vs 3.7 ± 6.2), concomitant drugs [116 (36.4%) vs 69 (43.8%) pts], past history [diabetes = 9 (2.8%) vs 4 (2.5%) pts; hypertension = 62 (19.4%) vs 25 (15.8%) pts].T was positive in 99 (31.1%) pts for A group and 101 (63.9%) for B group. T (+) ratio was identical in pts < 35 years [A group = 40/119 (33.6%); B group = 41/60 (68.3%)].
Conclusion: CP during T increases significantly the accuracy of the test for NCS diagnosis. If previously reported specificity (87 to 94%) was confirmed, CP-T might be the most valuable tool in the evaluation of pts with S or PS of unknown etiology.

P1569 The first recurrence of syncope within 1 month after a positive head-up tilt table test result predicts syncopal freq. in the long-term follow-up

A. Jovic, M. Borcilo, A. Knezevic, D. Zekanovic. *General Hospital Zadar, Cardiology, Zadar, Croatia*

Background: There are some clinical observations that vasovagal syncope shows predictable variations in frequency, often in the form of "clustering of events". However there were some indications that timing of the first syncope after positive head-up tilt table test (HUT) could predict the frequency of the events thereafter.
Objectives: The aim of this study was to determine whether the first recurrence of syncope within 1 month after positive HUT result, in the patients tested for suspected vaosovagal or syncope of unknown aetiology, predicts the incidence of syncope during long- term follow-up.
Methods: Eighty patients (43M, 37F, median age 48 years) with syncope, and positive basal tilt-table test according to Westminster protocol, or combined-"hybrid" test with isoproterenol/NTG, were included in this study. Patients with at least one syncope spell after a positive HUT were followed up for up to 8 years (mean 50 ± 18 months). The time from tilt table testing to the first recurrence of syncope was correlated.
Results: Patients who had the first syncope within 1 month of tilt testing, had significantly more spells during follow up (median 14 > 4 spells, t-4.0 $p < 0.00015$). Compared with patients who fainted for the first time one month after testing, the syncope rate or spell frequency was significantly higher as well (0.70 spells/month vs. 0.20 spells/month).
Conclusions: The time to the first recurrent syncope predicts the frequency of sycopal attacks after a positive tilt table test result.The patients with fisrt reccurence within one month have significantly higher rate of episodes thereafter in longterm follow-up period. This could have important role in managing patients with vasovagal syncope, especially according timing and mode of treatment.

ATRIAL FIBRILLATION – ELECTRICAL CARDIOVERSION

P1570 Thromboembolic complications after cardioversion of atrial flutter in comparison to atrial fibrillation

K. Seidl, H. Schwacke, M. Rameken, A. Brandt, M. Vater, R. Zahn, C. Kilkowski, J. Senges. *Klinikum Ludwigshafen, Cardiology Dept., Ludwigshafen, Germany*

Aim of the prospective single center observational study was to evaluate the thromboembolic risk after electrical cardioversion in 386 patients (pts) with atrial flutter (73% male, mean age 63 ± 12 years, organic heart disease 48%, atrial hypertension 43%, diabetes mellitus 14%, left atrial diameter 41 ± 8 mm, history of stroke 4%) compared with the thromboembolic risk in 1269 pts with atrial fibrillation (74% male, mean age 63 ± 10 years, organic heart disease 57%, atrial hypertension 54%, diabetes mellitus 12%, left atrial diameter 46 ± 6 mm, history of stroke 10%).
Methods: Anticoagulation strategy was similar in pts with atrial flutter and atrial fibrillation (effective anticoagulation at least 3 weeks before and 8 weeks after electrical cardioversion). Transesophageal echocardiography (TEE) was performed in 144 pts with atrial flutter and in 845 pts with atrial fibrillation before cardioversion.
Results: Pts with atrial fibrillation had more often an organic heart disease (57% vs 48%, p = 0.01) and more often a history of stroke (10% vs 4%, p = 0.001) compared to pts with atrial flutter. TEE revealed left atrial thrombi in 7.7% of pts with atrial fibrillation, in contrast to 4% in pts with atrial flutter.

	Atrial Fibrillation (1269 pts)	Atrial flutter (386 pts)
Cardioversion performed	1091 pts (86%)	341 pts (88%)
Embolic events < 48 h	2 pts (0.16%)	2 pts (0.52%)
Embolic events > 48 h < 4 weeks	9 pts (0.7%)	1 pt (0.26%)
Overall embolic events	11 pts (0.86%)	3 pts (0.78%)

Conclusion: Pts with atrial fibrillation had twice as much a history of stroke than pts with atrial flutter. Left atrial thrombi were detected twice as often in pts with atrial fibrillation than in pts with atrial flutter (7.7% vs. 4%). The embolic risk during the first 4 weeks after electrical cardioversion was similar in pts with atrial flutter and atrial fibrillation (0.78% vs. 0.86%).

P1571 Is direct current cardioversion in patients with atrial fibrillation safe? Complication rate in 1269 consecutive patients

K. Seidl, H. Schwacke, A. Droegemueller, M. Vater, M. Rameken, A. Brandt, J. Senges. *Klinikum Ludwigshafen, Cardiology Dept., Ludwigshafen, Germany*

Background: Direct current cardioversion (CV) of atrial fibrillation (AV) is the most effective method to restore normal sinus rhythm; however little is known about the complication rate of CV, if the recommended guidelines for anticoagulation prior to CV were followed.
Aim of this prospective study was to assess the complication rate of CV in patients (pts) with persistent AF.
Methods and Results: The study group comprised 1269 consecutive unselected pts with persistent AF who were admitted for CV of AF. In 845 of 1269 pts (67%) a transesophageal echocardiography (TEE) was performed before CV. At the time of intended CV anticoagulation was effective (INR 2-3) in 85% of pts. In 984 of 1269 pts (78%) CV was performed. All complications associated with CV, which occurred in between 48 h were registered. The complications associated with CV are listed below. None of the complications were associated with the TEE. Overall acute success rate of CV was 84%.

Complication of 1269 external CV

	Number of patients	in %
Asystole	3 pts	0.3
AV-block III	1 pt	0.1
AV-block II	3 pts	0.3
Sinus bradycardia	2 pts	0.2
Ventricular fibrillation	1 pt	0.1
Pacemaker malfunction	1 pt	0.1
Transient ischemic attack	2 pts	0.2
Adverse effect of etmoidate	2 pts	0.2
Overall complications	15 pts	1.5

Conclusion: Complication rate after CV is low with 1.5%. Arrhythmogenic complications were the most common complications after CV (1.1%). In 2 pts (0.2%) a transient ischemic attack occurred in between 48 h after CV despite effective anticoagulation and normal TEE.

P1572 Efficacy of monophasic and biphasic shocks for transthoracic cardioversion of chronic atrial fibrillation and post-shock skeletal muscle injury

M. Marinsek, M. Bervar, P. Zohar, M. Pekolj Bicanic, F. Skrabl Mocnik, M. Podbregar. *Petrovce, Slovenia*

Efficacy of monophasic and biphasic shocks for transthoracic cardioversion of chronic atrial fibrillation and post-shock skeletal muscle injury
Background: Biphasic (B) compared to monophasic (M) shocks are supposed to be more efficient for transthoracic cardioversion of chronic atrial fibrillation (AF); requiring less current and causing less post-procedure pain. We hypothesized that B shocks would have higher success rate and cause less skeletal muscle injury.
Methods: Eighty patients with chronic AF were randomised to receive either truncated exponential B (70, 100, 150 and 200 J) or damped sine wave M (100, 200, 300 and 360 J) sequential impedance compensated shocks. Crossover shock of maximal energy of the other waveform was delivered if AF persisted. Plasma levels of cardiospecific troponin T (cTnT), creatine kinase (CK) and myoglobin before, 6 hours and 24 hours after procedure were determined.
Results: Cumulative success rates were not significantly different between B and M shocks (37/41 (90.2%) vs. 36/39 (92.3%), respectively). Compared with M shocks, B shocks succeeded with less peak-current (17.5 ± 4.4 vs. 36.0 ± 8.0 A, p <0.0001), less cumulative energy (243 ± 164 vs. 507 ± 298 J, p < 0.0001) and less cumulative current (33.7 ± 19.0 [9-84] vs. 72,0 ± 30.9 [22-141] A, p < 0.0001). All crossover shocks failed. In all patients cTnT remained under discriminatory level (0.1 μg/l) of myocardial injury. Compared to M shocks, B shocks resulted in lower maximum level of CK (1.55 ± 3.91 vs. 8.50 ± 11.83 μkat/l, p < 0.001) and lower maximum level of myoglobin (87.04 ± 114.52 vs. 445.52 ± 525.93 ng/ml, p < 0.0001). The M shocks (relative risk 5.37, 95% CI 2.53-11.4, p<0.025) and cumulative current (relative risk 5.49, 95% CI 2.39-12.60, p<0.04) were independently associated with high myoglobin concentrations.
Conclusions: M and B shocks are similarly efficient for transthoracic cardioversion of chronic AF, and do not cause any myocardial damage. M shocks, and cumulative current are independently associated with skeletal muscle injury.

P1573 Highly successful atrial defibrillation using low-energy biphasic waveforms with no tilt

S.J. Walsh[1], G. Manoharan[1], J. Santos[2], O.J. Escalona[3], N. Evans[2], J.D. Allen[4], J.M.C.C. Anderson[2], A.A.J. Adgey[1]. *[1]Royal Victoria Hospital, Cardiology, Belfast, United Kingdom; [2]University of Ulster, Bio-Engineering, Jordanstown, United Kingdom; [3]Universidad Simon Bolivar, Caracas, Venezuela; [4]Queens University, Physiology, Belfast, United Kingdom*

Background: Conventional capacitor discharge defibrillators deliver shock waveforms with considerable tilt. The efficacy of defibrillation may be improved by reducing the tilt of the waveform. We investigated the feasibility, efficacy and safety of a novel device that delivered a biphasic direct current shock without tilt (square waves) in transvenous cardioversion of atrial fibrillation (AF).
Methods: The device was assessed in 10 anaesthetised and ventilated pigs (58 ± 2kg). Defibrillation leads were positioned fluoroscopically, one in the distal coronary sinus and the other in the lateral right atrium via the external jugular vein. The leads were then connected to the output of the novel defibrillator. Sustained AF was induced by rapid atrial pacing (Grass stimulator, 100Hz, 5 Volts). The biphasic waveform was assessed at two pulse width (PW) settings of 3/3 ms and 6/6 ms, and at varying first and second phase voltage settings ranging from 25 V to 100 V. Five attempts at cardioversion were made at each pulse width and voltage setting. Success was defined as reversion to sinus rhythm within 5 beats of shock delivery.
Results: No arrhythmic complications were observed for the total 750 shocks delivered (including 50 placebo shocks delivered to a 50 Ohm dummy load during AF). Data are expressed as mean % success (mean energy, J). PW 6/6ms: 50/-25V=92(0.35J), 75/-37.5V=98(0.82J), 100/-50V=100(1.45J), 25/-25V=24(0.12J), 50/-50V=80(0.54J), 75/-75V=98(1.27J), 100/-100V=100(2.26J); PW 3/3ms: 50/-25V=58(0.21J), 75/-37.5V=84(0.49J), 100/-50V=96(0.87J), 25/-25V=20(0.07J), 50/-50V=74(0.31J), 75/-75V=98(0.72J), 100/-100V=100(1.29J);Placebo: 6/6ms, 100/-50V to dummy load =6(0.00J).The 6/6ms 50/-25V setting was more efficacious than the 3/3ms 50/-50V (p= 0.002) and the 6/6ms 50/-50V settings (p=0.083).
Conclusion: Cardioversion using this novel biphasic waveform is safe and efficacious at very low voltage. The 6/6ms PW setting is more efficacious than the 3/3ms PW setting. The voltage setting at 50% second phase voltage was more efficacious than the setting with equal first and second phases. Design modification will enable the device to be used as an implantable defibrillator.

P1574 Electrical cardioversion of long lasting atrial fibrillation: analysis of success and recurrences

M. Kofler, M. Tüllmann, T. Brüggemann, C. Ehlers, M. Wiedemann, D. Andresen. *Vivantes Klinikum Am Urban, Dept. of Cardiology, Berlin, Germany*

The success rate of electrical cardioversion (CV) of atrial fibrillation (AF) seems to be inversely related to the duration of this arrhythmia. Thus, in clinical practice many patients (pts.) with AF lasting longer than one year are not considered to be candidates for a CV.

Purpose: Our aim was to evaluate success and recurrence rates in pts. with long lasting AF.

Method: 345 consecutive pts. with AF were enrolled in the Urban-AF-Database between Oct. 1998 and Dec. 1999(males 57%, mean age 66±11 years). Persistent AF was observed in 58% of pts. (201/345). AF lasted <= 1 year in 43% (86/201) (Group A). AF > 1 year was found in 57% (115/201)(Group B). Electrical cardioversion was attempted in all eligible cases regardless the duration of AF. A follow up at 12 month was achieved in 85% (171/201) of cases.

Results: No significant difference between both groups was observed with regard to age (66 vs. 67 years), gender (69 vs. 60% males), hypertension (59 vs. 52%), coronary artery disease (34 vs. 34%), valvular heart disease (6 vs. 9%), dilative cardiomyopathy (11 vs. 14%) and lone AF (9 vs. 14%). Electrical CV was attempted in 55% (group A) and 40% (group B) of pts. In group A 87% and in group B 71% of pts. were discharged in sinus rhythm (SR) after successful electrical CV. At a follow-up of 12 months 46% (group A) and 30% (group B) of pts. remained in SR (p = 0.16, ns).

Conclusion: 1. These data demonstrate that about 70% of pts. with long lasting AF can be discharged in SR. 2. There was no significant difference with respect to recurrence rate between patients with AF lasting longer or less than 1 year. Therefore, in clinical routine even in pts. with long lasting AF restoration of SR should be attempted.

P1575 Clinical value of left atrial appendage velocities for predicting of cardioversion success of atrial fibrillation of unknown duration

A. Pizzuti[1], E. Antonielli[2], A. Pálinkás[3], M. Stasi[4], A. Bonzano[1], A. Varga[3], A. Tomasello[1], F. Gaita[1]. [1]*Ospedale Mauriziano Umberto I, UO di Cardiologia, Torino, Italy;* [2]*Ospedale SS.Annunziata, UO Cardiologia, Savigliano, Italy;* [3]*A.Szent-György Medical Faculty, 2nd Dept. of Medicine and Cardiology, Szeged, Hungary;* [4]*Ordine Mauriziano-IRCC, UOA Fisica Sanitaria, Candiolo (TO), Italy*

Background: Duration of atrial fibrillation (AF), left atrial appendage (LAA) flow velocity pattern determined by transesophageal echocardiography and left atrial diameter provide valuable information for prediction of outcome of electric cardioversion (ECV) in patients with non-valvular AF. However, in substantial number of patients the duration of AF is unknown.

Objective: To evaluate the predictive power of LAA anterograde flow velocity for prediction of outcome of ECV in patients with AF of unknown duration, in a prospective, multicenter, international study design.

Methods: One hundred-ninety one consecutive patients (130 males, mean age 66±11 years) with non-valvular AF of unknown duration underwent transthoracic and transesophageal echocardiography < 24 h before ECV.

Results: ECV was successful in restoring sinus rhythm in 135 patients (71%). Neither the clinical (sex, body mass index and underlying diseases) nor the transthoracic echo parameters (left atrial diameter; left ventricular mass, end-diastolic diameter and ejection fraction) predicted the success of ECV, only the age tended to be lower (63.9±12.5 vs 67.2±10.3 years, p=0.061) in patients with successful ECV. On the basis of transesophageal echocardiographic variables, successfully converted patients had a significantly higher mean LAA emptying flow velocity than those with failure of ECV (29.1±14.6 vs 24.1±13.3 cm/sec; p=0.029), whereas the presence or absence of left atrial spontaneous echo contrast or the degree of mitral regurgitation provided no additional information.

Conclusion: In patients with non-valvular AF of unknown duration, measurement of LAA flow profile before electrical cardioversion provides valuable information for prediction of cardioversion success.

P1576 Clinical predictors of successful cardioversion of persistent atrial fibrillation with a balloon-tipped internal cardioversion catheter

E.M. Kanoupakis[1], E.G. Manios[1], H.E. Mavrakis[1], E.M. Kallergis[1], D.N. Dermitzaki[1], D.C. Kambouraki[1], P.E. Vardas[2]. [1]*Heraklion University Hospital, Cardiology Dept., Heraklion, Crete, Greece;* [2]*Heraklion University Hospital, Cardiology, Heraklion, Greece*

Background: Cardioversion of atrial fibrillation (AF) is feasible by either pharmacologic or electric approaches. Both treatment modalities carry a high risk of relapse to AF within one month. The variables associated with successful cardioversion and recurrences of AF after pharmacologic or external direct current cardioversion have been extensively studied; yet those predictive of success rate after internal cardioversion (ICV) and relapse to AF are not well characterized.

Methods and Results: We studied 109 patients with persistent AF (63±9 years, 57% male, mean duration: 23±34 months) treated with ICV using a balloon-tipped pulmonary artery catheter (ALERT®, EP MedSystems, Inc) with distal and proximal shock electrodes and biphasic shocks. One hundred of 109 patients (92%) were defibrillated successfully. Stepwise logistic regression analysis revealed that, left ventricular ejection fraction followed by left atrial diameter were the most significant independent predictors for conversion to sinus rhythm (p=0.011 and p=0.043 respectively). The mean energy for successful cardioversion was 7.8±3.2J. At one month of follow up AF recurred in 45 patients (45%). No clinical variable was found to predict recurrence within this interval. The table shows association between the test variables and success of ICV.

	Success	Failure	p
Age (yrs)	63±9	64±7	ns
Gender: m/f	57/43	5/4	ns
AF duration (months)	23±35	16±19	ns
LVEF (%)	51±11	59±7	0.011
LA diameter (mm)	44±4	48±3	0.043

Conclusions: Internal cardioversion is a very effective method for the restoration of sinus rhythm in patients with persistent atrial fibrillation. Success rate is associated with lower ejection fraction and smaller left atrial diameter, independent of AF duration. These findings may be useful for the most appropriate selection of patients for internal cardioversion.

P1577 Internal cardioversion as an alternative option to external cardioversion of atrial fibrillation in patients with congestive heart failure

E.M. Kanoupakis[1], E.G. Manios[1], H.E. Mavrakis[1], E.M. Kallergis[1], D.N. Dermitzaki[1], P.E. Vardas[2]. [1]*Heraklion University Hospital, Cardiology Dept., Heraklion, Crete, Greece;* [2]*Heraklion University Hospital, Cardiology, Heraklion, Greece*

Background: Atrial fibrillation (AF) is very common among patients with congestive heart failure (CHF). External cardioversion is often unsuccessful in these patients. Although internal cardioversion (ICV) has been frequently used in patients refractory to external cardioversion, this has been rarely performed in CHF patients, also due to the described high incidence of early recurrences. Aim of the study was to estimate the incidence and to evaluate potential predictors of early recurrences among patients with CHF and persistent AF.

Methods: Twenty-nine pts with CHF, persistent AF (3 months-5 years) and previous failed external CV, underwent ICV. Mean age was 65±7 years, mean NYHA class 2.7±0.6; all pts had a dilated left ventricle (LVEDD) with mean ejection fraction (LVEF) 31±7% and left atrial diameter (LAd) 52±7 mm. All patients received amiodarone 400 mg daily 4 weeks before and 200 mg daily after ICV.

Results: No significant adverse effects were observed during the procedure. Sinus rhythm (SR) was restored in twenty-six patients (86%) with a mean energy of 12±4 J. In three patients AF recurred within few minutes, in three within 24 hours, in six additional patients within one month. Comparison of patients in SR (14/29, 48%) vs. patients in AF at 1 month shows that patients with AF recurrence had significantly higher duration of arrhythmia (see table).

	Age (yrs)	NYHA	AF (months)	LVEF (%)	LVEDD (mm)	LAd (mm)
1 month SR	67 (8)	2.8 (0.5)	21 (28)	34 (7)	62 (12)	51 (6)
1 month AF	64 (6)	2.7 (0.5)	44 (22)	30 (7)	60 (14)	55 (9)
p value	0.4	0.6	0.048	0.6	0.8	0.3

Data of the two groups are presented as mean(SD)

Conclusions: Internal cardioversion, associated with amiodarone pretreatment, is safe and can effectively restore sinus rhythm, preventing recurrences in many patients with congestive heart failure and persistent atrial fibrillation.

P1578 Clinical value of left atrial appendage flow velocity for predicting of cardioversion success in patients with persistent atrial fibrillation

A. Navazio[1], E. Catellani[1], P. Montanari[2], A. Piazza[1], D. Giberti[2], A. Colli[1].
[1]*Franchini Hospital, Dept. of Cardiology, Montecchio Emilia (RE), Italy;*
[2]*Franchini Hospital, Dept of Internal Medicine, Montecchio Emilia (RE), Italy*

Background: Echocardiographic parameters for predicting cardioversion outcome in patients with persistent non valvular atrial fibrillation are not accurately defined.
Aim: To evaluate the role of left atrial appendage flow velocity detected by transesophageal echocardiography for prediction of cardioversion outcome in patients with persistent non valvular atrial fibrillation.
Methods: 62 patients (38 males, mean age 68±11 years) with persistent non-valvular atrial fibrillation of duration of more than 4 weeks but less 12 months duration underwent transthoracic and transesophageal echocardiography before electrical cardioversion.
Results: Cardioversion was successful in restorig sinus rhythm in 54 patients (87%). Mean left atrial appendage peak emptying flow velocity was significantly higher in patients with successful than those with unsuccessful cardioversion (34±16.4 cm/sec vs 24.3±14.7 cm/sec; $p < 0.001$); other independent predictors of cardioversion success at univariate analysis were left end-diastolic diameter > 57 mm ($p < 0.05$), ejection fraction > 50% ($p < 0.04$) and the pretreatment with antiarrhythmic drugs ($p < 0.04$). At multivariate regression analysis (Cox model) the mean left atrial appendage flow velocity > 33 cm/sec ($p = 0.0018$, OR 3.2, CI 95% = 1.7-5.8), the arrhythmia duration < 6 weeks ($p = 0.032$, OR 5.2, CI 95% = 2.4-14.3), the left atrial diameter (parasternal long axis) < 48 mm ($p = 0.036$, OR 2.3, CI 95% = 1.4-3.9) and pretreatment with antiarrhythmic drugs ($p = 0.04$, OR 2.4, CI 95% = 1.4-4.1) were independent predictors of cardioversion success.
Conclusions: In patients with persistent nonvalvular atrial fibrillation, measurement of left atrial appendage peak emptying flow velocity by transesophageal echocardiography before electrical cardioversion provides valuable information for prediction of cardioversion outcome. In transesophageal echocardiography guided management of atrial fibrillation, assessment of left atrial appendage velocity profile can be easily incorporated into pre-cardioversion echocardiographic examination.

P1579 External direct current cardioversion in atrial fibrillation – Efficacy and outcome in a consecutive patient cohort

A. Theiss, R. Schäfer, G. Janssen, T. Feldmann, M. Oeff. *Klinikum Brandenburg, Cardiology, Brandenburg, Germany*

External direct current Cardioversion (DC-CV) after suitable preparation (sufficiant anticoagulation or TEE) is an effective and low risk intervention for treatment of atrial fibrillation (afib). The outcome is dependent on numerous clinical variables.
Methods In 262 of 1307 consecutive afib patients (pts) included during a 2-year prospective registration in the Brandenburg Atrial Fibrillation Registry DC-CV was the treatment of choice. This was performed during 327 admissions.
Results Of 327 hospital stays within which DC-CV was required, 215 admissions electively, 91 because of acute afib symptoms and 21 because of other cardiac or non-cardiac diseases.
Primary successful DC-CV was achieved in 307 cases (94%). Success rate was 92% in those 180 pts with persistent afib of more than 1 month.
Early relapse occurred in 36 cases (12% of primarily successful converted pts), 1/3 within few sinus beats. 271 (83%) were discharged in stable SR (chronic afib: 152 pts, 78%), 162 (60%) of them with additional beta-blocker medication, 60 (22%) with specific antiarrhythmic drugs (others: no drugs for prevention of relapse).
Late recurrence requiring hospitalization for DC-CV occurred in 48 pts (65 stays) after a median of 85 days. Relapses in ambulant pts are subject of ongoing follow up.
Conclusion The vast majority of pts, even with chronic afib, could be cardioverted successfully and discharged from hospital in stable sinus rhythm.
Readmission to hospital because of relapse requiring DC-CV was necessary in a minority after a median of 85 days and was, thus, accepted by most pts as a reasonable therapeutic concept.

P1580 The relation between left atrial function and acceleration slope of mitral A wave after cardioversion in patients with acute atrial fibrillation

M. Eren, S. Gorgulu, D. Oz, S. Celik, B. Dagdeviren, N. Uslu, T. Norgaz, T. Tezel. *Siyami Ersek Hospital, Cardiology Dept., Istanbul, Turkey*

Purpose: After cardioversion of AF to sinus rhythm, atrial stunning occurs and it takes atrial function a few weeks to recover and precise determining of this period still associated with increase in the risk of thromboembolism is important to continue anticoagulation. This study was planned to evaluate the relation between the left atrial (LA) function and the acceleration slope (Acc-S) of mitral A wave after restoration of the sinus rhythm (SR) in patients with an acute lone atrial fibrillation (AF) attack.
Methods: Thirty patients (52±18 years, 19 female) with a lone AF attack were enrolled in the study. The SR was restored by the electrical cardioversion in 6 patients, the pharmacological cardioversion in 20 and spontaneously in 4. Echocardiographic examination was performed at the first and 30th days after restoration of the SR. The ejection fraction of the LA obtained by end diastolic and pre-p wave volumes of the LA was taken as reference method to determine the LA function. The mitral A velocity and its Acc-S were measured by placing PW Doppler sample volume at the tips of mitral leaflets.
Results: There were no differences for mitral A velocity (76±21 vs 80±21 cm/sec), the LA diameter (38±8 vs 38±7 mm) and end diastolic volume of the LA (32±33 vs 29±22 cm^3) between first and 30th day examinations whereas pre-p wave volume of the LA (28±19 vs 37±16 cm^3, p=0.03), the Acc-S (910±406 vs 1041±401 cm/sec, p= 0.01) and the ejection fraction of the LA (37±15 vs 52±22%, p= 0.008) had statistically significant differences. There were significant correlations between the Acc-S and the ejection fraction of the LA for both first ($r=0.67$, $p<0.001$) and 30th days ($r=0.74$, $p<0.001$).
Conclusion: The acceleration slope of mitral A wave was found to be closely related with the LA function in patients who have been converted to SR after AF. Thus it may be a new parameter to evaluate the LA function in clinical use.

P1581 Immediate haemodynamic effects of effective internal cardioversion in chronic persistent atrial fibrillation

G. Boriani, M. Biffi, C. Martignani, C. Camanini, L. Bacchi, C. Rapezzi, R. Zannoli, A. Branzi. *Inst of Cardiology, Bologna, Italy*

The aim of this study was to assess the immediate hemodynamic effects of sinus rhythm (SR) restoration by transvenous internal atrial cardioversion (CV). in chronic persistent atrial fibrillation (AF).
Fifty patients with chronic persistent AF (mean arrhythmia duration= 8.9±9.0 months, range 1-48) were enrolled and in 12 of them no underlying structural heart disease (HD) was detectable. Internal CV was performed after a wash out from antiarrhythmic drugs. Before CV and 15 min following restoration of stable SR, hemodynamic parameters were obtained using a Swan-Ganz thermodilution catheter.
Results: SR was restored by internal CV in all the patients, with a mean delivered energy of 5.8±3.2 joule (range 1.2-15.7). In patients with structural HD (n=38) restoration of SR was associated with a significant reduction in heart rate (HR) (from 92±19 to 72±14 bpm, $p<0.001$), a significant increase in cardiac index (CI)(from 2.09±0.51 to 2.22±0.55 $l/m/m^2$, $p<0.03$) and a significant increase in stroke work index (SWI) (from 24±10 to 32±12 $g.m/m^2$, $p<0.001$), with a reduction in pulmonary capillary wedge pressure (PCWP) of borderline significance. In patients without structural HD (n=12) restoration of SR was associated with a significant reduction in HR (from 103±23 to 74±9 bpm, $p<0.005$) and a significant increase in SWI (from 27±8 to 36±9 $g.m/m^2$, $p<0.02$); no significant changes was observed in CI (from 2.42±0.48 to 2.43±0.45 $l/m/m^2$, n.s.) and PCWP.
In conclusion, restoration of SR in patients with chronic persistent AF results in an immediate improvement of systolic function in patients with structural heart disease. In patients without structural heart disease this improvement is less noticeable.

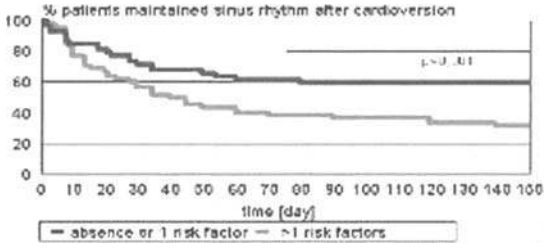
P1582 The factors influencing recurrence of atrial fibrillation after cardioversion

M. Dmochowska[1], K. Loboz-Grudzien[1], L. Sokalski[1], E. Jazwinska-Tarnawska[2]. [1]*Marciniak Hospital, Cardiology, Wroclaw, Poland;* [2]*University of Medicine, Pharmacology, Wroclaw, Poland*

Background: Factors which predict the maintenance of sinus rhythm (SR) after cardioversion in atrial fibrillation (AF), have not been well defined. There is few data concerning the impact of the recovery of the left atrial mechanical function (r.l.a.m.f.) on AF recurrence. The aim of the study was to identify the clinical and echocardiographic predictors for the recurrence of AF.

Methods: 112 consecutive pts mean age 62,1 yrs, after electric or pharmacological cardioversion were divided into: I gr. n=50 maintained SR during 6 months follow up and II gr. n=62 with the recurrence of AF. The clinical examination and 2D ECHO Doppler were performed. From Doppler mitral flow the r.l.a.m.f. at 1st day after cardioversion was evaluated.

Results: No significant relation was found between two groups in respect to age, sex, aetiology, duration of AF, left atrial size and ejection fraction. In univariate analysis the lack of r.l.a.m.f. at 1st day (relative risk rr=1,15, p<0,01), the functional NYHA class II-III (rr=1,86, p<0,005) and the history of AF episodes (rr=2,02 p<0,0005) were identified as predictors for recurrence of AF. In multivariate analysis using Cox proportional hazard model the above 2 factors remained independent also irrespectively of the therapeutic approach.The Kaplan-Meier analysis has shown that out of all analysed risk factors the most significant were functional NYHA class, history of AF and the lack of r.l.a.m.f. The Kaplan-Meier curves computed for selective risk factors - test log-rank (figure).



Conclusion: The history of AF, functional NYHA class II-III and the lack of r.l.a.m.f. seem to be independent predictors for recurrence of AF. The presence of more than 1 risk factor failed the maintenance of SR during 6 months follow-up.

P1583 Cardioversion of atrial fibrillation – Clinical results

S. Juul-Möller, K. Drivstedt, G. Balcha, J. Holm. *University Hospital, Cardiology, Malmö, Sweden*

Background: Treatment with DC-conversion (DC) for persistent atrial fibrillation (AF) includes a substantial risk för relapse. This risk has been demonstrated to be related to certain clinical risk factors. However, the risk and the risk factors have mainly been determined from controlled trials, including highly selected patients that does not mimic the clinical population with AF. Also, the duration of pharmacological antiarrhythmic treatment after DC varies in different studies.

Aim and methods: We wish to demonstrate the treatment effect of AF in all referred patients - only exclusion criteria was contraindication for anticoagulant (AC) treatment - mainly utilizing one treatment modality: 3 weeks of AC-treatment followed by 4 weeks of additional amiodarone treatment (400 mg OD). Then DC followed by 3 months of AC and amiodarone (200 mg OD) treatment. The patients were then re-referred to the primary practicians. These patients includes all planned DC in Malmö, a Swedish city with 250.000 inhabitants.

Patients: 351 patients were included. Mean age is 72 (range 29-92) years. 65% are males. 21% has performed earlier DC (mean 2,0, range 1-2) and the duration of AF is 12,6 (range 3-240) months. LVEF is (mean) 0,46 (range 0,15-0,70). 21% has LVEF < 0,35. The mean atrial diameter is 69,3 (range 52-110) mm. 14% have diabetes mellitus, 38% hypertension, 36% heart failure and 9% significant valve disease.

Results: Amiodarone treatment could be given to 73% of the 351 patients. Remaining patients received Sotalol or no antiarrhythmic treatment. 13% had thyroid disease. 79% of the patients regained sinus rhythm (SR)following the DC. After three months 60% were still in SR, while 6% har intermittent AF. 12 months after the DC 45% had SR. Between 3 and 12 months did 45% receive betablockers, and 10% digoxin. The only risk factors for relapse were duration of AF (P<0,05) and gender (P<007).

Conclusions: A time-limited treatment with an effective antiarrhythmic drug (amiodarone) combined with DC was highly effective in the treatment of patients with AF, comparable to the results from clinical trials with selected patients. Patients with AF-duration less than 3-5 years had the highest success-rate. Other traditional risk factors for relapse had no influence on the results.

INFLAMMATION IN ATHEROSCLEROSIS

P1584 Met-RANTES (chemokine receptor antagonist) treatment reduces atherogenesis

N R. Veillard[1], B R. Kwak[1], G. Pelli[1], F. Mulhaupt[1], R W. James[2], A. Proudfoot[3], F. Mach[1]. [1]*Cardiology Division,* [2]*Endocrinology and Diabetes, University Hospital Geneva, Geneva, Switzerland;* [3]*Serono Pharmaceutical Research, Geneva, Switzerland*

Recruitment of mononuclear leukocytes (macrophages and T lymphocytes) within atherosclerotic lesions is a critical feature of the chronic inflammatory and fibroproliferative response central to atherosclerosis. Attraction of leukocytes to tissues is controlled by chemokines, which has been implicated during atherogenesis. Besides MCP-1, the chemokine RANTES has been detected within atherosclerotic lesions. RANTES interacts at least with the chemokine-receptors CCR1, CCR3, CCR5 and has been implicated in several infectious diseases, during rejection following organ transplant, or arterial injury.In addition, we demonstrated that the chemokine analogous antagonist Met-RANTES (Met-R) inhibits leukocyte chemotaxis in vitro. Therefore, we decided to investigate if Met-R treatment could influence the progression of atherosclerosis in vivo.

LDLR-/- mice fed a high-cholesterol diet were divided in 3 groups (n=8 per group): controls, Met-R treatment (100μg) or saline treatment (100μl) twice/week intra-peritoneally. Animals were sacrificed after 12 weeks of treatment. Atherosclerotic lesion progression was determined by computer image analysis measuring the extent of sudanophilic lesions within the abdominal aorta and aortic root. Serum lipid profiles and body weight did not differ between groups.

Treatment with Met-R significantly reduced the progression of atherosclerosis within abdominal aorta and aortic root compared to controls. For the abdominal aorta, the lipid deposition in controls, saline and Met-R group were 16±1%, 15±1.5%, and 7±2%, respectively (p<0.05). Similar results were obtained in aortic root analysis.

To our knowledge, this is the first demonstration that blocking chemokine pathway by treatment with a chemokine analogous antagonist limits the progression of atherosclerosis in vivo. Knowing the important role of inflammation during atherogenesis, these findings indicate that blocking chemokine receptor/ligand interactions may provide novel and effective therapeutic strategies to reduce the evolution of this common disease.

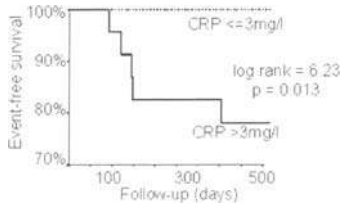
P1585 The prognostic value of C-reactive protein in patients with intermediate coronary lesions and a normal fractional flow reserve

M. Meuwissen[1], R.J. de Winter[1], S.A.J. Chamuleau[1], M. Heijne[1], K.T. Koch[1], J.P. van Straalen[2], G.T. Sanders[2], J.J. Piek[1]. [1]*Academic Medical Center, Cardiology Dept., Amsterdam, Netherlands;* [2]*Academic Medical Center, Clinical Chemistry, Amsterdam, Netherlands*

Aim: To assess the prognostic value of plasma C- reactive protein (CRP) in patients with intermediate coronary lesions (diameter stenosis (DS) 40-70%) who were deferred from angioplasty based on a FFR of >=0.75.

Methods: Pre procedural plasma levels of C-reactive protein were measured in 55 patients with stable angina undergoing cardiac catheterization for an intermediate coronary lesion with a mean DS of 53%(range 42-69%). Maximum hyperemia was induced by 15-20 mcg i.c. adenosine to determine FFR defined as the ratio of mean distal coronary pressure to mean aortic pressure during maximum hyperemia. Patients were followed for one year to document major adverse cardiac events (MACE; cardiac death, myocardial infarction, CABG, PTCA).

Results: During a mean follow up time of 323±17 days 5 cardiac events occurred (9.1%; 2xCABG, 3xPTCA). Initial DS (58±7% vs. 53±8%) and FFR (0.86±0.07 vs. 0.85±0.07) were not different between the groups with and without MACE. However, CRP was significantly higher in the group with compared to the group without MACE (median; 6.0 mg/l, range; 4,7-42,4 vs. 1,8 mg/l, 0,20-16,0, p=0.002). DS (53±2% vs. 52±2%) and FFR (0.84±0.11 vs. 0.86±0.15) were not different between patients with a CRP >3mg/l compared to patients with a CRP <=3mg/l. The survival curve below shows the increased risk for coronary events for patients with a CRP>3mg/l.



The Kaplan-Meier survival curve.

Conclusions: A normal C-reactive protein is strongly associated with uncomplicated follow up in patients with hemodynamic non-significant coronary lesions. Plasma levels of C-reactive protein adds additional information for optimal risk stratification in patients with intermediate coronary lesions.

P1586 C-reactive protein: associations with traditional cardiovascular risk factors among young, healthy Polish men

R. Olszewski, R. Grabysa, T. Makowski, J. Warmiński, R. Szczechowicz, W. Piechota, J. Adamus. *School of Military Medical Academy, Cardiology, Warsaw, Poland*

Objective: Several prospective epidemiological studies have demonstrated that inflammatory markers such as C-reactive protein (CRP) are predictors of future coronary events among apparently healthy men and women. The purpose of this study was to determine serum levels of CRP and their associations with traditional risk factors of atherosclerosis in population of young, healthy Polish men.
Methods: In 150 men (mean age 20,5±1,2 yrs) we evaluated clinical (age, history of smoking), anthropometric (body mass index-BMI, waist to hip ratio-W/H, arterial blood pressure-BP) and biochemical measurements (CRP, total cholesterol-TC, HDL-cholesterol, LDL_cholesterol by Friedwald's equation, triglycerides-TG, uric acid-uric, apolipoprotein A- apoA, apolipoprotein B-apoB and glucose-glc).
Results: In studied group there were a positive correlation between the levels of CRP and values of W/H ratio (r=0,20; p=0,05) and negative correlation between the levels of CRP and HDL-cholesterol (r= -0,21; p=0,05) as well as apo A (r=-0,34; p=0,05).

Studied parameters	mean	SD
CRP (mg/dl)	0,135	1,2
BMI (kg/m^2)	22,93	2,2
W/H	0,88	0,07
BP sys (mmHG)	131,4	14,5
BP dia (mmHG)	75,3	8,3
TC (mg/dl)	72,8	29,9
HDL-chol (mg/dl)	56,1	10,6
LDL-chol(mg/dl)	98,4	25,9
TG (mg/dl)	95,7	46,8
Uric (mg/dl)	4,8	0,8
Apo A (mg/dl)	1,64	0,21
Apo B (mg/dl)	0,77	0,18

Conclusions: CRP levels were associated with several risk factors of atherosclerosis (W/H ratio, HDL-cholesterol, apo A) which are regarded as parts of insulin resistance syndrome (IRS) which is of great importance role of pathogenesis of atherosclerosis. Our data suggests the potential role of inflammation in the pathogenesis of IRS.

P1587 The proatherogenic effects of C-reactive protein are mediated via endothelin-1 and interleukin-6 production: a novel observation

S. Verma, P.W.M. Fedak, S.H. Li, M.V. Badiwala, R.K. Li, D.A.G.M. Mickle, R.D. Weisel. *Toronto, Canada*

Background: C-reactive protein (CRP) is one of the most powerful predictors of myocardial infarction, stroke, and vascular death currently known. In addition to predicting adverse cardiovascular events, CRP has been suggested to actively participate in lesion development by inducing a variety of pro-atherogenic processes. In the present study, we examined the role of the potent endothelium-derived vasoactive factor endothelin-1 (ET-1) and the inflammatory cytokine interleukin-6 (IL-6) as mediators of CRP induced adhesion molecule expression, chemokine production and macrophage low-density lipoprotein (LDL) uptake.
Methods and Results: Study 1: Human saphenous vein endothelial cells (HSVECs) (n = 7 per group) were incubated with human recombinant CRP (25ug/ml, 24 hours) and the expression of vascular cell adhesion molecule (VCAM-1) and intracellular adhesion molecule (ICAM-1) were evaluated by flow cytometry.
Study 2: HSVECs were incubated as described above and the secretion of the monocyte chemoattractant chemokine-1 (MCP-1) was determined by ELISA.
Study 3: Monocytes were isolated from human blood and transformed into macrophages. CRP/LDL uptake was assessed by flow cytometry using immunofluroscent labeling of CD32 and CD14. In each study, the effect of endothelin antagonism (with Bosentan) and IL-6 inhibition (with monoclonal anti-IL-6 antibodies) was examined.
Study 4: The effects of CRP on the secretion of ET-1 and IL-6 from HSVECs were evaluated using ELISA.
Incubation of HSVECs with recombinant human CRP resulted in a marked increase in ICAM-1 and VCAM-1 expression ($p<0.001$). Likewise, CRP caused a significant increase in MCP-1 production, a key mediator of leukocyte transmigration ($p<0.001$). CRP caused a marked and sustained increase in native LDL uptake by macrophages ($p<0.05$). These pro-atherosclerotic effects of CRP were mediated, in part, via increased secretion of ET-1 and IL-6 ($p<0.05$) and were attenuated by both Bosentan and IL-6 antagonism ($p<0.01$).
Conclusions: CRP actively promotes a pro-atherosclerotic and pro-inflammatory phenotype. These effects are mediated, in part, via the production of ET-1 and IL-6 and are attenuated by mixed ETA/B receptor antagonism and IL-6 inhibition. Pharmacological interventions, such as Bosentan, may be useful in decreasing CRP mediated vascular disease.

P1588 Correlation of soluble cell adhesion molecule expression and heat production of atherosclerotic plaques

S. Vaina, C. Stefanadis, K. Toutouzas, E. Tsiamis, V. Katsi, M. Toutouza, C. Chrysohoou, P. Toutouzas. *Hippokration Hospital, Dept of Cardiology, Athens, Greece*

Background: Several studies have shown that inflammation plays an important role in the pathogenesis of coronary artery disease. Cell adhesion molecules are critical indicators of the inflammatory process. Recently ex vivo and in vivo studies demonstrated that atherosclerotic plaques show substantially warmer regions. Therefore, the aim of the present study was to measure the luminal surface temperature in patients with coronary artery disease (CAD) and to correlate it with the soluble cell adhesion molecules in order to discriminate the role of inflammation in heat production in acute coronary syndromes. Methods: Twenty-five patients were studied with CAD (12 with myocardial infarction during the last month and 13 with unstable angina) and 10 sex- and age-matched controls without CAD, by measuring plasma levels of soluble inter-cellular adhesion molecule-1 (ICAM) and vascular cell adhesion adhesion molecule (VCAM-1). Intracoronary temperature was measured with a thermography catheter developed in our Institution: a thermistor probe with a temperature accuracy of 0.05 °C, was attached at the distal end of a long 3F polyurethane shaft. Thus, the median temperature differences (TD) at the site of the lesion from the core temperature was measured. Results: It was found that the median TD at the site of the lesion from the core temperature was increased in patients with unstable angina (0.59±0.19 °C) and myocardial infarction (0.27±0.16 °C) ($p<0.001$). Furthermore, a good correlation was observed between levels of VCAM with TD($r=0.53$, $P=0.01$). Also, a correlation with ICAM was also observed without however reaching statistical significance. Conclusion: Local heat at the site of lesion is increased in patients with acute coronary syndromes and may arise from an aggressive inflammatory response occurring in these situations. Accordingly, temperature measurement of culprit lesions may be used in future studies to evaluate the effect of anti-inflammatory regimens on the atherosclerotic plaque.

P1589 Estimation of macrophage infiltration by the local angioscopic findings and vascular flow reserve

I. Toshiaki, T. Matsui, K. Matsumura, B. Takase, K. Hagisawa, A. Kurita. *National Defense Medical College, Biomedical Engineering, Tokorozawa, Japan*

Background: Macrophage infiltration appears to play an important role in plaque instability which occurs in acute coronary syndrome. Recent advances in angioscopy and the use of velocity guide wires can now accurately estimate vessel vulnerability. However, the grade of macrophages infiltrations has not yet to be well elucidated based on the angioscopic (AS) findings and vascular flow reserve (VFR). The aim of this study was to investigate whether the grade of macrophages infiltrations on the AS findings and significance of any changes on VFR.
Methods: We fed the New Zealand white rabbits a diet containing 1% cholesterol for 8 weeks as the control group (n=10). We induced an injury to produce the plaque lesion in the middle abdominal aorta (AA) of these rabbits using a 2F Fogarty balloon catheter as the untreated group (n=10). Further, we treated these rabbits by ramatroban (a TXA2 receptor antagonist; 10mg/kg/day) as the treated group (n=10). The morphology of plaque lesion in the AA was evaluated by 0.018-inch angioscope (6000 pixels). AS findings were classified into 2 groups (protruding or smooth). The VFR was evaluated by 0.014-inch Doppler guide wire (15MHz) for 30 seconds occlusion of the AA using a 2F Fogarty catheter. The VFR was provided by the average peak velocity (APV; cm/s) and was expressed as the ratio of basal to peak APV following reactive hyperemic response. After proceedings, the rabbits were sacrificed and the macrophage obtained from AA sections were stained with antibodies against the rabbit macrophages (RAM-11). The density of total macrophages was quantified into absolute areas of RAM-11.
Results: The macrophage cell densities in the observed lesion was the highest in the untreated group (70 ± 12%) comparing with the treated (30 ± 18%, $p< 0.05$) and control group (10 ± 12%, $p<0.01$). The values of VFR was the lowest (1.3 ± 0.4) in the untreated group comparing with the treated (2.0 ± 0.7, $p<0.05$) and control group (2.4 ± 0.5, $p<0.01$). Further, the incidences of protruding plaques were the most prominent in the untreated group (70 ± 15%) comparing with the treated (20 ± 5%, $p<0.05$) and control group (10 ± 15%, $p<0.01$).
Conclusion: This study clearly shows that the plaque lesions in rabbits AA were composed mostly by macrophage with protruding appearances. These lesions were reduced in the vascular functions. The treatment by RAMA was proved to stabilize these lesion.

P1590 Potential involvement of secretory phospholipase A2 activity in atherosclerosis. Correlation with the dyad CD40/CD40L

M.L. Nieto[1], L. Fuentes[1], M. Hernandez[1], M. Sanchez-Crespo[1], J.J. Alonso[2], F. Fernández-Avilés[2]. [1]*IBGM-Facultad de Medicina, Valladolid, Spain;* [2]*University Hospital of Valladolid, Institute of Heart Science (ICICOR), Valladolid, Spain*

Background: Acute coronary events commonly result from thrombosis triggered by disruption of an atherosclerotic plaque. Migratory immune cells, including activated macrophages and T lymphocytes, are the key cellular elements at all stages of atherosclerosis and abound a sites of plaque rupture. The development of a new concept of assessing the pathogenesis of atherosclerosis in the context of immune-inflammation in the vascular wall open new vistas for the comprehension and treatment of this disease, but the mechanism underlying this network are widely unknown.
Recent reports have pointed to the dyad CD40-CD40L as a stimulus for atheroma-associated cells. This system is a key mediator of cell communication in the immune system. Although originally was defined on B and T cells, recently has been reported that vascular cells, endothelial cells and macrophages can express functional CD40L as well as its receptor CD40, in vitro and in atherosclerotic plaques.
Result: To elucidate the regulatory biochemical pathways involved in the progression of the vascular lesion, we have studied the effect of type II secretory phospholipase A2 (sPLA2) on the expression and signaling of CD40 in the THP-1 cell line. This cell line shows remarkable functional similarities with the macrophages located in the vessel wall that exacerbate the local inflammatory response in the atherosclerotic lesion. We have also compared its effect with the classical proinflammatory citokine TNF-a. The monocitic cells, THP-1, express CD40 functional receptors. Both, sPLA2 and TNF-a treatment increased CD40 expression without affect the levels of CD40L. The cellular response to CD40 engagement includes cytosolic phospholipase A2 phosphorylation, arachidonic acid movilization and increase in the production of MCP-1 and in the expression of Fas/FasL. These effects were enhanced in the presence of sPLA2 and TNF-a. Although, CD40 ligation modulates the expression of the system Fas/FasL does affect neither survival nor cellular cycle and might represent a juxtacrine mechanism of signaling involving other cell types
Conclusions: These data show that sPLA2, besides its effects on the properties of LDL, elicits CD40 expression on macrophages, linking the inflammatory and the immune responses. Another finding from this study is the activation of the Fas-signaling pathway as a mechanism of resolution of inflammation under nonphlogistic conditions.

P1591 Activation of Toll-like receptor 4 by adventitial application of lipopolysaccharide augments neointima formation in a mouse model

J.J. van der Meer, A. Vink, B. van Middelaar, C. Borst, G. Pasterkamp, D.P.V. de Kleijn. *University Medical Center, Experimental Cardiology Laboratory, Utrecht, Netherlands*

Background: Previously, we demonstrated that the Gram-negative bacterium Chlamydia pneumoniae is frequently present in the adventitia of atherosclerotic arteries. Lipopolysaccharide (LPS) is the principal constituent of Gram-negative bacteria that is recognized by the innate immune system. Toll-like receptor 4 (TLR4) is the transmembrane receptor for LPS signaling. We recently demonstrated TLR4 expression in adventitial fibroblasts. Activation of adventitial fibroblasts induced the up-regulation of various cytokines. In the present study we hypothesized that adventitial application of LPS augments neointima formation in an in vivo situation and that TLR4 is involved in this process.
Methods: To study the effect of adventitial LPS application on the augmentation of neointima formation induced by a cuff, a non constrictive polyethylene cuff (ID 4mm, OD 8mm) was placed around the right femoral artery of wild type BALB/c mice. Gelatin with (n=9) or without (n=9) LPS (1μg/μl) was injected between the cuff and the artery. To study the role of TLR4 in the augmentation of neointima formation by adventitial LPS application, a cuff was placed around the right femoral artery of TLR4 defective BALB/c mice. Gelatin with LPS (n=8) was injected between the cuff and femoral artery. All mice were sacrificed after three weeks follow up.
Results: The wild type BALB/c mice treated with LPS-gelatin showed a significant larger neointima formation compared to wild type BALB/c mice only treated with gelatin: Intima(μm^2), 9134±5144 and 2353±3228 (p=0.003), respectively; intima/media ratio, 0.95±0.51 and 0.22±0.27 (p=0.002), respectively. The TLR4 defective BALB/c mice treated with LPS-gelatin showed a significant smaller neointima formation compared to the wild type BALB/c mice treated with LPS-gelatin: intima(μm^2), 3859±2556 and 9134±5144 (p=0.012), respectively; intima/media ratio, 0.46±0.30 and 0.95±0.51 (p=0.021), respectively.
Conclusions: Adventitial application of LPS augments neointima formation induced by a cuff and TLR4 is involved in this process. These results provide a possible link between adventitial inflammation and arterial obstructive diseases.

P1592 Plasma levels of sCD40 ligand predict the presence of lipid pool in human carotid plaque: an in-vivo study using high-resolution MRI

G. J. blake, R.J. Ostfeld, N. Varo, U. Schoenbeck, P. Libby, M. Gerhard, E.K. Yucel, P.M. Ridker. *Brigham and Women's Hospital, Cardiovascular Division, Boston, United States of America*

Introduction: Large lipid pools and thin fibrous caps characterize vulnerable plaque. CD40 ligand mediates several processes important in atherogenesis and the formation of high-risk plaque, and soluble CD40 ligand predicts risk of cardiovascular events prospectively.
Methods: We tested the hypothesis that plasma levels of soluble CD40 ligand (sCD40L) correlate with evidence of intra-plaque lipid on high-resolution carotid MRI. This study enrolled 41 outpatients with stenoses greater than or equal to 30% in either internal or common carotid artery by carotid ultrasonography (January 2001 to January 2002). All patients had a blood sample drawn, and underwent high-resolution MRI of the carotid arteries. A blinded study radiologist determined the presence or absence of intra-plaque lipid, based on the loss of signal between the TE 20 and TE 55 fast spin echo images. Plasma levels of sCD40L were measured by ELISA. The study was approved by the Human Research Committee of Brigham and Women's Hospital and written informed consent was obtained from all study participants.
Results: The 41 patients had a mean age of 70.0 years ± 8.4, 63.4% were male, 31.7% were diabetic, 80.5% had hypertension, and 12.2% were current smokers. Plasma levels of sCD40L in patients with evidence of intra-plaque lipid (n=13) exceeded those in patients without intra-plaque lipid (n=28) (median 2.57ng/ml, inter-quartile range (IQR) [2.01-3.52] vs 1.62ng/ml, IQR [1.21-2.47]; p=0.03). The relative risk for intra-plaque lipid associated with above median levels of sCD40 ligand compared to below median levels of sCD40L was 5.5 (p=0.046). Adjustment for diabetes, hypertension, smoking status, and ratio of total cholesterol: high-density lipoprotein cholesterol, did not change the magnitude of the predictive effect of elevated sCD40L (relative risk 5.1; p=0.10).
Conclusions: Plasma levels of sCD40L may predict patients with features suggestive of high-risk plaque. Interfacing high resolution MRI with studies of inflammation may provide novel insights into the pathogenesis of atherosclerosis.

P1593 A paradoxical increase in the surface expression of various cell adhesion molecules in human endothelial cells after treatment with statins

G. Basta[1], M. Massaro[2], R. Madonna[3], A. Pandolfi[4], A. Consoli[4], A. Zampolli[1], M A. Carluccio[2], R. De Caterina[3]. [1]*CNR Institute of Clinical Physiology, Laboratory for Thromb & Vasc Research, S.Cataldo - Pisa, Italy;* [2]*CNR Institute of Clinical Physiology, Laboratory of Vascular Research, Lecce, Italy;* [3]*Chair of Cardiology, Univ. of Chieti, Ospedale S. Camillo De Lellis, Chieti, Italy;* [4]*University of Chieti, Department of Diabetology, Chieti, Italy*

By decreasing LDL levels, statins decrease the substrate for LDL oxidation and therefore one of the main triggers of atherosclerosis. Thus, in vivo treatment of patients with therapeutic doses of simvastatin decreases urinary 8-iso-PGF2alpha excretion, an in vivo index of lipid peroxidation (De Caterina R et al, submitted). However, despite the removal of a main triggers for adhesion molecule expression, therapeutic doses of statins do not decrease circulating levels of soluble adhesion molecules such as Vascular Cell Adhesion Molecule-1 (VCAM-1), E-selectin and Intercellular Adhesion Molecule-1 (ICAM-1) (De Caterina R et al, data on file). In order to clarify this apparent paradox we assessed the in vitro effects of one commonly used lipophylic statin, simvastatin, on the induced surface expression of three proinflammatory adhesion molecules, VCAM-1, ICAM-1 and E-Selectin, and on endothelial nitric oxide synthase (eNOS) in human umbilical vein endothelial cells (HUVEC).
Methods: Simvastatin (10-1000 ng/mL), activated in vitro by alkaline hydrolysis, was incubated with HUVEC for 0-24 h, followed by co-incubation with tumor necrosis factor-alpha (TNF), lipopolysaccharide (LPS), or advanced glycation endproducts (AGEs) for further 12 h. After this time, VCAM-1, E-Selectin and ICAM-1 expressions were assessed by cell surface immunoassays (EIA), and eNOS protein levels determined by Western analysis.
Results and Conclusions: Pretreatment with simvastatin increased both the basal and the cytokine-downregulated expression of eNOS. Simvastatin also, slightly but significantly ($P<0.05$), boosted the expression of adhesion molecules induced by TNF, LPS and AGEs, as show in the table.

Adhesion molecule expression

Stimulus	VCAM-1	E-selectin (% of stimulated expression)	ICAM-1
AGEs (200 microg/mL)	153±23*	217±20*	128±10*
LPS (1 microg/mL)	150±10*	130±13*	133±14*
TNF (10 ng/mL)	135±23*	150±23*	130±10*

Adhesion molecule expression in the presence of simvastatin 600 ng/mL. * = $P<0.05$ vs stimulated control without simvastatin

These observations suggest the existence of an adverse pleiotropic effect of simvastatin on endothelial leukocyte adhesion molecule expression, likely counteracted in vivo by the decrease of LDL.

P1594 Interleukin-6 upregulates AT1 receptor gene expression in vascular smooth muscle cells

S. Wassmann, M. Stumpf, M. Boehm, G. Nickenig. *Universitaetskliniken des Saarlandes, Medizinische Klinik-Innere Medizin III, Homburg/Saar, Germany*

Inflammatory processes and the renin-angiotensin system play an important role in the pathogenesis of atherosclerosis. Activation of the AT1 receptor (AT1-R) leads to enhanced synthesis of the pro-inflammatory cytokine interleukin-6 (IL-6), and angiotensin II, AT1-R, and IL-6 are co-localized in atherosclerotic plaques. Therefore, we investigated whether IL-6 itself may influence AT1-R gene expression in vascular smooth muscle cells (VSMC).

Methods and Results: Cultured rat aortic VSMC were incubated with IL-6 for 0-24h. AT1-R gene expression was assessed by Northern and Western blotting. IL-6 (1 nmol/l) led to a significant, time-dependent upregulation of AT1-R mRNA expression to 150±19% of control after 12h incubation. This IL-6 effect was dose-dependent with a maximum at 5 nmol/l. AT1-R expression was also upregulated by IL-6 on protein level. Transcription blockade experiments showed that AT1-R mRNA stability is not altered and that IL-6-induced AT1-R regulation is mediated by transcriptional mechanisms. Co-incubation of VSMC with IL-6 and the specific pharmacological inhibitors wortmannin, LY294002, PD98059, SB203580, AG490, DPI, or genistein revealed that IL-6-mediated AT1-R upregulation involves activation of PI-3-kinase, p38-MAP-kinase, p42/44-MAP-kinase, and JAK2. Angiotensin II-induced production of reactive oxygen species in VSMC was enhanced after pre-incubation with IL-6 for 24h (DCF fluorescence lasermicroscopy).

Conclusions: IL-6 significantly upregulates AT1-R gene expression in VSMC involving PI-3-kinase, MAP-kinase, and JAK/STAT-dependent signal transduction pathways. This interaction of the pro-inflammatory cytokine interleukin-6 with the AT1 receptor may represent an important pathogenetic mechanism in the development and progression of atherosclerosis.

P1595 Risk factors for coronary artery disease in patients with systemic lupus erythematosus

A. Tudose[1], I. Agache[2], M. Radoi[3], E. Gheorghita[4]. [1]*Brasov County Hospital, Cardiology Department, Brasov, Romania;* [2]*Faculty of Medicine, Cardiology Department, Brasov, Romania;* [3]*Faculty of Medicine, Cardiology, Brasov, Romania;* [4]*Brasov County Hospital, Haematology, Brasov, Romania*

Background: Coronary artery disease (CAD), major cause of morbidity and mortality in systemic lupus erythematosus (SLE) patients, has a complex risk profile with SLE related and CAD risk factors.

Aims: Risk factors for CAD in SLE patients (pts) were evaluated in a 10 year longitudinal prospective study.

Design: 142 SLE pts fulfilling ARA criteria, 131(94.3%) females, 39 y mean age were divided in group A - 38 (26.8%) pts with SLE and CAD (angina and/or myocardial infarction) and group B - 104(73.2%) pts with SLE without CAD. CAD was documented by ECG, 2D echo, stress test, Th-201 myocardial scintigraphy. Pts were appreciated for CAD risk factors, steroid therapy > 10 mg/day more than 10 years and ELISA serum level for anticardiolipinic antibodies (ACL) > 25 UE/ml. Plasmatic cholesterol determined using a turbidimetric assay (normal plasma level < 200 mg/dl). Statistical analysis using multiple regression.

Results: The incidence of CAD risk factors is significantly higher in group A (table). In group A 25(65.6%) pts had 3 risk factors or more, 18(47.3%) pts with risk profile composed of steroid therapy > 10 mg/day more than 10 years, cholesterol plasma level > 200 mg/dl and ACL > 25 UE/ml.

Risk factors	Gr.A	Gr.B	p value
Cholesterol plasma level > 200 mg/dl	28(73.3%)	32(31.1%)	<0.001
Family history of CAD	12(31.7%)	10(9.8%)	<0.05
Sedentary life style	13(32.8%)	25(24.4%)	<0.1
Obesity	8(21.4%)	12(11.9%)	<0.1
Smoke	7(20.9%)	13(12.4%)	<0.01
Diabetes	6(17.9%)	8(8.4%)	<0.01
Hypertension	10(26.3%)	15(14.5%)	<0.01
Steroid therapy > 10 mg/day > 10 years	37(97.4%)	15(14.9%)	< 0.0001
ACL > 25 UE/ml	19(51.4%)	19(18.4%)	<0.001

Cardiovascular mortality was 7.8% in group A, 10% from total number of deaths, compared to total mortality 2.11% in group B.

Conclusions: In SLE patients chronic steroid therapy > 10 mg/day more than 10 years and increased titers of anticardiolipinic antibodies are additional risk factors for coronary artery disease.

P1596 Pregnancy-associated plasma protein a (PAPP-a) in determination of unstable coronary plaque

P. Hajek[1], M.M. Milan Macek[2], P.O. Petr Ostadal[1], J.V. Jan Vojacek[1], D.A. David Alan[1], V.D. Vaclav Durdil[1], J.F. Jiri Fiedler[1], M.M. Martin Maly[1]. [1]*Faculty Hospital Motol, Interventional Cardiology, Prague, Czech Republic;* [2]*University Hospital Motol and of 2nd M, Institute of Biology and Medical Genet, Prague, Czech Republic*

Objectives: The aim of our study was to assess whether elevation of PAPP-A (metalloproteinase used in fetal diagnosis of Down's syndrome) is associated with acute coronary syndromes.

PATIENTS AND METHODS: A total of 114 patients were included into this study: 65 patients with stable coronary artery disease (SCAD), 25 patients with normal coronary angiogram (N), and 24 patients with acute coronary syndrome (ACS; 14 patients with ST segment elevation acute myocardial infarction (STE AMI), 7 patients with non STE AMI, and 3 patients with unstable angina pectoris). Blood samples for determination of troponin I (TI), C-reactive protein (CRP) and PAPP-A were collected at admission and all patients underwent coronary angiography (and percutaneous coronary intervention if necessary).

Results: All baseline, clinical, and demographic data were comparable among the groups. The plasma level of PAPP-A in patients with ACS (26.5 ± 5.93 mIU/L) was significantly higher than in both control groups: SCAD (3.16 ± 0.26 mIU/L, p = 0.0009) and N (2.53 ± 0.25 mIU/L, p = 0.0007). There was no statistically significant difference between the group N and the group SCAD. The value of PAPP-A was independent on entry TI and CRP level;the PAPP-A threshold value of 9 mIU/L had 71% sensitivity and 100% specificity for ACS. In some patients with STE AMI PAPP-A was already elevated even before pozitivity of TI.

Conclusions: Our results suggest that circulating PAPP-A is a promising marker of unstable coronary plaque. Nevertheless further studies are needed to support this hypothesis.

CELLULAR BIOLOGY OF MYOCARDIAL PROTECTION

P1597 Preischaemic infusion of alpha-human atrial natriuretic peptide elicits myoprotection through nitric oxide-protein kinase C dependent mechanism

H. Okawa, H. Horimoto, Y. Nomura, S. Mieno, M. Yoshida, K. Nakahara, K. Asada, S. Sasaki. *Osaka Medical College, Thoracic and Cardiovascular Surgery, Takatsuki, Japan*

Background: Alpha human atrial natriuretic peptide (alpha-hANP) has been prescribed for the patients with heart failure due to its natriuretic and vasodilatory activity. Recent reports suggested that alpha-hANP generates nitric oxide (NO) that is known to be involved in myoprotective mechanisms. In this study, effects of preischemic infusion of alpha-hANP against ischemia reperfusion were evaluated.

Method: Isolated rat hearts were subjected to Langendorff perfusion with buffered Krebs-Henseleit solution and were divided into five groups. Six hearts received 0.1micro-M of alpha-hANP for 10 minutes (HANP), six hearts received 1mM of a NO synthetase inhibitor N(G)-nitro-L-arginine methyl ester (L-NAME) for 5 minutes before alpha-hANP (LNM), six hearts received 0.02 micro-M of a protein kinase C (PKC) inhibitor chelerythrine chloride for 5 minutes before alpha-hANP (CHE), six hearts received 10 micro-M of a cyclic guanosine monophosphate (cGMP) inhibitor methylene blue for 5 minutes before alpha-hANP (MB), and six hearts served as a control with no interventions (CON). All groups were, then, subjected to 20 minutes of global ischemia followed by 120 minutes of reperfusion. LV pressures, coronary flow and concentrations of cGMP in the perfusate were measured throughout the experiments and infarct sizes were detected at the end of experiments.

Results: Alpha-hANP significantly reduced infarct size as compared to control hearts, and this effect was reversed by either LNM or CHE, but not MB (HANP: CON: LNM: CHE: MB, 26.1±2.8: 42.7±2.3*: 39.0±1.6*: 40.0±2.0*: 29.6±2.6%, *=p<0.01 vs. HANP). Alpha-hANP significantly increased cGMP concentrations and this effect was reversed by L-NAME (HANP: CON: LNM: CHE: MB, 1.04±0.13: 0.16±0.7#: 0.27±0.16#: 0.80±0.15: 0.80±0.10%, #=p<0.05 vs. HANP). There was no significant deference among five groups in terms of LV pressures and coronary flow.

Conclusion: These data suggest that a preischemic infusion of alpha-hANP exerts myoprotective effects against ischemia reperfusion possibly through a NO-PKC dependent mechanism, although a NO-cGMP pathway was also activated.

P1598 The protective effect of bradykinin on ischaemic cardiac mitochondria is mediated by B2 membrane receptors

P. Monteiro[1], J.P. Moura[2], S. Silva[2], A. Moreno[2], L. Gonçalves[1], L.A. Providência[1]. [1]*Coimbra University Hospital, Cardiology Dept., Coimbra, Portugal;* [2]*Center for Neuroscience of Coimbra, Coimbra, Portugal*

Bradykinin (BD) interact with the endothelium and induces vasodilatation, in a process that seems to be mediated by the release of nitric oxide. An important part of the positive effects of BD appear to be mediated by B2 membrane receptors.

The aim of our study was to determine, during acute cardiac ischemia, the role of these receptors on the BD-mediated mitochondrial metabolism protection.

We used an ex-vivo global myocardial ischemia model (Lagendorff system). Forty Wistar rat's hearts were divided in 4 experimental groups - A (180 minutes of perfusion, with a Krebs modified solution), B (60 minutes of perfusion with the same solution, followed by 120 minutes of ischemia), C (as in B, but in the presence of BD 0.1 μM) and D (as in B, but in the presence of BD 0.1 μM and a B2 receptor antagonist - D-Arg-(Hyp3, D-Phe7, Leu8)-Bradykinin 100 μM). Cardiac mitochondria were then isolated by differential centrifugation and the activity of complexes I, II-III and IV of the mitochondrial respiratory chain (MRC) was evaluated, using their metabolic substrates (Glutamate/Malate, Succinate and Ascorbate/TMPD). Parameters assessed were: Respiratory Control Ratio (RCR), O2 consumption during state 3 of mitochondrial respiration (S3), Mitochondrial Membrane's Electrical Potential after Phosphorylation (Delta Psi), Phosphorylative Lag Phase (PLP), Energetic Charges (EC) and Enzymatic Activities (EA) of each of the MRC complexes - see table.

Groups/Parameters	BD BD	BD + D-Arg-(Hyp3, D-Phe7, Leu8)- Bradykinin (Group D)	p value (C vs. D)
PLP (Succinate)	239.2±14.8%	135.4±27.7%	p=0.003
PLP (Ascorbate/TMPD)	228.6±48.9%	63.5±5.1%	p=0.004
Delta Psi (Succinate)	1959.3±363%	625.9±296.3%	p=0.01
Delta Psi (Ascorbate/TMPD)	652.3±81.2%	401.9±100.8%	p=0.09

Note: Values are expressed as % of control (Group A).

When compared to the group treated with BD, the one exposed to D-Arg-(Hyp3, D-Phe7, Leu8)-Bradykinin was capable of reverting the BD's positive impact on PLP and on the Delta Psi recovered after a phosphorylative cycle. These results indicate for the first time, in an ex-vivo myocardial ischemia model, that the positive impact of BD on the mitochondrial phosphorylative system is mediated by B2 receptors.

P1599 Involvement of p38 MAPK in ischaemic preconditioning and thyroxine induced cardioprotection

I. Paizis[1], V. Malliopoulou[1], I. Mourouzis[1], S. Tzeis[1], D.D. Cokkinos[1], C. Pantos[1], D. Varonos[1], D.V. Cokkinos[2]. [1]*University of Athens, Pharmacology, Athens, Greece;* [2]*Onassis Cardiac Surgery Center, 1st Cardiology Department, Athens, Greece*

Background: Previous studies have shown that thyroxine administration is associated with enhanced tolerance of the heart against ischaemia. Furthermore, ischaemic preconditioning (PC) is a well established means of cardioprotection which involves alterations in p38 MAP kinase during the subsequent sustained ischaemia. The aim of the present study was to investigate whether long-term thyroxine administration protects the heart by interfering with mechanisms that are known to be involved in PC induced cardioprotection.

Methods: a. L-thyroxine (T4) was administered in Wistar rats (25μg/100g/day sc) for 2 weeks (THYR), while normal animals served as controls (NORM). Isolated rat hearts were perfused in a Langendorff mode. After an initial stabilization period, NORM and THYR hearts were subjected to either 20 min of zero-flow global ischaemia (I), THYR(I),n=5 and NORM(I), n=5. or to 20 min of I followed by 45 min of reperfusion (R), THYR(I/R),n=6 and NORM(I/R), n=6. b. NORM hearts were subjected to a four cycle PC protocol (3min of I and 5 min of R followed by 3 cycles of 5 min of I and 5 min of R) before 20 min of I only, NORM(PC+I), n=5 or 20 min of I and 45 min of R, NORM(PC+I/R), n=6. Postischaemic recovery of left ventricular developed pressure was expressed as % of the initial value (LVDP%). Total and phospho p38MAPK were measured by Western blot analysis at the end of 20 min of I and at the end of 45min of R.

Results: LVDP% was higher in THYR(I/R) than in NORM(I/R) [61.5 (6.6) vs 42.8 (4.9)], $p<0.05$. LVDP% was also higher in NORM(PC+I/R) than in NORM(I/R) [59.2 (4.6) vs 42.8 (4.9)], $p<0.05$. Phospho-p38 MAPK was 1.9 fold more in NORM(I) than in THYR(I), $p<0.05$ and 3.5 fold more in NORM(I) than in NORM(Pc+I), $p<0.05$. Furthermore, phospho p38 MAPK was 1.7 fold more in NORM(I/R) than in THYR(I/R), $p<0.05$ and 1.25 fold more in NORM(I/R) than in NORM(PC+I/R), p=0.09.

Conclusion: p38 MAPK activation is attenuated during ischaemia both in THYR and in PC hearts and at reperfusion only in THYR hearts, in a parallel fashion to improved postischemic recovery

P1600 Two-dimensional analysis of myocardial protein expression following myocardial ischaemia and reperfusion in rabbits

H.J. Schwertz[1], T. Längin[1], H. Platsch[2], J. Richert[2], S. Bomm[2], M. Schmidt[3], H. Hillen[3], M. Buerke[1]. [1]*Johannes Gutenberg University, II. Department of Medicine, Mainz, Germany;* [2]*BASF, Ludwigshafen, Germany;* [3]*Abbott Pharmaceutical, Ludwigshafen, Germany*

Myocardial ischemia and reperfusion injury (MI/R) can be related to leukocyte activation with subsequent release of cytokines and oxygen-derived free radicals. Activation of the complement system has been implicated in the pathogenesis of myocardial ischemia and reperfusion injury. Inflammatory injury will subsequently result in cellular activation and protein synthesis.

In the present study we analyzed the myocardial protein expression and its pattern following myocardial ischemia and reperfusion, with and without complement inhibition with the synthetic serine protease inhibitor FUT-175 known to inhibit classical and alternative complement pathway in a rabbit model of myocardial ischemia and reperfusion (60min I + 180min R). FUT-175 significantly reduced myocardial necrosis, i.e. creatine kinase release which were analyzed for the three groups ($p<0.05$). Similar, histological analysis demonstrated preservation of myocardial tissue injury and reduced leukocyte accumulation following FUT-175 treatment. Further, the myocardial protein expression was analyzed by two-dimensional gel electrophoresis following MI/R in the different groups. The protein patterns were evaluated by means of MELANIE III a computer-assisted gel analysis system. The biochemical identification of the proteins of interest was achieved using nanoHPLC/ESI-MS/MS. On average, 509±25 protein spots were found on the gels. A pattern of 480 spots with identical positions was found on every gel of five animals of each group. We analyzed 10 spots which were significantly altered, by using massspectrometry. Superoxide dismutase and aB-crystallin were identified. We compared sham group vs. vehicle group and vehicle group vs. FUT-175 treated animals. Expression of the two identified proteins decreased by half the amount in the vehicle group when compared to sham treated animals. Treatment with Fut-175 preserved significantly superoxide dismutase and aB-crystallin protein expression when compared to vehicle treated animals.

The results present profound differences in myocardial protein expression after ischemia and reperfusion and following treatment with the complement inhibitor FUT-175. Our results illustrate the application of proteomics to discover possible new therapeutic targets or to detect unexpected effects of pharmacological inhibitors.

P1601 The role of the apoptosome in nitric oxide-induced cardiac myocyte apoptosis

P. Andreka[1], Z. Nadhazi[1], K.A. Webster[2], N.H. Bishopric[2]. [1]*Semmelweis University Faculty of Medic, 2nd Dept. of Medicine, Budapest, Hungary;* [2]*University of Miami School of Medicine, Department of Pharmacology, Miami, United States of America*

Nitric oxide (NO) induces apoptosis in cardiac myocytes (CM) through an oxidant sensitive mechanism. However, additional factors modulate the timing and extent of NO effects. We investigated the cytoprotective role and possible targets of c-Jun N-terminal kinases (JNK) in NO-mediated apoptosis. We previously showed that cultured neonatal rat CM exposed to the NO donor S-nitrosoglutathione (GSNO), 1mM) undergo extensive (40-50%) apoptotic cell death beginning at 4 hr after treatment, preceded by strong activation of JNK. In this system, inhibition of JNK strongly enhances and accelerates NO-mediated apoptosis, while constitutive activation of JNK via MEKK1 reduces cell death by 50%. We examined specific effects of JNK inhibition on molecular events in NO-mediated apoptosis by using an adenovirus expressing a dominant negative mutant of JNK1 (Ad-dnJNK). NO appeared exclusively to utilize a mitochondria-dependent pathway for apoptosis, as it did not induce cleavage or activation of caspase-8, with or without JNK activation. Furthermore, NO did not activate cleavage or mitochondrial translocation of pro-apoptotic Bid, a target for caspase-8 and a mediator of cross-talk between the extrinsic and intrinsic apoptotic pathways. However, NO induced a rapid (30 min) translocation of anti-apoptotic Bcl-xL from CM mitochondria to cytosol and a concurrent movement of pro-apoptotic Bad from cytosol to mitochondria. Cytochrome C (cyt c) release from mitochondria permits formation of the ?apoptosome?, a cytosolic complex of cyt c, procaspase-9 and APAF-1 that leads to activation of caspase-9. Consistent with this, NO also induced rapid (10 min) cyt c leakage from mitochondria into cytosol, followed by cleavage and activation of caspase-9 after a lag of 4 hr. Infection with Ad-dnJNK abolished 99% of NO-induced JNK activity, but had no effect on cyt c leakage compared with blank virus-infected or uninfected cells? a Bcl-xL-expressing adenovirus delayed NO-induced cyt c leakage by 12 hr. However, Ad-dnJNK accelerated (by 2 hr) and enhanced (120%) the cleavage and activation of caspase-9. These data suggest that NO activates a mitochondria-dependent apoptotic pathway in CM, and that JNK activation blunts CM apoptosis at the level of the apoptosome.

P1602 Doxazosin induces apoptosis in HL-1 cardiomyocytes

J.R. González-Juanatey, C. Alcaide, M.J. Iglesias, R. Piñeiro, M.F. Lago.
Hospital Clínico Universitario, Unidad de Investigación, Santiago de Compostela, Spain

Background: Doxazosin is an alpha1-adrenoceptor antagonist used in the treatment of essential hypertension, but its administration has been associated with increased risk of major cardiovascular events. A biological mechanism to explain doxazosin's role in increasing cardiovascular disease has not been apparent. Our aim was to investigate a possible proapoptotic effect of doxazosin on cultured cardiomyocytes.
Methods and Results: HL-1 cardiomyocytes is a mouse AT-1 tumor lineage derived cell line that maintains the phenotypic characteristics of adult cardiac cells and yet are able to divide. Hoechst dye vital staining, MTT metabolic activity test, and flow citometry, demonstrated that doxazosin treatment induced apoptosis in HL-1 cardiomyocytes in a time- and dose-dependent manner. Hoechst dye vital staining showed that, at 12h, 10μM doxazosin induced a 42.63±5.04% of apoptosis vs. 22.12±0.97% of control (n=3, $p<0.01$), and higher doses increased dramatically apoptosis (78.96±0.57% at 20μM and 90.10±0.20% at 40μM; n=3, $p<0.001$). At 48h, 1 μM doxazosin increased apoptosis to 34.65±2.07% vs. 21.61±4.22% of control (n=3, $p<0.05$), 10 μM induced 44.49±3.22% of apoptosis (n=3, $p<0.001$), and almost 100% cells were dead at 20 and 40μM (n=3, $p<0.001$). MTT analysis showed a decrease of HL-1 cells metabolic activity as soon as at 12h of 50 μM doxazosin treatment (78.13±7.2% of control, n=3; $p<0.05$). Treatments for 24h with doxazosin decreased MTT activity to 69.21±4.22% of control(n=4; $p<0.05$)at 20μM; 64.5±4.38% of control at 40 μM (n=3; $p<0.001$); and 55.22±4.58% of control at 50 μM (n=3; $p<0.001$). The same pattern was observed at 48 and 72h, with a more dramatic decrease at low doses(47.81±7.23% of control at 20μM; n=3, $p<0.001$). Flow cytometry analysis of HL-1 cells treated with doxazosin revealed an increase of apoptosis consistent with a decrease of S/G2/M cell cycle phase. Exposure to phenoxybenzamine, an irreversible inhibitor of alpha1-adrenoceptors,did not influence the proapoptotic effect of doxazosin in HL-1 cells.
Conclusions: Cardiomyocyte apoptosis induced by doxazosin in HL-1 cardiomyocytes could help to explain the increase of cardiovascular risk associated with this drug.This apoptotic effect of doxazosin is independent of its capacity to antagonize alpha1-adrenoceptors.

P1603 Lack of cardiotoxicity after intracoronary paclitaxel application

B. Scheller[1], G. Nickenig[1], H.P. Stoll[1], M. Böhm[1], U. Speck[2]. [1]*University of Saarland, Internal Medicine III, Homburg/Saar, Germany;* [2]*Department of Radiology, Charite, Berlin, Germany*

Objective: Use of antiproliferative agents in cancer therapy is frequently complicated by cardiotoxicity. Intracoronary administration of liphophilic agents like taxane compounds is potentially suited for prevention of restenosis in interventional cardiology. The aim of the present study was to evaluate cardiotoxicity of intracoronary administration of the taxane Paclitaxel dissolved in a conventional contrast medium.
Methods: Coronary stents were implanted into LAD and CX arteries of 17 pigs. Io-promide was used in group I (control), the treatment groups were injected with 80 ml intravenous Iopromide plus 12.8 mg Paclitaxel (group II), 80 ml intracoronary Iopromide plus 6.4 mg Paclitaxel (group III), and 80 ml intracoronary Iopromide plus 12.8 mg Paclitaxel respectively (group IV). Left ventricular levocardiography was used to evaluate measures of left ventricular function from the pre-sacrifice angiography at 28-day follow-up.
Results: There were no thrombotic complications and no significant adverse events of ECG, blood pressure or contractility during or after Iopromide-Paclitaxel injections. At follow-up, there were no differences in parameters characterizing global and local left ventricular ejection fraction (see table).

Left ventricular function

	group I	group II	group III	group IV	p
# of pigs	6	3	4	4	
LVEDP [mmHg]	23.2±3.6	24.0±5.3	23.8±1.7	20.5±4.2	0.563
dp/dt [mmHg/s]	1.0±0.3	1.3±0.5	0.9±0.4	1.1±0.2	0.461
LV-EF [%]	38.5±10.2	49.0±12.0	45.5±9.8	46.3±6.2	0.418

LVEDP=left ventricular enddiastolic pressure, LV-EF left ventricular ejection fraction

Conclusion: Intracoronary application of the antiproliferative taxane compound Paclitaxel added to a conventional contrast agent does not induce impaired left ventricular function.

INFLUENCE OF GENE POLYMORPHISMS

P1604 Ethnic differences in beta 2 adrenergic receptor polymorphisms distribution

P. Castro[1], M. Chiong[2], M. Moreno[1], O. Perez[1], G. Díaz-Araya[2], I. Padilla[1], C. Nazzal[1], S. Lavandero[2]. [1]*Catholic University, Cardiovascular Diseases, Santiago, Chile;* [2]*University of Chile, Chemical and Pharmaceutical Sciences, Santiago, Chile*

Background: Polymorphisms of the beta 2 adrenergic receptor (AR) are important in cardiac physiology and could have a role in the expression of cardiovascular diseases.
Objective: This study investigates distribution of previously identified polymorphisms at three sites within the beta 2 AR gene in the chilean population and compares it to that observed in other populations.
Methods: Three sites within the beta 2 AR gene: the Arg16-Gly, Gln27-Glu and Thr164-Ile alleles were studied. Restriction enzyme analysis of amplified beta 2 AR gene products (PCR-RFLP) was used to analyse the frequency of the Arg16-Gly, Gln27-Glu and Thr164-Ile polymorphisms with the beta 2 AR gene in 165 chilean subjects. The results were compared with the reported prevalence in caucasian and japanaise population.
Results: The frequency of different beta 2 AR alleles in the three population is presented in the table.

Populations	Arg16Arg	Arg16Gly	Gly16Gly	Gln27Gln	Gln27Glu	Glu27Glu
Chilean(n=165)	16%	63%	21%	46%	68%	13%
Japanaise(n=836)	24%	48%	28%	89%	10%	1%
Caucasian(n=212)	16%	45%	39%	32%	53%	15%

There were no significant differences in the polymorphisms distribution at the sites 16 and 164 (not showed). However, the distribution at the site 27 was different between chilean and japanaise population ($p<0.001$). Moreover, in chilean population the proportion of polymorphism Gly16Gly was lower and the Glu27Glu higher than the observed in the caucasian population (p=0.001 and <0.01 respectively). In addition, Glu27Glu was less frequent in the japanaise population. The polymorphism Ileu164 was uncommon in all groups.
Conclusion: There are differences in beta 2 AR polymorphism distribution in the analized ethnic groups. In Chile the lower proportion of Gly16Gly (associated to increased downregulation) is balanced by Glu27Glu polymorphism (absence downregulation).
FONDECYT 1010992- DID TNAC-1402/01.

P1605 Relation of the G protein beta-3 subunit C825T polymorphism with left ventricular structure and function in a large population sample

K. Sedlacek, J. Erdmann, C. Hengstenberg, S. Holmer, M. Muscholl, A. Luchner, G.A. Riegger, H. Schunkert. *Universität Regensburg, Klinik für Innere Medizin II, Regensburg, Germany*

A G protein beta-3 subunit (GNB3) C825T polymorphism results in a truncated splice variant protein that is associated with enhanced transmembrane signaling, increased proliferative activity, and arterial hypertension. The aim of the present study was to further investigate the association of the GNB3 C825T polymorphism with the left ventricular structure and function.
2052 individuals from a large scale population-based sample were investigated for the GNB3 C825T polymorphism as well as anthropometrical and biochemical characteristics including echocardiographic parameters of left ventricular structure and function.
Complete genotyping and echocardiographic data were available in 1720 individuals (829 men and 891 women). The mean left ventricular mass indices in men with CC (n = 384) and TT (n = 84) genotypes were 98.3 ± 1.2 g/m^2 and 100.0 ± 2.8 g/m^2, respectively (p = 0.64). In women, the corresponding values were 83.1 ± 1.0 g/m^2 for the CC genotype (n = 397) and 83.8 ± 2.1 g/m^2 for the TT genotype (n = 91, p = 0.32). Likewise, septal and posterior wall thickness as well as left ventricular dimensions and parameters of the diastolic function were not associated with the GNB3 C825T polymorphism in the entire sample as well as in any of several subgroups, e.g. subjects without antihypertensive medication. Moreover, the C238T allele status was not a significant determinant of serologic markers of left ventricular mass, such as atrial or brain natriuretic peptide. Finally, multivariate analyses failed to show any influence of the GNB3 C825T polymorphism on the parameters of left ventricular structure and diastolic function after adjustment for potentially confounding factors including age, systolic blood pressure, sex, and body mass index.
In conclusion, we were not able to confirm in this large population sample the previously published associations of the GNB3 C825T polymorphism with left ventricular structure and diastolic function.

P1606 No influence of I/D polymorphism of angiotensin-converting enzyme gene on exercise-induced cardiac hypertrophy in teenagers

G. Galanti[1], M. Rizzo[1], P. Manetti[1], N. Pucci[1], A. Capalbo[1], M.C.R. Vono[1], C. Fatini[2], F. Gensini[2]. [1]*University of Florence, Non-Invasive Cardiac Laboratory, Florence, Italy;* [2]*University, Human Genetics, Florence, Italy*

Background: Long-term athletic training induces a physiological cardiac hypertrophy. However, similarly trained athletes develop LVM to a different extent, suggesting that genetic factors may modulate heart size. I/D polymorphism of Angiotensin Converting Enzyme (ACE) gene has been associated with exercise-induced cardiac hypertrophy in adults.
Aim of the study was to investigate the influence of I/D polymorphysm of ACE gene in the development of LVM in a group of teenage athletes.
Matherials and Methods. 75 competitive soccer players aged 14 to 18 (mean±DS=15±1,2) were examined by echocardiography (echo) and bioelectrical impedance analysis (BIA).Anthropometric data, body composition and standard echo measurements were compared to mean, lower and upper limits (5th and 95th percentile) of 52 normal controls aged 14 to 18 (mean±DS=15±1,6). ACE genotype was also assessed in all subjects.
Results: Genotype distribution was in agreement with Hardy-Weimberg equilibrium and allele frequency were comparable to those found in controls.Body surface area (BSA) (1,8±0,1 vs 1,7±0,2; p<0,001), fat-free mass(FFM) (58,6±7 vs 52±8,5;p<0,001) and all mean echo measurements (left atrium size 29,3±2,2mm vs 28,3±2,9mm; septal thickness 9,5±0,1 vs 8,5±1;posterior wall thickness 9,5±1,1mm vs 8,3±0,9mm; left ventricular(LV) diastolic diameter 51,4±4,4mm vs 49,4±3,5mm; LV systolic diameter 32,1±3,6mm vs 30±3,3mm; Lvmass 195,3±32g vs 165,3±37,6g; Lvmass/BSA 115,5±18,9g/mq vs 95±18,2g/mq; Lvmass/FFM 3,5±0,5g/Kg vs 3±0,4g/Kg; p<0,001 for all variables) were significantly greater in athletes than in controls.Increased left ventricular mass was found in athletes as a results of increased left ventricular cavity dimension and wall thickness.Left ventricular hypertrophy was found in 17 athletes, but no association was found with ACE genotype (II=41%, DD=41%, ID=18%)
Conclusione. Our results show the adaptative cardiac hypertrophy in response to physical training in a group of homogeneus teenage athletes. It appeares as a moderate and physiological hypertrophy with normal systolic and diastolic functions. In young people, ACE genotype seems to have none influence in the development of LVM.

P1607 Novel BNP C-1563T promotor-polymorphism associated with blood pressure and left ventricular mass

A. Luchner[1], E.-M. Seuss[1], J. Erdmann[1], H.-W. Hense[2], A. Doering[3], G. Riegger[1], S. Holmer[1], H. Schunkert[1]. [1]*Klinikum der Universität, Innere Medizin II, Regensburg, Germany;* [2]*Universitaet, Institut für Epidemiologie, Muenster, Germany;* [3]*Institut für Epidemiologie, GSF Forschungszentrum, München, Germany*

The cardiac natriuretic peptide BNP (brain natriuretic peptide) is secreted from the left ventricle (LV) in response to increased stretch and has potent vasodilatory and antihypertrophic effects. Recently, a novel C/T-polymorphism (TGA[C/T]ATCA) in the putative cAMP response like element (CRE) of the BNP promoter has been described.
To assess the frequency of this polymorphism as well as the association with blood pressure (BP) and LV mass index (by echocardiography), a total of 2153 subjects (n=1059 female, 1094 male) of two population-based surveys (MONICA Augsburg) were genotyped. The respective frequencies of the genotypes were 93,5% (CC), 5,8% (CT), and 0,8% (**TT**). In subjects with the less frequent genotypes CT and **TT**, systolic BP was significantly lower as compared to subjects with CC (133±22 mmHg vs. 138±21; p<0.003), even in the normotensive (BP<140/90mmHg) subgroup (n=740, CT 119±12 mmHg vs. CC 123±13; p<0.008). Presence of a T-allele was also associated with lower systolic BP after adjustment for age, body mass index, and gender in this subgroup (p=0.02 multivariate, β-coefficient -3,4). Presence of the T-allele was further associated with a significantly lower LV mass index (CT&**TT** 83±19 gr/m^2 vs. CC 88±24; p<0.008), particularly in male subjects (n=717, CT&**TT** 88±19 gr/m^2 vs. CC 96±25; p<0.008; TT 72±25 gr/m^2; p<0.007 vs. CC und p<0,05 vs. CT). The association of the T-allele with lower LV mass index was partially independent from BP and remained statistically significant even after adjustment for age, body mass index, systolic BP and LV function (p=0.02, β-coefficient -6,3).
The C-1563T polymorphism of the BNP promotor is rare. Since the T-allele is independently associated with substantial effects on blood pressure and LV mass in these observational studies, further clinical and functional studies are warranted to investigate the relevance of this genetic variant.

P1608 The 807CC genotype of platelet glycoprotein Ia as a protective factor against recurrent acute coronary syndromes: results of a 5-year follow-up

A.M. Leone[1], F. Burzotta[2], I. Casorelli[3], K. Paciaroni[3], A. Sciahbasi[2], V. De Stefano[3], G. Leone[3], F. Andreotti[2]. [1]*Università Cattolica del Sacro Cuore, Medicina Cardiovascolare, Rome, Italy;* [2]*Istituto di Cardiologia, Roma, Italy;* [3]*Istituto di Ematologia, Roma, Italy*

Background; Glycoprotein (Gp) Ia/IIa is a heterodimeric membrane complex that mediates platelet adhesion to collagen, inducing platelets to aggregate. Recently, a functional gene polymorphism of the Ia subunit has been reported, consisting in a C807T transition (linked with A873G), associated with a variable expression of the platelet surface receptor. We hypothesized that the lower receptor density associated with the 807CC genotype might protect against recurrent events in patients with acute coronary syndromes.
Methods: 88 patients (14 females, mean age 53 years), who were admitted to our CCU for acute myocardial infarction (MI, n=61) or severe unstable angina (n=27) as first manifestation of heart disease before the age of 65, were followed for a maximum duration of 60 months.
Results: Gpla genotyping revealed 807 CC in 40 patients (46%, 7 females, mean 52 years), 807CT in 38 patients (43%, 7 females, mean 53 years), and 807TT in 10 patients (11%, all males, mean 54 years). Patients with the 807CC genotype, compared to carriers of the 807T allele, showed fewer acute coronary events during follow-up (9 vs 21, OR 0.37, 95% confidence interval - C.I. - 0.15-0.95, p=0.0439) and, in particular, fewer MIs (1 vs 10 events, OR 0.10, 95%C.I. 0.01-0.80, p=0.010). Comparison of Kaplan Meier curves confirmed the data (p=0.0441). Moreover, patients with the 807CC genotype had significantly longer median event-free survivals compared to patients with the 807CT or 807 TT genotype (19 vs 11 months, p=0.040).
Conclusions: These data suggest that, among patients with a first acute coronary syndrome, those with the Gpla 807CC genotype (characterized by a lower collagen receptor density on the platelet membrane) may have a lower risk of recurrent events, in particular MI, and a longer event-free survival compared to carriers of the 807T allele.

P1609 Myocardial gene expression analysis using real-time RT-PCR in paediatric patients – Validation of potential reference genes

D. Rawer[1], H. Akintürk[2], A. Borkhardt[3], D. Schranz[1], J. Kreuder[4]. [1]*Justus Liebig University, Department of Paediatric Cardiology, Giessen, Germany;* [2]*Justus Liebig University, Department of Cardiothoracic Surgery, Giessen, Germany;* [3]*Justus Liebig University, Department of Paediatric Haematology, Giessen, Germany;* [4]*Justus Liebig University, Department of Paediatric Cardiology, Giessen, Germany*

Real-time, fluorescent RT-PCR is a highly sensitive method to quantify gene expression. The choice of a reference gene and the quality of pre-PCR protocols like reverse transcription may markedly influence the validity of this method. Therefore, the different steps of real-time RT-PCR and potential reference genes were systematically evaluated for their applicability on myocardial gene expression analysis in hearts with congenital malformations.
Material: Right ventricular myocardium was taken from 22 patients with tetralogy of Fallot (age 4 months - 18 years) during primary corrective operation (n=18) or secondary operation (n=4).
Methods: The following steps of real-time PCR were separately examined: 1. RNA extraction using TRIzol® and incubation with DNAfree®(Ambion) -> quantification by spectrophotometry, 2. real-time PCR for DNA specific single-copy c-Myc -> measurement of contaminating genomic DNA, 3. reverse transcription -> quantification of cDNA using OliGreen®(Molecular Probes), a fluorescent nucleic acid stain, after pre-incubation with RNAse -> comparison of RNA vs cDNA concentrations (efficiency of RT); 4. real-time PCR using ABI Prism 7700 Taqman® -> determination of copy numbers by standard curves (ranging between 101 and 108 copies per well) of cDNA plasmids (Invitrogen). Several genes were analyzed regarding their validity as reference genes: abelson (ABL), β2-microglobulin (B2M), glyceraldehyd-P-dehydrogenase (GAPDH), hypoxanthine-phosphoribosyl-transferase (HPRT), phorphobilinogen deaminase (PBGD), β-glucuronidase (GUS), calsequestrin 2 (CASQ2), 18S ribosomal RNA (18S) and large ribosomal protein P0 (RPLP0), the latter two being intronless and thus not mRNA-specific.
Results: The efficiency of RT varied from 23% to 104%, emphasizing the importance of cDNA measurement for reference gene validation. PCR proved to have high efficiency (ranging from 83% for CASQ2 to 105% for 18S) and low intra-assay variability (4.9% for ABL to 11.2% for 18S). Sample-to-sample variation of copy numbers related to cDNA content was lowest for HPRT (32%), ABL (35%) and PBGD (36%) and highest for GAPDH (60%).
Conclusions: For quantitative real-time RT-PCR of myocardial tissue in children and adolescents PBGD, HPRT and ABL appear to be the most suitable reference genes. The simultaneous use of several reference genes may be useful.

OXIDATION AND ATHEROSCLEROSIS

P1610 Mechanisms of increased vascular superoxide generation in human coronary arteries from patients with coronary artery disease

T.J. Guzik[1], B. Kapelak[2], B. Guzik[2], A. Jopek[3], K. Wierzbicki[2], R. Korbut[4], J. Sadowski[2], K.M. Channon[1]. *[1]University of Oxford, J Radcliffe Hosp, Dept. of Cardiovascular Medicine, Oxford, United Kingdom; [2]Dept. of Cardiovascular Surgery[3]Dept. of Medicne, J. Dietl Hosp., [4]Department of Pharmacology, Jagiellonian University, Cracow, Poland*

Oxidative stress manifested by increased vascular superoxide generation (O2-) is a characteristic feature of vascular disease states. The predominant source of superoxide in animal models of atherosclerosis is vascular NAD(P)H oxidase, but the sources and importance of increased superoxide generation in human coronary artery disease (CAD) are unknown. We used segments of human coronary arteries to elucidate sources of superoxide generation in human coronary arteries from patients with or without CAD. Methods: Segments of human coronary arteries without atherosclerotic plaque were obtained from freshly explanted hearts of patients with or without angiographic CAD (n=14 in each group; matched for sex and age). Vascular superoxide generation was measured using both lucigenin enhanced chemiluminescence (LGCL; 5μM), by SOD-inhibitable ferricytochrome c reduction, and by dihydroethidium (DHE; 2μM) staining. The presence of the NADPH oxidase p22phox and p67phox subunits were evaluated by Western blotting.

Results: Both LGCL and DHE staining indicated that basal superoxide production was greater in coronary arteries from patients with CAD. Superoxide production was localised predominantly in the endothelium and the media. NAD(P)H oxidase inhibitors diphenyliodonium (10μM) and apocynin (1mM) greatly inhibited superoxide generation whereas other oxidase inhibitors had only modest or no effect (Table 1). NADPH and NADH greatly increased superoxide production. NAD(P)H oxidase activity measured in vascular homogenates was also significantly higher in CAD (11±3 vs 5.3±1 RLU/sec/mg protein; p=0.02). Immunoblots, normalized against alpha-actin, showed higher levels of p22phox and p67phox protein in coronary arteries from CAD patients.

Table 1. Sources of O2- in coronary arteries

inhibitors:	native	DPI	apocynin	oxypur.	rotenone	indo	L-NAME
CAD	16.9±0.9	4.8±0.5*	5.9±0.7*	14.8±2.4	16.4±1.4	16.9±2.3	19.6±3.0
non CAD	10.8±1.1	3.6±0.4*	4.3±0.7*	10.5±0.5	11.7±0.8	10.8±2.2	15.1±2.9*
p value	0.009	0.3	0.4	0.03	0.03	0.02	0.1

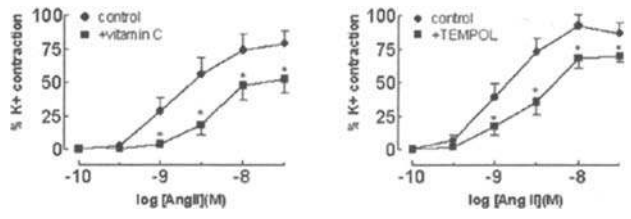
*-p<0.05 vs. native

Conclusions: NADPH oxidase(s) are functionally the most important source of superoxide in human coronary arteries. NADPH oxidase activity and protein levels are increased in coronary arteries from patients with CAD, supporting the role for this oxidase in atherosclerotic endothelial dysfunction in human coronary arteries.

P1611 Superoxide contributes to angiotensin II induced contractions of human resistance arteries

M.B. Hussain, T.K. Khong, D.R.J. Singer. *St George's Hospital Medical School, Pharmacology & Clinical Pharmacology, London, United Kingdom*

Increased formation of reactive oxygen species (ROS) may contribute to vascular dysfunction. As Ang II stimulates superoxide production in human conduit vessels, we investigated reactivity of human resistance arteries to Ang II and the role of superoxide in this response. Resistance arteries were isolated from biopsies of subcutaneous fat obtained from 15 patients undergoing cardiac surgery (14 male; age 66±3(SEM)yrs BP138/73±4/3mmHg; cholesterol 4.0±0.3mmol/L; 38 vessels). Arteries (239±12μm diameter) were mounted on a Mulvany-Halpern small vessel myograph, set to an internal diameter eqivalent to physiological pressure. Arteries were treated with vehicle, the antioxidant vitamin C (1mM, pH buffered) or the superoxide mimetic TEMPOL (1mM) for 30 min before a single concentration-response-curve (CRC) to Ang II (0.1nM-100nM) was carried out in each tissue. Data is shown as % of initial K^+ contraction and analysed by ANOVA for repeated measures (see Figure; *P<0.05 vs. control). In the presence of vitamin C, both potency of Ang II (pEC50 8.8±0.2 and 8.4±0.1, vehicle vs. vitamin C) and maximum response (80.5±10.3% & 53.5±7.7%, vehicle vs. vitamin C) were reduced (n=8; F=5.54; P=0.03). Decreased Ang II responses were also seen after treatment with TEMPOL (pEC50 8.9±0.1 & 8.5±0.1 (vehicle vs. TEMPOL); maximum 90.2±6.3% & 75.1±7.8% (vehicle vs. TEMPOL); n=9; F=5.93; P=0.03). Decreased potency of Ang II after treatment with vitamin C or TEMPOL is consistent with involvement of prooxidant pathways in the contractile response of human resistance arteries to Ang II. The similar magnitude of the shift of Ang II CRC in the presence of both of these antioxidants supports the concept that superoxide is the major oxidant involved.



Vit C or TEMPOL & Ang II contraction.

P1612 Systemic levels of oxidative stress and title of MDA-autoantibodies in patients with ischaemic heart disease at their first clinical manifestation

S. Garibaldi, P. Fabbi, P. Altieri, S. Nasti, P. Spallarossa, G. Ghigliotti, A. Barsotti, C. Brunelli. *University of Genova, Dept of Internal Medicine, Cardiology, Genova, Italy*

Classical risk factors explain only part of the epidemiological features of atherosclerotic disease. Oxidative stress and immune responses are possibly involved in the onset and progression of atherosclerosis (ATS). Modified lipoproteins and autoantibodies against modified biomolecules have been suggested as other factors that may increase the risk of atherosclerosis, both taken alone or in combination with the classical ones.

Detection of autoantibodies against malondialdehyde-modified low-density lipoproteins (MDA-Abs) has been used as a proof of in-vivo immune response to oxidized proteins. Conflicting results emerged by measurements of plasmatic levels of MDA-Abs in different groups of patients (pts) with coronary ATS.

This study was aimed to compare the titre of MDA-Abs and the plasma levels of malondialdehyde expressed as thiobarbituric acid reactive substances (TBARS) in thirthy male pts with unstable angina (UA) at the time of their first clinical manifestation and in thirty age-matched healthy control subjects (CONTROL).

Pts with UA were characterized by more elevated levels of lipid peroxidation products, when compared to CONTROL group ($p < 0.001$). Plasmatic markers of inflammation (total WBC, fibrinogen) showed a trend for more elevated levels in UA than in CONTROL group.

More patients with UA had high titres for MDA-Abs, when compared to CONTROL group (30% vs 7%, levels over 75° percentile). Out of UA pts, elevated levels of MDA-Abs were not predicted by an increased incidence of traditional risk factors for ATS, by severity of atherosclerosis according to the Gensini score, and had not a consistent association with elevated levels of TBARS.

The results presented here suggest that autoantibodies against MDA seem not to be related with the classical risk factors for ATS. However the potential relevance for MDA-Abs in ATS may be suggested by the observation that out of subjects who had elevated values of MDA-Abs, as defined by a level >75° percentile, mostly were UA pts. Moreover, because increased levels of MDA-Abs were not associated with higher TBARS levels, other determinants to mount an immune response against MDA have to be characterized.

P1613 Levels of oxidative stress are associated with C-reactive protein levels in patients with stable and unstable angina

I. Seljeflot[1], O. Aase[2], H. Eid[1], T. Lyberg[1], H. Arnesen[1]. [1]*Ullevål University Hospital, Center for Clinical Research, Oslo, Norway;* [2]*Ullevaal University Hospital, Medicine, Oslo, Norway*

Increased formation of reactive oxygen species (ROS) is generally associated with oxidative stress and subsequent cardiovascular tissue injury. Superoxide anion (O2-), and peroxinitrite (ONOO-) have been shown to be implicated in the development of atherosclerosis. It is suggested that some of their functions include upregulation of the redox-sensitive transcription factor NF-kB, an important regulator of inflammatory response.

In the present study we have investigated the levels of ROS in circulating leukocytes, in basal state and after in vitro stimulation, in patients with stable (SA) and unstable (UA) angina pectoris as related to their levels of C-reactive protein (CRP). Twenty-one patients with SA (aged 39-78 yrs; f/m:2/19) and 15 patients with UA (aged 38-79 yrs; f/m: 4/11) were included. Blood samples were drawn in fasting state and analyses of ROS (citrated whole blood) were started within 15 min. Applying flow cytometric techniques, the basal levels and the phorbol 12-myristate 13-acetate (PMA, 100 ng/mL) stimulated production of ROS were measured in circulating granulocytes (Gr). The mean fluorescence intensity (MFI) in 10.000 leukocytes of the fluorochromes dihydroethidium (DHE, 5 mM) and dihydrorhodamine 123 (DHR, 5 mM), reflecting mainly the levels of O2- and ONOO-, respectively, was recorded. When evaluating the PMA-stimulated results, a stimulation index (SI) in which the autofluorescence of the cells and the procedure related influences are calculated, was used.

Results (medians): Levels of CRP were significantly raised in UA vs SA (6.5 vs 2.4 mg/L, p=0.001). Basal levels of O2- and ONOO- in Gr were elevated in UA compared to SA, however not statistically significant (1.75 vs 1.56 MFI and 2.61 vs 2.40, respectively), whereas the SI-levels were significantly lower in UA vs SA (128 vs 192 and 137 vs 195, respectively, p<0.001 for both). Statistically significant correlations were observed between CRP and basal ROS, whereas negative correlations were seen with the SI-levels (CRP vs basal O2-: r=0.462, p=0.005 and vs basal ONOO-: r=0.441, p=0.008; CRP vs SI- O2-: r=-0.408, p=0.015 and vs SI- ONOO-: r=-0.414, p=0.014).

In conclusion: The higher levels of basal ROS found in circulating granulocytes from UA patients as compared to SA patients, significantly associated with the higher levels of CRP, indicate UA patients to be at higher levels of oxidative stress in parallel with increased inflammatory activity. The reduced capacity for in vitro ROS production in UA might indicate that the cells are partly exhausted in this unstable condition.

CONTRAST ECHOCARDIOGRAPHY AND TISSUE CHARACTERISATION

P1614 Cyclic variation of myocardial contrast intensity during real time imaging

A. Filusch, R. Bekeredjian, G. Korosoglou, H. Kücherer. *University of Heidelberg, Cardiology Dept., Heidelberg, Germany*

Background: Cyclic intensity variation during real-time myocardial perfusion imaging has been observed in clinical and experimental settings but discrepant results have been reported (systolic vs. diastolic predominance). Aim: We investigated whether cyclic intensity variation is systematically found during real-time perfusion imaging and whether such variations are related to regional contractile function, temporal distribution of contrast intensities or to estimates of capillary blood volume (A) and flow velocity β.

Methods: Real-time Power pulse inversion images were obtained in 14 patients with CAD (3 f, 11m, ages 69±10 years) following i.v. slow bolus injection of 0.7 ml of Optison® and in 12 pigs before, during and after LAD occlusion during continuous infusion of Sonovue (60ml/h). Following bolus injections in patients, instantaneous regional systolic to diastolic (S/D) intensity ratios were calculated when contrast first appeared in the myocardium, before high mechanical index flash and during the subsequent replenishment phase. In animals, A and β were measured in reperfused zones 5 min following release of stenosis and compared to control. Instantaneous S/D ratios were calculated.

Results: In patients, cyclic S/D variation was observed only during the diagnostic window (initial bolus phae: mean S/D: 1.7±2.0 vs. diagnostic phase: septal 1.4±0.3, apical: 1.1±0.3, lateral 1.2±0.3). Cyclic S/D intensity variation was consistently seen throughout early (S/D 1.3±0.7) and late (S/D 1.25±0.7) portions of the replenishment curve. Cyclic S/D variation was not related to regional fractional shortening, nor to the levels of A or β (all r < 0.3, n.s.). In reperfused areas peak A and β and fractional area shortening were lower when compared to control (Arep 5.61±1.0dB; vs. Acontrol 8.6±1.1dB p<0.01) (βrep 0.690±0.095 vs. βcontrol 0.895±0.081; p<0.05; (FAScontrol 30.0±4.3% vs. FASrep 2.3±1.2%; p<0.001). Overall S/D-ratio was > 1 (1.28±0.44, n=645 beats; p<0.001) and stable throughout the replenishment curve. There was no significant difference between S/D-ratio between pre-infarction and reperfusion and between risk area and control area, nor did S/D correlate with FAS (r=0.21), β (r=0.19) and A (r=0.26).

Summary: Cyclic variation of myocardial intensity can be seen with predominant signal intensities during systole. This variation is unrelated to regional function and to estimates of myocardial blood volume and flow velocities. It may relate to contrast distribution, attenuation factors or venular and arteriolar cyclic flow changes ("milking effect").

P1615 Identification of stunned myocardium with real time perfusion image in a Dog Model

P.M.M. Dourado[1], J.M. Tsutsui[2], A.C.P. Chagas[1], W. Mathias Jr[2], J.L. Andrade[2], P.L. da Luz[1]. [1]*Heart Institute (Incor), Atherosclerosis, São Paulo, Brazil;* [2]*Heart Institute (Incor), Echocardiography, São Paulo, Brazil*

Echocardiographic distinction between stunned and necrotic myocardium can be challenging. Real Time Perfusion Image (RTPI) permits simultaneous assessment of wall motion and myocardial perfusion.

Objective: Evaluation of stunned myocardial by RTPI in an open-chest canine model of ischaemia and reperfusion.

Methods: Seven anesthetized dogs underwent 20 min of left anterior descending (LAD) coronary artery occlusion followed by 180 min of reperfusion. RTPI was performed using power pulse inversion and flash technique (ATL, Bothell, WA), in the apical long axis view. Perfluorocarbon-exposed dextrose albumin (PESDA) injected in bolus was used as contrast agent. Wall motion and myocardial perfusion was analyzed visually at baseline, 20 min of LAD occlusion and after 180 min of reperfusion. Abnormally contracting areas (ACA) and perfusional defects areas (PDA) were calculated by planimetry during diastole. Blood pressure and heart rate were monitored and LAD coronary flow (CF) was measured by electromagnetic flowmeter. After experiment, the hearts were explanted and stained by triphenyltetrazolium chloride (TTC). A p value < 0.05 was considered significant.

Results: At baseline, no contractility or perfusional abnormalities were observed. LAD CF was 22.4+7.52 ml/sec.

	ACA (cm^2)	PDA (cm^2)	CF (ml/sec)
LAD Occlusion (20 min)	5.49 ± 0.79	2.43 ± 0.79	0.32 ± 0.34
Reperfusion (180 min)	4.93 ± 1.03	0.18 ± 0.40	23.62 ± 9.47
p	0.068	0.043*	0.0053*

Values are expressed as mean and standard deviation

TTC confirmed no necrotic areas in all hearts. CF returned to baseline after 180 min of reperfusion.

Conclusion: After a period of ischaemia and reperfusion, RTPI showed that there was a persistence of wall motion abnormality with decrease of perfusional defects in these areas, demonstrating the presence of stunned myocardium. These results could have important implications in the noninvasive diagnosis of coronary artery disease and in the evaluation of myocardial reperfusion procedures.

P1616 Coronary tree assessed with contrast harmonic imaging

L. Lim[1], H. Yamaguchi[1], M. Mishima[1], F. Ishikura[2], S. Beppu[2]. [1]*Kawachi General Hospital, Cardiology, Higashi-Osaka, Japan;* [2]*, Faculty of Medicine, Osaka Universit, School of Allied Health Sciences, Osaka, Japan*

Myocardial contrast echo (MCE) is performed intravenously using intermittent imaging. Recently real time MCE has been possible using third harmonic imaging. Circulation of coronary tree may be visualized at several different levels by changing frame rate, because MCE at different frame rate images coronary flow at different flow velocities. Study population consisted of 20 patients with ischemic heart disease. We performed 3 kinds of MCE, i.e., intermittent, semi real and real time third harmonic imaging using Levovist. 1. Myocardial blood flow velocity and volume were obtained as A and Beta value from TI curve using intermittent imaging (1:1 to 1:8 in pulsing interval). Curve fitting was possible in 76.5% of the targeted ROI (A =5.3±3.8 and Beta =1.0±1.0). Myocardial perfusion image obtained with slow frame rate visualized capillary circulation. 2. Semi real time perfusion image was obtained (frame rate: 5/sec). We observed a cyclic variation of echo intensity in one cardiac cycle in only viable region (Peak intensity: 53±29 AU in end diastole and 33±27 AU in end-systole, p<0.05). This phenomenon may result from the compression of arterioles according to cardiac beat. Myocardial perfusion image obtained with intermediate frame rate visualized pre-capillary (arteriole level) circulation. 3. Real time perfusion image was obtained (frame rate: 26/sec). We observed line form small artery flows in high frame B-mode image in the 80% of viable area. Myocardial vascular image obtained with high frame rate visualized small artery flow. Thus, coronary tree following major epicardial coronary arteries was visualized noninvasively from the small artery to the capillary bed with 3-staged intravenous-MCE in clinical settings.

P1617 Contrast superharmonic imaging: a new specific contrast imaging method

F. Ten Cate[1], B. Krenning[1], A. Bouakaz[1], N. de Jong[2]. [1]Erasmus MC, Cardiology, Rotterdam, Netherlands; [2]ICIN, Cardiology, Utrecht, Netherlands

Background: Second harmonic imaging (2H) has provided a significant improvement in image quality and is nowadays clinically used for both contrast and tissue imaging. However, differentiation between contrast and tissue usually termed contrast to tissue ratio (CTR) is sometimes cumbersome. Super harmonic (SH) imaging is a new technique based on receiving the higher harmonic components of microbubbles. This techniques showed to be more sensitive to contrast by increasing the signal form contrast and suppressing that from tissue (high CTR). To receive the superharmonic components, we developed a wideband transducer containing two types of elements. The total number of elements is 96 and the total bandwidth extends from the fundamental frequency up to the fifth harmonic.
Objective: Determine the clinical feasibility and usefulness of SHI in patients using a contrast agent (Sono Vue®.) for quantification of myocardial perfusion.
Methods: Six patients with various cardiac disease were assessed. Apical four-chamber views were acquired using 2H and SH in triggered mode before and after a bolus injection of 1.0 mL of Sono Vue®. (0.8 MHz, MI = 0.4). Tissue harmonic imaging was determined visually (scale 0-2) and quantitatively using RF processing from regions of interest.
Results: Prior to contrast injection, 2H tissue components were seen in all available segments, whereas the superharmonics were entirely absent. After administration of SonoVue®, myocardial opacification was visualized by SH after contrast entering the myocardium. The total number of segments seen with SH after contrast injection increased significantly to 36 (visual score of 1-2). These scores were confirmed by Rf-data measurements, showing an increase of 10-15 dB in the signal from the bubbles above tissue level. Consequently, using superharmonic imaging, the CTR increased by 5-10 dB compared to 2H imaging.
Conclusion: These preliminary clinical results show two advantages of SHI over 2H: 1. increased CTR with SH and 2. specific imaging of myocardial contrast perfusion. Further studies are underway to determine the clinical value of this promising novel technology.

P1618 Which is the best quantitative method to analyse regional endoepicardial contrast gradient with real-time myocardial contrast echocardiography?

E. Perez[1], M.A. García Fernández[2], R. Rosas[2], M. Desco[3], M.J. Ledesma[4], A. Santos[4], M. Moreno[2], N. Malpica[4]. [1]Majadahonda, Spain; [2]Hospital General Gregorio Maranon, Cardiology Dept., Madrid, Spain; [3]HGU Gregorio Maranon, Cardiology Dept., Madrid, Spain; [4]Polytechnic University, Madrid, Spain

Background: The optimal way of contrast agent administration and image acquisition in myocardial contrast echo (MCE) is not determined, especially to assess endo and epicardial perfusion, The aim of this study is to perform MCE in endo and epicardium, and to assess accuracy of bolus (B) versus continuous infusion (CI) as well as relative accuracy of different imaging acquisition techniques for real-time MCE comparing it with a standard method (dye-trak microspheres, MS).
Methods: Real-time MCE with coherent contrast imaging (CCI-Acuson-Siemens), a single-pulse cancellation method, was performed in 6 open-chest anaesthetised minipigs, both in basal conditions and after creating a flow-limiting stenosis by reducing LAD flow by 70% of the baseline value. As echo-enhancer, Sonovue, a preparation of sulphur hexafluoride, was used in B (1 ml) and CI (2 ml/min), using low mechanical index (MI) to allow myocardial replenishment after a flash of high MI. In both cases, sequences of 150 telediastolic frames were acquired in endocardium and epicardium of anterior septum (AS) and posterior wall (PW) in short axis view and stored to be processed with propietary software. During continuous infusion, sequences of 200 frames with a temporal resolution of 50-75 ms were also acquired. MCE derived A (peak VDI) and area under the curve (AUC) obtained with the three methods were compared to MS in the same regions of interest(ROI).
Results: Bolus showed the poorest correlation with MS endoepicardial flow ratio (r=0.48, p=0.4 for A endoepicardial ratio and r=0.79, p=0.006 for AUC endoepicardial ratio). Continuous perfusion with telediastolic frame acquisition obtained the highest correlation with MS (r=0.90 p=0.013 for A endoepicardial ratio and r=0.70, p=0.01 for AUC endoepicardial ratio), whereas 50-75 ms acquisition showed a slightly lower correlation with MS (r=0.71 p=0.01 for A endoepicardial ratio and r=0.80, p=0.02 for AUC endoepicardial ratio)
Conclusions: Continuous perfusion of contrast agents seem more accurate than bolus for quantitation of regional endo-epicardial perfusion. MCE performed with continuous perfusion and telediastolic frame acquisition showed an excellent correlation with endoepicardial blood flow ratio.

P1619 Albumin- and phospholipid-microbubbles influence the respiratory burst activity of polymorphonuclear neutrophil granulocytes

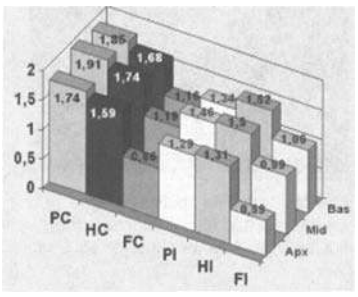
G. Korosoglou, G. Da Silva, A. Hansen, R. Bekeredjian, S. Hardt, M. Browatzki, R. Kranzhoefer, H. Kuecherer. University Hospital, Internal Medicine, Cardiology, Heidelberg, Germany

Background: Activated leucocytes that are adherent to the venular endothelial surface can bind and subsequently phagocytose microbubbles that are used for contrast-enhanced ultrasound assessment. The purpose of this study was to investigate whether left heart contrast agents can influence the respiratory burst activity of human polymorphonuclear neutrophil granulocytes (PMN).
Methods: PMN isolated from peripheral blood of healthy volunteers were incubated with albumin- (Optison®) or phospholipid-microbubbles (Sonovue®) for 40 minutes and then stimulated with the bacterial peptide fMLP or with the calcium ionophore A23187. In other experiments priming of PMN was performed using TNF-alpha or the protein kinase C activator phorbol-myristate-acetate (PMA) before incubation with the microbubbles. The neutrophil respiratory burst activity was quantified in both cases photometrically through the superoxide-induced reduction of cytochrome C.
Results: Albumin- and phospholipid-microbubbles (starting at contrast agent concentrations of 2.5-4x105 microbubbles/ml for Optison® and 1-2.5x105 microbubbles/ml for Sonovue®) induced an extensive oxidative response of human PMN to fMLP as well as to the calcium ionophor A23187 (maximum 181±9% for Optison® and 153±5% for Sonovue® for fMLP and 232±6% for Optison® and 199±15% for Sonovue® for A23187). Priming PMN with TNF-alpha or with PMA induced a more extensive oxidative response of human PMN and was possible at 10–fold lower contrast agent concentrations (maximum 227±25% for Optison® and 191±9% for Sonovue® for TNF-alpha and 291±11% for Optison® and 238±17% for Sonovue® for PMA). The effect of both left heart contrast agents on burst activity of PMA activated PMN could be significantly inhibited by preincubation of the cells with the polymerisation-inhibitor Cytochalasin B (63±13% for Optison® and 93±4% for Sonovue®), indicating that phagocytosis contributes to their effect on the burst activity. Soluble human albumin was also capable to provoke a minor but significant stimulatory effect of the respiratory burst activity of PMA activated PMN (maximum 161±7%).
Conclusions: Left heart contrast agents used for contrast-enhanced ultrasound assessment can activate human PMN in vitro inducing an extensive respiratory burst to secondary stimuli. The potential clinical relevance of this effect remains to be elucidated.

P1620 Endocardial delineation in technically difficult echocardiograms by native and contrast-enhanced fundamental,harmonic and pulse inversion imaging

J.D. Kasprzak, J. Drozdz, M. Krzeminska-Pakula, M. Zwierzak, M. Plewka. Medical University, Cardiology IMW, Lodz, Poland

Aim: The visualization of left ventricular endocardial border (LVEB) is essential for echocardiographic assessment of cardiac function. Fundamental imaging(FI) is often insufficient for this purpose. Novel modalities have been applied to improve the echocardiographic LVEB detection but data regarding their comparative value are few.
Methods: Endocardial visualization index(EVI) was studied in a group of 25 patients with insufficient endocardial detection in FI. EVI was defined as the average of individual scores for segments assigned in 3-point scale:0-invisible,1-incomplete,2-complete visualization. FI was directly compared with harmonic imaging (HI), pulse inversion imaging (PI) without contrast and with Optison enhancement (FC,HC,PC resp.) Imaging was performed using ATL 5000HDI and bolus injections of 0.3-0.5ml Optison.
Results: HI and PI improved significantly the visualization of LVEB, however, the addition of contrast provided further improvement, most significant in the studies with poorest quality. EVI values (apical window) for individual modalities were: FI:0,94±0,37; FC:1,17±0,48; PI: 1,34±0,47; HI:1,50±0,37; HC:1,69±0,23; PC:1,86±0,18, each difference significant. HI surpassed PI mainly in the basal segments(fig.1). EVI values in non-enhanced modes from parasternal window were: FI: 1,09±0,84; HI: 1,44±0,80; PI: 1,35±0,80 ($p<0.05$ for HI,PI vs FI; p=NS for PI vs HI).The persistence of contrast effect was 58±49s in FI,116±58s in HI and 157±66s in PI ($p<0.001$ for all).



Conclusions: HI and PI markedly improve the endocardial visualization in difficult echocardiograms. Contrast provides additional benefit in most challenging studies. As opposed to native imaging, in contrast studies PI provides the optimal LVEB delineation.

P1621 Evaluation of left ventricular function in ventilated patients: contrast imaging in comparison with transoesophageal echocardiography

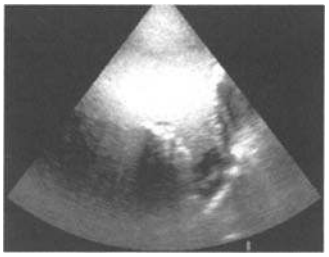
B. Cosyns[1], P. El Haddad[2], H. Lignian[2], J. Van der Auwera[1], M. Menassel[1], K. Daniels[3], C. Weijntjes[3], G. Van Camp[3]. [1]*Hopital de Braine, Cardiology, Braine l'Alleud, Belgium;* [2]*Braine Hospital, Intensive Care Unit, Brainel'Alleud, Belgium;* [3]*AZ VUB, Cardiology, Brussels, Belgium*

Background: Echocardiograms done in the Intensive Care Units (ICU) are often suboptimal, especially in ventilated patients. The ICU patients often require an evaluation of their ventricular function. Consequently, a transoesophageal echocardiography (TOE) represents an alternative in order to improve quality of the images. For a few years, the echo of contrast (CE) has made it possible to evaluate the global and regional function among poorly echogenic patients.
Objectives: The study examined the value of contrast echocardiography in the assessment of left ventricular (LV) wall motion in ventilated patients in comparison with TOE.
Methods: Transthoracic echocardiograms were done in 32 ventilated patients. Wall motion was evaluated on standard echocardiography (SE), CE and TOE using a score on a scale of 2 to 0 for each of 16 segments. The segment was assigned a value of 2 if the segment was seen in both systole and diastole, 1 if seen only in systole or diastole, and 0 if not seen at all. A confidence score was also given for each segment with each technique (unable to evaluate; not sure; sure). The EF was estimated visually for each technique, and a confidence score was applied to the EF.
Results: Uninterpretable wall motion was present in 6.1 segments/patient on SE, 1.1 on CE ($p < 0.0001$) and 1.0 on TOE ($p < 0.0001$). An average of 8.7 segments were read with surety on SE, 13.7 on CE ($p < 0.0001$) and 14.5 on TOE ($p < 0.0001$). There was no significant difference for CE vs TOE. Ejection fraction was uninterpretable in 31% on SE, 0% on CE ($p < 0.001$) and 0% on TOE ($p< 0.001$). The EF was read with surety in 51% of patients on SE, 89% on CE ($p < 0.0001$) and 92% with TOE ($p<0.0001$) with no difference for CE vs TOE. Thus, wall motion was seen with more confidence on CE and TOE.
Conclusions: CE gets an equivalent improvement of the image that the TOE. Because CE is less invasive, less expensive and more comfortable than TOE, it should be used in all ventilated patients with suboptimal transthoracic echocardiograms for the evaluation of the LV function.

P1622 Contrast echocardiography for the exclusion of left atrial thrombi in patients with atrial fibrillation prior to cardioversion

G. von der Recke, S. Illien, H. Schmidt, B. Lüderitz, H. Omran. *University of Bonn, Dept. of Cardiology, Bonn, Germany*

Background: Transesophageal echocardiographic (TEE) guidance of cardioversion in patients with atrial fibrillation (AF) is an alternative method to conventional anticoagulation. Although TEE is considered the gold standard for excluding left atrial (LA) thrombi, in some cases dense spontaneous echo contrast and artifacts may hamper identifying or excluding LA thrombi. Often those patients are refused cardioversion. The purpose of this study was to determine, whether the application of echo contrast (Optison®) facilitates the exclusion of LA thrombi in the latter patient group and may allow for safer cardioversion.
Methods and results: 41 patients with AF and dense spontaneous echo contrast or inconclusive TEE findings were given echo contrast. 14 patients with SR served as controls. Echo contrast completely reduced artefacts in 13 of 22 cases. In 12 of 19 cases with spontaneous echo contrast the LA appendage was completely filled after the application of echo contrast and thus, spontaneous echo contrast was completely suppressed. In 13 of 41 cases it was filled incompletely and in 9 of 41 cases a new mass resembling a thrombus was detected (figure 1). In total in 25 of 41 cases with inconclusive TEE findings an atrial thrombus was definetively excluded. Those patients underwent cardioversion. None of those patients had a cerebral embolic complications as assessed by cranial MR imaging.



Conclusion: The application of echo contrast facilitates the TEE exclusion of LA thrombi and hence improves the safety of TEE guided cardioversion in particular in patients with spontaneous echo contrast.

P1623 Reversible perfusion defects during dipyridamole myocardial contrast echocardiography for the detection of coronary artery disease

R. Senior[1], W. Lepper[2], A. Pasquet[3], G. Chung[1], R. Hoffman[2], J.L. Vanoverschelde[3], S. Kaul[4]. [1]*Northwick Park Hospital, Cardiology, Middlesex, United Kingdom;* [2]*University Hospital RWTH, Aachen, Germany;* [3]*University Hospital St Luc, Brussels, Belgium;* [4]*University of Virginia, Virginia, United States of America*

Background: We hypothesized that stress myocardial contrast echocardiography (MCE) technique can detect coronary artery disease (CAD) in the absence of prior infarction on the basis of reversible perfusion defects.
Methods: 55 patients with suspected CAD and no previous myocardial infarction or wall motion abnormality were recruited from 3 centers in Europe. They underwent high mechanical index intermittent B-mode MCE during a continuous infusion of Sonazoid (Nycomed-Amersham) and coronary arteriography (CA) within 1 month of each other. Visual analysis of MCE data and quantitative CA were performed by blinded observers at 2 different centers in the United States.
Results: Forty-two (76%) had ^{3} 50% stenosis of one or more coronary arteries. MCE detected reversible perfusion defect in one or more segment in 83% of these patients. The rate of CAD detection increased with higher degrees of stenosis: 88% in >75% stenosis and 100% in more than 90% stenosis. The specificity for a cut-off <50% stenosis was 44% in this patient population with chest pain. The accuracy of dipyridamole MCE for the detection of >=50% stenosis was 76%.
Conclusion: MCE (using intermittent high mechanical index B-mode imaging) performed very well against quantitative coronary angiography for the detection of CAD in patients without previous infarction or wall motion abnormality. The relatively lower specificity was probably related to selection bias in patients undergoing coronary angiography for chest pain evaluation.

P1624 Dobutamine stress myocardial contrast echocardiography. Intermittent triggering in real-time era

M.S. Hashem[1], H. El-Khateeb[2], A. Shaaban[1], M.L. Selim[3], A.K. Shaalan[4], A.H. Mostafa[5], Z. Feteih[3]. [1]*Erfan General Hospital, Cardiac Lab., Jeddah, Saudi Arabia;* [2]*Erfan Hospital, Cardiology, Jeddah, Saudi Arabia;* [3]*Erfan General Hospital, Cardiac Cath Lab., Jeddah, Saudi Arabia;* [4]*Arab Consultants, Design & Analysis, Dammam, Saudi Arabia;* [5]*Cairo Unicersity,School of Medicine, Cardiology Department, Cairo, Egypt*

Purpose: We sought to compare the accuracy of myocardial contrast echo (MCE) methods i.e; intermittent triggered imaging(ITI) versus real-time (RTI) modes in patients undergoing standard high dose dobutamine stress echo (DSE) to rule out ischemia (CAD),validated by coronary angiography.
Methods: After an informed consent,patients undergoing DSE had simultaneous studies in grayscale ITI and Pulse Inversion (PI); and in RTI -in grayscale (PI)®, or pulse inversion Doppler (PPI)®- plus regional wall motion (RWM)studies. Intravenous boluses of Optison® were administered, at rest and prior to peak DSE dose. System settings are outlined in table-1. Off-line interpretation and scoring of myocardial enhancement and RWM was determined by blind review, in 16 segment left ventricle model. Coronary angiography was performed within two weeks of the MCE study. CAD was graded according to visually determined percent luminal diameter stenosis, where 50% and 70% stenoses were taken as cutoff values. Test accuracy and statistical correlation was determined.
Results: Study included 29 subjects. Mean age=57y. A total of 464 segments were each read in 3 methods. 29/29 had ITI & RWM studies. 23/29 in RTI; of whom 14 were in grayscale PI, and 9 in PPI. 16/29 had coronary angiography. Pearson correlation coefficient for global wall motion (WM) & ITI was determined; $r = 0.83$, $p<0.0001$ and for global WM & RTI: $r = 0.86$,$p<0.0001$. Test accuracy of RWM; ITI and RTI was: 75%; 88% & 94% respectively for LAD disease; 44%; 75% & 75% for LCX, and finally 75%; 81% & 63% respectively for RCA disease.

MCE settings on ATL HDI 5000 system

Imaging mode	Intermittent Triggering (PI)	Real-Time (PI)/Doppler (PPI)
Scanhead & Preset	P4-2, CSI	P4-2, CSI
Mechanical Index (MI)	0.53 - 0.8 MHz	0.16 - 0.22 MHz
PRF, Scan Line Density	2500, A	2500, A
Persistence/Dynamic Range	Low/Low	Low/Low
Sensitivity/Frame Rate	Medium/Medium	Medium/Medium
Color Gain	–	55-65% (PPI only)
Potentiometers	Max TGC but for top 2	Max TGC but for top 2
Focus	10 - 13 cm	10 - 13 cm

PI= Grayscale Pulse Inversion, PPI= Power Doppler Pulse Inversion

Conclusion: MCE in either ITI or RTI is of added value to RWM, in DSE; especially for LAD disease diagnosis.

P1625 Contrast echocardiography is superior to single photon emission computed tomography for detection of functional significant coronary stenosis

W. Lepper[1], A. Franke[2], S. Kaul[1], P. Hanrath[2], R. Hoffmann[2].
[1]Cardiovascular Division, University of Virginia, Charlottesville, United States of America; [2]University Clinic RWTH Aachen, Med. Clinic I, Aachen, Germany

Objective: Comparison of myocardial contrast echocardiography (MCE) and single photon emission computed tomography (SPECT) during vasodilator stress for the detection of functional significant coronary heart disease in patients (pts) without previous myocardial infarction. Methods: 21 consecutive pts (mean age 60±9 years) were studied with simultaneous myocardial contrast echocardiography (MCE) using a continuous intravenous infusion of Sonazoid® (NC100100) and SPECT (99mTc) after standard dipyridamole stress (0.852 mg/kg over 6 minutes). Regional function (RF) was assessed at rest and stress in real time. MCE was performed using intermittent pulse inversion imaging (ATL 5000) with increasing trigger intervals. Measurement of myocardial fractional flow reserve (FFR) with a cut-off value of 0.75 obtained during coronary angiography was used as reference method to assess the functional severity of coronary artery stenosis. All images from the MCE studies were stored digitally and assessed visually independent from wall motion by a blinded observer.
Results: 16 pts showed functional significant stenosis according to the FFR measurements (mean FFR 0.54±0.10, 10 LAD-, 4 CX- and 2 RCA-territory) and 5 patients showed less severe stenosis (mean FFR = 0.86±0.09, 3 LAD, 1 CX and 1 RCA territory). On a per patient analysis, the sensitivity to detect functional significant coronary heart disease of MCE and SPECT were 94% and 63% respectively, while RF became abnormal only in 32% of patients ($p<0.001$ vs MCE and 0.156 vs SPECT). Specificity was 80% for MCE and RF and 100% for SPECT.
Conclusion: In pts without previous myocardial infarction MCE using intermittent pulse inversion imaging is superior to SPECT for the detection of functional significant coronary heart disease. Both perfusion methods were better than RF assessment in this regard.

P1626 Accuracy of adenosine contrast echocardiography is higher in patients with single-vessel than multi-vessel coronary artery disease

A. Moraes[1], C. Medeiros[1], F. Morcerf[1], M. Carrinho[1], R. Morcerf[1], A.C. Nogueira[1], F. Salek[1], H. Dohmann[2]. [1]Hospital Pro-Cardiaco, Echocardiography Dept., Rio de Janeiro, Brazil; [2]Hospital Pro-Cardiaco, Cardiology, Rio de Janeiro, Brazil

Background: We have previously shown that myocardial perfusion is accurately assessed by adenosine contrast echocardiography (ACE) following PESDA infusion in pts with coronary artery disease (CAD). The aim was to compare this accuracy in single-vessel (SV) versus multi-vessel (MV) pts with angiographic diagnosis of coronary artery disease (CAD).
Methods: ACE with PESDA was performed in 74 pts with SV CAD (57 male, 61±11 years) and 57 with MV CAD (44 male, 62±12 years). ACE with PESDA was visually assessed, at rest and after IV bolus injection of 6-18 mg of adenosine (ADN) using triggered (1:1) 2nd harmonic imaging. Normal perfusion was defined as a marked increase in the wall contrast enhancement after ADN and abnormal perfusion was the abscense of this enhancement after ADN. Angiography was done not later than 30 days from ACE. For each pt 3 LV territories (LAD, RCA and CX arteries) were considered (171 segments in the MV group and 222 in the SV). Sensitivity (Sens), specificity (Spec), accuracy (Accur), positive (PPV) and negative (NPV) predictive values were calculated.
Results: Gender (p=0.851) and age (p=0.619) were similar for both groups. Table shows the comparison between groups.

	Sens	Spec	PPV	NPV	Accur
SV n=74 pts	95.9% (71/74)	99.3% (147/148)	98.6% (71/72)	98% (147/150)	98.2% (218/222)
MV n=57 pts	89.6% (121/135)	100% (36/36)	100% (121/121)	72% (36/50)	91.8% (157/171)
p	0.185	0.460	0.785	0.0001	0.006

Conclusion: ACE is a reliable method to detect CAD with higher NPV and accuracy in SV CAD patients.

P1627 Detection of myocardial viability using dobutamine stress echocardiography and myocardial contrast after acute myocardial infarction

J.C. Sbano, J. Tsutsui, E. Abreu, J.C. Meneghetti, J.L. Andrade, S.B. Leal, W. Mathias. Heart Institute, São Paulo, Brazil

Background: The discovery of a microbubble based echocardiographic contrast agent emerged the potential of improvement in the diagnostic accuracy of stress echocardiography.
Objective: We evaluated the diagnostic value of dobutamine stress echocardiography (DSE) and myocardial contrast echocardiography (MCE) using second harmonic with and without intermittent imaging in the detection of myocardial viability after acute myocardial infarction (AMI) treated with successful thrombolysis.
Methods: We studied 50 patients (pts) in the first week after AMI, at rest with low dose DSE, with and without MCE. We evaluated the recovery of left ventricular ejection fraction (LVEF) at rest by two-dimensional echocardiography as well as by myocardial scintigraphy (Mibi Spect), between the fourth and sixth month of follow-up. According to a absolute 5% increase in LVEF measured by the two Mibi Spect studies, pts were divided in group I, with functional recovery (19 pts) and group II, without functional recovery (31 pts). To analyze the contractility and myocardial perfusion, a left ventricular wall motion score index (WMSI) and myocardial perfusion score (MPSI) index at rest and after dobutamine were created.
Results: When using the evaluation of contractility by DSE in order to predict the LVEF recovery, sensitivity was 95%, specificity 87%, positive predictive value 82%, negative predictive value 96% and diagnostic accuracy 90% (kappa= 0.794). When we analyzed the diagnostic accuracy of MCE, we demonstrated sensitivity of 95%, specificity of 52%, positive predictive value of 54%, negative predictive value of 94% and diagnostic accuracy of 68% (kappa= 0.479).
Conclusion: The detection of contractile reserve by the use of DSE was sensitive and specific in predicting LVEF in pts after AMI treated with successful thrombolytic therapy, while MCE demonstrated high negative predictive value.

P1628 Cyclic variation of backscatter myocardial signal in type I diabetes and in hypertension: an ultrasonic tissue characterization study

V. Di Bello[1], P. Marchetti[2], R. Pedrinelli[1], E. Talini[1], R. Giannarelli[2], E. De Felice[1], S. Del Prato[2], M. Mariani[1]. [1]University of Pisa, Cardiac and Thoracic Dept, Pisa, Italy; [2]Endocrinologic Metabolic Department, Pisa, Italy

Early changes detected in myocardial ultrastructure of diabetic and hypertensive heart consist of increased interstitial collagen deposition, although with different physiopathologic patterns. Aim of this study was to characterize both myocardial echodensity and its cyclic variation in type 1- diabetes, compared with essential hypertensive patients, both with normal conventional 2D echo findings, and to determine whether ultrasound tissue characterization can detect ultrastructural changes of myocardium, as an increase in collagen content. We evaluated 10 type-I-diabetic pts (D), 10 essential hypertensive pts (H), both with normal regional and global resting function and 10 age- and sex-matched controls (C). All D were affected by diabetic nephropathy with renal failure and mild degree of hypertension. By selection, all D and H pts. had a negative maximal exercise stress test, to avoid confounding effects of coronary artery disease. All study subjects performed: conventional 2D-Doppler echocardiography; ultrasonic myocardial integrated backscatter (IBS) trough Acoustic Densitometry package (Philips Sonos 5500). We considered: absolute diastolic IBS value both at interventricular septum and at posterior level, indexed (%) by pericardial IBS value, to optimise the comparison between subjects, (expression of echodensity) and systo-diastolic variation of the backscatter (Cyclic Variation Index (CVIibs), as index of intrinsic myocardial contractility. Left ventricular mass was significantly higher in hypertensive, although within normal range (H: 119±4 vs D: 113±24 and C: 96±12; $p<.01$). Systolic function overlapped in three groups. Diastolic function obtained trough the E/A ratio of mitral flow velocity pattern showed slightly but significant difference of both groups with controls (H: 1.10±0.2 vs. D:1.18±0.3 vs C: 1.6±0.3; $p<0.001$). Echodensity at interventricular septum level was significantly higher in diabetic patients in comparison both with hypertensive and controls (D: 68 ±3 vs H 51.3 ±11 and C: 50.6±12.8; $p< 0.005$). CVIibs at interventricular septum level was significantly lower both in hypertensive an diabetics in whom overlapped, in comparison with controls (D: 10.7±9.6 vs H:12.7±9.9 and C: 24.6 ±4.5; $p<0.001$). The coexistence of diabetes (plus renal failure) and hypertension is able to induce a further increase in collagen deposition at myocardial level, thus altering the intrinsic contractility. This physiopathologic worsening could prelude to develope a preclinical or overt overall left ventricular dysfunction.

P1629 Detection of early myocardial changes in diabetic heart disease

Z.Y. Fang, S. Yuda, T. Marwick. *University of Queensland, Dept of Medicine, Brisbane, Australia*

Background: Diabetes is associated with increased interstitial collagen deposition. We sought whether early changes in myocardial contractility could be identified with tissue characterization, and to compare pts with diabetes with and without LV hypertrophy, to determine whether these changes in the diabetic heart are independent of LV hypertrophy.
Methods: We studied 179 pts with normal ejection fraction and no evidence of coronary disease based on symptoms, ECG and stress echo; 48 with diabetes only (DM group), 45 with both diabetes and LVH (DH group), 44 with LVH only (LVH group), and 42 normal controls (CON group). Cyclic variation (CV) of integrated backscatter (IB) of 16 segments and strain and strain rate of 6 walls in apical four, long axis and two chamber views were evaluated and averaged for each patient. Calibrated IB was assessed by comparison of the septal or posterior wall with pericardial IB intensity in parasternal long axis view.
Results: Three patient groups (DM, DH, LVH vs CON) showed significant decreases in CV, end-systolic strain, peak strain, strain rate and increases in calibrated IB in both the septum and posterior wall compared with controls. There were no significant differences found in CV among DM, DH and LVH groups and end-systolic strain, peak strain and strain rate between DM and LVH groups, but significant differences were found between DM and DH groups and between LVH and DH groups in end-systolic strain ($p < 0.01, 0.05$), peak strain ($p < 0.05, 0.01$) and strain rate ($p<0.01, 0.01$). Only significant difference was found between DM and DH groups in posterior calibrated IB.

CV and strain parameters

	DM	DH	LVH	CON
CV	6.39 + 1.36	6.24 + 1.03	6.66 + 1.15	7.59 + 1.35
End-systolic strain	22.29 + 2.67	20.68 + 2.70	21.90 + 2.87	24.70 + 3.54
Peak strain	23.37 + 3.02	22.05 + 2.87	23.97 + 3.04	26.31 + 3.67
Calibrated IB	-18.64 + 7.89	-17.13 + 7.02	-17.47 + 6.41	-22.0 + 6.76

Conclusions: Cyclic variation, strain and strain rate are decreased and calibrated IB is increased in diabetic patients without overt heart disease. Although similar to changes caused by LVH, these changes are independent of LVH and do not appear to be additive. These findings diabetes may independently be associated with reduced myocardial contractility.

P1630 Ultrasonic integrated backscatter of the myocardium in anorexia nervosa

F. Franzoni, G. Santoro, M. Rolla, F. Pastine, F. Pentimone, F. galetta. *university of pisa, internal medicine, Pisa, Italy*

Background: Cardiac involvement is an important feature of anorexia nervosa. A reduced left ventricular mass with preserved myocardial contractile function has been previously reported. The aim of the present study was to evaluate the cyclic variation of integrated backscatter (IBS-CV) of the myocardium in patients with anorexia nervosa and whether the examination of cardiac acoustic reflectivity plays a role to detecting initial stage of myocardial abnormality in these patients.
Methods: Twenty-five female (aged 21.3±3.7 years) with anorexia nervosa, compared with 25 age-matched thin and 25 age-matched controls with BMI >20 Kg/m^2, underwent either conventional 2-dimensional echocardiogram or analysis of IBS-CV.
Results: Anorexic patients, compared with thin and control women, showed reduced left ventricular mass (LVM: 82.9±17.1 vs 119.9±13.8 and vs 126.12±16.4 g, $p<0.0001$; LVM indexed 21.4±3.3 vs 29.4±2.5 and vs 31.2±3.1 g/m^2.7, $p<0.0001$), and IBS-CV (septum: -0.49±2.18 vs 6.86±1.3 and vs 6.61±1.74 db, $p<0.0001$; posterior wall: 2.77±2.12 vs 7.15±2.12 and vs 7.48±2.23 db, $p<0.01$). Moreover, IBS-CV is related to LVM, as absolute ($r=0.55$, $p<0.05$; $r=0.48$, $p<0.05$) and indexed ($r=0.70$, $p<0.005$; $r=0.58$, $p<0.05$) values.
Conclusion: The present study confirms a reduced LVM in the starvation phase of anorexia nervosa and demonstrates a significant reduction of the IBS-CV at septum and posterior wall levels, which is also related to left ventricular hypotrophy. Since these abnormalities in ultrasonic properties has been substantially related to variations of the intramural contractile performance, our findings could represent a pre-clinic index of myocardial dysfunction in patients with anorexia nervosa.

P1631 Cyclic variation of the myocardial integrated backscatter signal in essential hypertensive patients with microalbuminuria

C. ceyhan[1], H. Akar[2], T. Tekten[3], A. Onbasili[3], E. Ercan[3], M. Kaya[3], N. Ozgel[2]. [1]*Adnan Menderes University, Cardiology, Aydin, Turkey;* [2]*Nefrology Dept, Internal Medicine, Aydin, Turkey;* [3]*Adnan Menderes University, cardiology, Aydin, Turkey*

Microalbuminuria (MA) is a well-recognized marker of cardiovascular complications in hypertension. Since acoustic properties of the myocardium are sensitive to the myocardial structure and the contractile conditions of myocyte, we evaluated cardiac dysfunction based on the integrated ultrasonic backscatter. The aim of study was to analyze the cyclic variation of integrated backscatter (CVIBS) in 2 groups of hypertensive patients with microalbumiuria or not.
Method: A group of 28 essential hypertensive patients (mean age 51±8) who had controlled blood pressure (mean 24-h BP <140 and/or < 90 mm Hg) were analyzed with a group of age comparable normotensive subjects as controls (n=20). MA was found in 10 patients, classified as MA+ (urinary albumin excretion (UAE) 20 to 300 mg/24 h); 18 patients had normal UAE (< 30 mg/24 h) and were classified as MA-. Microalbuminuria was evaluated as mean value of 24-h UAE from 24-h urine collection. Diabetes mellitus and major noncardiovascular diseases were the exclusion criteria. The parasternal short-axis view at the papillary muscle level was used to obtain the 2-D image of integrated backscatter. For each patient, three regions of interest were chosen in the same parasternal short-axis image (Midanteroseptal, midposterolateral, midinferior areas). We determined the magnitude of CVIBS in decibels as the difference between the maximal and minimal values in a cardiac cycle.
Results: The MA (+) and MA (-) groups did not differ with regard to age, sex, body mass index and left ventricular hypertrophy. The left ventricular mass index values between control group and hypertensive patients were significantly different ($p<0.05$). The three regions of myocardial CVIBS values of MA+ group were significantly lower than MA- hypertensive group and control group ($p<0.05$).

	MA +(1)	MA -(2)	Control(3)	P(1-2)	P(1-3)	P(2-3)
CVIBS AS	5.4±1.5	7.4±1.3	7.5±1.2	*	*	NS
CVIBS PS	6.1±1.4	7.8±1.2	7.6±1.3	*	*	NS
CVIBS MI	6.1±1.6	7.4±1.2	7.3±1.1	*	*	NS

CVIBS:Cyclic variation of integrated backscatterAS: anteroseptal PS: posteroseptalMI: midinferiorNS: Non-significant*: $p<0.05$

Conclusion: These data suggest that myocardial integrated backscatter of hipertensive microalbuminuric patients may help define the presence and extent of myocardial structural abnormalities.

P1632 Accuracy of stress-induced reduction of subendocardial backscatter variations in CAD patients with or without EKG signs of myocardial ischaemia

P. Colonna[1], R. Montisci[1], M. Ruscazio[1], C. Cadeddu[1], L. Chen[1], L. Meloni[1], S. Iliceto[2]. [1]*University of Cagliari, Cardiovascular and Neurological Dept, Cagliari, Italy;* [2]*University of Padua, Division of Cardiology, Padua, Italy*

Background: During peak stress test, myocardial ischemia occurs earlier in the subendocardium (ENDO) than in the subepicardium (EPI), impairs at first myocardial contractility and only later surface EKG. Since integrated backscatter cyclic variations (IBCV) are reduced during ischemia, we hypothesized a reduction of ENDO IBCV earlier than EKG signs of ischemia.
Methods: We analyzed 78 myocardial segments supplied by a coronary artery with >50% stenosis (CAD) in 37 patients and 27 segments in a control group of 12 patients with no-CAD. In each patient a transgastric two-chamber view was acquired during an atrial pacing stress test. IBCV were calculated in ENDO and EPI at rest, and during peak (150 b/m') atrial pacing (stress) and immediately after pacing interruption.
Results In the control group of no-CAD segments both ENDO and epi IBCV remained unchanged in all the steps of pacing stress test. At peak stress, 12 of the CAD patients, with 25 myocardial segments, showed ST EKG-changes significant for myocardial ischemia (ISCH) and 25 of the CAD patients with 53 segments did not show ischemia (NO-ISCH). In both NO-ISCH and ISCH segments the ENDO IBCV decreased from rest (7.9±2.3 and 8.2±2.3) to stress (5.5±2.1 and 5.3±1.3, $p<0.0001$ vs rest), and recovered immediately after pacing interruption (7.7±2.9, and 7.3±3.4 $p<0.0001$ vs peak); the EPI IBCV did not change along the protocol.

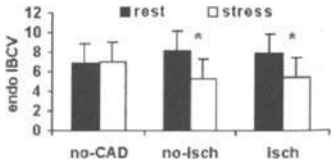


Figure: IBScv subendo at rest and stress.

Conclusion: ENDO IBCV are accurate in detecting subendocardial ischemia in CAD patients with or without ST EKG-changes.

P1633 Ultrasonic tissue characterization (backscatter) in the analysis of left ventricular myocardial intrinsic function in systemic amyloidosis

V. Di Bello[1], V. Panichi[2], D. Giorgi[1], C. Palagi[1], E. Talini[1], L. Papi[1], L. Garritano[1], M. Mariani[1]. [1]*University of Pisa, Cardiac and Thoracic Dept, Pisa, Italy;* [2]*University of Pisa, Internal Medicine Dept, Pisa, Italy*

Amyloidosis is a systemic illness characterized by the deposition in the extracellular compartment of protein fibrillar autholog material (amyloid), that determines organ damage. Aim of study is to evaluate if ultrasonic tissue characterization can allow a precocious detection of amyloidosic cardiac involvement. We have studied 15 patients with sistemic amyloidosis (GROUP A) (positive ness of the biopsy of the subcutaneous fat to red Congo), and an age-sex-matched healthy group(GROUP B). All subjects performed a conventional color Doppler echocardiography (Philips, Sonos 5500),for evaluation of left ventricle systolic and diastolic function. Acoustic Densitometry was applied for analysis of backscatter (IBS) sampled in a R.O.I. placed at septum level and posterior wall, both at end-diastole (IBSd) and end -systole (IBSs). The pericardial backscatter value in dB was placed equal to 100 towards the diastolic level of the values IBS of the septum and the posterior wall. Cyclic variation of the signal in backscatter both to posterior wall and septum (CVI = IBSd-IBSs/IBSd*100) was also calculated, as an index of intrinsic contractility of the myocardium.

Left ventricular mass was higher in the group A. (A.: 157.3± 39.9, B: 101.5 ±12.9 g/m^2, $p < 0.0001$) and particularly for diastolic thickness of the septum (A.: 1.29 ± 0.27, B: 0.98± 0.08 cm, $p < 0.001$) and of posterior wall (A.: 1.10± 0.19, B: 0.92 ± 0.08 cm, $p < 0.002$), that resulted significantly higher in the group A. Left ventricular systolic function (fractional shortening) was comparable in the two groups. The E/A relationship of the diastolic transmitral flow in the amyloidosic subjects, was significantly lower in comparison with control group (A.: 0.95± 0.3, B: 1.5 ± 0.33, $p < 0.01$). The CVI at septum level (A.: 17.3% ±s 12.5, B: 40.5%± 12.9, $p < 0.0001$) and at posterior wall level(A.: 20.4% ±s 18.5, B: 44.5%± 14.9, $p < 0.001$) were significantly lower in the amyloidosic group. The percentage of the IBSd in comparison to the pericardium, both for the septum and for posterior wall was significantly higher in Group A. The reduction of the CVI in the group A, could be the expression of a precocious alteration of the intrinsic myocardial contractility, also when the normal indexes of left ventricular systolic function are still normal. Therefore, the ultrasonic tissue characterization could be useful in the precocious detection of alterations of the myocardial " texture" in sistemic amyloidosis, which could be in relationship to deposit of amyloid at myocardial level.

COMPARATIVE MYOCARDIAL IMAGING

P1634 Assessment of segmental wall motion using real-time magnetic resonance imaging: comparison with 2D echocardiography and breath-hold true FISP

H.P. Kühl[1], A. Bücker[2], A. Wall[3], E. Spüntrup[2], A. Franke[3], R.W. Günther[2], P. Hanrath[3]. [1]*University Hospital, Medical Clinic I, Aachen, Germany;* [2]*University Hospital, Department of Radiology, Aachen, Germany;* [3]*University Hospital RWTH, Medical Clinic I, Aachen, Germany*

Non-triggered, non-breath-hold real-time cardiac MRI may be a valuable alternative to echocardiography for the assessment of regional wall motion in patients with poor acoustic window. We compared standard 2D echocardiography with second harmonic imaging (ECHO) to two different interactive real-time MRI techniques using 1) a spiral gradient echo sequence (SPIRAL; TE/TR 4/30 ms, 3 interleaves, matrix 128x256) and 2) a radial true FISP sequence (RADIAL, TE/TR 1.3/2.9 ms, 80 radials, matrix 128x128). An ECG-triggered, breathhold trueFISP sequence (BH-TF, TE/TR 1.8/3.6ms, matrix 128x256) was used as reference standard for wall motion assessment. MRI was performed on a 1.5 T scanner (ACS-NT, Philips, Best, The Netherlands). An interactive user interface allowed on-the-fly free plane definition during real-time scanning. With all modalities standard views including a mid-ventricular short-axis view and 3 long-axis views were acquired. Segmental endocardial visibility (0=poor to 2=good) and regional wall motion (0=not evaluable to 4 dyskinesia) were scored according to the 16 segment model of the ASE for all techniques. 33 non-selected patients referred for routine echocardiography were included.

Results: Nine patients had atrial fibrillation. Out of matched 528 segments acquired with all four modalities poor visibility was present in 18.6% of segments with ECHO, 14.5% with SPIRAL (ns vs. ECHO), 1.4% with RADIAL ($p<0.001$ vs. ECHO and SPIRAL) and 0.4% with BH-TF (ns vs. RADIAL). For the short-axis view the percentage of segments with good image quality was *not* different between the three MRI approaches but was significantly larger compared to ECHO ($p<0.001$). However, for the long-axis views the percentage of segments with good image quality was least for SPIRAL ($p<0.05$ compared to ECHO) and largest for RADIAL and BH-TF ($p<0.001$ vs. ECHO; p=ns vs. RADIAL). There was a tendency for a higher mean wall motion score for ECHO compared to BH-TF (p=0.06). Agreement on the scoring of regional wall motion relative to BH-TF increased form ECHO (Kappa 0.71) to SPIRAL (Kappa 0.84) to RADIAL (Kappa 0.92).

Conclusion: Interactive real-time MRI using RADIAL is of similar quality to standard BH-TF and superior to ECHO and SPIRAL for the visualization of segmental wall motion in this group of unselected patients. RADIAL may complement echocardiography for the assessment of regional function in patients with a limited acoustic window.

P1635 Quantitative myocardial perfusion imaging in a combined PET-CT scanner: CT- versus germanium-transmission using different reconstruction algorithms

P. Koepfli[1], C.A. Wyss[2], C. Burger[2], T. Berthold[2], C. Britt[2], T.F. Hany[2], G.K. von Schulthess[2], P.A. Kaufmann[2]. [1]*University Hospital, Nuclear Cardiology, Cardiovasc. Center, Zurich, Switzerland;* [2]*University Hospital, Nuclear Cardiology, Cardiovasc. Center, Zurich, Switzerland*

Background: In routine PET-scanning a 20 minute transmission scan for attenuation correction with a rotating 68 Germanium (Ge) source - reconstructed iteratively (IT) or with filtered backprojection (FBP) - is commonly used. This is a time-consuming procedure which could be considerably shortened by use of a rapid CT-scan for attenuation correction.

Aim: To evaluate the influence of reconstruction parameters on absolute values of myocardial blood flow (MBF) using conventional transmission scans vs. CT scans for attenuation correction in a combined PET-CT scanner (GEMS, Milwaukee, USA).

Methods: 13N-labelled NH3 and PET was used to measure MBF (ml/min/g) at rest in 4 patients with documented coronary artery disease. Emission was preceeded and followed by three CT scans (140 kV, 10 mA, scan length 15cm, rotation time 0.5 sec., total scan time 3.7 sec.) and one Ge transmission. Emission was then reconstructed using CT (n=24) vs. Ge (n=8) for attenuation correction, both with IT and FBP.

Results: Values for MBF (given in ml/min/g) at rest were: Ge(FBP) 0.75 ± 0.14, Ge(IT) 0.76 ± 0.21 (p=ns); CT(FBP) 0.80 ± 0.10, CT(IT) 0.74 ± 0.20 ($p<0.05$). The reproducibility coefficient for comparison of each measurement to conventionally corrected PET is given below according to Bland and Altmann (1.96 x SD of mean difference).

Conclusions: Use of CT attenuation correction is feasible and provides results which are highly comparable to those achieved by Ge attenuation correction. However, use of the same reconstruction algorithm is crucial.

P1636 The correlation between myocardial absolute uptake of ^{99m}Tc-MIBI and pressure-derived myocardial fractional flow reserve in the LAD versus RCA

T. Morishima, T. Chikamori, T. Hatano, H. Yanagisawa, Y. Usui, S. Hida, K. Harafuji, A. Yamashina. *Tokyo Medical University, 2nd Department of Internal Medicine, Tokyo, Japan*

The development of coronary pressurewire facilitates the measurement of fractional flow reserve (FFR) to assess the functional severity of coronary-artery stenoses. To evaluate the correlations between FFR and myocardial absolute uptake of 99mTc-MIBI in LAD versus RCA, 34 patients underwent 99mTc-MIBI SPECT with two-day protocol using 740MBq of 99mTc-MIBI each day. Quantitative analysis with the measurement of percent uptake and absolute count of 99mTc-MIBI was performed. In all patients, exercise-induced increase in 99mTc-MIBI percent uptake and absolute count correlated with FFR ($r=0.42$, $p<0.02$ and $r=0.38$, $p<0.03$, respectively). In 22 patients in whom LAD was evaluated, the best correlation of $r=0.58$ ($p<0.005$) was found between exercise-induced increase in 99mTc-MIBI absolute count and FFR, followed by the correlation ($r=0.50$, $p<0.02$) obtained with exercise-induced increase in 99mTc-MIBI percent uptake. In the remaining 12 patients in whom RCA was evaluated, no significant correlation was observed between exercise-induced 99mTc-MIBI increase either with relative or absolute count measurements. These results suggest that noninvasive assessment of coronary physiology may be limited in RCA, due partly to the influence of RI count of extracardiac organs such as the liver. In LAD, however, 99mTc-MIBI scintigraphy using quantitative analysis enables the noninvasive assessment of the magnitude of functional significance of coronary artery stenosis, which is far more important than the conventional evaluation of the coronary lumen.

P1637 Comparison of dobutamine echocardiography and dual SPECT (^{201}Tl and ^{123}I-BMIPP) for prediction of functional recovery after acute myocardial infarction

N. Yasugi[1], S. Koyanagi[1], K. Oozono[2], K. Sakai[2], S. Sako[2], T. Matsumoto[2], T. Hiroki[3]. [1]*National Hukuoka-Higashi Hospital, Cardiology, Koga, Japan;* [2]*National Kyushu Medical Center, Cardiology, Fukuoka, Japan;* [3]*Fukuoka University Chikushi Hospital, Internal Medicine, Chikushino, Japan*

Purpose: Discordance between I-123 BMIPP and Tl-201 SPECT is an effective method to assess myocardial viability (MV). This study was performed to compare low dose dobutamine echocardiography (LDDE) and dual SPECT for assessment of MV and prediction of functional recovery after acute myocardial infarction (AMI).
Methods: LDDE and dual SPECT were studied in 35 pts 7 to 14 days after AMI, of which 28 pts underwent coronary revascularization at the acute stage. Assessment of dual SPECT was performed by comparing defect score of I-123 BMIPP and Tl-201, and MV was considered positive when difference of the defect score was significant. Left ventricular wall motion score (WMS) was estimated, and MV was considered positive when WMS decreased during LDDE. Echocardiography was performed 6 month later to assess functional recovery of the dysfunctional myocardium.
Results: The rate of agreement of MV between dual SPECT and LDDE in early stage of MI was 77% ($P<0.01$). In 22 pts with positive MV by SPECT, LDDE showed MV in 16 (positive predictive value = 73%). In 13 pts with negative MV by SPECT, 11 showed negative MV by LDDE (negative predictive value = 85%). The long -term functional recovery was observed in 20 of 33 pts (60%). The positive and negative predictive values for functional recovery by dual SPECT were 73% (16/22) and 64% (7/11), respectively ($p<0.05$). The positive and negative predictive values for functional recovery by LDDE were 100% (18/18) and 87%(13/15), respectively ($p=0.00001$). Five of 6 pts with positive MV by dual SPECT without functional recovery had residual stenosis at the infarct-related arteries.
SPECT score was compared in pts with and without functional recovery. Both 201-TlCl and 123I-BMIPP scores were significantly smaller in pts with functional recovery ($p<0.01$), but the difference of the two scores was greater in pts with functional recovery ($p<0.01$).
Conclusion: Assessment of MV using LDDE is concordant with those by dual SPECT in the early stage of AMI. LDDE had a higher predictive value for long - term functional recovery at the infarct area in comparison with dual SPECT. However, positive MV by dual SPECT without functional recovery may reflect residual stenosis at the infarct-related arteries. Thus, combining assessment of dual SPECT and LDDE is an useful method to detect myocardial viability and residual stenosis at the infarct-related vessels and to predict long-term functional recovery. In addition, the study suggested that the extent of myocardial viability was greater in pts with smaller size of infarct or risk area.

P1638 Contrast-enhanced MRI for the assessment of myocardial viability: comparison with ^{18}F-fluorodeoxyglucose-positron emission tomography

H.P. Kühl[1], A.M. Beek[2], A.P. van der Weerdt[2], C.A. Visser[2], F.C. Visser[2], A.C. van Rossum[2]. [1]*University Hospital, Medical Clinic I, Aachen, Germany;* [2]*VU University Medical Center, Department of Cardiology, Amsterdam, Netherlands*

Contrast-enhanced (CE) MRI has been shown to predict recovery of function after revascularization in patients with chronic coronary artery disease. The value of the technique in comparison to the in-vivo gold standard for viability assessment, 18F-Fluorodeoxyglucose positron emission tomography (FDG-PET), is not fully established. We compared CE-MRI to FDG-PET in 23 patients with chronic ischemic heart disease and left ventricular dysfunction referred for myocardial viability assessment. For CE-MRI an inversion-recovery gradient-echo sequence (TE/TR 4.4/9.6 ms, FA 25°, typical TI 250-300 ms, resolution 1.3x1.6x5mm) was used on a 1.5T MR scanner (Magnetom Sonata, Siemens, Erlangen, Germany) 20 minutes after administration of 0.2 mmol/kg Gadolinium-DTPA. Data acquisition was performed in short-axis views covering the whole left ventricle and in selected long-axis views. FDG-PET was performed under hyperinsulinemic euglycemic clamp (ECAT EXACT HR+, Siemens, CTI). Resting perfusion was assessed using SPECT. For data analysis we used a 17-segment model including 6 basal, 6 midventricular, 4 distal segments and the apex. According to PET/SPECT findings segments were categorized as either viable or non-viable. Results of quantitative FDG-PET analysis were compared to the segmental extent of hyperenhancement (SEH) at CE-MRI in corresponding segments.
Results: Mean ejection fraction was 31±11%. A total of 391 segments were analyzed with both techniques. Viable segments by FDG-PET showed significantly less SEH compared to non-viable segments (8.5±16.3% vs. 80.2±23.1%; $p<0.001$). The segmental glucose uptake at PET was inversely related to the SEH ($r=-0.78$; $p<0.001$). By ROC analysis the area under the curve was 0.97. Using a cutoff value of 37% given by the ROC curve the accuracy for identification of myocardial viability was 94% in all segments and 88% in akinetic segments with a high level of agreement (Kappa 0.77).
Conclusion: CE-MRI has comparable diagnostic accuracy as PET for the evaluation of myocardial viability in patients with chronic ischemic heart disease and left ventricular dysfunction.

P1639 Magnetic resonance angiography versus conventional coronary angiography to diagnose coronary artery disease

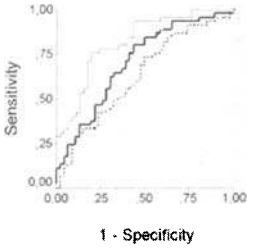
M. Schlueter, T. Tuebler, J.-C. Steffens, J. Schofer. *Center for Cardiology, Hamburg, Germany*

Magnetic resonance angiography (MRA) has recently emerged as an alternative to the "gold standard" of conventional coronary angiography (CA) for the diagnosis of coronary artery disease. Sensitivity and specificity of MRA still need to be established. Methods: Thirty-three consecutive pts (23 m; 60 ± 11 years) with suspected, or suspected progressive, coronary artery disease underwent MRA prior to CA. MRA and CA findings were evaluated independently by a radiologist and a cardiologist, respectively. Only stenoses > 50% by visual assessment were entered into the analysis. Results: On CA, 14 pts had no lesions, whereas the other 19 pts had a median of 1 (range 1-4) lesion, for a total of 32 lesions. There were 7 lesions in the left anterior descending coronary artery (LAD), including 3 in the first diagonal branch, 11 in the left circumflex coronary artery (LCx), including 4 in the obtuse marginal branch, 13 in the right coronary artery (RCA), and 1 in the left main coronary artery. The former 3 arteries were divided into proximal, medial and distal segments. Sensitivity and specificity of MRA (with CA findings serving as reference) in diagnosing LAD lesions were 57.1 and 61.5%, respectively, with 30.3% false positive (FP) and 9.1% false negative (FN) findings. Corresponding values for the LCx were 63.6 and 63.6%, respectively (FP 24.2%, FN 12.1%), and for the RCA 84.6% and 95.0%, respectively (FP 3.0%, FN 6.1%). When sidebranches and distal vessel segments were excluded from the analysis, MRA sensitivity and specificity improved to 80.0 and 75.0% (LAD), 100 and 74.1% (LCx), and 91.7 and 95.2% (RCA), respectively. Of the 33 pts, only 1 pt (3%) who had a 90% stenosis of the medial RCA on CA was diagnosed by MRA as having no lesions. Conclusion: MRA has a high sensitivity and specificity in diagnosing proximal and medial coronary artery lesions. The diagnostic accuracy of the technique needs to be improved for distal lesions and sidebranches before MRA can supplant CA.

P1640 NOGA electromechanical mapping versus PET in prediction of post-revascularization myocardial function in patients with severe heart failure

H. Wiggers[1], H.E. Bøtker[1], P. Søgaard[1], A. Kaltoft[1], F. Hermansen[2], W.Y. Kim[1], L. Krusell[1], L. Thuesen[1]. [1]*Skejby Hospital, Dept of Cardiology, Aarhus, Denmark;* [2]*Aarhus Kommunehospital, The PET center, 8000 Aarhus C, Denmark*

We compared catheter-based electromechanical mapping (NOGA®) with PET for prediction of reversibly (RDM) and irreversibly dysfunctional myocardium (IDM) in pts with ischemic cardiomyopathy. Furthermore, we identified the optimum discriminatory value of NOGA measurements for distinction between RDM and IDM.
Methods: 20 pts (19 males, age (mean±SD) 60±16 years, EF 29±6%) underwent viability testing with NOGA and PET prior to CABG (N=11) or PTCA (N=9). MRI and 3-D echocardiography was performed at baseline and 6 months after revascularization (9 segment model) to identify RDM and IDM regions.
Results: EF increased to 34±13% 6 months after revascularization ($P<0.05$ vs baseline). The correlation between regional myocardial PET tracer uptake and NOGA unipolar voltage amplitude (UVA) was modest ($r=0.29$, $P<0.01$). The 58 RDM and 57 IDM regions differed with regard to UVA (9.2±3.9 mV vs 7.6±4.0 mV, $P<0.05$), normalized UVA (106±54% vs 75±39%, $P<0.05$), and tracer uptake (76±17% vs 60±20%, $P<0.05$). NOGA local shortening did not distinguish between RDM and IDM (6.4±5.8% vs 5.4±6.6%). By ROC-curve analysis (figure) PET tracer uptake had better diagnostic performance than UVA (area±SE: 0.82±0.04 vs 0.63±0.05, $P<0.05$) and normalized UVA (area 0.70±0.04, $P<0.05$ vs tracer uptake). Optimum threshold was defined as the value yielding sensitivity = specificity for prediction of RDM. Sensitivity and specificity was 59% at a UVA of 8.4 mV, 65% at a normalized UVA of 83%, and 78% at a tracer uptake of 69%.



ROC-curve analysis. Upper curve: PET tracer uptake; Middle curve: NOGA normalized UVA; Lower curve: NOGA UVA.

Conclusions: NOGA can discriminate between RDM and IDM using UVA. However, the diagnostic characteristics of PET are superior to NOGA in pts with severe heart failure. Optimum discriminatory values for absolute and normalized UVA are 8.4 mV and 83%, respectively.

P1641 Blood oxygen level dependent (BOLD) MRI for the detection of scarred and viable myocardium, a PET comparative study

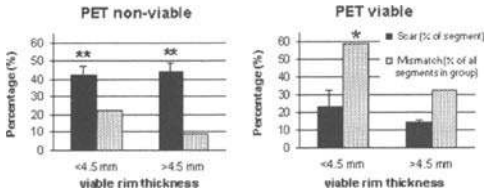
M. Egred[1], A. Al-Mohammad[1], G. Waiter[2], T. Redpath[2], S. Semple[2], A. Welch[3], M. Norton[3], S. Walton[1]. [1]*Aberdeen Royal Infirmary, Cardiac Research, Aberdeen, United Kingdom;* [2]*University of Aberdeen, Biomedical Physics, MRI unit, Aberdeen, United Kingdom;* [3]*Aberdeen Royal Infirmary, Pet scan centre, Aberdeen, United Kingdom*

The identification of impaired but viable myocardium in patients with coronary heart disease is of crucial clinical importance since it is likely to benefit from revascularisation. Positron Emission Tomography (PET) is the gold standard in detecting viable myocardium. However, it is expensive and not widely available.
Aim: to investigate the use of a new modality of magnetic resonance imaging (MRI), Blood Oxygen Level Dependent (BOLD) that relies on changes in deoxyhaemoglobin level under stress, in the detection of scarred and viable myocardium in comparison to PET images.
Method: nineteen patients with established coronary artery disease and impaired left ventricular contraction and at least one area of akinesis, underwent a rest and dipyridamole stress MRI, using a double breath hold T2* weighted, ECG gated sequence to produce BOLD contrast images. A dynamic 13N-ammonia (13NH3) and ECG gated 18F-fluorodeoxyglucose (FDG) PET scans followed the MRI. The signal change on BOLD MRI and Wall thickening were compared between rest and stress images in the viable and scarred segments, identified on PET scans. Scarred myocardium is defined by the matched decrease in perfusion and metabolism, while the presence of perfusion-metabolism mismatch defects defines impaired but viable myocardium.
Results: Two short axis slices of mid ventricle, with 8 segments each, were analysed giving a total of 304 segments. The slices were matched anatomically between MRI and PET. Using PET, 68 segments were identified as viable and 42 segments as scarred tissue. The viable segments were found on MRI to have an average signal change of –9.53 between rest and stress, while the average signal change in the scarred segments was –2.15 (P=0.008). The average wall thickness in the viable segments was 8.7 mm compared to 5.9 mm in the scarred segments (P<0.0001).
Conclusion: BOLD MRI with measurement of wall thickness may be used for detection of scarred and viable myocardium and help in identifying suitable patients for revascularisation. Further larger studies are needed to establish sensitivity and specificity.

P1642 Quantification of viable rim thickness by contrast-enhanced magnetic resonance of dysfunctional myocardium and its relation to metabolic state

J. Schwitter[1], P.R. Knuesel[2], D. Nanz[2], C. Wyss[3], M. Buechi[1], P.A. Kaufmann[3], T.F. Luescher[1], G.K. von Schulthess[3]. [1]*Division of Cardiology, DIM,* [2]*Radiology,* [3]*Nuclear Medicine, Zurich, University Hospital Zurich, Switzerland*

Background: Metabolic assessment of dysfunctional myocardium by PET allows prediction of recovery of contractile function following revascularization. Contrast-enhanced MR was used to determine the transmural distribution of viable tissue and scar in PET-viable and non-viable myocardium.
Methods and results: Seventeen patients with old myocardial infarctions were studied with MR and PET. In 56-64 segments/heart mass and thickness of viable tissue on MR (0.25mmol/kg of GD-DTPA-BMA, inversion recovery technique) was compared with 18F-fluorodeoxy-glucose (FDG)-uptake of corresponding segments. Mass of viable tissue and FDG-uptake (both normalized to the segment with highest resting flow on 13N-ammonia-PET) correlated (p<0.0001) with both, segments with balanced flow-metabolism (ratio <1.4; r=0.82) and slightly worse with mismatch segments (r=0.62). A ROC analysis yielded a sensitivity/specificity of 91%/86% (AUC 0.94) for MR to detect viable myocardium (≥50% FDG-uptake). Rim thickness correlated with FDG-uptake (r=0.80). FDG-uptake of ≥50% predictive for functional recovery coincided with a rim of 4.5mm. 82% of all dysfunctional segments were viable on PET, in 96% of these segments viable rim was ≥4.5mm and scar was low 14±1% (mean±SEM, figure, **p<0.001 vs PET-non-viable). In the remaining 4% with a small rim (<4.5mm) the portion of mismatch segments was highest (59%, figure, *overall-p<0.005). In 47% of PET-nonviable segments a viable rim ≥4.5mm was found with a scar mass as high as in segments classified non-viable by both techniques.



Conclusions: Contrast-enhanced MR detects viable tissue with high sensitivity and specificity. Combining MR and PET findings identifies different subsets of myocardial segments which may improve prediction of functional recovery.

PERCUTANEOUS CORONARY INTERVENTION OUTCOMES

P1643 Long-term outcome of stenting of bifurcation lesions, based on side branch size and stenosis

R. sundrani, A. Hussain, B. Lewis, M. Sochanski, L. Steen, E. Grassman, F. Leya. *Loyola University Medical Center, Interventional Cardiology, Maywood, United States of America*

Background: Percutaneous Coronary intervention (PCI) of bifurcation lesions pose increased risk of complications. The impact of side branch size and stenosis on the long term outcome of PCI of these lesions is not well known.
Methods: We retrospectively analyzed 700 consecutive angioplasty films and identified 71 patients (10.1%) with bifurcation lesions meeting study criteria. All patients had successful main vessel PCI & stenting with or without side branch PCI. Patients were divided into 3 study groups based on side branch PCI: Group I had successful side branch rescue PCI, Group II had acute side branch occlusion and failed rescue PCI, Group III had small side branch, which did not warrant PCI, but had post procedural side branch residual stenosis of > or equal to 70%. Each patient received standard doses of I.V heparin, Gp II b/IIIa inhibitors and clopidogrel.
Results: Refer to the table below for results. Severely stenosed large side branch (Grp II) are more likely to close during PCI and have worse clinical outcome. Patients with successful rescue PCI of large side branch (Grp I) as well as patients without rescue PCI of smaller side branch (Grp III) have good short and long term outcome.
Conclusions: Aggressive strategies to preserve large side branches result in much better clinical outcome.

Abstract P 1643 – Table: Outcome of Bifurcation Lesions

Groups	Size of the side branch	Pre PCI stenosis (side branch)	Post PCI stenosis (side branch)	Residual side branch stenosis	Death	In Hospital MI	Recurrent Angina	CABG at Follow-up	PTCA at Follow-up	Follow-up (months)
I (n=49)	2.6+0.3 mm	70.2+6%*	88.4+4.7%**	14+4.3%	0%	0%	34%	20%	14%	18+4.1

P1644 Stent treatment of bifurcated coronary lesions: clinical and angiographic results of a French multicenter study

R. Koning[1], B. Huret[2], C. Caussin[3], O. Tavolaro[4], S. Sayah[5], P. Garot[6], J. Bille[7], M. Bedossa[8]. *[1]Clinique St Hilaire, Rouen, France; [2]CHP St martin, Caen, France; [3]M. Lannelongue, Centre Chirurgical, Le Plessis Robinson, France; [4]La Roseraie, Cardiologie Interventionnelle, Aubervilliers, France; [5]University Hospital, Cardiology, Compiegne, France; [6]University Hospital, Cardiology, Creteil, France; [7]CHP Résidence du Parc, Cardiology, Marseille, France; [8]Dpt de cardiologie medicale CHU RENNES, 35033, rennes, France*

Major bifurcated lesions offer a wide variety of anatomic and angiographic features with no standardized percutaneous approach. The aim of this study was to evaluate clinical, technical and angiographic results of treatment of bifurcated coronary lesions, prospectively included in 19 centers from January to August 2001, using in all cases the same slotted tube stent (Helistent, Hexacath.). All patients (pts) had symptoms of ischemic heart disease. Bifurcated lesions were defined by a lesion located in a main vessel (MV) > 3mm including a side-branch (SB) > 2mm. Pts were pretreated with clopidogrel-aspirin. Quantitative coronary angiographic analysis (QCA) was performed off-line by an independant core-lab. Complete angiographic success was defined by a diameter stenosis < 50% in the main vessel and side branch with a normal flow.
Results: 253 pts (63 ± 11 years, 80% males) were included and 316 Helistents (250 in main artery, 66 in side-branch) were implanted in left anterior descending-diagonal (52%), circumflex-obtuse marginal (25%) and right coronary-posterior descending (23%). Six-french guiding catheter was used in 80% pts and in 67% of pts a second wire was placed in the side branch. On QCA, reference diameter of MV and SB were respectively 3.13 ± 0.36 mm and 2.37 ± 0.33 mm. Direct stenting in MV was performed in 42% of pts, kissing balloon in 41% and the T stent technique in only 25%. Despite no lesion before the procedure, the SB was compromised in 22% pts and needed subsequent PTCA. The complete angiographic success rate was 93%. Major in-hospital cardiac events occurred in 5 pts (2%; 1 death, 3 non fatal myocardial infarction, 1 rePTCA). At 6-month follow-up (93% of pts) only 1 pt died. A target lesion revascularization was performed in 26 pts (12%, including 4 bypass-grafts)
Conclusions: Despite the complexity of treatment of bifurcation lesions, this multicenter prospective study demonstrates excellent immediate clinical and angiographic results and a low incidence of target lesion revascularisation at mid term follow-up.

P1645 Coronary stenting versus stent-like balloon angioplasty: one-year clinical follow-up results

F. Addad[1], H. Gamra[2], K. Ben Hamda[1], F. Betbout[1], F. Maatouk[1], Z. Dridi[1], M.A. Zidi[1], M. Ben Farhat[1]. *[1]University Hospital, Monastir, Tunisia; [2]University Hospital, Cardiology department, Monastir, Tunisia*

Coronary stenting reduces the rate of angiographic restenosis and improves short-term clinical outcome. However, management of in-stent restenosis is often complex and the high cost of drug eluting stent will be an economic burden in limited ressources countries.
The aim of our study was to compare the one-year clinical outcome of patients (pts) who had a stent-like result following balloon angioplasty (PTCA) to the ones who had a coronary stenting in a non-selected population.
Methods: The results of "stent like" PTCA (post-procedural residual stenosis < 10%) in 333 pts were compared to the ones in 189 pts with stent implantation. The baseline clinical characteristics were similar between the two groups in particular with regard to diabetes(37.2% vs 38.6%, p=NS). There were more complex lesions (type B2-C) in the stent group (49% vs 25%, p<0.01).
Results: Minimal luminal diameter after the procedure was similar between the 2 groups (2.75±0.6 balloon PTCA vs 2.6±1.1mm for stent, p=NS). At a mean follow-up of 7±1 months angiographic restenosis was 35.8% after stent-like result versus 36.2% after elective stenting, p=NS.
There was no difference between the balloon PTCA and stent groups respectively with regard to the incidence of death(0.6% vs 1.5%), myocardial infarction (0.9% vs 1.5%) and target lesion revascularisation (20% vs 17%).
Conclusions: These results suggest that stent-like balloon angioplasty is a reasonable approach for the treatment of coronary lesions.

P1646 Coronary angioplasty – a real alternative to coronary artery surgery in diabetics with multi-vessel disease: a prospective registry 1998–2000

A. Kapur, D. Bartolini, E. Mostafavi, K.J. Beatt. *Hammersmith Hospital, Department of Cardiology, London, United Kingdom*

Background Limited data from randomised controlled trials of coronary artery bypass grafting (CABG) versus coronary angioplasty (PCI) suggest better survival in the CABG arms. However, registry data from these and other studies, show that when diabetics are treated in accordance with physician preference the results are more variable.
Objective To use prospective registry data to
(a) define the clinical and angiographic characteristics of diabetics undergoing coronary revascularisation according to physician preference
(b) to report clinical outcome at hospital discharge and at one year follow-up
(c) to track any change in clinical practice pertaining to coronary intervention in diabetics over the time of the study
Methods Between January 1998 and December 2000 we prospectively identified diabetic patients with multivessel coronary artery disease undergoing cardiac catheterisation, defined as at least two vessels with narrowings of 50% or more.
Results Of 7850 coronary angiograms, 1409 (17.9%) were in diabetics of whom 739 patients had multivessel disease. CABG was performed in 230 (31.1%), PCI in 272 (36.8%) whilst 237 (32.1%) were treated medically. Angiographically, the number of diseased vessels ((mean (SD)) was significantly higher in the CABG group 2.91 (0.53) versus the PCI group 2.48 (0.53) and the medically treated group 2.73 (0.58) p<0.001. The number of vessels revascularised (mean(SD)) in the CABG group 3.15 (0.56) was greater than in the PCI group 1.36 (0.56) p<0.0001, but this difference decreased over the course of the study. Clinical differences at baseline among the groups were not marked, although there were significantly more patients managed urgently by PCI as compared with CABG. In hospital mortality was 2.2% in the PCI group and 3.5% in the CABG group. Cardiogenic shock was related to increased mortality in the PCI group, whilst significant left main stem disease (>50% stenosis) was a predictor of poor outcome in the CABG group. Rates of repeat revascularisation at one year were 23.9% in the PCI group and 2.2% in the CABG group (p<0.0001).
Over 60% of one year follow up of MACE (Major Adverse Cardiac Events) is complete and thus far one year mortality did not differ between the two groups.
Conclusion Detailed registry data can differ from that obtained from randomised trials and may give valuable insight into management decisions in high risk diabetics.

P1647 Stenting during coronary intervention improves procedural and long-term clinical outcomes in diabetics

R. Siegel[1], A. Bhaskaran[1], B. Barker[1], N. Goldberg[2], T. Khalil[1], S. Young[1], J. Vermillion[1], S. Christison[1]. *[1]Advanced Cardiac Specialists, Cardiovascular Research, Phoenix, United States of America; [2]Advanced Cardiac Specialists, Interventional Cardiology Dept., Phoenix AZ, United States of America*

Diabetes is an adverse risk factor for restenosis following transcatheter intervention. Limited data is available on long-term outcomes following stenting (ST) in diabetics. We evaluated procedural and 12-month clinical outcomes following ST versus optimal PTCA in diabetics who underwent coronary intervention at our center. From 1/98 to 1/02, 1,428 diabetic patients (mean age 64 years; 45% female) presenting with acute coronary syndromes, underwent PTCA (N=911) or ST (N=517). Co-morbid factors included age >70, 32%; prior MI, 31%; prior CABG, 24%; EF <40%, 22%; multivessel disease, 18%; cardiogenic shock, 3%. ST vessels were > or =3.0 mm in diameter. Adjunctive IABP support was employed in 17.4%. Results: Procedural success (TIMI 3 flow; residual stenosis <20%) was 96% with PTCA and 99% with ST (p=0.002). CABG rate was 0.9% with PTCA and 0.2% with ST (p=0.13), with 3 (0.3%) deaths in the PTCA group (p=0.13). There was no subacute ST thrombosis in either group. At 12-month follow up, the incidence of re-PTCA (6.2% vs 4.8%; p=0.09) and CABG (4.5% vs 1.4%; p=0.88) were higher in the PTCA group but this did not reach statistical significance. Cardiac mortality was significantly lower in the ST group (1.4% vs 4.1%; p=0.04). Mean rise in LVEF was significantly higher in the ST group (4.48% vs 1.42%; p=0.04). Event-free survival was significantly higher in the ST group (93% vs 81.2%; p=0.03).
Conclusions: 1. In this large series of diabetic patients, procedural success was significantly better in coronary lesions treated with ST, compared to optimal PTCA. 2. In-hospital event rates were comparable. 3. At 1-year follow-up, absolute and event-free survival were significantly better in the ST group. 4. Long-term index lesion revascularization rates were lower with ST. 5. The ST cohort showed significant increase in LV systolic function, compared to the PTCA group. 6. In diabetics, routine stenting of coronary lesions should be considered, as acute and long-term clinical outcomes, including survival, appear to be significantly superior to optimal balloon PTCA results.

Abstract 1648 – Table

	large vessels short lesions	large vessels long lesions	small vessels short lesions	small vessels long lesions
No lesions thin:thickstrut	group I, 881 (452:429)	group II, 298 (98:200)	group III, 532 (219:313)	group IV, 151 (58:93)

P1648 Effect of strut thickness on angiographic restenosis rate after coronary stenting

G.S. Stankovic, M.F. Ferraro, K.T. Toutouzas, C.B. Briguori, N.C. Corvaja, R.A. Albiero, C.D.M. Di Mario, A.C. Colombo. *EMO Centro Cuore Columbus, Milan, Italy*

The study was performed to evaluate the effect of stent strut thickness on angiographic restenosis rates in different subsets of coronary vessel sizes and lesion lengths.

Methods: Coronary lesions situated in native vessels and treated with a single stent, for whom angiographic follow up was obtained, were selected for this analysis. In-stent restenotic lesions, lesions treated with radiation therapy, and chronic total occlusions were excluded. A total of 1862 lesions, from 1428 patients remained for the analysis.

Twenty-six different stent types (slotted tube and ring design) were implanted, and according to strut thickness were divided in thin-strut (strut thickness of <0.1mm) and thick-strut (strut thickness of >=0.1mm) groups.

Coronary lesions were divided into 4 groups according to various combinations of reference vessel size (Ref) and lesion length (LL): group I – Ref >=2.8mm and LL <15mm; group II - Ref >=2.8mm and LL >=15mm; group III - Ref <2.8mm and LL <15mm; and group IV - Ref < 2.8mm and LL >=15mm.

Results: There were no significant differences in baseline lesion characteristics inside groups. Procedural and follow up angiographic results for thin-strut vs. thick-strut stents are shown in table. In large vessels with focal lesions significantly higher angiographic restenosis rate was found in the thick-strut group (RR, 1.76; 95%CI, 1.26-2.44).

Conclusion: Implantation of a thin-strut stent is associated with a significant lower late lumen loss in focal lesions. In long lesions there is only a numerical difference favoring thin-strut stents. This fact could be a consequence of the smaller number of lesions or of the impact of other factors in this higher risk group.

P1649 Comparison of direct stenting with optimal balloon angioplasty: intermediate results from Polish randomized, multicenter trial

R. Gil[1], T. Pawlowski[2], K. Zmudka[3], D. Dudek[3], G. Horszczaruk[4], M. Lesiak[5], A. Witkowski[6], J. Kubica[7] on behalf of Direct Stenting vs Optimal Angioplasty Investigators. [1]*Invasive Cardiology Department, Central Hospital of Internal Affairs, Warsaw, Poland;* [2]*Pmeranian Academy of Medicine, Cardiac Catherisation Laboratory, Szczecin, Poland;* [3]*Colegium Medicum UJ, Cardiac Catherisation Department, Cracow, Poland;* [4]*Medical Academy, Department of Cardiology, Warsaw, Poland;* [5]*Medical Academy, Department of Cardiology, Poznan, Poland;* [6]*National Institute of Cardiology, Cardiac Catherisation Laboratory, Warsaw, Poland;* [7]*Medical Academy, Department of Cardiology, Bydgoszcz, Poland*

Background: Selection of the most effective percutaneous intervention (PTCR) for patients with coronary stenoses has not been clearly defined yet. It is likely that proper PTCR guidance may improve their late results. Therefore we designed multicenter, randomized study comparing direct stenting guided with quantitative coronary angiography (QCA) or intracoronary ultrasound (ICUS) with optimal balloon angioplasty guided with ICUS or fractional flow reserve (FFR).

Methods: Till September 2001, two hundred seventy nine patients (56 F, 123M, mean age 54±9y) were enrolled into our study. They were divided into 4 groups: Gr1-direct stenting guided with QCA (80 pts), Gr2-direct stenting guided with ICUS (83 pts), Gr3- optimal balloon angioplasty guided with ICUS (96 pts) and Gr4- optimal balloon angioplasty guided with FFR (20 pts). During 6 months follow-up we recorded evidence of MACE (death, myocardial infarction, target vessel revascularisation) and in case of recurrence of angina coronary angiography was performed

Results: Procedural success was achieved in 95% of cases, however crossover to stenting was necessary in 60 (62%) patients of Gr3 and in 2 (10%) of Gr4. Periprocedural complications (abrupt vessel closure or slow flow phenomenon) occurred only in Gr3, and 11 (11,4%) patients required use of ReoPro®. QCA measurements are presented in the table below. Among studied groups, biggest balloons were used in Gr2, resulting in largest postprocedural lumen. Lowest rate of MACE and restenosis at 6 months follow up were found in Gr 2. Comparison with other groups is presented in the table.

	Gr1	Gr2	Gr3	Gr4
MLD post (mm)	3,06±0,52	3,34±0,55#	2,94±0,62	3,0±0,59
RD pre (mm)	3,19±0,54	3,21±0,64	3,28±0,62	3,16±0,69
Balloon size (mm)	3,36±0,39	3,74±0,43*	3,14±0,55	3,15±0,65
MACE (%)	11,6	6,3*	17,7	13,3
Restenosis rate (%)	25	9,1**	12	20

*p<0,001 between Gr2 and Gr1,3,4 #p<0,05 between Gr2 and Gr3,4 **p<0,05 between Gr2 and Gr1

Conclusion: Our results suggest that ICUS guided DS is coronary intervention providing the biggest postprocedural lumen gain, that is responsible for better late patients outcome.

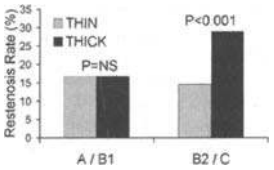
P1650 Lesion complexity makes differences in stent performance evident: lessons from the randomized ISAR-STEREO trial

J. Hausleiter[1], A. Kastrati[1], J. Mehilli[1], H. Schühlen[1], J. Pache[1], F. Dotzer[2], J. Dirschinger[1], A. Schömig[1]. [1]*Deutsches Herzzentrum München, München, Germany;* [2]*Krankenhaus Garmisch-Partenkirchen, Garmisch-Partenkirchen, Germany*

A number of stent vs. stent trials have not been able to disclose differences in stent performance at long-term follow-up. It has been hypothesized that this was caused by the inclusion of only non-complex lesions in these trials. However, the role of lesion complexity on the ability of the trial to distinguish between superior and inferior stents in terms of restenosis has not yet been investigated. The randomized ISAR-STEREO trial has shown, that reduced stent strut thickness is associated with a reduced risk for restenosis. The objective of this analysis was to investigate the role of lesion complexity to detect differences between the 2 stents tested in the ISAR-STEREO trial.

Methods: In ISAR-STEREO, 651 patients were randomized to receive either a thin-strut stent (Thin, n=326) or a thick-strut stent (Thick, n=325) with a comparable stent design. Angiographic follow-up was available in 80.6% of eligible patients (79.1 vs. 82.1% for Thin vs. Thick, p=ns). Lesion complexity was assessed using the modified ACC/AHA classification (type A to C).

Results: Non-complex (type A or B1) and complex (type B2 or C) lesions were treated in 25.3% and 74.7% of patients, respectively. The differential role of lesion complexity to detect differences in the restenosis rate between stent types is shown in the figure.



Restenosis results.

Conclusions: Significant differences in the long-term angiographic outcome were seen between thin- and thick-strut stents. These differences were only seen when complex lesions were treated. This finding may be relevant when planning new stent vs. stent trials.

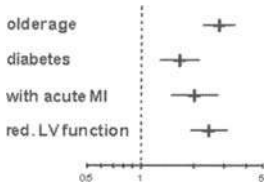
P1651 Predictors of late mortality after successful coronary stent placement

H. Schühlen[1], A. Kastrati[1], V. Eimannsberger[1], H. Holle[1], J. Hausleiter[1], J. Mehilli[1], J. Dirschinger[2], A. Schömig[1]. [1]*Deutsches Herzzentrum München, München, Germany;* [2]*Technische Universität, 1. Med. Klinik rechts der Isar, München, Germany*

The rationale for this analysis was to identify independent clinical and angiographic risk factors for long-term mortality after successful coronary stent placement.

Methods: We evaluated all 2362 patients with successful stent placement from May 1992 throughout December 1996. A clinical follow-up at four years was obtained in >90% of patients. We analyzed 40 clinical, angiographic and procedural variables for their association with 4-year mortality, followed by a multivariate model to identify independent factors.

Results: Mortality was 1.2% after 30 days, 5.9% at 1 year, 8.0% at 2 years, 9.8% at 3 years, and 11.7% at 4 years. There were several significant differences between patients who died during follow-up compared to those alive. In particular, they were older, had more frequently diabetes mellitus, a history of CABG, a reduced LV function and multivessel disease; more frequently they were treated for acute myocardial infarction, they had higher-grade stenoses before the procedure, which were less likely located in the LAD and required more stents to achieve procedural success. In the multivariate analysis, only the variables illustrated in the graph below were identified as independent factors for 4-year mortality (illustrated by their adjusted risk ± 95% confidence interval).



Independent predictors of mortality.

Conclusions: Older age, presence of diabetes mellitus, a reduced LV function and presentation with an acute myocardial infarction are all independent risk factors for 4-year mortality. These data suggest that lesion- and procedure-related factors do not have a significant impact on long-term mortality.

P1652 Primary stenting of occluded native coronary arteries: final results of the PRISON study

B. rahel[1], M.J. Suttorp[1], G.J. Laarman[2], E.T. Bal[1], E.G. Mast[1], J.M.P.G. Ernst[1], J.M. ten Berg[1], H.W.M. Plokker[1]. [1]*HLCU, location: St. Antonius Hospital, Cardiology, Nieuwegein, Netherlands;* [2]*Onze Lieve Vrouwe Gasthuis, Cardiology, Amsterdam, Netherlands*

Background: Primary or elective intracoronary stent placement after successfully crossing chronic total coronary occlusions may decrease the high restenosis rate at long-term follow-up compared with conventional balloon angioplasty.

Methods: In a prospective, two-center randomized trial, standard balloon angioplasty was compared with stent implantation for the treatment of chronic total occlusions. A total of 200 patients were enrolled. Patients were followed for 12 months with angiographic follow-up at 6 months. Quantitative coronary analysis was performed by an independent core lab.

Results: Baseline patient characteristics were evenly distributed. After the procedure the mean minimal luminal diameter (MLD) in the conventional group was 2.34±0.46mm versus 2.90±0.41mm in the stented group ($p<0.001$). The 6-month angiographic follow-up showed a mean MLD of 1.57±0.74mm in the conventional group versus 1.93±0.85mm in the stented group ($p=0.009$) and a mean diameter stenosis of 44.7±25.0% versus 35.5±26.5% ($p=0.036$). Binary angiographic restenosis (>50% diameter stenosis) was seen in 33% in the conventional group versus 22% in the stented group ($p=0.137$). The reocclusion rates were 7.3% and 8.2% respectively (p=ns). At 12 month follow-up, the rate of target lesion revascularization was significantly higher in the conventional group (29% versus 13%, $p<0.0001$).

Conclusions: Primary stenting of chronic coronary occlusions is superior to balloon angioplasty alone, improving angiographic results and reducing the need for target vessel revascularization, with a trend towards lower restenosis rates. It is striking that the 6 month angiographic results of both stent implantation and balloon angioplasty are superior to the results of all previously reported trials on this issue.

P1653 Outcome after treatment of coronary in-stent restenosis: results from a meta-analysis including 3012 patients

P.W. Radke[1], A. Kaiser[1], C. Frost[2], U. Sigwart[3]. [1]*RWTH University Hospital, Medical Clinic I, Aachen, Germany;* [2]*School of Hygiene & Tropical Medicine, Medical Statistics Unit, London, United Kingdom;* [3]*Hospitaux Universitaires, Centre de Cardiologie, Geneve, Switzerland*

The aim of this study was to evaluate the clinical outcome after treatment of coronary in-stent restenosis using descriptive statistics and meta-analysis methods.

Methods: For identification of the relevant literature a MEDLINE search from 1987 to 2001 was performed with restrictions (type of study: human) using a combination of the terms "Coronary", "Stent", "Restenosis", and "Treatment". This analysis intended to include all clinical trials conducted since 1987 (a) that described a study population treated for in-stent restenosis in a randomised or non- randomised fashion; (b) that used a specified technique to treat ISR; (c) that enrolled >30 patients; (4) that included a follow-up period >3 month; (5) that provided information on the rate of major adverse cardiac events (MACE) as defined by death, myocardial infarction or target lesion (vessel) revascularisation. Based on the selected literature, a systematic review using descriptive statistics and meta-analysis methods regarding the outcome after treatment of coronary in-stent restenosis was performed. The proportion of patients experiencing a major adverse cardiac event (death, myocardial infarction, target lesion revascularisation) was defined as the main outcome measure.

Results: A total of 1304 citations were identified. Among these, 28 studies (6 different treatment modalities: ballon angioplasty, stent-in-stent, rotational atherectomy, directional coronary atherectomy, LASER angioplasty, intracoronary radiation therapy) including a total of 3012 patients met the inclusion criteria and were incorporated into this analysis. The estimated average probability of experiencing a major cardiac adverse event after treatment for in-stent restenosis with a follow-up period of 9±4 months was 30.0% (25.0%- 34.9%, 95% CI) with strong evidence for heterogeneity between study specific results ($p=0.0001$). The clinical outcome was not significantly different between treatment modalities. After adjustment for confounding factors, however, patients undergoing intracoronary radiation showed an estimated advantage of 16.9% as compared to balloon angioplasty. The postinterventional diameter stenosis was a major predictor for the long-term outcome after treatment of in-stent restenosis.

Conclusions: Treatment of in- stent restenosis is associated with an overall 30% rate of major adverse cardiac events. Currently, repeat angioplasty is recommended for focal lesions and intracoronary radiation should be considered in cases with therapy refractory forms of diffuse in-stent restenosis.

P1654 Three dimensional intravascular ultrasound imaging is superior to coronary angiography in illustrating the vessel anatomy in diabetic patients

N. Yahya, B. Syeda, P. Wexberg, A. Stemberger, M. Gottsauner-Wolf, I. Lang, P. Siostrzonek, D. Glogar. *AKH-Wien, Cardiology Dept., Wien, Austria*

Background and Objective: Even though coronary angiography is the gold standard for imaging of the coronary arteries, the question remains open if coronary angiography is capable of outlining the diffusely diseased vessels in diabetic patients. We therefore aimed to compare postinterventional quantitative angiographic results with three- dimensional Intravascular Ultrasound (IVUS) imaging in diabetic patients undergoing coronary angioplasty.

Methods: Postinterventional IVUS images were obtained in 28 vessels of diabetic patients. Postinterventional minimal lumen diameter (MLD), reference diameters (RD), lengths of stenosis and percent diameter stenosis (%DS) were measured with a quantitative coronary angiography (QCA) edge-detection algorithm (ACOMPC, Siemens). Computer-assisted analysis was used to analyze the IVUS images in off-line mode (QCU-CMS, Medis). Volumetric quantification was performed by means of a semi-automated contour detection system and three-dimensional reconstruction. Volumetric measurement were performed every 0.1mm±0.05mm at the site of the lesion and at the proximal and distal reference segments. The vessel diameter and lumen diameter (VD and LD), as well as vessel area (VA) and lumen area (LA) were measured for each analyzed slice. Plaque area (PA) was calculated as VA minus LA. Volumetric plaque burden was calculated as the difference between vessel volume and lumen volume at the site of the lesion.

Results: Mean stenosis length was 13.2±4.5mm in QCA vs 17.1mm±9.0mm in IVUS ($p=0.02$). MLD was calculated as 2.56±0.54mm in QCA vs 2.4±0.5mm in IVUS (p=NS), %DS as 14.3±10.4% vs 27.23±6.5% ($p<0.001$), and VD as 3.0±0.5mm vs 4.5±0.7mm ($p<0.001$) respectively. Mean VA, LA and PA at the site of the lesion were 6.4±2.1mm^2, 16.6±3.7 mm^2 and 10.2±2.8 mm^2. Respective volumetric measurements were 275.6±129.1mm^3, 102.9±172.7mm^3, and 172.7±92.2mm^3.

Conclusion: Angiographic diagnosis of coronary arteries in diabetic patients may be distorted due to large plaque burden over longer vessel segments and resulting absence of plaque-free reference segments. This distortion is found more pronounced in QCA analysis requiring the reference diameter (i.e. for assessment of vessel diameter and %DS). In contrast, volumetric IVUS imaging is more precise in illustrating the lumen and vessel dimensions according the anatomic structures. IVUS guided coronary intervention should therefore be considered in diabetic patients for optimal evaluation of the vessel diameter.

P1655 Clinical and angiographic evaluation of small vessel stenting with "dedicated" versus conventional stents

L. Fiocca, M. Di Biasi, M. Ciuffreda, M. Cleri, F. Zumbo, A.S. Montenero.
Multimedica Hospital, Cardiology department, Sesto San Giovanni, Italy

Background: Percutaneous coronary interventions in small vessels have less favorable outcomes in comparison with larger coronary arteries (> 3 mm), and stent implantation does not give significant benefits as shown by recent trials. In order to improve immediate and long term outcomes, new stents especially designed for small vessels, have been recently introduced in clinical practice. At present, there are not randomized trials that compare these new devices with the conventional ones.
Purpose of the study: This study randomly compares "dedicated" versus "non dedicated" stents in small vessels.
Materials and methods: At our hospital, from October 2000 to September 2001, 160 patients (pts) underwent coronary stent implantation in vessels with diameter < 2.6 mm. Patients were randomly assigned to receive either dedicated (group I) or conventional stents (group II). In group I (70 pts) the Biodivysio Small Vessel and the Multilink Pixel were used, in group II (90 pts) Multilink Tetra, Bestent 2, and Jomed stent were implanted. Acute myocardial infarction, cardiogenic shock, total chronic occlusion, and diffuse disease (lesions longer than 20 mm) have been excluded. Clinical and angiographic follow-up was planned.
Results: Clinical characteristics were similar in the two groups. Baseline reference diameter was comparable in the two groups (2.26 ± 0.3 and 2.27 ± 0.23 mm respectively). There were not diferences in minimal lumen diameter (0.64 ± 0.29 vs 0.63 ± 0.37). The acute gain resulted 1.93 ± 0.39 mm in group I and 1.89 ± 0.24 mm in group II (p 0.4). Multivessel angioplasty was performed in 25% of the cases in group I and 34% in group II (p 0.09). Procedural success was achieved in 98.7% (158/160). The incidence of MACE (death, AMI, CABG, TLR) during follow-up was 25% in group I, and 29% in group II (p 0.5). Angiographic follow-up was performed in 70% of the elegible pts. The incidence of restenosis was 26% in group I and 32% in group II (p 0.46).
Conclusions: Stents "dedicated" to small coronary arteries do not significantly improve acute and long-term outcomes, compared with conventional ones.

P1656 Stent design and stent surface material determine intimal hyperplasia. An intravascular ultrasound study on human coronary arteries

R. Hoffmann[1], G.S. Mintz[2], P. Haager[1], E. Grube[3], M. Gross[4], H. Mudra[5], J. vom Dahl[1], P. Hanrath[1]. *[1]University Aachen, Medical Clinic I, Aachen, Germany; [2]Cardiovascular Research Foundation, New York, United States of America; [3]Herzzentrum Siegburg, Siegburg, Germany; [4]University Clinic Charite, Department of Cardiology, Berlin, Germany; [5]Krankenhaus Neuperlach, Munich, Germany*

Background: A variety of different stent designs and coatings has become available. This study sought to determine the impact of stent design and gold-coating of stents on intimal hyperplasia in human atherosclerotic coronary arteries in relationship to known procedure, lesion and patient related predictors of restenosis.
Methods: Angiographic and intravascular ultrasound (IVUS) studies were performed at 6 month follow-up on 311 native coronary lesions of 311 patients treated with 99 Multi-LinkTM stents, 74 InFlowTM steel stents, 73 InFlowTM gold-coated stents, 41 Palmaz-SchatzTM stents, 12 NirTM steel stents and 12 gold-coated Nir RoyalTM stents. Lumen and stent cross-sectional area (CSA) were measured at one mm axial increments. Mean intimal hyperplasia CSA (stent CSA - lumen CSA) and mean intimal hyperplasia thickness were calculated and averaged over the total stent length.
Results: Angiographic late loss was non-significantly different between stent types, ranging from 0.84±0.76 to 1.17±0.66 mm (p=0.131). IVUS demonstrated different levels of intimal hyperplasia for the six stents. Mean intimal hyperplasia thickness ranged from 0.20±0.13 mm for Multi-Link stents to 0.43±0.14 mm for InFlow gold-coated stents (P<0.001). Multivariate analysis confirmed non Multi-Link stent design (R^2=0.019, p=0.014), gold stent coating (R^2=0.144, p<0.001)and diabetes (R^2=0.014, p=0.041) to be the only independent predictors of IH thickness. Multivariate logistic analysis proved non Multi-Link stent design (OR=3.45, 95%CI=1.13-11.11, p<0.034) and gold coating (OR=3.78, 95%CI=1.88-7.54, p<0.001) to be the only independent predictors of intimal hyperplasia thickness greater 0.3 mm.
Conclusion: Intimal hyperplasia thickness differs significantly between different stent types. Stent design and surface material have a greater impact on the intimal hyperplasia response to stents than known procedure, lesion and patient related factors. However, the differences in intimal hyperplasia thickness between the analyzed stents are relatively small compared to the absolute lumen dimensions. Angiographic analysis fails to detect differences in late lumen loss.

P1657 Immediate and long-term outcome following the treatment of very long (>50 mm) chronic total coronary artery occlusions

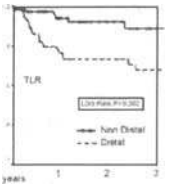
I. sheiban[1], K. Prathap[2], R. Grimaldi[2], T. Montaldo[2], F. Baqaraj[2], C. Moretti[2], G.P. Trevi[2]. *[1]Depart. Internal Medicine, Divison of Cardiology - Cath Lab, Torino, Italy; [2]Division of Cardiology, Department of Internal Medicine, 20126 Turin, Italy*

Objective: The follow-up patency rates, and the angiographic variables associated with it, after stenting of very long (>50 mm) and chronic (> 6 months) total coronary artery occlusive lesions are not well documented. Aim of the present study was to evaluate the early results and mid-term outcome following angioplasty of such lesions.
Methods: Between January 2000 and may 2001we treated 273 chronic coronary occlusions. Of these, 78 (78 patients) were in lesions [3] 50 mm long and these patients constituted the study population. Recanalizations attempts was performed iusing specific wires for total occlusions and over-the-wire ballosns in order to provide more support to guide wires and to have the opportunity to change the wire without losing the position acquired.
Results: Mean duration of occlusion was 8±2 months (range: 6 to 17 months). Procedural success was obtained in 69 (88%) patients. A total of 203 coronary stents (2.6±0.9 stent/patient) were implanted. Periprocedural MACE occurred in 7 (8.9%) patients. During a 8±2 months follow-up, 45 (58%) patients remained angina free, 3 (3.8%) had a new myocardial infarction and no death was reported. Target vessel revascularization was required in 27 (34.6%) patients. Angiographic follow-up was obtained in 61 (78%) patients. Restenosis was observed in 28 (46%) patients, of whom, 9 had reocclusion. A significant correlation was observed between the need for reintervention and lesion length (R 0.52), residual stenosis (R 0.73) and diabetes mellitus (0.68).
Conclusion: Although coronary artery stenting for very long (> 50 mm) chronically occlusive lesions is feasible, safe and is associated with a low incidence of peri-procedural adverse clinical events, these complex and expensive procedures are still associated with a high 6-month restenosis rate. Brachitherapy and drug-eluting stents might provide better long term results.

P1658 Anatomical location of lesion predicts restenosis in unprotected left main coronary artery stenting

N. Mulvihill, M. Boccalatte, B. Farah, J.C. Laborde, J.P. Bounhoure, J. Fadajet, J. Marco. *Clinique Pasteur, Unité de Cardiologie Interventionelle, Toulouse, France*

Unprotected left main (LM) coronary stenting is now an attractive alternative to coronary surgery with excellent immediate and long term outcomes in selected patients. However the impact of the anatomical location of the target lesion on clinical outcome is unknown. We set out to assess the impact of target lesion location on mortality and restenosis in unprotected LM stenting.
Methods and Results: Between Jan 1994 and Jan 2002 we performed unprotected LM stenting on 197 consecutive patients. There were 154 (78%) male patients, mean age 74±9 years, 25% diabetic, 12% renal insufficiency, mean LVEF 57±15%. The clinical indication for the procedure was: recent acute MI 14%, unstable angina 62% and stable angina 24%. The anatomical location of the target lesion in the LM was: ostial 26%, mid-shaft 19% and distal bifurcation lesions 55%. Initial procedural success was 100%. There were 16 in-hospital MACE events (7 deaths, 8 MI and 1 TLR). Follow up on 187 (98%) was completed for a mean of 23±20 months. MACE rates during follow up were as follows (33 deaths, 4 MI and 29 TLR). The freedom from TLR was: 92% and 73%, p=0.003 for non-distal and distal LM lesions respectively (Fig. 1). There was no significant difference in the incidence of diabetes between non-distal and distal groups: 33% vs 24%, p=NS. There was no difference in mortality between distal and non-distal lesions.



Kaplan-Meier freedom from TLR.

Conclusion: Unprotected LM stenting can be performed with excellent immediate and long term outcomes in ostial and mid-shaft lesions. Stenting of unprotected distal LM lesions is associated with an increased risk of restenosis and this subset of patients may benefit most from novel anti-restenosis therapies.

P1659 Effect of stent design an strut thickness on long-term outcome of coronary stent placement. Results from the ISAR-STEREO-2 trial

H. Schühlen[1], J. Pache[2], A. Kastrati[1], F. Dotzer[3], J. Mehilli[1], U. Sattelberger[4], J. Dirschinger[2], A. Schömig[1]. [1]*Deutsches Herzzentrum München, München, Germany;* [2]*Technische Universität, 1. Med. Klinik rechts der Isar, München, Germany;* [3]*Med. Klinik I, Garmisch-Partenkirchen, Germany;* [4]*Med. Klinik I, Ingolstadt, Germany*

Background: Stent design and strut thickness may have a significant impact on long-term outcome after coronary stent placement. The ISAR-STEREO-1 trial had compared 2 stents of very similar design but different strut thickness (ACS RX Multi-Link and Multi-Link RX Duet). A significantly lower restenosis rate was observed after placement of thinner-strut stents (ACS RX Multi-Link). Hypothesis for the multicenter ISAR-STEREO-2 trial was that the impact of strut thickness is independent of stent design.
Methods: A total of 611 patients with lesions in native coronary arteries >2.8mm in diameter were randomly assigned to either the Guidant ACS RX Multi-Link stent (strut thickness 50μm; n=309) or Cordis BX Velocity stent (strut thickness 140μm; n=302). The primary endpoint was angiographic restenosis (>50% diameter stenosis at follow-up angiography). Secondary endpoints were clinical restenosis (target vessel revascularization, TVR) and the combined rate of death and myocardial infarction at 1 year.
Results: There were no significant differences in baseline clincal and angiographic characteristics. Procedural success rates were similar (99.4% for thin-strut stents vs. 99.0% for thick-strut stents; p=0.64); yet, a difference was observed for device success rate (87.6 vs. 98.7%; p=0.09). Acute angiographic results were almost identical (final diameter stenosis, 4.3±9.7 vs. 4.2±11.6%; p=0.78). At follow-up angiography, late lumen loss was significantly lower in the thin-strut group (0.94±0.61 vs. 1.20±0.69mm; p<0.001) as well as the angiographic restenosis rate (18.9% vs. 31.6%; p=0.0002). In parallel, the TVR rate was significantly lower (12.3 vs. 21.2%; p=0.003). No difference was observed in the combined rate of death and myocardial infarction after 1 year (5.2% vs. 6.0%; p=0.67).
Conclusions: Strut thickness of coronary stents has a significant impact on long-term outcome. These data confirm that thinner strut stents are associated with lower restenosis rates, and suggest that this effect is independent of stent design.

P1660 The major profit of stent implantation is reduction of periprocedural MACE

G. Herrmann, M. Gruetters, M. Lins, R. Simon. *1. Medizinische Klinik, Klinik für Kardiologie, Kiel, Germany*

Reduction of restenosis rate is widely used as front argument for an increased frequency of stenting during coronary interventions. Data on this subject, however, are available only for highly selected pt. groups in randomised studies.
Between 1990 and 2001 a total of 8453 pts underwent PTCA at our institution. Out of these a total of 3050 (36%) had coronary stent implantation in the same session. During the early phase(1990-94), 289/3401 (8,5%) pts. received stents followed by coumadine/aspirin therapy. After introduction of ticlopidine as replacement for coumadine, 928/2311 (40%) of our pts received stents until 1998. From 1998 on clopidogrel was available, and 1839/2741 (67%) of our pts received stent implantation. Throughout the same time periods, the rate of periprocedural MI decreased from 2,1% to 1,6% and 0,6%, respectively(p< 0.05).Emergency CABG was necessary in 1,9% of pts during the early phase, in 1,4% in the ticlopidine era and in only 0,4% with clopidogrel (p<0,05). Restenosis rate did not change from1990 through 2001,but remained stable between 25%and 30% at angiographic follow up available for 80% of the entire cohort.
We conclude from these data, that the reduction of periprocedural MACE and not a decrease in restenosis rate is the primary advantage of stenting in larger non selected groups of pts.

P1661 Reduction of restenosis rate for direct stenting with intracoronary ultrasound guidance. Results from the prospective, randomized trial

R. Gil[1], T. Pawlowski[2], K. Zmudka[3], D. Dudek[3], J. Kubica[4], M. Lesiak[4], G. Horszczaruk[5], M. Dabrowski[6] on behalf of Direct Stenting vs Optimal Angioplasty Trial Investigators. [1]*Invasive Cardiology Department, Central Hospital of Internal Affairs, Warsaw, Poland;* [2]*Pomeranian Academy of Medicine, Cardiac Catherisation Laboratory, Szczecin, Poland;* [3]*Colegium Medicum UJ, Cardiac Catherisation Department, Cracow, Poland;* [4]*Medical Academy, Department of Cardiology, Poznan, Poland;* [5]*Medical Academy, Department of Cardiology, Warsaw, Poland;* [6]*National Institute of Cardiology, Cardiac Catherisation Laboratory, Warsaw, Poland*

Background: Results of direct stenting (DS) and stenting with predilation were compared in many angiographic trials, but expected superiority of DS was not confirmed. The aim of this study was comparative analysis of early and late results of DS guided with quantitative coronary angiography (QCA) and with intracoronary ultrasound (ICUS).
Methods: Study population consists of 120 patients divided into 2 groups due to type of stent implantation guidance. There were 62 pts in DS-QCA (Gr1) group and 58 pts in DS-ICUS (Gr2) group. In Gr1 stent was sized according to QCA vessel reference diameter (RD), when in Gr2 media to media diameter measured with ICUS was used for that reason. Stent length was chosen in accordance with QCA (Gr1) and with ICUS (Gr2) measurements. Major adverse cardiac events (MACE) and target vessel revascularisation (TLR) were observed during follow-up. Coronary angiography for restenosis detection between 6-9 monts after stenting was planned.
Results: There was 100% procedural success and no early (30 days) complications in our study. There were no differences in procedural variables (max. inflation pressure & time) between two groups. Mean stent size used for DS was significantly bigger in Gr2 than in Gr1 (3,8±0,55mm vs 3,41±0,42mm, p<0,001). The need for stent redilatation was 33% in Gr1 and 39% in Gr2 (p=NS). QCA results did not differ between groups besides minimal lumen diameter obtained after procedure (2,98±0, 62 mm vs 3,35±0, 56 mm, respectively Gr1 vs Gr2, p<0,05). The evidence of MACE at 6 month follow-up was 18,4% and 10,4% for Gr 1 & Gr 2 respectively (p=NS). The control angiography revealed in-stent restenosis in 23,7% of Gr 1 and 9,3% of Gr 2 patients (p<0,05).
Conclusion: ICUS guided DS is associated with use of bigger stent size that provides better clinical outcome and lower restenosis rate.

P1662 Long coronary dissections after balloon angioplasty treated with spot stenting or entire length stenting-role of IVUS guidance

R. Gil[1], T. Pawlowski[2], J. Kubica[3], G. Horszczaruk[4], D. Dudek[5], K. Zmudka[5], M. Lesiak[6], A. Witkowski[7] on behalf of Direct Stenting vs Optimal Angioplasty Trial Investigators. [1]*Invasive Cardiology Department, Central Hospital of Internal Affairs, Warsaw, Poland;* [2]*Pmeranian Academy of Medicine, Cardiac Catherisation Laboratory, Szczecin, Poland;* [3]*Medical Academy, Department of Cardiology, Bydgoszcz, Poland;* [4]*Medical Academy, Department of Cardiology, Warsaw, Poland;* [5]*Colegium Medicum UJ, Cardiac Catherisation Department, Cracow, Poland;* [6]*Medical Academy, Department of Cardiology, Poznan, Poland;* [7]*National Institute of Cardiology, Cardiac Catherisation Laboratory, Warsaw, Poland*

Long coronary wall dissection after balloon angioplasty causing flow impairment is an indication for stent implantation. The aim of the study was a comparison of spot stenting vs entire length stenting with use of intracoronary ultrasound (ICUS).
Methods: Multicenter, randomized trial comparing direct stenting with optimal balloon angioplasty guided by ICUS was designed and carried out. Till December 2001 two hundred seventy four patients were enrolled into the study. Group of optimal angioplasty consisted of 96 patients. Sixty eight of them (mean age 56±10 y) after balloon dilatations presented wall dissection longer than 15 mm with flow impairment. The choice of stenting strategy was based on operator decision. Studied population was divided into two groups: Gr1 (39 pts) treated with spot stenting (SS) and Gr2 (29 pts) treated with long stenting (LS). Endpoints for the SS were MUSIC trial criteria for stented segments and at least 6,0 mm^2 for adjacent segments when for LS were at least 7,5 mm^2 along the entire length of the stent. During 6 months follow-up we recorded evidence of MACE (death, myocardial infarction, target vessel revascularisation) and in case of recurrence of angina coronary angiography was performed.
Results: Procedural success was achieved in 93% of cases. There was need for abciximab administration in 2 (5,1%) cases of Gr1 and 4 (13,7%) of Gr2. The mean length of used stents was 11,3±4,1 mm in Gr1 and 22,2±3,8 mm in Gr2 (p<0,05), but their nominal size didn't differ signifficantly between two groups (3,43±0,43 vs 3,28±0,54 mm). Angiographic and ICUS results are presented in the table 1.

	SS	LS	p
MLD post (mm)	3,45±0,65	3,54±0,72	NS
Ref.D. pre (mm)	3,01±0,43	3,11±0,53	NS
Stent area post (mm^2)	8,32±2,03	7,86±1,87	NS

During follow-up period major adverse cardiac events occurred in 4 pts (13,7%) of Gr1 and 5 pts (26,7%) of Gr2 (p=NS). Control angiography revealed a restenosis rate equal 10,3% and 21,0%, respectively; p=0,055.
Conclusions: Spot stenting of long coronary dissections with use of ICUS guidance facilitates identification of dissection entry that can be translated into clinical benefit in comparison with long stenting.

P1663 Does optimal lesion debulking need stenting?: one year follow-up results of ESPRIT

E. Tsuchikane, Y. Takeda, N. Awata, T. Kobayashi. *Osaka Medical Center, Cardiology, Osaka, Japan*

Stenting inhibits the constrictive geometric remodeling after percutaneous coronary intervention. Cilostazol, an antiplatelet agent, is reported to control neointimal proliferation. The aim of ESPRIT (Elimination of restenosis after Stenting following Plaque Reduction with platelet Inhibitor Trial) was to evaluate the efficacy of debulking stenting followed by administration of cilostazol. Of 117 patients (pts) with a lesion successfully dilated by optimal directional coronary atherectomy (DCA) using intravascular ultrasound (IVUS), 58 pts were randomly assigned to the DCA-stent and 59 pts to the DCA alone group. Multilink stent(s) was implanted in the DCA-stent group. Medication of cilostazol (200mg/day) without aspirin was commenced after the procedure and continued until 6 month follow-up in both groups. Ticlopidine was added in the DCA-stent group for 1 month to prevent subacute thrombosis. No adverse events were observed during the hospital stay. All pts were followed up for 1 year. Eligible 6 month follow-up angiogram was obtained in 112 pts. No pts discontinued medication of cilostazol due to side effects. By 1 year, there was no death or QMI. Target lesion revascularization (TLR) was needed only in 3 pts (5.2%) of the DCA-stent and 5 pts (8.5%) of the DCA alone group. CABG was performed in 1 pt in the DCA-stent group due to refractory instent restenosis. Six month angiographic and IVUS and 1 year clinical Fu results are shown in the table. Neointimal proliferation was significantly larger in the DCA-stent group.

QCA, QCU and clinical follow-up results

	DCA-stent	DCA alone	P value
Post MLD (mm)	3.27±0.27	2.92±0.33	<0.0001
Follow-up MLD (mm)	2.53±0.59	2.41±0.69	NS
Neointima area ((mm^2)	4.2±2.4	1.5±2.8	<0.0001
TLR	5.2%	8.5%	NS

MLD = minimal lumen diameter, TLR = target lesion revascularization

Conclusion: Debulking stenting provides a larger immediate lumen, however, follow-up outcomes do not differ compared with debulking alone followed by the administration of cilostazol. These results suggest optimal lesion debulking need not always adjunctive stenting if cilostazol is administered.

P1664 Coronary artery aneurysm: incidence in 15920 patients, angiographic pattern, therapeutical options and follow-up results

J. Rath[1], I. Trommer[2], M.P. Heintzen[2], M.G. Hennersdorf[2], M. Kelm[2], B.E. Strauer[2]. [1]*Department of Cardiology and Angiology, University Hospital Herne, Herne, Germany;* [2]*university of duesseldorf, cardiology, Duesseldorf, Germany*

Coronary artery aneurysm (CAA) are a rare finding in patients undergoing angiography of coronary arteries (CA). The incidence varies from 0,2 to 4,9% in different sized studies. There are only case reports about therapeutical options. We report about a single center, retrospectiv analysis of 15920 patients with regard to incidence of CAA in a sequent series, to angiographic pattern, therapeutic approaches and follow up results. Between 1995 and 2000 a total of 58 (0,4%) patients with CAA could be identified. 57 (98,3%) had coronary artery disease (CAD). The CAA were predominantly (49/80,1%) found at the branches of the left coronary artery (LCA) and in the proximal third (37/63,8%) of the CA. 35 (60,3%) of all CAA were closely (< 10 mm) located to a stenosis of a CA. Of these 20 (57,1%) were located poststenotic and 10 (28,6%) in the stenotic segment. 53% of all CAA were measured between 3-5 mm in diameter. The patients showed mainly the risk factors hyperlipidemia (81%) and hypertension (61%). We could not find any relation of CAA apperance to a history of vasculitis, other aneurysmatic vascular malformations or prior therapeutic use of steroids.

The major part of all patients was treated conservativly (27/46,6%). 18 (31,6%) were sent to bypass surgery due to severe three vessel CAD. 13 (22,4%) patients were treated with percutaneus intervention (PCI) of a stenosis in the area of CAA, 4 with ballon angioplasty alone and 9 with additional Stent implantation (uncoated stents). The ballon group showed only 1 effectiv closure of a CAA, the Stent group 7 (78%) immediately and at 6 month controll. In the group of conservativly treated patients angiographic follow up in a mean intervall of 24 month documented 100% persistence of CAA without increase in size.

Summerized, CAA are a rare entity of CAD, mostly in close relation to a stenosis of a CA and often in the proximal branches of the LCA. An therapeutic strategy with PCI provides a high closure rate of CAA when Stents are used. But even in conservativ approach short time angiographic follow up showed stable CAA diameter, what may allow to monitor the natural course of the disease.

P1665 Body mass index and late outcomes after CABG and stenting for the treatment of multivessel disease: results from the ARTS trial

L. Gruberg[1], N. Mercado[2], S. Milo[1], E. Boersma[2], P. Lemos[2], W. Wijns[3], M. Ben Tzvi[1], R. Beyar[1] on behalf of ARTS Group. [1]*Rambam Medical Center, Department of Cardiology, Haifa, Israel;* [2]*Thoraxcenter, Rotterdam, Netherlands;* [3]*Cardiovascular Center, Aalst, Belgium*

Background: Obesity is associated with advanced coronary artery disease. However, the relation between body mass index (BMI) and outcome after percutaneous coronary intervention (PCI) and coronary artery bypass surgery (CABG) remains controversial. The purpose of the study was to assess the impact of BMI on the one-year outcomes after coronary artery revascularization in patients with multivessel disease who underwent either stent implantation or CABG.

Methods: A total of 1,203 patients with multivessel coronary artery disease, who were considered to be equally treatable with both modalities, were randomly assigned to CABG or stenting in the Arterial Revascularization Therapies Study (ARTS). The primary clinical endpoint was freedom from major adverse cardiac and cerebrovascular events (MACCE). Patients were divided into three groups according to BMI: 1) normal weight (BMI: 18.5-24.9), 2) overweight (BMI: 25-30) and obese (BMI >30).

Results: Baseline clinical characteristics were similar among the groups, except for a higher incidence of diabetes (p<0.0001) in obese patients who underwent stenting and younger age (±3 years) in obese patients who underwent surgery (p=0.009). Results are shown in the table (*p=0.04).

	Stenting			CABG		
	Normal (n=168)	Overweight (n=307)	Obese (n=124)	Normal (n=169)	Overweight (n=299)	Obese (n=136)
Death (%)	1.8	2.6	3.2	3.5	2.6	2.2
Stroke (%)	2.3	1.9	0	2.3	2.3	1.4
MI (%)	5.3	5.5	8.8	7.1	3.7	4.4
Revascularization (%)	18.4	22.4	20.9	5.3	4.3	0.7
MACCE (%)	27.8	32.4	32.9	16.5*	12.0*	7.3*

Conclusions: 1) At one-year follow-up, multivessel stenting was as safe as CABG regarding death, stroke or myocardial infarction in normal BMI, overweight and obese patients. However, the incidence of repeat revascularization was lower in CABG patients in all BMI groups. 2) Obese and overweight patients are at a lower risk of MACCE after bypass surgery compared to patients with normal BMI, but on average, they were approximately 3 years younger than their normal BMI counterparts. 3) BMI did not appear to influence the clinical outcome after coronary stenting.

PAEDIATRIC CARDIOLOGY/OTHERS

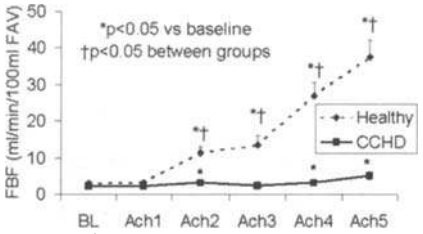
P1666 Endothelial dysfunction in patients with cyanotic congenital heart disease

E. Oechslin, W. Kiowski, R. Schindler, B. Julius, A. Bernheim, R. Jenni, H.P. Brunner-La Rocca. *University Hospital, Cardiology, Zurich, Switzerland*

In cyanotic congenital heart disease (CCHD), secondary erythrocytosis results in increased whole blood viscosity and shear stress, causing release of nitric oxide (NO). Thus, reduced pulmonary NO production, as seen in CCHD, is not necessarily accompanied with reduced NO production in the systemic circulation. However, no data are available if vasodilation is altered in CCHD. Moreover, elevated endothelin-1 (ET-1) may contribute to increased tissue vascularity, but it is unclear if this is of importance in CCHD.

Methods: Responses to arterial endothelium-dependent (Acetylcholin [Ach]) and -independent (sodium nitroprussid [SNP]) vasodilation, NO synthase blockade (L-NMMA), ET-1 and ET-1 receptor blockade by BQ-123 of 11 CCHD patients (O2-saturation <90%, mean 79±1%, age 39±2 years) were compared with those of 10 age-matched healthy controls (HC), using forearm venous occlusion plethysmography.

Results: Resting blood flow was slightly lower in CCHD than in HC (2.2±0.4 vs 3.5±0.4ml/min/100ml forearm volume [FAV], p<0.05). While response to SNP was similar in both groups (p>.1; CCHD 2.0±0.3 to 8.3±1.0; HC 3.6±0.7 to 11.9±1.2 ml/min/100ml FAV), response to Ach was reduced (figure; p<.001). L-NMMA was less effective in CCDH (25±6% vs 40±4%, p<.05). ET-1 caused a smaller vasoconstriction in CCHD (-25±9% vs. -51±7%, p<.05), but the response to BQ-123 was similar in both groups (32±9 vs 27±9%).



Response to intra-arterial acetylcholin.

Conclusions: In CCHD, there is no vasodilation at rest, caused by reduced NO production. Although the response to SNP was not impaired, endothelial dysfunction is evident in CCHD. Due to elevated ET-1 levels, the response to exogenous ET-1 is reduced, but indicated by the similar response to BQ-123, the effects of endogenous ET-1 on arterial tone is not enhanced.

P1667 Endothelium function in normotensive patients after successful coactation repair

S. Brili, C. Aggeli, C. Antoniadis, D. Tousoulis, M. Toutouza, C. Pitsavos, C. Stefanadis, P. Toutouzas. *Athens, Greece*

Adult patients (pts) even after successful coarctation repair (SCR) suffer from relapse of hypertension and their life expectancy is shorter than normal because of premature coronary and cerebrovascular events, In previous studies we have shown that structural and functional abnormalities of the carotid arteries are present in pts after SCR. In this study we aimed at detecting the endothelium function in this category of pts as well as the inflammatory markers SVCAM-1 and SICAM-1 secreated from endothelium.

Methods: Twelve pts, 27±12 years old, 15±9 years after SCR (Group 1) and twelve matched controls selected to have the same age, sex, smoking habits, as well as lipid profile (Group 2) were enrolled in our study.

In all pts and controls were measured: SVCAM-1, SICAM-1 (ngr/ml) as well as the forearm blood flow using venous occlusion strain-gauge plethysmography. Endothelium dependent flow mediated vasodilation (FMD) was expressed as the % change from baseline to post reactive hyperemia blood flow. Endothelium independet flow was expressed as the % change from baseline to post sublingual nitroglycerin administration flow (NITR).

Results: FMD and SVCAM-1 were SS different in Group 1 than Group 2 (73.8±7.7 vs 117.5±15.8, p<0.05), (444.5±36.2 vs 295.6±39.1, p<0.05), respectively. SICAM-1 and NITR did not have any SS difference between Group 1 and Group 2 (258.4±15.9 vs 250.0±21.4, p=NS), (78.4±7.6 vs 88.7±11.5, p=NS), respectively.

Conclusions: From our data it is concluded that there is endothelial dysfunction in pts with SCR expressed with the investigated SS difference of the FMD in the two groups. Also the SVCAM-1 inflammatory marker is SS increased in SCR pts. These results may explain the high incidence of coronary artery disease in pts with repaired coarctation.

P1668 Prognostic value of brain natriuretic peptide in patients with complex congenital heart disease

H.M. Gabriel, N. Jordanova, R. Rosenhek, M. Zehetgruber, J. Bergler, K. Huber, G. Maurer, H. Baumgartner. *University of Vienna, Cardiology Dept., Vienna, Austria*

Background: Serum brain natriuretic peptide (BNP) has been reported to indicate ventricular dysfunction and to be an independent predictor of outcome in patients with cardiomyopathy and primary pulmonary hypertension. However, its prognostic value in patients with congenital heart disease (CHD) has not been studied, yet.

Methods: To evaluate its prognostic value, BNP was measured in 72 pts. (36 female, mean age 34 ± 12 years) with complex CHD who were followed for 17±8 months. The relation of BNP levels to NYHA functional class and ventricular function (VF) at entry as well as to the occurrence of events during follow-up in terms of death, transplantation or congestive heart failure requiring hospital admission (CHF) was analyzed.

Results: In 36 pts. with pulmonary hypertension (PHT) consisting of Eisenmenger pts. and other pts. with complex CHD and significant pulmonary vascular disease, 12 events occurred during FU (deaths 7, transplantation 2, CHF 3). BNP was significantly higher in pts. with as compared to those without events (338±254 vs 61±133 pg/ml; p<.0001). Pts. with events were on average also in a higher NYHA class (3.0±.5 vs 1.9±6; p<.0001) and presented more frequently with abnormal ventricular function (p<.005). BNP was significantly higher in pts. with abnormal as compared to those with normal VF in this group (335±270 vs 51±92 pg/ml; p<.0001). Of 12 pts. with BNP >150 pg/ml (group A; BNP 325±162 pg/ml) 10 had an event during FU (83%) whereas only 2 of 24 pts. with BNP smaller or equal to 150 (group B, BNP 31±34 pg/ml) had an event (17%). All pts. except 1 (sudden death) with events in group A developed CHF and 6 eventually died, one underwent lung transplant. Events in group B were sudden death (1) and heart lung transplantation (1). Only one pt. In group A remained stable whereas 22 of 24 pts. in group B remained stable during FU.

In 36 pts. with complex CHD but without significant PHT, no event occurred during FU. Nevertheless, 9 of them had BNP levels >150 pg/ml (325±162 pg/ml). In contrast to the pts. with PHT, in this group of pts. without PHT, BNP levels did not significantly differ between pts. with normal and those with abnormal VF (96±138 vs. 128±193; NS).

Conclusion: Serum BNP level appears to be an important predictor of outcome in pts. with complex congenital heart disease who have pulmonary hypertension. In this group, pts. with BNP > 150 pg/ml require close follow-up and intensive treatment. They may require transplantation within a short time period.

P1669 Serum soluble adhesion molecules and systemic tissue factor activation in paediatric cardiac allograft recipients

U. Krämer[1], A. Hilgendorff[2], J. Bauer[1], J. Thul[1], H. Hölschermann[2], B. Kemkes-Matthes[2], H. Akintürk[1], J. Kreuder[1]. [1]*Kinderherzzentrum, Kinderkardiologie, Giessen;* [2]*Zentrum für Innere Medizin, Gießen, Germany*

Purpose: Chronic rejection and transplant coronary artery disease (TCAD) has a major influence on the overall mortality and morbidity in children after heart transplantation (HTx). In TCAD, there is a diffuse, concentric and sometimes rapidly progressive stenosis of the epicardial and intramyocardial coronary arteries of the graft. Interaction between the immunologically mediated alterations of the coronary artery endothelium and the activation of the intravascular coagulation system has been proposed to be an important factor.
Patients and methods: Blood samples of 52 paediatric allograft recipients (age at HTx: 7-24months, time after HTx: 6-142 months) were examined during routine follow-up at 2-4 different times. During the study period, patients did not show any signs of severe infection or acute graft rejection. The control group consisted of 65 children before elective surgery. The concentrations of soluble adhesion molecules sICAM-1 and sVCAM-1, tissue factor (TF), TF-pathway inhibitors(TF-PI) and D-dimer were determined by commercially available ELISA assays.
Results: Patients after HTx showed significant higher plasma levels of sICAM-1 and sVCAM-1 and higher D-dimer concentrations than the control group. The higher levels of TF and TF-pathway inhibitors in the HTx group did not reach statistical significance (see table).

		s-ICAM-1 (pg/ml	s-VCAM-1 (pg/ml)	TF (ng/ml)	TF-PI (ng/ml)	D-dimer (ng/ml)
Htx	mean ±SE	1045 ±35	1832 ±64	263 ±43	65.2 ± 5.2	760 ± 74
	range	111-3534	492-4540	20-5480	8-470	139-5260
controls	mean ± SE	797 +/ 34	1191 ± 49	208 ±21	57.4 ± 4.8	356 ± 90
	range	62-1200	561-2643	80-425	18-123	124-2620
p-value		<0.000	<0.0001	n.s.	n.s.	<0.01

60% of the patients with hypertrophy of the left ventricular posterior wall or of the septum also showed increased sVCAM-1 levels. Furthermore patients with more than 2 acute rejections demonstrated significantly higher levels of sVCAM-1. Multiple regression analysis revealed a significant correlation between TCAD and maximum sICAM-1 and D-dimer levels (r=0,4, p<0,05).
Conclusion: These findings suggest an increased interaction between the activated endothelium and the intravasal coagulation system as a relevant process in paediatric HTx and TCAD development.

P1670 Normal left ventricular anatomy and its variants as classified by second harmonic echocardiography

G. Tamborini, M. Pepi, F. Celeste, F. Susini, M. Muratori, A. Maltagliati, P. Caruso. *Fondazione Monzino, IRCCS, Centro Cardiologico, Milan, Italy*

Two-dimensional transthoracic echocardiography (2DTT) is the standard and routine technique for anatomic and functional evaluation of the left ventricle (LV). Over the last 5 years advancements in transducers, and introduction of high resolution and second harmonic technology improved the evaluation of LV anatomy and in particular endocardial surface at the mid and apical levels. The "old" echocardiographic description of the LV cavity might be re-written on the basis of this new technology trying to better define the normal anatomy of the LV endocardial surface and to describe anatomical variants such as apical false tendons and apical trabeculations. We included in this study 1252 adult consecutive patients undergoing 2DTT (second harmonic and high-resolution technology) for various pathologies. Images were stored in magneto-optical disks and reviewed by two independent experts; "anomalous apical images" (AAI) were classified as: false tendons (FT: number, site and diastolic length), abnormal trabeculations (TR: site and systolic TR/left ventricular wall thickness ratio, TR/LVWT), apical thrombi (TH: site and area). AAI were observed in 555 out of 1252 cases (44,3%); the majority of AAI were FT (81,1%), while TR were found in 16%, TH in 2,4%, FT+TR in 16% and FT+TH in 0,5% of cases. To better define the incidence of these AAI in the study population, cases were divided into two groups: normal LV (normal size, dimension and systolic function) and pathological LV (5 categories: dilated LV, hypertrophied LV, inferior/lateral akinesis, anterior/septal akinesis, valve disease). Incidence of AAI was significantly greater in pathological LV (466/863, 53,9%, with higher prevalence in dilated hearts and apical infarctions) than in normal LV (158/389, 40,6%). No differences in age, LV end-diastolic volume or ejection fraction were found in patients with and without AAI; AAI were more frequently in male (344/706, 48%) than in female (201/529, 37,9%,) FT were isolated in 73%, while two (24%), three or more FT were less common. Their lenght was 3 ± 1 cm and these structures transverse the LV cavity (septum to lateral wall) in the majority of cases. TR were more frequently found at the apical-septal or apical-lateral site; TR/LVWT was 1,4:1. These preliminary data confirm a high prevalence of AAI in patients with and without pathological hearts suggesting the need of updating LV anatomy in the light of these new echocardiographic findings.

P1671 Discrete subvalvular aortic stenosis (DSAS) – Pitfall in the diagnosis of patients with hypertrophic obstructive cardiomyopathy (HOCM)

G. Beer, C. Strunk-Müller, F H. Gietzen, H. Kuhn. *Städtische Kliniken Bielefeld-Mitte, 2. Medizinische Klinik/Kardiologie, Bielefeld, Germany*

Introduction: Generally, diagnosis of typical HOCM with subaortic obstruction and dynamic pressure gradient accross the left ventricular outflow tract is made by non invasive diagnostic procedures with great certainty by employing transthoracic and/or transoesophageal echocardiography. However, in pts. with asymmetric septal hypertrophy additional discrete subvalvular membrane may be a potential pitfall in the diagnosis of HOCM as it is described in several casuistic reports in the literature. The exclusion of DSAS is of special importance in pts. referred for catheter interventional therapy. To date systematic investigations concerning the frequency of DSAS in symptomatic pts. referred for catheter interventional therapy of HOCM are lacking.
Methods: Therefore, we investigated for the first time in a systematic study 180 consecutive symptomatic (functional class III-IV according to NYHA) pts. with HOCM who were referred for this new catheter interventional therapy. In all pts. transthoracic echocardiography (TTE), bicycle exercise Doppler echocardiography and multiplane transoesophageal echocardiography (TEE) were performed.
Results: In 4 of 180 pts. (2,2%) the diagnosis of DSAS (4 pts.; 3 female pts. and 1 male pt.; age 41 years, range 20 to 58 years; functional class III according to NYHA; mean septal diameter 19 mm) was made. 3 of these pts. belonged to the membranous type of DSAS; in one pt. a tunnel-like form of DSAS was present. In all cases the diagnosis could be confirmed by surgical treatment. TEE evaluation was of crucial importance with demonstration of a typical subvalvular membrane (in 3 pts.) which was situated a few millimeters below the aortic valve. In all cases a typical asymmetric septal hypertrophy mimicking HOCM was seen. A Sam-like motion was demonstrated in all 4 cases. However, only in one pt. a Sam-septal contact was present. In one of these 4 pts. DSAS could be identified definitely only after shrinkage of the intraventricular septum due to catheter interventional therapy with persisting gradient.
Conclusion: The frequency of DSAS in symptomatic pts. referred for HOCM is unexpectedly high (approximately 2,5%). Especially in pts. in whom TTE evaluation is of insufficient quality, investigation employing multiplane TEE with careful evaluation of the small poststenotic subvalvular area in HOCM is of crucial importance in diagnosing and classifying DSAS (membranous type, fibromuscular ring, tunnel type). This is of special importance because DSAS can only be treated by surgery.

P1672 Persistence of left ventricular hypertrophy in normotensive adult survivors of coarctation repair in childhood

N.A.Y. Chung[1], D.A. Lane[1], G.Y.H. Lip[1], D.G. Beevers[1], T.A. Millane[2]. [1]*University Department of Medicine,* [2]*Department of Cardiology, City Hospital, Birmingham, United Kingdom*

Objectives: To investigate the prevalence of left ventricular hypertrophy (LVH) in normotensive adult survivors of aortic coarctation corrected in childhood as assessed by transthoracic echocardiography (TTE) and 24 hour ambulatory blood pressure monitoring (ABPM).
Methods: Concurrent TTE and ABPM were undertaken in 19 patients with corrected coarctation and a clinic systolic blood pressure (SBP) <140mmHg, recruited consecutively from the Adult Congenital Heart Disease Clinic. All patients had undergone their first intervention more than 10 years previously. Population normative data, corrected for body surface area, were used for comparative purposes for TTE data, and age- and sex-matched normotensive controls for the ABPM parameters.
Results: There were no significant differences in any standard ABPM parameter among the 19 patients and 19 controls (average daytime SBP<135mmHg) although a non-significant trend toward a reduction in day-night systolic variation was noted. Adequate TTE images were obtained in 16 patients; 5 males, median age 32.5 years (range 28-48). Left ventricular (LV) posterior wall diameter (diastole) was greater than 11 mm in 4 (25%) patients, all of whom had concentric LVH. Septal dimensions were increased in a further 5 patients (56% in total). LV mass index was increased in 4/5 males and 8/11 women. LV ejection fraction (Simpson) and fractional shortening were normal in all but one patient. Diastolic function as assessed by mitral inflow Doppler studies was normal in all patients (E:A ratio 1.3-2.5). Isovolumetric relaxation time was prolonged in only 2 patients, both of whom had concentric LVH and increased LV mass.
Conclusion: Left ventricular hypertrophy and increased left ventricular mass, assessed echocardiographically, are very common in adults after successful coarctation repair in childhood. This does not seem to be as a result of persistent systolic hypertension and deserves further investigation. The presence of LVH implies a poorer prognosis in other fields of cardiology - implications for this large patient group are, of course,unknown. Further studies, both in terms of mechanism and outcome, are indicated.

P1673 Global autonomic nervous system impairment late after the Fontan operation

C.H. Davos[1], M.F.E. Leenarts[2], S.C. Yap[2], P.A. Davlouros[3], R. Wensel[1], M. Piepoli[1], N. Sreeram[2], M. Gatzoulis[3]. [1]National Heart and Lung Institute, Clinical Cardiology Dept., London, United Kingdom; [2]Wilhelmina Children's Hospital, Utrech, Netherlands; [3]Royal Brompton Hospital, Adult Congenital Heart Unit, London, United Kingdom

Background: Arrhythmias is the most common complication late after the Fontan (F) operation. Although heart rate variability (HRV) and baroreflex sensitivity (BRS) are independent markers of autonomic nervous system (ANS) activity and strong predictors of sudden cardiac death in other cardiovascular disease, little is known about their role in adult patients with F operations.
Methods: We measured HRV and BRS in 23 patients late after F repair (9 male, age 27±9y, 14±7y after repair) and in 23 age- and sex-matched normal controls (30±8y, p=0.2 vs F). All subjects underwent 20min of resting measurements of heart rate (ECG) and non-invasive beat-to-beat systolic blood pressure (SBP). A 5min period of 0.1Hz controlled breathing was also recorded. BRS was computed by: a) the a-index (square root of the ratio between RR interval and SBP spectral powers in the low (0.04-0.15Hz, a-LF) and high frequency (0.15-0.4Hz, a-HF) bands, b) the ratio of the average amplitude of oscillations in RR interval and in SBP during controlled breathing (BRSCbr) and c) the sequence method (linear regression slope of RR interval vs SBP, BRSseq). Time domain (SDNN, RMSSD, triangular index) and frequency domain (LF, HF) HRV variables were also measured. Age at F, years from F, and antiarrhythmic therapy (AT) were taken into account.
Results: All HRV and BRS indices were markedly impaired compared to controls (table). Within the F group, BRS and HRV measures did not relate to age at F, years from F and AT.

mean value (SD)	Fontan (n=23)	Control (n=23)
log SDNN	1.5 (0.3)	1.9 (0.2)**
log RMSSD	1.4 (0.4)	1.8 (0.2)*
Triangular index	121 (74)	297 (91)**
log LF	1.9 (0.8)	2.8 (0.4)**
log HF	1.9 (0.8)	2.8 (0.4)**
log a-LF	0.7 (0.4)	1.1 (0.2)**
log a-HF	0.9 (0.4)	1.4 (0.2)**
log BRSSeq	0.9 (0.3)	1.3 (0.2)**
log BRSCbr	0.8 (0.3)	1.3 (0.2)**

Unpaired t-test: *p<0.01, **p<0.0001

Conclusions: There is a global impairment of ANS regulation late after the F operation that may have prognostic implications in these patients.

P1674 Reduced cardiopulmonary exercise performance after tetralogy of Fallot repair is not related to resting central haemodynamics assessed with MRI

P. A. Davlouros[1], R. Wensel[2], S. Bayne[2], A.A. Karatza[1], P.J. Kilner[3], M.J. Mullen[1], A.J.S Coats[2], M.A. Gatzoulis[1]. [1]Royal Brompton Hospital, Adult Congenital Heart Programme, London; [2]NHLI Imperial College, Clinical Cardiology, London [3]Royal Brompton Hospital, Magnetic Resonance Imaging, London, United Kingdom

Introduction: Adults with repaired tetralogy of Fallot (rToF) have reduced exercise capacity. This has been mainly attributed to pulmonary regurgitation (PR). We aimed to investigate any relationship between cardiopulmonary exercise performance indices and resting haemodynamics assessed noninvasively with MRI.
Methods: Cardiopulmonary exercise test was performed in 94 consecutive patients with rToF aged 32±11years (range16-57). Ninety patients underwent MRI on the same day for determination of biventricular volumes, mass, EF and pulmonary regurgitant fraction (PRF). Patients with a respiratory quotient <1 at peak exercise (*n*=18) were excluded. Values obtained for oxygen consumption at peak exercise (peakVO2), anaerobic threshold (AT) and VE/VCO2 slope, were also expressed as percentage of age and sex-matched predicted values.
Results: (table) PeakVO2 in patients was 81±20% of predicted. Percent predicted peakVO2 (%peakVO2) was inversely correlated with PRF (r=-0.4, p<0.01) and the number of reoperations on the right ventricular outflow tract (RVOT) (r=-0.4, p=0.05). PRF was the only independent predictor of %peakVO2 (multiple regression: b=-0.004, p=0.003). There was no correlation of peakVO2 or %peakVO2 with biventricular volumes, EF, or mass.

	Min	Max	Mean	SD
Years after repair	7	39	24	8
peakVO2	13.1	74	30.4	9.3
%peakVO2	40	168	81	20
VE/VCO2slope	13.8	42.3	27.7	6.7
%VE/VCO2slope	48	180	100	24
AT	9	30	18.6	5.1
%AT	17	152	84	24
%Heart rate	65	111	90	11

Conclusions: Cardiopulmonary performance in adults with rToF is reduced. PR and RVOT reoperations have a negative-albeit weak- association with exercise capacity. However biventricular volumes, EF and mass as assessed by MRI do not relate directly with exercise aerobic capacity. Assessment of central haemodynamics during exercise may offer better insight into the mechanisms of reduced exercise capacity in this population.

P1675 Restrictive right ventricular physiology predicts superior exercise hamodynamics in surgically corrected tetralogy of Fallot patients

Z.I. Khan, B-H. Tzeng, S.G. Williams, R. Riley, G.J. Williams, L.B. Tan. *Non Invasive Department, Leeds, United Kingdom*

Conflicting reports on the effect of restrictive right ventricular (RV) physiology affecting exercise capacity in surgically repaired tetralogy of Fallot (rTOF) patients have been reported. Restrictive RV is defined as positive flow seen in the base of the pulmonary artery during late diastole coincident with atrial contraction due to the right ventricle being restrictive the, impulse of atrial contractions continued into the pulmonary artery as a result of forward displacement of the pulmonary valve. This is therefore reflected as a positive wave during late diastole. We sought to see the relation between exercise haemodynamics and restrictive Vs non-restrictive RV Vs normal controls. The patients underwent formal cardiopulmonary exercise testing with assessment of exercise haemodynamic parameters
Results are expressed as mean ±SEM. 23 rTOF patients, of which 13 had restrictive RV physiology, were compared 11 against aged matched controls. Both the restrictive and non-restrictive rTOF groups had reduced exercise duration (8.70±2.86mins Vs 13.51±2.67mins, p<0.001). The non-restrictive group had significantly prolonged QRS complex (140±32.66ms Vs 84.55±12.14ms, p<0.001), higher Ability Index (1.7±0.82 Vs 1±0.00, p<0.05) and reduced peak oxygen consumption (26.90±7.35ml/min/kg Vs 36.21ml/min/kg, p<0.03), peak exercise cardiac output (11.63±3.53l/min Vs 16.58±3.91l/min, p<0.01), cardiac reserve (6.44±2.18l/min Vs 10.05±3.40l/min, p<0.01), peak exercise cardiac power output (2.84±0.98W Vs 4.05±0.89W, p<0.02) and cardiac power reserve (1.83±0.79W Vs 2.65±0.71W, p<0.03). There was no significant difference between the control group and the restrictive group in any of the above parameters of exercise haemodynamics.
Conclusion There was no difference in exercise haemodynamics between the two-rTOF groups however non-restrictive RV physiology was associated with reduced exercise duration and haemodynamics along with a prolonged QRS complex compared to the normal population. This suggests these patients have impaired cardiac function and therefore a reduced prognosis.

P1676 Progressive aortic root dilatation in adults late after repair of tetralogy of Fallot

A. A. Karatza[1], P. A. Davlouros[2], W. Li[2], A.G. Magee[1], M. Mullen[2], M.A. Gatzoulis[2]. [1]Paediatric Cardiology, [2]Adult Congenital Heart Programme, Royal Brompton Hospital, London, United Kingdom

Background: Aortic root dilatation has been previously reported in patients with repaired tetralogy of Fallot.
Methods: We studied 56 consecutive adults with repaired tetralogy of Fallot aged 36±10 years (range 18-62 years, 21 females and 35 males) with cross sectional echocardiography. Median age at repair was 8 years (range 1.5-51 years). Measured indices were compared with those derived from echocardiograms performed at least 30 months previously (50±13 months, range 30-77 months) at our institution. All patients were over 15 years old at first study. A single blinded investigator performed all measurements. Aortic root diameter was measured on standard long axis parasternal 2-D images. Left ventricular dimensions and function were assessed on long axis parasternal M-mode views.
Results: 2-D aortic root diameter increased significantly over time at the level of the sinuses of Valsava (Ao2) (3.61±0.71cm vs 3.85±0.76cm, p=0.0002) and at the sinotubular junction (Ao3) (3.44±0.75cm vs 3.76±0.78cm, p=0.0002), but not at the level of the aortic valve (Ao1) (2.75±0.66cm vs 2.92±0.63cm, p=0.09). There was no increase in aortic regurgitation or any change in left ventricular dimensions and function with time. There was a weak but significant positive correlation between age at repair and aortic root size at the first (Ao1: r=0.616, p<0.0001; Ao2: r=0.492, p=0.0002 and Ao3: r=0.382, p=0.02, respectively) and current echocardiogram (Ao1: r=0.458, p=0.0006;Ao2: r=0.382, p=0.005 and Ao3: r=0.371, p=0.009, respectively).
Conclusions: Aortic root size relates to age at repair suggesting that increased aortic flow prior to repair might be responsible for aortic root dilatation. Furthermore, there is ongoing aortic root dilaation late after repair of tetralogy of Fallot. Prospective follow-up is needed for determination of the significance of our findings.

P1677 Right ventricular function in patients with transposition of the great arteries and atrial switch operation: tissue Doppler evaluation

G.P. Meyer, L. Steinemann, C. Ceconi, P. Lippolt, A. Schaefer, M. Westhoff-Bleck. *Medical School Hannover, Dept. of Cardiology, Hannover, Germany*

Background: The major clinical problem associated with the atrial correction for complete transposition of the great arteries (=TGA) is the development of right ventricular (=RV) failure. The evaluation of the RV by echocardiography (=Echo) is limited by the complex shape of the RV. The estimated ejection fraction (=EF) by Echo often does not correlate with the patients symptoms. Tissue Doppler (=TD) has the potential to estimate systolic function, irrespective of visualisation of the whole ventricle.
Methods: In 40 patients with TGA (mean age 21.6 ± 2.8 years) echo was performed to evaluate regional myocardial function by TD and global ejection fraction of the RV. All patients received a cardiopulmonary exercise test the same day to determine peak oxygene uptake (=peak VO2).
Results: Mean peak VO2 was 28.2 ± 6.7 ml/kg/min; mean EF was 43 ± 9.6%; mean systolic velocity of the basal lateral RV- segments was 7.5 ± 2.5 cm/s. There was no significant correlation of EF and peak VO2. The maximum systolic myocardial velocities correlated positively with the peak VO2 ($p<0.05$; $r=0.66$).
Conclusion: TD of the RV correlates with cardiopulmonary exercise capacities in patients with TGA. TD was a more accurate method in the evaluation than ejection fraction.

P1678 Pulse pressure as a risk factor of the injury of the systemic right ventricle after atrial repair of transposition of the great arteries

P. Szymanski[1], P. Hoffman[1], B. Lubiszewska[2], A. Teresińska[3], J. Rozanski[4]. *[1]National Institute of Cardiology, Noninvasive Cardiology Dept., Warsaw, Poland; [2]Grochowski Hospital, Cardiology Dept., Warsaw, Poland; [3]National Institute of Cardiology, Radionuclide Imaging Laboratory, Warsaw, Poland; [4]National Institute of Cardiology, Dept. of Cardiac Surgery, Warsaw, Poland*

Background: There is a discussion on how patients with complete transposition of great arteries (TGA) with systemically functioning right ventricle after atrial switch should be treated, and whether and when prevention of right ventricular dysfunction is warranted. Hence we analyzed the association between pulse pressure (PP) and blood pressure (BP) at rest and exercise during treadmill exercise test and function of the systemic ventricle.
Methods and Results: The studied population consisted of unselected patients with simple TGA 11.5±2.7 years after atrial switch procedure. All patients had BP values (systolic 109.1±11.7 mm Hg and diastolic 72.3±9.7 mm Hg)well within the thresholds for normal systemic circulation. Patients were divided into subgroups according to the severity of systemic ventricular dysfunction (EF <=0.40 vs >0.40), the occurrence of perfusion abnormalities in radionuclide study (absent or mild vs moderate-to-severe) and the degree of systemic venous valve regurgitation (absent-to-mild vs moderate-to-severe). Mean EF in the first pass angiography was 0.36±0.07, ranging from 0.20 to 0.53, moderate-to-severe perfusion abnormalities were detected in 21 patients (35.1%, moderate to severe systemic venous valve regurgitation in 12 (20%). When BP values together with clinical variables were entered into a multivariate backward logistic regression model with EF as a dependent value, PP at rest, as well as systemic venous valve regurgitation remained in the equation with the Chi square of 19.414 at p level of 0.0001; with systemic venous valve regurgitation as a dependent value, age and diastolic BP at exercise remained in the equation with a Chi square of 25.175 at p level of <0.0001; with perfusion abnormalities as a dependent value, body surface area and systolic BP at rest remained in the equation with a Chi square of 9.668 at p level of <0.008.
Conclusions: In "normotensive" TGA patients with systemically functioning morphologic right ventricle after atrial switch procedure there was a significant correlation between BP and PP values both at rest and exercise and systolic dysfunction, perfusion abnormalities and severity of systemic atrio-ventricular valve regurgitation. This further supports the point that unloading therapy, even within the normal range of BP values, might be warranted.

P1679 The degree of tricuspid insufficiency is a useful indicator of perfusion and function of the systemic ventricle in complete transposition

P. Hoffman[1], P. Szymanski[1], B. Lubiszewska[2], A. Teresinska[3], J. Rozanski[4]. *[1]National Institute of Cardiology, Noninvasive Cardiology Dept., Warsaw, Poland; [2]National Institute of Cardiology, Dept. of Cardiology, Warsawa, Poland; [3]National Institute of Cardiology, Radionuclide Imaging Laboratory, Warsaw, Poland; [4]National Institute of Cardiology, Dept. of Cardiac Surgery, Warsaw, Poland*

Background: One of the late problems associated with the atrial correction for complete transposition (TGA) is right ventricular (RV) failure. The purpose of our study was to assess whether echocardiographically evaluated tricuspid regurgitation (TR) is a useful indicator of the functional status of the systemic RV in TGA.
Methods: 60 patients (14.9±14.5 years old) with simple TGA, 11.5±12.7 years after Mustard or Senning operation were included in the study. Echocardiographic examination and myocardial perfusion imaging at rest and exercise were performed on the two successive days of the study. RV ejection fraction (RVEF) was calculated from background-corrected end-diastolic and end-systolic counts of the first-pass angiogram. TR was classified as mild or moderate-to-severe using a standard semiquantitative Doppler method.
Results: 48 (80%) patients had mild and 12 (20%) moderate-to-severe TR. TR correlated significantly with RVEF (-0.30; $P<=0.03$), QRS width (0.45; $P<=0.001$), cardiothoracic ratio (0.39; $P<=0.02$), body surface area (0.27; $P<=0.04$) and age at surgery (0.44; $P<=0.001$). Patients with moderate-to-severe TR had lower RVEF (0.30 vs 0.36; $P<=0.01$) and tended to have more frequently significant perfusion abnormalities at exercise (28% vs 8%; $P=0.056$), compared to patients with mild TR.
Conclusion: TR was a simple indicator of the functional status of the systemic ventricle in TGA. Significant TR was associated with the depressed systolic RV function and increasing perfusion abnormalities in patients after atrial switch procedure for TGA.

P1680 Ventilatory response and pulmonary gas exchange at rest and during exercise in patients after the Fontan operation

H. Ohuchi, H. Ohasshi, J. Park, A. Miyazaki, O. Yamada, S. Echigo. *National Cardiovascular Center, Pediatrics, Osaka, Japan*

Background: Although abnormal pulmonary circulation, lung function and respiratory response during exercise are well known characteristics in Fontan patients, the relationships between these impaired functions have not been well established.
Methods and Results: Pulmonary function and cardiopulmonary exercise tests were performed in 95 Fontan patients (mean age = 13.6 years, atriopulmonary connection in 29, total cavopulmonary connection in 66) and 44 controls. Vital capacity (VC) and diffusion capacity were significantly lower in Fontan patients than in controls. VC was associated with the number of surgical procedures and decreased significantly during follow-up, being significantly related to the higher frequency and smaller tidal volume (respiratory pattern) during exercise, while did not relate to the dead space ventilation (VD/VT), ventilatory equivalent for CO_2 production (ventilatory efficiency) or peak oxygen uptake. Rest and exercise minute ventilation was accelerated and the VD/VT was higher during exercise in Fontan patients. Lower arterial saturation was related with accelerated ventilation, resulting lower resting $PaCO_2$ and resting arterial gas tensions and alveolar ventilation to CO_2 production ratio, not the types of repair or VC, determined PaO_2 and $PaCO_2$ dynamics during exercise. Fontan patients with left ventricular type had higher diffusion capacity, superior ventrilatory efficiency and peak oxygen uptake compared with those without.
Conclusions: After the Fontan operation, progressive restrictive ventilatory impairment determines the exercise respiratory pattern. Resting slight but significant hypoxia and high VD/VT during exercise have a great impact on accelerated ventilation. However, the ventricular morphology rather than the lung volume or respiratoty pattern have a greater impact on not only their exercise capacity but exercise ventilatory efficiency.

P1681 Cardiomyopathy in Alstrom syndrome

C. Carey[1], J. Marshall[2], A. Nordstrom[3], K. Parkinson[4]. [1]*Torbay Hospital, Heart and Lung Unit, Torquay, United Kingdom;* [2]*Jackson Laboratory, Bar Harbor, Maine, United States of America;* [3]*Jackson Laboratory, Bar Harbor, Maine, United States of America;* [4]*Society of Alstrom Syndrome Families, Devon, United Kingdom*

Purpose: Alstrom Syndrome (AS) is a rare recessive genetic disorder located on chromosome 2p13. Cardiomyopathy in childhood has been described in AS, but the frequency and natural history are unknown.
The cardinal features of AS include infantile nystagmus and photophobia, with early visual loss (retinal pigmentary degeneration), sensori-neural deafness, childhood truncal obesity and insulin resistant diabetes mellitus. Intelligence is usually normal. Additional metabolic problems may occur. Late diagnosis is common since several cardinal features only become apparent with time.
Methods: In this study we identified patients with AS through referrals to a specialist genetic centre, by contact with the website for Alstrom Syndrome and through the Society for Alstrom Syndrome Families. Patients were included if the standard diagnostic criteria were confirmed by review of the patient and/or their medical records, (supplemented by data from a structured medico-social questionnaire completed by 65 patients and families).
Results: We identified 122 patients with AS, ranging in age from 14 days to 48 years, with an equal sex ratio. Over half the patients had experienced childhood cardiomyopathy [74/122 (60%)].Typically, acute heart failure developed in infancy, between the age of 2 weeks and 10 months (median onset 2 months). Although 12/54 died (22%), all but 3 of the survivors made an apparently full recovery. However, on long-term follow-up, 9 (21%) have subsequently developed dilated cardiomyopathy (age at relapse 5 - 36 years, median 16). There were 20 AS patients in whom heart failure was not apparent until after infancy (onset age 2.5 - 36 years, median 11 years). This group appear to have a more typical progressive dilated cardiomyopathy with a higher mortality rate (10/20, 50%).
The remaining AS patients are so far free from cardiac disease at follow-up, age 7 months to 48 years.
Overall, 33/122 (27%) of the patient group have died, 23 from cardiac disease, 6 from non-cardiac disease and 4 infants from unknown cause.
Conclusions: 1. Childhood cardiomyopathy affects over 50% AS patients and is the main cause of premature death.
2. AS patients need lifelong cardiac evaluation with a high index of suspicion for cardiac involvement.
3. Greater awareness of the association between infantile cardiomyopathy and the distinctive eye signs will enable earlier diagnosis of AS.

P1682 Early surgical treatment of infective endocarditis in congenital heart diseases. Outcome and prognosis

S. Di Filippo, B. Semiond, F. Sassolas, A. Bozio. *Hôpital Cardiovasculaire, Cardiologie Pédiatrique, LYON cedex 03, France*

The aim of this retrospective study was to determine the prognostic significance of early surgical treatment for infective endocarditis (IE) in patients with congenital heart diseases (CHD).
From 1966 to 2000, 167 IE occurred in 153 pts, aged 3.6days to 78.5years(y) (median 10y); 125 were <18y of age and 42 were adults. Underlying CHDs were: ventricular septal defect isolated (15%: repaired 24%, unoperated 76%) or not (8%: repaired 60%), complex cardiopathy cyanotic (18%: palliated 77%) or acyanotic (7%: palliated 33%, non-operated 41%), Tetralogy of Fallot (8%: repaired 50%, palliated 36%), aortic (9% including bicuspidia 2.4% and prothesis 4%) or mitral (7% including MVP 2.4%, non-operated 100%) valvulopathies, and ductus arteriosus (2 non-operated), atrial septal defect + mitral anomaly (3= 2 repaired, 1 non-operated), pulmonary stenosis(1 non-operated). Route was unknown (31%), dental (25%), post cardiac surgery (19%), cutaneous (9%), ENT (6%) or other. Blood cultures were negative in 14%; streptococcus and staphylococcus were the commonest agents. Clinical cardiac complications occurred in 26%, embolias in 31%. Vegetations were the most frequent echographic lesion (42%). Early surgery (< 3d month after diagnosis) occurred in 31% of the cases and was indicated for haemodynamic instability, uncontrolled sepsis or multiple embolias. Risk factors for early surgical treatment were: underlying CHD (mitral and/or aortic valvulopathy, p=0.0008), clinical cardiac failure (p<0.0001), embolias (p= 0.0014), extracardiac complications due to embolia (p= 0.0026), site of IE (mitral and/or aortic, p<0.0001), echographic lesions (vegetations, p<0.0001). Age, period, time to diagnosis, bacterial agent were not significant factors. Early surgical treatment included mitral and/or aortic prosthesis (50%), mitral repair (8%), valvular homografts (8%), Ross operation (8%), interventricular patch (11%), ductus ligation (2%) and miscellaneous. Thirty-four patients died (21%), 1 day to 19.5y after diagnosis (median 6mths), from post-IE (48.5%), cardiac non-IE (39%) or unknown (12%) causes. Survival was 93%, 89%, 87%, 76% and 56%, at 1mth, 6mths, 1y, 10y and 25y. Early surgical treatment did not influence mortality nor survival.
Our results show that left heart cardiopathies and locations, clinical complications and echographic vegetations lead more often to early surgery without increase in mortality.

P1683 Comparative rate of haemodynamic progression of discrete subaortic and right mid-ventricular obstructions in adults. Management implications

P. Gallego Garcia D[1], J. Oliver[2], A. González[2], A. Garrido[2], A. Aroca[2], J. Mesa[2], J.A. Sobrino[2]. [1]*Virgen Macarena University Hospital, Sevilla, Spain;* [2]*La Paz University Hospital, Adult Congenital Heart Disease Unit, Madrid, Spain*

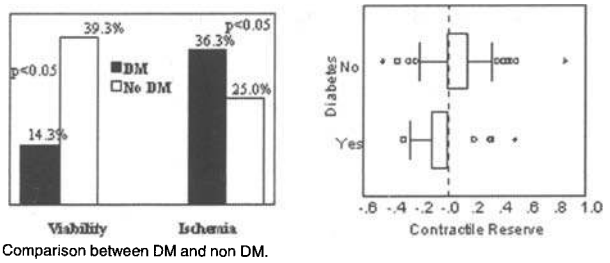
Background: Discrete subaortic stenosis (DSS) and right mid-ventricular obstruction (RMVO) represent unique cardiac lesions, as they do occur very infrequently in neonatal period and might progress in severity during lifetime. The purpose of this study was to compare the rate of progression of these two entities during adulthood in an attempt to make clear the indications for surgical management.
Methods and Results: The clinical and echocardiographic findings in 93 adults with DSS (mean age 36 ± 19 years) and 25 adults with RMVO (mean age 26 ± 6 years) who survived into adulthood without previous intervention have been retrospectively analyzed and compared. The relationship between peak pressure gradient (PPG) and age was analyzed. Mean change in PPG with time was determined in those patients with two or more available Doppler echocardiographic examination performed with at least a two-year interval. A significant correlation between PPG and age was found in DSS (r=0.61, p<0.001) and RMVO (r=0.63, p=0.001) but the slope of regression was steeper in RMVO (y=3.4x, 95% confidence interval [CI] 1.5 to 5.3) than in DSS (y= 1.3x, 95% CI 0.94 to 1.65). Peak pressure gradient increased from 39.2±28 mm Hg to 46.8 ± 34 mm Hg (p=0.01) during a mean follow-up of 4.8±1.8 years in 25 patients with DSS and from 31 ± 26 mm Hg to 67 ± 35 mm Hg (p<0.001) during a mean follow-up of 6.17 ± 2.7 years in 13 patients with RMVO. The slope of the change in PPG was also steeper in RMVO (6.1 ± 3.0 mm Hg per year) than in DSS (2.25 ± 4.7 mm Hg per year).
Conclusions: Both DSS and RMVO show a progressive nature along the adult life, but the rate of progression is slow in DSS and accelerated in RMVO. These data suggest a more conservative surgical approach in DSS than in RMVO.

DIABETES AND CARDIOVASCULAR DISEASE

P1684 Diabetes leads to less contractile reserve after myocardial infarction

R. Moreno, J. Zamorano, C. Almeria, L. Alvarez, J.L. Rodrigo, D. Herrera, A. Aubele, L. Sánchez-Harguindey. *Hospital Clinico San Carlos, Cardiology Dept., Madrid, Spain*

Although several reasons for the worse prognosis of acute myocardial infarction (AMI) in diabetic (DM) patients have been recognized, left ventricular ejection fraction seems not to be lower in DM. The aim of this study was to evaluate whether, although having a similar left ventricular ejection fraction at rest, DM patients with AMI have a reduced left ventricular contractile reserve in comparison with non-DM.
Patients and methods: 108 patients were included in the study after having suffered an AMI. Low-dose dobutamine echocardiography was performed, beginning at 5 ìg/kg/min and increasing the infusion rate every 3 min up to 20-40 ìg/kg/min. Contractile reserve was considered to be present when systolic function improved at least in one degree during dobutamine infusion in hypoquinetic or aquinetic segments. Patients with (28, 25.9%) versus without (80, 74.1%) DM were compared.
Results: Mean age was 66±10 yr, and 91 (84.3%) were male. Out of the 108 patients, 28 (25.9%) were DM and 80 (74.1%) non DM. Baseline left ventricular wall motion index was not different between DM and non DM (1.67±0.44 vs. 1.60±0.39, p = NS). In 33 of the 108 patients (30.6%) contractile reserve (myocardial viability) was present, and 31 (28.7%) showed ischemia during dobutamine echocardiography. Importantly, the presence of myocardial viability was significantly less frequent in DM than in non DM (14.3% vs. 36.3%, p = 0.033) (see figure).



Comparison between DM and non DM.

Conclusion: Although having a similar left ventricular systolic function at rest, the presence of contractile reserve after AMI is less frequent in DM patients in comparison with non DM. This could contribute to the poorer prognosis of DM when suffering an AMI in comparison with non DM.

P1685 Presentation of fluid retention in diabetic patients with chronic heart failure using thiazolidinediones

W.H. Tang, G.S. Francis, J.B. Young. *Cleveland Clinic Foundation, Cardiology, Cleveland, United States of America*

Background: Insulin resistance and poor glycemic control adversely affect prognosis of chronic heart failure. Thiazolidinediones (TZDs) appear to have a remarkably potent and beneficial effect on endothelial function in addition to improving insulin sensitivity. However, TZDs are contraindicated in patients with heart failure due to their propensity for fluid retention, although the characteristics of patients with heart failure and fluid retention remain poorly understood.
Methods: We identified patients with chronic stable heart failure (NYHA I-III, EF ≤45%) and diabetes mellitus who are referred to the Cleveland Clinic for heart failure management, in which TZDs (troglitazone, pioglitazone or rosiglitazone) have been previously initiated. Retrospective chart review is performed to evaluate for baseline ejection fraction and glycemic control prior to TZD initiation, as well as changes in weight and clinical course at the end of 6 months following TZD therapy. Fluid retention is defined as involuntary weight gain (>10 pounds over 6 months) with clinical evidence of fluid overload. Univariate analyses using t- and chi-square tests comparing demographic and echocardiographic variables between the upper tertile(GAINERS) and lower tertile(NON-GAINERS)of weight changes are performed to identify clinical predictors for fluid retention following treatment with TZDs.
Results: Of the 111 consecutive patients (mean age 55 ±9 years, 68% male, mean LVEF 28.9 ±7%) identified, the mean change in weight over 6 months of TZD therapy is 5.9 ±8 pounds. GAINERS (mean weight gain 14.1 pounds) are significantly differed from NON GAINERS (mean weight gain 0.6 pounds) in larger body mass index, more females and less treated with insulin. Weight gain is independent of the baseline severity of heart failure (either by ejection fraction or by NYHA class). Overall, 17.1% patients present with refractory fluid retention (>10 pounds despite intensified diuretic therapy) mimicking decompensated heart failure within 6 months following TZD initiation. Only 2 patients have clinical evidence of pulmonary edema and none have significant hepatotoxicity. Following TZD discontinuation, all have resolution of their fluid retention.
Conclusion: Presentation of fluid retention following treatment with TZDs in diabetic patients with systolic dysfunction may mimic heart failure decompensation. This manifestation is reversible following TZD withdrawal. However, no direct association can be made between the risk of fluid retention and the baseline severity of heart failure.

P1686 Significant mortality benefit of prior beta-blocker use in diabetic patients undergoing coronary intervention

D. Mukherjee[1], D. Smith[1], E. Kline-Rogers[1], S. Chetcuti[1], K A. Eagle[1], P. Michael Grossman[1], D. Share[2], M. Moscucci[1] on behalf of the Blue Cross Blue Shield of Michigan Cardiovascular Consortium. *[1]Univ. of Michigan, Div. of Cardiology, [2]Blue Cross and Blue Shield Foundation, Ann Arbor, USA*

Background: Studies have shown beta-blockers (BB) to be one of the best classes of drugs to treat coronary artery disease. However, physicians traditionally have avoided prescribing BB for people with diabetes primarily because these drugs can "mask" the warning signs of low blood sugar. Whether prior BB use may be beneficial in diabetic patients undergoing percutaneous coronary intervention (PCI) remains undetermined.
Methods: Study samples consisted of 18,309 consecutive coronary interventions (PCI) performed between July 1997 and February 2001 in a consortium of 8 hospitals. Of the 18,309 patients who underwent PCI, 4,856 were diabetics. In the diabetic cohort, 1,772 had insulin dependent (IDDM) and 3,084 patients had non insulin-dependent (NIDDM). Clinical, procedure, and outcome data were collected prospectively by use of a standardized data collection form agreed on by the participating centers.
Results: There was significant reduction in unadjusted peri-procedural mortality rates in diabetic patients receiving beta-blockers (table). After adjustment for demographics and comorbidities, prior beta-blocker use was associated with a significant survival benefit in IDDM with adjusted odds ratio of 0.49 (95% CI: 0.25 - 0.97, p=0.03) and no significant difference in NIDDM with odds ratio of 0.75 (95% CI: 0.38-1.49, p=0.42).

	IDDM (no BB) n=580	IBBM + BB n=1192	NIDDM (no BB) n=887	NIDDM + BB n=2197
Death	4.48%	2.35%	2.82%	1.32%
MI	0.69%	3.36%	2.37%	2.05%
Stroke	0.52%	0.25%	0.23%	0.36%
Emergent CABG	0.86%	1.01%	0.79%	0.68%
Death/MI/stroke/CABG	6.38%	6.46%	5.64%	3.73%

Effect of prior beta-blocker (BB) use in diabetis undergoing percutaneous coronary intervention. Diabetic status is stratified by insulin dependent (IDDM) and non insulin dependent (NIDDM)

Conclusions: In this cohort of diabetics undergoing PCI use of beta-blockers was associated with significantly improved peri-procedural survival. A logistic regression model suggests significantly improved risk-adjusted survival with prior beta-blocker use in IDDM patients.

P1687 Lack of benefit of intravenous GP IIb/IIIa inhibitors in diabetic patients undergoing percutaneous coronary intervention is explained by differences in baseline characteristics

D. Mukherjee[1], D. Smith[1], S. Chetcuti[1], D. Share[2], E. Kline-Rogers[1], K A. Eagle[1], P. Michael Grossman[1], M. Moscucci[1] on behalf of The Blue Cross Blue Shield of Michigan Cardiovascular Consortium. *[1]University of Michigan, Division of Cardiology, Ann Arbor, United States of America; [2]Blue Cross and Blue Shield Foundation, Ann Arbor, United States of America*

Background: There has been conflicting evidence in the literature regarding effect of IIb/IIIa inhibitors in diabetic patients with coronary artery disease. The EPISTENT trial showed significant benefit in diabetic patients receiving IIb/IIIa inhibitors whereas the ASSENT-3 study showed worse outcome in diabetics with these agents. We systematically analyzed clinical outcomes in consecutive diabetic patients undergoing percutaneous coronary intervention (PCI) stratified by glycoprotein IIb/IIIa use.
Methods: Study samples consisted of 18,309 consecutive PCI performed between July 1997 and February 2001 in a consortium of 8 hospitals. Of the 18,309 patients who underwent PCI, 4856 were diabetics. In the diabetic cohort, 1,772 had IDDM and 3,084 patients had NIDDM. Clinical, procedure, and outcome data were collected prospectively by use of a standardized data collection form agreed on by the participating centers.
Results: Mortality and the composite of death/MI/stroke/emergent CABG occurred significantly more often in diabetic patients receiving IIb/IIIa inhibitors. After adjustment for demographics and comorbidities, the adjusted odds ratios of death with IIb/IIIa vs no-IIb/IIIa in IDDM (OR 1.9, 95% CI 0.9-3.7, p=0.06) and NIDDM (OR 1.03, 95% CI 0.5-2.0, p=0.91) patients were not significantly different.

	IDDM (no IIb/IIIa) n=1050	IDDM+IIb/IIIa n=722	NIDDM (no IIb/IIIa) n=1719	NIDDM+IIb/IIIa n=1365
Death	2.19%	4.29%	1.51%	2.05%
MI	1.71%	3.60%	1.69%	2.71%
Stroke	0.29%	0.42%	0.06%	0.66%
Emergent CABG	1.14%	0.69%	0.76%	066%
Death/MI/Stroke/CABG	5.05%	8.45%	3.72%	4.98%

Clinical outcomes of diabetic patients undergoing percutaneous intervention stratified by glycoprotein IIb/IIIa use

Conclusions: In this cohort of diabetics undergoing PCI use of IIb/IIIa inhibitors was associated with worse outcomes particularly in patients with IDDM. Multivariate analyses revealed that the adverse clinical outcomes were explained by differences in prevalent and incident disease characteristics between diabetics and non-diabetics.

P1688 Pregnancy induced changes in type I diabetic women

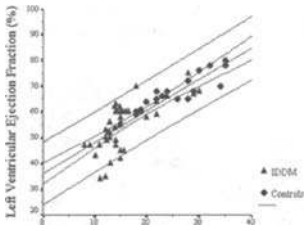
C.M. Schannwell, F.C. Schoebel, G. Plehn, R. Marx, B.E. Strauer. *Duesseldorf, Germany*

Background: Pregnancy induces changes in blood volume and cardiac output. Aim of the following study was to investigate the course of hemodynamic parameters under the increased volume load during pregnancy and delivery in women with insulin dependent diabetes mellitus (IDDM).
Methods: Therefore we examined 34 pregnant women with IDDM. The control group (C) consists of 23 healthy pregnant women. All women underwent echocardiography at the 8th, 12th, 24th, 32th week of gestation and postpartum. Using M-mode echocardiography morphological parameters (left ventricular(LV) mass index) and systolic function (fractional shortening FS; %) were determined. The parameters of LV diastolic function were assessed by Doppler-echocardiographic analysis of the diastolic transmitral flow: the maximal early (VE) and late velocity of diastolic filling; the E/A-ratio; the deceleration time (DT) and the isovolumetric relaxation time(IVRT).
Results: In all women an increase of LVMMI (60±2 vs 69±3 g/m^2; p=n.s.), a decrease of FS (35 vs 28%) and diastolic dysfunction was documented. In C a delayed relaxation pattern (VE: 0.54±0.05 m/s; E/A: 0.8±0.2, DT: 241±11 ms; IVRT: 129±8 ms) at the 32th week of gestation was found. 16 diabetics already showed these signs at the beginning of pregnancy. From midpregnancy these women developed a restrictive diastolic filling pattern (VE: 1.1±0.07 m/s; E/A: 2.1±0.1; DT: 123±8 ms; IVRT: 62±2 ms). The remaining 8 diabetics had a comparable restrictive filling pattern during vaginal delivery. There were no complications in C. In women with IDDM 1 maternal and 2 fetal deaths occurred during labor/delivery and 7 women suffered from ventricular arrhythmias ($p < 0.001$). All changes induced by pregnancy were reversible in C within days, but persisted over weeks in diabetics.
Thus: In healthy women pregnancy induces a reversible physiologic LV hypertrophy, a delayed relaxation pattern and a temporarly decrease of FS. Pregnant women with IDDM developed signs of restriction and had a markedly increased risk of maternal and fetal mortality.

P1689 Myocardial perfusion and function in type 1 diabetic patients

C. Negut[1], R. Scognamiglio[1], A. Avogaro[2], S. Vigili de Kreutzenberg[2], M. Palisi[1], S. Cukon-Buttignoni[1], S. Iliceto[1], A. Tiengo[2]. [1]*Division of Cardiology, Clinical and Experimental Medicine, Padua, Italy;* [2]*Division of Metabolic Diseases, Clinical and Experimental Medicine, Padua, Italy*

To investigate the relationship among myocardial perfusion and function, and circulating levels of inflammatory cytokines in young adult patients with IDDM. Twenty two patients (BMI 23±2 kg/m^2; age 32±8.3 years) without macro- or microvascular complications and arterial hypertension, and 10 healthy subjects (controls: BMI 24±2 kg/m^2; age 31±3 years) were studied. LV dimensions (LVEDVI) and function (LVEF) were measured by 2D echocardiography; myocardial perfusion (myocardial peak intensity, MPI) was assessed with contrast echocardiography at rest and during handgrip. Patients and controls had similar baseline values for LVEDVI and LVEF. Patients were classified into two groups on the basis of LV response to handgrip: group A-LVEF decline of >0.05 units, group B-LVEF increase or no change. Baseline (14.2±1 and 16.6±3.8 vs 20.5±2.2 gray scales; pA<0.001, and pB<0.05) and peak handgrip values for MPI (12.8±1.6 and 21.3±7.9 vs 30.7±3.3 gray scales; pA<0.001, pB<0.05) were significantly lower in diabetic patients as compared to controls. Among patients, group B had higher values of MPI both at rest (p<0.05) and at peak handgrip (p=0.008). Considering both baseline and peak handgrip values in patients and controls (n=64), a strong correlation between MPI and LVEF was seen (r=0.828, p<0.0001, Figure 1).



In diabetic patients plasma levels of TNF-alfa (8.5±1.2 vs 1.1±1.0 pg/ml, p<0.001) and IL-6 (2.5±0.3 vs 0.7±0.2 pg/ml, p<0.01) were significantly higher than in controls. Myocardial perfusion is impaired in young IDDM patients without micro- and macrovascular complications. This abnormality is strongly related to myocardial function and conditioned LV performance during isometric exercise, and is associated with high plasma levels of TNF-alfa and IL-6.

P1690 Prognostic value of dobutamine-atropine stress myocardial perfusion imaging in patients with diabetes mellitus

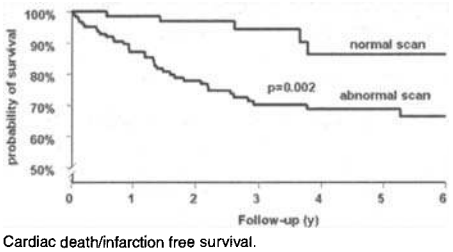
A.F.L. Schinkel, A. Elhendy, R.T. van Domburg, J.J. Bax, E.C. Vourvouri, F.B. Sozzi, J.R.T.C. Roelandt, D. Poldermans. *Erasmus Medical Center Rotterdam, Cardiology Dept., Rotterdam, Netherlands*

Objective: Exercise tolerance in patients with diabetes mellitus is frequently impaired due to non-cardiac disease, as claudication and polyneuropathy. This study assesses the prognostic value of dobutamine stress myocardial perfusion imaging in patients with diabetes mellitus.

Methods: A total of 207 consecutive diabetic patients unable to perform an exercise test underwent dobutamine-atropine stress myocardial perfusion imaging. Follow-up was successful in 206 of 207 (99.5%) patients. Twelve patients underwent early (<60 days) revascularization and were excluded from the analysis. End points during follow up were hard cardiac events defined as cardiac death and non-fatal myocardial infarction.

Results: Abnormal myocardial perfusion was detected in 125 (64%) patients. During 4.1±2.4 year follow-up, 73 (38%) deaths occurred of which 36 (49%) were due to cardiac causes. Nonfatal myocardial infarction occurred in 7 (4%) patients and 45 (23%) patients underwent late coronary revascularization. Cardiac death occurred in 2 of 69 (3%) patients with normal myocardial perfusion and in 34 of 125 (27%) patients with perfusion abnormalities (P<0.0001). A multivariable Cox proportional-hazards model demonstrated that the presence of an abnormal scan had an incremental prognostic value for the prediction of cardiac death (hazard ratio = 7.5, 95%CI 1.8-32), additional to clinical and stress test data. The summed stress score (SSS) was an important predictor of cardiac death, with a hazard ratio of 1.2 (95%CI 1.07-1.34) per 1 unit increment.

Conclusions: Dobutamine-atropine stress myocardial perfusion imaging provides prognostic information incremental to clinical data in patients with diabetes mellitus unable to perform an exercise stress test.



Cardiac death/infarction free survival.

P1691 Prognostic value of dobutamine stress echocardiography in patients with diabetes mellitus

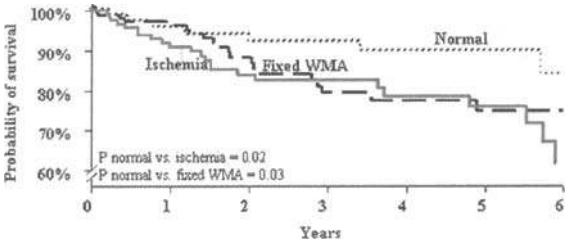
F.B. Sozzi[1], A. Elhendy[1], D. Poldermans[1], R.T. van Domburg[1], A.F.L. Schinkel[1], E.C. Vourvouri[1], D. Ardissino[2], J.R.T.C. Roelandt[1]. [1]*Thoraxcentre, Erasmus Medical Centre, Rotterdam, Netherlands;* [2]*Cardiology Dept, Parma, Italy*

Purpose: The aim of this study was to assess the incremental value of dobutamine stress echocardiography (DSE) for the risk stratification of diabetic patients.

Background: Exercise capacity is frequently impaired in patients with diabetes mellitus. The role of DSE in the risk stratification of diabetic patients has not been well defined.

Patients and methods: We studied 396 diabetic patients [mean age 61±11 years, 252 men (64%)] who underwent DSE for evaluation of known or suspected coronary artery disease. Endpoints were hard cardiac events (cardiac death and nonfatal myocardial infarction) and all causes of mortality.

Results: During a median follow up of 3 years, 97 patients (24%) died (55 cardiac deaths) and 27 patients had nonfatal myocardial infarction. Curves for survival free of hard cardiac events in patients with normal DSE, ischemia and fixed wall motion abnormalities (WMA) are presented in the picture below: P value between normal DSE and ischemia was 0,02; P value between normal DSE and fixed WMA was 0,03. In an incremental multivariate analysis model, clinical predictors of hard cardiac events were history of congestive heart failure and previous myocardial infarction. The percentage of ischemic segments was incremental to the clinical model in the prediction of hard cardiac events (chi square 37 vs. 18, p<0,05). Clinical predictors of all causes of mortality were history of congestive heart failure, age and hypercholesterolemia. Wall motion score index at peak stress was incremental to the clinical model in the prediction of mortality (chi square = 47 vs. 33, p<0,05).



Survival curves for hard cardiac events.

Conclusions: DSE provides incremental data for the prediction of mortality and hard cardiac events in patients with diabetes mellitus.

P1692 Detection and treatment of silent myocardial ischaemia in high risk diabetic patients decrease the occurrence of major cardiac events

G. Vanzetto[1], S. Halimi[2], O. Ormezzano[1], H. Bouvaist[1], J. Machecourt[1]. [1]CHU Grenoble, Cardiologie,[2]Univ. Hosp., Diabetology, Grenoble, France

Background: Because silent myocardial ischemia (SMI) has been demonstrated to be harmful in diabetic patients, recent guidelines recommend detection of SMI in high risk asymptomatic subjects. The impact of treatments in such patients however has not been fully established. Accordingly, we aimed to determine the ability of an ischemia guided strategy to decrease the occurrence of major cardiac adverse events (MACEs = cardiac death + non fatal myocardial infarction (MI) in high risk asymptomatic diabetic patients.
Methods: This monocenter prospective study compared the occurrence of MACEs in 2 groups of asymptomatic diabetic patients presenting with 2 or more associated risk factors, and/or proteinuria, and/or peripheral vascular disease. Each patient underwent an exercise or dipyridamole thallium 201 perfusion scan for detection of SMI. Group I consisted in a population of 204 patients prospectively included between 1991 and 1995, in which therapeutic measures were left at the discretion of the referral physician. Group II (n = 166 patients included between 1997 and 2000) underwent predifined systematic medical treatments and/or revascularisation: statins if LDLc > 130 mg/dl, ACE inhibitors for high blood pressure, beta-blockers and aspirin in case of abnormal perfusion scan, and invasive strategy (coronary angiography and revascularisation when suitable) in case of perfusion defect involving > 15% of left ventricle. Follow-up was similar for both group (24±12 vs 22±8 months).
Results: Baseline data were similar in Group I and II: men 86 vs 85%, age 59±11 vs 58±12 yrs, body mass index 28.7±5.6 vs 29.0±5.3, type II diabetes 76 vs 81%, duration of diabetes 14±8 vs 12±9 yrs, and mean number of risk factors 3.9±1.5 vs 4.2±2.0 respectively, NS for all. Proteinuria however was more frequent in group I (58 vs 43%, p=0.06).
MACEs occurred more frequently in group I than in group II: n=29 - 14.2% vs n=10 - 6.1% - Odd ratio 2.4 [1.2-4.1], p <0.01. This decrease in MACEs in group II was related to a lower occurrence of MI (n=19 - 9.3% vs n=3 - 1.8%, p<0.05), without significant decrease in cardiac death (n=10 - 4.9% vs n=7 - 4.2%, NS). After adjustment for baseline variables, the 2 independent predictors of future MACEs were an aged > 65 yrs (p=0.04) and belonging to group I (p=0.04).
Conclusion: Detection and aggressive treatments of SMI in high risk diabetic patients is efficient for decreasing MACEs and non fatal MI in the present study. Larger studies are needed to assess the impact of such risk reduction strategies on mortality.

P1693 The effect of diabetes on plasma potassium concentrations in acute coronary syndromes

K. Foo[1], N. Sekhri[1], C. Knight[2], A. Deaner[2], K. Ranjadayalan[1], A.D. Timmis[3]. [1]Newham Healthcare Trust, Cardiology Dept., London, United Kingdom; [2]King George Hospital, Cardiology Dept, Ilford, United Kingdom; [3]London Chest Hospital, Cardiology, London, United Kingdom

Objectives: To compare plasma potassium concentrations in diabetic and non-diabetic patients with acute coronary syndromes (ACS).
Background: Acute phase hypokalaemia in ACS occurs in response to adrenergic activation which stimulates membrane bound sodium-potassium-ATPase and drives potassium into the cells. It is not known if the hypokalaemia is attenuated in patients with diabetes, due to the high prevalence of sympathetic nerve dysfunction.
Methods: Prospective cohort study of 1783 patients presenting with ACS. Patients were stratified by duration of chest pain, diabetic status and pretreatment with beta-blockers.
Results: In patients presenting within 6 hours of symptom onset, there was a progressive increase in plasma potassium concentrations from 4.08±0.47 mmol/l in patients presenting within 2 hours (n=438), through 4.18±0.47 mmol/l in patients presenting between 2 and 4 hours (n=237), to 4.25 ±0.56 mmol/l in patients presenting between 4 and 6 hours (n=122, p=0.0007). This pattern of increasing plasma potassium concentration with duration of chest pain was not seen in patients pretreated with beta-blockers or in patients with diabetes in whom potassium concentrations were significantly higher than in patients without diabetes (4.3±0.53 versus 4.1±0.46, p<0.0001). Multivariate analysis identified diabetes as a predictor of a plasma potassium concentration in the upper half of the distribution (OR 1.69; CI 1.34-2.13), independently of renal dysfunction, ACE-inhibition, diuretic therapy and a range of other baseline variables. Acute phase ventricular arrhythmias during the first 6 hours were recorded less frequently in patients with than without diabetes (3.7% versus 8.6%, p=0.02).
Conclusion: Relative insulin deficiency almost certainly accounted for the increased plasma potassium concentrations in diabetic patients with ACS, but the absence of an early potassium dip in this group was also seen in patients on beta-blockers and is more plausibly attributed to sympathetic nerve dysfunction. This may be beneficial if it helps protect diabetic patients against acute phase ventricular arrhythmias.

P1694 Diabetic patients after percutaneous interventions in native coronary arteries: gender differences in clinical outcomes at 1-year follow-up

F. Kuepper[1], G. Dangas[2], A.J. Lansky[2], I. Iakovou[1], D.T. Ashby[2], M. Farkouh[3], M.B. Leon[2], R. Mehran[2]. [1]Cardiovascular Research Foundation, New York, NY; [2]Lenox Hill Hospital, Interventional Cardiology, New York, NY; [3]Mount Sinai Medical Center, Cardiovascular Institute, New York NY, United States of America

Background: We assessed whether female gender is a risk factor for clinical events at 1-year follow-up in diabetic patients undergoing percutaneous coronary interventions (PCI).
Methods: Among 1832 consecutive diabetic patients who underwent 2291 PCIs in native coronary vessels, 716 pts (39%) were women. Pts with acute MI within 72h before PCI or pts with vein graft PCI were excluded.
Results: Women were older (66±11 yrs vs. 64±10 yrs, P<.0001) and had less prior MI (50% vs. 55%, P=.047) and prior CABG (29% vs. 35%, P<.0019) than men. Chronic renal insufficiency (CRI, 14% vs. 12%, P=.152) and peripheral vascular disease (PVD, 28% vs. 25%,P=.108) were similar in the two groups. Multivessel PCI occurred in 26% of both genders (P=.796). In-hospital, women had higher rates of (i) acute renal failure (8% vs. 4%, p<.0001),(ii) non-Q-wave MI (14% vs. 10%, P=.014),(iii) major vascular complication (8% vs. 3%, P<.0001) and (iv) blood transfusion (12% vs. 3%, P.<0001). In-hospital mortality (1.7% vs. 1.0%, P=0.163) repeat PCI (3% vs. 2%, P=0.106), CABG (2% vs 2%, P=.517) and stroke (0.2% vs. 0.1% P=.565) were similar in the two groups. At 1-year follow-up, mortality was higher in women than in men (11.3% vs. 7.7%, P=.0063). Multivariate predictors of 1-year mortality included age (OR=1.06, P<.0001), CRI (OR=3.67, P<.0.0001), prior CABG (OR=1.85, P=.0002) and PVD (OR=2.13, P<.0001), but not female gender. Other clinical events were similar at 1-year (table).

Results @ 1-year follow-up

	Female	Male	P value
Death (%)	11.3	7.7	0.006
Q-wave-MI (%)	1.9	1.2	0.216
CABG (%)	7.4	8.2	0.563
PCI (%)	16.6	16.4	0.893
MACE	33.2	31.5	0.407

CABG = Coronary artery bypass grafting; MACE=Death; MI; Target vessel revascularization

Conclusions: In diabetics undergoing PCI, women have more in-hospital bleeding and major vascular complications, but similar in-hospital ischemic complications compared to men. At 1-year, total mortality is higher in women, but this finding appears to be related to older age and comorbid conditions of women rather than female gender.

P1695 Spectral analysis of heart rate variability during orthostatic load: improvement in diagnostics of cardiovascular diabetic autonomic neuropathy?

J. Pumprla[1], K. Howorka[1], A. Jirkovska[2], S. Lacigova[3], A. Schabmann[4]. [1]Univ. General Hosp. AKH, Dept. Biomed. Eng. & Physics, Vienna, Austria; [2]IKEM- Inst. of Clin. and Exp. Medicine, Dept of Diabetology, Prague, Czech Republic; [3]Charles Univ. Med School Hosp., Dept. of Internal Medicine, Plzen, Czech Republic; [4]Univ. Vienna, Dept. of Applied Psychology, Vienna, Austria

Aim: To improve sensitivity of short-term spectral analysis of heart rate variability (SA-HRV) in assessment of autonomic dysfunction in diabetes.
Methods: Comparison of results of short-term time- and frequency-domain analysis of HRV as obtained by system VariaCardio TF4® during single positions and during modified orthostatic load (supine1-standing-supine2, each position 300 seconds) in diabetic patients with excellent metabolic control (n=80, age 39.2±12.9, diabetes duration 16.4±10.4 years, HbA1c =146±21% of mean reference range), and in non-diabetic controls (n=150, age 40.6±13.2 years). A standard reflex tests battery as proposed by Ewing [Ewing et al, 1985] was performed for excluding cardiovascular autonomic neuropathy (CAN) in diabetic subjects. Coronary artery disease was excluded clinically.
Results: None of short-term frequency-domain parameters (absolute and logarithmic (LN) values of spectral powers in total (TF), low- (LF) and high-frequency (HF) bands and its centroid frequencies) obtained in single "supine" or "standing" positions revealed a significant difference between well-controlled patients and healthy controls (p>0.3). However, during modified orthostatic load, significant differences in Delta LN TF(supine1-supine2) and in Delta LN LF(supine1-supine2) values between diabetic and healthy subjects were recorded (-0.3 vs. -0.2 LN(ms2), p=0.05 and -0.4 vs. 0.1 LN(ms2), p=0.001, resp.) along with no significant intergroup differences in related centroid frequencies, which suggests a delayed recovery of LF spectral power in well-controlled diabetic subjects after active orthostatic manipulation.
Conclusions: When compared with single position measurements, the modified orthostatic load seems to improve the sensitivity of SA-HRV examination. In well-controlled diabetic subjects without CAN, the delayed recovery of LF band spectral power after active orthostatic manipulation might represent an early warning sign of autonomic dysfunction.

P1696 Evidence of decreased left ventricular longitudinal contraction despite normal ejection fraction in patients with type 2 diabetes mellitus

N.H. Andersen[1], S.H. Poulsen[2], H. Eiskjær[2], P.L. Poulsen[1], C.E. Mogensen[1]. [1]*Aarhus Kommunehospital, Internal Medicine Dept M, Aarhus, Denmark;* [2]*Aarhus Universityhospital, Department of Cardiology, Aarhus, Denmark*

Left ventricular diastolic dysfunction may be a very early abnormality in type 2 diabetes. New echocardiographic techniques, including color M-mode and Doppler tissue tracking seems to improve the detection of the pseudonormal diastolic filling pattern and analysis of the longitudinal myocardial performance of the left ventricle. The aim of the present study was to evaluate left ventricular systolic and diastolic function in patients with type 2 diabetes without complications using these echocardiographic methods.

We examined 32 patients with type 2 diabetes mellitus. Average age was 52.7 years (39-72 years). Mean diabetes duration was 4 years (0.5- 20 years). Thirty age and sex matched normal subjects served as controls.

Exclusion criteria's were blood pressure > 130/85 mmHg, ejection fraction < 55%, history of cardiac disease, abnormal ECG, valvulopathy, albuminuria above 20 mg/l or presence of any other diabetes related complication.

Left ventricular systolic function was evaluated by fractional shortening and ejection fraction obtained by Simpson's disc-summation method, using second harmonic imaging. Diastolic function was evaluated by combined analysis of mitral inflow and color M-mode flow propagation. To assess longitudinal myocardial performance of the left ventricle, tissue tracking imaging was performed and presented as a 16 segments tissue tracking wall-motion-score.

Mean ejection fraction was 64%. Diastolic dysfunction was present in 15 patients with 16 patients exhibiting impaired relaxation pattern and 9 patients with pseudonormal filling pattern. Patients with diabetes had significantly lower tissue tracking score compared to normal subjects (6.0 ± 1.5 mm vs 7.6 ± 1.5 mm)($p<0.01$). Patients with diastolic dysfunction had a more profound reduction in tissue tracking score compared to patients without diastolic dysfunction (5.6 ± 1.3 mm vs 6.7 ± 1.5 mm) ($p<0.05$). Results were not correlated to BMI, HbA1c, blood pressure or type of antidiabetic therapy.

In conclusion, decreased longitudinal contraction of the left ventricle was found in normotensive patients with type 2 diabetes, indicating the presence of abnormal systolic function, which is not detected by conventional 2D echocardiography.

P1697 Effect of diabetes on major determinants of myocardial oxygen demand in acute coronary syndromes

K. Foo[1], N. Sekhri[1], C. Knight[2], A. Deaner[2], K. Ranjadayalan[1], A. Suliman[1], A.D. Timmis[3]. [1]*Newham Healthcare Trust, Cardiology Dept., London, United Kingdom;* [2]*King George Hospital, Cardiology Dept, Ilford, United Kingdom;* [3]*London Chest Hospital, Cardiology, London, United Kingdom*

Objectives To determine whether major determinants of myocardial oxygen demand (heart rate and blood pressure) are increased in diabetic patients with acute coronary syndromes.

Background Contractile dysfunction remote from the myocardium at risk may contribute to the poor outcome in diabetic patients with acute coronary syndromes. This in turn may reflect problems with oxygen delivery due to severe coronary artery disease but it is not known if oxygen demand is also affected.

Methods Prospective cohort study of 1783 patients with acute coronary syndromes. The presenting heart rate and blood pressure were compared in diabetic (n=483) and nondiabetic (n=1300) subgroups.

Results Rates of heart failure were higher (18.9% versus 12.4%, p=0.0009) in diabetic than nondiabetic patients. Major haemodynamic determinants of myocardial oxygen demand were also higher in diabetic patients: heart rate 82±20 versus 77±19 beats/minute (p=0.0002); systolic blood pressure 148±30 versus 143±29 mmHg (p=0.0005); rate-pressure product 12321±4160 versus 11121±3820 beats/minute.mmHg ($p<0.0001$). Logistic regression analysis confirmed diabetes as a significant determinant of presenting heart rate (OR 1.62; CI 1.23-2.14), systolic blood pressure (OR 1.28; CI 1.03-1.60) and rate pressure product (OR 1.65; CI 1.25-2.18). These effects of diabetes were independent of multiple baseline variables including: previous acute coronary syndromes, presentation with unstable angina or myocardial infarction, heart failure, and drug therapy.

Conclusions In diabetic patients with acute coronary syndromes, heart failure is more common and major determinants of myocardial oxygen demand are increased compared with nondiabetic patients. The increase in oxygen demand is independent of heart failure and multiple other baseline variables. It provides a potential contributory mechanism of exaggerated regional ischaemia and propensity to heart failure in this high risk group.

P1698 Coronary artery disease progression in diabetics compared to non diabetics

A. Saidi[1], L. Bonnevie[2], V. Stratiev[1], F. Tarragano[1], R. Fressonnet[1], I. Azancot[1], P. Beaufils[1], P. Henry[1]. [1]*Lariboisiere, Cardiology, Paris, France;* [2]*Begin hospital, Cardiology, St. Mandé, France*

Background: Diabetes mellitus is a strong risk factor for coronary artery disease (CAD). However, the progression over time of CAD in diabetic patients has never been compared to non diabetics.

Methods: The progression of CAD in 23 consecutive diabetics was compared to 36 age-matched (mean age 65 y.o. in both groups) non diabetics undergoing 2 coronary angiograms with a delay of more than 3 years between both exams (mean 4.75 y. - 3 to 7 y. in both groups). Patients with a history of CABG were excluded. Coronary angiographies were independently analysed by two experimented observers. For each arterial segment, the severity of stenosis and the length of the diseased segment were analysed (visual quantification). Stenosis treated by coronary angioplasty were excluded from the analysis. The analysis was also conducted separately on proximal (left main, LAD 1 and 2, circumflex 1, 2 and 3 when dominant and RCA 1, 2 and 3 when dominant) and distal (other coronary segments) coronary bed.

Results: Other coronary risk factors were similar in diabetics and non diabetics. At the first coronary angiogram, diabetics had a higher rate of significant (>50%) stenosis compared to non diabetics (2.29 ± 1.33 stenosis/patient vs. 1.47 ± 1.54 respectively, mean ± SEM, $p<0.05$). The second coronary angiogram demonstrated a higher rate of significant stenosis in diabetics compared to non-diabetics (4.79 ± 1.52 stenosis/patient vs. 3.34 ± 2.11 respectively, $p<0.05$). Compared to the first exam, CAD progression on the second exam was mainly due to an increase of the rate of stenosis on distal arteries in diabetics compared to non diabetics (0.71 ± 0.70 stenosis/patient vs. 0.44 ± 0.76 respectively at the first exam and 2.36 ± 1.29 vs. 1.34 ± 1.30 at the second exam respectively $p<0.05$ - corresponding to an increase of 0.35 stenosis/y. in diabetics vs. 0.19 stenosis/y. in non diabetics, $p<0.05$). The progression of CAD on proximal segments was similar in diabetics and non diabetics (1.57 ± 1.18 stenosis/patient vs. 1.03 ± 0.03 respectively at the first exam and 2.42 ± 1.29 vs. 2.00 ± 1.26 respectively at the second exam $p<0.05$ - corresponding to an increase of 0.18 stenosis/y. vs. 0.20 stenosis/y. respectively, p=NS). Similar results were found considering the length of diseased segments.

Conclusion: The progression of CAD appears to be more rapid on distal branches in diabetics compared to non diabetics. This result must be taken into consideration when a decision of revascularisation is discussed in diabetic patients.

NUTRITION, ALCOHOL AND CARDIOVASCULAR RISK

P1699 Daily intake of red wine inhibits mural thrombosis, platelet Rho-A membrane protein translocation and monocyte tissue factor mRNA expression

L. Casani, G. Vilahur, E. Segales, A. Bayés de Luna, L. Badimon.
Cardiovascular Research Center, IIBB/CSIC-HSCSP-UAB, Barcelona, Spain

Moderate consumption of red wine has been associated to a reduction in cardiovascular diseases, but the mechanisms are not fully understood.
Objectives: We have studied whether the protective effects of dietary red wine (local variety of Tempranillo, 12.8% alcohol v/v) could be related to inhibition of thrombosis.
Methods: Two groups of animals (A and B) were fed for 100 days an hyperlipidemic diet containing 2% of cholesterol and 20% of saturated fat. Group B also received a daily moderate dose of alcohol (40g alcohol/day) provided by red wine. Thrombosis triggered by vascular injury was evaluated in the previously validated and standardized Badimon perfusion chamber by radioisotopic evaluation of deposited platelets.Blood was collected and platelets isolated by standard methods, processed with homogenate buffer and subfractioned into cytoplasm and membrane proteins that were analyzed by Western Blotting for Rho-A. Peripheral blood monocytes were obtained by elutriation, seeded in culture dishes and activated with LPS (0.1μg/dish). Cell extracts were processed by conventional molecular biology techniques to obtain mRNA. TF mRNA and a control GAPDH mRNA were coamplified in a semiquantitative RT-PCR analysis.
Results: Mural platelet deposition was significantly reduced both on severely (56±10 vs 30±6 PLT*106/cm^2, $p<0.05$, for Groups A and B respectively) and mildly (8±1 vs 5±0.8 PLT*106/cm^2, $p<0.05$, Groups A and B respectively) damaged vessel wall in wine-fed animals. Expression of Rho-A in the platelet membrane (active form) was reduced in wine-fed animals while the cytoplasmatic Rho-A expression (inactive form) increased. Aditionally, TFmRNA expression in LPS stimulated monocytes was reduced in Group B. Total cholesterol levels were not significantly different between both groups.
Conclusions: Moderate red wine intake significantly reduces platelet deposition triggered by damaged vessel wall. This inhibitory effect is evident at all levels of vascular damage indicating a general passivation effect of the thrombotic response to injury. Wine intake inhibits Rho-A translocation to the platelet membrane. Rho-A, a small G-protein, needs to be localized in the membrane to be active for biological actions, a major one being the regulation of cellular cytoskeleton assembly and shape change. Peripheral blood monocytes of animals ingesting wine have a lower capacity to induce TF mRNA expression. Hence a daily moderate intake of wine inhibits different pathways that converge in a reduced thrombotic risk.

P1700 Moderate alcohol consumption is associated with slower progression of coronary atherosclerosis in middle aged women with CAD – FemCorRisk study

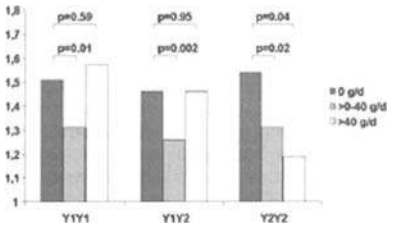
I. Janszky[1], M.A. Mittleman[2], A. Romelsjo[3], K.J. Mukamal[2], B. Svane[4], K. Schenck-Gustafsson[4], K. Orth-Gomer[1]. *[1]Karolinska Institute, Public Health Sciences, Stockholm, Sweden; [2]Harvard Medical School, Public Health, Boston, USA; [3]Stockholm University, Social Sciences, Stockholm, USA; [4]Karolinska Institute, Cardiology, Stockholm, Sweden*

Background: Moderate alcohol intake is associated with lower risk of coronary heart disease and related to reduced mortality after acute myocardial infarction. However, to our knowledge, no previous study has examined the effect of alcohol on human coronary arteries with serial computer-assisted quantitative coronary angiography (QCA) which provides a reliable approach to investigate the progression of coronary atherosclerosis in vivo.
Aim: to investigate the relationship between alcohol consumption and the progression of coronary artery disease in terms of repeated quantitative coronary angiography in middle aged women with coronary heart disease.
Method: The Stockholm Female Coronary Risk (FemCorRisk) study consisted of 292 women patients (age 56±7) who were hospitalized for acute coronary events, 110 for acute myocardial infarction and 182 for unstable angina. Computer-assisted coronary angiography was performed within 3 to 6 months of the visit to the research clinic and 3 years and 3 months (range between 2 to 5 years) later, on 106 patients. QCA measurements were carried out primarily because the patients were participants in the FemCorRisk study. Alcohol consumption was assessed by a standard measure of frequency and quantity, and alcohol intake (gram per day) was calculated on the basis of the known alcohol content of beverages.
Results: Ninety-six patients had valid alcohol data and repeated QCA measurements (mean alcohol consumption 4.18±6.95 g/day). Patients consuming over 5g/day of alcohol (N=58) had significantly lower mean segment diameter progression then the abstainers (N=14) and patients between 0-5 g/day (N=24): -0.011±0.031 mm versus 0.127±0.044 mm and 0.134±0,021 mm, respectively (p=.0005). The results remained essentially the same after adjusting for age, event of inclusion to the study, smoking, educational status, history of diabetes mellitus, sedentary lifestyle, BMI, history of hyperlipidemia, triglycerides, HDL, fibrinogen, history of hypertension and menopausal status.
Conclusion: in middle aged women with coronary heart disease moderate alcohol consumption showed an inverse association with the progression of coronary atherosclerosis independently of well-established clinical markers.

P1701 Genetic variation in alcohol dehydrogenase and effect of alcohol consumption on C-reactive protein in a large population-based study

A. Imhof[1], N. Klopp[2], M. Froehlich[1], H. Loewel[2], T. Illig[2], W. Koenig[1]. *[1]University of Ulm, Internal Medicine II, Ulm, Germany; [2]Institute for Epidemiology, GSF-Research Center, Neuherberg, Germany*

Background: A polymorphism in the gene for alcohol dehydrogenase type 3 (ADH3) alters the rate of alcohol metabolism. Recently, it has been reported that this polymorphism might modify the beneficial effects of moderate alcohol consumption on coronary events. A strong association between C-reactive protein (CRP) and coronary events has been frequently reported. We investigated the effect of alcohol consumption on levels of CRP and its relation to the ADH3-polymorphism.
Methods: A subsample of 3650 men and women aged 25-74 years of the third MONICA-Augsburg survey (1994/95) was studied. CRP was measured by high-sensitive IRMA (range 0.05-10.0 mg/L), the ADH3-polymorphism was determined by polymerase chain reaction and subsequent MALDI-TOFF analysis. Differences of geometric mean levels of CRP adjusted for age, gender, smoking status, BMI, Hdl-cholesterol, education, and physical activity were calculated between categories of alcohol intake (0 g/day = reference).



Results: A U-shaped relation between daily alcohol intake and adjusted geometric mean levels of CRP was seen in the whole sample. However, homozygosity for the Y22 allel was associated with the largest decreased CRP levels (figure). Thus, slow metabolizers showed the most pronounced decrease of CRP levels.
Conclusion: These findings might contribute to explain the beneficial effects of moderate alcohol intake on cardiovascular mortality.

P1702 Effect of alcohol intake on C-reactive protein: Consistent Results from three different geographical areas

A. Imhof[1], M. Froehlich[1], B. Thorand[2], P. Amouyel[3], N. Helbecque[3], G.D.O. Lowe[4], A. Rumley[4], W. Koenig[1]. *[1]University of Ulm, Internal Medicine II, Ulm, Germany; [2]Institute for Epidemiology, GSF-Research Center, Neuherberg, Germany; [3]Institut Pasteur de Lille, Inserm 508, Lille, France; [4]Royal Infirmary, Dept. of Medicine, Glasgow, United Kingdom*

Alcohol intake is associated in a U-shaped manner with risk of CHD. The aim of the present study was to confirm and extend the recently reported antiinflammatory effects of moderate alcohol intake.
We investigated the relationship between alcohol intake and C-reactive protein (CRP) in population-based cross-sectional samples of three European communities, in Germany, the UK, and in France (MONICA Augsburg 1994/95, 2275 men and 2186 women, 25-74 years; Glasgow MONICA 1994/95, 525/597, 25-74 years, and MONICA Lille 1994/95, 581/574, 35-64 years). Alcohol intake was collected by standardized interview and CRP determined by IRMA (range 0.05-10 mg/L). Geometric means of CRP were calculated among categories of alcohol intake by general linear regression after adjustment for several potential confounders including age, gender, smoking status, body-mass-index, HDL-cholesterol, education, and physical activity for each sample.
We were able to confirm the reported U-shaped relationship between alcohol intake and CRP in three independent, random samples of the general population (table). The amount of alcohol consumed a day associated with the lowest CRP levels differed between samples and between men and women.

Alcohol g/d	0	>0-20	>20-40	>40-60	>60-80	>80	p*	p#
Augsburg	1.52	1.36	1.37	1.46	1.66	1.65	0.17	0.04
Glasgow	1.54	1.28	1.49	1.31	1.55	1.69	0.14	0.35
Lille	1.62	1.33	1.29	1.55	1.61	1.92	0.53	0.11

Geometric Means of CRP by Alcohol Intake: adjusted for age, sex, smoking status, BMI, HDL, physical activity, education.p* for linear term, p# for quadratic term

Conclusion: Non-drinkers and heavy drinkers had higher CRP levels than moderate drinkers in representative population-based samples. Since CRP represents an CHD risk factor, this association might represent a link between moderate alcohol intake and reduced CHD mortality.

P1703 Mediterranean diet: an "ecological" paradox or inverse association with clinical and biochemical markers related to cardiovascular risk

C. Chrysohoou, C. Pitsavos, J. Skoumas, D. Panagiotakos, N. Papaioannou, M. Toutouza, C. Stefanadis, P. Toutouzas. *Hippokration Hospital, University of Athens, Attica, Greece*

Background: Many investigators based on the results from the Seven Countries study and the Lyon Heart Study have recognized the beneficial role of the Mediterranean diet in cardiovascular diseases. The aim of this work is to evaluate the effect of the Mediterranean-type of diet on several clinical and biochemical markers, associated to CVD risk.

Methods: The ATTICA study is a prospective population -based cohort designed to enroll 3073 men and women from the greater area of Athens. A random algorithm was developed and stratified, by sex- age; sampling was performed, during 2001. In this work data from 654 men (18-87 years old) and 826 women (18-89 years old) were analysed. The consumption of red meat, chicken, fishes, vegetables, legumes, pasta, salads, cereals, diary products, sweets and fruits was investigated as an average per week, during the past year, using a special nutritional questionnaire, developed by the National School of Public Health. We defined subjects who adopt this type of diet using as cut-off points the median values of the monthly food consumption score.

Results: 583 (39%) of the subjects were defined closer to the Mediterranean diet. The adoption of Mediterranean diet is associated with a reduction of total cholesterol (212±25 vs. 217 ±38 mg/dl, P<0.05), triglycerides (112±17 vs. 127 ±19 mg/dl, P<0.01), blood glucose concentration (90±8 vs. 94 ±12 mg/dl, P<0.01), fibrinogen (312±33 vs. 328± 31 mg/dl, P<0.05), homocysteine (12±3 vs. 14±5 mg/dl, P<0.05) and systolic blood pressure (122 ± 12 vs. 126 ± 8 mmHg, P<0.05). On the other hand, diet increases HDL-cholesterol (50 ± 5 vs. 47 ± 6 mg/dl, P<0.01) and apoA1 (156±22 vs. 149±24 mg/dl, P<0.01). No associations were found between the adoption of Mediterranean diet and Lp(a), apoB, uric acid, social status (described by educational and financial level), age and sex (P>0.700).

Conclusion: Despite the "ecological" paradox regarding low CVD mortality in Mediterranean populations, where Keys and his colleagues reported at the early 1970s, the protective effect of this traditional diet on atherosclerosis seems to be explained, mainly, due to the modification of several biochemical and clinical markers.

P1704 Moderate alcohol consumption, C-reactive protein and long-term prognosis following successful coronary stenting

M. Zairis[1], P. Batika[2], O. Papadaki[2], D. Beldekos[2], S. Hadanis[2], S. Argyrakis[2], S. Foussas[2], D.V. Cokkinos[3]. [1]*Piraeus, Greece;* [2]*Tzanio Hospital, Cardiology Dept., Piraeus, Greece;* [3]*Onassis Cardiac Surgery Center, Cardiology Dept., Athens, Greece*

Background: It is well established that moderate alcohol consumption is associated with better long-term prognosis in patients with coronary artery disease. However, the underlying pathophysiologic mechanism is not well known. Moreover, several studies have shown the fundamental role of inflammation in the pathophysiology and outcome of coronary artery disease.We evaluated the influnce of the moderate alcohol consumption (red wine) on the long term prognosis according to the baseline CRP values in patients enrolled in GENERATION study.

Methods: The GENERATION study was designed to evaluate globally, the impact of several serum markets estimated upon admittance (CRP, Lpa, homocystein and seropositivity for chlamydial infection) on the long-term cardiovascular morbidity and mortality as well as on the restenosis rate after successful coronary stenting (CS). For the purpose of this study a total of 483 consecutive patients treated for stable or unstable coronary syndromes, were recruited in a period of 28 months in our institute. Complete clinical follow up was obtained from 465 (96.3%) pts for a period of 3-years. Information concerning alcohol consumption (red wine) was prospectively collected.

Results: Out of 166 (166/465; 35.7%) patiens have reported moderate alcohol consumtion during the follow-up. By 3-year the incidence of the composite endpoint of cardiac death new myocardial infarction and rehospitalization for unstable angina was 16.3%. Patients with a baseline plasma CRP value <0.68mg/dl (defined by ROC analysis) did not show any benefit in the composite endpoint from moderate alcohol consumption (8% among alcohol consumers vs. 7.3% among those who did not drink; p=0.8). However, patient with a plasma CRP >=0.68mg/dl got the greater benefit from moderate alcohol consumption (22.7% among alcohol consumers vs. 40.4% among those who did not drink; p=0.02)

Conclusions: The results of the present analysis suggest that the beneficial effect of alcohol consumption on the long-term complications following successful CS are strongly asociated to the patients' inflammatory status. An antiinflammatory effect of alcohol could not be excluded. More studies are needed to elucidate this issue.

P1705 Micronutrient deficiency, hyperhomocysteinaemia and subclinical atherosclerosis

K.S. Woo[1], G.G. Wang[2], P. Chook[1], M. Qiao[1], X.S. Huang[3], D.S. Guo[4], C.W.K. Lam[5], D.S. Celermajer[6]. [1]*The Chinese University of Hong Kong, Dept of Medicine & Therapeutics, NT, Hong Kong;* [2]*Cardiovascular Institute, Department of Emergency, Beijing, China;* [3]*Guangdong Provincial Hospital, Department of Cardiovascular Medicine, Guangzhou, China;* [4]*Yu County Hospital, Department of Cardiac Research, Shanxi, China;* [5]*The Chinese University of Hong Kong, Department of Chemical Pathology, Hong Kong, Hong Kong;* [6]*The University of Sydney, Department of Cardiology, Sydney, Australia*

Background: While meta-analysis confirmed a lower mortality from ischaemic heart disease in vegetarians (consuming dairy or egg products) than non-vegetarians, the mortality in vegans (consuming no animal products) was not significantly different, suggesting a possible vascular-protective effect of micronutrient

Methods: To test the hypothesis that micronutrient (folate and vitamin B-12) deficiency in rural northern China predisposes to atherosclerosis, we studied 463 asymptomatic Chinese (354 in rural Shanxi, Yu County and 109 age and gender-matched subjects in Hong Kong). Their mean age was 44.7±1.0 yr; 55.3% were males. Carotid intima-media thickness (surrogate atherosclerosis marker, IMT) was measured by high-resolution ultrasound, using an off-line automatic edge-detection and measurement computer software.

Results: The 2 groups of non-smoker (175 from Yu County and 99 from Hong Kong) were matched for renal function, glucose and body mass index. Blood pressures (SBP, DBP), total fasting homocysteine (tHcy) and IMT were significantly higher (p<0.003) and low density lipoprotein cholesterol (LDL-C), folate and vitamin B-12 were significantly lower (p<0.0001) in Yu County. On multivariate linear analysis, age, systolic blood pressure, tHcy and folate but not LDL-C were significantly correlated with carotid IMT (R=0.59; F-value=20.3; p<0.001). On stepwise backward regression analysis of both current smokers and non-smokers in both sites, tHcy (>12μmol/l; odd ratio=2.0; 95% CI=1.2-3.2; p=0.007), diastolic blood pressure, male gender, age and waist-hip ratio were significantly associated with increased IMT (>0.65mm).

Clinical Parameter of Non-smokers

	Yu County	Hong Kong	p-Value
SBP (mmHg)	122.9±14.7	116.6±13.6	0.003
DBP (mmHg)	0.4±10.6	75.7±9.6	0.002
LDL-C (mmol/l)	2.2±0.8	3.5±0.8	<0.0001
Folate (nmol/l)	15.5±15.3	34.2±14.1	<0.0001
Vit B-12 (pmol/l)	148.5±64.4	310.4±139.5	<0.0001
tHcy (umol/l)	19.0±11.6	9.2±2.4	<0.0001
IMT (mm)	0.62±0.09	0.55±0.1	<0.0001

Conclusion: Micronutrient deficiency is associated with higher blood pressure and homocysteine level, and predisposes to atherosclerosis.

P1706 Specific features of nutrition, arterial blood pressure and blood lipids in the long-livers of the north caucasus

L.M. Khuranova. *Kabardino-Balkarian State University, Medical faculty, Nalchik, Russian Federation*

Of all the long-livers' populations, the highest long-living index (93.2%) has been observed in the rural-areas Balkars. They live in the Southern Russia, the North Caucasus, at an altitude 1.500 to 1.200 metres above sea level, engaged in cattle breeding. As it is generally known, in addition to genetic factors, long-living also depends on traditional nutrition.

Aim: Studies of nutritional features, blood pressure (BP), and blood lipids (BL) in long-livers Balkars.

Methods: Using the standard internationally-accepted WHO-recommended epidemiological methods, nutrition, BP level, BL have been studied in the long-livers, aged 91 to 102 (n = 27) and a random sample of men, aged 40 to 59 (n = 122), i.e. the control group.

Results: Basic sources of protein, fats and carbohydrates in the long-livers' food ration are as follows: lactic acid foods, cheese, yeast-free unleavened bread of maize/wheat flour. Widely taken are honey, numerous wild berries, grasses, featuring probiotic and antihypoxant effect, like lactic acid foods, with no margarine and restricted use of refined sugar.

Tab.1

Variable	Long-Livers	Control group	P-value for difference
n	27	122	
Protein, g/day	122 ± 62.9	93 ± 43.9	0.005
Animal protein, g/day	79 ± 42.6	51 ± 32.2	0.002
Fats, g/day	125 ± 60.4	110 ± 54.0	0.2333
Carbohydrates, g/day	357 ± 148.7	403 ± 193.0	0.2464
Sugar, g/day	40.1 ± 13.0	85 ± 66.7	0.0007
Systolic BP, mm Hg	126.2 ± 6.64	137.6 ± 20.2	0.0044
Diastolic BP, mm Hg	68.0 ± 5.76	88.4 ± 11.3	0.00001
Total cholesterole, mg/dl	175.7 ± 18.4	193.0 ± 48.2	0.069
Triglycererides, mg/dl	54.6 ± 10.23	129.1 ± 91.4	0.0001
HDL cholesterol, mg/dl	40.52 ± 10.1	41.8 ± 12.0	0.6

Long-livers' nutrition with high content of animal protein, lower content of refined sugar is associated with more optimal level of BP and triglyperides (TG). Optimized BP level and blood TG content seems to be in the relation with the use of large quantities of probiotic foods, vegetable origin antioxidants, producing a favourable effect on the intestinal microflora and all kinds of metabolism.

P1707 Validation of a short food questionnaire for assessment of dietary habits

A. Svilaas, E.C. Ström, T. Svilaas, M. Thoresen, A. Borgejordet, L. Ose. *Lipid Clinic, Oslo, Norway*

Background: Dietary changes such as reducing the consumption of foods high in saturated fat and increasing the daily intake of fruits and vegetables can have beneficial effects on long-term health. Necessary for dietary counseling is accurate information on patient's diets. Most methods used to examine an individual's diet (food record, diet interview, food frequency questionnaires)are too complicated and time-consuming in routine clinical use. There is need for a fast tool for food assessment.

Objectives: To evaluate a simple food questionnaire for use in clinical practice, with emphasis on intake of fat, fiber, fruit and vegetables representative for the usual diet.

Methods: A 15–item questionnaire was completed twice in 111 participants in order to study reproducibility. To check its validity, it was compared with a 7–day weighed diet record for 101 subjects.

Results: The participants reported a positive attitude to the questionnaire. Comparing the sum score of the questionnaire and the food record, the reproducibility and validity studies gave correlation coefficients of 0.95 and 0.73 respectively, indicative of good agreement. The reproducibility study showed weighted Kappa coefficients varying between 0.97 for milk and snacks, and 0.75 for vegetables. In the validity assessment, the weighted Kappa coefficients ranged from 0.73 for butter and margarine, to 0.14–0.25 for vegetables, fish and snacks. The correlation coefficient between the sum score of the questionnaire and the percentage of saturated fat in the diet was –0.59.

Conclusions: This simple self-administered questionnaire allows for rapid assessment of constituents of the usual diet in an individual. It gives a good estimation of dietary fat and fiber but is less accurate as regards the intake of vegetables, fish and snacks. It provides an opportunity to discuss central points in the improvement of dietary habits and may be a useful health educational tool in clinical practice.

P1708 Alcohol consumption and clinical, biochemical markers related to cardiovascular disease; a J-shape association

C. Chrysohoou, C. Pitsavos, J. Skoumas, D. Panagiotakos, N. Papaioannou, M. Toutouza, C. Stefanadis, P. Toutouzas. *Hippokration Hospital, University of Athens, Attica, Greece*

Background: Alcohol consumption has believed to have ambiguous effect on the cardiovascular risk, especially compared to other well-established risk factors. The aim of this study is to investigate the association between alcohol intake and other clinical and biochemical parameters in cardiovascular disease free men and women.

Methods: The ATTICA study is a prospective population - based cohort designed to enroll 3073 men and women from the greater area of Athens. A random algorithm was developed and stratified, by sex- age; sampling was performed, during 2001. In this work data from 654 men (18-87 years old) and 826 women (18-89 years old) were analysed. Using multiple regression analysis the association between arterial diastolic blood pressure levels, fibrinogen levels, glucose concentration, total cholesterol levels, High and Low density Lipoprotein cholesterol, Apo A-I, Apo B, Lp(a), uric acid, triglycerides, C-reactive protein, homocysteine and alcohol consumption (in wine/glasses per day), were investigated.

Results: A J-shape association was found between alcohol intake (none, 1-2, 3-4, 5+ wine glasses/day) and DBP (76±9 vs. 74±8 vs. 80±10 vs. 86±11 mmHg, P=0.006), SBP (123±29 vs. 121±38 vs. 126±45 vs. 130±41 mmHg, P=0.003), homocysteine (12.9±1.9 vs. 12.1±1.6 vs. 14.5±3.0 vs. 16.5±3.1 mgr/dl P=0.001), blood glucose (93±19 vs. 90±26 vs. 97±30 vs. 99±31 mgr/dl P=0.021), HDL (49±16 vs. 52±17 vs. 47±11 vs. 46±10 mgr/dl, P=0.061), LDL (164±15 vs. 160±18 vs. 173±20 vs. 173±17 mg/dl, P=0.005), Apo A-I (153±35 vs. 168±28 vs. 155±25 vs. 145±25 mg/dl, P=0.026), Apo B (111±26 vs. 108±21 vs. 121±21 vs. 123±17 mgr/dl, P=0.01), Lp(a) (19±3 vs. 18±4 vs. 20±3 vs. 23±5 mgr/dl P=0.021), total cholesterol (214±27 vs. 206±26 vs. 223±28 vs. 226±29 mg/dl, P=0.024), and uric acid (4.26±0.75 vs. 4.09±0.53 vs. 4.76±1.01 vs. 5±1.2 mgr/dl, P=0.009). The previous associations were confirmed (at 5% probability level) from multivariate analysis after taking into account age, sex, smoking habits, lipidemic medication, dietary patterns and physical activity levels.

Conclusions: The controversial association between alcohol intake and cardiovascular disease may be, partially, attributed to the J-shape association between several biochemical markers related to atherosclerosis and the amount of alcohol consumed.

DRUG THERAPY IN HEART FAILURE

P1709 Anticytokine effect of doxycycline in patients with congestive heart failure

A.B. Nargizyan[1], L.R. Tumasyan[2], L.G. Budagyan[3], V.A. Mkrtchyan[3]. *[1]Institute of Cardiology, Heart Failure, Yerevan, Armenia; [2]Institute of Cardiology, Heart Failure, Yerevan, Armenia; [3]Institute of Cardiology, Immunology, Yerevan, Armenia*

Previous studies have shown increased circulating concentrations of proinflammatory cytokines (CK), such as tumor necrosis factor-alpha (TNF-á) and interleukin-6 (IL-6), and markers of inflammation in patients (pts) with congestive heart failure (CHF). Tetracyclines have recently been shown to exert anti-inflammatory and immunomodulatory activities, independent of their antibiotic properties.

The aim of our study was to estimate 1) the relationship between circulating concentrations of CK, markers of inflammation and hemodynamic parameters in pts with postinfarction CHF, and 2) influence of standard therapy of CHF (ST) and adding of doxycycline (D) on CK levels.

Methods: The study group consisted of 82 pts (age 65.4 ± 1.2 years, infarct age over one year) with CHF [NYHA functional classes (FC) III: 67/82, IV: 15/82]. Echocardiography and 6 minute walking test (6MWT) were performed and blood samples were taken from pts at admission and after four weeks. Serum levels of TNF-á and IL-6 (ELISA), C reactive protein (CRP), fibrinogen (F), and also erythrocyte sedimentation rate (ESR) and white blood cell count (WBC) were determined. ST consisted ACE inhibitors, diuretics, beta-blockers, nitrates and digitalis. D effects were estimated in 51 pts, treated of 4 weeks with D (100 mg/day), adding to ST.

Results: In admission TNF-á concentrations were moderately correlated with FC (r=0.31, p< 0.005), CRP (r= 0.31, p< 0.005), IL-6 (r= 0.51, p< 0.001), left ventricular ejection fraction (EF) (r= -0.32, p< 0.005), 6MWT distance (r= - 0.32, p< 0.005). Levels of IL-6 were strongly correlated with EF (r= - 0.70, p< 0.001), moderately with 6MWT distance (r= -0.55, p< 0.001) and CRP (r= 0.42, p< 0.001) and weakly with ESR (r= 0.23, p< 0.05) and F (r= 0.22, p< 0.05). ST was resulted to significant increasing of EF (at 21.7%, p< 0.01) and 6MWD (at 51%, p< 0.001) and decreasing of IL-6 (at 36.9%, p< 0.01) and CRP (at 35.7%, p<0.001) from baseline. In pts receiving D in addition to ST besides significant increasing of EF (at 23.6%, p< 0.001) and 6MWT distance (at 56.7%, p< 0.001), decreasing of IL-6 (at 53.6%, p< 0.001) and CRP (at 56.7%, p< 0.001), also were shown significant decreasing of TNF-á (at 32.1%, p< 0.001) and F (at 13.7%, p< 0.01) and trend to decreasing of ESR (at 31%, n.s.).

In conclusion, clinical and hemodynamic improvement after ST in pts with severe CHF cause significant decreasing of IL-6, but not TNF-á. However, adding of D to ST leading to decrease the levels of both tested CK and some markers of inflammation.

P1710 Differential systemic and pulmonary haemodynamic effects of systemic selective endothelin A and dual endothelin A/B antagonism heart failure

S. Leslie[1], J.C.S. Spratt[2], S. McKee[2], F.E. Strachan[3], D.E. Newby[2], D.B. Northridge[1], M.A. Denvir[1], D.J. Webb[3]. *[1]University of Edinburgh, Department of Cardiology, Edinburgh, United Kingdom; [2]University of Edinburgh, Department of Cardiology, Edinburgh, United Kingdom; [3]University of Edinburgh, Department of Clinical Pharmacology, Edinburgh, United Kingdom*

Background: Plasma concentrations of endothelin-1 (ET-1) are elevated in patients with chronic heart failure (CHF) and levels correlate with a poor prognosis (Pousset et al 1997). There is evidence that selective ETB blockade results in deleterious haemodynamic changes in CHF with increases in systemic vascular resistance (SVR) suggesting that the balance at the ETB receptor is in favour of vasodilatation (Cowburn et al 1999). However, recent studies have demonstrated that both selective ETA (Spieker et al 2000) and dual ETA/B blockade (Kiowski et al 1995) cause potentially beneficial haemodynamic effects in patients with CHF. Whether selective ETA blockade will have beneficial haemodynamic effects over dual ETA/B blockade has not been previously examined.

Methods: 9 patients with symptomatic CHF (NYHA II-III) were studied in this cross-over randomised controlled trial. Blood pressure and heart rate were measured non-invasively and cardiac output, pulmonary artery and left and right atrial pressure were measured invasively using a pulmonary artery catheter.

Results: Selective ETA blockade increased cardiac output (CO)(p=0.03) and reduced mean arterial pressure (MAP)(p=0.001), systemic vascular resistance (SVR)(p=0.01), mean pulmonary artery pressure (MPAP)(p=0.01), pulmonary vascular resistance (PVR)(p=0.006) and pulmonary capillary wedge pressure (PCWP) (p=0.02).Concomitant ETB blockade attenuated the effects on CCO(p<0.05), SVR (p=0.04), and PVR (p=0.02) but caused a trend towards a further reduction in MPAP and PCWP. Selective ETA blockade did not increase plasma ET-1 concentration whereas concommitant ETB blockade resulted in an increase in plasma ET-1 after both low dose (39±14%, p=0.02) and high dose antagonism (75±24%, p<0.02) thus confirming the role of the ETB receptor in clearance of ET-1.

Conclusions: Chronic heart failure is a leading cause of morbidity and mortality worldwide. Endothelin receptor blockers are being developed as potential therapies in CHF. We have demonstrated significant differences in the effects of selective versus dual blockade of the ET system, whether these potentially benefitial haemodynamic changes will translate into benefits in terms of morbidity and mortality will require large scale clinical trials.

P1711 Medical therapy in patients with acute cardiogenic pulmonary oedema – What helps, what is harmful? (which is a friend and a foe?)

M. Fiutowski[1], T. Waszyrowski[1], M. Krzeminska-Pakula[2], J.D. Kasprzak[2]. *[1]Jonscher Hospital, Cardiology, Lodz, Poland; [2]Medical University IMW, Cardiology, Lodz, Poland*

Background: Acute cardiogenic pulmonary oedema (CPO) is related with high rehospitalization rate. Patients after CPO receive medical polytherapy although few data are available regarding the efficacy of individual cardiovascular drugs in such scenario. AIM: The aim of this study was to elucidate the safety and efficacy of different cardiovascular drugs used in treatment of patients with acute cardiogenic pulmonary oedema during hospitalisation and two-year follow up. METHODS: 276 consecutive patients (128 males, 148 females; median age 70 years) admitted to two departments of cardiology with CPO between 1998-2000 were retrospectively identified and followed-up for a period of 498±272 days (range 5-932 days), with 94% completeness of follow-up. Ischemic heart disease, hypertension, valvular heart disease and diabetes mellitus were present in 95%, 69%, 33% and 35% of patients respectively. During hospitalisation 58 patients (21%) died and 218 (79%) were discharged. During next two years 13 patients (6%) were lost for follow up. Of those 205 patients discharged from the hospital, an additional 81 (40%) were dead at two years, giving an overall two-year mortality of 53%. Prognostic significance of cardiovascular drugs received in acute and chronic stage was analysed with respect to mortality. RESULTS: Non-survivors more frequently needed intravenous catecholamines (OR=17,89; CI95%; 17,57-18,20; p<0,001), steroids (OR=13,52; CI95%; 13,23-13,81; p<0,001) and morphine (OR=2,16; CI95%; 1,90-2,38; p<0,015) injections whereas less frequently received: angiotensin converting enzyme inhibitors (OR=0,07; CI95%; -0,23-0,36; p<0,001), nitroglycerin (OR=0,16; CI95%; -0,12-0,45; p<0,001), beta-adrenolytics (OR=0,28; CI95%; 0,07-0,62; p=0,002) and acetylsalicylic acid (OR=0,29; CI95%; 0,01-0,58; p<0,001) during hospitalisation. Long-term mortality was associated with digoxin use in hospital (OR=2,4; CI95%; 2,11-2,68; p=0,013) and during follow up (OR=1,97; CI95%; 1,71-2,22; p=0,034). Furthermore, patients who were treated with beta-adrenolytics after hospitalisation had better long-term prognosis (OR=0,54; CI95%; 0,29-0,79; p=0,049). CONCLUSIONS: Treatment with nitroglycerin, beta-adrenolytics, acetylsalicylic acid and angiotensin converting enzyme inhibitors is related to beneficial in-hospital survival. Patients after CPO treated ambulatory with digoxin are at risk of higher mortality whereas the treatment with beta-adrenolytics after hospitalisation is related to favourable long-term survival.

P1712 Combined neurohormonal therapy rather than monotherapy is effective in heart failure patients

G. Poelzl[1], H. Huegel[1], G. Gouya[1], H. Ulmer[2], O. Pachinger[1]. [1]*University of Innsbruck, Internal Medicine, Div. Cardiology, Innsbruck, Austria;* [2]*Institute of Biostatistics, University of Innsbruck, Innsbruck, Austria*

Background: Since landmark trials have established ACE inhibitors (ACEI) and beta-blockers (BB), combined therapy with these substances is recommended in European and US guidelines for the treatment of heart failure patients. However, several studies have clearly shown that both substances are underutilised (ACEI are prescribed in about 50%, BB in about 25% of heart failure patients)
The current study was performed to determine whether optimisation of heart failure therapy translates into improved outcome in clinical practice.
Methods: All patients with systolic heart failure and ejection fraction < 35% referred to the Innsbruck Heart Failure and Transplantation Program between February 2000 and October 2001 were identified. Data of 121 pts. (age 57,2±11,8; males 80,2%; ischemic CMP 36,4%; ejection fraction 21,6±5,4%; LVEDD 69,9±9,9mm; atrial fibrillation 27,3%; heart rate 78,5±15,3 beats/min; RR 119,1±20,5 mmHg; sodium 139,7±4,1mmol/l; creatinine 1,26±0,4 mg/dl) followed for > 40 days (224±164) were analysed. Patients were divided according to their treatment at last follow-up visit into group I: 86 pts. on combined neurohumoral therapy (ACEI and BB) and group II: 35 pts. on neurohumoral monotherapy (ACEI or BB). Outcome was judged by NYHA class and the combined endpoint of death and hospitalisation for worsening heart failure.
Results: There were no significant differences in baseline characteristics among groups. Improvement in NYHA class was significantly higher in group I (2,42±0,77 to 1,8±0,82 vs. 2,6±0,77 to 2,2±0,88, respectively; p=0,028). Likewise, Kaplan-Meier curves examining time to first event of the combined end point showed a clear divergence between the groups (p<0,05). Differences remained significant (p=0,022) after adjusting for NYHA class at referral, age, gender, etiology of CMP, ejection fraction, and atrial fibrillation in Cox regression analysis.
Conclusion: Combined neurohumoral therapy is more effective in heart failure patients than neurohumoral monotherapy, thus emphasizing the need for application of guidelines into clinical practice.

P1713 International variation in the treatment of chronic heart failure with preserved left ventricular systolic function

J. McMurray on behalf of the CHARM Committees and Investigators.
University of Glasgow, CRI in Heart Failure, Glasgow, United Kingdom

Background and methods: There is little information on how physicians treat patients with chronic heart failure (CHF) but preserved left ventricular (LV) systolic function. The Candesartan in Heart Failure - Assessment of Reduction in Mortality and morbidity (CHARM) programme consists of 3 prospective randomised placebo controlled trials, one of which includes 3023 patients with a LV ejection fraction > 40% (the CHARM Preserved trial). This analysis describes geographical variation in the treatment in this patient group. The 26 participating countries were grouped as follows: 1. Belgium, France, Netherlands, Luxembourg 2. UK, Ireland, Australia, South Africa 3. Czech Republic, Hungary, Poland 4. Germany, Switzerland 5. Italy, Spain, Portugal 6. Norway, Denmark, Sweden, Iceland, Finland 7. Russia 8. USA 9. Canada. Malaysia and Singapore [n=70] are not included in this analysis, because of small numbers.

	Geographical region								
treatment (%)	1	2	3	4	5	6	7	8	9
(number of patients)	325	224	196	331	202	431	132	734	378
ACE inhibitors	11	21	5	27	18	8	13	25	30
digitalis	20	25	24	25	31	28	14	37	29
spironolactone	19	16	12	5	21	11	2	11	10
beta-blocker	48	38	69	76	30	56	63	59	52
CCB	25	31	30	18	37	28	22	38	40
nitrates	24	32	59	30	45	28	78	26	31

Conclusions: There is a striking, 2 to 6-fold, regional variation in the use of particular treatments for CHF with preserved LV systolic function. This variation emphasises the lack of evidence to support therapeutic practice and the need for randomised trials in this area.

P1714 Antithrombotic treatment does not seem beneficial in CHF. Interim results of HELAS (HEart failure Long-term Antithrombotic Study)

D.V. Cokkinos[1], G.C. Haralabopoulos[1], J. Kostis[2], P.K. Toutouzas[2]. [1]*Onassis Cardiac Surgery Center, Cardiology, Athens, Greece;* [2]*University of Athens, Athens, Greece*

Background: The HELAS study (HEart failure Long term Antithrombotic Study) is a multicenter, randomized, double-blind, placebo controlled trial designed to assess and compare relative benefits and risks of already existing antithrombotic treatment (ATT) for patients (pts) with heart failure (HF).
Methods: 332 pts presenting with signs and symptoms of congestive HF and an EF < 35% were enrolled between January 1998 and August 1999. Pts diagnosed with Ischemic Heart Disease (I) were randomized to receive either aspirin (ASA) 325mg or Warfarin (W) whereas pts diagnosed with Dilated Cardiomyopathy (D) were randomized to receive W or placebo (P). The primary endpoint was the composite of non-fatal stroke, peripheral or pulmonary embolism, myocardial (re)infarction, hospitalization (Hosp), exacerbation of heart failure (EX), or death from any cause in the two year follow up period. Altogether, 80% of pts were receiving an ACE inhibitor.
Results: An analysis of the data from the first 450 patient years showed the following incidence of endpoint events per 100 patient years as summarised in the table below. There were no peripheral or pulmonary emboli. Echocardiographic follow up for 2 years showed: An increase in total EF from 28.2±6 to 30.3±7 p<0.05, accounted primarily by D patients EF 27.2±5 to 30.2±9 p<0.05 at two years regardless of P or W while changes were NS for I, regardless of ASA or W therapy.

Observed events/100 patient years

Event	I/ASA	I/W	D/P	D/W
Stroke	2.1	2.1	1.5	0
MI	0	1.1	0	1.3
Hosp/Ex	3.3	12.5	5	4.5
Death	9.3	12.5	9.3	3.1
Hemorrhage	0	6.2	0	4.5

Conclusions: 1)Overall embolic events are few in heart failure regardless of treatment. 2)Treatment does not seem to affect outcome. 3)Co-administration of ACE inhibitors and ASA or W does not influence anatomic and functional state. 4)EF seems to improve in patients who are carefully monitored in a controlled clinical trial. 5)It seems doubtful whether ATT will prove beneficial at the completion of our study.

P1715 Pentoxifylline improves left-ventricular ejection fraction in ischaemic and hypertensive cardiomyopathy

P. Bahrmann, U. Schnittler, B.M. Richartz, H.R. Figulla.
Friedrich-Schiller-Universität, Klinik für Innere Medizin III, Jena, Germany

Introduction: Tumor necrosis factor (TNF)-alpha is significantly elevated in patients with severe congestive heart failure. Pentoxifylline, a xanthin-derived agent, is known to inhibit the production of TNF-alpha. Recent studies have shown benefical effects of pentoxifylline on left-ventricular performance in patients with idiopathic dilated cardiomyopathy [(Sliwa, K. et al. Lancet. 1998,351,1091-93.), (Skudicky, D. et al. Circulation. 2001,103,1083-88.)]. Therefore, we studied the effects of pentoxifylline on left-ventricular function in ischemic and hypertensive cardiomyopathy.
Methods and Results: 30 patients were randomly assigned to pentoxifylline 600mg TID (n=15) or placebo (n=15) if they had a compensated chronic heart failure with a left-ventricular ejection fraction <40% (50% ischemic, 33.3% hypertensive, 16.7% ischemic and hypertensive cardiomyopathy) and had taken their standard treatment consisting of ACE inhibitors, diuretics and β-blockers for at least 3 months. Baseline demographic and clinical characteristics of each group were similar. Primary end point was left-ventricular ejection fraction (LVEF) assessed by contrast two-dimensional echocardiography. Secondary end points were maximal oxygen uptake (VO2max) assessed by cardiopulmonary exercise testing and Minnesota Heart Failure Index. 24 patients completed the study protocoll and were analysed for primary and secondary outcome. After 6 months of treatment, LVEF was significantly higher in the pentoxifylline group than in the placebo group (P=0.03). VO2max and the Minnesota Heart Failure Index were similar in both groups.

Results at Baseline and at 6 Months

	Placebo (n=13)		P	Pentoxifylline (n=11)		P
	Baseline	6 Months		Baseline	6 Months	
LV EDD (mm)	69 ± 7	64 ± 5	NS	68 ± 8	66 ± 9	NS
LVEF (%)	31 ± 7	31 ± 6	NS	31 ± 8	37 ± 13	0.03
VO2max (mL/kg/min)	15 ± 4	18 ± 6	NS	15 ± 5	19 ± 5	NS
Exercise time (min)	9 ± 3	10 ± 4	NS	9 ± 3	11 ± 4	0.05
Minnesota Heart Failure Index	28 ± 14	32 ± 14	NS	34 ± 16	29 ± 22	NS

Conclusion: In patients with ischemic and/or hypertensive cardiomyopathy, the addition of pentoxifylline to standard treatment improves significantly left-ventricular ejection fraction.

P1716 Impact of additional neurohormonal (NH) antagonism in severe CHF patients already receiving a combination of NH antagonists in COPERNICUS

H. Krum[1], M.B. Fowler[2], H.A. Katus[3], P. Mohasci[4], J.L. Rouleau[5], M. Tendera[6], E.B. Roecker[7], M. Packer[8] on behalf of the COPERNICUS Study Group. *[1]Monash University, Clinical Pharmacology Medicine Dept., Prahran, Australia; [2]Stanford University Medical Center, Cardiology Dept., Stanford, United States of America; [3]Lubeck University, Cardiology Dept., Luebeck, Germany; [4]University Hospital Bern, Cardiology Dept., Bern, Switzerland; [5]UHN and Mount Sinai Hospital, Cardiology Dept., Toronto, Canada; [6]Silesian School of Medicine, Cardiology Dept., Katowice, Poland; [7]University of Wisconsin, Madison, United States of America; [8]Columbia Presbyterian Medical Center, Circulatory Physiology, New York City, United States of America*

Background: The results of the Val-HeFT study suggested that broad based neurohormonal blockade may have deleterious effects in patients with heart failure (CHF), but this hypothesis has not been evaluated in other trials.
Methods: The 2289 patients with severe CHF in the COPERNICUS trial were randomized to placebo (PBO) or carvedilol (CRV), which were added to diuretics and an ACE inhibitor (± digitalis) for up to 29 months. Of these patients, 445 were also on spironolactone at baseline and thus received 3 neurohormonal antagonists if they were randomized to CRV. Compared with those not on spironolactone, patients on spironolactone had more advanced CHF at baseline, as reflected by a lower blood pressure and serum Na (both $P < 0.001$) but were similar in other baseline characteristics.
Results: Shown in the Table are 1-year Kaplan-Meier rates and hazard ratios (CRV:PBO) [Cox model]. CRV reduced the risk of a major clinical event in patients on spironolactone to an extent similar to that seen in patients not on spironolactone.

	Spironolactone			No spironolactone		
	PBO (n=225)	CRV (n=220)	Hazard ratio	PBO (n=908)	CRV (n=936)	Hazard ratio
All-cause mortality	19.1%	11.4%	0.65	18.4%	11.3%	0.65
Death or hospitalization for worsening CHF	39.3%	26.3%	0.63	37.5%	25.4%	0.70
Death or cardiovacular hospitalization	41.6%	29.1%	0.61	41.6%	30.4%	0.75
Death or any hospitalization	47.2%	38.4%	0.76	53.3%	42.1%	0.76

Conclusion: These data indicate that the morbidity and mortality of patients with severe CHF receiving drugs that interfere with more than one neurohormonal target can be reduced substantially with further neurohormonal antagonism (with CRV).

P1717 Nitric oxide inhalation in the treatment of right ventricular infarction

F. Wagner, S. Buz, R. Hetzer. *Deutsches Herzzentrum Berlin, Cardiothoracic and vascular surgery, Berlin, Germany*

In the treatment of right ventricular infarction maintenance of right ventricular (RV) preload, reduction of RV afterload, inotropic support and early reperfusion are considered to be the mainstays of therapy. However, in some patients volume loading only further elevates the right-sided filling pressure with no improvement in cardiac output. Inhaled nitric oxide (NO) has been shown to reduce RV afterlod by its selective vasodilating effect on the pulmonary vasculature. NO inhalation might be a useful optional therapy by reducing RV afterload in patients with right ventricular infarction not adequately responding to conventional therapy. We therefore investigated the effects of supplemental NO inhalation in the treatment of right ventricular infarction complicated by a low-cardiac-output-syndrome.
Methods: In 10 patients (mean age 67.8 years, range 51-76 years) with coronary artery disease and low-cardiac-output-syndrome following right ventricular infarction (9 postoperative, 1 preoperative) NO-inhalation therapy was initiated in addition to volume loading and inotropic support.
Results: Prior to NO inhalation CVP, PA mean and CI were 18±4 mmHg, 26±8 mmHg and 2.4±0.5 L/min/m^2 with high inotropic support (epinephrine at a mean dose of 0.48±0.13 μg/kg/min). A significant hemodynamic improvement was observed following NO inhalation, administered at a dose of 20-50 ppm. At 24 hours of continuous NO therapy CVP, PA mean and CI were measured to be 11±2 mmHg, 22±6 mmHg and 3.1±0.4 L/min/m^2, respectively. Epinephrine had been progressively reduced to 0.17±0.08 μg/kg/min. NO therapy was successfully weaned at a mean of 50 hours (range 16-74 hours) without hemodynamic deterioration.
Conclusion: In patients with right ventricular infarction and consecutive low-cardiac-output-syndrome supplemental NO-inhalation therapy reduces RV afterload thereby effectively improving cardiac output and may be a promising adjunct to conventional therapy.

P1718 Sensitivity and specificity of a BNP rapid assay in the diagnosis of impalred left ventricular function

U. Desch, C. Hansen, A. Vogt, U. Zeymer, J. Neuzner. *Klinikum Kassel, Kardiologie, Kassel, Germany*

Objective: The sensitivity and specificity of a brain-type natriuretic peptide (BNP) rapid assay (VIVA Diagnostica) for identification of patients with left ventricular dysfunction was investigated.
Patients/methods: In 76 consecutive patients BNP was measured during cardiac angiography. The left ventricular enddiastolic pressure (LVEDP) and the left ventricular ejection fraction (LVEF) were determined as hemodynamic parameters. The threshold for elevated BNP levels was set at 100 pg/ml.
Results: 53/76 patients showed ischemic heart disease (70%). The mean LVEF was 40.6±11%, 30 patients (39.5%) had a LVEF of < 40%. The mean LVEDP was 17.2±6 mmHg, a LVEDP of >20mmHg was measured in 38% of the study patients. The mean BNP value was 225.4±259 pg/ml (range: 2.3-1300). An elevated BNP value of > 100 pg/ml was found in 43/76 patients (57%).
(PPV: positive predictive value; NPV: negative predictive value)

Characteristics	Sensitivity	Specificity	PPV	NPV
LVEDP>20mmHg	82.8%	59.6%	55.8%	84.8%
LVEF< 40%	90%	65.2%	62.8%	91%

Conclusion: The studied BNP rapid assay shows a very high sensitivity in the detection of patients with left ventricular function. The excellent results regarding the negative predictive values underlines the potential relevance of this test in clinical practice.

P1719 Chromogranin and BNP predict prognosis but not hospitalisation in patients presenting with heart failure for the first time

M. Cowie[1], K. Fox[2], C. Metcalfe[3], C. Ceconi[4], D.A. Wood[2], S.G. Thompson[3], R. Ferrari[4], P.A. Poole-Wilson[1]. *[1]National heart & Lung Institute, Cardiac Medicine, London, United Kingdom; [2]Imperial College, Cardiology Dept Charing Cross Hospital, London, United Kingdom; [3]MRC Biostatistics Unit, Cambridge, United Kingdom; [4]University of Ferrara, Gussago, Italy*

The serum concentration of chromogranin (CgA) - a chemically and biologically stable Ca^{2+} binding protein co-secreted with many neurohormones - is raised in patients with heart failure, rising with symptom severity. We compare the relative value of serum CgA and plasma B-type natriuretic peptide (BNP) in predicting the prognosis of patients with a new diagnosis of heart failure. Methods: CgA and BNP were measured in 102 patients (68 male; 90% age range 55-88 years) with a new diagnosis of heart failure identified in a population-based study. Patients were prospectively followed up for hospitalisation and death. Median follow-up was 20 months for hospitalisation and 39 months for death. Results: 37 patients died (31 of cardiovascular causes). 27 patients had one or more unplanned hospitalisations for worsening heart failure. Univariate proportional hazards regression indicated that both CgA and BNP at the time of first presentation were strongly associated with survival (Hazard ratio [95% confidence interval] for a doubling in concentration: CgA 2.08 [1.38-3.28]; BNP 2.71 [1.56-4.71]). Multivariate regression suggested that CgA added prognostic information to that provided by BNP alone (multivariate hazards ratio: CgA 1.62 [0.99-2.66], BNP 2.25 [1.28-3.98). Very similar results were obtained when the analysis was restricted to cardiovascular deaths. Neither measure was associated with the likelihood of experiencing an unplanned hospitalisation for worsening heart failure. Conclusion: Both serum CgA and plasma BNP measured at first presentation are strongly associated with subsequent mortality (but not risk of hospitalisation) in a population-based cohort of patients with a new diagnosis of heart failure. Each provides information about prognosis that is unavailable from the other.

P1720 Differential effects of omapatrilat and hydrochlorothiazide on arterial function in hypertension

G.G. Belz[1], K. Breithaupt-Groegler[1], S. Roll[1], B. Mangold[2], R.A. Reeves[2], E. Strack[2]. [1]*Center for Cardiovascular Pharmacology, Wiesbaden, Germany;* [2]*Pharmaceutical Research Institute, Bristol-Myers Squibb, Princeton, NJ, United States of America*

Arterial stiffness and elasticity represent relevant factors in the pathophysiology of cardiovascular diseases and exert a major influence on morbidity and mortality. The vasopeptidase inhibitor omapatrilat (Oma) may have beneficial effects on aortic properties above those expected from a decrease in blood pressure. In a double-blind parallel group study, patients with systolic hypertension (SBP 145-179 mmHg) were randomized to: Oma 40 mg qd or hydrochlorothiazide (HCTZ) 25 mg qd (n = 48/treatment) monotherapy for 3 months. Aorto-femoral pulse wave velocity (PWV; sphygmography), late systolic augmentation (applanation tonometry) and total peripheral resistance (TPR) were used to assess the elastic properties of the aorta, large arteries, and arterioles, respectively. The mean changes (± 95% CI) from baseline in supine SBP and resting aortic properties after 3 months of treatment are presented in the table below.

	SBP (mmHg)	PWV (m/s)	Aortic Augmentation Index (%)	Aortic Augmentation (mmHg)	TPR (dyn s/cm^5)
Oma	-30.9* #	-0.79*	-11.9* #	-6.2* #	-14%* #
95%CI	(-34.5,-27.3)	(-1.14,-0.44)	(-15.0,-8.9)	(-7.3,-5.1)	(-0.81,-0.92)
HCTZ	-14.3*	-0.84*	-3.7*	-2.6*	+2%
95%CI	(-18.1,-10.6)	(-1.20,-0.47)	(-6.8,-0.5)	(-3.8,-1.5)	(-0.96,-1.08)

*significant difference to baseline, # significant difference between groups ($p < 0.0001$)

Oma significantly reduced SBP to a greater extent compared to HCTZ. Both Oma and HCTZ reduced aortic PWV to a similar extent: however, aortic augmentation index, aortic augmentation and TPR were significantly reduced with Oma compared to HCTZ.

The study demonstrates that while both drugs favorably influence aortic stiffness, only Oma improves elastic properties of large vascular arteries and arterioles. These properties may have clinical relevance not limited to the treatment of hypertension.

P1721 Effects of enalapril or the endothelin antagonist enrasentan on left ventricular dimensions in patients with asymptomatic systolic dysfunction

T.N. Martin[1], B.A. Groenning[1], M. Barlow[1], J. Foster[2], I. Ford[3], J.F. Cleland[4], D.J. Pennell[5], H.J. Dargie[1]. [1]*Western Infirmary, Department of Cardiology, Glasgow, United Kingdom;* [2]*Western Infirmary, Department of Clinical Physics, Glasgow, United Kingdom;* [3]*University of Glasgow, Department of Biostatistics, Glasgow, United Kingdom;* [4]*Castle Hill Hospital, Department of Cardiology, Hull, United Kingdom;* [5]*Royal Brompton Hospital, Cardiac Magnetic Resonance Unit, London, United Kingdom*

Background: Excessive release of endothelin has been demonstrated in patients with heart failure. The purpose of the present study was to compare the effects of enrasentan (a mixed endothelin receptor antagonist that has been shown to be active in animal models of cardiovascular disease) with enalapril on left ventricular (LV) dimensions and systolic function in patients with asymptomatic LV systolic dysfunction.

Methods: Seventy-two patients (66 males and 6 females, mean (SE) age = 62 ± 1.0) with asymptomatic LV dysfunction (LV ejection fraction <40% for echocardiography or <45% for cardiac magnetic resonance imaging (MRI)) were randomized to receive either enrasentan (90 mg target dose) or enalapril (20 mg target dose). The patients were examined with cardiac MRI at baseline and after 6 months. MRI measures of LV dimensions included: LV end-diastolic (LVEDVI) and end-systolic (LVESVI) volume indices, LV ejection fraction (LVEF) and LV myocardial mass index (LVMI).

Results: Demographic data was comparable between the two groups with respect to sex, age and race. In the enrasentan group, baseline LVEDVI was (mean ± S.E.M) 65 ± 3.0 ml/m^2, the change at 6 months 3.9 ± 1.8 ml/m^2, and for the enalapril group, baseline LVEDVI was 64 ± 3.5 ml/m^2, the change at 6 months -3.4 ± 1.3 ml/m^2 (p=0.001 between groups). The changes in LVESVI were -0.06 ± 1.1 ml/m^2 and -2.0 ± 0.93 ml/m^2 for enrasentan and enalapril, respectively (NS). In the enrasentan group, baseline LVMI was 97 ± 2.6 ml/m^2 and the change at 6 months 0.67 ± 1.6 ml/m^2. For the enalapril group, baseline LVMI was 95 ± 3.7 ml/m^2 and the change at 6 months -3.8 ± 1.6 ml/m^2 (NS). In the enrasentan group, baseline LVEF was 0.65 ± 0.021 and the change at 6 months 0.018 ± 0.008. For the enalapril group, baseline LVEF was 0.63 ± 0.020 and the change at 6 months 0.015 ± 0.010 (NS).

Conclusion: In patients with asymptomatic systolic dysfunction, we found a significant decrease in LVEDVI after 6 months treatment with enalapril when compared to enrasentan. In the present study, treatment with enrasentan was associated with an unfavorable effect on LV dimensions.

P1722 Addition of angiotensin II receptor blockade to angiotensin-converting enzyme inhibition improves baroreflex function in patients with left ventricular dysfunction

A. Kawamura[1], F. Yuasa[1], R. Yuyama[1], J. Mimura[1], M. Iwasaki[1], T. Sugiura[2], T. Iwasaka[1]. [1]*Kansai Medical University, Cardiovascular Center, Osaka, Japan;* [2]*Clinical Laboratory Medicine, Kochi Medical School, Kochi, Japan*

Background: Incomplete suppression of the rennin-angiotensin system (RAS) during long-term angiotensin-converting enzyme (ACE) inhibitors may contribute to increasing sympathetic activity in patients with left ventricular dysfunction (LVD). Combined angiotensin II receptor blockade (ARB) and ACE inhibition completely suppress the activated RAS. However, whether ARB with valsartan improves baroreflex function in patients with LVD already treated with ACE inhibitors is unknown.

Method: We assessed baroreflex control of sympathetic nerve activity and heart rate (HR) in 10 patients with LVD (ejection fraction 38.8±7.2%) receiving long-term ACE inhibitor therapy before and after valsartan (80mg). Arterial baroreflexes were perturbed by bolus administration of phenylephrine. Cardiopulmonary baroreflexes were perturbed by lower body negative pressure (LBNP; -10mmHg). Muscle sympathetic nerve activity (MSNA) was recorded by microneurography.

Results: Resting MSNA did not change after valsartan despite reductions in arterial blood pressure. (from 31.3±9.6 to 28.8±5.3 burst/min) Arterial baroreflex sensitivity improved significantly from 7.6±4.2 to 11.0±6.8 msec/mmHg after valsartan ($p<0.05$). Both arterial and cardiopulmonary baroreflex control of MSNA was enhanced by valsartan (from -40±11% to -55±17% by phenylephrine method, from 25±11% to 58±32% by LBNP method, $p<0.05$).

Conclusion: ARB improves baroreflex control of heart rate and sympathetic nerve activity in patients with LVD already treated with ACE inhibitors.

P1723 Valsartan shows consistent efficacy across heart failure patient subgroups: results from Val-HeFT

A. Maggioni[1], P. Carson[2], J. Soler[3], Y-T. Chiang[4], N. Aknay[4], J.N. Cohn[5]. [1]*ANMCO Research Center, GISSI Group, Florence and Milan, Italy;* [2]*Medical Center, Department of Veterans Affairs, Washington DC, United States of America;* [3]*Hospital Valle de Hebron, Servicio de Cardiologia, Barcelona, Spain;* [4]*Novartis Pharmaceuticals Corp, East Hanover, New Jersey, United States of America;* [5]*Universtiy of Minnesota, Dept of Medicine, Minneapolis, Minnesota, United States of America*

Background: The efficacy of drugs prescribed for heart failure (HF) may be influenced by demographic and/or clinical characteristics. Thus, subgroup analysis is routinely performed in clinical trials to test the general applicability of results. In the Valsartan Heart Failure Trial (Val-HeFT), which compared the angiotensin receptor blocker valsartan to placebo. Valsartan reduced the primary morbidity/mortality endpoint with concordant reductions in subgroups based on patient characteristics. (Cohn & Tognoni, NEJM 2001).

Aims: Here we analyze the efficacy of valsartan on the secondary endpoints of 1st non-fatal morbid (NFM) event (defined as sudden death with resuscitation, therapy for HF, or HF hospitalization), 1st HF hospitalization, and cardiovascular death within non-predefined subgroups based on age, gender, NYHA class, coronary heart disease (CHD) etiology, left ventricular ejection fraction (LVEF), LV internal diastolic diameter (LVIDd) and history of diabetes.

Methods: 5010 patients with mild to moderate HF were randomized to receive either valsartan (force-titrated to 160 mg bid) or placebo in addition to their standard HF therapy. The effect of treatment on the secondary endpoints was evaluated using Cox regression analysis for risk ratio (RR) and log rank test for P-value.

Results: Statistically significant treatment differences and reduced risks of NFM event were observed with valsartan compared to placebo irrespective of age (>=65 years: RR=0.712, p<0.001; <65 years: RR=0.739, p=0.009), gender (Male: RR=0.717, p<0.001; Female: RR=0.742, p=0.013), NYHA class (I-II: RR=0.701, p=0.001; III-IV: 0.742, p=0.001), CHD etiology (yes: RR=0.788, p=0.007; no: RR=0.643, p<0.001) and LVEF (< 27%: RR=0.742, p=0.001; >= 27%: RR=0.707, p=0.001). The RR did favor valsartan in the subgroups of patients with diabetes (RR=0.870, pp=0.281) or LVIDD <3.57 cm/m^2 (RR=0.872, p=0.234) but these differences were not significant as they were in patients without diabetes (RR=0.661, p<0.001) or LVIDD>=3.57cm/m^2 (RR=0.634, p<0.001). Similar results were found for 1st HF hospitalization. Valsartan did not significantly reduce the risk of cardiovascular death for any of the subgroups examined.

Conclusions: Valsartan treatment shows consistent reductions in the risk of NFM event and 1st HF hospitalization across patient subgroups.

CALCIUM AND SIGNAL TRANSDUCTION

P1724 Afterload-induced diastolic disfunction, SERCA2a and PLB gene expression in the development of heart failure

J. Correia-Pinto[1], R. Roncon-Albuquerque Jr[1], H. Kögler[2], T. Henriques-Coelho[1], O. Hartmann[2], O.E. Brodde[3], G. Hasenfuss[2], A.F. Leite-Moreira[1]. *[1]Faculty of Medicine, Physiology Dept., Porto, Portugal; [2]Georg August University Göttingen, Cardiology and Pneumology, Göttingen, Germany; [3]Martin Luther University of Halle, Pharmacology and Toxicology, Halle, Germany*

Load dependence of diastolic function and gene expression of sarcoplasmic reticulum calcium ATPase (SERCA2a) and phospholamban (PLB) were evaluated in the development of heart failure.

The study was carried in the monocrotaline (MCT) model of pulmonary hypertension. Eighteen Wistar rats (10 weeks) were divided to receive either an ip injection of 60 mg/kg of MCT (MCT group; n=8) or a similar volume of the vehicle (Ctrl group; n=10). Four weeks later the rats were instrumented to record left ventricular (LV) pressure and septal-free wall diameter. Beat-to-beat aortic constrictions increased LV pressure from baseline up to isovolumetric. Effects of afterload on relaxation rate were assessed by the % changes in the time constant Tau, while its effects on diastolic function were evaluated by the position of the end-diastolic pressure-diameter (ED-PD) relation. An additional set of animals (n=16; 10 weeks) was divided to receive either a subcutaneous injection of 60 mg/kg of monocrotaline (MCT group; n=8) or a similar volume of the vehicle (Ctrl group; n=8). After 3 weeks, RV free wall samples were collected for SERCA2a and PLB mRNA quantification by RT-PCR using calsequestrin (CSQ) as the house-keeping gene. Results: mean±SEM, $p<0.05$.

In response to aortic constrictions LV pressure increased, in the Ctrl group, from 95±7 mmHg at baseline to 180±6 and 202±7 mmHg in the afterloaded and isovolumetric beats, while in the MCT group it increased from 102±10 mmHg to 181±6 and 206±7 mmHg (p=ns, Ctrl vs. MCT). Tau decreased 25±6% in the afterloaded beats and remained similar in the isovolumetric beats, in the Ctrl group, whereas, in the MCT group Tau increased 24±7% and 49±6% in the afterloaded and isovolumetric beats, respectively. The position of the ED-PD relation was not affected by afterload in the Ctrl group, but it was upward shifted in the MCT group by 1.5±0.6 and 5.2±0.5 mmHg in the afterloaded and isovolumetric beats, respectively. In the MCT group there was a downregulation of RV SERCA2a and PLB mRNA levels, expressed by decreased SERCA2a/CSQ (0,52±0,03 Ctrl vs. 0,24±0,03 MCT) and PLB/CSQ (0,90±0,11 Ctrl vs. 0,48±0,06 MCT) ratios. SERCA2a/PLB ratio was not affected by MCT treatment.

Afterload induced diastolic dysfunction was observed only in the MCT group. Downregulation of SERCA2a and PLB mRNA suggests that afterload-induced diastolic dysfunction might be related to impaired sarcoplasmic calcium reuptake during relaxation. Afterload-induced diastolic dysfunction and impaired calcium handling were, therefore, observed prior to systolic function disturbances.

P1725 S100A1 gene transfer augments Frank-Starling mechanism, Ca^{2+} and β-adrenergic response in engineered heart tissue (EHT)

S.T. Pleger[1], J. Lindenkamp[1], E.K. Löffler[1], P. Most[1], T. Eschenhagen[2], W.J. Koch[3], H.A. Katus[1], A. Remppis[1]. *[1]University of Luebeck, Internal Medicine II, Luebeck, Germany; [2]Institute of Pharmacology, University of Erlangen, Erlangen, Germany; [3]Duke University Medical Center, Department of Surgery, Durham, United States of America*

Background: Heart failure, characterized by impaired contractile performance and loss of contractile mass is associated with down-regulation of the Ca^{2+} binding protein S100A1 protein. As cardiac tissue engineering is an emerging field which offers new perspectives for tissue replacement therapy, we assessed the effect of gene-transfer of the recently identified novel inotropic factor S100A1 in engineered heart tissue (EHT) which displays characteristic contractile properties of differentiated myocardium. S100A1-supplemented EHT's allowed us to elucidate the impact of S100A1 on (a) length-dependent force-development (Frank-Starling), (b) extracellular Ca^{2+}-stimulated force-generation (Ca^{2+}-treppe) and (c) β-adrenergic response.

Methods and Results: Lattice EHT's from neonatal rat cardiomyocytes and S100A1-adenovirus (SV) were generated according to standard protocols while an adenovirus devoid of S100A1 cDNA served as control (CV). Isometric force of adenovirally transfected EHT's (SV=8 and CV=13; MOI 10 PFU) was measured 12 days after gene transfer at 2 Hz, 37°C and pH 7.4. Western-Blot analysis confirmed a 5-fold S100A1 protein overexpression in SV transfected EHT's (n=4; $P<0.01$) that caused a significant increase of length-dependent maximal isometric force compared to control (mN/mm²; SV 0.37±0.04 vs. CV 0.23±0.03; $P<0.03$). In addition, S100A1 overexpression enhanced both maximal $[Ca^{2+}]_e$-stimulated force-generation by +57% ($P<0.03$) and $[Ca^{2+}]_e$ sensitivity of EHT's (EC50% $[Ca^{2+}]_e$, mM; SV 0.21±0.03 vs. CV 0.33±0.04; $P<0.03$). Moreover, the S100A1-mediated gain in basal contractility was preserved throughout a series of isoproterenol interventions (10-9-10-6 M).

Conclusion: Our study clearly demonstrates that S100A1 gene-transfer in EHT is feasible and augments EHT contractile performance. S100A1 overexpression improved (a) length-dependent force-development (Frank-Starling mechanism), (b) extracellular Ca^{2+}-stimulated force-generation (Ca^{2+}-treppe) and (c) β-adrenergic response. Thus, as S100A1 has recently been identified as a novel inotropic regulator of cardiac contractility, our study provides further insight into S100A1 effects on cardiac contractility while S100A1-supplemented EHT's may provide an interesting tool for cardiac-tissue replacement therapy.

P1726 The sarcoplasmic reticulum Ca^{2+}-load is increased in human failing myocardium by protein kinase A-dependent stimulation

K. Brixius, D. Keller-Bartel, A. Wollmer, B. Bölck, R.H.G. Schwinger. *Clinic III of Internal Medicine, Lab. of Muscle Res.& Mol. Cardiology, Cologne, Germany*

In human heart failure the activity of the sarcoplasmic reticulum Ca-ATPase has been shown to be reduced, which may be, at least partly, due to a reduced phosphorylation of phospholamban. The present study investigated the functional consequences of reduced SERCA 2a activity in human myocardium. As the Na/Ca exchanger may partly compensate for reduced SERCA 2a-activity in DCM, only DCM with reduced SERCA 2a-activity and normal Na/Ca exchanger-activity were used.

Simultaneous measurements of the intracellular Ca-transient (fura-2 ratio method) and force of contraction were performed in isolated ventricular muscle strips from failing human myocardium (dilative cardiomyopathy, DCM, heart transplants, n=6) in comparison to non-failing myocardium (rejected donor hearts, NF, n=9) at increasing stimulation frequencies (0.5 to 3.0 Hz). In DCM, diastolic $[Ca^{2+}]_i$ was increased and systolic $[Ca^{2+}]_i$ was decreased as compared to NF (0.5 Hz, diastolic $[Ca^{2+}]_i$: 134±27 vs. 73±33 nmol/L; systolic $[Ca^{2+}]_i$: 186±29 vs. 289±63 nmol/L). Only in NF, force and systolic $[Ca^{2+}]_i$ frequency-dependently increased ($p<0.05$). To investigate whether the blunted intracellular Ca-homeostasis in DCM was due to a dysregulation of the Ca-uptake and/or Ca-release from the sarcoplasmic reticulum, the coffeine - induced Ca-release was measured in saponine (5 mg/l, 30 min., 4°C) -skinned fiber preparations in the presence and in the absence of protein kinase A (500 U/ml, 1 h, 20°C, pH 7.5) at constant Ca-loading conditions (pCa 7.0, 30s, 20°C,pH 7.0). Under basal conditions, there was no difference in the coffeine-induced Ca-release as measured by the ratio coffeine-induced force over maximal Ca-induced (pCa 4.5) force (NF: 57±3%, DCM: 68±5%). After incubation in PKA, the ratio coffeine (25 mM)-induced force over maximal Ca-induced force was increased in DCM (96±3%).

Conclusions: The impaired Ca/force-frequency relationship in human failing myocardium may, at least partly, be due to an impaired function of SERCA 2a accompanied by a reduced peak systolic as well as enhanced diastolic Ca-level intracelluarly. Phosphorylation of Ser16-Plb in human failing myocardium is able to improve Ca-release from the sarcoplasmic reticulum and may help to restore the blunted force-frequency relationship in human failing myocardium.

P1727 Baseline hypercontractility and disturbed Ca^{2+} homeostasis in monocrotaline-induced right ventricular hypertrophy of the rat

H. Kögler[1], O. Hartmann[1], R. Roncon-Albuquerque[2], P. Nguyen van[1], K. Leineweber[3], A. Leite-Moreira[2], O-E. Brodde[3], G. Hasenfuss[1]. [1]*University of Göttingen, Cardiology and Respiratory Care, Göttingen, Germany;* [2]*University of Porto, Physiology, Porto, Portugal;* [3]*University of Halle, Pharmacology and Toxicology, Halle, Germany*

Background: Treatment of rats with the Crotalaria alkaloid monocrotaline causes obliterative vasculitis of the lung arterioles which results in increased pressure within the lung circulation and right ventricular (RV) hypertrophy. In some of the animals heart failure develops. The consequences of this hypertrophy for RV myocardial contractility have not been studied in detail. Methods: We examined at 37°C isometric twitches of intact RV trabeculae from rats in the compensated phase of hypertrophy, 20 to 24 days after a single s.c. injection of 50mg/kg monocrotaline (MCT). Control animals were treated with saline. mRNA expression levels were determined using quantitative rtPCR. Protein expression was analyzed using SDS-PAGE and Western blot. Results: Baseline contractility at $[Ca^{2+}]_o$ 1.25mM and 2Hz stimulation rate in MCT preparations was enhanced by 174% compared to controls (P=0.006; n=8 each). In control preparations, raising the stimulation rate resulted in a monotonous increase in developed force, while in MCT preparations the force-frequency relationship was negative, such that at a physiological rate of 5Hz no significant difference in developed force was observed. Examination of the post-rest behavior in MCT preparations compared to controls revealed a dramatic reduction in the ability of the sarcoplasmic reticulum (SR) to accumulate Ca^{2+} during rest intervals exceeding a duration of 2s (P=0.01; n=8 controls, n=9 MCT). SR Ca^{2+}-ATPase (SERCA2a) mRNA expression in MCT myocardium was reduced by 53% (P<0.001; n=8 each), while no significant change in the mRNA expression levels of the sarcolemmal Na^+/Ca^{2+} exchanger was observed. Maximum Ca^{2+}-activated tension was significantly enhanced in Triton X-100-permeabilized MCT preparations (P = 0.013). While control RV myocardium expressed only trace amounts of beta-myosin heavy chain (beta-MHC), 18% of total MHC was present in the beta-isoform in MCT myocardium (P < 0.001). Conclusions: Ca^{2+} homeostasis is substantially impaired in MCT myocardium, resembling that found in other experimental hypertrophy models. A likely cause for this behavior is the reduction in SERCA2a expression levels. Enhanced myofilament Ca^{2+} responsiveness is probably the result of beta-MHC expression and represents a potent compensatory mechanism which explains the baseline hypercontractility.

P1728 The mechanism of pyruvate in human failing myocardium

C. Luers, D. von Lewinski, L.S. Maier, B. Pieske. *University of Goettingen, Cardiology and Pneumology Dept., Goettingen, Germany*

Introduction: It is still controversial whether positive inotropic effects of pyruvate are Ca^{2+}-dependent or result from intracellular alkalosis with enhanced Ca^{2+}-responsiveness of myofilaments. We investigated the effects of pyruvate on intracellular pH-changes and of sarcoplasmatic reticulum Ca^{2+}-content in failing and non-failing human myocardium.

Methods: Isolated left ventricular trabeculae from non-failing (n=6) and failing human hearts (n=22) were electrically stimulated (basal stimulation rate 1 Hz, 370C, isometric contractions). A subgroup of muscles was loaded with the fluorescent pH-indicator BCECF-AM (15μM for 45 min). Pyruvate (10 mM) was added under steady-state conditions in bicarbonate-containing buffer. pHi, rapid cooling contractures (RCC's as a measure of sarcoplasmatic reticulum Ca^{2+} content) and force-parameters were recorded. pHi-signals after each experiment were calibrated with the "high-K^+-Nigericin"-method. Average values are given as means ± SEM, analysed by the unpaired students t-test. Values of p<0.05 were considered significant.

Results: Pyruvate increased force of contraction by 82±4% (p<0.05) and RCC amplitudes by 51±3% (p<0.05; rF/rRCC=1.6) in non-failing human myocardium. In failing human myocardium, developed force increased by 67±9% (p<0.05) and RCC amplitudes increased by 29±1% (p<0.05; rF/rRCC=2.3). In parallel, intracellular pH increased from 7.33±0.04 to 7.40±0.04 (p<0.05) in failing human myocardium.

Conclusion: 1. In isolated human myocardium pyruvate induces a Ca^{2+}-dependent and pH-dependent positive inotropic effect. 2. In failing human myocardium the inotropic response was only slightly reduced despite a clear reduction in RCC potentiation. Therefore, intracellular alkalinization may represent a major inotropic mechanism of pyruvate in failing human myocardium.

DIASTOLIC FUNCTION IN HEART FAILURE

P1729 Lean body mass rather than diastolic function predicts exercise capacity in normal older individuals

H C. Oxenham[1], G.D. Gamble[1], J. Aoina[2], K.L. McFarlane[2], J.C. Baldi[2], I. Reid[3], R.N. Doughty[1], N. Sharpe[1]. [1]*Cardiovascular Research,* [2]*Dept. of Exercise and Sports Science,* [3]*Division of Medicine, Auckland, University of Auckland, New Zealand*

The most commonly used measure of aerobic capacity is maximum oxygen consumption during exercise, expressed as millilitres of oxygen per kilogram body weight per minute. Factors that limit maximum exercise capacity, (VO2max) in normal subjects remain disputed. Previous studies have suggested that left ventricular diastolic performance contributes significantly, whilst skeletal muscle mass has been shown to be an independent predictor in subjects with heart failure.

Aim The relative contributions of left ventricular diastolic function, anthropometric variables and resting cardiovascular function to VO2max measured in millilitres per minute were evaluated in 63 healthy, sedentary volunteers using a variety of iterative multiple regression techniques.

Methods VO2max was quantified by respiratory gas analysis during treadmill exercise. It was defined as a plateau in oxygen uptake despite increasing workload, attainment of age-predicted maximum heart rate and a respiratory exchange ratio greater than 1.1. Diastolic function was assessed by measuring Doppler transmitral flow, (E and A velocities) and tissue Doppler imaging of the mitral annulus (E' velocity). Lean body mass was measured using total body dual energy X-ray absorptiometry (DEXA).

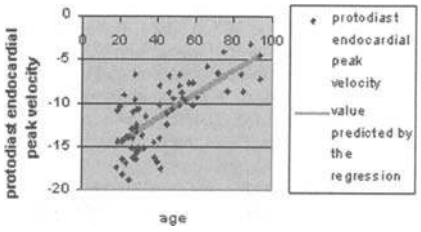
Results The subjects had no evidence of cardiovascular disease and had a mean age of 67 years, (range 60-79). Mean BMI was 25.4(± 3.4) and 57% were women. Mean VO2max was 1880 ml/min (range 927 to 3063). In the univariate analysis the only diastolic variable to be positively correlated with VO2max was E/A, p = 0.0035. However, in the multiple regression analysis, lean body mass was the most significant independent predictor of VO2max, explaining 54% of the variance, p< 0.0001. Maximum workload (METS) accounted for an additional 11% of the variance, p = 0.0002, BMI for 7% of the variance, p = 0.0004 and pulse 4%, p = 0.0055.

Conclusions These data suggest that lean body mass is a stronger independent predictor of exercise capacity than diastolic function and other anthropomorphic or resting haemodynamic variables. Correcting absolute VO2 for skeletal muscle mass rather than body weight may therefore enhance the value of VO2max in defining functional status.

P1730 Age-related intramyocardial patterns during diastole in healthy subjects. Analysis with color M-mode Doppler tissue imaging

E. Perez[1], M.A. García Fernández[2], M. Desco[3], M.J. Ledesma[4], M. Carazo[2], J.C. Antoranz[5], M. Moreno[2], A. Santos[4]. [1]*Majadahonda, Spain;* [2]*Hospital General Gregorio Maranon, Cardiology Dept., Madrid;* [3]*HGU Gregorio Maranon, Cardiology Dept., Madrid;* [4]*Polytechnic University, Madrid;* [5]*UNED, Mathematical Physics and fluids, Madrid, Spain*

Anatomical changes take place across the left ventricle myocardial wall in the aging heart, with preferential effects in the subendocardium. The aim of this study is to analyse functional correlates of these findings studying the relation of spatial distribution of myocardial velocities (MV) and myocardial velocity gradients (MVG) during diastole with age with color M-mode Doppler Tissue imaging (DTI). Sixty-six healthy subjects, no hypertensive nor diabetic were studied with DTI. Mean age was 42±20 yo. Postprocessing of images was accomplished with propietary software that allows division of myocardial wall in three layers:endo (End), meso (Mes) and epicardium (Epi). MV of all layers and MVG time curves were obtained. Early and late diastolic peak MV were identified.
Results: Peak protodiastolic MV decreased with age in the three layers. Correlation with age was stronger in End (r=0.77, b= 0.135±0.017, p=0.0005) than in Mes and Epi (r=0.62, b=0.088±0.016, p=0.0005 and r=0.5 b=0.053±0.013, p=0.0001), and was comparable to that observed between protodiastolic MVG and age (r=0.82, b=0.122±0.013 p=0.0001). Peak telediastolic MV and telediastolic MVG increased in the three layers (r=0.70 p=0.0005, r=0.68 p=0.0005 and 0.64 p=0.0005 in End, Mes and Epi). Correlation of DTI parameters and mitral flow data was also studied, obtaining an excellent correlation between protodiastolic peak mitral flow and peak protodiastolic endocardial MV (r=0.79, p=0.0005).



Protodiastolic endocardial velocities.

Conclusions: Functional changes in diastolic function related to aging are mainly located in the subendocardium. Protodiastolic endocardial peak MV also showed a high correlation with protodiastolic peak mitral flow confirming that early relaxation depends on the correct performance of subendocardium.

P1731 Body fat mass is a strong predictor of left ventricular diastolic dysfunction: results from a Doppler echocardiographic based survey of a population sample

M. Fischer[1], A. Baessler[1], C. Hengstenberg[1], M. Muscholl[1], A. Doering[2], H.W. Hense[3], G.A.J. Riegger[1], H. Schunkert[1]. [1]*University of Regensburg, Medical Department II, Regensburg, Germany;* [2]*GSF Institute, Munich, Germany;* [3]*Institute for Epidemiology, Muenster, Germany*

An elevated body mass index is associated with a higher prevalence of left ventricular diastolic dysfunction (LVDD). However, it is unclear whether this risk is due to an elevated body fat mass or an elevated fat free mass. Thus, we correlated fat mass with parameters of diastolic dysfunction in a population sample of 1366 men and women aged 25 to 74 years. Left ventricular diastolic function was evaluated echocardiographically (early [E wave] and late [A wave] left ventricular filling as well as isovolumic relaxation). LVDD was defined as proposed by the European Study Group on Diastolic Heart Failure, which allowed adaption of the upper limit for the isovolumic relaxation time and the lower limit for the E/A ratio with increasing age. Fat mass (fat) was determined by bioelectrical impedance analysis and indexed to body weight and body height squared, respectively. In men and in women the E/A ratio decreased and the isovolumic relaxation time (IVRT) increased dramatically with increasing fat/weight and fat/height squared ($p<0.0001$). As a consequence, the crude prevalence of LVDD increased from 6% in individuals in the lowest quartile of fat mass distribution to 16% in individuals beyond the 75% quartile. In both men and women fat mass indices were also correlated with systolic and diastolic blood pressure as well as left ventricular mass. In multivariate analysis, fat mass indexed by weight or height squared could be confirmed as strong independent predictor of an elevated prevalence of LVDD in women (10% increase of risk per 1% higher fat/weight%, OR=1.102 [1.043-1.164], $p<0.0006$). In men, the strong relation between elevated fat mass and LVDD was largely related to concomitant hypertension and LV hypertrophy. In conclusion, body fat mass is a strong independent predictor of diastolic dysfunction in women. In men, fat mass is related with systolic and diastolic blood pressure, as well as left ventricular hypertrophy and, therefore, affects diastolic function "only" indirectly.

P1732 The clinical problem of heart failure with preserved systolic function – a study of incident heart failure presenting in the community

M.D. Thomas[1], K.F. Fox[2], D.A. Wood[2], J.S.R. Gibbs[2], A.J.S. Coats[2], M.Y. Henein[2], P. Poole-Wilson[2], G.C. Sutton[2]. [1]*London, United Kingdom;* [2]*National Heart & Lung Institute, Imperial College School of Medicine, London, United Kingdom*

Background: The clinical syndrome of heart failure (HF) is usually due to a reduction in systolic function (SHF) although HF can occur when systolic function is preserved. If diastolic dysfunction is present the diagnosis of diastolic heart failure (DHF) is then made, although the syndrome of HF can occur with normal systolic and diastolic function.
Methods: One hundred and seventy four consecutive patients with suspected HF referred to a rapid access heart failure clinic (RAHFC) were assessed by history, examination, ECG, CXR, B-type natriuretic peptide (BNP) assay and standard transthoracic echocardiogram (TTE). A panel of 3 cardiologists met to review all cases and determined whether the European Society of Cardiology (ESC) clinical definitions of either systolic or diastolic HF were fulfilled. Those with normal systolic function (ejection fraction >45%) underwent detailed echocardiography measuring diastolic parameters and where appropriate dobutamine stress echo and cardio-pulmonary exercise testing.
Results: Of the 174 patients (median age 72, range 31-90) 36 (21%) were classified by the panel as SHF. A further 49 (28%) had symptoms or signs of HF with objective evidence of a cardiac abnormality. Of these, 21 (12%) had diastolic abnormalities according to ESC criteria. The remaining 28 (16%) had neither systolic nor diastolic abnormalities. There was poor correlation between BNP levels, MVO2 and echocardiographic findings between the three groups.
Conclusions: Over half of all cases considered to have HF according to ESC definitions had preserved systolic function. Only half of these cases had DHF on expert review and only two thirds of them had confirmatory evidence of HF with abnormal BNP or MVO2. An ESC definition of HF with preserved systolic function is required which takes account of clinical, biochemical and physiological criteria.

P1733 The occurrence of left ventricular isolated diastolic dysfunction assessed by Doppler-flow derived parameters in 647 individuals aged 50 to 89

F. Pedersen[1], I. Raymond[1], L.H. Madsen[1], J. Mehlsen[2], D. Atar[1], P. Hildebrandt[1]. [1]*Frederiksberg University Hospital, Department of Cardiology-Endocrinology, Frederiksberg, Copenhagen, Denmark;* [2]*Frederiksberg University Hospital, Department of Clinical Physiology, Copenhagen, Denmark*

Background: While comprehensive evidence exists about the prevalence of left ventricular (LV) systolic dysfunction, very scarce data have been published about the occurrence of heart failure on the basis of isolated diastolic dysfunction.
Objectives: To assess the occurrence of LV diastolic dysfunction measured by Doppler-flow derived parameters in an elderly population aged 50 to 89 years in which LV systolic function is preserved.
Methods: A total of 647 subjects (382 female and 265 male, median age 66 years) participated in this cross sectional survey. The study population was recruited from general practitioners and was stratified to include a minimum of 150 persons in each age decade stratum (in the age group 80-89 years, N=100). Each participant answered a heart failure questionnaire, and a clinical examination and an echocardiography were performed. Exclusion criteria were an LV ejection fraction <50% or atrial fibrillation.
Results: Using age- and gender-specific cut-off values for normality of E/A-ratio and deceleration time (DT) as recently published in The Tromso Study, the occurrence of impaired relaxation was 2.7% (95% CI: 1.5-4.1%). However, when fixed cut-off values for subjects above the age of 50 as recommended in the guidelines of 'The European Study Group on Diastolic Heart Failure' were utilized, the corresponding prevalence was 0.5% (95% CI: 0-1.0%). Furthermore, in a subpopulation of 166 participants (mean age 74 + 8 years), the occurrence of pseudonormal filling pattern defined by E/A-ratio between 1.0 and 2.0 and peak E/flow propagation velocity (Vp) >1.5 was 3.6% (95% CI: 0.8-6.4%). About 1/3 of subjects with diastolic dysfunction had complaints of dyspnea.
Conclusion: In this age-controlled population study the occurrence of impaired relaxation as assessed by state-of-the-art Doppler-flow derived parameters was lower using fixed cut-off values for normality of E/A-ratio and DT (prevalence 0.5%) than age- and gender-specific cut-off values (prevalence 2.7%). The occurrence of pseudonormal filling pattern was 3.6%. When correlating these findings to the symptoms reported, only 1/3 of subjects with diastolic dysfunction had complaints of dyspnea. These findings suggest that either diastolic dysfunction is often asymptomatic, or that Doppler-flow derived parameters as a diagnostic method for diastolic dysfunction have a low specificity when used as a screening tool in the general population.

P1734 Significance of early and atrial wave propagation velocity for the differentiation of normal and pseudonormal mitral filling pattern

K. Wierzbowska, J. Drozdz, P. Wejner-Mik, M. Krzeminska-Pakula, J.D. Kasprzak. *Medical University of Lodz, Cardiology Dept., Lodz, Poland*

Purpose: The assessment of diastolic function limited to mitral inflow pattern analysis is often ambiguous. The occurrence of pseudonormalization requires the incorporation of other parameters for correct diagnosis. We aimed to compare propagation velocity of mitral E and A wave (Ep, Ap) between patients with normal and pseudonormal mitral inflow pattern and to determine optimal cut-off values of Ep and Ap for their differentiation.
Methods: We studied 160 patients (60 after myocardial infarction, 50 with proved coronary artery disease and 50 healthy persons) by transthoracic echocardiography with comprehensive assessment of diastolic function. The subgroup of patients with E/A ratio between 1 and 2, were divided into normal and pseudonormal mitral inflow group according to classic, age adjusted normal values of E wave deceleration time. Ep and Ap were measured in color Doppler M-mode from apical 4-chamber view. Different cutoff values of Ep and Ap for predicting severe diastolic dysfunction were tested.
Results: In pseudonormal group Ep and Ap differed from that measured in persons with normal filling: 27±14 vs 46±9 cm/s, $p<0,0001$ and 36±13 cm/s vs 42±10 cm/s, $p<0,05$. For Ep value below or equal 45 cm/s sensitivity, specificity, positive predictive value, negative predictive value and accuracy for the detection of increased filling pressures (pseudonormal pattern) were: 89%, 54%, 41%, 93%, 63%. For Ep value below or equal 40 cm/s: 83%, 76%, 56%, 93%, 78% respectively and for cutoff 35 cm/s these values were: 83%, 88%, 71%, 94%, 87%.
Ap below or equal 40 cm/s yielded respective values of: 72%, 48%, 33%, 83%, 54%. Ap lower than 35 cm/s: 44%, 70%, 35%, 78%, 63%, Ap lower than 30 cm/s: 39%, 86%, 50%, 80%, 74%. For cutoff value 25 cm/s these values were: 28%, 98%, 83%, 79%, 79%.
For Ep lower than 35 cm/s we have 3 false negative and 6 false positive results. In false negative there was not Ap below 40 cm/s and in false positive there was not Ap below 30 cm/s. Respective values were: false negative Ep: 55,45,60, Ap:67,40,37, false positive Ep: 32,23,35,35,30,31, Ap: 55,34,45,32,40,48.
Conclusions: Ep allows accurate differentiation of normal and pseudonormal mitral flow pattern. However cutoff values lower than commonly recomended 45 cm/s offer better accuracy, with threshold of 35 cm/s being the optimal criterion. Ap is a specific new parameter with high positive and negative predictive value at cut-off 25 cm/s.

P1735 The effects of exercise training on diastolic function in older people: a randomised controlled trial

H C. Oxenham[1], R.N. Doughty[2], J.C. Baldi[3], K.L. McFarlane[3], J. Aoina[3], H.J. Walsh[2], G.D. Gamble[2], N. Sharpe[2]. *[1]Cardiovascular Research, Auckland, New Zealand; [2]University of Auckland, Cardiovascular Research, Auckland, New Zealand; [3]University of Auckland, Dept of Exercise and Sports Science, Auckland, New Zealand*

Advancing age is associated with significant changes in diastolic function in most healthy individuals. These changes are less marked in master athletes but their permanence and significance in older people is unclear. Studies assessing the effect of exercise training on diastolic function have previously been non-randomised or were in animal models. A randomised controlled trial was therefore performed to assess the effects of exercise training on diastolic function in older people.
Following screening to exclude cardiovascular disease, sedentary volunteers aged 60 to 80 years were randomised to either control or exercise groups. Exercise training consisted of 3 supervised exercise sessions per week for 6 months. The control group maintained pre-randomisation activity levels. Diastolic function was evaluated at baseline and 6 months by measuring Doppler transmitral flow (E and A velocities) and tissue Doppler imaging of the mitral annulus (E' velocity). Body composition was assessed using DEXA imaging and VO2max measured with maximal treadmill testing. Group comparison of parameter changes over the 6-month period was performed.
63 subjects were enrolled in the trial, mean age 67 years (range 60-79), 57% were female. Despite a 13% drop out rate in the exercise group, there was a significant increase in VO2max compared to the control group after 6 months (Table). Trends towards a reduction in heart rate, blood pressure, triglycerides and total body fat and an increase in HDL concentration were noted in the exercise group. However, there were no significant differences in any parameter of diastolic function between the groups (table).

Changes in diastolic parameters

	Control	Intervention	2p
Change in vO2max (ml/kg/min)	-0.5 (3.7)	+4.5 (4.7)	0.0001
Change in E/A	-0.03 (0.2)	0.01 (0.2)	0.78
Change in E' (cm/sec)	0.28 (2.0)	0.48 (1.7)	0.71
Change in E/E'	0.28 (2.0)	0.11 (1.7)	0.64

Conclusions Significant improvements in fitness can be achieved in sedentary elderly volunteers after 6 months of exercise training. Despite this, no statistically significant changes in diastolic function were identified. These data suggest that exercise training does not significantly alter diastolic function in elderly subjects.

NEURO-HORMONAL CONTROL MECHANISMS IN HEART FAILURE

P1736 Skeletal muscle reflex in heart failure patients: role of serum hydrogen

A.C. Scott[1], R. Wensel[1], D.H. Davos[1], P. Georgiadou[1], A.J.S. Coats[1], M. Piepoli[2]. *[1]Imperial College School of Medicine, Cardiac Medicine, London, United Kingdom; [2]Piacenza, Italy*

Background: The overactivity of muscle ergoreceptors (intra-muscular afferents sensitive to metabolites produced by muscle work) may be responsible for the abnormal reflex responses to exercise and for the genesis of symptoms of exercise intolerance in chronic heart failure (CHF). By using interventional methods we sought to identify the role of H^+, K^+, lactate and peripheral haemodynamics on ergoreflex overactivation.
Methods: 10 stable CHF patients (67.9±2.5 years, peakVO2 16.3±1.2 ml/kg/min) and 10 age and sex-matched healthy subjects were studied. The ergoreflex contribution to ventilation was assessed by post handgrip regional circulatory occlusion (PH-RCO) and computed as the difference in ventilation between PH-RCO and a control run without PHRCO. This test was performed on 6 separate occasions. On each occasion a different chemical was infused (insulin, sodium nitroprusside, sodium bicarbonate, dopamine, saline) or a 36-hour glucose free diet was undertaken before the test. During all stages of the protocol, the local muscular blood effluent concentrations of H^+, K^+, glucose and lactate were assessed.
Results: Patients vs. normals had a ventilatory ergoreflex effect on the ventilatory response during the saline infusions (6.7±2.3 L/min v -0.1±0.5 L/min, $p<0.01$). The only intervention to significantly lower the ergoreflex was sodium bicarbonate (0.4±0.3 L/min v -0.2±0.4 L/min on saline, p=NS), which also reduced H^+ concentration during exercise.
Conclusion: A reduction of the serum H^+ concentration by infusion of sodium bicarbonate abolishes the increased ergoreceptor activity in CHF patients. This suggests that H^+ is either a direct mediator or a trigger of such a mediator of the ergoreflex.

P1737 Paradoxical effect of isoprenaline infusion

B. brembilla-perrot, M. nippert, A.C. vançon, D. beurrier, P. houriez, O. claudon, C. suty-selton. *CHU de Brabois, Cardiologie, Vandoeuvre, France*

Isoprenaline is a beta adrenergic drug used to increase the heart rate and during electrophysiologic study to facilitate the induction of supraventricular and ventricular tachycardias. The purpose of the study was to know the significance of a paradoxical bradycardia induced by isoprenaline infusion.
Methods: electrophysiologic study was performed for the evaluation of tachycardias or dizziness/syncope in 678 patients aged from 15 to 85 years. The study was negative in the basal state; the study was repeated after isoprenaline infusion (20/50 μg).
Results: in most of the patients this perfusion increased the heart rate up to 100/140 beats/min. A bradycardia was noted in 35 patients (5%): 1) Sinus or junctional bradycardia (< 65/min) occurred in 28 pts, aged 15 to 70 years; 25 of them were studied for unexplained syncope; 6 of these patients had a hypertrophic cardiomyopathy; 1 of them developed bradycardia-related atrial fibrillation; other patients had no arrhythmia; 4 young patients (<50 years) were asymptomatic and studied for ventricular or supraventricular tachycardia. 2) Seven other patients developed a second degree AV block which was suprahisian in 3 patients and infrahisian in 4 patients; all patients were studied for exercise-related syncope and AV block was reproduced by ajmaline testing. Isoprenaline has revealed an organic conduction disturbance.
In conclusion the occurrence of paradoxical bradycardia is a rare finding during isoprenaline infusion (5%); it can be without clinical significance in young patients, but was rare (0.5% of the testings). In remaining patients, sinus or junctional bradycardia was associated with hypervagotonia and was more frequent in patients with hypertrophic cardiomyopathy. The development of a second-degree AV block was always pathological and associated with AV conduction disturbances, which occurred spontaneously during exercise.Isoprenaline infusion is a simple means to detect organic AV conduction disturbance especially in patients complaining of exercise-related dizziness/syncope.

P1738 Endothelins and myocardial fibrosis

F.J.A. Ramires, V.L. Nunes, M.K. Koike, F. Fernandes, C. Mady, J.A.F. Ramires. *University of São Paulo-Medical School, Heart Institute (InCor), São Paulo, Brazil*

The role of endothelins (ET) upon myocardial collagen deposition has been widely studied. Despite of its vasoconstrictor effect ET may work as a mediator of myocardial fibrosis. We investigated in vivo the role of ET on myocardial fibrosis independently of its hemodynamic effects. 40 Wistar male rats were divided into 4 groups: 1) control, 2) sham operated, 3) myocardial infarcted (MI) and 4) MI plus SB209670X (SB), 3mg/Kg bid (ip), an ET A/B blocker. MI was created by LCA ligation and the animals were kept for 4 wk. We evaluated the tail BP before, 2 wk and in the end of experiment. We also evaluated left ventricular end diastolic pressure (LVEDP) before, right after MI and in the end of the study. Interstitial collagen deposition (ICVF) of left and right ventricle (LV, RV) and MI size (IS) were quantifieded by an image system analysis using a picrosirius red stained tissue. We used ANOVA for statistical analysis. The MI size was MI:43.1 ±3.1 and MI+SB 43.3 ±3.3 (p=0.9).

Results:

		CONT	SHAM	MI	MI + SB	p
LVEDP (mmHg)	before	6.1	5.0	6.9	8.0	ns
	after	6.8*	5.2*	11.0	15.0	<0.05
	4wk	5.8*	6.0*	11.6	11.7	<0.05
BP (mmHg)	before	122	116	120	114	ns
	after	128*	110	102	106	<0.05
	4wk	123*	119*	102	103	<0.05
ICVF (%LV)		0.3	0.4	3.0*	1.3	<0.05
ICVF (%RV)		0.5	0.8	1.9*	0.9	<0.05

The ET A/B receptor blockade attenuated myocardial collagen accumulation despite of hemodynamic effects or infarction size. It confirms in vivo that ET stimulate directly myocardial fibrosis as a mediator peptide.

P1739 Left ventricular filling pattern and neurohumoral activation in heart failure. Relationship to exercise tolerance

F.I. Parthenakis[1], A.P. Patrianakos[1], G.F. Diakakis[1], H.E. Mavrakis[1], D. Nikitovic[2], M.C Saatsaki[1], P.E. Vardas[3]. [1]*Heraklion University Hospital, Cardiology Dept., Heraklion, Crete, Greece;* [2]*Heraklion University Hospital, Clinical Chemistry - Biochemisty Dept., Heraklion, Greece;* [3]*Heraklion University Hospital, Cardiology, Heraklion, Greece*

Back ground: Heart Failure (HF) is characterized by increased cytokines and natriuretic peptides circulating levels. Left Ventricular (LV) restrictive filling pattern has been recognized as a predictor of a lower survival rate and reduced cardiopulmonary exercise capacity (CPE) in these patients.

Objectives: The purpose of the study was to assess the relationship between LV diastolic filling pattern, circulating proinflammatory cytokines and natriuretic peptides levels and exercise tolerance in patients with Idiopathic Dilated cardiomyopathy (IDC).

Methods: We analyzed circulating levels of Tumor necrosis factor-a (TNF-a)and its receptors, sTNFr1 and sTNFr2, Interleukine-1 (IL-1) and -6 (IL-6), and N-terminal -Atrial (ANP) and brain (BNP) natiuretic peptides by immunoassay, in 90 pts, age 56±12y, with angiographically proven IDC, functional NYHA class II-III and LV ejection fraction 31±9%, in a clinically stable condition during the last month. A complete Echocardiographic study and cardiopulmonary exercise test with a Naughton Protocol was performed on all patients and maximal exercise duration and oxygen consumption at peak exercise (PVO2) were calculated.

Results: According to Doppler transmitral early (Em) to late (Am) filling Velocity or Deceleration Em time (DTE) patients were divided into restrictive (E/A>2 or E/A=1-2 and DTE<140msec, 35 patients) or non-restrictive (55 patients) groups. There was no significant difference in LV dimensions or LV ejection fraction between the two groups. The restrictive Group showed lower right ventricular ejection fraction (EF)(34±10 vs 43±11%, p=0.01) and increased circulating levels of IL-6 (6.8 ± 3.6 vs 3.8±2.8 pg/ml, p<0.001), sTNFr2 (4.09 ±1.6 vs 3.1 ±0.89 pg/ml, p=0.04), ANP (4± 0.7 vs 2.8±1.7 pg/ml, p=0.04) and BNP (1.01± 0.24 vs 0.66 ± 0.33 pg/ml, p=0.03).

Exercise duration (471±243 vs 719±376 sec, p=0.01) and maximal oxygen consumption at peak exercise (17.8±4.8 vs 22.2±6.2 ml/kgr/min, p=0.009) were significantly reduced in restrictive compared to non-restrictive group.

A significant correlation between E/A ratio and IL-6 levels (r=0.29, p=0.01), sTNFR2 levels (r=0.45, p=0.004), BNP (r=0.34, p=0.05), and PVO2 (r=-0.30, p=0.02) was found. The IL-6 was independently associated with E/A ratio(r=0.53, p=0.002.

Conclusions: The restrictive LV filling pattern is associated with increased proinflammatory cytokines and natriuretic peptides levels and impaired exercise tolerance in IDC. The increased LV end-diastolic pressures maybe responsible for the increased neurohumoral activation in those patients.

P1740 Novel, systemic neutral endopeptidase and endothelin converting enzyme inhibition in humans using orally active, SLV 306

A. Seed[1], R. Kuc[2], A. Davenport[2], C. Hillier[3], H. Essers[4], J.J.V. McMurray[1]. [1]*University of Glasgow, CRI in Heart Failure, Glasgow;* [2]*University of Cambridge, Cambridge;* [3]*Caledonian University, Biomedical Sciences, Glasgow, United Kingdom;* [4]*Solvay Pharmaceuticals, Weesp, Netherlands*

Introduction: Simultaneous manipulation of several endogenous neurohumoral systems is a new and promising therapeutic approach. SLV 306, through its active metabolite KC 12615, has dual neutral endopeptidase (NEP) and endothelin converting enzyme (ECE) inhibiting activity in vitro. The aim of this study was to demonstrate these actions in humans.

Methods: 13 healthy males, studied on 4 occasions, were randomised to placebo or one of 3 doses of SLV 306. Each visit involved, taking a single dose of SLV or placebo, supine rest (3 hours) and infusions of 8 and 12 pmol/kg/min of big ET-1 (20 minutes each). Systolic and diastolic blood pressure (SBP, DBP), ANP, big ET and its cleavage product through the action of ECE on big ET-1, endothelin-1 (ET-1), were measured over 4 hours.

Results: Mean peak changes in SBP (mmHg) after the second big ET-1 infusion were:19.4 (placebo),16.5 (dose 1),14.6 (dose 2),12.9 (dose 3) ($P<0.05$). The respective changes in DBP were 16.2, 14.3, 12.0 and 11.4 ($P<0.05$). The mean, placebo corrected, peptide changes following the second big ET-1 infusion for doses 1, 2 and 3 were; ANP: 7, 11, 15 pg/mL ($p<0.01$), big ET-1: 33, 89, 121 fmol/mL ($p<0.01$) and ET-1: 0.95, 0.56, 0.02 fmol/mL. ET-1 levels did not increase as would have been expected from a pure NEP-inhibitor, whereas big ET levels were increased dose dependently in the SLV 306 groups compared to placebo, indicating that the breakdown of big ET was inhibited. SLV 306 was well tolerated.

Conclusions: This is the first demonstration in humans of both systemic ECE and NEP inhibition. SLV 306, the lead orally active agent in this new class of combined metalloprotease inhibitors, may have therapeutic potential in hypertension and heart failure.

P1741 Sympathetic nerve activity restrains vasodilatory response during exercise in advanced heart failure patients

M.J. Nunes Alves[1], M.U.P.B. Rondon[1], A.C. Santos[1], H.R. Middlekauff[2], A.C. Pereira Barretto[1], E.M. Krieger[1], J.A.F. Ramires[1], C.E. Negrão[3]. [1]*Heart Institute(InCor), Univ. of São Paulo Medical School, São Paulo, Brazil;* [2]*Univ. of California, Dept. of Cardiology, Los Angeles, USA;* [3]*School of Physical and Ed. Sports and, Heart Institute (InCor) Univ. São Paulo, São Paulo, Brazil*

We tested the hypothesis that the resting and reflex abnormalities in vascular tone in advanced heart failure patients (HF) are mediated by increased sympathetic nerve activity. Sixteen HF (NYHA, CF= III/IV), and 16 normal controls (NC) were studied. Blood flow was measured in the resting non-dominant forearm with venous occlusion plethysmography at rest and during 3 minutes of isometric exercise (30% MVC). Blood pressure was intra-arterially measured. Saline control (0.5mL/min), phentolamine (100mg/min), or bretylium (2.5mg/min) or acetylcholine (0.64m/min) was infused into the brachial artery. At rest, forearm vascular conductance (FVC) was lower in HF patients than in NC [saline = 0.020±0.002 vs. 0.042±0.01 mL $mmHg^{-1}$ min^{-1} $(100mL)^{-1}$, $P<0.02$)]. Phentolamine or phentolamine plus bretylium significantly increased FVC in HF patients [saline vs. phentolamine (0.020±0.002 vs. 0.055±0.01, $P<0.0001$), vs. phentolamine plus bretylium (0.057±0.01, $P<0.0001$)], and NC [saline vs. phentolamine (0.042±0.01 vs. 0.086±0.02, $P<0.0001$) or vs. phentolamine plus bretylium (0.10±0.02 mL $mmHg^{-1}$ min^{-1} $(100mL)^{-1}$, $P<0.001$)]. At rest, forearm vascular conductance (FVC) with acetylcholine was lower in HF patients than in NC [acetylcholine = 0.059±0.003 vs. 0.188±0.025 mL $mmHg^{-1}$ min^{-1} $(100mL)^{-1}$, $P<0.01$)]. During exercise with phentolamine or phentolamine plus bretylium, the increase in FVC was significantly greater than during saline in HF patients [saline vs. phentolamine (0.001±0.001 vs. 0.02±0.009, $P<0.02$) or vs. phentolamine plus bretylium (0.022±0.008 mL $mmHg^{-1}$ min^{-1} $(100mL)^{-1}$, $P<0.01$)], but no change was found with acetylcholine [saline vs. acetylcholine (0.006±0.002 vs. 0.011± 0.004 mL $mmHg^{-1}$ min^{-1} $(100mL)^{-1}$, $P<0.57$)]. Furthermore, during exercise with saline or acetylcholine the increase in FVC was lower in HF patients than in NC [saline = 0.006±0.002 vs. 0.16±0.053, $P<0.02$; acetylcholine= 0.011±0.004 vs. 0.20±0.069mL $mmHg^{-1}$ min^{-1} $(100mL)^{-1}$, $P<0.002$)], but not during exercise with phentolamine or phentolamine plus bretylium [saline= 0.001±0.001 vs. 0.011±0.004, $P<0.02$; phentolamine = 0.02±0.009 vs. 0.032±0.01, $P<0.49$; phentolamine plus bretylium = 0.022±0.009 vs. 0.03±0.01 mL $mmHg^{-1}$ min^{-1} $(100mL)^{-1}$, $P<0.52$)]. Because sympathetic blockade with phentolamine plus bretylium, in contrast to acetylcholine, dramatically increases FVC compared with saline control in HF patients, and rises FVC to similar levels than NC, we conclude that the increase the sympathetic nerve activity explains, at least in part, the blunted vasodilatory response during exercise in HF patients.

P1742 Relative preservation of the renin-aldosterone system in patients with type 2 diabetes and autonomic neuropathy

E.A. Jarmuzewska[1], A. Ghidoni[1], A.A. Mangoni[2]. [1]Ospedale Maggiore, University of Milan, Internal Medicine, Policlinico IRCCS, Milan, Italy; [2]King's College London, Health Care of the Elderly, London, United Kingdom

Objective: Autonomic neuropathy (AN) is a very serious and often overlooked component of diabetic neuropathy, which is associated with a reduced 10-year survival rate in type 2 diabetic patients (T2D). Although parasympathetic dysfunction usually antedates sympathetic failure in the natural history of AN, the pathophysiologic mechanisms involved in the progression of AN in humans remain largely unknown. We addressed this issue by investigating the neurohormonal responses during sympathetic activation (orthostatism, O) in subjects with different degrees of AN.
Methods: Plasma noradrenaline (NA, pg/ml), adrenaline (A, pg/ml), renin activity (PRA, angiotensin I, ng/ml/h), and aldosterone (ALD, pg/ml) were measured in the supine position (baseline) and after 2 and 20 min O in 4 groups: 10 healthy subjects (CTR, age 50±12 years, mean±SD), 9 T2D without AN (T2D, 58±7 years), 14 T2D with parasympathetic AN (T2D_PS, 56±4 years), and 7 T2D with sympathetic AN and postural hypotension (T2D_PH, 55±7 years).
Results: See table.

	CTR	T2D	T2D_PS	T2D_PH
NA baseline	181+29	177+84	191+73	103+21
NA 2 min O	292+57***	283+87***	303+110***	181+49**
NA 20 min O	430+154**	393+126***	420+176***	177+96
A baseline	32+12	27+11	22+12	18+11
A 2 min O	53+14***	38+11**	28+20	23+12
A 20 min O	64+20**	49+14***	37+20**	33+20**
PRA baseline	0.59+0.16	0.99+1.00	1.11+0.77	1.28+1.13
PRA 20 min O	2.60+0.44***	2.65+2.29**	2.51+2.68*	2.23+1.48**
ALD baseline	90+44	98+74	90+40	118+75
ALD 20 min O	229+56***	163+62**	150+75***	176+76*

Means+SD; *p<0.05, **p<0.01, ***p<0.001 vs. baseline.

Conclusions: The results show a relative preservation of the renin-aldosterone system (RAS) in advanced AN. By contrast, the impairment of adrenaline response seems to antedate the onset of sympathetic failure whereas the impaired noradrenaline secretion represents a marker of T2D_PH. Although RAS blocking agents may prevent the progression of diabetic neuropathy, their use in advanced AN might potentially exacerbate PH as these patients are highly RAS-dependent.

P1743 Neuroendocrine-mediated induction of interleukin-6 in the heart

S. Rohrbach[1], S. Engelhardt[2], D.N. Müller[3], R. Dechend[3], J. Holtz[4], K. Werdan[1], M.J. Lohse[2], U. Muller-Werdan[1]. [1]Martin-Luther-University Halle, Department of Medicine III, Halle, Germany; [2]University of Würzburg, Institute of Pharmacology, Würzburg, Germany; [3]Humboldt University, Franz-Volhard-Clinic, Berlin, Germany; [4]Martin-Luther-University, Institute of Pathophysiology, Halle, Germany

Background: In heart failure blood levels of both noradrenalin and several cytokines among them IL-6 have been found to be chronically elevated, increasing with the progression of the underlying disease. The source of these cytokines as well as possible trigger mechanisms stimulating cytokine release are not yet very well defined.
Methods and Results: IL-6 mRNA expression in left ventricular tissue from patients with severe heart failure is increased compared to healthy donors. Furthermore, transgenic mice with cardiac overexpression of beta1-adrenergic receptor and transgenic rats with overexpression of the human renin and angiotensinogen gene also demonstrated a significant increase in IL-6 mRNA (RT-PCR, Northern blot). Therefore, we examined the putative link between neurohormonal dysbalance with enhanced sympathetic tone and activated renin-angiotensin-system (RAAS) and the release of IL-6 in rat neonatal cardiomyocytes under stimulation with different alpha- and beta-adrenergic agonists, angiotensin II or endothelin. The adrenergic agonists noradrenalin, methoxamin or isoproterenol as well as angiotensin II and endothelin-1 significantly enhanced IL-6 mRNA and protein expression and led to a IL-6 secretion by neonatal cardiomyocytes into the medium. The maximal mRNA induction was detectable after 3 hours, slowly declining within 48 hours after first exposure. A rise in intracellular cAMP by incubation with dbc AMP strongly induced IL-6 and phosphodiesterase inhibtion exaggerated isoproterenol- or noradrenalin-mediated IL-6 release from cardiomyocytes.
Conclusion: Enhanced sympathetic tone and activated RAAS promote IL-6 release from cardiomyocytes, indicating a proinflammatory component of catecholamine and RAAS action and a possible contribution of those mediators to the elaboration of IL-6 in heart failure.

IL-6 expression in cardiomyocytes

	control	noradrenaline	isoproterenol	methoxamine	angiotensin II	endothelin
mRNA	1.08±0.02	1.93±0.02 *	2.26±0.29 *	1.84±0.10 *	1.52±0.06 *	1.76±0.09 *

P1744 Prognostic power of neurohormones depends on the mode of death in patients with chronic heart failure

R. Berger[1], M. Huelsmann[1], K. Strecker[2], A. Bojic[3], B. Stanek[1], R. Pacher[1]. [1]University of Vienna, General Hospital, Dpt of Cardiology, Vienna, Austria; [2]Ludwig Boltzmann Institute, Experimental Endocrinology, Vienna, Austria; [3]Ludwig Boltzmann Institute, Cardiovascular Research, Vienna, Austria

Background: Due to increasing therapeutic progress, risk estimation of sudden death and pump failure is getting an important issue. We tested the prognostic power of various neurohormones for prediction of sudden death and pump failure, respectively, and combined the best prognostic markers of each mode of death for a simple risk stratification schedule.
Methods: BNP, N-BNP, N-ANP and big endothelin levels, in addition to clinical and hemodynamic variables, were obtained from 452 patients with a LVEF <35%. For prediction of sudden death and pump failure, two multivariate analyses were performed. Cut-off values were selected to define patients with low and high risk of sudden death and pump failure, respectively.
Results: Up to 3 years, the only independent predictor of sudden death was log BNP (P=0.0006), best independent predictor of pump failure was log N-ANP (P=0.0001). Using Kaplan Meier analysis, significantly fewer patients with BNP<130pg/ml and N-ANP<6300fmol/ml (Group A) died sudden (1%) compared to patients with BNP>130 and N-ANP<6300fmol/ml (Group B; 18%; P=0.0001) and patients with BNP>130fmol/ml and N-ANP>6300fmol/ml (Group C; 19%; P=0.0001). Significantly more patients of Group C (34%) died of pump failure compared to Group B (6%; P=0.0001) and Group A (0%; P=0.0001).
Conclusion: Prognostic power of neurohormones depends on the mode of death. The combined determination of BNP and N-ANP identifies 1) patients with minimal risk of death (sudden 1%, pump failure 0%), 2) patients with elevated sudden death (18%) but low pump failure (6%) and 3) patients with elevated sudden death (19%) and pump failure (34%) risk.

P1745 Fusion pattern of the transmitral flow in patients with heart failure and sinus rhythm

R. Isnard[1], F. Pousset[1], A. Cachier[1], O. Chafirovskaia[1], A. Gackowski[1], A. Carayon[2], D. Thomas[1], M. Komajda[1]. [1]Pitié-Salpetrière Hospital, Cardiology Dept., Paris, France; [2]Pitié-Salpetrière Hospital, Biochemistry Dept., Paris, France

A restrictive pattern of the transmitral flow has been shown to be associated with high plasma brain natriuretic peptide (BNP) and poor prognosis in chronic heart failure (CHF). However, little is known about the significance of a fusion between the E and the A waves of the transmitral flow in patients with CHF and sinus rhythm.
We studied 213 patients with chronic heart failure due to LV systolic dysfunction (EF < 45%); all patients were in stable conditions for at least 2 weeks; all had a measurement of plasma BNP (RIA) and an echocardiographic study. A restrictive pattern was defined as E/A ratio > 2 or 1<E/A ratio<2 and a deceleration time of E < 130 ms. A non restrictive pattern was defined as E/A ratio < 1 or 1<E/A ratio< 2 and a deceleration time of E > 130 ms. A fusion pattern was defined as an unique diastolic transmitral wave due to superimposed E and A waves. Patients with atrial fibrillation were excluded. After a median follow-up of 2 years, there were 31 deaths and 2 urgent cardiac transplantation. Patients with a fusion pattern had higher plasma concentrations of BNP and a poorer prognosis than patients with restrictive and non restrictive pattern. Among them, a widened QRS was observed in 18/31 (58%) and in patient with normal QRS duration, the heart rate was > 90 bpm in 7/13.

Plasma BNP and mortality

	Non restrictive (n=98)	Restrictive (n=84)	Fusion (n=31)
Plasma BNP (pg/ml)	120±146	214±199*	338± 262*$
One year Mortality	1%	8.6%*	33%*$

* p < 0.01 versus non restrictive; $ p< 0.01 versus restrictive

Thus, a fusion pattern of the transmitral flow is frequently associated with intraventricular conduction disorders or an increased heart rate, and is a marker of severity in patients with CHF in sinus rhythm.

P1746 Correlation of plasma cardiotrophin-1 and exercise derived prognostic indicators in chronic heart failure

S.G. Williams[1], D.J. Wright[1], J.P. Diesch[1], Z. Khan[1], R. O'Brien[2], L.B. Tan[1], L.L. Ng[2]. [1]*Leeds General Infirmary, Institute For Cardiovascular Research, Leeds, United Kingdom;* [2]*University of Leicester, Medicine and Therapeutics, Leicester, United Kingdom*

Cardiotrophin-1 (CT-1) a recently identified member of the interleukin (IL) 6 family of cytokines, elevated in the plasma of patients with chronic heart failure (CHF), has previously been shown to correlate with echocardiographic markers of left ventricular dysfunction. We examined the relationship between CT-1 and indicators of exercise capacity in an unselected group of patients with CHF.
86 patients with CHF (mean age 56 years, 84% male, mean LVEF 36.8±2%) and 10 healthy controls (mean age 52 years, 90% male) underwent cardiopulmonary exercise testing with measurement of peak oxygen consumption (VO2) and peak cardiac power output (CPO), both strong predictors of prognosis. A sample of venous blood was obtained and plasma CT-1 was determined using a novel non-competitive two site immunoluminetric assay.
CT-1 levels were elevated in the CHF group (294.7±67.5 fmol/ml, mean±SEM) compared with the control group (94.9±28.0 fmol/ml, $P<0.008$). In the CHF group, there was significant negative correlation of log CT-1 with peak CPO ($r = -0.493$, $p<0.02$), but not with peak VO2 ($r = 0.052$, p=NS). There was no significant correlation between CT-1 and exercise derived data in the healthy control group.
Plasma levels of CT-1 correlated significantly with peak CPO, a strong prognostic exercise derived parameter in CHF. Whether CT-1 will have a predictive prognostic power in CHF remains to be seen.

P1747 17-β-oestradiol in human myocardium: effects on contractile function and intracellular calcium handling

E. Bisping, A. Schnellinger, H. Kögler, B. Pieske. *Georg-August Universitaet Goettingen, Department of Cardiology and Pneumology, Goettingen, Germany*

The heart is a target organ for 17-β-estradiol which has both genomic and non-genomic effects. We investigated the effect of 17-β-estradiol on contractility and intracellular calcium handling in isolated human myocardium.
Methods: Isolated ventricular muscle strips (n=40) from failing human hearts (n=16). Electrical stimulation, 37°C, 1 Hz. Cumulative concentration-response curves (0.1-100 μmol/l) without and with preincubation of a specific estradiol receptor antagonist (ICI 182.780; 1 μmol/l). Additional experiments with a single concentration (10 μmol/l) of estradiol. Simultaneous registration of force of contraction and calcium transients (Aequorin method) or of sarcoplasmic reticulum (SR) calcium content (rapid cooling contractures, RCC).
Results: Estradiol exerted concentration- dependent negative inotropic effects (by maximally 64 ± 4% of basal value at 100 μmol/l; $p<0.05$). The IC50 was 8.2 ± 0.9 μmol/l. ICI 182.780 shifted the concentration- response curve to the right (IC50 for estradiol in the presence of ICI 182.780 was 12.4 ± 1.1 μmol/l, $p<0.05$ vs. estradiol alone). The negative inotropic effects of estradiol (by 36 ± 8% at 10 μmol/l) were associated with a proportional decrease in aequorin light signal (by 38 ± 1%) and a decrease in the amplitude of RCCs (by 19 ± 5%; all $p<0,05$).
Conclusions: Estradiol exerts direct negative inotropic effects in failing human myocardium. These effects are related to depressed intracellular Calcium transients and SR calcium content and at least in part mediated by specific estradiol receptors.

CARDIAC AND VASCULAR ALTERATIONS IN HYPERTENSION

P1748 Changes in geometric adaptation of the left ventricle in hypertensive patients: do they have prognostic significance ?

M. Muiesan, M. Salvetti, C. Monteduro, D. Rizzoni, M. Castellano, B. Bonzi, S. Viola, E. Agabiti-Rosei. *University of Brescia, Medical and Surgical Sciences, Brescia, Italy*

Objective: to evaluate the prognostic significance of left ventricular hypertrophy (LVH) regression or persistence as related to changes of LV geometric patterns.
Patients and methods: Five-hundred-twenty-two consecutively seen uncomplicated hypertensive patients underwent baseline echocardiogram for LVMI evaluation and 419 (237 M, 182 F, age range 18-71 years) repeated the echocardiographic examination 2 to 18 years, *mean(SD): 6.2(4.4)*, after the initial study. All but 65 patients received antihypertensive medication during the follow up period. According to the presence of LVH (LVMI > 51 g/ $m^{2.7}$ in both genders) at baseline and at the end of follow-up patients were divided in four groups: with normal LV mass at both examinations (n 205), with regression of LVH (n 59), with persistence of LVH (n 117) and with hypertrophy development (n=38).
Results: Months or years after the follow-up visit 56 patients suffered a first cardiovascular morbid event. Relative wall thickness (RWT) was greater in patients who experienced cardiovascular events then in those patients without events, both at baseline and at follow-up (0.45 + 0.09 vs 0.40 + 0.09 and 0.40 + 0.07 vs 0.38 + 0.07, $p< 0.001$ e $p<0.02$ respectively) After adjustment for traditional cardiovascular risk factors, the cumulative incidence of non fatal CV events was significantly higher in the group of patients without regression of LVH. In all patients the number of morbid CV events was significantly greater in those with a concentric geometry both at baseline and at follow-up in respect to those patients with an eccentric geometry ((38% vs 14%, $p = 0.002$). When considering only patients with LVH at baseline, the number of CV events was greater in those with concentric then in those with eccentric geometry (46% vs 14%, $p = 0.002$). Cox survival analysis showed the presence of LVH at the end of follow up as the most important independent predictor of CV events (Relative risk = 4.58 (2.32-9.03), $p<0.001$) in patients with persistence of LVH and 1.34 (0.46-3.9) in patients with regression of LVH.
Conclusions: These findings strongly confirm that the regression of LVH represents a favourable prognostic index independent from other CV risk factors; changes of LV geometric pattern of adaptation may give additional informations.

P1749 Conversion of atrial fibrillation in hypertensive patients: effects on left atrial size and function

A.V. Mattioli, S. Bonatti, L. Bonetti, L. Fontanesi, C. Mariani, M. Zennaro, G. Mattioli. *University of Modena and Reggio E., Dpt of Cardiology, Modena, Italy*

The aim of the study was to evaluate the Left Atrial (LA) contribution to left ventricular (LV) filling after conversion of atrial fibrillation in hypertrophic hearts. We selected 80 patients (pts) with a first diagnosis of hypertension who had a mild LV hypertrophy. Pts were hospitalized because of an episode of atrial fibrillation and were successfully cardioverted. Pts population included 55 men and 25 women with a mean age of 54 ± 9 years. Pts were compared with a control population of 80 pts cardioverted because of Lone atrial fibrillation without cardiac hypertrophy (mean age 56 ± 12 yrs). Atrial function and size were assessed by Doppler echocardiography and the following parameters were measured: transmitral peak A velocity (A) and integral (Ai), atrial filling fraction (AFF), atrial ejection force (AEF), peak E velocity (E),deceleration time (dec t)and Isolumic relaxation time (IVRT), LA max volume (LA max vol) and minimal volume (LA min vol), LV cardiac mass index (LVMI). Doppler data were correlate to LVMI.
Diastolic function was impaired in the study group: peak E vel was 0,49 ± 0.08 m/sec vs control 0,75 ± 0,10 m/sec ($p<0.01$), peak A vel was 0,79 ± 0.1 m/sec vs control 0,55 ± 0,12 m/sec ($p<0.01$), dec t was 282 ± 39 vs control 201 ± 35 ($p<0.01$), IVRT was 109 ± 15 vs control 88 ± 13. All pts had an increased LVMI (278 ± 47 vs control 110 ± 44 g/m^2; $p <0.001$). AEF increased significantly with age in normal subjects ($r=0.87$; $p<0.001$)and was strongly related to peak A velocity. In hypertensive patients the relation of AEF with age was weak ($r=0.43$; $p <0.05$), the values were significantly higher than in normal subjects. A strong relation was reported between LVMI and AEF ($r=0.75$;$p <0.001$)in the study group while a weaker relation was reported beween LVMI and the other atrial function parameters. LA size was reduced in Hypertensive pts after cardioversion. La max vol decrease from 31 ± 8 to 27 ± 5 cm^3 ($p<0.05$), La min vol decrease from 19 ± 6 to 12 ± 7 cm^3 ($p<0.05$). A relationship between LA maximal and minimal volumes and AEF was observed in hypertensive pts ($r=-0.74$, $p<0.01$ and $r=-0.69$, $p<0.05$)
In conclusion these data suggest that the influence of age in hypertensive pts appeared to be overridden by the effect of the disease process. Hypertrophy had a strong influence on atrial function in pts with hypertension and atrial fibrillation.

P1750 The limited value of plasma B-type natriuretic peptide for identification of left ventricular hypertrophy among hypertensive subjects

M. Nakamura[1], H. Endo[2], M. Nasu[2], N. Arakawa[2], K. Koyamada[3], K. Hiramori[2]. [1]*Iwate Medical University Hospital, Dept. of Medicine 2, Morioka, Japan;* [2]*Iwate Medical University, Medicine 2, Morioka, Japan;* [3]*IHMA, Morioka, Japan*

Objectives: Hypertensive left ventricular hypertrophy (LVH) is known to be a strong risk factor for future cardiovascular events. A reduction in LVH during antihypertensive treatment reduces an adverse outcome. Several reports have suggested that plasma B-type natriuretic peptide (BNP) is elevated in hypertensive patients especially with LVH. However, no data have been available concerning the utility of plasma BNP for identifying hypertensive LVH in a screening setting for hypertensive subjects.
Methods: We measured plasma BNP concentrations in 1,586 volunteers in a health screening program (mean age; 56 years). All subjects underwent ECG, chest X-ray, and echocardiography. Patients having typical heart diseases (ie; old myocardial infarction, valvular heart disease, cardiomyopathy, atrial fibrillation) were excluded from the study.
Among the sample, 383 subjects were designated as hypertensive as they were on anti-hypertensive drugs and/or showed elevated systemic blood pressure (>=140 in systolic and/or >= 90 mmHg in diastolic). By echocardiography, 50 of these 383 subjects showed significant LVH (LV mass index > 134 g/m^2 in men and > 110 g/m^2 in women).
Results: Age did not differ significantly between LVH group and non-LVH group (60 ± 9 vs. 59 ± 9 years; NS). Plasma BNP level in LVH group was significantly higher than in non-LVH group (25.1 ± 23.7 vs 18.7 ± 18.9 pg/ml; $p < 0.05$). However, the ability of plasma BNP levels to discriminate LVH patients from non-LVH patients was not sufficient as the area under the receiver-operating characteristic curve was 0.60 (95%CI, 0.55 - 0.65) with sensitivity of 48.0% and specificity of 69.7%. Positive and negative predictive values to select LVH from hypertensive subjects were 19.2% and 89.9%, respectively.
Conclusion: Plasma BNP testing in a mass screening setting is of limited use for identification of LVH patients among hypertensive subjects with heterogeneous etiology.

P1751 Midwall fractional shortening identifies extracardiac organ damage in essential hypertension

V. Sebastiani[1], G.P. Bezante[1], L. Deferrari[1], M. Ravera[2], F. Viazzi[2], R. Pontremoli[2], G. Deferrari[2], A. Barsotti[1]. [1]*Cardiologia, DIMI - Dipartimento Medicina Interna, Genova, Italy;* [2]*Nefrologia, Dipartimento di Medicina Interna, Genova, Italy*

The evaluation of subclinal target organ damage (TOD) is an important task for the stratification of absolute cardiovascular risk profile in essential hypertension (EH). To study the relationship between left ventricular (LV) midwall fractional shortening (MFS) and extracardiac organ damage in a group of 344 untreated hypertensive patients.Left ventricular mass index (LVMI) and function (MFS) were assessed by M-B mode echocardiography (LV hypertrophy LVH= LVMI > 51g/m$^{2.7}$; depressed MFS<14%). Albuminuria was measured as albumin to creatinine ratio (ACR) in three non consecutive first morning urine samples (negative urine culture). Persistent Mi (Alb+) was defined as an average ACR between 2.38-19 (males) and 2.96-20 (females). Carotid wall geometry was evaluated by high resolution US scan, and retinal vascular changes by direct ophthalmoscopy (Keith-Wagener classification).
The prevalence of LV hypertrophy and depressed MFS were 46 and 13% respectively; the prevalence of carotid plaque, microalbuminuria, and retinal changes were 25, 13, and 67% respectively. There were no differences as for blood pressure, lipid profile, smoking habits and alcohol intake among groups of patients divided according to MFS quintiles. Patients in the bottom quintile of MFS showed a higher LVMI (56±2.3, 53±1.9, 54±2, 48±1.8 and 48±1.8 g/m$^{2.7}$ respectively; P<0.01) as well as a higher prevalence of LVH (65, 53, 54, 27, and 32%, respectively; P<0.01) especially concentric hypertrophy (65, 45, 36, 15, and 12%, respectively; P<0.001). Moreover hypertensives with subclinical impairment of LV function, i.e. the bottom quintile of MFS, showed early signs of extracardiac damage, namely increased carotid surface area (CSA) (19.3±2.1, 15,3±0.9, 16.9±2.3, 14.7±1.3, and 13.6±0.9 respectively; P<0.01) and ACR (3.1±0.9, 1.5±0.4, 1.6±0.4, 0.9±0.2, and 0.9±0.2, respectively; P=0.01), a higher prevalence of microalbuminuria (28, 16, 15, 3, and 7%, respectively; P<0.05) and retinopathy (84, 67, 58, 67, and 60%, respectively; P=0.02) compared to the other MFS quintiles. Furthermore, MFS was inversely correlated with mean blood pressure (r= -0.15, P<0.05) and signs of early TOD, namely LVMI (r= -0.23, P<0.01), A/C (r=-0.2, P<0.01), and CSA (r=-0.25, P<0.02). Patients with a depressed MFS show a higher prevalence of LVH and early signs of extracardiac vascular damage. MFS may contribute to identify hypertensive patients at higher cardiovascular profile risk for whom are indicated more aggressive preventive and therapeutic measurements.

P1752 Relationship between weight reduction and regression of hypertensive left ventricular hypertrophy

I. Tasic[1], B. Lovic[1], S. Ilic[1], D. Djordjevic[1], N. Miladinovic Tasic[2]. [1]*Institute for cardiology, Cardiology, Niska Banja, Yugoslavia;* [2]*Institute for Public Health, Mycrobiology, Nis, Yugoslavia*

Aim of the study is assessment of relationships between weight reduction and regression of hypertensive left ventricular hypertrophy. 73 patients with II-III stage hypertension (43 male), average age 55.9 ± 8 and LVH determinated by echocardiography (average left ventricular mass (LVM) index: 164 ± 32 g/m^2; Penn convention) have been treated (by medication and by diet) for a year. Each subject underwent two-dimensional and Doppler echocardiography, 12-lead electrocardiogram examination, exercise stress testing (Bruce - protocol), 24-h ambulatory monitoring blood pressure (ABPM), 24-h Holter monitoring with Lown classification of ventricular arrhythmia's and heart rate variability. Mean body mass index (BMI) was 28.7 ± 3.6 kg/m^2 (23 to 39), and 28 (39%) patients were obese (BMI > 30 kg/m^2) (OH group). After one year systolic BP (SBP) was reduced on average 168 ± 26 to 158.2 ± 21 mmHg, diastolic BP (DBP) from 102 ± 12.7 to 97 ± 11 mmHg. LV mass index was reduced from 163 ± 32 to 150.2 ± 27 g/m^2 (all p<0.001). 22 patents (30.1%) lost weight more than 5%. These patients significantly decreased LV mass 309 ± 79 vs 278.4 ± 61 g; t=3.22 p<0.004), LV mass index (161 ± 35 vs 148 ± 29 kg/m^2; t=2.68; p<0.02), LV diastolic dimension (52.3 ± 4.7 vs 50.5 ± 4.4 mm; t=2.95, p<0.008), Cornell's index (1.55 ± 0.4 vs 1.41 ± 0.4, p<0.02), peak double product (DP) (27.3 ± 5 vs 24.4 ± 5, t=2.8, p<0.02), DP/METTs (2.48 ± 1 vs 1.84 ± 1, t=2,15; p< 0.05), mean 24h systolic BP (SBP) (144.1 ± 17 vs 138.6 ± 16 mmHg, t=2.2 p<0.04), mean 24h diastolic BP (DBP) (89.5 ± 11 vs 85.7 ± 12 mmHg, t=2.2, p<0.04), mean SBP per day (148.2 ± 18 vs 141 ± 16 mmHg, t=2.6, p<0.02), mean DBP per day (92.7 ± 11 vs 88 ± 13 mmHg, t=2.6, p < 0.02) and increase of mean 24h RR intervals per night (938.2 vs 999 ms; t= 3, p<0,007). Patients (51.70%) who didn't achieve significant loss of weight significantly decreased LV mass index (163 ± 30 vs 152 ± 25 kg/m^2; t=2.1; p<0.05), office SBP (170.3 ± 27 vs 158.9 ± 19, t=2.2, p<0.03), grades of ventricular arrhythmias (2.73 vs 1.95, t=2.1, p<0.04), and mean VES/24h (66.6 vs 20, t=2.22, p<0.04). Hypertensive patients with LVH with significant loss of weight after one year, achieved higher grade of LVH regression (on account of decrease of LV diastolic dimension), lower DP at exercise, lower values of BP during 24-hour monitoring and improvement of heart rate variability, than patients without significant loss of weight.

P1753 Quantification of regional myocardial function improved estimation of coronary flow reserve in left ventricular hypertrophy

M. Deljanin Ilic[1], S. Ilic[2], D. Kalimanovska Ostric[3], B. Vujisic Tesic[3], A. Djordjevic Dikic[3], M. Dekleva[3]. [1]*Institute of Cardiology, Echo Lab, Niska Banja, Yugoslavia;* [2]*Institute of Cardiology, Clinical Cardiology, Niska Banja, Yugoslavia;* [3]*Institute of Cardiology, Echo lab, Belgrade, Yugoslavia*

The aim of the study was a quantitative assessment of regional systolic and diastolic myocardial velocities (m.v.) changes in the presence of stress induced myocardial ischemia (m.i.) in hypertensive patients (pts) using pulsed wave Doppler myocardial imaging (PW-DMI).
Methods: We studied forty-three hypertensive pts (29 male, 14 female; mean age 56.8 ± 9.8 years) with left ventricular hypertrophy (LVH) and known or suspected coronary artery disease. In all pts dobutamine stress echocardiography (DSE; from 5 up to 40 mcg/kg/min infused in 3 minute stages plus atropine 1mg if needed) was performed. DSE identified ischemia by the occurrence of wall motion abnormalities (WMA) with stress - positive DSE. Apical views were used to assess m.v. on baseline and at the peak stress. The sample volume was placed in each of the 11 adequately visualized segment in which left ventricle was divided. In each segment peak m.v. of systolic (S), early (E) and late (A) diastolic waves and ratio E/A (index of regional diastolic function) were calculated.
Results: Myocardial velocities were measured in 405 (85.6%) out of 473 possible myocardial segments. During DSE, in 28 (65.2%) pts WMA were detected in 97 (37.1%) out of 262 adequately visualized segments, while in 15 (34.8%) pts WMA were not appeared. In segments with DSE provoked WMA, E decreased from 7.9 ± 3.1 to 6.4 ± 3.5 cm/s (P<0.05), A increased from 9.2 ± 2.9 to 9.8 ± 3.3 cm/s (NS), S decreased from 9.6 ± 3.2 to 8.1 ± 3.4 cm/s (P<0.005) and ratio E/A decreased significantly (P<0.001) compared to baseline values. Out of 143 evaluated myocardial segments in 15 pts with negative DSE, in 4 (26.6%) pts 13 (9.1%) segments demonstrated inversion of E/A ratio after DSE (from 1.02 ±0.08 to 0.91 ± 0.09, P<0.005). Evaluation of m.v. in other 298 segments without WMA showed significant increased of E/A ratio (P<0.001) and S (P<0.005) after DSE.
Conclusion: Quantification of regional m.v. changes during conventional DSE showed that m.i. is associated with significant decreased E/A ratio, S and E m.v. Inverted regional E/A ratio as an earlier diastolic marker of m.i. is superior to WMA in the detection of reduced coronary flow reserve in pts with hypertensive LVH.

P1754 Exercise-induced ischaemia is related to impaired coronary vasodilator capacity and increased pulse pressure in hypertensive patients

M. Kozàkovà[1], C. Morizzo[2], C. Palombo[1]. [1]University of Pisa, Department of Internal Medicine, Pisa, Italy; [2]Clinical Physiology Institute, CNR, Pisa, Italy

Background: increased Pulse Pressure (PP), i.e. the pulsatile component of arterial pressure, augments the hemodynamic load on left ventricle (LV), promotes LV hypertrophy and represents an independent predictor of cardiovascular risk.
Aim of the study was to investigate the possible relationship between PP, coronary flow reserve (CFR), minimum coronary resistance (MCR), and inducible ischemia in middle-aged hypertensive patients without CAD.
Methods: Sixty-four patients with systo-diastolic hypertension (HBP, 40 males,mean age 53±8 yrs, BP 171±16/100±10 mmHg, LVMI 65±24 g/h2.7)and without significant CAD ruled out by means of symptom-limited stepwise exercise test (bycicle, ETT), high-dose dipyridamole echo (all), and coronary angiography (31 patients), were studied. TEE-Doppler was used to measure coronary flow velocity in LAD at baseline and during dipyridamole infusion (0.84 mg/kg/8 min), and to calculate CFR and MCR. LV mass, mean and relative LV wall thickness (RWT, MWT), and normalized stroke volume/PP, an index of total arterial compliance(AC), were assessed by M-mode US.
Results: ETT was positive for myocardial ischemia (ETT+) in 14 patients, negative in 26 (ETT-) and non-diagnostic in 24. From the lowest to the highest tertile of PP, CFR decreased (2.8±0.4, 2.5±0.5, 2.4±0.3) and MCR increased (1.1±0.2, 1.2±0.1, 1.3±0.2 mmHg*s*cm-1) ($p<0.01$ for the lowest vs the highest tertile); both indexes were comparable through tertiles of mean BP. In univariate regression analysis, CFR was related inversely, and MCR directly, to PP, MWT, and RWT, while CFR was related directly and MCR inversely to AC (r value from 0.25 to 0.40; p from 0.05 and 0.01). In the multivariate model, PP and MWT remained independently related to CFR, and AC and MWT to MCR. Patients with ETT+ had, compared with ETT-, higher PP (74±10 vs 65±12 mmHg) and MCR (1.4±0.3 vs 1.2±0.2), and lower CFR (2.3±0.5 vs 2.7±0.4) and AC (79±18 vs 94±21%) ($p <$ at least 0.05). In the logistic regression, ETT+ was independently associated with AC.
Conclusions: in middle-aged hypertensive patients without CAD, PP comes out as a major factor contributing to a reduced coronary vasodilator capacity and exercise-induced myocardial ischemia. Such an association seems to be at least partially mediated through increased LV wall thickness and impaired arterial compliance.

P1755 Baroreflex control of heart rate and myocardial repolarization in hypertensive patients with renal failure

M. Johansson[1], G. Bergström[1], J. Carlström[2], S. Ljungman[3], G. Jensen[3], T. Ivarsson[4], F-D. Nielsen[5], U. Strömbom[6]. [1]Sahlgrenska University hospital, Clinical Physiology, Göteborg, Sweden; [2]NÄL, Nephrology, Vänersborg, Sweden; [3]Sahlgrenska Univesrity Hospital, Nephrology, Göteborg, Sweden; [4]KSS, Nephrology, Skövde, Sweden; [5]SÄS, Nephrology, Borås, Sweden; [6]Internal Medicine, Varberg, Sweden

Background: Hypertensive patients with renal failure have an increased cardiovascular mortality. Previous studies in patients with various cardiovascular diseases have shown that reduced modulation of heart rate in response to blood pressure fluctuations and altered myocardial repolarization are associated with an adverse prognosis. The aim of the present study was to investigate baroreflex sensitivity and the variability of both heart rate and QT interval in hypertensive patients with renal failure.
Methods: Hypertensive patients (n=77) with renal failure (glomerular filtration rate <20 ml/min) and healthy subject (n=13) were studied. ECG and beat-to-beat blood pressure were continuously registered during 30 minutes rest. Spontaneous baroreflex sensitivity and the numbers of baroreflex-mediated sequences were measured using the sequence method. Heart rate variability in the time domain was calculated as the standard deviation of normal RR intervals and temporal QT variability was calculated as the QT variability index (QTVI) using a validated pattern recognition algorithm.
Results: Hypertensive patients with renal failure had reduced number of baroreflex mediated sequences (24±31 vs 69±10 sequences/1000 beats), reduced baroreflex sensitivity (5±3 vs 9±5 ms/mm Hg) and reduced heart rate variability (21±14 ms vs 40±19 ms), whereas QTVI was increased (-0.70±0.50 vs -1.32±0.26) compared to healthy subjects ($p <0.01$ for all).
Conclusion: Hypertensive patients with renal failure have markedly reduced ability to modulate cardiac parasympathetic nerve activity. This, together with altered myocardial repolarization, may predispose to ventricular arrhythmia and sudden death,

P1756 Nocturnal systolic blood pressure fall

V. Kotsis, V. Pitiriga, S. Toumanidis, J. Lekakis, K. Vemmos, S. Rokas, C. Papamichail, N. Zakopoulos. Alexandra Hospital, Department of Clinical Therapeutics, Athens University, Greece

The purpose of the present study was to evaluate the relation of the nocturnal systolic blood pressure (BP) fall to the carotid lesions and left ventricular (L V) mass index. Also we examine the relation of the nocturnal systolic blood pressure fall to age and parameters derived from the 24h arterial blood pressure monitoring. **Patient population-Methods:** A total of 1544 subjects underwent clinic blood pressure (CBP) readings, 24h ambulatory blood pressure monitoring (AB PM) and ultrasound imaging of the carotid arteries and the myocardium. They had not been given any kind of drug that might have affected their BP level for at least 3 weeks before entering the study. Measurements of 24h arterial BP monitoring (systolic, diastolic and average BP, pulse pressure, abnormal values of systolic/diastolic BP and heart rate), intima-media thickness (IMT) of the carotid arteries and L V mass index were determined in all patients. Their systolic/diastolic 24h ambulatory blood pressure varied from 80/50 to 199/132 mmHg. Three hundred twenty five patients from the total 1544 subjects with known coronary artery disease underwent coronary arteriography and the severity of coronary heart disease evaluated with Gensini score. In order to have the nocturnal systolic BP fall as a continue parameter we calculated the difference between mean daytime -nighttime systolic blood pressure. All subjects were classified into groups by their nocturnal systolic blood pressure fall (extreme-dippers, with >=20% nocturnal systolic BP fall; dippers, with >= 10% but <20% fall; nondippers, with ≥0% but <10% fall; and reverse-dippers, with <0% fall). **Results:** Nocturnal systolic blood pressure fall is related to pulse pressure (multivariate analysis, ABPM derivatives as independent variables, P=0.02, negative), age (bivariate analysis, negative, P=0,00), left ventricular mass index (bivariate analysis, negative, P=0.01), MCCA- IMT (bivariate analysis, negative, P=0.01) but not with Gensini score. There was no difference between men and women in nocturnal BP fall. Left ventricular mass index were significantly higher in nondippers (P=0,00) and reverse -dippers (P=0.02). Mean CCA-IMT was significantly higher in reverse-dippers (P=0.03). Gensini score was significantly higher in extreme-dippers (P=0.04) but the number of patients was very low (n=5). **Conclusions:** Nocturnal BP fall is related to pulse pressure, carotid IMT and L V mass index, indicating that this parameter could be a marker of global cardiovascular risk.

P1757 The "non-dipper" hypertension in the elderly: is it a clinical entity or a bias?

R. Pasqualini, C. Mussi, M. Foroni, G. Salvioli. Estense Hospital, Geriatrics Dept., Modena, Italy

Introduction: Sleep disturbances are common in the elderly, and they influence the nocturnal blood pressure (BP) determining a "non-dipper"(ND) status (a fall <10% in BP at night), but some data show that the blunted reduction in BP during night could be caused by the discomfort of the ambulatory BP monitoring (ABPM). Actigraphy is a non-invasive and objective method used to estimate sleep-wake schedules by measurement of activity. Our aim is to ascertain whether elderly hypertensive patients (EHP), who experience the discomfort of the cuff-inflation during ABPM, report a poorer quality of sleep able to influence the ND status.
Materials and Methods: Forty-six consecutive EHP (mean age 74.5 ± 6.7 years, 30% males) were evaluated to assess comorbidity (by means of the Cumulative Illness Rating Scale, CIRS), and drug history. Actigraphy (Actiwatch, model AW4, placed on the non-dominant wrist) and ABPM were simultaneously performed for 24 hours.The Sleep Questionnaire (SQ) was administered in the morning before the recording night. Patients were divided in two groups according to the night-time decrease in BP:>10%: dippers (DP, N=29); <10%: non dippers (ND, N=17).
Results: Actigraph data (expressed as mean ± SD) are shown in the table. NDP obtained a higher score to the SQ (4.6±2.9 vs. 3.0±1.1, p=0.030), and used more benzodiazepines (33.1% vs. 10.7%, p=0.035). The mean number of drugs and the CIRS score were higher in NDP (3.6±1.7 vs. 2.7 ±1.6, p=0.046 and 11.0±3.4 vs. 7.9±4.2, p=0.014).

	DP (N=29)	NDP (N=17)	p
Sleep efficiency (%)	87.1±9.7	78.9±11.8	0.022
Actual sleep time (%)	90.7±7.2	83.0±9.9	0.009
Actual wake number	0.5±0.6	1.1±0.9	0.022
N° of immobile phases	98.6±42.4	57.4±31.4	0.002

Conclusions: The actigraphic data demonstrate a poorer sleep quality in NDP; nevertheless, the blunted fall of nocturnal BP of ND group seems independent from the discomfort of the cuff-inflation during night, since they report sleep disturbances in the previous month, with a higher need of benzodiazepines. NDP have a greater comorbidity and polypharmacy, meaning that the ND hypertension in the elderly is not a bias, but it is related to worse clinical conditions that should be studied in depth.

P1758 Is nocturnal pulse pressure useful in predicting of renal function in mild to moderate essential hypertensives?

P.A. Zelveian, E.V. Oschepkova, M.S. Buniatian, A.N. Rogoza. *Cardiology Research Complex, Moscow, Russian Federation*

The aim of this study was to investigate the relations between glomerular filtration rate and blood pressure (BP) profile parameters in mild to moderate essential hypertensives (EH).
Design and Methods: 120 hospitalized, untreated EH pts (97m, 23f, 50±1y) underwent 24-h BP monitoring (SL-90207). Glomerular filtration rate was assessed by creatinine clearance (Ccr), estimated from serum creatinine values (Cockcroft D., 1976). Pts were divided into three tertiles according to the Ccr: gr.I - 68±1; gr.II - 88±1; gr.III - 112±2 ml/min. Differences between groups were tested by Student t-2 test, the relationship between Ccr and BP parameters - by Pirson correlation analysis. $P<0.05$ was considered statistically significant.
Results: No significant differences have been found between groups by mean age (52±1, 50±1 and 49±1 y) and duration of AH (13±2 10±1; 11±1y). Body mass index was significantly higher in gr.II and gr.III in comparison with gr.I (26±1; 28±1; 30±1 kg/m^2, $p<0.002$). There were no significant differences between groups by mean values of 24-h, day- and nighttime systolic and diastolic BP-s (SBP, DBP). Only nighttime values of pulse pressure (PP) was significantly lower in the gr.II (51±2; 48±1; 52±2 mm Hg, $p<0.04$). Were observed significant relationships between Ccr and nighttime SBP (gr.I - r=-0.38; gr.II - r=0.33; gr.III - r=0.36), DBP (gr.I - r=-0.15; gr.II - r=0.20; gr.III - r=0.32) and PP (gr.I - r=-0.43; gr.II - r=0.31; gr.III - r=0.28).The stronger relationship were observed between Ccr and nighttime PP, but only the low-tertile group presented a negative association. Positive correlations in the gr.II and gr.III, probably showed a presence of compensatory hyperfiltration in EH, which can be conditioned by high hydrostatic pressure. The negative association of reduced Ccr with PP, a correlate of the pulsitile hemodnamic load and conduit vessel stiffness well as an important cardiovascular risk factor, may explain why pts with minor impairment of renal function are at higher risk of cardiovascular events.
Conclusion: These results appeared that the nocturnal PP might be useful in predicting of the hypertension-induced organ damage in particular of renal function.

P1759 Dissociation between the clustering of newer risk factors and estrogen-induced improvement in aortic elasticity in hypertensive women

C. Tsioufis, K. Tzioumis, M. Toutouza, I. Kallikazaros, E. Tsiamis, C. Pitsavos, C. Stefanadis, P. Toutouzas. *Hippokration, Univ. of Athens, Dept. of Cardiology, Melissia, Greece*

It has been suggested that newer risk factors as hyperinsulinemia, hyperhomocystenemia and hyperleptinemia accelerate menopause-induced atherosclerotic process. However, their potential effect on estrogen-induced alteration on aortic elastic properties has not been investigated.
Methods: Towards this end, we evaluated aortic compliance non-invasively on the basis of Doppler ultrasound measurements of pulse wave velocity (PWV) from the carotid to femoral artery by the foot-to-foot method in 52 postmenopausal women (age 53 years, 3.1±1 years after menopause) with untreated, newly diagnosed mild essential hypertension at baseline as well as 20 mins after the sublingual administration of 1mg of 17-â estradiol. Venous blood samples were drawn for determination of insulin, homocysteine and leptin plasma levels according to established methods. All women were free of other cardiovascular risk factors and were without any sign of atherosclerotic disease.
Results: In our women BMI was 29±4 Kgr/m^2, office BP 145/93 mmHg, left ventricular mass index (LVMI) 106±26 gr/m^2, plasma levels of total cholesterol 230±21mg/dl, leptin 34±24 ng/ml, homocysteine 9.5±2 ìmol/l and insulin 12±7 mU/L. Estrogen induced a significant decrease in aortic PWV (236±27 vs 216±22 cm/sec, $p<0.005$) while BP and heart rate values did not change significantly. The aortic PWV, at baseline, as well as the estrogen-induced reduction of aortic PWV were not correlated with the baseline plasma concentrations of insulin, homocysteine and leptin.
Conclusion: Estrogen-induced improvement in aortic compliance is independent of the cluster of newer risk factors in postmenopausal women with mild hypertension.

P1760 Effects of different wines on endothelial function of subcutaneous small resistance arteries of normotensive subjects and hypertensive patients

E. Porteri[1], D. Rizzoni[1], M. Castellano[1], D. Guelfi[1], C. De Ciuceis[1], G. Boari[1], G.A.M Tiberio[2], E. Agabiti Rosei[1]. [1]*Dept.of Medical and Surgical Sciences, Chair of Internal Medicine, Brescia, Italy;* [2]*University of Brescia, Chair of General Surgery, Brescia, Italy*

In animal models, red wines seem to have a protective effect on the vascular endothelium. However, it is not known whether this effect is present also in human small vessels, and if it is specific for certain wines.
Objective: To investigate the vasodilator effect of different wines in subcutaneous small resistance arteries of normotensive subjects (NT) and of patients with essential hypertension (EH).
Methods: 16 EH and 7 NT were included in the study. Subcutaneous small arteries (relaxed diameter 160-280 mm) were dissected and mounted on a micromyograph. A concentration-response curve (CRC) to acetylcholine (ACH) (cumulative concentrations from 10^{-9} to 10^{-5} mol/L) was performed, after precontraction with norepinephrine 5×10^{-6} mol/L. In addition, the vasodilation produced by different wines was tested as CRC (20, 30 and 50 ml) to: a) a red wine produced "en barrique" (EB), b) a red wine produced in large wood barrels (LB), and c) a red wine produced in steel tanks (ST), after precontraction with norepinephrine 5*10-6 mol/L, in the presence or absence of L-NMMA 100 mmol/L).
The vasodilator response to ACH was greater in NT compared to EH (ANOVA $p<0.001$ between curves). A dose-dependent vasodilator effect of red wines (particularly EB) was detected in both NT and HT. The vasodilation observed with EB and LB involved mainly non-endothelial mechanisms, since it was usually not significantly reduced after pre-incubation with L-NMMA (a decrease was observed only with LB in NT).

Table	50 ml	50 ml + L-NMMA
EB in NT	-65.7±26.8 ***	-69.1±27.5 ***
LB in NT	-47,6±11.1 **	-26.8±16.6*°
ST in NT	-54.4±33.6 *	N/A
EB in EH	-71.9±23.2 ***	-70.1±21.8 ***
LB in EH	-63.2±28.8 ***	-55.3±26.2 ***
ST in EH	-55.8±24.7 *	N/A

Reduction in wall tension in KPa in respect to precontraction; *=p<0.05. **=P<0.01, ***=p<0.001 vs. precontraction, °=p<0.05 vs. 50 ml alone.

Conclusions: Our results suggest that, both in NT and in EH, red wines may possess vasodilator properties, possibly depending on the content of flavonoids or tannic acid. These results may, at least in part, explain the organ-protective properties attributed to a moderate red wine intake.

P1761 Glyceryl trinitrate – A complex vascular intervention resolved by wave intensity analysis

E. Nicolaides, L. Boden, A.G. Fraser, M.P. Frenneaux, C.J.H. Jones. *University Hospital of Wales, Welsh Heart Research Institute, Cardiff., United Kingdom*

In an artery, instantaneous wave intensity (WI) measures the balance between forward and backward travelling waves. It has the potential to separate cardiac (forward waves) from microvascular (reflected, backward waves) influences on blood flow. Sublingual glyceryl trinitrate (GTN) is a common intervention with complex effects, including vasodilatation and reflex sympathetic activation. We used WI to resolve the simultaneous upstream and downstream effects of GTN on arterial blood flow.
Methods: WI is the product of derivatives of blood pressure (P) and velocity (U) - dP/dt x dU/dt. A specially designed ultrasound system (Aloka SSD-5500) with B-mode (7.5MHz) and M-mode wall tracking was used to measure non-invasively diameter and velocity waveforms in the right carotid artery. Systemic P was measured and diameter waveforms were converted to P for WI analysis on-line. The system also measured beta, a measure of arterial stiffness. 12 normal subjects (mean age 29 years) were studied on two separate occasions under standardised, controlled conditions. After stable baseline recordings, sublingual GTN (Nitromin spray, 400ug) or matching placebo were administered blind. Paired t tests were used to compare GTN- and placebo-induced changes from baseline.
Results: WI showed two positive peaks, indicating forward waves of cardiac origin in early and late systole. A contractility-related forward compression wave caused initial acceleration and a forward expansion wave caused deceleration and aortic valve closure. In mid-systole, negative WI indicated a backward, reflected wave that increased P and decreased U. GTN caused marked changes in systemic haemodynamics and WI. Diastolic P decreased (-21%, $p<0.01$), consistent with microvascular dilatation, and heart rate increased (+14%, $p<0.01$), consistent with reflex sympathetic activation. Negative WI in mid-systole decreased relative to the forward wave (-27%, $p<0.01$), due to decreased reflection, but the forward compression wave (+41%, $p<0.01$) and beta (+36%, $p<0.01$) increased, due to increases in contractility and arterial stiffness.
Conclusion: This study confirms the potential of WI to resolve complex interventions into upstream and downstream influences on blood flow. In the carotid artery, WI shows that GTN reduces cerebral wave reflection but increases forward compression wave travel from the heart. Arterial stiffness is increased. These changes will be mediated by direct microvascular dilatation and indirect sympathetic activation with increased initial force of myocardial contraction.

P1762 Effect of physical training on arterial stiffness in essential hypertension

E. Trzos, M. Kurpesa, Z. Bednarkiewicz, M. Krzeminska-Pakula. *Bieganski Hospital, Cardiology, Lodz, Poland*

The vascular training is a problem in patients with hypertension. Pulse wave velocity (PWV) is a non-invasive measurement of the mechanical properties of arteries. The aim of this study was to determine the effect of physical training (PT) on arterial elasticity.
Material and methods: The study group consisted of 116 patients with essential moderate arterial hypertension (HA). They were randomised into two groups. Group 1 (65 pts) underwent physical training programme (series of 16 interval trainings on ergometers) and group 2 (51 pts)without PT. Groups were comparable according to age, gender and treatment of HA. The parameters of PWV were evaluated using a computer system Complior. For automatic measurement of PWV pressure waveforms were digitized at rate 500 Hz for carotid femoral distance. 12 healthy volunteers constituted a control group. Arterial elasticity wetre calculated before, post and 3 month after PT.
Results: After 3 momths PWV in control group did not change(7,21± 1,23m/s at baseline vs 7,72±1,31m/s in follow up).
Physical training in group 1 caused the significant reduction of PWV (from 12,8±1,3m/s to 8,1±0,7m/s post PT and 8,7±1,2m/s after 3 months p<0,001).In group 2 PWV was slightly decreassed (from 12,3±1,2m/s at baseline to 11,2±1,3m/s after 3 months period NS).
Conclusion: Physical training in hypertensive patients improves systemic arterial compliance.

P1763 Microalbuminuria is closely related with unfavorable alterations in arterial pressure waveform shape in untreated patients with hypertension

C. Tsioufis, D. Antoniadis, M. Toutouza, K. Toutouzas, I. Kallikazaros, C. Pitsavos, C. Stefanadis, P. Toutouzas. *Hippokration, University of Athens, Department of Cardiology, Melissia, Greece*

Although a slight increased urinary albumin excretion (UAE) and an impaired arterial mechanics have both been identified as predictors of cardiovascular events in hypertensive subjects, the interaction between arterial pressure wave (APW) contour and microalbuminuria (MA) has not been well defined
Methods: MA was determined in 3 non-consecutive 24-h urine samples as UAE of 20-200mg/24h in a group of 130 untreated hypertensive subjects. APW was recorded by carotid applanation tonometry and waveform shape was expressed by the augmentation index (AI).
Results: The group of patients with MA(n=48) was matched for demographics with those without MA (n=82). Subjects with MA had significantly increased left ventricular mass index (101 vs 85 g/m^2, p<0.0001), office blood pressure (164/100 vs 146/94 mmHg, p<0.005) and AI (0.16 vs 0.04, p<0.03). Hypertensive patients with A type APW had significant increased values of the log 24-hour UAE compared to those with type B and C type APW. The percentage of patients with A type APW was significantly greater in microalbuminuric patients compared to normoalbuminuric (67 vs 33%, p<0.005); in contrast the percentage of patients with B type or C type APW was significantly greater in normoalbuminuric patients compared to the microalbuminuric patients (68 vs 36%, p<0.005). By multiple regression analysis and analysis of variance it was revealed that increased AI was significantly and independently associated with increased values of UAE (p<0.05).
Conclusion: Hypertensive patients with MA, exhibit an earlier systolic augmentation of arterial pressure reflecting more impaired arterial elasticity compared with hypertensive without MA. These findings may account for the worse cardiovascular outcomes associated with the presence of an increased UAE in hypertensive subjects.

DIRECT PERCUTANEOUS CORONARY INTERVENTION IN ACUTE MYOCARDIAL INFARCTION

P1764 Is the time to treatment of myocardial infarction more important with primary PTCA or with thrombolysis?

S. Simek, L. Hemzsky, F. Holm, L. Golan, J. Humhal, A. Linhart, M. Psenicka, M. Aschermann. *General Faculty Hospital,Charles Univ., IInd Med. Dep., Praha 2, Czech Republic*

Background: The benefit of thrombolysis in patients with acute myocardial infarction (AMI) strongly depends on the time from the onset of symptoms to the initiation of treatment. For AMI patients treated with PTCA this time seems to be important only to a certain time level.
Objectives: to assess the influence of time to treatment of AMI with coronary angioplasty on short term and long term prognosis.
Methods: We followed 339 consecutive AMI patients treated with coronary angioplasty from 1995 to 1999 in a cardiac care unit in Czech Republic. Patients were divided into 5 groups according to time to treatment. There was no significant difference in gender, localization of AMI, multivessel CAD, diabetes mellitus, hypertension, smoking and Killip class between the groups. Older patients were treated later, patients with prior AMI were treated earlier. 44 (12,9%) patients were in cardiogenic shock in time of admission.
Results: Time to treatment < 1,5h was achieved in 35; 1,5-3,5h in 105; 3,5-5,5h in 72; 5,5-11,5h in 74; 11,5-24h in 53 patients. Ischemic time in the consecutive groups was <2h; 2-4h; 4-6h; 6-12h; I2-24h respectively. TIMI III flow after PTCA was achieved in 93,6% of patients with time to treatment shorter than 3,5 hours and in 83,9% of patients treated later. The lower 30 day mortality (3,6% vs. 11,1%, p=0,012), lower 3 year mortality (8,6% vs. 19,1%, p=0,003), lover frequency of heart failure (11,4% vs. 28,1%, p<0,001) as well as lower maximal level of released kreatinkinase (32+29 vs 44+39 μkat/l, p=0,005) was observed in patients treated within 3,5 hours from symptoms onset compared to patients treated later.
Conclusions: Compared to thrombolysis the succes rate of primary PTCA remains high even if started late. In studied group the patients short term + long term prognosis is best when reperfusion occurred within 4 h. from symptoms onset. After 4th h. the mortality became independent on reperfusion time. Patients without a chance for reperfusion with thrombolytic therapy within 4 h. should be considered candidates for PTCA regardless the time of transportation. In patients with chance to reperfuse infarct related artery within 4h. from symptoms onset with thrombolytic treatment (thrombolysis needs to be started before 2,5 - 3rd h.) while having low probability to start PTCA within 3,5h., the thrombolysis should be given first and PTCA performed later if needed.

P1765 Primary coronary angioplasty versus pre-hospital thrombolysis in acute myocardial infarction: a medico-economic analysis

G. Vanzetto[1], J. Machecourt[1], A. Dompnier[1], M. Frossard[2] on behalf of the CAPTIM study investigators. [1]*CHU de Grenoble, Cardiologie, Grenoble, France;* [2]*Mendes France University, Department of economic sciences, Grenoble, France*

Background: The recent CAPTIM study did not demonstrate any significant difference in results between PCA and PHT for the treatment of acute MI concerning the predefined 30-day composite end point (death + recurrent MI + disabling stroke). This analysis aims to assess the in-hospital cost effectiveness of these two widely used reperfusion therapies.
Methods: 217 consecutive patients included in the CAPTIM study in the university hospitals of Grenoble and Lyon were used for this cost analysis (PCA n = 108, PHT n = 109, men = 82%, age = 59 ± 12 yrs). For each individual patient, a real cost analysis was performed based on the costs of pre-hospital care, key hospital resources, duration of hospitalization, medications, biogical and radiological examinations, coronary angiography and angioplasty devices, and staff.
Results: There were no significant differences between the PCA and PHT groups regarding baseline data, clinical presentation, and characteristics of MI. Hospitalization duration was shorter in the PCA than in the PHT group (8.7 ± 6.1 versus 10.3 ± 6.7 days p = 0.08), mainly because of the delay to planned coronary angiography (66 pts - 60%) and elective angioplasty (40 pts - 37%) in the PHT group. Total in hospital real costs were 6675 ± 6504 Euros for the PCA group and 7689 ± 4611 Euros for the PHT group (p = 0.18); 43% of these costs were related to the duration of hospitalization (cf table).
Sixteen patients (7.4%) died during hospitalization, 8 in each group. The additionnal cost per life saved during the acute phase was 1400 Euros in the PHT group when compared to the PCA group, corresponding to a 18% overcost.

Repartition of costs

	PCA	PHT
Pre-hospital care	863 ± 315	1030 ± 361 *
Examinations	1265 ± 1610	1449 ± 1086
Medications	412 ± 988	1008 ± 382 *
Cath. Laboratory	1280 ± 571	916 ± 748 *
Hospital resources	2829 ± 3931	3283 ± 3254

Prices are in Euro. * = p < 0.001 versus PCA

Conclusion: PCA and PHT are equally cost effective for the treatment of acute MI. PCA however allows earlier hospital discharge, and offers appreciable cost saving per life saved when compared to PHT. One year cost effectiveness and cost utility analyses are needed to confirm these results.

P1766 Are mechanical reperfusion results in acute myocardial infarction patients influenced by geographical distribution? Results from the CADILLAC trial

E. García[1], C. Grines[1], G. Guagliumi[1], D. Cox[1], J. Tcheng[1], R. Moreno[2], C. Macaya[2], G. Stone[1] on behalf of CADILLAC investigators. *[1]Hospital Gregorio Marañón, Interventional Cardiology Dept., Madrid, Spain; [2]Hospital Clinico San Carlos, Cardiology Dept., Madrid, Spain*

In the CADILLAC trial, 2082 AMI patients recruited in 76 centers of 9 countries in North America, Europe and South America were randomized to one of four reperfusion strategies: balloon angioplasty (n=517), angioplasty + abciximab (n= 529), Multilink stent (n=512) and stent + abciximab (n=524).The primary endpoint was a composite incidence of death, reinfarction, disable stroke or ischemia driven target vessel revascularization.
In order to determine the possible geographical influence on the clinical outcome, the results of the patients treated in United States (n=1703) were compared with those outside Unites States (n=379).
Results: see table.

US vs non-US patients

	U.S.	Non U.S.	p value
Age	59±12	63±12	<0.001
Prior MI	15%	7.7%	<0.001
Hypertension	35%	27%	0.007
Prior PTCA	12%	5%	<0.001
Prior CABG	2.2%	0.5%	0.002
Symptoms to ER (min)	155±148	194±161	<0.001
ER to procedure (min)	129±117	57±46	<0.001
Anterior location MI	35%	46%	0.001
Pre-procedure TIMI 0/1	67%	76%	0.001
Post-procedure TIMI 3	96%	94%	0.22
MACE at 1-year	17%	15%	0.16
1-year death	3.9%	5.5%	0.19
1-year re-AMI	2.2%	1.6%	0.30
1-year stroke	0.9%	0.8%	1.0
1-year ischemia TVR	13%	8%	0.006

ER = Emergency Room.

Conclusions: In the CADILLAC trial, patients treated in US were younger, but had more prevalence of hypertension and had undergone more often prior revascularization procedures. US patients appeared earlier in the ER, but they had longer delay in receiving reperfusion treatment. The rate of procedural success was similar in both groups. No differences in outcome was observed through one year observation period except less revascularization procedures of the target vessel in the non-US patients.

P1767 In-hospital outcome in octognenarians with acute myocardial infarction undergoing primary coronary angioplasty

K. Ando, Y. Nakagawa, M. Iwabuchi, H. Yokoi, N. Hamasaki, T. Kimura, H. Nosaka, M. Nobuyoshi. *Kokura Memorial Hospital, Cardiology Dept., Kitakyushu, Japan*

Background: Because elderly patients (pts), especially those 80 years of age or older, have been excluded from most studies of primary coronary angioplasty (PCA) in pts with acute myocardial infarction (AMI), in-hospital outcome in these pts are not well known. The purpose of this study was to evaluate in-hospital outcome in octogenarians with AMI undergoing PCA.
Methods: We analyzed consecutive pts who were 80 years of age or older and underwent PCA within 72 hours onset of AMI between January 1991 and June 2001 at Kokura Memorial Hospital. A multivariable logistic regression analysis was developed to ascertain predictors of in-hospital mortality.
Results: This study population comprised of 237 pts with a mean age of 83.9 ± 3.5 years, 51% of male gender, and 41% with anterior wall localization. Pts underwent PCA within 9.3±12.9 hours from the onset of chest pains and coronary stenting performed in 127 pts (53.6%). The incidence of TIMI 3 flow at the end of PCA was 94.1% and complications associated with PCA occurred in 9.7% (acute closure 7 pts, puncture site bleeding 5 pts, stroke 7 pts, acute renal failure 2 pts, coronary perforation 1 patient and peripheral vascular embolism 1 patient). Overall in-hospital mortality rate was 10.9% and the clinical success (final TIMI 3 flow without death or complications) was achieved in 183 pts (77.2%). Multivariate analysis revealed that cardiogenic shock (OR 5.96, 95%CI 1.26-28.23, p=0.0245), left main disease (OR 7.66, 95%CI 1.09-53.63, p=0.0403), renal dysfunction (OR 13.74, 95%CI 3.32-56.86, p=0.0003), need for IABP (OR 5.16, 95%CI 1.29-20.7, p=0.0205), LVEF<40% (OR 10.92, 95%CI 1.43-83.7, p=0.0241) and coronary stenting (OR 0.096, 95%CI 0.019-0.481, p=0.0043) were significantly associated with in-hospital mortality.
Conclusion: Octogenarinans undergoing PCA could obtain a high rate of final TIMI 3 flow and acceptable clinical success rate, but remained at high risk of complications. Coronary stenting seems to be important to improve in-hospital outcome in octogenarians with AMI.

P1768 Is the outcome different after spontaneous reperfusion (TIMI-3 flow) or direct PTCA for acute myocardial infarction in survivors of out-of-hospital cardiac arrest?

P. Garot[1], E. Fonseca[1], A. Belarbi[1], A. Margenet[2], E. Aptecar[1], P. Dupouy[1], J.L. Dubois-Rande[1], E. Teiger[1]. *[1]Henri Mondor Hospital, Cardiology Dept., Creteil, France; [2]Henri Mondor Hospital, SAMU 94, Creteil, France*

Background: The outcome of pts presenting with AMI and a spontaneously reperfused (TIMI-3 flow) IRA was demonstrated to be not different when compared to pts with an occluded IRA who underwent successful coronary reopening within 6 hours after the onset of AMI. However, this was not shown in a specific subset of AMI pts in which sudden death has revealed or complicated the acute phase of AMI before the admission in the cath-lab.
Methods and Results: Between Jan 1998 and Dec 2000, 62 survivors of out-of-hospital cardiac arrest (CA) were referred to the catheterization laboratory of our institution. Among them, 45 pts had evidence of acute ischemic syndrome with subsequent coronary artery disease. Direct PTCA was systematically attempted in 25 pts (and successful in 22/25) with significant coronary blood flow reduction (TIMI 0 to 2). Conversely, pts with TIMI-3 flow (N=20) were treated conventionally. There was no difference with regard to mean age, history of prior AMI, diabetes mellitus and total of >60% coronary artery stenosis between the two groups. When compared to pts treated conventionally, pts who were treated by angioplasty had worse LV ejection fraction (31.2%±11.3% vs. 39.3±11.4%, p<0.05) and a higher rate of cardiogenic shock (56% vs. 40%, p<0.05) on admission. Kaplan-Meier survival analysis showed a reduction of 33% in the risk of death from any cause in pts with coronary occlusion who underwent immediate PTCA as compared to those with a patent coronary artery (relative risk, 2.5; Log-rank, p<0.01). By multivariate logistic-regression analysis, PTCA was a strong and independent predictor of survival (0.53; 95% CI, 0.13-0.94; p<0.01).
Conclusion: In pts in which sudden death has complicated the early course of AMI, emergency PTCA appeared as an independent predictor of 6 months survival despite worse baseline characteristics. Randomised studies are required to assess the benefit of direct PTCA in survivors of cardiac arrest with TIMI-3 coronary artery disease.

P1769 Gender differences and angiographic findings in primary angioplasty for acute myocardial infarction

A.H.E.M. Maas[1], J.P. Ottervanger[2], A.W.J. van 't Hof[3], J.C.A. Hoorntje[3], H. Suryapranata[3], J.H. Dambrink[3], M.J. de Boer[3], F. Zijlstra[3]. *[1]Isala Klinieken, Cardiology, Zwolle, Netherlands; [2]Academic Hospital Dijkzigt, Cardiology, Rotterdam, Netherlands; [3]Isala Klinieken, Cardiology, Zwolle, Netherlands*

Background: Female gender may be a risk factor for mortality after acute myocardial infarction, which can not entirely be explained by differences in baseline characteristics. Reports on gender differences in the angiographic findings in patients treated with primary angioplasty have not yet been reported.
Objective: To assess differences in angiographic findings between males and females in a large cohort of patients with primary angioplasty for acute myocardial infarction.
Results: A total of 1702 patients with acute myocardial infarction were studied, consisting of 340 females and 1362 males. Females were older (65 years ± 11.6) than males (59 years ± 11 years, p <0.001). TIMI 3 flow of the infarct related vessel before angioplasty was observed in 14.7% of females compared to 12.8% of males (p=0.35). In females with inferior infarct location, the RCA was the infarct related vessel in 22% compared to 27% in males with inferior location (p=0.2). After angioplasty, there was TIMI 3 flow in 89% of females compared to 91% in males (p=0.3). Myocardial blush grade 2 or 3 after angioplasty was observed in 73% of females compared to 76% in males.
Conclusions: Angiographic findings in primary angioplasty for acute myocardial infarction are comparable between males and females. In both groups there is a high incidence of successful primary angioplasty with TIMI 3 flow and good myocardial blush.

P1770 Primary, rescue, and facilitated PTCA in the community setting: a prospective observation of reperfusion and outcomes in 400 consecutive patients

G. Steffenino, A. Dellavalle, P. Russo, E. LaScala, L. Riva, F. Meinardi, F. Margaria, A. Vado. *Azienda Ospedaliera S.Croce, Cardiology, Cuneo, Italy*

Background: Primary PTCA (P-PTCA) is an established treatment in AMI. Rescue PTCA (R-PTCA) may reestablish myocardial perfusion, and possibly save lives. Facilitated PTCA (F-PTCA) may accelerate and improve reperfusion, and save myocardium. The comparative outcomes of these reperfusion treatments in current practice are poorly studied. Purpose: To study the acute outcomes of pts treated with P-PTCA, R-PTCA and F-PTCA in our referral centre, as part of a Quality Assurance protocol. Methods: 400 consecutive pts with high-risk ST elevation AMI (extensive, or recurrent, or with pump failure) <12 h were prospectively included from 1992 through 2001. Pts sent to cathlab for P-PTCA were those admitted to this Hospital, whereas R-PTCA pts were mostly transferred from nearby centres after failed reperfusion and/or with pump failure. F-PTCA (1 r-PA bolus or start of accelerated t-PA, followed by PTCA asap) was begun in Aug. 2000, as a bridge to PTCA when waiting time was >30 min. The angiograms were re-evaluated blindly by 3 operators. Results: P-PTCA, R-PTCA and F-PTCA were actually performed in 282, 82 and 26 pts, respectively. Baseline population data were: age 62±11y, f 16%, diabetics 23%, previous MI 23%, ant.MI 51%, RV MI 24%, leads with ST elevation 5±2, tot ST deviation 19±12mm, time onset-1st Emergency Room (ER) 140±106 min, mv CAD 52%, stent use 70%, gpIIb/IIIa use 16%, and were similar in the 3 cohorts. For P-PTCA, R-PTCA and F-PTCA pts, respectively, time from 1st ER-cathlab was 60±56 min, 161±117 min and 80±51 min (p<.001); Shock on admission was present in 6%, 12% and 0 (p=.052); initial TIMI flow 2-3 was present in 20%, 31% and 58% (p<.001); final flow was TIMI 3 in 75%, 62% and 80% (p=.04); ST resolution was >50% in 65%, 59% and 76% (p=.046); TIMI 3 + >50% ST res. was present in 53%, 42% and 64% (p=.048); Death rate was 9%,12% and 4% (ns); Re-MI was 4%, 4% and 0 (ns); Stroke 1%,1% and 0 (ns); the combined in-hospital end-point of death/re-MI/stroke occurred in 13%, 13% and 0. Conclusions: In our 9-year observation of evolving practice in the community setting, high-risk AMI pts with R-PTCA had a worse risk profile and slightly less favourable acute outcomes than pts with P-PTCA. F-PTCA pts, albeit limited in number and with a better risk profile, had the best vessel patency both before and after PTCA, the most complete ST resolution, and the best acute outcomes. F-PTCA as used in clinical practice deserves more extensive study.

P1771 Transradial coronary intervention for acute myocardial infarction in the elderly ≥ 75 yrs of age: feasibility and in-hospital outcome

S. Fujiwara, N. Endo, M. Terashima, Y. Itoh, S. Abe, T. Ootomo, K. Ogata, T. Meguro. *Sendai Kosei Hospital, Cardiology, Sendai, Japan*

We evaluated the feasibility and in-hospital outcome of transradial coronary intervention (TRI) in elderly patients with acute myocardial infarction (AMI) ≥ 75 yrs of age. From January 1999 to September 2001, 195 elderly patients (81.1 ± 4.6 yrs) with AMI underwent percutaneous coronary intervention (PCI). Among them, TRI could be performed in 165 (84.6%) patients. The remaining 30 patients received PCI from femoral (n = 29) or brachial artery (n = 1) because of cardiogenic shock (n = 22), narrow radial arteries (n = 4) Allen test abnormality (n = 1), chronic hemodialysis patients (n = 1), radial artery spasm (n = 1) and occlusion of subclavian arteries (n = 1). Unless contraindications for radial artery cannulation were present, cardiogenic shock was an independent predictor to limit radial artery approach. Baseline characteristics, procedural and in-hospital outcomes are shown in table.

Baseline characteristics and outcomes

Age (yrs)	81.2 ± 4.7
.Gender (M/F)	91/74
Killip class (I/II/III/IV)	117/34/9/5
Culprit artery (LAD/LCx/RCA/LMT)	69/23/70/3
Lesion type (occluded/A/B1/B2/C)	105/0/9/33/18
Peak CK (IU)	1720 ± 1345
Stent use (%)	83.6
Procedure success (%)	96.4
In-hospital death (Cardiac/Total; %)	6.7/7.9

LAD indicates left anterior descending artery; LCx, left circumflex artery; RCA, right coronary artery; LMT, left main trank, CK, creatine kinase.

Access site bleeding or hematoma requiring transfusion and procedure related death were not observed in any patients. We conclude that TRI for AMI is feasible and can be performed with high success and low complication rate even in elderly patients ≥ 75 years of age.

P1772 Direct infarct intervention in the diabetic: does it really work?

R. Siegel[1], A. Bhaskaran[1], K. Moon[2], B. Barker[1], C. Jost[2], T. Sargent[1], K. Kinkade[1], J. Vermillion[1]. [1]*Advanced Cardiac Specialists, Cardiovascular Research, Phoenix, United States of America;* [2]*Advanced Cardiac Specialists, Interventional Cardiology Dept., Phoenix AZ, United States of America*

Diabetic patients undergoing intervention in coronary heart disease have been shown to be at increased risk for adverse clinical outcomes. Limited data is available on how diabetics fare following direct infart intervention (d-PTCA) in acute MI. We evaluated clinical outcomes following d-PTCA with optimal result in this high-risk clinical subset. From 1/98 to 1/02, 250 patients (male 58%; mean age 63 years) underwent d-PTCA of 271 lesions in 265 vessels. Comorbid risks factors included: age > 70 years, 30.4%; prior MI, 24%; prior CABG, 16.4%; EF < 40%, 33.3%; multi-vessel disease, 21%. Cardiogenic shock was present in 10%. Anterior MI constituted 38.4%. Majority of the lesions (74.9%) were AHA/ACC type B2/C. Stent was deployed in 32%. Patients received ACT-guided IV heparin during the procedure, followed by antiplatelet therapy. Results: Procedural success (TIMI 3 flow; residual stenosis <20%) was obtained in 98%. In-hospital event rate was low: no acute re-closure, 4 (1.6%) CABG, and 1 (0.4%) death. Mean hospital stay was 2.7 days. Mean global LVEF was 42.7% at discharge. There was 1 subacute stent thrombosis. At 12-Month Follow-Up (96.4% complete; mean 6.28 + 4.88 months), the incidence of reinfarction (8.9%), re-PTCA (6%) and stroke (4.4%) were acceptable. Cardiac mortality was 2.2% in the first year following intervention. Event-free survival was seen in 115 patients (86%). Mean LVEF rose to 50.2% at 12-month follow-up (p=0.008).

Conclusions: 1. Direct infarct intervention is safe and effective in diabetic patients presenting with acute MI. 2. Procedural success is high and in-hospital cardiac events are low and comparable to non-diabetics. 3. This translates into low revascularization rates and favorable event-free survival in the long-term. 4) There was highly significant improvement in global left ventricular systolic function at 12-month follow-up. 5) Our data indicates that optimal acute results, both in flow and luminal diameter gain, with prompt and effective salvage of jeopardized myocardium, may be an important determinant in a post-MI diabetic's long-term event free survival.

P1773 Factors influencing the use of primary angioplasty in unselected patients with acute myocardial infarction: results of the AMI-Florence Registry

E. Buiatti[1], A. Barchielli[2], D. Balzi[2], S. Valente[3], N. Carrabba[3], M. Filice[2], M. Monami[3], I. Olivotto[3]. [1]*Tuscany Health Agency, Florence, Italy;* [2]*Health Unit, Florence, Italy;* [3]*Careggi Hospital, Florence, Italy*

Background: Primary angioplasty (P-PTCA) is an effective treatment for patients (pts) with acute myocardial infarction (AMI) presenting with ST segment elevation. As P-PTCA has fewer contraindications than thrombolysis, the availability of P-PTCA should increase the proportion of pts who undergo reperfusion treatment (RT).

Methods: The study was designed as a prospective observational registry including all the Florence area residents who experienced AMI from March 1, 2000 to February 28, 2001. P-PTCA represents the most common modality of RT in the Florence area, which includes 2 high-volume centres with P-PTCA programs and 5 hospitals without the facilities to perform P-PTCA. This analysis refers to the 706 pts with ST-elevation AMI who were admitted within 12 h from symptom onset.

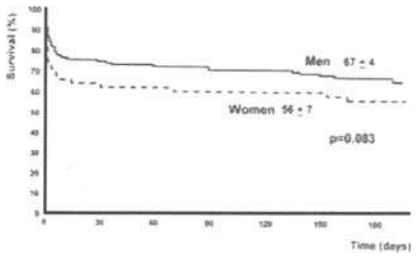
Results: Of these pts, 243 (34.4%) were treated conservatively and 463 (65.6%) received RT: P-PTCA in 423 (59.9%), thrombolysis in 35 (5.0%) and rescue PTCA in 5 (0.7%).The rate of P-PTCA was 85.2% in the 2 centres with P-PTCA facilities and 37.6% (range 17-78%) in the 5 hospitals without (p<0.000). The use of P-PTCA was 66.4% in pts admitted in the office hours and 56.0% in pts admitted in the non-office hours and in the weekends (p=0.004). At multivariate analysis the only factor associated with increased probability of P-PTCA was the admission to a centre with invasive facilities (OR 7.8, 95%CI 5.1-11.8) while factors influencing the exclusion from P-PTCA were age as a continuous variable (OR 0.97, 95%CI 0.96-0.99), history of heart failure (OR 0.26, 95%CI 0.11-0.65), previous myocardial infarction (OR 0.55, 95%CI 0.33-0.93), time from symptom onset to hospital admission as a continuous variable (OR 0.91, 95%CI 0.84-0.99), AMI other than anterior (OR 0.32, 95%CI 0.21-0.50), Killip class 3-4 (OR 0.44, 95%CI 0.24-0.83), admission in non-office hours (OR 0.59, 95%CI 0.39-0.88). In-hospital and 6-month mortality was 5.8% and 8.8% in pts treated with RT vs 14.8% and 23.9% in pts treated conservatively (both p<0.000).

Conclusion: Although P-PTCA can be performed in almost all pts, more than 30% of unselected AMI pts do not actually receive RT. Pts admitted to a hospital with invasive facilities have about eightfold higher probability to be treated with P-PTCA. Pts with a more severe risk profile who are more likely to benefit from the procedure are less likely to undergo it.

P1774 An early revascularization strategy in cardiogenic shock provides similar benefits in men and women

D. Antoniucci, R. Valenti, A. Migliorini, G. Moschi, G.M. Santoro, L. Bolognese, P. Buonamici, G. Cerisano. *Careggi Hospital, Division of Cardiology, Florence, Italy*

Background: The Shock Trial did not show any benefit of an early revascularization strategy in women with AMI complicated by cardiogenic shock (CS), while the Shock Registry showed similar benefits in men and women.
Methods: Comparison of outcomes of 143 men and 65 women with CS undergoing primary percutaneous intervention (PCI).
Results: Women were older than men (74 ± 10 yrs vs 66 ± 12 yrs, p<0.001). There were no differences between groups in the other baseline characteristics. Primary PCI success rates were similar (95% vs 96%) and coronary stenting was accomplished in most pts of both groups. The six-month survival rate was 56 ± 7% for women and 67 ± 4% for men (p=0.083). There were no differences in reinfarction (2% vs 3%, p=0.619) and target vessel revascularization rates (12% vs 7%, p=0.249). After adjusting for multiple variables, female sex was not related to survival, while the only independent predictor of mortality was age (OR 1.07, 95% CI 1.04-1.09, p<0.001).



Six-month survival.

Conclusion: An early revascularization strategy in patients with cardiogenic shock provides similar effects on outcomes in men and women.

P1775 Primary angioplasty as preferred reperfusion therapy in an unselected population: 6-month follow-up results of the AMI-Florence Registry

E. Buiatti[1], G M. Santoro[2], D. Balzi[3], M C. Landini[3], N. Marchionni[2], M. Torri[3], S. Valente[2], V. Verdiani[2]. [1]*Tuscany Health Agency, Florence, Italy;* [2]*Careggi Hospital, Florence, Italy;* [3]*Health Unit, Florence, Italy*

Background: Reperfusion therapy (RT) improves survival in patients (pts) with acute myocardial infarction (AMI). Primary PTCA (P-PTCA) represents the most frequently utilized modality of RT in the Florence area, due to the presence of two high-volume centres with P-PTCA programs.
Methods: The study was designed as a prospective observational registry including all the Florence area residents who experienced AMI from March 1, 2000 to February 28, 2001 and were admitted to hospital within 24 hours from symptom onset. The analysis concerning 806 pts with ST-elevation AMI entered in the registry is presented here.
Results: Mean age was 69.5±13 years, 69% were males, 20.6% had diabetes, 50.4% hypertension, 27% dyslipidemia, 29.3% were current smokers, 15.4% had had a prior myocardial infarction and 6.6% prior revascularization (PTCA or CABG). Killip class >1 was observed in 27.2%; cardiogenic shock was present in 5.2%. Time from symptom onset to admission was <6 h in 82.5%. Among the 494 patients (61.3%) treated with RT, 91.7% underwent P-PTCA. In these pts median door-to-balloon time was 41 min; stents were used in 96%. Overall in-hospital mortality was 9.6%: 6.0% in P-PTCA pts (4.0% in non-shock pts) and 15.7% in pts not treated with RT; one of the 41 pts treated with fibrinolysis died. In P-PTCA pts mortality varied according to time from symptom onset to hospital admission (5.0% if less than 3 hours vs 7.8%, p=0.23) and to door-to-balloon-time (3.0% if time <30 min vs 8.8%, p=0.011).
Overall 6-month mortality was 14.9%: 9.5% in P-PTCA pts, 7.3% in pts treated with fibrinolysis, and 23.7% in pts not treated with RT.
Using a multivariate logistic regression model, Killip >1 (OR 3.9, 95%CI 2.5-6.1), age as a continuous variable (OR 1.08, 95%CI 1.05-1.10), a history of angina (OR 1.61; 95%CI 1.03-2.53) and a previous ictus (OR 2.52, 95%CI 1.30-4.87) were significantly associated with an increase in 6-month mortality, while the use of RT was a protective factor (OR 0.59, 95%CI 0.38-0.93).
Conclusion: P-PTCA, when used as preferred RT, is applicable to a large part of unselected pts with AMI and is associated with excellent 6-month outcome. However, older pts with heart failure at admission and a history of angina or ictus remain at higher risk for 6-month mortality.

P1776 Primary coronary stent implantation for acute myocardial infarction in diabetic versus nondiabetic patients: in-hospital and follow-up results

I. Demir, H. Yilmaz, I. Basarici, E. Altekin, O. Sancaktar, N. Deger. *akdeniz university, cardiology, ANTALYA, Turkey*

Objectives: The outcome of diabetic patients after myocardial infarction (MI) has been worse than in their nondiabetic patients before and during the thrombolytic therapy era. In order to evaluate the impact of diabetes on the acute and late clinical outcomes in a consecutive series of patients undergoing coronary stent implantation in AMI, we compared in-hospital and follow-up clinical outcomes among diabetic and nondiabetic patients.
Material and Methods: From 1997 to 2001 we performed primary coronary stent implantation in 774 patients for acute MI. We compared the angiographic and clinical outcome of nondiabetic (aged 55.9 ± 10.6 years; 82.6% male) and diabetic (aged 56.8 ± 11.7 years; 63.1% male) patients consecutively treated with primary stenting for acute MI. The in-hospital results and follow-up clinical outcomes of each group were retrospectively analyzed.
Results: The nondiabetic group comprised 633 (81.8%) patients and the diabetic group 141 (18.2%) patients. Basic clinical and angiographic characteristics were similar. Angiographic and clinical success was in diabetics = 66.7% and 90.7% vs. in nondiabetics = 78.7% and 95.1% (respectively p=0.006, 0.04). Diabetic patients had a much higher incidence of in-hospital death and overall events (p=0.028). At 1-month follow-up, diabetic patients had a much higher incidence of target vessel revascularization (5.6% vs 1.6%; P = 0.006), which accounted for the majority of the major cardiac events at 1 month (20.6% vs 7.4%; P = 0.003). At a mean follow-up of 7.2 ± 2.7months, 92.9% of nondiabetic and 88% of diabetic patients were alive (p = 0.05). Overall freedom from a major cardiac event (death, MI, target vessel revascularization) at 7.2 ± 2.7month follow-up was 75.8% for nondiabetics and 58.1% for diabetic patients (P <001). By multivariate analysis, age, diabetes, shock, hemodynamic instability and female gender were the most important predictor for development of 1-month and late major cardiovascular events.
Conclusion: Primary stenting in acute MI is effective in restoring immediate TIMI 3 coronary flow in diabetic and nondiabetic patients. This procedure may improve benefit in terms of mortality rate to both groups, particularly in diabetic patients, compared with previous reports with thrombolytic therapy. Nevertheless, major cardiovascular events at 1 month and medium-term follow-up are more frequent in diabetic patients.

P1777 Rescue percutaneous coronary intervention after failed thrombolysis versus primary percutaneous coronary intervention in acute myocardial infarction: registry of the Arbeitsgemeinschaft Leitender Kardiologischer Krankenhausärzte

A. Vogt[1], W. Niederer[2], H.-J. Engel[3], K.-W. Heinrich[4], T. Bonzel[5], R. Uebis[6], M. Gottwik[7] on behalf of ALKK study group. [1]*Klinikum Kassel gGmbH, Medizinische Klinik II, Kassel, Germany;* [2]*Krankenhaus der Barmherzigen Brüder, Regensburg, Germany;* [3]*Krankenhaus Links der Weser, Bremen, Germany;* [4]*Herzzentrum Kaiser-Wilhelm-Krankenhaus, Duisburg, Germany;* [5]*Klinikum, Fulda, Germany;* [6]*Klinikum, Aschaffenburg, Germany;* [7]*Klinikum, Medizinische Klinik 8, Nürnberg, Germany*

From 1994 to 2000 all PCI-procedures were recorded from 87 German centres. This analysis includes all procedures for AMI <24 h in de-novo coronary lesions:

Rescue vs. primary PCI

	Rescue-PCI	Primary PCI	P=
No.	2210	8736	
% female pts.	22.8	26.5	0.03
age (Y ± SD)	59 ± 12	61 ± 12	<0.001
% 3-vessel-disease	22.6	25.4	0.03
symptoms to PCI (h)	7.1 ± 5.1	5.7 ± 4.9	<0.001
% ST-elevation	94.5	88.8	<0.001
% shock	18.8	14.3	<0.001
% TIMI 0/1 before PCI	66.0	81.5	<0.001
% TIMI 3 after PCI	84.0	86.6	0.03
% stent	60.7	56.2	0.006
max. CK (U/l ± SD)	1249 ± 1275	982 ± 1066	<0.001
% reinfarction	2.6	2.0	n.s.
% in-hospital death	13.4	10.4	0.004

Patients with rescue-PCI were younger, less women, had less 3-vessel-CHD, but longer delay to reperfusion and more shock. Predictors of in-hospital death were shock (OR 17.3; 95%-CI 14.8-20.2), failed PCI (OR 5.1; 4.3-6.1), reinfarction (OR 5.0; 3.5-7.1), age (OR 1.5 per decade; 1.4-1.6), 3-vessel-CHD (OR 1.9; 1.7-2.3), and female gender (OR 1.2; 1.01-1.4). Time to PCI, stent, and maximum CK were not significantly associated with mortality. In multivariate analysis (logistic regression), rescue-PCI had significantly higher mortality than primary PCI (OR 1.25; 95%-CI 1.04-1.50).

P1778 Long-term follow-up after rescue stenting in acute myocardial infarction

L. La Vecchia[1], L. Favero[1], P. Vincenzi[1], M. Martini[1], L. Varotto[1], A. Rubboli[2], A. Fontanelli[1]. [1]S.Bortolo Hospital, Cardiology, Vicenza, Italy; [2]Maggiore Hospital, Cardiology, Bologna, Italy

A large amount of clinical data support the concept that stenting in acute myocardial infarction (AMI) represents a feasible and effective revascularization strategy. However, very few information are available in the subgroup of patients (pts) who receive a coronary stent after failed systemic thrombolysis (so-called "rescue" stenting).

Methods: We analyzed long term follow-up (mean 28 months, range 6-85 mo) of 123 consecutive pts (age 60±12 yrs; 78% males) treated with rescue stenting because of persistence or early recurrence of ST segment elevation after full dose TPA (according to GUSTO protocol) in the period 1996-2001.

Results: Coronary stenting was attempted in 123/123 and was successful in 119/123 (96.7%); abciximab was used in 57/123 (46%) and intra-aortic balloon pumping (IABP) in 35/123 (28%). The stented segment was 18±8 mm long. Treated vessel was LAD (48%), RCA (40%), LCX (9%) and vein graft (3%). At the end of the procedure, TIMI 3 flow was obtained in 104/123 (85%) and TIMI 2 in 14 (11%). There were 10 in-hospital deaths and 4 late deaths, with a long term survival of 89%. Target lesion revascularization occurred in 17 cases (14% of discharged pts). Overall, event-free survival was 77%. Predictors of in-hospital mortality were all clinical parameters of high risk: age (p=0.01), Killip class 4 (p<0.001), cardiac arrest (p=0.009), 3 vessel or left main disease (p=0.02), ejection fraction (p<0.001) but not pre-coronary time, infarct location or use of abciximab or IABP. Predictors of late mortality were: age (p=0.007), peak troponin I (p=0.01) and previous infarction (p=0.006). TIMI flow <3 post-procedure has a negative impact on early (p=0.008) but not late mortality. At multivariate analysis, independent predictors of survival were age (p=0.014) and ejection fraction (p=0.006).

Conclusions: These data are among the few available concerning long term follow-up after rescue stenting and show that late mortality is relatively low, comparing favourably with results obtained in primary stenting. Although the scenario of percutaneous revascularization in AMI represents a field of rapidly evolving strategies, these data suggest that rescue stenting should not be denied to appropriately selected patients after failed thrombolysis.

P1779 Effect of abciximab and adenosine on microvascular reperfusion during direct angioplasty for acute myocardial infarction

M.J. Claeys, J.M. Bosmans, M. De Ceuninck, G. Vermeire, S. De Groof, C. Vrints. *Antwerp University Hospital, Cardiology Dpt, Edegem, Belgium*

Background: Despite early recanalization of an occluded infarct artery, up to one third op the patients still fail to obtain complete myocardial reperfusion and remain at risk of developing large infarcts. This study sought to assess whether adjunctive therapy with abciximab and adenosine might attenuate this process of impaired microvascular reperfusion and its detrimental implications.

Methods and Results: Microvascular reperfusion was studied in 200 patients with AMI by evaluation of the resolution of ST-segment elevation after successful percutaneous coronary intervention (PCI). An historical cohort of 102 patients receiving no adjunctive therapy constituted the control group (G1). A total of 5O patients received adjunctive therapy wiht abciximab alone(G2) and 48 patients received combined adjunctive therapy of IV abciximab and intracoronary infusion of adenosine during PCI (G3).The phenomenon of impaired microvascular reperfusion defined as the presence of persistent (>50% of initial value)ST segment elevation despite successful recanalization (%ST > 50%), occurred in 17% of G3 vs 37% in G2 vs 33% in G1 (p=0.01).Multivariate analysis identified combined adjunctive therapy (G3) as an independent protective factor for microvascular reperfusion. Major cardiac event rate (death and MI) at one month tended to be lower in patients receiving adjunctive treatment: 10% in G1 vs 6% in G2 and vs 7% in G3. This positive effect on clinical outcome was mainly observed in the 61 patients with impaired reperfusion (%ST > 50%) and was related to abciximab treatment: MACE rate of 23% in G1 vs 11% in G2 vs 12% in G3. The outcome of the 139 patients without impaired microvascular reperfusion was excellent for all studygroups (MACE rate: 3%, 5%, 5%)

Conclusion: Adjunctive therapy with abciximab and adenosine during PCI for AMI has a beneficial effect on outcome: it attenuates the process of microvascular reperfusion injury (mainly adenosine effect) and it seems to prevent thrombotic complications particularly in patients with impaired microvascular reperfusion (mainly abciximab effect)

P1780 Abciximab use in unselected patients with acute myocardial infarction treated with primary PTCA: data from the AMI-Florence Registry

G M. Santoro[1], M. Margheri[1], E. Buiatti[2], S. Valente[1], M. Monami[1], A. Fantini[3], M. Granelli[3], F A. Tarmum[3]. [1]Careggi Hospital, Florence, Italy; [2]Tuscany Health Agency, Florence, Italy; [3]Health Unit, Florence, Italy

Background: Factors influencing the use of abciximab (ABC) in unselected patients (pts) with acute myocardial infarction (AMI) treated with primary PTCA (P-PTCA) have not been fully explored yet. Furthermore, the potential benefit of ABC treatment in this population remains controversial.

Methods: Data are derived from the AMI – Florence Registry, a prospective observational registry including all the Florence area residents who experienced AMI from March 1, 2000 to February 28, 2001 and were admitted to hospital within 24 hours from symptom onset. Florence area includes 7 hospitals, 5 without the facilities to perform P-PTCA and 2 with specific programs for P-PTCA. This analysis refers to the 462 pts with ST-elevation AMI included in the registry who underwent P-PTCA.

Results: Of these pts, 281 (60.8%)were treated with ABC (bolus followed by 12 h infusion) and 181 (39.2%) were not. The corresponding rates of stent use were 96.4% vs 95.4%; TIMI 3 flow was restored in 99.3% vs 96.4%. At multivariate analysis, factors positively associated with ABC use were admission to a hospital with P-PTCA facilities (OR 2.2, 95%CI 1.4-3.3) and history of angina (OR 1.5, 95%CI 1.1-1.9), while factors associated with no ABC treatment were age as a continuous variable (OR 0.97, 95%CI 0.96-0.99) and AMI location other than anterior (OR 0.58, 95%CI 0.38-0.88); pts in Killip class > 1 were less likely to receive ABC (OR 0.53, 95%CI 0.32-0.88). In-hospital mortality was 2.5% in ABC-treated patients and 13.3% in the others (p<0.001). At multivariate analysis determinants of in-hospital mortality were age as a continuous variable (OR 1.11, CI 1.06-1.18) and Killip class > 1 (OR 3.9, CI 1.5-9.8). ABC treatment was associated with reduced mortality (OR 0.36, CI 0.13-0.99). In-hospital reinfarction and re-PTCA were 10.3% in ABC-treated pts and 8.8% in the others (p=0.60). Left ventricular ejection fraction of the pts alive at discharge was the same in the 2 groups (mean 45±12%).

Conclusion: Patients admitted to hospitals with P-PTCA facilities are more likely to receive ABC treatment. The reduced mortality observed in ABC-treated patients depends on their more favourable risk profile, even if an independent effect of ABC use is also suggested.

P1781 Facilitated percutaneous coronary interventions in patients with acute myocardial infarction transferred from remote hospitals

D. Dudek, K. Zmudka, M. Kuta, A. Dziewierz, C. Zorkun, S. Bartus, W. Tracz, J S. Dubiel. *Jagiellonian University, Institute of Cardiology, Krakow, Poland*

Primary percutaneous coronary intervention (PCI) is a preferred therapy for myocardial infarction (MI) in centers having access to immediate invasive treatment but is frequently inaccessible to the community hospitals without catheterization facilities. We studied the safety and efficacy of facilitated PCI in patients (pts) with acute MI transferred from remote hospitals to catheterization facilities.

Methods: 200 pts with MI admitted to remote hospitals were enrolled if they presented within 12 hrs of chest pain onset, were eligible for thrombolysis and if the anticipated transfer time to catheterization laboratory was > 90 min. All pts received i.v. bolus of 60U/kg heparin, 15 mg alteplase and 0.25 mg/kg abciximab at the remote hospital and were immediately transferred to angiography. Infusion of alteplase (35mg/60 min) and abciximab (0.125 ug/kg/min) was continued during transfer.

Results: Average transport time was 97±39 min, and remote hospital door to needle time was 158±61 min. No death, and one ventricular fibrillation occurred during transportation. Mean time from lytic therapy administration to angiography was 124±39 min. In baseline angiography TIMI 3 flow was present in 71%, and patent infarct related artery (TIMI 3+2) was found in 86% of pts. Immediate PCI was performed in 150 pts with 92% procedural success rate. Corrected TIMI frame count before PCI was 35±30 and after PCI decreased to 20±13. In 42% of pts TIMI Myocardial Perfusion Grade (MPG) 3, and in 26% of pts MPG2 was achieved after PCI. The frequency of adverse cardiovascular events in the 30-day follow-up was rather low with 3.5% mortality rate, 1% recurrent MI, 1.5% repeat PCI and 1% intracranial bleeding. However, there were also 3% severe, 1.5% moderate and 14% mild bleeding complications.

Conclusions: Transferring patients from remote (>90 min. transfer time) hospitals to angioplasty center after administration of combined lytic and IIb/IIIa blocker therapy was feasible and safe. This combined therapy resulted in 71% TIMI 3 flow and opened infarct related artery in 86% of pts before PCI. Patients after such combined lytic therapy could undergo immediate PCI procedure (facilitated PCI) with high procedural success rate. However, bleeding complications occurred with rather high frequency.

P1782 Effect of stent-implantation versus balloon angioplasty on blood thrombogenicity in patients with acute myocarial infarction

M. Jaster, P. Schwimmbeck, M. Pauschinger, S. Spencker, H.P. Schultheiss, U. Rauch. *Universityhospital Benjamin Franklin, Klinik for Cardiology, Berlin, Germany*

Background: Activated platelets are an independent predictor for thrombotic events after percutanous coronary intervention and stent implantation. Newer trials point to the benefit of early platelet inhibition and blockade of platelet-leukocyte interaction for prevention of coronary thrombosis. Our study examined platelet-leukocyte interaction and platelet activation in blood in patients with acute myocardial infarction (AMI) randomised to stent-implantation versus balloon angioplasty.
Methods and Results: 57 patients with AMI were included into our study. Patients were excluded when receiving fibrinolytic agents or GP IIb/IIIa receptor antagonists. All patients were treated with heparin, ticlopidine (250 mg BID) and aspirin (100 mg). Blood samples were taken from a peripheral vein before, immediately after intervention and after 24 hours and analysed by flow cytometry. Platelet-leukocyte aggregates in blood were comparable before intervention in patients randomised to stent-implantation (n=31) or balloon angioplasty (n=26) (3,9% (2,8; 4,7) versus 4,05% (3,4; 4,5)). Patients with implantation of a heparin-coated coiled wire stent showed a significant decrease in platelet-leukocyte aggregates 24 hours after intervention (3,9% (2,8; 4,7) versus 3,2% (2,4; 4,1); $p < 0,01$). No difference in platelet-leukocyte aggregation was found in patients treated with balloon angioplasty only. Platelet activation was increased immediately after intervention in both groups.
Conclusion: An inhibitory effect of stent-implantation on platelet-leukocyte aggregation in blood was demonstrated in patients with AMI. Passivation of the vessel wall and removal of the dissection-membrane by the stent reduces platelet-leukocyte interaction in the circulation and may relate to the clinical benefit of stenting in AMI.

P1783 Comparison of Culprit lesion targeting versus multi lesion trageting for primary and early percutaneous coronary intervention in acute myocardial infarction

S. Rux, K. Lenßen, S. Sonntag, T. Thieme, F.X. Kleber. *ukb, Internal medicine/cardiology, Berlin, Germany*

Treatment of acute myocardial infarction (AMI) has undergone dramatic changes due to new interventional techniques and improved thrombolytic agents. Primary PCI, especially stenting of the culprit lesion under GPIIb/IIIa blockade, is a world wide accepted approach. A certain amount of patients suffering from AMI have multi-vessel coronary artery disease with several other high-grade stenosis beside the culprit lesion (cpl). There is very limited data on patient 's outcome after PCI targeting the cpl alone compared to targeting of additional lesions beside the cpl.
Between January 1st 1999 and February 1st 2002 346/346 patients underwent diagnostic and 288/346 immediate therapeutic cardiac catheterization for treatment of AMI. 58/346 patients were either transferred for CABG, underwent PCI later or had no significant stenosis. 1-vessel-disease was present in 82/288, 2-vessel-disease in 100/288 and 3-vessel disease in 103/288 patients. PCI of the cpl alone was performed in 191/288 patients and 97/288 underwent multiple interventions. Overall inhospital mortality was 12/288 patients (4.1%) undergoing PCI and additional non-fatal MACE occurred in 11/288 patients (3.8%).
No significant difference concerning mortality, occurrence of non-fatal MACE and duration of hospitalisation was found in comparison of the 6 groups presented in the table. Patients were divided into the 6 groups according to the targeted lesions (Cpl= intervention of the culprit lesion, IRA= intervention of an additional lesion in the infarct related artery (IRA), non-IRA= intervention of an additional lesion located in an artery not related to the acute MI).

Affected vessels	Procedures (n)	Location of intervention	Patients (n)	Hospital days	Death n (%)	MACE n (%)	Level of significance
1	1	Cpl	62	5.0	1 (1.6)	2 (3.2)	n.s.
1	>1	Cpl + IRA	20	5.3	0	0	n.s.
2	1	Cpl	66	5.7	5 (7.6)	1 (1.5)	n.s.
2	>1	Cpl + IRA/non-IRA	34	6.1	1 (2.9)	1 (2.9)	n.s.
3	1	Cpl	63	6.9	3 (4.8)	4 (6.4)	n.s.
3	>1	Cpl + IRA/non-IRA	43	5.9	2 (4.7)	3 (6.9)	n.s.

We conclude that complex interventional coronary r revascularisation in AMI is safe and effective. Randomised trials including a larger number of patients are warranted to verify our experience.

P1784 Reduction of coronary blood flow during early phase of reperfusion as a predictor of microvascular injury during acute myocardial infarction

J. Zalewski, W. Zajdel, P. Czunko, P. Musialek, C. Zorcun, A. Kadzielski, T. Przewlocki, K. Zmudka. *St. John Paul Hospital II, Institute of Cardiology, Kraków, Poland*

In acute myocardial infarction (AMI), recanalization of the infarct related artery (IRA) with primary angioplasty leads usually to restoration of epicardial blood flow. This, however, may not translate into appropriate perfusion, since hypoxia and reperfusion impair coronary microcirculation and induce cardiac myocyte damage. The aim of the study was to estimate the relation between dynamic changes of coronary blood flow in IRA during the early phase of reperfusion and microvascular injury in 272 consecutive patients (pts) with AMI (mean age 54.7±10.5 years) treated with primary angioplasty in our institution.
The pts were divided into two groups: reflow (TIMI-3) and no-reflow (TIMI<3). ECG (total ST elevation in all leads, [tST]) and hemodynamic status (heart rate [HR]/systolic blood pressure [SP]) were collected before [B], straight after completion of the procedure [C] and 24 hours later [C24]. Coronary flow (TIMI scale and corrected TIMI frame count, CTFC) was evaluated at the above time points and, in addition, immediately after opening of the IRA [O]. Microvascular injury was assessed by (i) regression of ST segment elevation (tST-C/tST-B and tST-C24/tST-B); (ii) maximal CK-MB release (iii) HR/SP-B, HR/SP-C, HR/SP-C24. Coronary flow impairment (CTFC-red [frame]) was defined as the difference between CTFC-C and CTFC-O.
TIMI-3 flow was achieved in 236 pts [90,8%] immediately after IRA opening. In the early phase of acute reperfusion (6-30 min, on average 12.6 min), between IRA opening and end of PCI we found a reduction in TIMI flow by at least 1 point in 19 pts. Thus, at the end of PCI 224 (86,2%) pts had TIMI-3 flow, whereas in 19 (13,8%) pts the no-reflow phenomenon (TIMI<3) occurred.
CTFC-C was bigger than CTFC-O in group reflow (18,98±6,92 vs. 21,04±7,48; p=0,03) and in group no-reflow (43,44±26,94 vs. 89,84±47,86; p=0,004). CTFC-red in the reflow group was 2,02±6,28 and in the no-reflow group was 46,34±42,82 (p<0,001). CTFC-red in groups with LAD vs. non-LAD IRA was 3,74±4,86 vs. 1,44±6,74 (p=0,041). CTFC-red correlates with tST-C/tST-B (r=0,52, p<0,001), tST-C24/tST-B (r=0,59, p<0,001), maximal CK-MB (r=0,35, p=0,001) and HR/RR-C24 (r=0,44, p<0,001).
Conclusions: 1.In patients with AMI treated by primary angioplasty, successful IRA opening is usually followed by a subsequent reduction in coronary flow in the early phase of reperfusion.
2.The reduction in coronary flow correlates with microvascular injury.
3.Our data indicate that the reduction in IRA flow following successful IRA opening may be a clinically useful early indicator of microvascular injury.

P1785 Intracoronary localregional delivery of abciximab over a 3 French catheter in acute myocardial infarction

K. Kronberg[1], B. Hullmann[1], M S. Claus[2], G-H. Reil[1]. [1]*Klinikum Oldenburg, Kardiologie, Oldenburg, Germany;* [2]*OFFIS, Health Information Systems, Oldenburg, Germany*

Background: In acute myocardial infarction a subset of patients treated with primary angioplasty maintained an occluded vessel even after multiple dilatations. In these cases of occlusive intracoronary thrombi the systemic application of platelet glycoprotein IIb/IIIa antagonists could not reach the small vessels distal of the stenosis and restore the flow in the microcirculation. We evaluated the localregional delivery of abciximab. The drug was injected through a 3 French (F) multipurpose catheter directly into the distal coronary vessel.
Methods: From June 1999 until July 2001 we performed primary angioplasty at 208 consecutive patients with acute myocardial infarction. We could restore a TIMI 3 flow in 188 patients with balloon dilatation and if necessary with systemic application of abciximab. In 20 (9,6%) cases we found even after repeated balloon angioplasty a thrombotic occlusion or a slow flow (TIMI 0-2). The average age of these patients was 63,4 years, 14 (70%) were males and 5 (26%) of them had undergone a prior bypass operation. Half of the dose of abciximab was given through the guiding catheter and the other half through a 3 F catheter distal of the stenosis. All patients received a stent and were treated with additional acetylsalicyclic acid and clopidogrel.
Results: After localregional delivery of abciximab and balloon angioplasty in 18 of 20 cases (90%) a TIMI 3 flow could be restored, in the other 2 (10%) a TIMI 2 flow was achieved. On average it lasted 40.9 minutes (15 to 82 minutes) from the beginning of the procedure to the time the blood flow was restored. The maximum of the creatinine kinase was 1218 U/l on average. One patient died 13 days after the infarction in cardiogenic shock. After 6 months the angina classification was CCS I of 18 patients on average (one non related death). 16 patients were event free, one patient needed coronary bypass grafting and one other had a myocardial infarction. The left ventricular ejection fraction rose from 43,7% at discharge to 55,7% in 6 months after the therapy.
Conclusion: The intracoronary localregional delivery of abciximab restored blood flow in the infarct related vessel in a high percentage. The TIMI 3 rates (90%) and the 6 months clinical results encourage the use of localregional application of abciximab in occluded vessels to improve microvascular circulation.

P1786 Improved myocardial salvage with gradual reperfusion angioplasty compared to coronary stenting for acute anterior myocardial infarction

K. Ohsato, S. Mizuno, T. Murakami, I. Moriuchi, Y. Arai, H. Kokado, M. Ohnaka. *Fukui Cardiovascular Center, Internal Medicine Dept., Fukui, Japan*

Experimental studies indicate that staged reperfusion plays a role for restoration of reperfusion injury in occluded coronary artery. We sought to evaluate the impact of gradual reperfusion angioplasty to coronary stenting in patients with acute myocardial infarction (AMI). We performed a prospective analysis of 127 patients with anterior AMI. Prolonged (10 minute) dilatations were performed in 40 patients using perfusion balloon (GRA), 43 patients delivered coronary stenting (SRA), and the other 44 patients received standard (1 minute) dilatations using standard balloon (BRA). GRA group had a less ST re-elevation (GRA30%, SRA67%, and BRA64%; $p<0.05$) and a lower rate of major arrhythmia (15%, 46%, and 45%; $p<0.05$) in the acute phase. Regional wall motion improved significantly over the baseline (-2.65 SD/chord) at the time of AMI when seen at 1 month (-2.35, p=0.048) and 6 months (-2.20, p=0.047), and 3 years (-2.12, p=0.045) after the infarction in GRA group, which was not observed in SRA and BRA groups. At 3-year follow-up, the rate of target vessel revascularization was 27.3%, 23.3% and 47.7%, respectively (p=0.035). Mismatch of thallium-201 and fatty acid metabolism imagings was 33.0%, 15.1%, 11.8%, respectively (p=0.042). Major adverse cardiac events occurred less frequently in GRA group (0%, 11.6%, 2.3%: p=0.028). Gradual reperfusion angioplasty may prevent reperfusion syndrome and ventricular remodeling in AMI, reducing cardiovascular events for a long term.

P1787 Direct coronary angioplasty of non-protected left main coronary artery in acute myocardial infarction

K. Sakai, Y. Nakagawa, T. Kimura, H. Yokoi, M. Iwabuchi, N. Hamasaki, H. Nosaka, M. Nobuyoshi. *Kokura Memorial Hospital, Cardiology, Kitakyushu, Japan*

Background: Although acute myocardial infarction (AMI) of left main coronary artery (LMCA) is a rare clinical entity, it carries a very high mortality rate.
Methods and Results: To evaluate the effect of balloon angioplasty (BA) and stenting in those patients (pts), data bank of 2195 AMI pts admitted in Kokura Memorial Hospital between January 1992 and December 2000 was searched. Emergency angiography showed LMCA obstruction in 38 pts (1.7%), and all of them received direct BA and needed IABP support to prevent development of cardiogenic shock. Of the 38 pts, 17 pts (45%) discharged alive and in-hospital death occurred in 21 pts (55%).
Successful reperfusion rate was significantly higher in survived pts than in died pts (17/17, or 100% VS 12/21, or 57%; $p<0.01$). Use of PCPS (18% VS 57%), time from onset to angioplasty (3.7±2.8 hrs VS 2.3±1.6 hrs), and incidence of emergency CABG (35% VS 14%) had no significant difference between survived and died pts. Survived pts were less likely to have cardiogenic shock (10/17, or 59% VS 20/21, 95%; $P<0.01$). On arrival to emergency room, base excess (BE) and pH were higher in survived pts than in died pts; BE: -4.3±4.0 mmol/l VS -11.0±6.3 mmol/l ($p<0.001$), pH: 7.40±0.10 VS 7.29±0.15 ($p<0.01$). Stent implantation in LMCA was subsequently attempted after BA in 26 pts (68%). Reocclusion of LMCA occurred in 2 pts (17%) of 12 non-stented pts and in none of 26 stented pts; $p<0.05$.
Conclusions: 1) Mortality rate of LMCA-AMI is high, especially complicated by cardiogenic shock. 2) To achieve successful reperfusion by direct angioplasty is an indispensable condition requisite for survival. 3) Prognosis on LMCA-AMI would be associated with hemodynamic changes on admission due to cardiogenic shock. 4) Stenting is effective to prevent reocclusion.

P1788 Long-term outcome in patients with early restrictive filling pattern after anterior acute myocardial infarction treated with primary PTCA

G. Cerisano, L. Bolognese, A. Migliorini, P. Buonamici, R. Valenti, E.V. Dovellini, P.D. Pucci, D. Antoniucci. *Careggi Hospital, Division of Cardiology, Florence, Italy*

Background: Preliminary studies have shown that patients with a restrictive left ventricular (LV) filling pattern early after acute myocardial infarction (AMI) had a poor outcome at medium follow-up even if successfully treated with primary percutaneous angioplasty (PTCA). However, information about the long-term impact of restrictive LV filling pattern in this clinical setting are still missing.
Objective: We sought to assess the long-term outcome in patients with restrictive LV filling pattern early after a first anterior AMI successfully treated with PTCA.
Methods: In 104 patients, two-dimensional and Doppler echocardiograms were obtained three days after the index AMI. Coronary angiography was performed in all patients at six months after PTCA. The patients were classified into two groups according to the Doppler-derived mitral deceleration time (DT): group 1 (n = 34) with DT $\leq$ 130 msec (restrictive filling pattern) and group 2 (n = 70 patients) with DT > 130 msec (non-restrictive filling pattern). All patients were followed-up for a mean (± SD) period of 53 ± 15 months.
Results: The 6-month coronary patency rate was similar (92%) in both groups. During the follow-up period, 17 patients (16.5%) were admitted to the hospital for congestive heart failure, 14 (41%) in the group 1 and 7 (10%) in the group 2 ($p < 0.001$), and 12 patients (11,5%) died, 9 (26%) in group 1 and 3 (4%) in group 2 ($p < 0.001$). Re-infarction occurred in 1 patients in both groups (3% vs 1%, p= 0.598). The survival rate and the event-free survival rate at mean follow-up were 74% vs 96% ($p < 0.001$) and 44% vs 94% ($p < 0.001$), respectively. Finally, in the survived patients the NYHA class was significantly higher in the restrictive group that in the non-restrictive group (2.1 ± 0.9 vs 1.4 ± 0.6, $p < 0.001$).
Conclusion: Patients with a restrictive LV filling pattern early after a first anterior infarction successfully treated with primary PTCA have a poor clinical long-term outcome.

P1789 Relations of myocardial viability to coronary flow reserve after anterior myocardial infarction treated with PTCA

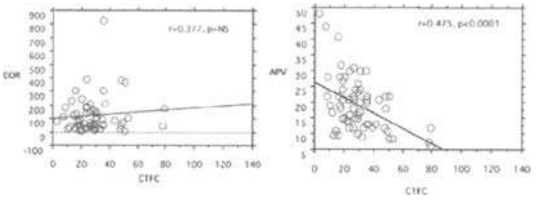
F. Innocenti[1], C. Agresti[2], F. Tarantini[2], N. Marchionni[2], G.J. Baldereschi[1], G. Masotti[2], R. Pini[2]. [1]*Ospedale Careggi, Gerontology and Geriatrics, Firenze, Italy;* [2]*University of Firenze, Critical Care Medicine and Surgery, Firenze, Italy*

Objective: To assess the relationship of myocardial viability to coronary flow reserve evaluated by transthoracic echocardiography in the infarct-related coronary artery after anterior myocardial infarction (AMI) treated with primary PTCA.
Methods: 54 patients with AMI (mean age 64±11 years, 72% males) were treated with primary PTCA (latency 4±3 hours) and underwent dobutamine stress echocardiography (DSE) and coronary flow reserve (CFR) study within three months of the acute event. Under continuous electrocardiographic and echocardiographic monitoring, dobutamine was administered in incremental doses of 5, 10, 20, 30 and 40 μg/kg/min, the first two stages lasting 5 minutes (low doses, LD), the others 3 minutes (high doses, HD), adding atropine when 85% of predicted maximal heart rate (endpoint) was not attained. Presence of positive ischemic response or occurrence of arrhythmias, hypotension, abnormal pressure increase, were all criteria for premature DSE test interruption, prior to endpoint. In 37 patients, CFR was assessed as the ratio of diastolic peak velocity after adenosine infusion (140 μg/kg/min for 5 minutes) to baseline diastolic peak velocity in the distal left anterior descending coronary artery, visualized by trans-thoracic echocardiography with contrast enhancement. Left ventricular (LV) wall motion score index (WMSI) was calculated on 16 segments (1=normal motion; 2 hypo-, 3 a-, 4 dys-kinesia; 5=aneurysm).
Results: baseline WMSI correlated positively with enzymatic peak values and LV volumes, and negatively with LV ejection fraction; changes in WMSI indicated some myocardial viability within necrotic area, with minimal ischemic response (infarct area WMSI: baseline 2.4±0.5, LD 2.1±0.6, HD 2.2±0.6). CFR (1.9±0.4) correlated negatively with LV end-diastolic and end-systolic volumes (r=-0.36 and r=-0.48, respectively) and positively to ejection fraction (r=0.55)(all $p<0.05$); CFR was also negatively related to WMSI at all DSE stages (r=-0.30 at baseline, r=-0.46 at LD, and r=-0.41 at HD) and positively with WMSI changes from baseline DSE to LD (r=0.48, all $p<0.05$).
Conclusions: in AMI survivors treated with primary PTCA, the presence of viable myocardium within infarct area correlates positively with CFR in the infarct-related artery. Early revascularization appears to contribute to less severe myocardial ischemic injury and to preserve CFR, with a favorable impact on LV geometry and systolic function. This is suggested by the positive correlation of CFR to smaller LV dimensions and better systolic function.

P1790 Corrected TIMI frame count does not assess microvascular injury in patients with acute myocardial infarction after primary coronary angioplasty

Y. Ohara, Y. Hiasa, T. Nada, T. Ogata, T. Takahashi, S. Hosokawa, K. Kishi, R. Ohtani. *Tokushima Red Cross Hospital, Cardiology, Komatsushima, Japan*

Objectives: The aim of this study was to evaluate the corrected Thrombolysis in Myocardial Infarction (TIMI) frame count (CTFC) as a predictor of microvascular injury of the coronary bed in patients with acute myocardial function (AMI).
Background: Some studies have shown that average systolic peak velocity (ASPV) and diastolic deceleration rate (DDR), measured by using a Doppler guidewire, predict the degree of microvascular injury of the coronary bed.
Methods and Results: We measured CTFC and coronary flow velocity immediately after primary coronary angioplasty in 71 patients with anterior AMI. CTFC correlated with average peak velocity (APV) (r=0.475; p<0.0001). However, there was no significant correlation with DDR (r=0.145; p=NS) or ASPV (r=0.377, p=NS).



Comparison of DDR & APV with CTFC.

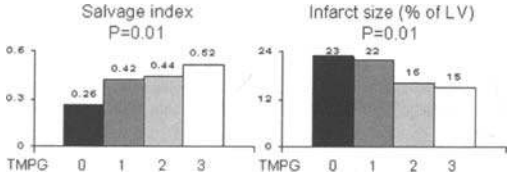
Conclusions: Although CTFC reflects coronary flow velocity, it is not accurate enough to assess the degree of microvascular injury after primary coronary angioplasty.

INTERVENTIONS AFTER MYOCARDIAL INFARCTION

P1791 TIMI myocardial perfusion grade (TMPG) correlates with myocardial salvage in patients with acute myocardial infarction treated with thrombolysis and stenting

A. Dibra[1], J. Mehilli[2], J. Dirschinger[3], J. Pache[3], K. Hösl[2], H. Schühlen[2], A. Kastrati[2], A. Schömig[2]. *[1]Deutsches Herzzentrum München, Cardiology, Munich, Germany; [2]Deutsches Herzzentrum, Cardiology Dept., Munich, Germany; [3]Rechts Der Isar, 1. Med. Klinik, Munich, Germany*

TMPG has recently been introduced as an angiographic index of myocardial perfusion. In recent studies, it has been associated with mortality and infarct size after thrombolysis for acute myocardial infarction (AMI). Its relationship to myocardial salvage as assessed by single photon emission computed tomography after thrombolysis or stenting for AMI has not been examined.
We studied the relationship of TMPG to myocardial salvage and infarct size in 248 patients (pts) enrolled in the randomized STOPAMI 1 and STOPAMI 2 trials. These trials compared stenting with thrombolysis in pts with AMI. Area at risk was measured by scintigraphy at baseline. Final infarct size was measured by a second scintigraphy at 1-2 weeks after randomization. Salvage index was calculated as the proportion of area at risk salvaged by reperfusion. Pts of both interventional and thrombolytic arms were scheduled for coronary angiography at 1-2 weeks after randomization. TMPG was assessed according to the definition of Gibson et al (Circulation 2000; 101:125-130).
There were 52 pts with TMPG 0, 47 pts with TMPG 1, 59 pts with TMPG 2 and 90 pts with TMPG 3. They did not differ with respect to the area at risk (p>0.3). The analysis showed that TMPG was significantly related to salvage index and infarct size: the higher the TMPG the greater the salvage index and the smaller the infarct size. In the multivariate analysis, the relation between TMPG and salvage index was independent from the form of reperfusion therapy.



Conclusions: These results confirm previous findings on the relationship between TMPG and final infarct size. In addition, our study shows that TMPG is a useful marker of the degree of myocardial salvage achieved with intervention or thrombolysis.

P1792 One-year benefitial effect of stenting in anterior acute myocardial infarction due to proximal LAD occlusion. Results from the CADILLAC trial

E. Garcia[1], D. Cox[1], C. Grines[1], R. Moreno[2], J. Tcheng[1], T. Stuckey[1], B. Rutherford[1], G. Stone[1] on behalf of the CADILLAC investigators. *[1]Hospital Gregorio Marañón, Interventional Cardiology Dept., Madrid, Spain; [2]Hospital Clinico San Carlos, Cardiology Dept., Madrid, Spain*

Among patients with anterior MI, those with proximal LAD occlusion have a poorer prognosis. Whether stenting is of benefit in this subset is still under debate. This issue has been analysed from the data obtaines in the CADILLAC study.
The multicenter international CADILLAC trial included 2082 AMI patients treated with primary PTCA, that were randomized to 4 different strategies: balloon, balloon plus abciximab, stent and stent plus abciximab. Out of the 2082 patients, 441 (21.2%) presented a proximal LAD infarction, this subset comprising the study group. Of them, 224 (50.8%) were treated with balloon and 217 (48.2%) were asigned to stent implantation.
Results: Table shows differences in outcome between patients randomized to balloon or stent.

Ballon vs stent in prox LAD infarction

	Balloon	Stent	p
MACE at 30 days	15 (5.8%)	18 (8.3%)	0.305
Death	6 (2.7%)	11 (5.1%)	0.190
Disabling stroke	0	0	
Re-MI	1 (0.5%)	3 (1.4%)	0.365
Ischemic TVR	7 (3.1%)	6 (2.8%)	0.823
CABG	1 (0.5%)	3 (1.4%)	0.365
PCI	6 (2.7%)	3 (1.4%)	0.504
Severe bleeding	0	1 (0.5%)	0.492
MACE at 1 year	53 (23.7%)	40 (18.4%)	0.178
Death	12 (5.4%)	18 (8.35)	0.219
Disabling stroke	0	0	
Re-MI	8 (3.4%)	8 (3.4%)	0.948
Ischemic TVR	41 (18.3%)	19 (8.8%)	0.003
CABG	8 (3.4%)	7 (3.2%)	0.841
PCI	33 (14.7%)	12 (5.5%)	0.001
SAT	5 (2.2%)	1 (0.5%)	0.216

Conclusion: In patients with anterior MI secondary to proximal LAD occlusion, coronary stenting is associated with a 52% reduction in the rate of ischemia driven TVR at 1 year. Stent implantation in this subset should be considered mandatory when possible.

P1793 Determinants of transferral to a hospital with invasive facilities and outcome in acute myocardial infarction patients first admitted to community hospitals

E. Buiatti[1], N. Carrabba[2], D. Balzi[3], F. Cecchi[3], N. Marchionni[2], I. Berni[3], I. Olivotto[2], R. Vergassola[3]. *[1]Tuscany Health Agency, Florence, Italy; [2]Careggi Hospital, Florence, Italy; [3]Health Unit, Florence, Italy*

Background: Primary PTCA (P-PTCA) is an effective reperfusion treatment in patients (pts) with acute myocardial infarction (AMI), but this technique can hardly be widespread to community hospitals (CH). In pts first admitted to CH, the appropriateness of transferring criteria to tertiary centres with invasive facilities may be a relevant determinant of outcome.
Methods: The AMI-Florence Registry is a prospective observational registry including all the Florence area residents who experienced AMI from March 1, 2000 to February 28, 2001. This analysis refers to the 539 pts with ST-elevation AMI included in the registry who were admitted to the 5 CH of the Florence area without P-PTCA facilities.
Results: Of these pts, 377 (70%) were treated locally (11.4% with thrombolysis) (Group 1), and 162 (30%) were transferred to centres with P-PTCA facilities (Group 2). According to univariate analysis, Group 1 pts were older (age 74.1 ± 12.4 vs. 68.1 ± 12.6 years, p<0.001), had more frequently AMI other than anterior (77.7% vs. 53.0%, p<0.000), previous heart failure (16.2% vs. 3.1%, p<0.000)and were more frequently in Killip class >1 at admission (40.3% vs. 25.9% p=0.006). According to multivariate analysis, the variables negatively associated with transferral to a tertiary hospital were older age as a continuous variable (OR 0.98, 95%CI 0.96-0.99), AMI other than anterior (OR 0.26, 95%CI 0.17-0.41) and previous heart failure (OR 0.28, 95%CI 0.11-0.75). The history of angina (<1 month) was the only factor positively associated with transferral (OR 2.30, 95%CI 1.41-3.75). In-hospital and 6-month mortality was 14.3% and 25.2% in Group 1 vs 6.2% and 12.4% in Group 2 (p=0.007 and p=0.001, respectively).
Conclusion: Older and more severe pts were less likely to be transferred from CH to tertiary hospitals to undergo P-PTCA. These data rise doubts about the appropriateness of the used transferring criteria.

P1794 Outcome of elderly patients with acute myocardial infarction complicated by cardiogenic shock undergoing routine early coronary revascularization

D. Antoniucci, R. Valenti, A. Migliorini, G. Moschi, M. Trapani, G.M. Santoro, L. Bolognese, E.V. Dovellini. *Careggi Hospital, Division of Cardiology, Florence, Italy*

Background: The Shock Trial did not show any benefit of an early invasive strategy in elderly patients (pts) with acute myocardial infarction (AMI) complicated by cardiogenic shock (CS). Morever, elderly pts with cardiogenic shock are poorly represented in the Shock Trial and in several Registries of CS.
Methods: Analysis of the outcome of pts aged > 75 with AMI complicated by cardiogenic shock.
Results: Out of 205 pts with cardiogenic shock, 71 were aged > 75, and 134 were younger than 75 years. There was a greater incidence of women in the elderly group (51% vs 20%, p<0.001), while there were no differences between groups in the other baseline variables. The primary procedural success rates were indentical for the two groups (96%), and most pts had primary coronary stenting. The six-month mortality rate was 51% for elderly and 25% for younger pts (p<0.001). Multivariate analysis showed age (OR 1.07, 95% CI 1.04- 1.09), multivessel disease (OR 1.90, 95% CI 1.06-3.39) and anterior AMI (OR 1.90, 95% CI 1.05-3.46) to be independent predictors of mortality.
Conclusion: Age is a strong predictor of mortality in pts with cardiogenic shock after successful early coronary revascularization. However, the six-month survival of 49% in this high risk subset of pts suggests that the benefit of an early revascularization strategy persits also in elderly pts.

P1795 Safety of early transferring of thrombolysed patients with ST-segment elevated acute myocardial infarction to undergo coronary intervention: results from the GRACIA trial

F. Fernández-Avilés[1], F. Gimeno[1], B. Ramos[1], A. Serrador[1], I. Calvo[2], L. Martinez-Elbal[3], F. Frutos-Nogal[4], J. Goicolea[5] on behalf of GRACIA group. [1]*University Hospital of Valladolid, Institute of Heart Science (ICICOR), Valladolid, Spain;* [2]*H. Miguel Servet, Zaragoza, Spain;* [3]*H. Clinico de la Princesa, Madrid, Spain;* [4]*H. Severo Ochoa, Leganes, Spain;* [5]*H. do Meixoeiro, Vigo, Spain*

Background: Because of the efficacy of stenting in achieving a stable normal flow, coronary interventions performed immediately or hours after thrombolysis grow sharply. However, safety of transportation during recent or ongoing reperfusion remains undetermined.
Methods: The GRACIA trial included 500 pts randomly assigned to angiography and intervention within 24 hours of thrombolysis, or conservative posthrombolysis ischemia-guided approach. Interventional arm of this trial included 189 pts admitted and randomised in tertiary hospitals and 61 pts admitted in hospitals without interventional facilities, who needed posthrombolysis ambulance transferring to undergo coronary intervention. To assess the safety and feasibility of early posthrombolysis transferring, we compared the outcome of interventional transferred (n=61) and non-transferred patients (n=189). Travel distance was 34.9±35 Km. Transportation lasted 29±19 minutes. In 92% of cases pts were accompanied by well trained paramedics and a physician from the referring hospital.
Results: There were no differences between transferred and non-transferred pts in terms of clinical profile and infarct characteristics. Time delay between thrombolysis and angiography was longer among transferred pts (881±452 min vs 697±532 min, p=0.01). There was only one event (angina) during transportation (1.6%). Incidence of cardiac events from thrombolysis to angiography was similar in both groups (transferred: 20% non-transferred: 13%, p=0.22) and no patient died during this period. Bradycardia was more frequent among transferred patients (13 vs 5%, p= 0.05), but the incidence of ventricular tachycardia or fibrillation was similar in both groups (transferred: 1.6%; non-transferred: 3%, p= 0.85)
Conclusions: In the setting of AMI with ST segment elevation recently thrombolysed, ambulance transportation of patients to undergo complementary coronary interventions is feasible and safe.

P1796 Left ventricular remodelling after first anterior wall myocardial infarction: effect of delayed angioplasty (a new aspect for an old theory)

A. alballat[1], M. Al Setaiha[1], F. Al Sheshtawi[1], M. Ashmawi[1], I. Algendi[1], M. Tayel[1], M. Badr[1], M. Al sherbeeni[2]. [1]*Tanta, Egypt;* [2]*Ain Shams University, Cardiology, Cairo, Egypt*

Background: The concept that a patent infarct related artery (IRA) and myocardial reperfusion confer a benefit beyond that resulting from myocardial salvage has given rise to the "open artery theory" which now receives a considerable support.
Aim of this work is to evaluate the effect of delayed (within one month after AMI) percutaneous coronary interventional (PCI) revascularization procedure on LV remodeling after first anterior wall Q-wave acute myocardial infarction (AMI).
Patients and methods: A total of 80 patients, with first anterior AMI and <2 TIMI flow grade of the IRA, were selected and divided into: group A (40 patients) received, in addition to their conventional medical treatment, a PCI within one month after AMI and group B who received, only, the conventional medical treatment.. Left ventricular remodeling was assessed by echocardiography by measuring the end-diastolic (EDVI) and end-systolic volume indices (ESVI), resting wall motion scoring index, and LV ejection fraction (EF). These variables were measured as baseline, one, three and six months after AMI in both groups. Follow up coronary arteriography was done for all patients in the intervention group at the end of the six–month study to exclude patients in whom restenosis occurred.
Results At the 3-month study, ESVI and WMSI were significantly less in group A than group B (ESVI: 46.18±15.16 versus 49.95±12.42 ml3/m^2, p value <0.05, and WMSI: 1.28±0.17 versus 1.39±0.19, p<0.01, for group A and B respectively). At the 6-month the EDVI, ESVI and WMSI were significantly less in group A as compared to group B (EDVI: 132±25 versus 146±25.5 ml3/m^2, p<0.05 and ESVI: 43±13.8 versus 54±14.6 ml3/m^2, p<0.01, WMSI: 1.27±0.16 versus 1.46±0.21, p<0.01, in group A and B respectively. Global EF% increased significantly in group A as compared to group B (64.8±5.7 versus 56±6.8%, p<0.01).
Conclusion: These findings suggest that delayed PCI can reduce left ventricular remodeling after acute anterior wall myocardial infarction. The present study may serve as a basis for a large prospective mortality trial on this important issue

P1797 Outcome of elective percutaneous coronary interventions in ASSENT-3

C. Dubois[1], A. Belmans[1], P. Armstrong[2], C. Granger[3], L. Wallentin[4], F. Van de Werf[1] on behalf of the ASSENT-3 Investigators. [1]*University Hospital Gasthuisberg, Cardiology, Leuven, Belgium;* [2]*Edmonton, Canada;* [3]*DCRI, Durham, United States of America;* [4]*Uppsala, Sweden*

Background When compared with unfractionated heparin (UFH), co-therapy with enoxaparin (ENOX) or abciximab (ABC) results in a reduction of ischaemic complications after ST-elevation acute myocardial infarction (AMI) treated with TNK-tPA (ASSENT-3; n=6095). The effect of these new co-therapies on clinical outcomes in patients undergoing an elective percutaneous coronary intervention (PCI) after the acute event is not known.
Methods Clinical outcomes in patients undergoing elective PCI early after AMI in the ASSENT-3 trial (n=1064; 17.5% of total study population) were compared.
Results A similar number of patients underwent an elective PCI in the 3 treatment arms. The results are shown in the table.

Endpoints	UFH (n=332)	ENOX (n=348)	ABC (n=384)	P-value
Median time to PCI (days)	5	5	5	0.76
Primary efficacy endpoint *	22 (6.63%)	15 (4.31%)	20 (5.21%)	0.41
30-day mortality	4 (1.20%)	2 (0.57%)	6 (1.56%)	0.42
In-hospital myocardial reinfarction	10 (3.01%)	5 (1.44%)	6 (1.56%)	0.28
Reinfarction after PCI	5 (1.51%)	2 (0.57%)	2 (0.52%)	0.32
In-hospital refractory ischaemia	10 (3.01%)	9 (2.59%)	9 (2.34%)	0.86
Intracranial haemorrhage (ICH)	1 (0.30%)	1 (0.29%)	0 (0.00%)	0.41
In-hospital major bleeds (excl. ICH)	10 (3.01%)	7 (2.01%)	11 (2.86%)	0.66
Major bleed at arterial puncture site	3 (0.90%)	3 (0.86%)	2 (0.52%)	0.80
Minor bleed at arterial puncture site	35 (10.54%)	31 (8.91%)	36 (9.38%)	0.76

* Primary efficacy endpoint of ASSENT-3: 30-day mortality + in-hospital myocardial reinfarction + in-hospital refractory ischaemia; P-value: likelihood ratio test for overall difference between treatment groups

Conclusions In this post-hoc analysis of the ASSENT-3 trial, clinical outcomes in patients undergoing an elective PCI early after AMI were similar in the 3 treatment arms with a trend towards fewer efficacy endpoints in the ENOX and ABC arms. No excess of bleeding complications was observed after co-therapy with ENOX or ABC when compared with UFH.

P1798 Reperfusion block: the availability of primary PTCA does not increase the percentage of myocardial infarction patients receiving reperfusion therapy

J. Leor[1], H. Hod[2], S. Gottlieb[2], A. Battler[2], D. Zahger[2], V. Boyko[2], A. Caspi[2], S. Behar[2] on behalf of Israel Heart Society. [1]*Neufeld Cardiac Research Institute, Sheba Medical Center, Tel-Hashomer, Israel;* [2]*Neufeld Cardiac Research Institute, Cardiology Dept., Tel-Hashomer, Israel*

Background: The current guidelines recommend the use of thrombolytic treatment in patients with acute myocardial infarction (AMI) who present to the hospital within 12 hours of symptom onset. For patients with contraindications to thrombolytic treatment or who are at increased risk of bleeding, primary angioplasty is recommended. We hypothesized that the increasing number of cath labs and the availability of primary PTCA in Israel would render an increase in the % of MI patients treated with reperfusion therapy.

Methods and Results: We analyzed data obtained from 4 national surveys conducted in all CCUs in Israel from 1992 to 2000. In the last survey (2000) 19 of the 26 CCUs had on-site cath labs.

Trends in Reperfusion 1992 to 2000

	1992 (n=941)	1996 (n=2386)	1998 (n=1076)	2000 (n=1244)	p for trend
Age (yrs)	63+13	63+13	64+12	63+13	0.05
Male %	75	74	74	77	0.55
ST > MI%	-	-	75	76	NA
Aspirin %	72	91	94	96	<0.001
Beta-block %	31	55	60	64	<0.001
ACE-inhib %	19	50	53	53	<0.001
Lysis %	44	49	42	38	<0.001
Prim PTCA %	-	4	6	10	<0.001
Reperfusion %	44	53	48	48	0.46
Angio	22	37	49	51	<0.001
Any PCI %	7	22	28	39	<0.001
Death 30d %	13.5	9.7	9.6	10.4	0.05
Death 1 yr %	19.3	14.2	15.1	NA	0.005

Conclusions: Over the last decade, the overall % of MI patients who received reperfusion therapy remained constant. The increased utilization of primary PCI was associated with a parallel decrease in the use of thrombolysis. The decline in MI mortality observed in the early 90's leveled off since the mid 90's. Further efforts are needed to expand the proportion of MI pts who receive reperfusion therapy. If successful, such efforts would lead to a renewed decline in MI mortality.

P1799 Percutaneous angioplasty for late opening of infarct related arteries: predictors of one year clinical outcome

F. Schiele, L. Thebault, P. Sewoke, M.F. Seronde, N. Meneveau, P. Robles Encinas, L.I.U. PinMing, J.P. Bassand. *Department of Cardiology, Besancon, France*

Background: The potential benefit of re-opening occluded infarct-related arteries (IRA) by percutaneous coronary intervention (PCI) is still debated. We assessed the immediate and long term clinical outcome of patients submitted to systematic attempt at IRA re-opening in a setting of a sub acute (>72 hours and <10 days) myocardial infarction (MI).

Methods and Results: 199 consecutive patients matching these criteria were submitted to PCI and followed up for one year. Three endpoints were defined: (1)=composite of death, new Q wave MI, peri-procedural creatine kinase (CK) release >3 times the upper limit of normal, stroke, major bleeding, or need for urgent revascularisation at 30 days; (2)=one year survival without stroke, new MI or unstable angina; and (3)=endpoint #2 plus need for target lesion revascularization. Re-opening of the IRA was successful 159/199 (80%) patients, with stent implantation in 99 (50%). Endpoint #1 occurred in 16 (8%) patients; endpoint #2 in 30 (15%) and endpoint (3) in 44 (22%). Two year event free probability was 0.75±0.05 and 0.72±0.04 for endpoints #2 and #3 respectively. Left ventricular ejection fraction (LVEF) (odds ratio = 0.86 [0.79;0.94], p=0.001 per additional percent of LVEF) and CK release (1.01 [1.00;1.01], p=0.04 per additional unit of CK released) were independent predictors for endpoint #2, with LVEF being the only independent predictor of endpoint #3. Lack of stent implantation (odds ratio = 0.28 [0.05;0.5], p=0.04) and CK release (1.01 [1.00;1.01], p=0.03) were independent predictors of death.

Conclusion: Clinical outcome of patients submitted to systematic attempts to re-open occluded IRA in the setting defined in this study is mostly influenced by post MI LV function. Peri-procedural enzyme leakage and lack of stent implantation negatively influence late clinical outcome.

P1800 The effect of revacularization rate on prognosis of high risk acute myocardial infarction patients. An OPTIMAAL substudy

M.S. Nieminen[1], A. Zeiher[2], E. Myhre[3], I. Squire[4], S. Snapinn[5], K. Dickstein[6], J. Kjekshus[7]. [1]*University Central Hospital, Division of Cardiology, Helsinki, Finland;* [2]*Goethe University, Internal Medicine, Dept.IV, Frankfurt, Germany;* [3]*Central Hospital, Vest Agder, Norway;* [4]*Leicester, United Kingdom;* [5]*Merck Co, Statistics, Blue Bell, United States of America;* [6]*Central hospital in Rogaland, Cardiology Division, Stavanger, Norway;* [7]*Rikshospitalet, Cardiology, Oslo, Norway*

The effect of revascularization on prognosis in high risk post myocardial infarction (MI) pts, who were not candidates for initial interventional therapy, but with optimal medical therapy incuding ACE inhibitor or Angiotensin II blocker, has not been tested.

Material: Patients (pts) with MI (n= 5477)during initial hospitalization, with high risk profile including signs of heart failure or anterior MI with optimal medical therapy were included into analysis. Patients for whom immediate revascularization was planned were excluded from the study. Early revascularization was performed within 30 days in 550pts (10%, 398 PCI, 143 CABG and 9 had both) and within 360 days in total 1407 (25,7%, 789 PCI, 569 CABG and 49 had both procedures) of pts. The distribution of revascularization procedures at 1 year was uneven in this multinational population: Finland 28,1%, Denmark 29,3%, Norway 23,1%, Sweden 23,5%, UK 14% and Germany 38%. At baseline more patients were smokers in Denmark 42,1%, while in Germany 43,9% of pts had had previous PCI and with higher use of betablocking agents in Finland. There was no major difference in age, cholesterol, previous myocardial infarction or other characteristics.

Results: The mortality was reduced by revacsularizations in total study population by 48% (p< 0,0001), in PCI group by -50% (P<0,0001) and -40% by CABG (p<0,0001). In patients with lower EF (<35%) greater effect of revascularization on mortality is seen in PCI pts (52% lower) and in CABG pts (51% lower).

The reduction in mortality varied, with -74% decrease in Denmark, Finland -40%, concomitantly Norway -57%, Sweden -56%, UK -48%, Germany only -16% with highest revascularization rate. During up to 3 y follow-up the total death rate was 17%, while in Germany 12%.

Conclusion: These results suggest that revascularization either with PCI or CABG improves prognosis significantly in high risk patients after myocardial infarction.

P1801 Effect of late recanalization for acute myocardial infarction on left ventricular remodelling. A prospective randomized study – Preliminary data

J.C. Silva[1], C.E. Rochitte[2], L.F. Ávila[2], J.R. Parga[2], J.M. Andrade[2], R. Kalil-Filho[2], E.E. Martinez-Filho[2], J.C. Nicolau[2]. *[1]University of São Paulo Medical School, Heart Institute (InCor), São Paulo, Brazil; [2]University of São Paulo Medical School, Heart Institute (InCor), São Paulo, Brazil*

Background: Clinical benefits of infarct related artery (IRA) recanalization later than 12h from symptoms onset(SO) after acute myocardial infarction (MI) still remain unclear.Objectives: We investigated whether IRA late recanalization would improve left ventricular(LV) remodeling at 6 months follow-up (FU).
Methods: We studied 12 anterior MI pts with: SO between 12h-14 days prior to enrollment(E), occluded(0CC) IRA (TIMI 0/1) on angiography, and no evidence of myocardial ischemia or viability on anterior wall by scintigraphy. The were randomized to either IRA recanalization by PTCA(O-6 pts) or no intervention (OCC-6 pts). Myocardial tagging and delayed-enhanced MRI were performed at E and FU. Infarct size (IS), LV end diastolic (EDV) and systolic volumes (ESV), ejection fraction (EF)and LV mass were measured. The influence of infarct transmurality (IT) on myocardial 2D strains (maximal shortening (MS), circumferential shortening (Ecc), radial thickening (Err)) were analized on infarcted, adjacent (Adj) and remote (Rem) LV segments.
Results are shown on table 1, where *p<0.05 (E vs. FU) and # p<0.05 (O vs. Occ). At FU, O had significantly better % MS, Ecc, Err when IT was <50%. No differences were found when IT was >50%. Adj and Rem segments had greater strains on OCC at FU.
Conclusion: This study demonstrates that late recanalization of IRA using PTCA improves LV remodeling and LV regional contractility over a period of 6 months. These findings support the open-artery hypothesis and may significantly impact clinical prognosis.

P1802 Single vessel versus multivessel revascularization for non-ST-segment elevation acute coronary syndromes in the elderly

M. D'Urbano[1], P. Vandoni[2], A. Poli[3], R. Fetiveau[3], F. Cafiero[3], S. De Servi[3]. *[1]Legnano Hospital, Division o Cardiology, Legnano (Milan), Italy; [2]Milan, Italy; [3]Legnano Hospital, Division of Cardiology, Legnano (Milan), Italy*

Outcome of patients submitted to PCI is heavily affected by advanced age and clinical instability. Moreover prevalence of multivessel disease in patients with acute coronary syndromes (ACS) increases with age.
Aim of the study is to compare immediate results and mid term outcome of lone culprit lesion revascularization versus multivessel PCI in over-75 years old pts. admitted for non ST elevation ACS.
Population and results: from October 1997 to August 2001 300 consecutive over-75 yrs old pts (mean age 78, range 75-91, age >80 (24%) underwent PTCA in our cath lab. A multivessel disease was present in 195 pts. (65%). In 137 pts. (70.2%) only the culprit vessel was treated (group A); at least two vessel were treated in 58 pts.(29.8%) (group B) during the same hospitalisation. Mean age, male to female ratio, left ventricular function, severity of angina (Braunwald classification), incidence of peripheral and cerebral vascular disease, diabetes, renal insufficiency, and procedure technique (number of stents, use of rotational atherectomy) as well as use of IIbIIIa inhibitors were not different in the two groups. LAD coronary artery was more frequently the culprit vessel in group B.
A procedural success was achieved in 98% of pts in both groups. During hospitalization in group A 1 Q wave MI (0.7%), 2 non-Q wave MI (1.4%), 1 stroke (0.7%), 10 (7.3%) vascular access complications were observed whereas in group B 2 pts died ((3.4%), 1 Q wave MI (1.7%), 3 non-Q wave MI (5%), 5 vascular access complications (8.6%). Follow up (4-24 months) was possible in all but two pts.: in group A 5 pts (3.8%) died; 1 Q wave MI (0.8%) and 1 non-Q wave MI were observed and 10 revascularization procedures (PCI or CABG) were performed (7.5%); in group B no death, 2 non-Q wave MI (3.4%) were observed and 3 coronary revascularization were performed (5%). Stable angina was present in 12 patients of group A (9%) and in 3 patients of group B (5%).
Conclusions: in elderly people with non ST elevation ACS and multivessel disease, PTCA of the culprit vessel respect to multivessel percutaneous revascularization is associated with a better immediate outcome but has an increased incidence of clinical events at follow up. Individual criteria such as quality of life and life expectancy and procedural difficulties should guide the choice between the two strategies of percutaneous revascularization.

P1803 The switch from conservative to invasive strategy in non-ST-segment elevation acute coronary syndromes in a peripheral coronary care unit; does it have a prognostic impact?

E. Balli[1], M. Comeglio[2], A. Giomi[1], M. Margheri[2], G.F. Gensini[2], F. Del Citerna[1]. *[1]Della Robbia Hospital, Coronary Care Unit, Pistoia, Italy; [2]University of Florence, Dept. Internal Medicine and Cardiology, Florence, Italy*

Many landmark trials have discussed during the '90s the relative merits of the conservative and invasive strategies in the now called non-ST elevation acute coronary syndromes (ACS). A conservative approach has always been the initial choice in our Coronary Care Unit (CCU) without hemodynamic-interventional facilities and surgical back-up. Is this still clinically valuable and ethical? To investigate this item, we analyzed the short (30 days) and long (1 year) term prognosis of ACS patients (pts) admitted to our CCU from 1999 to 2001 (group A n=588) and historical controls from 1990 to 1992 (group B, n=534). Pts were matched (all p=n.s.) with respect to age (A 66+12 vs B 67+11 years), sex (males 75 vs 77%), previous myocardial infarction (MI) (14 vs 13.2%), diabetes (17 vs 18.1%), hypertension (48 vs 46.4%). Use of aspirin and nitrates did not differ; thrombolysis (12 vs 2%), i.v. heparin (86 vs 64%), calcium-channel blockers (74 vs 28%) had a higher use in group B (p<0.001), beta-blockers (43 vs 27%, p<0.001) and PCIs (4 vs 42%, p<0.0001) in group A, whose pts received also statins (87%), LMWHeparins (48%) and GP2b3a-ibitors (12%). Severity of angina, presence and entity of ST depression, younger age, Killip class >2 were indipendent predictors of PCIs, while troponins, 2-D echo data, previous MI were not. Group A had a shorter lenght of hospital stay (5.7 vs 7.8 days, p<0.01). At 30-day follow-up mortality (A 3.7 vs B 4.8%) and (re)MI (A 2.4 vs B 2.3%) did not differ (p=n.s.), while at 1-year follow-up group A had a lower mortality (7.2 vs 10.4%, p<0.01) and a tendency to lower (re)MI (4. vs 5.6%, =0.058). At multivariate analysis PCI (OR 0.57, 95%IC 0.43-0.88) was the most powerful predictor of improved survival, followed by beta-blockers (OR 0.74, 95%IC 0.56-0.99). In the daily experience of a medium-sized CCU the switch to a "primary" invasive strategy in ACS, associated to a careful secondary pharmacological prevention, has prognostic benefit and is cost-effective. Hemodynamic and interventional facilities should be extended, with the support of a "core" reference laboratory, in order to obtain a widespread optimization of ACS pts' therapy.

P1804 Randomized double blind study of percutaneous myocardial laser in chronic refractory angina

M. Salem[1], S. Rotevatn[1], S. Stavnes[2], M. Brekke[2], R. Pettersen[1], K. Kuiper[1], J.E. Nordrehaug[1]. [1]*Haukeland University Hospital, Department of Heart disease, Bergen, Norway;* [2]*Ullevål Hospital, Radiological Department, Oslo, Norway*

Transmyocardial or percutaneous myocardial laser (PML) has been suggested to relieve symptoms in patients with chronic angina pectoris. However, the mechanism by which laser relieves symptoms is not known, and no previous study has been able to exclude a placebo effect. We included 82 patients into a double blind randomized study, of whom 40 underwent percutaneous myocardial laser (YAG: holmium) and 42 patients had a sham procedure. Statistical power calculation was based on improvement of CCS functional class. Among the 82 patients, 86.6% were in CCS class **III**, and 13.4% in class IV. The mean left ventricular ejection fraction was 64.7%, 82.9% of patients had triple vessel disease, 67.1% had previous myocardial infarction, and 89% had previous coronary interventions. The treatment groups were comparable at baseline. A mean of 19.7 laser/sham positions were obtained, and a mean of 78.7 pulses/sham were fired. The procedure was successfully completed in 97.5% of the laser group versus 97.6% of sham. Hospital mortality was 1.2%, one patient had a pericardiocentesis and there was one transient ischemic attack. Total mortality at 12 months was 7.3%. At 12 months 64% of patients in the laser group had improved 1 CCS class or more compared to 40% in the sham group (p=0.009). Improvement of 2 CCS classes or more was 36% versus 15% respectively (p=0.009). There was no significant increase in exercise time or oxygen uptake. We conclude that there is a significant improvement of angina symptoms after percutaneous myocardial laser compared to sham procedure.

P1805 Women with acute myocardial infarction or acute coronary syndromes benefit from an aggressive coronary intervention

M. Sansa[1], F. Damnotti[1], A.S. Bongo[1], A. Campi[1], G. Giacomarra[1], G.L. Fornaro[1], M. Panella[2], C. Cernigliaro[3]. [1]*Ospedale Maggiore, Cardiologia Ospedaliera, Novara, Italy;* [2]*Università Piemonte Orientale, Ist. Igiene, Novara, Italy;* [3]*Ospedale Maggiore, Cardiologia Ospedaliera, Novara, Italy*

A high mortality risk for women with acute myocardial infarction (AMI) or acute coronary syndromes (ACS) after percutaneous coronary intervention (PCI) is a common finding in literature.

Study objective: to assess the impact of PCI on the outcome of a consecutive series of women with AMI or ACS treated with an aggressive invasive or medical strategy.

Population and methods: from Jan 1996 to Dec 2001, 983 consecutive women of 73±11 years of age were admitted to CCU for AMI (n=456) or ACS (n=527). PCI was performed in 581 patients (240 AMI and 341 ACS). Case load in our institution is about 120 PCI/year/operator.

Results: sixty-five patients died during hospitalization (6.6%). We analyzed the relationship between mortality and the following independent variables a) clinical presentation b) PCI therapy c) age (Table).

	AMI vs ACS	PCI vs no PCI	Age
ODDS RATIO	1.913	0.344	1.023
- 95% CL	1.106	0.189	0.997
+ 95% CL	3.310	0.625	1.050

Conclusion: women treated with PCI had a significant lower in-hospital mortality than women treated with an aggressive medical therapy. The benefit obtained with PCI was not influenced by the age of patients. Mortality was higher in patients with AMI.

P1806 Availability of on-site interventional facilities and clinical outcomes in patients acute coronary syndromes. Results from an Italian registry

F. Ottani[1], M. Galvani[2], P.C. Pavesi[3], F. Bologna[4], O. Gaddi[5], P. Alboni[6] on behalf of AI-CARE 2 Investigators. [1]*Fondazione Sacco, Cardiovascular Research Unit, Forlì, Italy;* [2]*G.B. Morgagni, Cardiology, Forlì, Italy;* [3]*Ospedale Maggiore, Cardiology, Bologna, Italy;* [4]*Ospedale degli Infermi, Cardiology, Rimini, Italy;* [5]*Ospedale S.Maria Nuova, Cardiology, Reggio Emilia, Italy;* [6]*Ospedale Civile, Cardiology, Cento, Italy*

Aims: to compare management and clinical outcomes in hospitals stratified by the availability of on-site interventional facilities in a registry of consecutive patients admitted to italian hospitals for an acute coronary syndrome. Methods and Results: we studied 1074 patients enrolled in 25 hospitals in the Emilia-Romagna area over a 2-month period (Jan-March 2000). Only initial admissions were counted. Forty-nine percent of patients presented with ST elevation/BB (58% treated with a reperfusion strategy), 27% with ST depression, and 24% with T-wave inversion or a normal ECG. Thirteen percent of hospitals had 24-h, 30% day-only, and 57% no on-site interventional facilities. Six-month rates of coronary angiography (64%, 63%, 50%) and revascularization (46%, 47%, 33%) were higher in hospitals with increasing access to on-site facilities (P=0.0001). The presence of a 24-h on-site facility was the strongest predictor of angiography during the index admission (odds ratio 2.2, 95% CI 1.4-3.5). Only 15.3% of coronary angiographies were performed within 72 h from admission; 9% of patients received GPIIB/IIIA blockers. There were no major differences in patient outcomes during the index admission when hospitals were stratified by availability of on-site catheterization (in-hospital mortality 7.0%, 5.0%, and 7.0% respectively P=NS). Adjusted 6-month mortality was similar between groups of hospitals (odds ratio for hospitals with 24-h facilities 1.26 [0.76–2.08] and odds ratio for day-only 0.65 [0.35–1.18] compared to no availability). Conclusions: there is a significant variation in procedure use by the availability of on-site interventional facilities with no major differences in patient outcomes. Few patients however are aggressively treated with optimal anti-thrombotic therapy and early revascularization according to current clinical guidelines.

P1807 Acute myocardial infarction: is immediate surgical revascularisation justified?

J.M. Albes, M. Gross, U. Franke, H. Brandes, J. Wippermann, T. Cohnert, T.H. Wahlers. *University Hospital Jena, Cardiac-, Thoracic-, Vascular Surgery, Jena, Germany*

Background: Hemodynamic compromise and crescendo-angina require acute surgical intervention when PTCA measures alone are not successful. We stratified the risks of acute revascularisation with and without MI in contrast to urgent and elective bypass surgery.

Methods: 517 patients were investigated. 39 patients underwent acute revascularisation because of enzyme or ECG proven MI accompanied by crescendo-angina, hemodynamic compromise, or both. Necessity of intraaortic balloon pumping (IABP), temporary hemofiltration (CVVH), early mortality (EM), Cleveland-Score (CS), and EuroSCORE (ES) were compared with 32 emergent, 61 urgent, and 385 elective patients without MI, who underwent isolated coronary revascularisation. Multivariate risk factor analysis was performed.

Results: EM of the MI cohort was 15.4%, while 15.6% of the emergent, none of the urgent, and 2.1% of the elective patients deceased early. IABP was necessary in 49% MI patients, while performed in 28% emergent, 6.6% urgent, and in 2.6% elective cases. CVVH was performed in 29% of the MI, 15% of the emergent, 4.9% of the urgent, and in 3.4% of the elective patients. Preoperative risk factors, such as stability (stable, unstable, resuscitation), sex, body mass index, diabetes mellitus, and renal insufficiency did not influence EM but necessity of IABP and CVVH. CS was significantly higher in the MI group (8.5) than in the emergent cohort (5.8) while ES did not diclose differences between MI (9.6) and emergent patients (8.2). Both scores exhibited significantly higher values in the two immediate groups when compared to urgent (CS: 2.2; ES: 5.3) and elective (CS: 2.0; ES: 4.6) cases.

Conclusions: Patients undergoing immediate revascularisation had an elevated risk to die early independent from the presence or absence of acute MI. In almost two third of the patients with acute MI temporary CVVH was necessary implying a severely reduced perioperative hemodynamic condition. Although it should be addressed as a separated high risk group immediate revascularisation in the presence of acute MI is not contraindicated.

P1808 Rescue percutaneous thrombectomy catheter is less beneficial in acute myocardial infarction with large vessel diameter

K. Yamaguchi, Y. Hiasa, T. Nada, T. Ogata, T. Takefumi, S. Hosokawa, K. Kishi, R. Ohtani. *Tokushima Red Cross Hospital, Cardiology, Komatsushima, Japan*

Background: Rescue Percutaneous Thrombectomy (PT) catheter is a new simple thrombectomy system to retrieve thrombi from the culprit lesion. The aim of this study was to identify clinical and anatomical characteristics, which may not benefit from Rescue PT catheter in patients with acute myocardial infarction (AMI).
Methods: Forty-nine consecutive inferior AMI patients, who had extensive thrombi in the diseased lesion and underwent primary coronary angioplasty, were enrolled in this study. TIMI frame count (TFC) was measured immediately after using Rescue PT catheter. We defined "inadequate reflow" as TFC>40 according to the previous report. The patients were divided into two groups: TFC =40 or less group (n=36) and TFC>40 group (n=13). Univariate and multivariate analysis were performed to identify clinical and anatomical factors in predicting "inadequate reflow" immediately after using Rescue PT catheter.
Results: There were significant differences between the two groups with regard to smoking, early reperfusion, bend lesion, and vessel diameter. In a multivariate model, large vessel diameter was the only independent predictor for "inadequate reflow" ($p<0.05$).

	TFC≤40 (n=36)	TFC>40 (n=13)	P value
Smoking	15 (42%)	10 (77%)	0.03
Reperfusion time (≤2h)	14 (39%)	0	0.01
Bend lesion (>45°)	16 (44%)	10 (77%)	0.04
Vessel diamter (mm)	3.0±0.5	4.0±0.4	<0.01

Conclusion: Large vessel diameter is independently associated with "inadequate reflow" immediately after using Rescue PT catheter in patients with inferior AMI.Patients Characteristics

CARDIOVASCULAR DISEASES IN THE 21ST CENTURY: THE CHALLENGES FOR NURSES

P1809 Why patients with myocardial infarction don't choose ambulance

I. Johansson, E.S. Eva Swahn. *University Hospital, Dept of Cardiology, Linköping, Sweden*

Background: The Swedish guidelines state that ST-elevation myocardial infarction (STEMI) patients should be admitted to hospital < 45 minutes and thrombolysis be given < 90 minutes after start of symptoms. Most ambulances have ECG-possibilities and telecommunication with the hospital. It's thus possible to start early prehospital treatment. The patients must therefore be aware of the advantages of the medical care that paramedics can offer. Earlier studies have shown that only 30% of patients with chest pain arrive at the emergency ward in ambulance. The aim of this study was to explain why the majority of patients with acute MI do not call emergency number 112.
Methods: 110 CCU-patients hospitalized because of acute MI filled in a survey regarding their thoughts and acts before the present hospital admittance.
Results: The patients stated in average 3 symptoms in connection with falling ill, where the most common symptom was chest pain. The dominating character was "oppression" (42%). They experienced their symptoms as "anxieting" (41%), "discomforting" (36%) and "troublesome" (31%). 39% delayed >2 hours before seeking medical care. Anyhow 38% decided to seek already < 30 minutes. Altogether 77% considered their symptoms to be related to the heart. Of the rest, 65% delayed >1 hour. 62% arrived by ambulance directly to the hospital, but only 6 patients called themselves. Mostly the spouse (40%) contacted the alarm centre. Those with symptoms for a shorter time, and being at home chose the ambulance more frequently than those who fell ill somewhere else and had symptoms for a longer time. The most common reason for not choosing ambulance was the feeling that " I am not sick enough " (43%), "I never thought about it" (38%) or "Unnecessary to order ambulance" (26%). In a multiple regression analysis the reasons for not choosing ambulance turned out to be: daily work, tiring symptoms and "this is probably not serious and will pass". Predictor for choosing ambulance was nausea/coldsweat, unbearable or cramping pain and high pain-intensity. STEMI-patients choosing ambulance, reduced their delay-time to reperfusion by 21 minutes.
Conclusion: The ambulance is not an option for patients unless they feel really sick. The time gain is anyhow of great importance for those STEMI-patients choosing the ambulance.

P1810 Morbidity and mortality in patients with myocardial infarction complicated by nosocomial infection

B. Caramelli, P.C. Grandini, M. Monachini, T.M.V. Strabelli, M.A.S. Teixeira, D.E. Uip. *University of Sao Paulo Medical School, Heart Institute (InCor), Sao Paulo, Brazil*

Introduction: Complications of myocardial infarction (MI) are responsible for a significant percentage of deaths. Information regarding the importance of nosocomial infection as a complication of MI is lacking. This study analyzed the incidence and the impact of infectious complications of MI on morbidity and mortality as well as its relation with the invasive procedures undergone in this setting.
Methods: This was a retrospective and clinical study, performed by the analysis of medical records. The population of the study was constituted by patients admitted with a confirmed diagnosis of MI, from January 1996 to December 1999, at the Coronary Care Unit from the Heart Institute of the University of Sao Paulo Medical School in Brazil.
Results: 1,227 patients were analyzed, 60 (4.89%) of them fulfilled the diagnostic criteria of a nosocomial infection complicating MI (Infected Group). The other 1,167 patients constituted the Control Group. Univariated analysis indicated that the mean age (67.5 and 62.6 years old, p=0.003), the length of hospital stay (26.6 and 12.0 days, p=0.0000) and mortality (45% and 12.25%, p=0.0000) were greater in the Infected Group than in the Control Group respectively. Predictors of mortality assessed by multivariate analysis were age and being part of the Infected Group. Every 10 years increment on age was associated with an odds ratio for mortality of 1.31 for the Infected Group and 2.15 for the Control Group. For a patient with 60 years old, the odds ratio for mortality is 40.01 if in the Infected Group and 7.71 if in the Control Group. In the Infected Group, the average of invasive procedures done per patient was 3.38 and correlated to Killip class and mortality. The most frequent infections were pulmonary (63.3%), urinary tract (36.6%) and blood (8.3%).
Conclusion: Nosocomial infection, as a complication of myocardial infarction has a great impact on morbidity and mortality in patients admitted in the coronary care unit.

P1811 Status of CPR in the Swedish population in the year 2000. A nation wide survey

A. Axelsson[1], A-B. Thorén[2], S. Holmberg[2], J. Herlitz[2] on behalf of A Axelsson. [1]*Halmstad University, School of Social and Health Sciences, Halmstad, Sweden;* [2]*Sahlgrenska University Hospital, div. of Cardiology, Göteborg, Sweden*

Aim of this study was to determine the proportion of cardiopulmonary resuscitation (CPR) trained adults in Sweden and the non-trained population's willingness to be trained in CPR.
Methods: In a nation wide survey 5000 randomly selected adult inhabitants, aged 18 to 79 years, were approached with a postal questionnaire, resulting in 3159 responders. Sweden has 6.5 million inhabitants in the current ages, the sample was randomly selected by the Swedish person and address register and stratified to correlate to the population's geographically distribution. The questionnaire was constructed by the investigators and based on previous questionnaires used by the research-group.
Results: The mean age was 46 (± 16) years and 54% of the respondents were women. 11% respondents were born outside Sweden and 9% could be regarded as professionals (health and rescue personnel). 45% (n=1417) had been trained in CPR and nearly half had been trained more than once and 52% reported having trained CPR 1996 or more recently. The most common reasons given for CPR education was job requirement and general interest. Among the non-trained responders 50% was willing to learn CPR (both chest compression and mouth-to-mouth ventilation). Of the 847 respondents reporting unwilling or unsure to learn CPR 12% were willing to learn CPR if only chest compressions were included. Regarding the reason not to be trained, it was most common not to know about the possibility to have a CPR course (26%) and 14% did not know where or how to receive CPR training. 21% stated that they had not had the interest of learning CPR. 416 respondents (13%) reported having witnessed a cardiac arrest and 4% (120) reported having performed CPR without professional obligations.
Conclusion: From this survey it can be assumed that about 45% of the adult Swedish population is trained in CPR and 4% have used their knowledge in a situation of cardiac arrest. Half of the non-trained population is willing to learn CPR but it is common not to know about the possibilities to receive CPR training. The Swedish population is highly willing to learn CPR but the community and the educating organisations should intensify their information about the possibilities to receive CPR training.

P1812 Anxiety and well-being in first-time coronary angioplasty patients and repeaters

M.J. Lenzen. *Erasmus MC, cardiology, Rotterdam, Netherlands*

Introduction: Preparatory information before an invasive procedure has been shown to have positive effects (e,g, on recovery, anxiety and well-being). However, preparation of patients for a repeat procedure is hardly investigated. The question is whether these patients benefit from the same preparatory information. Aims: To determine whether there are differences in terms of anxiety and well-being between patients undergoing their first Percutaneous Transluminal Coronary Angioplasty (PTCA) and those undergoing a repeat PTCA, and secondly to gain information on how patients prepare themselves for a repeat PTCA. Design: Descriptive correlational study with a quantitative and qualitative research component. Method: First-time PTCA patients (n=46) and re-PTCA patients (n=40) were asked to complete three psychological self-report questionnaires (HADS, HPPQ and VAS) the evening before the procedure. Five re-PTCA patients were interviewed the day after the procedure. Results: The anxiety scores (HADS and VAS) show a trend towards a worse condition in the re-PTCA group: HADS 6.5 versus 5.0 and VAS 4.0 versus 2.6. The HPPQ reveals a slightly lower well-being in re-PTCA patients: 18.0 versus 19.0. These differences between the two groups are not statistically significant. Once the interview data were coded, four themes were apparent, namely: recurrent symptoms, information, experience and future prospects. Conclusion: A trend is seen towards a worse condition in the re-PTCA group with respect to anxiety and well-being. However the observed differences are not significant, they seem to be clinically relevant. The interviews point out that the return of symptoms and future prospects, rather than the procedure itself, are an important part in preparing for a repeat intervention. This aspect is currently no part of the provided preparatory information. Future research will have to determine the most beneficial method of preparing these patients (e.g. tailored preparation, emotional support, coaching).

P1813 Early discharge after coronary angiograms using the femoral approach

J. Boggiano, A. Fernandez, E. Torresani, S. Brieva, D. Chambre, N. Weisshein, G. Martino, J.H. Leguizamon. *Clinica Santa Isabel, Interventional cardiology, Buenos Aires, Argentina*

Femoral approach is stablished as a safe one for coronary angiograms; however, the consecutive bed-rest increases hospital stay and costs.
Objective: To report the incidence of events in patients submitted for coronary angiograms (CA), using femoral approach (FA) with early hospital disharge (EHD) 3 hours after the procedure.
Material and Methods: We analyzed 300 consecutive patients (51.5 years, 86% male and 87,5 kg mean weight) submitted for CA, using FA (6 french introducers), heparin dose 1000 UI and EHD, in the period 01/2001 to 01/2002.
Exclusion criteria: Age >75 years, coronary angioplasty, manual compression>15 minutes to achieve an effective groin hemostasis and refusal of this technique by the refering physician. After 3 hours bed-rest, all pts. were discharged one hour after a professional-asisted walk. We report the following clinical events: 1- Ischemic: angor or death; 2- Hemorrhage: minor and major using TIMI criteria.
Results: No patients presented ischemic events or major hemorrhage. 98,66% (n=296) of this population have an uncomplicated walk after 3 hours bed-rest and hospital discharge one hour later. One patient was excluded from analysis due to severe hypotension. Only 3 patients (1%) suffered one minor hemorrhagic event, all well managed with additional local compression. No seudoaneurisms were reported.
Conclusion: Early discharge after coronary angiograms using the femoral approach emerged as an effective and safe strategy, reducing hospital stay and costs.

P1814 Ambulatory blood pressure monitoring: nurse management

S. Mancini, R. Rossini, M. Amadori, R. Gesi, B. Orsini, S. Pasetti, I. Marchetti. *University of Pisa, Cardiothoracic Dept, Pisa, Italy*

Background: Ambulatory blood pressure monitoring (ABPM) is relatively easy to use, and yields many more BP parameters than do clinic BP measurements. However, it might be inaccurate for a variety of reasons: incorrect technique, operator error, and environmental factors. The patient's compliance may significantly limit the feasibility of ABPM. A nurse assistant can easily be trained to follow a standardized procedure. The aim of the study was to evaluate the efficacy of a nurse management of ABPM.
Methods: We studied 466 patients (358 male; 56±11 years) submitted to ABPM in the last two years. We have experienced a nurse management of ABPM in the last 12 months (N = 253 pts). All nurses had been previously undergone to a specific training, which allowed the practice of both the instrument and the software. A standard protocol was then performed in order to obtain in each patient the accurate identification of clinical history, risk factors (such as age, gender, family history, diabetes, smoke, dislipidemia and hypertension) and related diseases (such as coronary artery disease, cerebro-vascular disease and peripheral arterial disease). To obtain the highest patient compliance and to reduce the incidence of incomplete measurements, each patient was adequately informed about the exam characteristics.
Results: A significant reduction of the mechanical problems of the instruments was obtained, as compared with the previous year (2% vs 19%; $p<0.05$). Moreover, also the number of not diagnostic exams (correct measurements <85%), due to technical problems or lack of patient compliance, was significantly reduced (7% vs 25%; $p<0,05$). All the obtained data were stored in a database, thus available for medical epidemiological and statistical analysis.
Conclusions: The management of ABPM by trained nurses seems to improve the quality of the test, to increase the patient compliance and to collect all the data available to further statistic analysis.

P1815 SCAN: Smoking Cessation by Ambulant Nurse-intervention

S. Johansen[1], L. Eksten[2], L. Pedersen[2]. [1]*Hilleroed Sygehus, Intensive care unit 0531, Hilleroed, Denmark;* [2]*Hilleroed Sygehus, Medical dept. B, Section of Cardiology, Hilleroed, Denmark*

SCAN: Smoking Cessation by Ambulant Nurse-intervention
A randomised study of the effect of a smoking cessation programme in patients admitted to a coronary care unit with a 12 months' follow-up.
Smoking is still the most significant cause of ischemic heart disease. In Denmark approximately one third of the adult population can be classified as smokers. The purpose of this study was to evaluate the effect of a systematic intervention programme. The smoking cessation programme followed the nationally approved guidelines.
Material and methods: SCAN is a randomised,prospective intervention study of the effect of a systematic smoking cessation programme. The entire programme was conducted by specially trained nurses.
During a period of two years all patients admitted to the coronary care unit were screened.
Smokers motivated for participation in the study were randomised into either intervention group (I) or control group (C). All patients in the I-group were offered five individual consultations with a nurse specially trained to give information about smoking cessation.
All patients in the I and C group received the usual standard information at the department about cardiac risk factors and possible prophylactic precautions.
All participants were contacted by telephone 3, 6 and 12 months following discharge. None of the nurses from the intervention programme were involved with this part of the study.
Results: Among the 3.982 screened patients 1.175 (29,5%) were smokers. Out of those 105 (9%) fulfilled the inclusion criteria and were randomised into either group I or C respectively. Smoking cessation after 12 months in the two groups were as follows: 63% in group I and 50% in group C respectively. This result showed a insignificant difference between the two groups.
Conclusions: The proportion of smokers in the screened population was lower than expected.
Only one out ten smokers was motivated for participation in the study.
The lack of effect of the intervention programme could be explained by the fact that all patients randomised were highly motivated which can be supported by the relatively high numbers of non-smokers in both groups after 12 months.
It is our recommendation that future studies should focus on the prognosis of the 91% of smokers who were unwilling to participate in a systematic intervention programme.

P1816 Are cardiac rehabilitation programmes needed in hospital practice?

C.J. Koppelaar, W.J.M. Scholte op Reimer, E. Boersma, J.W. Deckers.
Erasmus Medical Centre Rotterdam, Dept. of Cardiology, Room Bd377, Rotterdam, Netherlands

Background - Cardiac rehabilitation has shown to be beneficial and is stimulated through international guidelines. Programmes that define the delivery of cardiac rehabilitation are available for outpatient care, but not for the hospital phase.
Aim - To assess the need for inpatient cardiac rehabilitation programmes, we investigated the extent to which cardiac rehabilitation guidelines are followed during hospital care.
Methods - We included 83 consecutive patients hospitalised for myocardial infarction, angina or first diagnosis of heart failure. To assess whether topics in the guidelines on cardiac rehabilitation (secondary prevention, physical exercise, handling chest pain, and psychosocial support) were addressed during hospitalisation, activities related to cardiac rehabilitation were abstracted from medical and nursing charts, after hospital discharge. To assess a patients's need for cardiac rehabilitation (i.e., presence of cardiovascular risk factors or anxiety as measured with the Hospital Anxiety Depression Scale) patients were asked to fill out a questionnaire on the 5th day of hospitalisation.
Results - Of the 64 patients (77%) who had cardiovascular risk factors, 52% of them were provided with information, advice or the offer to start with a guided programme. For example, support was registered in 58% of 45 smokers, 43% of 28 patients with a high cholesterol level (>= 5 mmol/L), 2% of 47 patients who are overweight (BMI >= 25 kg/m^2), and 2% of 48 patients with a sedentary lifestyle. In 99% of all patients, information, advice or guidance regarding exercise tolerance was documented. For instance, in 88% the presence or absence of chest pain was registered, and progress in mobilisation was considered in 51% of all patients. With regard to handling chest pain, 16 patients (19%) reported that they would not take nitro-glycerine in case of chest pain. The psychosocial situation was documented in 54% of all patients. However, none of the 19 patients (20%) who experienced anxiety received the attention needed.
Conclusion - Currently, cardiac rehabilitation during hospitalisation is mainly focussed on physical recovery. Insufficient attention is given to patients' psychosocial situation, handling chest pain, and cardiovascular risk factors. Our results show which areas of in-hospital cardiac rehabilitation require additional attention. We recommend the development of multidisciplinary inpatient cardiac rehabilitation programmes to meet the needs of in-hospital patients.

P1817 Impact of an educational program through a new nurse heart failure knowledge score

J. Roncalli, A. Pathak, L. Spinazze, S. Mazon, J. Fourcade, P. Massabuau, J.M. Fauvel, M. Galinier on behalf of CEPIC: Centre d'Éducation pour l'Insuffisance Cardiaque. *CHU Rangueil, Cardiologie Dept., Toulouse, France*

Background: Multidisciplinary heart failure disease management improve clinical outcomes in congestive heart failure patients. Evaluation and validation of educational intervention remain a controversial and difficult process. Establishment of a "knowledge score" could provide some insight about patients need and help practitioners in prescribing educational intervention. The aim of this pilot study was to evaluate a new score of knowledge in heart failure patients before and after education session.
Method: In this study, 21 patients (mean age: 56±18 years, 71.4% of male, 29.4% of left ventricular ejection) attended an education session of one day about heart failure. A multidisciplinary program was established in collaboration with physician, nurse, dietician, physiotherapist and medical social worker. Using a self-questioning data sheet prepared in collaboration with nurses leading the educational program, we analysed six major topics: knowledge about disease, clinical evaluation (signs and symptoms of deterioration of heart failure), daily physical activity, diet, medical follow-up and medical treatment. Multiple choice questions were used to evaluate level of knowledge for each topics. Each answer was rated with points to obtain an end score from 0 to 20 for each topic. Evaluation was made before and one month after heart failure education session.
Results: Evolution of the knowledge score after the education program is presented for each topic as follow (before vs after): knowledge of disease (9.45 vs 18.33), clinical evaluation (7.12 vs 13.50), physical activity (6.74 vs 11.60), diet (7.57 vs 14.36), medical follow-up (12.19 vs 17.95) and medical treatment (7.98 vs 14.43). All these results were statistically significant ($p<0.0001$).
Conclusion: This pilot study confirms that i) our knowledge score is feasible, ii) the level of knowledge about heart failure in patients of South West of France is low, iii) heart failure education program improves significantly knowledge of our patient as assessed by this score. A validation of this knowledge score remains necessary with larger study.

P1818 Individual quality of life assessment in adults with congenital heart disease

P. Moons[1], E. Raes[1], K. Van Deyk[1], S. De Geest[2], M. Gewillig[3], W. Budts[3]. *[1]Catholic University of Leuven, Centre for Health Serv. & Nursing Res., Leuven, Belgium; [2]University of Basel, Institute of Nursing Science, Basel, Switzerland; [3]University Hospitals of Leuven, Division of Congenital Cardiology, Leuven, Belgium*

Many patients with congenital heart disease experience the heart defect intruding on their daily life. The aim of this study was to examine quality of life (QOL) and its individual determinants in adults with congenital heart disease.
Methods: This cross-sectional study included 134 patients (67.2% males). QOL and its determinants was measured using a Visual Analogue Scale (VAS) ranging from 0 to 100, and the SEIQoL-DW, respectively. This latter instrument comprises 3 successive steps: (1) nomination by the respondent of the 5 areas most important for his/her QOL, (2) rating of the actual status for each specified area on a VAS from 0 to 100, and (3) quantification of the relative importance of each nominated area in comparison with each other, using a 5-segment disk.
Results: Patients perceive their overall QOL as good (VAS median 80; Q1=73; Q3=86). The SEIQoL-DW identified 13 areas affecting patients' QOL. The table describes the percentage of patients reporting the respective areas (step 1), the median actual status (step 2), and the relative importance for each cue (step 3).

individual quality of life measured usin

	Step 1	Step 2	Step 3
Significant others	73.9%	85.5	23%
Job/education	51.5%	68	18%
Leisure	50%	74	17%
Health	49.3%	76	23%
Social network	49.3%	75	20%
Personal values with respect to others, life and society	47%	79	20%
Financial means and material well-being	29.9%	67	16%
Psychological well-being	14.2%	76	19%
Capacities and impediments due to the heart defect	11.9%	49	17%
Future	10.4%	80	20%
Health care	3%	87.5	16.5%
Nourishment	3%	76	12%
Pets	2.2%	91	27%

Conclusion: Individual QOL assessment in adults with congenital heart disease provides a detailed picture of issues relevant for QOL. These issues should be addressed in comprehensive health care, aiming at improving patients' QOL.

MYOCARDITIS AND PERICARDITIS

P1819 Celiac disease associated with autoimmune myocarditis

C. Chimenti[1], M. Pieroni[1], L. Cuoco[2], R. Verardo[1], N. Gentiloni[2], G. Gasbarrini[2], A. Maseri[3], A. Frustaci[1]. *[1]Catholic University, Department of Cardiology, Rome, Italy; [2]Catholic University, Internal Medicine, Rome, Italy; [3]Istituto San Raffaele, Department of cardiology, Milan, Italy*

Background: Both celiac disease (CD) and myocarditis can be associated with systemic autoimmune disorders; however the coexistence of the two entities has never been investigated while its identification may have clinical impact.
Methods: We screened the serum of 187 consecutive patients (pts) with myocarditis (118 M, 69 F, mean age 41.7±14.3 years) for the presence of cardiac autoantibodies, anti-transglutaminase (IgA-tTG) and anti-endomysial antibodies (AEA). IgA-tTG and AEA positive pts underwent duodenal endoscopy and biopsy and HLA analysis.
Results: Thirteen of the 187 pts were positive for IgA-tTG and 9 of them (4.4%) for AEA. These 9 pts had iron-deficient anemia and duodenal endoscopic and histologic evidence of CD. CD was observed in 1/306 (0.3%) of normal controls ($p<0.003$). In CD pts myocarditis manifested with heart failure in 5 pts and ventricular arrhythmias (Lown class III-IVa) in 4. At histology a lymphocytic infiltrate was present in 8 pts and giant-cell myocarditis in one; circulating cardiac autoantibodies were positive and myocardial viral genomes negative in all. HLA of pts with CD and myocarditis was DQ2-DR3 in 8 pts and DQ2-DR5(11)/DR7 in one. The 5 pts with myocarditis and heart failure received immunosuppression (azathioprine 1 mg/Kg/daily for 5 months and prednisone 1.25 mg/Kg/daily for 4 weeks tapered to 0.33 mg/Kg/daily for 5 months) and gluten-free diet with recovery of cardiac volumes and function. The four pts with arrhythmias, put on gluten-free diet alone, showed arrhythmias' improvement (Lown Class I).
Conclusions: A common autoimmune process toward antigenic components of myocardium and small bowel can be found in >4% of pts with myocarditis. In these pts immunosuppression and gluten-free diet can be effective therapeutic options.

P1820 Immunomodulation of murine Coxsackie B3 myocarditis with interleukin-15

P.L. Schwimmbeck, B. Bigalke, A. Wrusch, F. Spillmann, M. Noutsias, M. Pauschinger, C. Tschöpe, H.P. Schultheiss. *Benjamin Franklin Hospital, Dept. of Internal Medicine/Cardiology, Berlin, Germany*

Cytokines play an important role both for the initiation and perpetuation of viral myocarditis. We examined the influence of IL-15, an important proinflammatory cytokine, on the course of myocarditis in the Coxsackie B3 (CB3) infected mouse.

Methods: Eight-week-old male BALB/c mice were intraperitoneally infected with 500000 plaque forming units of CB3, strain Nancy, and subsequently treated with daily injections of recombinant murine IL-15 (330ng) or an equivalent dose of IL-15 fusion protein (250μg), which inhibits the physiological effects of IL-15. After twelve days the slope of the left ventricular pressure pulse was measured with a Millar-tip catheter in the anesthetized and respirated animal. Uninfected and infected animals without further treatment served as controls. For immunohistological evaluation cryosections of the hearts were prepared and stained with monoclonal antibodies against several leukocyte surface antigens.

Results: Infected and uninfected respectively infected and IL-15 treated animals showed significant differences in regard to body weight, left ventricular function and cellular infiltrates in the myocardium (see table). Treatment of infected animals with IL-15 resulted in an almost normal body weight, whereas animals that were infected and injected with IL-15 fusion protein showed the lowest body weigths. Similar results were seen for the slope of the left ventricular pressure pulse as a parameter for the left ventricular function.

	Uninfected (n=14)	Infected (n=14)	Infected + IL-15 (n=6)	Infected + IL-15 fusion protein (n=6)
body weight (g)	26.8 ± 2.5	20.11 ± 2.3	24.5 ± 3.3*	19.4 ± 0.8**
dP/dt max (mmHg)	5928.7 ± 1206.1	4377.8 ± 953.8	5862.2 ± 1174.9*	3871.5 ± 471.9**
CD4-positive cells (cells/hpf)	0.006 ± 0.015	0.877 ± 0.3	0.544 ± 0.16*	0.619 ± 0.33**

*p<0.05 compared to infected, **p<0.05 compared to uninfected

Conclusions: Treatment with IL-15 showed a positive effect on the clinical course of CB3 induced murine myocarditis, whereas inhibition of the intrinsic IL-15 with fusion protein had a detrimental effect.

P1821 Beneficial effects of interleukin-4 on the regulation of cardiac function, MMP-3 and TIMP-1 expression in murine myocarditis by the induction of TGF-β1

S. Leschka, J. Li, P.L. Schwimmbeck, M. Noutsias, F. Spillmann, K. Hoppe, H.P. Schultheiss, M. Pauschinger. *University Hospital Benjamin Franklin, Department of Cardiology & Pneumology, Berlin, Germany*

Cytokines are involved in the regulation of myocardial extracellular matrix remodelling. Aim of this study was to analyze the in vivo roles of IL-4 for the mRNA expressions of myocardial metalloproteinase-3 (MMP-3), tissue inhibitors of MMPs (TIMP-1) and TGF-β1 during coxsackievirus B3 (CVB3; Nancy strain; 500000 PFU)-induced myocarditis in BALB/c mice. Myocardial samples from infected (n=8) and uninfected control (n=8) BALB/c mice under the treatment of murine rIL-4 (200 ng/mouse/day; i.p.) as well as infected (n=8) and uninfected control (n=8) mice without treatment at ten days after coxsackievirus B3 inoculation were analyzed by semi-quantitative RT-PCR. In viral infected mice, left ventricular dysfunction, upregulated MMP-3 and downregulated TIMP-1 were demonstrated. IL-4 treatment led to significant improvement of left ventricular function, suppression of MMP-3 mRNA induction as well as the increment of TIMP-1 mRNA. In addition, the effects of IL-4 treatment was associated with an significant induction of TGF-β1 expression (Table).

	MMP-3	TIMP-1	TGF-β1
control (n=8)	0,66±0,24	1,33±0,29	0,74±0,11
infected (n=8)	1,21±0,22*	0,34±0,11*	1,18±0,13*
infected+IL-4 (n=8)	0,85±0,05**	0,89±0,07**	1,64±0,04**

*p<0,05 vs control; **p<0,01 vs infected.

Conclusions: The suppression of MMP-3 induction and the increment of TIMP-1 expression may contribute to the improvement of left ventricular function through the upregulation of TGF-β1 by IL-4 mediated immunomodulation.

P1822 Beneficial effects of gene-transfered interleukin-10 on autoimmune myocarditis in the rat

N. Nakazawa[1], K. Watanabe[2], M. Ma[2], W.M. Imam[2], T. Ohnuki[3], T. Nagatomo[3], M. Kodama[4], Y. Aizawa[4]. *[1]Niigata University, Faculty of Med, School of Health Sciences, Niigata, Japan; [2]Niigata College of Pharmacy, Clinical Pharmacology, Niigata, Japan; [3]Niigata College of Pharmacy, Pharmacology, Nigata, Japan; [4]Niigata University, Division of Cardiology, Niigata, Japan*

Effectiveness of the immunosupressive therapy of myocarditis is controversial, although it has attracted a great deal of attention. Interleukin (IL)-10 has a variety of immunomodulatory properties. We examined effects of murine IL-10 (mIL-10) gene transfer on the heart failure induced by experimental autoimmune myocarditis in the rat. Nine-week-old Lewis rats were immunized with pig cardiac myosin (day 0). These immunized rats developed myocarditis during day 14 to 21 with sever inflammatory changes. The morbidity of this experimental autoimmune myocarditis was 100% in the rats. A plasmid vector expressing mIL-10 cDNA (800 μg/rat) was transferred into the tibialis anterior muscles by electroporation and control rats received empty plasmid. Because of the limitation of its expression duration, we used three times applications of electroporation (5 days before immunization, day 4, and day 13 after immunization). The 21-day survival in rats treated with mIL-10 cDNA was higher (20/20 = 100%) than that in the control group (18/24 = 75%). Furthermore, mIL-10 treatment significantly attenuated myocardial lesions and improved hemodynamic parameters on day 21. The 49-day survival in mIL-10-treated rats was higher (10/10=100%) than that in the control group (8/10=80%). Hemodynamic parameters were also improved by mIL-10 treatment. These findings showed that gene transfer into muscle by electroporation in vivo is an effective means of delivery of IL-10 for the treatment of heart failure induced by autoimmune myocarditis and IL-10 does not delay the onset of autoimmune myocarditis but suppresses it.

P1823 Cardiac magnetic resonance imaging for diagnosis of viral myocarditis – significance of MRI-guided endomyocardial biopsy

I. Janzen[1], B. Schwaab[2], G. Schneider[3], K. Altmeyer[3], R. Kandolf[4], M. Böhm[1], B. Hennen[1]. *[1]Universitätskliniken des Saarlandes, Innere Medizin III, Homburg/Saar, Germany; [2]Curschmann-Klinik, Timmendorfer Strand, Germany; [3]Universitätskliniken des Saarlandes, Abteilung für Radiodiagnostik, Homburg/Saar, Germany; [4]Universitätsklinikum, Abteilung für Molekulare Pathologie, Tübingen, Germany*

Purpose: Definite diagnosis of myocarditis is only possible by histological and molecularpathological analysis of endomyocardial biopsies. As reported an estimated number of 17 biopsy specimens are required to achieve a sensitivity of 80% for diagnostic of myocarditis if unguided biopsy sampling is performed. In this study, inflammatory myocardium was prospectively visualized by MRI. To minimize the sampling error, target-specific biopsies were taken from left ventricular areas as detected by MRI.

Methods: In 42 patients with suspected myocarditis, ECG-triggered cardiac MRI studies were performed using a 1,5 T scanner. T2-weighted images included a single-shot "HASTE"-sequence and a fat-suppressed "inversion recovery"-sequence. T1-weighted images were performed in breath-holding technique, unenhanced, and after gadolinium injection. The MRI was considered positive if myocardium with increased signal intensity was detected in T2-weighted images with and without fat-suppression. In each patient 4 left ventricular biopsies were taken from the suspected area. Biopsies were considered positive in case of acute myocarditis (with myocyte necrosis), in case of chronic myocarditis (with an increased number of T-lymphocytes and/or macrophages with or without viral genome) or in case of virus persistence without cellular inflammatory reaction. Viral genome in myocardial biopsies were detected by PCR and in situ-hybridisation. Biopsies without an increase of inflammatory cells and without viral genome were considered negative.

Results: Acute myocarditis with evidence of viral genome was detected once; chronic myocarditis was diagnosed in 14 patients (33%), with evidence of viral genome in 11 cases. Virus persistence was observed in 10 patients (24%). Biopsies were negative in 17 patients (41%). MRI studies were positive in 14 of 15 patients (93%) with acute or chronic myocarditis proven by endomyocardial biopsy. MRI study was negative in 11 of 17 patients with negative biopsy. MRI revealed a sensitivity of 93% and a specifity of 52% to prove myocarditis resulting in a negative predictive value of 93% and a positive predictive value of 52%.

Conclusion: Cardiac MRI serves as a noninvasive screening method in suspected myocarditis. MRI facilitates myocardial biopsy of topographically defined foci. The MRI-guided endomyocardial biopsy reduces the otherwise inevitable sampling error and minimizes effectively the number of biopsy specimens needed to get the definite diagnosis of myocarditis with high sensitivity.

P1824 Lone HCV myocarditis responsive to immunosuppressive therapy

M. Pieroni[1], C. Chimenti[1], F. Calabrese[2], R. Verardo[1], G. Thiene[2], A. Maseri[3], A. Frustaci[1]. [1]*Catholic University, Department of Cardiology, Rome, Italy;* [2]*University of Padua, Department of Pathology, Padua, Italy;* [3]*Istituto San Raffaele, Department of cardiology, Milan, Italy*

Objectives: This study analyses the causal role of HCV infection in patients with lone myocarditis and its susceptibility to an immunosuppressive therapy.
Methods and Results: Among 49 consecutive patients with myocarditis serologically screened for HCV in addition to other cardiotropic viruses, four had anti-HCV antibodies. Clinical manifestation was severe heart failure in three cases and chest pain with left bundle branch block (LBBB) and moderate cardiac dysfunction in one case. These 4 patients underwent 2D-echo, coronary angiography and endomyocardial biopsy. Nested-polymerase chain reaction (PCR) for positive and negative strand of HCV was performed on sera and myocardial samples. PCR was also used to detect genomic sequences of cardiotropic viruses including enterovirus, adenovirus, influenza virus A and B, herpes simplex viruses, Epstein Barr virus, parvovirus B19 and cytomegalovirus. HCV in the myocardium was detected by TORDJI-22 antibody. Five subjects without myocarditis, two with and three without HCV infection, were used as controls. Histologically, a lymphocytic myocarditis associated with myocytes positively stained by TORDJI-22 was shown in all. Cardiac autoantibodies were detected in all cases. Nested-PCR showed both positive and negative strands of HCV RNA in serum and myocardium, while other viral genomes were absent. None of the five controls had HCV RNA in the myocardium. Patients were treated with prednisone and azathioprine for 6 months. Recovery of cardiac volumes and function occurred in all patients with disappearance of chest pain and LBBB in patient 4. At 4-weeks control biopsy myocarditis progressed to a healed phase, though HCV RNA was still detectable in the serum and myocardium. Cardiac improvement was maintained at 12 month overall follow-up.
Conclusions: HCV can be detected in the myocardium of as many as 8% of patients with lone myocarditis; HCV myocarditis can benefit from immunosuppression despite persistence of viral genome, suggesting an immunomediated mechanism of damage.

P1825 Prevalence of parvovirus B19 genome in endomyocardial biopsies

S. Pankuweit, H. Eckhardt, M. Crombach, I. Portig, G. Hufnagel, B. Maisch. *Philipps-University Marburg, Dept. Internal Medicine - Cardiology, Marburg, Germany*

Introduction: Although enteroviruses were considered the most common cause of inflammatory heart muscle diseases, Parvovirus B 19 (PB 19) has become a new and frequent candidate for myocarditis (M) and dilated cardiomyopathy with (DCMi) and without inflammation (DCM). Infection with PB 19 can lead to several clinical manifestations, which include myopericarditis, erythema infectiosum, arthropathy, hydrops fetalis as well as acute hepatitis. PB 19 genome has been shown in the myocardium and liver tissue.
Methods: We investigated leftventricular endomyocardial biopsies (EMB) from 110 consecutive patients with clinically suspected inflammatory heart disease for the presence of parvovirus B19 genome by polymerase chain reaction (PCR). Diagnosis of M, DCM, DCMi and perimyocarditis (Pm) was confirmed by clinical data as well as immunohistochemical and histopathological investigations of the EMB. A control group consisting of patients with arterial hypertension was investigated, too. Results: The prevalence of PB 19 genome was highest in patients with DCMi (23%) and patients with myocarditis (19%); in patients with DCM and Pm the prevalence was 16%. In patients with resolved M no PB 19 genome was detected, in patients with no inflammation and controls prevalence was 4% and 7%, only.
Conclusions: These findings suggest an association of parvovirus B19 genome in the EMB of adults with the development of DCM, DCMi and chronic myocarditis in far more cases than previously expected. PB 19 should be recognized as a potential cardiogenic pathogen in patients of all ages. An early treatment of persistent PB 19 infection by immunoglobulins should be worth striving to prevent cardiac complications and the development of left ventricular dilatation and heart failure.

P1826 Pericardial cytokines in pericarditis versus coronary artery disease

A.D. Ristic[1], S. Pankuweit[2], E. Meyer[2], P.M. Seferovic[3], H. Köster[4], S. Vogt[4], R. Moosdorf[4], B. Maisch[2]. [1]*University Inst. for Cardiovasc. Dis., Belgrade, Yugoslavia;* [2]*Philipps University, Dept. of Internal Medicine-Cardiology, Marburg, Germany;* [3]*University Inst. for Cardiovasc. Dis., Klinicki Centar Srbije, Belgrade, Yugoslavia;* [4]*Philipps University, Dept. of Cardiac Surgery, Marburg, Germany*

Background: The activation of cytokines in various forms of pericarditis is incompletely investigated. To elucidate this issue we have analyzed IL-6, TGF-beta1, TNF-alpha, IFN-gama, and GM-CSF in pericardial effusion (PE) and serum of patients with pericarditis and in pericardial fluid of bypass surgery patients.
Methods: Pericardial fluid was obtained after pericardiocentesis (Group 1: 30 pericarditis patients, 60% males, 52.4±14.2 years) or after sternotomy (Group 2: 21 bypass surgery patients, 42.9% males, 67.2±7.4 years). Samples were promptly aliquoted, frozen and stored at -70°C. The cytokines were estimated using quantikine enzyme amplified-sensitivity immuno-assays (R&D Systems, MN). Cytokines concentrations in pericardial fluid of group 1 (40% neoplastic, 23.3% autoreactive, 13.3% viral, 13.3% lymphocytic, and 10% iatrogenic PE) were compared with serum levels, and with group 2.
Results: IL-6 was significantly increased in PE in comparison to serum in all forms of pericarditis and increased in comparison to pericardial fluid of by-pass surgery patients (except in autoreactive PE). TGF-beta1 was strikingly lower in PE than in serum of all pericarditis patients. However, TGF-beta1 PE levels were significantly higher in all patients in Group 1 than in Group 2, except in infectious pericarditis. TNF-alpha was increased only in PE of patients with infectious pericarditis in comparison to Group 2. IFN-gama levels did not significantly differ between PE and serum or in comparison to Group 2. GM-CSF was present only in small proportion of patients with neoplastic and autoreactive PE.
Conclusions: Significant differences in the activation of IL-6 and TGF-beta1 in pericardial effusion in comparison to serum values in the same patients and in the pericardial fluid of by-pass surgery patients implies their possible role in the pathophysiology of the disease. The pattern "high TNF-alpha/low TGF-beta1" was found in infectious pericarditis and low IL-6 in autoreactive pericardial effusion.

P1827 Chronic versus recurrent pericarditis: should we give colchicine to everybody?

P.M. Seferovic[1], A.D. Ristic[2], R. Maksimovic[1], D. Simeunovic[1], D. Trifunovic[1], M. Ostojic[1]. [1]*University Inst. for Cardiovasc. Dis., Klinicki Centar Srbije, Belgrade, Yugoslavia;* [2]*University Inst. for Cardiovasc. Dis., Belgrade, Yugoslavia*

Background: Colchicine has been successfully applied in the management of patients with recurrent and acute pericarditis. The aim of the present study was to investigate its therapeutic effect in chronic non-recurring pericardial inflammation.
Methods: Study population included 17 patients with idiopathic pericardial effusion. Group 1 comprised seven patients with idiopathic chronic non-recurring pericarditis (28.6% males, mean age 50.4±18.2 years). Additional ten patients with idiopathic recurring pericarditis were assigned as Group 2 (30% males, mean age 52.7±5.1 years). All patients were resistant to previous non-steroid anti-inflammatory (NSAI) treatment. In both groups colchicine was given at a loading dose of 2 mg for one week and a maintenance dose of 1.5 mg daily for five months, tapering of the doses by 0.5 mg per week in additional three weeks. All patients were included in monthly clinical and echocardiography follow-up for the period of 12 months.
Results: During the six-months of treatment period colchicine was effective in relieving symptoms in 28.6% of pts from Group 1 vs. 80% of pts from Group 2 ($p<0.05$). Furthermore, colchicine regimen resulted in disappearance of the pericardial effusion in 14.3% of pts from Group 1 vs. 60% of pts from Group 2 ($p<0.05$). In additional six months follow-up after the withdrawal of colchicine treatment the therapeutic effect remained unchanged.
Conclusion: Efficacy of six-months colchicine regimen was very low in pts with chronic idiopathic non-recurrent pericarditis in comparison to patients with recurrent pericarditis, both regarding symptoms relief and disappearance of pericardial effusion. In patients with recurrent pericarditis therapeutic effect remained unchanged six months after the withdrawal of medications.

P1828 Feasibility and diagnostic value of pericardial biopsy: the role of flexible percutaneous pericardioscopy

P.M. Seferovic, A.D. Ristic, V. Tatic, R. Maksimovic, D. Simeunovic, M. Ostojic, V. Kanjuh. *University Inst. for Cardiovasc. Dis., Belgrade, Yugoslavia*

Background: The clinical significance of pericardial biopsy is controversial. The aim of the study was to assess the feasibility and diagnostic value of three approaches to pericardial biopsy: fluoroscopic control and standard sampling, pericardioscopy guidance with standard or extensive sampling.
Methods and Results: Forty-two subsequent patients with a large pericardial effusion underwent parietal pericardial biopsy. In group 1 (12 patients, 66.7% males, age 46.7±12.2 years) pericardial biopsy was guided by fluoroscopy (3-6 samples/patient). Group 2 included 22 patients (50% males, age 50.8±10.4 years) undergoing 4-6 pericardial biopsies/patient guided by pericardioscopy (16F flexible endoscope). In group 3 extensive pericardial sampling was performed guided by pericardioscopy (10 patients, 60% males, age 42.3±14.6 years, 18-20 samples/patient). Sampling efficiency was better with pericardioscopy (group 2 - 84.9%; group 3 - 87.3%) in comparison to fluoroscopic guidance (group 1 - 43.7%; $p<0.01$). Diagnostic value was defined as: a new diagnosis uncovered, etiology revealed, clinical diagnosis confirmed, and the biopsy false negative. Pericardial biopsy in group 3 had higher diagnostic value than in group 1 in revealing new diagnosis (40% vs. 8.3%, $p<0.05$) and etiology (50% vs. 8.3%, $p<0.05$). In group 2 pericardial biopsy had a higher yield in establishing etiology than in group 1 (40.9% vs. 8.3%; $p<0.05$). Pericardial biopsy was false negative in 58.3%, 45.4%, and 10% in groups 1, 2, and 3, respectively. There were no major complications.
Conclusions: Pericardioscopic guidance enhanced pericardial sampling efficiency. The diagnostic value of pericardial biopsy was significantly improved by extensive sampling made possible by flexible percutaneous pericardioscopy.

P1829 High prevalence of enterovirus infection in chronic, effusive pericarditis

L. Archard[1], T. Peng[1], S. Liu[2], Z. Pan[3], Y. Ji[4], H. Zhang[1], Y. Li[1]. *[1]Imperial College Faculty of Medicine, Division of Biomedical Sciences, London, United Kingdom; [2]Changzhou Hospital, Department of Cardiology, Changzhou, Hebei Province, China; [3]Zhongshan Hospital, Department of General Practice, Shanghai, China; [4]Zhongshan Hospital, Department of Pathology, Shanghai, China*

Background: Clinical and experimental studies suggest persistent enteroviral infection in chronic pericarditis, but direct evidence of viral infection in pericardial tissue has been lacking.
Materials and Methods: Formalin-fixed, paraffin-embedded pericardial samples from 4 patients with chronic effusive pericarditis and 7 patients with chronic constrictive pericarditis of unknown origin were obtained in Changzhou Hospital, Hebei Province, China and Zhongshan Hospital, Shanghai, China. These were investigated for enteroviral capsid protein VP1 by immunohistochemical staining with the enterovirus group-specific monoclonal antibody D8/1 and for virus genomic RNA by nested RT-PCR or in situ hybridization with group-specific oligonucleotides. Pericardial tissue collected during surgical resection from 3 patients with chronic tuberculous pericarditis was used for comparison. Myocardial tissue from a pediatric case of fatal, acute enteroviral myocarditis was used as positive control.
Results: Enteroviral capsid protein VP1 was found in pericardial tissue from 3 of 4 (75%) cases of effusive pericarditis and 1 of 7 cases (14.3%) of constrictive pericarditis. nRT-PCR and in situ hybridization showed enteroviral RNA in one case of effusive pericarditis only, which was positive also for viral capsid protein. The nucleotide sequence of RT-PCR-amplified enteroviral RNA, determined by automatic cycle sequencing in both orientations, was most homologous with poliovirus type 3. Capsid protein VP1 and viral genomic RNA were both present in autopsy tissue from the case of acute myocarditis but neither was found in tissue from any case of tuberculous pericarditis.
Conclusions: This is the first study to show the persistence of enterovirus antigen and viral RNA in pericardial tissue and indicates that enteroviruses are frequently involved in chronic, effusive pericarditis.

P1830 Regulation of eNOSs expression by aspirin in pericardial tissue during inflammation

M.M. Arriero, L. Rico, A. Jiménez-Fernández, C. Carrasco, J. Farré, J.M. Rubio, R. de Andrés, A. Lopez-Farré. *Fundación Jiménez Díaz, Cardiovascular Research Laboratory, Madrid, Spain*

The aim was to analyze if pericardial tissue expresses endothelial nitric oxide synthase (eNOS) protein and to determine the presence of cytosolic proteins that bind to eNOS mRNA favouring its destabilization. The effect of aspirin on the above mentioned parameters was also analyzed. eNOS protein was expressed in pericardial tissue from male guinea-pigs. Escherichia Coli lipopolysaccharide (10 μg/mL, LPS) and Staphylococcus aureus endotoxin (10 μg/mL, SA) reduced eNOS protein expression and shortened the half-life of the eNOS messenger. Under basal conditions, cytosolic extracts from pericardial samples bound to the 3'-UTR of eNOS mRNA which was enhanced by LPS and SA. Proteinase K fully prevented the binding of cytosolic pericardial extracts to 3'-UTR of eNOS mRNA, suggesting the involvement of proteins that were further characterized as 60-KDa and 51-KDa proteins by cross-linking assay. Aspirin (1-10 mmol/L) restored eNOS expression in either LPS and SA-stimulated pericardial samples and reduced binding activity of the pericardial cytosolic proteins to 3'-UTR of eNOS mRNA. Indomethacin also reduced the downregulation of eNOS by LPS and diminished the binding activity of the cytosolic proteins although higher doses of indomethacin than of aspirin were needed to improve these parameters. In conclusion, eNOS protein is expressed in guinea-pig pericardial tissue. LPS and SA stimulate the binding activity of pericardial cytosolic proteins to 3'-UTR of eNOS mRNA and reduce eNOS protein expression. High doses of aspirin and indomethacin protect eNOS protein expression and reduce the binding activity of the cytosolic proteins to 3'-UTR of eNOS mRNA, suggesting an inverse association between the presence of these cytosolic proteins and eNOS expression. A better knowledge of the mechanism by which aspirin and indomethacin protects the expression of eNOS protein in the pericardium may lead to new pharmacological strategies in the prevention of the pericardial dysfunction associated with pericardial inflammation.

ARRHYTHMOGENIC RIGHT VENTRICULAR CARDIOMYOPATHY

P1831 Long-term experience with ICDs in the management of patients with arrhythmogenic right ventricular cardiomyopathy

F. Duru, C. Lemola, C. Brunckhorst, T.F. Lüscher, R. Candinas. *University Hospital Zurich, Cardiovascular Center, Zurich, Switzerland*

Background: Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) is a genetically determined heart disease characterized by a progressive loss of right ventricular myocardium and its replacement by fibro-fatty tissue. The disease is frequently associated with life-threatening ventricular tachyarrhythmias. Therefore, therapy with implantable cardioverter-defibrillators (ICD) is considered in selected cases. However, there is limited published data concerning the role of ICD therapy in this disease in the long term.
Methods and Results: Twenty-two patients (19 male, age: 42 ± 14 years) who were diagnosed to have ARVC based on standardized criteria underwent implantation of an ICD at our institution. Indication for ICD implantation was presence of hemodynamically significant ventricular tachyarrhythmias (inducible and nonsuppressible, or associated with marked right ventricular dilatation and/or left ventricular involvement) in 20 patients (91%), and strong family history of sudden death in 2 patients. The mean follow-up period was 30 months (range: 6 - 82). Ten patients (45%) developed a total of 624 episodes. 95% of these episodes were successfully terminated by painless antitachycardia pacing therapies. Six patients (27%) received inappropriate therapies, which were due to supraventricular arrhythmias in five cases. There were two deaths; one patient died because of intractable heart failure, and another died suddenly despite delivery of appropriate ICD therapies.
Conclusion: Ventricular tachyarrhythmias occur commonly in ICD recipients who have ARVC. Antitachycardia pacing therapies can terminate the vast majority of these episodes. Inappropriate therapies are also relatively common and may complicate management of these patients. Overall, however, ICD implantation should be considered in ARVC patients with a high-risk profile.

P1832 Autosomal dominant familial left ventricular ARVC

M. Norman[1], B. Mist[1], A. O'Donoghue[1], J. Mogensen[1], M. Simpson[2], A. Crosby[2], W J. McKenna[1]. [1]*St George's Hospital, Cardiological Sciences Dept., London, United Kingdom;* [2]*St. Georges Hospital Medical School, Medical Genetics, London, United Kingdom*

Background: Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) is a heart muscle disease typically characterised by fibro-fatty replacement of the right ventricle. Isolated post-mortem cases of fibro-fatty replacement of left ventricular myocardium are reported.
Familial ARVC has been described with recurrent left ventricular involvement in only small families, with three small families linked to chromosome 2q32 by using a cumulative LOD score approach. However, cumulative LOD scores can only be used in the absence of genetic heterogeneity. We describe a single family of sufficient size to provide linkage by two-point linkage analysis with primary left-ventricular ARVC.
Methods: Detailed clinical assessment of a large pedigree of 52 individuals considered to have primary left ventricular ARVC with ECG, echocardiography, signal averaged ECG, exercise testing and Holter monitoring was performed. The index case suffered a sudden cardiac death aged 23 with post-mortem findings of fibro-fatty replacement of the left ventricular myocardium.
Results: 14/52 individuals were considered to be affected by a primary left ventricular variant of ARVC. Consistent clinical features were T wave inversion in the inferolateral leads (8 individuals) and left ventricular dilatation with an LVED>117% (6 individuals). 9 individuals had significant arrhythmia on exercise treadmill testing. 7 individuals had a positive signal averaged ECG. In addition Holter monitoring has identified frequent polymorphic ventricular arrhythmias. Segregation analysis supports an autosomal dominant mode of inheritance. Simulation with the linkage programme calculated a maximum LOD score of 3.6.
Conclusions: ARVC is an inherited disorder, with autosomal dominant disease present as both a primary right ventricular fibro-fatty replacement and left ventricular fibro-fatty replacement. Clinical manifestations of primary left ventricular ARVC are quite distinct from those in the more typical right ventricular form of the disease. T wave inversion in the right pre-cordial leads identifies individuals with the typical form of ARVC, and T wave inversion in the inferolateral leads identifies those individuals with the left ventricular variant. In addition structural alteration of the left ventricle with left ventricular dilatation with normal right ventricular measurements highlights the contrasting expression of this phenotype. It may be that the genes responsible for fibro-fatty replacement of the myocardium may not be cardiac chamber specific and may affect the right ventricle, the left ventricle or both.

P1833 Differences in the clinical expression of arrhythmogenic right ventricular cardiomyopathy in male and female patients

B. Bauce[1], C. Basso[2], G. Frigo[1], A.F. Folino[1], P. Turrini[1], L. Daliento[1], G. Thiene[2], A. Nava[1]. [1]*University of Padua, Department of Cardiology, Padua, Italy;* [2]*University of Padua, Department of Pathology, Padua, Italy*

Background: arrhythmogenic right ventricular cardiomyopathy (ARVC) is a myocardial disease that can lead to juvenile sudden death (SD). Although genetic studies demonstrated an autosomic inheritance, the prevalence of affected patients and SD is higher in males than females in all series.
Aim of the study: to investigate the different penetrance of ARVC in males respect with females in a series of consecutive patients affected by the disease.
Materials and methods: 195 consecutive patients diagnosed with ARVC in our center were analyzed. The diagnosis was made following the ISFC major and minor criteria. There were 145 males, 50 females, mean age 34±15 years. The clinical and instrumental findings of 50 consecutive male and female patients were evaluated. All patients underwent clinical examination, 12-lead ECG, signal averaged ECG (SAECG), two-dimensional and Doppler echocardiogram and 24 hours Holter ECG. In patients with life-threatening ventricular arrhythmias invasive cardiac examination was also carried out.
Results: Familial history of SD and/or ARVC was similar in the two groups (24% vs 20%, p=NS). Among males the percentage of competitive athletes was significantly higher (38% vs 16%, p=0.01). The right end diastolic volume was larger in males than females (86±24 ml/m^2 vs. 64±16 ml/m^2, p<0.0001) and right ventricular ejection fraction was lower (54±8% vs. 58±8%, p=0.01). Although the presence of late potentials was not significantly different in the two groups, QRS duration and filtered QRS at 25, 40, and 80 Hz filters were significantly more altered in men (101±15 vs 92±14, 131±19 vs 119±14, 124±20 vs 111±15, 112±20 vs 99±15, p=0.003, p=0.0004, p=0.0002, p=0.0003 respectively). The incidence of overall ventricular arrhythmias were similar in the two groups, however life-threatening arrhythmias (sustained ventricular tachycardia and ventricular fibrillation) were significantly more frequent in males (32% vs 14%, p=0.03).
Conclusions: the prevalence and severity of ARVC is higher in male than female patients. Environmental factors could play a role in this gender clinical difference; among these, strenuous physical activity resulted to be significantly higher in the male group. However, the possible role of endogenous factors cannot be excluded.

P1834 Diagnosis of arrhythmogenic right ventricular cardiomyopathy: standard electrocardiogram revisited

S. Peters, M. Trümmel. *Klinikum D.Chr.Erxleben Quedlinburg, Kardiologie Abt., Quedlinburg, Germany*

Similar to long QT syndrome and Brugada syndrome arrhythmogenic right ventricular dysplasia-cardiomyopathy (ARVD) is thought to be a primarily electrical disease. Whether ARVD is characterised by a few ECG features as the above mentioned syndromes should be analysed retrospectively.
Results: In a cohort of 231 patients (130 males, mean age 47.6 years) with ESC/IFSC criteria of ARVD the following ECG features could be found:
Localised right precordial QRS prolongation of at least 100 msec in 227 patients (98%), right precordial T inversions in 134 cases (58%), complete right bundle branch block (RBBB) in 18 patients (8%), incomplete RBBB in 28 patients (12%), "pseudo" incomplete RBBB (no S wave in V5 + V6) in 6 cases (3%), R > S wave amplitude in V2 with QRS interval of at least 110 msec in 29 patients (13%), localised QRS prolongation in inferior leads in 49 patients (21%), right precordial ST elevation in 62 cases (27%) and loss of R wave in V1 - V3 in 12 cases (5%).
In conclusion, the variety of ECG findings demonstrates that ARVD is not only an electrical disease but is characterised by different morphological changes of the right and in about 50% of cases the left ventricle. Similar to long QT syndrome and Brugada syndrome a central ECG finding - localised right precordial QRS prolongation of at least 100 msec - can be found in ARVD cases and contributes significantly to the diagnosis of ARVD.

P1835 Clinical presentation of index arrhythmogenic right ventricular cardiomyopathy cases: a tertiary centre experience

M.S. Hamid, R. Thaman, S. Firoozi, M. Norman, A. Quaraishi, B. Sachdev, P.M Elliott, W.J McKenna. *St. George's Hospital Medical School, Cardiological Sciences, London, United Kingdom*

Introduction: The clinical features of arrhythmogenic right ventricular cardiomyopathy (ARVC) include arrhythmia, heart failure and sudden cardiac death. We studied the mode of clinical presentation and results of non-invasive cardiac evaluation using ARVC task force criteria, in a consecutive series of index cases.
Methods: ARVC index cases were identified at our centre, referred from other centres or discovered at autopsy. Family members were interviewed about symptoms among the deceased cases. Live cases underwent historical assessment, 12-lead and signal-averaged ECG, 2-D echo, Holter monitoring and exercise testing. The families of these cases were offered cardiac evaluation.
Results: Of 75 index cases (age 31 ± 11 years), 44 (59%) presented with sudden cardiac death (SCD) and were diagnosed at autopsy. They presented at a younger age than the live cases (age 28 ± 9 v 36 ± 13 years; p<0.005) and the majority were male (71%). Six (14%) of this group experienced syncope one month prior to their death. Therefore, 38 (51%) cases had SCD as their initial clinical feature with no preceding symptoms. Live cases presented with palpitations/pre-syncope 16 (53%), syncope 10 (33%), VF arrest 2 (7%)and heart failure 2(7%).
Presence of ARVC task force criteria are summarised below.

Table showing prevalence of criteria

Task Force Criteria	Prevalence
T-inversion in leads V1-3	20 (64%)
Epsilon waves	1 (3%)
QRS duration>110 milliseconds	6 (19%)
Abnormal signal-averaged ECG	18 (58%)
>1000 ventricular ectopics/24 hours	13 (42%)
Major RV echocardiographic abnormalities	16 (52%)
Minor RV echocardiographic abnormalities	15 (48%)
Left bundle branch block VT	29 (sustained 70%, NSVT 23%)

Conclusion: The commonest presentation of index ARVC cases to our centre was with SCD, presenting at a younger age compared to other clinical features. The majority of live cases presented with features of ventricular arrhythmias. ARVC task force criteria involve routine cardiac tests, most being available at secondary and tertiary centres. Our experience shows that they should enable better diagnostic success.

P1836 Evaluation of electrocardiographic and echocardiographic diagnostic criteria for ARVC in Naxos genotyped population

N. Protonotarios[1], A. Tsatsopoulou[1], A. Anastasakis[2], A. Miliou[2], D. Panagiotakos[2], P. Toutouzas[2]. [1]Yannis Protonotarios Medical Center, Cardiology, Naxos, Greece; [2]University of Athens, Cardiology, Athens, Greece

Background The diagnosis of arrhythmogenic right ventricular cardiomyopathy (ARVC) is based on established criteria by ESC/ISFC. Naxos disease is an autosomal recessive ARVC, 100% penetrant by adolescence due to a deletion mutation in plakoglobin. Genotyped population of all Naxos disease families was available to evaluate the sensitivity and specificity of electrocardiographic and echocardiographic diagnostic criteria.
Methods Resting 12-lead ECG and two-dimensional echocardiography were studied in all adult homozygous carriers for plakoglobin mutation (13 men and 13 women, age 42.5±19 years) and in 35 homozygous for normal allele (12men and 23 women, age 41.2±14 years) from 12 families. T wave inversion, QRS complex duration, QRS dispersion (QRS width in V1-V3 minus that in V6), epsilon waves and right ventricular (RV) dimensions/wall motion were evaluated using a standard protocol. Sensitivity and specificity analysis was applied using the receiver operating characteristic curve in order to identify optimal cut-off points for the evaluated diagnostic parameters.
Results Sensitivity and specificity of ECG and echocardiographic findings are presented in the table.

	Sensitivity	Specificity
T wave inversion in V1	88%	22%
T wave inversion in V2	81%	79%
T wave inversion in V3	73%	92%
QRS width > 110ms in V1-V3	73%	100%
QRS dispersion > 25ms	58%	91%
Epsilon waves	54%	100%
Ventricular extrasystoles (LBBB)	88%	94%
RV outflow tract diameter > 32.5mm	85%	94%
RV inflow tract diameter > 35.5mm	89%	85%
RV wall motion abnormalities	100%	100%

Conclusions T wave inversion in V2 or V3, QRS complex prolongation in V1-V3, ventricular extrasystoles of RV origin, as well as RV dilatation and wall motion abnormalities seem to be the best diagnostic criteria in this ARVC group. QRS dispersion and epsilon waves although specific for the disease they show rather low sensitivity.

IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR – TECHNICAL ASPECTS

1889 Detection of tachyarrhythmia with a dual chamber defibrillator connected to a defibrillation lead with a free-floating atrial bipole

A. Schuchert[1], B. Lemke[2], D. Schmitz[3], U. Wiegand[4], H-J. Bondke[5], T. Zerm[6], M.A. Aydin[1], T. Meinertz[1]. [1]University-Hospital Hamburg-Eppendorf, Department of Cardiology, Hamburg, Germany; [2]BG Clinic Bergmannsheil, Bochum, Germany; [3]St. Johannis Hospital, Dortmund, Germany; [4]University Lübeck, Lübeck, Germany; [5]University-Hospital Charite, Berlin, Germany; [6]Karl-Gustav University, Dresden, Germany

The aim of the study was to assess the sensitivity and specificity of new modified dual chamber cardioverter defibrillator (ICD) connected to a defibrillation lead with a free-floating atrial bipole. The study included 72 patients (63 ± 10 years, ejection fraction 38 ± 14%, coronary heart disease n = 61) who received as a first implant the dual chamber ICD Deikos A + and the single-coil defibrillation lead with a free-floating atrial bipole Kainox VDD (Biotronik). Indications for ICD implantation were ventricular tachycardia in 45, ventricular fibrillation in 18, and other indications in 9 patients. The ICD has a more sensitive atrial detection channel and enhanced detection algorithms for the discrimination between atrial and ventricular arrhythmia. At discharge, the enhanced detection algorithms were programmed on. There are two lead models with 15-cm and 17-cm distance between electrode tip and atrial dipole.
Results: A lead with a 17-cm distance was implanted in 61 and with 15-cm distance in 11 patients. Procedure duration was 103 ± 43 minutes. Induced ventricular fibrillation was successfully terminated as recommended with maximal 20 Joule in all patients. Unfiltered P-wave amplitude at implantation was 1.0 ± 1.0 mV. Filtered P-wave amplitude was 5.2 ± 1.6 mV at implantation, 4.6 ± 1.7 mV at month 1, 4.6 ± 2.0 mV at month 3, and 5,0 ± 1.8 mV at month 6. There were 125 spontaneous episodes during 4.5 ± 3 months follow-up with 18 episodes of ventricular fibrillation, 43 episodes of ventricular tachycardia, 30 episodes of supraventricular tachycardia, and 34 episodes of sinus tachycardia. The ICD correctly detected all episodes of ventricular fibrillation, 98% of the ventricular tachycardia episodes, 89% of the supraventricular tachycardia episodes, and 97% of the sinus tachycardia episodes.
Conclusions: The dual chamber ICD connected to the defibrillation lead with a free-floating atrial bipole detected due to the more sensitive atrial channel P-wave signals with a high amplitude. The device had a sensitivity of 98% and specificity of 91% for the detection of tachyarrhythmias.

1890 Programming assistant for implantable cardioverter/defibrillators: multi-centric evaluation of a rule-based expert system

B.H. Diem[1], V. Lang[2], M. Mlynski[3], A.M. Sinha[1], C. Stellbrink[1], K. Mitchell[2], W. Ameling[3], P. Hanrath[1]. [1]University Clinics Aachen, Dept. of Cardiology, Aachen, Germany; [2]MSEI, Lake Oswego, United States of America; [3]CWA, Aachen, Germany

Modern implantable cardioverter/defibrillators (ICD) put growing demands on the physician, as their complexity requires increasing knowledge and effort for handling these devices. To overcome this development a Programmer-Assistant (PA) was developed, which transfers the clinical data entered by the physician into a complete parameter set for the programming of a dual-chamber ICD (Tachos DR, Biotronik) for DFT testing (DFT-P) and the first permanent programming after implant (First-P).
Methods: 168 patient files from routine implantations were evaluated by ICD experts of 15 centers in USA, UK and Germany. After entering the data in the PA the experts evaluated, separately for DFT-P and First-P, each single parameter and the parameter set as a whole.
Results: 168 patients (136 m, 32 f), age 66 ± 12 years, ejection fraction 30 ± 12%, cardiac disease: coronary artery disease 119, dilated cardiomyopathy 21, valvular 20, Long-QT syndrome 3, hypertrophic cardiomyopathy 2, idiopathic ventricular fibrillation 3.
The evaluation of the single parameter is summarized in the table. The DFT-P was accepted as a whole program in 159 cases (94,6%), not accepted in 9 (5,4%). For First-P the result was 157 (93,5%) vs. 11 (6,5%) case. None of the DFT-P and First-P was considered harmful. The disapproval of the 9 respectively 11 cases was based only on center-specific preferences. The PA was adapted to include these preferences.

Single Parameter Evaluation

mean ± SD	Identical	Acceptable	Not Acceptable	Harmful
DFT-P	98,4 ± 1,8	1,0 ± 1,4	0,5 ± 1,2	0,0 ± 0,0
First-P	96,1 ± 3,7	2,4 ± 2,2	1,5 ± 2,2	0,05 ± 0,2

The percentage of parameters in each category per patient is averaged over all patients.

Conclusion: The PA, which allows the physician to program ICDs directly with clinical data, is a safe method to simplify the programming of modern complex ICDs.

1891 Development of a rechargeable implantable cardioverter-defibrillator: first results of in-vitro measurements

M. Niehaus[1], D. Detsch[2], M. de Sousa[1], T. Korte[1], J. Tebbenjohanns[1]. [1]Hannover Medical School, Dept. of Cardiology And Angiology, Hannover, Germany; [2]Inst f. Basics of Electr Engineering, University of Hannover, Hannover, Germany

Present ICD-systems use a conventional dry battery as energy source. Therefore most often life span of this system is determined by the capacity of the battery, which amounts depending upon demand 3-5 years. If the battery is exhausted, the entire device must be exchanged. An expensive operation with many physical and psychological risks and side effects for the patient is the consequence, which can significantly affect the quality of life. If the energy source in these systems would be rechargeable, most of these exchange operations could be omitted.
Methods: The project deals with recharging of batteries through the intact skin via a magnetic field. The aim of the study is to improve the energy transfer into the ICD without any tissue damage. We started with simulations with finite-element-programs to optimize the magnetic field dependent on different coil forms. Furthermore, in-vitro-measurements were carried out to identify the appropriate frequency of the magnetic field. An automatic compensation of variable boundary conditions (e.g. tissue thickness) was tested. The Ventak Prizm II (Guidant, MN) widened with a receiving coil for energy transmission and a charging electronic was used as prototype.
Results: A large coil around the can for energy receiving was identified having the best transmitting results. The higher the field frequency the higher the absorption of the housing of the ICD that could be estimated at 16dB at 100 kHz. The optimum frequency for energy transmission is 100 kHz. There was no significant heating of tissue between both coils.
Conclusion: Using optimized parameters, transmission of energy intended to recharge batteries of ICDs is possible without unacceptable heating of the surrounding tissue.

1892 Efficacy and reliability of transvenous ICD-lead extraction using mechanical and electrosurgical devices

V. Dörnberger[1], R. Bosch[1], D. Bail[2], A. Menon[2], V. Kuehlkamp[3].
[1]*Eberhard-Karls-Universitaet, Medizinische Klinik III, Tuebingen, Germany;* [2]*Eberhard-Karls-Universitaet, Heart and Thoracic Surgery, Tuebingen, Germany;* [3]*Eberhard-Karls-Universitaet, Medizinische Klinik III, Tuebingen, Germany*

Introduction: Defect ICD- leads should be removed before implanting new ones as electromechanical interactions between defibrillation coils may produce oversensing and unexpected shock delivery.
Material and method: Since march 1995, 44 defect transvenous ICD- leads had to be removed at the University Hospital of Tübingen. Mean age of patients was 59.7 years (range 20 to 81), gender 38 males and 6 females, 34 pectoral and 10 abdominal devices. Mean lead age was 42.1 months (range 1 to 109) including 18x Transvene- (Medtronic), 18x Endotak- (CPI/Guidant), one Intermedics- and one Teletronic- lead. Extractions were performed in a thoracic- and heart- operation theatre with HLM stand-by and TEE- monitoring. Clinical evidence of lead defects were oversensing in 31 cases, exitblock in 9 cases, Twiddler syndrome in 3 cases and one infection. Vascoextor stilett (Vascomed) alone was used in 5 patients, 4 times in combination with a plastic sheath (COOK), Cook liberator stilett (or stilett 0.017-0.019) combined with plastic sheath seize 11,5-13 Fr. in 24 patients, 4 times electrosurgical dissection sheath (EDS COOK), and in 7 cases without supporter devices (lead age < 6 months).
Results: One Endotak lead (age 77.6 months) could not be extracted by mechanical devices without EDS support. Thoracotomy was necessary to remove the distal defibrillation coil from the embedding scar tissue in the right ventricular area. In one case the plastic sheath perforated the wall of the right ventricle during contermove with the liberator- stilett (one of the first extractions). Resuscitation, thoracotomy and closure of the defect was successful. In all other cases the transvenous approach for lead extraction was successful, in four of these cases electrosurgical dissection sheaths were necessary. New leads were implanted during the same session using Seldinger-technique.
Conclusions: Transvenous lead extraction may be performed successfully and safely in almost all cases. Extractions should be done in an operation theatre with availability of thoracic and heart surgery, HLM stand-by and TEE monitoring. Plastic sheaths should carry x-ray dense markers to improve visibility during fluoroscopy.

1893 Excimer laser sheath is emerging as a safe and effective alternative for the extraction of complicated pacemaker and ICD leads

T. Padder[1], B. Kantharia[1], F. Padder[1], G. Panjrath[2], A. Ivanov[1], M. Albatani[1], C. Saari[1], S.P Kutalek[1]. [1]*Hahnemann University Hospital, Cardiac Electyrophysiology, Philadelphia, United States of America;* [2]*Hahnemann University Hospital, Nuclear Cardiology, Philadelphia, United States of America*

Background: Historically, conventional techniques for extraction of pacemaker and defibrillator leads have resulted in a variety of complications. When thoracotomy procedures were mainstay of lead extraction management, extraction procedures were reserved only for the most life threatening situations. With the advent of new extraction equipment like laser sheath, the risk/benefit analysis allows the physician to utilize extraction techniques more readily.
Purpose: The purpose of the study was to determine the safety and efficacy of excimer laser sheath for complicated pacemaker and ICD leads.
Method: Prospective data analysis was done for the extraction of pacemaker and defibrillator leads at Hahnemann University Hospital. Only patients who could not be extracted with conventional techniques were selected.
Results: 450 patients with 802 leads were referred to our center for the extraction of pacemaker and defibrillator leads during the period Jan.1991-Nov. 2001.Laser-assisted extraction techniques were utilized in 65 patients with 92 leads. The study population included 50 male and 15 female patients with mean age of 60±14 years (range 30-90 years). The indications for these extractions were malfunction (47%), infection (44%) and others (12%). Laser sheath was undertaken if conventional techniques failed. The mean implant duration was 105 months (range 2 - 228 months) and the mean extraction time excluding the reimplantation was 40 minutes (range 10 - 120 minutes.) Complete lead extraction was achieved in 98% patients. All attempted reimplantation procedures was successful. The overall complication rate was 5% with cardiac tamponade being the most significant complication.
Conclusion: Excimer laser sheath appears to be safe and effective technique for the extraction of heavy fibrotic pacemaker and defibrillator leads. Although with high success rate it was also associated with significant complications. These complications were most likely due to the increased chronicity and complexity of leads extracted by this method.

1894 Rhythm discrimination in single and dual-chamber implantable cardioverter defibrillators: usefulness of QRS analysis by morphology discrimination

G. Boriani[1], M. Biffi[1], A. Dall'Acqua[2], P. Silvestri[2], C. Martignani[1], L. Frabetti[1], R. Zannoli[1], A. Branzi[1]. [1]*Inst of Cardiology, Bologna, Italy;* [2]*St. Jude Medical Italy, CRMD, Milan, Italy*

Morphology Discrimination (MD) is a rhythm discriminator based on the analysis of QRS complex morphology.
The clinical relevance of MD in improving rhythm discrimination in combination with other discriminators (i.e. Sudden Onset and Stability) was assessed in patients (pts) implanted with a cardioverter defibrillator (CD). Two series of pts were analysed: 26 pts with a single-chamber CD (mean follow up 29 months) and 25 pts with a dual-chamber CD (mean follow up 14 months). All detections were reviewed and classified. Sensitivity (SE) and Specificity (SP) in rhythm discrimination were evaluated according to various potential diagnostic settings for ventricular tachycardia (VT) diagnosis (i.e. with "any" or "all" the discriminators indicating VT). In single-chamber CDs also the diagnostic setting with "2 out of 3" discriminators was considered. The net advantage of MD was evaluated by assessing the diagnostic performance without use of MD.
Overall 400 detections (184 VT, 25 ventricular fibrillation [VF] and 191 supraventricular tachyarrhythmias [SVT] were analysed in single-chamber CDs and 645 (234 VT, 397 SVT and 14 VF)in dual-chamber CDs. The results are shown in the table.

Diagnostic setting		Single-chamber CD		Dual-chamber CD	
		with MD	without MD	with MD	without MD
"Any"	SE	100% (184/184)	100% (184/184)	100% (234/234)	
	SP	37.7% (72/191)	41.4% (79/191)	73.5% (292/397)	
"All"	SE	73.9% (136/184)	75.0% (138/184)	98.7% (231/234)	98.7% (231/234)
	SP	94.2% (180/191)	94.2% (180/191)	90.9% (361/397)	74.7% (296/397)
"2 out of 3"	SE	97.3% (179/184)			
	SP	79.1% (151/191)			

Legend: SE = sensitivity; SP = specificity.

In conclusion, use of MD in appropriate combination with Sudden Onset and Stability allows to obtain in single-chamber CDs a SP of 79.1% with maintenance of 97.3% of SE; thus, in single-chamber CDs the net advantage of MD is an increase in SP without an harmful drop in SE. In dual-chamber CDs, SE is high (98.7-100%) both with and without MD; however, use of MD allows an improvement in SP from 74.7% to 90.9%. Therefore, the implementation of MD implies a net advantage in rhythm discrimination, even when more traditional rhythm discriminators (i.e. Sudden Onset and Stability) are considered.

SYNCOPE – TILT TEST AND LONG-TERM OUTCOME

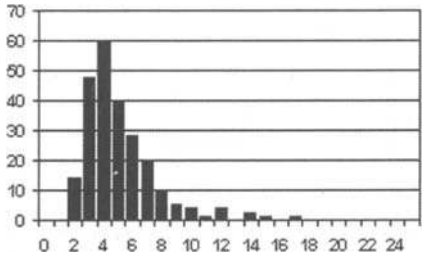
1895 Head-up tilt test potentiated with nitroglycerin. Which is the optimal duration of the test after the administration of the drug?

F.J. Lacunza, A. Garcia-Alberola, J.J. Sánchez-Muñoz, J. Martínez-Sánchez, C. Llamas, J. Barnés, M. Valdés. *University Hospital Virgen Arrixaca, Cardiology (Electrophysiology), El Palmar, Spain*

Numerous variations in the methods used for tilt-table testing potentiated with nitrates have been reported. After the administration of nitroglycerin, between 10 and 25 minutes of continued tilting have been recommended. The objective of this study is to assess the optimal duration of the pharmacologic phase of the tilt-table test potentiated with sublingual administration of nitroglycerin spray (NTG-TT).

Methods: The records of 470 consecutive NTG-TT performed in 379 patients were reviewed. Our protocol consists of a 20-minutes drug-free phase at 60°. If syncope did not develop, 400 μg of sublingual nitroglycerin spray were administered and the patient continued to be tilted for a further 25 minutes. The test results and time to a positive response were analyzed.

Results: The result of NTG-TT was positive in 269 procedures, most of them after nitroglycerin administration (238, 88.5%). The mean time to a positive response was 10.5 ± 7.2 min and 5.1 ± 2.4 during the control and pharmacologic phases respectively. Most positive responses concentrated between 3 and 5 minutes after drug administration. The time to syncope after nitroglycerin administration was superior to 10 minutes in 5 patients, and to 15 minutes in only one.



Time to a positive response.

Conclusions: The duration of the pharmacologic phase of tilt-table testing potentiated with sublingual nitroglycerin spray may be reduced to 15 minutes without loss of sensitivity. A further reduction to 10 minutes would decrease the rate of positive responses only by a small amount and may be considered acceptable from a clinical perspective.

1896 Three to five year follow-up after a positive tilt-table test for neurocardiogenic syncope in Israeli soldiers

V. Zeldetz, A. Wagshal, A. Katz, E. Damri, E. Hashavia, R. Ilia. *Soroka Medical Center, Cardiology, Beer-Sheva, Israel*

Neurocardiogenic syncope (NCS) is the most common cause of syncope in young otherwise healthy pts, can be readily diagnosed with tilt-table testing, and is usually responsive to therapy with either medications or pacemakers. However, information on the natural history of the disease and thus the duration that treatment is required is limited; that most pts. with NCS are young suggests that pts. may outgrow the disorder with time.

To examine the long-term course of NCS, we performed telephone interviews in 45 young Israeli solders (age 20 ± 1.6 y, range 18 to 24, 67% male) a mean of 4.0 ± 0.7 y (range 3 to 5.5 y) after a positive tilt test diagnostic for NCS (defined as syncope or near-syncope associated with both bradycardia and hypotension). The pts. had a mean of 9 ± 8 (range 2 – 30) prior syncopal episodes. Of the 45 pts., 31 had a positive baseline tilt test (30 min, 70° upright tilt) while the remaining 14 pts. had positive tests only with isoproterenol provocation (2 mcg/min for 10 min). (161 other soldiers with recurrent syncope tested during the same time period had negative tilt tests and were not included in the study, and 3 pts. with positive tilt tests were unavailable for interview). All but 3 pts were treated with drug therapy (beta-blockers used in 39 pts., florinef in 3, and serotonin-uptake inhibitors in 8) and re-assessed with repeat tilt-table tests until a negative test was achieved; 35 pts. were treated successfully with a single drug while 7 pts. required combination therapy. To avoid bias, pts. were not followed by us but rather returned to their regular army physicians and told to continue on the drug therapy. We found only 2 pts. were still taking medication, 1 pt. (2%) still reported frequent syncopal or near-syncopal episodes, 4 pts. (9%) had rare symptoms (defined as no more than 1 syncopal episode per year for each of the past 2 years) while the remaining 38 (84%) were symptom - free off of medications. Some pts. attributed relief of their symptoms to discharge from the army.

We conclude that NCS, at least in young pts., even when confirmed by a positive tilt-table test, is often a self-limited disorder, perhaps stress-related or situational in nature, and that the overwhelming number of pts. are asymptomatic and stop taking medications within 1 - 2 years. This study has obvious implications in choosing therapy for NCS pts. (such as drug therapy vs. pacemaker therapy), prescribing the duration of therapy, and in providing recommendations regarding occupation and restrictions on driving or athletic activity.

1897 Clomipramine versus conventional tilt table test: a prospective, randomized study, comparing sensitivity and specificity between the two tests

G.N. Theodorakis, D. Leftheriotis, E.G. Livanis, P. Flevari, G. Karabela, E. Zarvalis, D.T.H. Kremastinos. *Onassis Cardiac Surgery Center, B' Cardiology, Athens, Greece*

Central serotonergic activation participates in the pathogenesis of neurocardiogenic syncope. In this study, we assessed the sensitivity and specificity of the head-up tilt test with central serotonergic activation, using the serotonin reuptake inhibitor clomipramine (CL-HUT). We also compared this test with the conventional 60° head-up tilt test (CON-HUT) with or without isoproterenol.

Methods: We prospectively studied 126 patients (pts) with a positive history of recurrent VVS (mean age 41±16 yrs, 66 women, 60 men) and 27 healthy control subjects (mean age 46±15 yrs). Both pts and controls underwent sequentially a CL-HUT and a CON-HUT, in random order. During CL-HUT, clomipramine was infused (5 mg in 5 min) at the beginning of the 20 min lasting head-up tilting. CON-HUT was performed at 60° for 30 min and if negative, isoproterenol infusion followed (2-4 μ/min, for 10 min). A 24 hours interval has interspersed between the two tests.

Results: (Table, pos: positive, neg: negative).

The sensitivity and specificity of CL-HUT was 83% and 93% respectively, while for CON-HUT it was 41% and 96%. As shown in the table, the sensitivity and specificity of each test was not dependent on whether it was the 1st or the 2nd one in the randomized order.

	pts			controls		
	1st test	2nd test	total	1st test	2nd test	total
CL-HUT pos	51 (81%)	54 (86%)	105 (83%)	1 (8%)	1 (7%)	2 (7%)
CL-HUT neg	12 (19%)	9 (14%)	21 (17%)	12 (92%)	13 (93%)	25 (93%)
CON-HUT pos	27 (43%)	25 (40%)	52 (41%)	0 (0%)	1 (8%)	1 (4%)
CON-HUT neg	36 (57%)	38 (60%)	74 (59%)	14 (100%)	12 (92%)	26 (96%)

Conclusion: Clomipramine infusion improves the diagnostic value of HUT compared to conventional test, without a loss of specificity. The reproducibility of CL-HUT remains high, independently on whether it is performed as the 1st or the 2nd HUT.

1898 Syncope in young competitive athletes: prevalence, clinical correlates and long-term outcome

F. Colivicchi, F. Ammirati, C. Racani, A. Biffi, V. Altamura, M. Santini. *S. Filippo Neri, Cardiology Dept., Rome, Italy*

Between January 1989 and September 2001, 7568 consecutive young competitive athletes (67,9% males, mean age 16 yrs) underwent a preparticipation cardiovascular screening. Syncopal spells (at least one episode) were reported by 474/7568 athletes (6,2%; mean number of syncopal episodes: 1,2). Syncope was unrelated with exercise in 411/474 athletes (86,7%), post-exertional in 57/474 (12,0%) and exertional in 6/474 (1,3%). In all athletes with non-exertional and post-exertional syncope, the episodes showed the typical clinical features of vasovagal fainting and cardiovascular screening was negative. Athletes with exertional syncope underwent further testing (echocardiography, Holter ECG and maximal exercise testing). Such work-up showed normal results in 4 cases. As to the remaining 2 athletes, echocardiography allowed the diagnosis of hypertrophic cardiomyopathy in 1 case, while repeated episodes of non-sustained ventricular tachycardia were noted during Holter ECG in the other. Both of these athletes were disqualified from further participation in competitive sports. Athletes were followed for a mean period of 84,6 months. Follow-up data were available for 6887 athletes (91,0%), including all subjects who had reported syncopal spells during the initial evaluation. During the follow-up period, 58/411 (14,1%) athletes with previous non-exertional and 9/57 (15,7%) with previous post-exertional syncope showed recurrence of syncope. None of the athletes who had reported exertional syncope had any recurrence of syncope during the follow-up period. Moreover, 1,0% (66/6413) of the athletes who did not report any syncopal spell at the initial evaluation had a non-exertional syncopal episode during the follow-up period. No other major adverse cardiovascular event was noted during the follow-up period. In this study, both non-exertional and post-exertional syncopal spells in athletes were not associated with abnormal cardiovascular findings. Exertional syncope is a rare event in young athletes, but may be associated with significant cardiac abnormalities requiring disqualification.

1899 Dysfunctional baroreflex regulation of sympathetic nerve activity in patients with vasovagal syncope

M. Béchir[1], C. Binggeli[2], R. Chevenard[2], F. Ruschitzka[2], T F. Lüscher[2], G. Noll[2]. [1]*University Hospital Zürich, Cardiologie, Zürich, Switzerland;* [2]*University hospital Zürich, Cardiologie, Zuerich, Switzerland*

Background: The interplay of resting muscle sympathetic nerve activity (MSA) and baroreceptor reflex in patients with vasovagal syncope remains still elusive. Hence, the aim of the present study was to investigate MSA, baroreceptor sensitivity (BRS), heart rate and blood pressure in resting condition and under orthostatic stress in patients with vasovagal syncope.
Methods: MSA was measured using microneurography at rest and during lower body negative pressure (LBNP) to mimic orthostatic stress in patients with a history of vasovagal syncope (n=7) and age-machted healthy volunteers as control (n=7). Heart rate and blood pressure were simultaneously recorded. BRS was calculated with the spectral technique (a coefficient).
Results: Resting MSA in the syncopal group was significantly increased vs. control (26.6±11.0 vs. 44.0±7.9 bursts/min, P=.005). Activation of MSA during orthostatic stress in the syncopal group was significantly blunted (15.2±4.6 vs. 4.6±5.3 bursts/min at LBNP -50 mmHg, P=.0046). The baroreceptor sensitivity was significantly reduced under supine resting conditions and also under orthostatic stress in the group of the patients (7.98 ± 2.58 vs. 13.42 ± 3.48 ms/mmHg, P=.0116; 6.55 ± 2.16 vs. 13.86 ± 4.77 ms/mmHg, P=.0066). BRS remained stable vs. baseline within the groups under LBNP.
Conclusions: This study shows (1) that resting sympathetic nerve activity is increased in patients with vasovagal syncope and (2) baroreflex regulation during orthostatic stress is blunted in these patients, thus leading to impaired MSA adaptation. These results provide the rationale for pharmacological approach to modulate barorecetor sensitivity in treatment of neuromediated syncope.

1900 Value of subcutaneous implantable loop recorder for detection of paroxysmal asystole underlying unexplained syncope

L.V.A Boersma[1], L. Mont[2], A. Sionis[2], E. Garcia[2], J. Brugada[2]. [1]*St. Antonius Hospital/HLCU, Cardiology Department, Nieuwegein, Netherlands;* [2]*Cardiovascular Institute, Arrhythmia Unit Hospital Clínic, Barcelona, Spain*

Introduction: Intermitent cardiac arrhythmias underlying syncope may remain undetected with convential methods. Continuous cardiac monitoring with a subcutaneous implantable loop recorder (ILR) has been introduced as a new diagnostic tool. We evaluated it's diagnostic yield in patients with unexplained syncope.
Methods: Between 1998 and 2000, 26 patients with undiagnosed syncope received an ILR after a negative complete evaluation that included ECG, carotid sinus massage, 24-hour Holter recording, echocardiogram, and electrophysiological study (EPS). The mean age was 58±16 yrs, 16 were male, and 5 had suffered trauma due to the event. Patients were included irrespective of the result of a head-up tilt test(HUTT)because of the severity of symptoms. The ILR (Reveal 9525/9526) was implanted subcutaneously in the left subclavicular, submammary, or subcostal position, and patients were instructed in the use of manual device activation. Follow-up was performed every 3 months or after events.
Results: During a follow-up of 14±5 months, 16 of the 26 patients experienced a total of 44 events. The majority of events consisted of palpitations or dizziness without syncope and the ILR was useful to rule out arrhythmias. True syncope occurred in only 10 patients(38%)during follow up. In 5 of them, the ILR recorded slowing of sinus rhythm followed by asystole and syncope, suggesting a neurally-mediated event. The previous cardiac workup had demonstrated one patient with an old inferior myocardial infarction, one with chronic AF, one with RBBB and LAFB, one with a nocturnal pause < 2 seconds on Holter, and one with a completely normal screening. All patients with a recorded asystole were treated with a pacemaker. In the other 5 patients with recurrence of syncope, no arrhythmias were documented. Two patients were found to have epilepsy while in the remaining 3 patients no diagnosis could be established. Of interest, the HUTT was positive in 5 of the 16 patients that did not have a renewed episode of syncope, but negative in 9 of the 10 patients that did have a true syncopal recurrence. In all patients EPS was normal and no arrhythmias were inducible, despite structural heart disease in some. There were no device related adverse effects during follow-up.
Conclusions: The ILR is a safe and simple diagnostic tool to detect cardiac asystole in selected patients with unexplained syncopal events, and it helps in ruling out arrhythmic causes in others. The HUTT did not predict paroxysmal asystole in this group of patients, in spite of the suspected neurocardiogenic origin.

SMOKING IN PATIENTS WITH ISCHAEMIC HEART DISEASE: RISK ASSESSMENT AND TREATMENT

1922 In the life course, CVD incidence and prevalence is smaller among smokers than among non-smokers: a multistate life table analysis of Framingham

L. Bonneux[1], A.A. Mamun[2], A. Peeters[1] on behalf of NEDCOM. [1]*Erasmus University Rotterdam, Dept of Public Health, Rotterdam, Netherlands;* [2]*University of Groningen, Population Research Centre, Groningen, Netherlands*

Background: The thesis of compression of morbidity suggest that life style modification, with smoking as example, can compress morbidity: incidence can be postponed, but mortality can not decrease beyond natural limits. We investigated this hypothesis by studying cardiovascular morbidity of smokers and non-smokers in the long lasting cohort of the Framingham Heart Study.
Methods: Individual life courses are constructed by estimating annual age specific transition probabilities in multistate life tables describing the states 'free of CVD, CVD, death'. Similar life tables are constructed for CHD, MI, stroke and CHF. Non smokers are defined as participants where smoking was recorded in less than 20% of the available biannual surveys, smokers are participants where smoking was recorded in more than 80% of the surveys.
Results: 70.0% of 5057 persons included had less than 20% of the exams missing. Respectively 24% and 48% of the men were defined as non smokers and smokers, compared to 59% and 25% of the women.
Male non smokers had consistently higher probabilities than smokers of ever having CVD (+1%), coronary heart disease (+4%), MI (+7%), CHF (+5%), but a lower probability of stroke (-10%). Female non smokers had higher probabilities than similar smokers of ever having CVD (+3%) and coronary heart disease (+5%), but a similar probability of MI, and lower probabilities of CHF (-2%) and stroke (-1%).
Male non smokers lived considerably longer with cardiovascular disease: + 2.1 y (CVD), +1.2 y (coronary heart disease), +0.6 y (MI), +0.5 y (CHF) and +0.4 y (stroke). Female non smokers lived longer with cardiovascular disease too, but not with all types: +1.7 y (CVD), + 1.6 y (coronary heart disease), + 0.3 y (stroke), but - 0.1 y (MI and CHF).
The main reason of these apparently surprising results is that male non-smokers lived 7.4 years longer than smokers, but 'only' 5.4 years longer free of CVD. Female non-smokers lived 6.4 years longer, and 4.8 years longer free of CVD.
Conclusion: Ageing causes the paradoxes of health: the better our health, the longer we live, the more we are exposed to age related disorders, the more we need care. The assumption that life style modifications might save health care needs is naive and dangerous to health care budgets. For 2 years added with cardiovascular disease (many of which are asymptomatic), non smokers live 5 years more free of disease. This is sufficient foundation for an anti tobacco policy, as the aim of public health is not to save money, but to save lifeyears.

1923 Smoking and cardiovascular risk following myocardial infarction

H. Jaatun[1], K. Dickstein[1], S. Snapinn[2] on behalf of the OPTIMAAL Study Group. [1]*Central Hospital in Rogaland, Cardiology Division, Stavanger, Norway;* [2]*Merck Research Laboratories, West Point, PA, United States of America*

Background: Smoking is an important risk factor for the development of cardiovascular disease, especially in young patients. However, these patients paradoxically have favourable outcomes compared to non-smokers. Smokers may have less complicated coronary lesions more susceptible to thrombolysis, have a higher incidence of inferior infarction and are generally younger.
Methods: The OPTIMAAL trial compared the effects of losartan and captopril in high-risk patients following AMI. The primary endpoint was all-cause mortality. A total of 5477 patients were randomised from 7 Western European Countries. 67.5% of the patients were smokers or former smokers at randomisation. We assessed all-cause mortality in patients with complicated MI with regard to smoking status and age.
Results: A total of 5477 patients were included in the trial and 926 deaths have occurred. Current smokers had 41% lower risk of death (11.6% vs 19.5%) and 27% lower risk of reinfarction (8,5% vs 11,6%) than other patients. Current and former smokers had 26% lower risk of death (15.9% vs 18.9%) and 18% lower risk of re-infarction (9.9% vs 12.1%). However, after stratifying by age, smoking was associated with an unfavourable outcome. In patients < 60 years, non-smokers had 16% lower risk of death - in patients from 60-69 years, non-smokers had 18% lower risk of death - in patients >70 years, non-smokers had a mortality similar to current/previous smokers.

All cause mortality

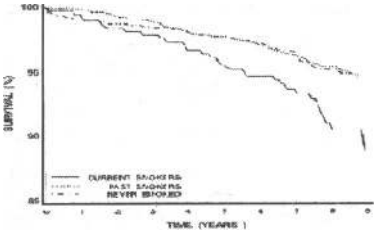
Age group	Current/former smokers	Non-smokers
All	15,9%	18,9%
<60 yrs.	6,8%	5,7%
60-69 yrs.	11,3%	9,3%
>69 yrs.	27,6%	27,1%

Conclusion: It has been reported that smokers apparently have lower rates of mortality and better short-term outcomes than non-smokers following MI. We demonstrate that by stratifying patients into age groups, without correcting for other comorbidity or risk factors, the apparent increase in all-cause mortality in the non-smoker group is explained by the fact that the smokers are generally younger with a better prognosis due to their age. Previous and current smokers had slightly higher mortality during the trial when the data is age-adjusted.

1924 Smoking cessation significantly attenuates sudden cardiac death risk in patients with stable angina and/or healed myocardial infarction

I. Goldenberg[1], M. Jonas[2], A. Tenenbaum[2], V. Boyco[2], A. Shotan[2], S. Behar[2], H. Reicher-Reiss[2]. [1]*Sheba Medical Center, Heart Institute, Ramat Gan, Israel;* [2]*Sheba Medical Center, Heart Institute, Tel Hashomer, Ramat Gan, Israel*

Background: The aim of this study was to evaluate the impact of current cigarette smoking and smoking cessation on sudden cardiac death (SCD) risk in patients with coronary artery disease (CAD).
Methods: We prospectively studied 3,122 patients with a previous myocardial infarction or stable angina who participated in the Bezafibrate Infarction Prevention (BIP) trial. Three hundred and seventy patients were active smokers at randomization and throughout the study period; 1,821 patients had quit smoking before inclusion in the study; 931 patients had never smoked. We compared the incidence of SCD in the 3 groups over a mean follow-up period of 8.2 years.
Results: In current smokers, 30 sudden deaths occurred (8.1%), whereas 83 sudden deaths occurred in patients who had quit smoking (4.6%) and 43 cases of SCD in patients who had never smoked (4.6%, p=0.014). In multivariate analyses, current smoking was associated with a significant increase in the risk of SCD (hazard ratio - 2.47, 95%CI 1.46-4.19). Patients who had stopped smoking had no significant increase in the risk of SCD compared to patients who had never smoked (hazard ratio - 1.06, 95%CI 0.70-1.62). Kaplan Meier survival curves (see figure) showed that After 8.2 years, the estimated rate of survival free of SCD was 95% for past smokers and never smokers and 89% for patients who continued to smoke (p=0.006)
Conclusions: We conclude that current cigarette smoking is a powerful independent predictor of SCD risk in patients with CAD. Patients who quit smoking experienced a significant reduction in SCD risk. Thus, efforts to reduce the burden of mortality from SCD in patients with CAD should include vigorous smoking cessation strategies



Kaplan-Meier survival curves.

1925 Impact of smoking status on outcomes in acute coronary syndromes: the ex-smokers' paradox

W. Lankes[1], D. Himbert[1], H. Littwitz[1], K. White[2], D. Gulba[1] on behalf of the GRACE Investigators. [1]*Krankenhaus Düren, Innere Medizin I, Düren, Germany;* [2]*U Mass Med School, Center for Outcomes Research, Worcester, United States of America*

Epidemiological data describe a smokers' paradox: younger age, yet better survival for smokers in the setting of ST-elevation myocardial infarction (STEMI). Data on the whole range of acute coronary syndromes (ACS): STEMI, non ST-elevation myocardial infarction (NSTEMI) and unstable angina (UA) are lacking.
Methods: The Global Registry of Acute Coronary Events (GRACE) collects data from 10000 ACS cases in 14 countries annually. Treatment and outcome of 15434 patients were analyzed in the STEMI, NSTEMI, and the UA groups.
Results: Smokers (S) more frequently presented with an STEMI (45.7%) than former smokers (FS) (27.3%) and non-smokers (NS) (29.8%). Smokers were mostly males, younger, and more aggressively treated than the FS and the NS in the three groups of ACS.
The in-hospital mortality rates were higher in NS compared with FS and S in each of the three groups of ACS. The multivariate logistic analysis in the ACS patients showed that the in-hospital mortality rate was significantly lower for S (3.3%) and FS (4.3%), but after adjustment for age this benefit only remained for the FS group(OR 0.78).

Smoking status and outcomes in ACS

	STEMI			NSTEMI			UA		
	S	FS	NS	S	FS	NS	S	FS	NS
N	1898	1248	2000	1096	1446	1983	1161	1876	2726
Age median y	56.2	66.4	71.3*	57.9	69.3	72.5*	56.6	66.4	70.2*
Males (%)	81.6	82.0	55.2*	78.2	80.2	50.6*	75.1	75.7	47.5*
History of PCI/CABG (%)	6.5	16.4	9.3*	15.6	30.2	20.6*	22.1	43.4	30.9*
Cath (%)	60.1	60.3	51.4*	59.6	58.4	50.1*	46.8	46.3	38.9*
PCI (%)	44.5	42.4	37.6*	32.9	28.9	26.8*	25.2	19.3	16.3*
Lytics (%)	53.6	42.3	39.9*	6.7	3.1	3.6*	7.4	3.0	3.5*
GP IIb/IIIa (%)	26.9	27.7	24.3	25.6	22.5	20.1*	11.1	7.3	7.5*
Death (%)	3.7	6.5	11.4*	3.3	5.4	6.0*	2.7	1.9	3.8*
Major bleed (%)	3.5	5.2	5.4**	3.0	4.8	4.7**	2.5	2.4	2.2

*Statistically significant at a = <0.001; **Statistically significant at a = <0.05. S = smoker; FS = former smoker; NS = non-smoker; PCI = percutaneous coronary intervention; CABG = coronary artery bypass grafting

Conclusion: Survival benefits for smokers in the setting of ACS can be attributed to younger age and the resultant more aggressive treatment strategies. The reasons for a reduced mortality in ex-smokers remain to be elucidated.

1926 Zyban™ is an effective and well tolerated aid to smoking cessation in smokers with cardiovascular disease – 12 month follow-up phase data

S. Tonstad[1], M. Murphy[2], C. Astbury[3], A. Hider[4], R. Sweet[3] on behalf of the Zyban™ Cardiovascular Study Team. [1]*Ulleval Hospital, Oslo, Norway;* [2]*Oxford Consortium Group, Oxford, United Kingdom;* [3]*GlaxoSmithKline R&D, Psychiatry CDMA, Greenford, United Kingdom;* [4]*GlaxoSmithKine Research & Development, Biomedical Data Sciences, Greenford, United Kingdom*

Cigarette smoking increases cardiovascular disease (CVD) morbidity and mortality, however patients with CVD who quit smoking significantly reduce their risk of subsequent cardiac events and death(1). The OBJECTIVE of this study (ZYB40014) was to demonstrate the efficacy (smoking abstinence) and tolerability of Zyban™ (bupropion SR) compared to placebo in a population of smokers who have CVD, and this abstract details new 12 month follow-up phase data.

Methods: 629 smokers with a history of myocardial infarction, angina, cardiac procedure, heart failure or peripheral vascular disease who were motivated to quit and smoked > 10 cigarettes/day were randomised (1:1) from 28 centres across 10 countries. Subjects received Zyban™ 150mg twice daily or placebo for 7 weeks as out-patients with weekly motivational support. Follow-up visits were attended up to 52 weeks.

Results: Baseline characteristics were similar between treatment groups and subjects had a mean smoking history of 49.6 pack years (S.D. = 25.4). Four week continuous abstinence (weeks 4-7) was more than double in the Zyban™ group, 43%, versus placebo, 19% ($p<0.001$, odds ratio 3.27). Continuous abstinence rates from weeks 4-52 continued to be more than double for Zyban™ compared to placebo (22% vs.9%, $p<0.001$, odds ratio 2.78). From Week 3 through Week 52 weekly point prevalence abstinence in the Zyban™ group was significantly higher compared to placebo (Week 52: 27% vs. 12%, $p<0.001$, odds ratio 2.87). Common adverse events for both treatment groups were insomnia, dry mouth, nausea and dizziness (incidence was greater in the Zyban™ arm) and headache (similar incidence in both treatment groups). Adverse Events leading to withdrawal were comparable between treatment groups (Zyban™ 5% vs. placebo 6%). Analysis of the blood pressure data did not show any statistically or clinically significant effect of treatment.

Conclusions: Our study is the first to show that after 7 weeks treatment with Zyban™, more than twice as many smokers with cardiovascular disease were abstinent at one year compared to placebo, and the safety profile of Zyban™ was similar to that seen in studies conducted in a general smoking population.

THE VESSEL WALL AS A TARGET OF HYPERTENSION

1936 AT2-mediated and NO-dependent vasorelaxation by angiotensin II in SHR treated with losartan

C. Savoia[1], F. Cosentino[1], A. Maffei[2], P. Spinsanti[1], P. De Paolis[1], P. Francia[1], G. Lembo[2], M. Volpe[1]. [1]*"La Sapienza" University, Experimental Medicine and Pathology, Rome, Italy;* [2]*IRCCS, "Neuromed", Pozzilli (Is), Italy*

Vasoconstrictive and proliferative effects of Ang II are mediated by AT1 receptors. The effects of Ang II mediated via AT2 subtypes are less defined. However, growing evidence show that AT2 may be involved in cardiovascular responses to Ang II under certein conditions. The present study was designed to investigate the role of AT2 receptors on aortic vasoreactivity during chronic AT1 blockade with losartan in spontaneously hypertensive rats (SHR).

SHR and WKY (12-13 weeks old n=8) received losartan (30 mg/Kg/day) in the drinking water for 8 weeks. Untreated animals were also studied (n=8). Systolic blood pressure (BP) was measured before and at the end of the treatment by tail cuff method. Isometric tension was continuously recorded in isolated aortic rings. Nitric oxide (NO) release was detected by using the fluorescent probe diaminofluorescein (DAF-2).

BP was significantly reduced only in SHR treated with losartan ($p<0.05$). During submaximal contraction to norepinephrine (10-6 mol/L), Ang II (10^{-6}-10^{-4} mol/L) induced concentration-dependent relaxations only in aortas isolated from treated SHR and not in the untreated animals of both strains. These relaxations were inhibited by the selective AT2 receptor blocker PD123319 ($3x10^{-5}$ mol/L) as well as L-NAME ($3x10^{-5}$ mol/L) and B2 receptor antagonist Hoe-140 ($3x10^{-5}$ mol/L, n=6-8, $p<0.05$). Accordingly, NO production was significantly increased by Ang II only in SHR treated with losartan as assessed by DAF-2 (21±3 and 33±6 relative units for quiescent vs stimulated rings, respectively, n=3, $p<0.05$). By contrast, Ang II did not exert any stimulatory effect in untreated SHR (24±3 and 23±1 relative units for quiescent vs stimulated rings, respectively). Furthermore, DAF-2 fluorescence did not differ in quiescent and Ang II stimulated rings isolated from treated and untreated WKY (19±1 and 19±1 vs 25±3 and 28±1 relative units, respectively, n=3). In a separate group of SHR (n=5) acute exposure to losartan did not unmask any vasorelaxant effect of Ang II.

The present findings demonstrate for the first time an AT2 mediated vasorelaxation by Ang II in SHR chronically treated with losartan. Our results also suggest an involvement of the bradykinin-NO pathway in Ang II-induced vasorelaxation.

1937 Relaxin, a newly described cardiac hormone, is a potent, endothelium dependent, vasodilator in human resistance arteries

C. Fisher[1], F. Johnston[2], C. Hillier[2], J. McMurray[1]. [1]*CRI in Heart Failure, Wolfson Building, Glasgow, United Kingdom;* [2]*Caledonian University, Glasgow, United Kingdom*

Introduction: Though traditionally recognised as a hormone of parturition, relaxin has been shown to be secreted by the myocardium and production is increased in heart failure. We have compared the vasodilator action of relaxin to that of another cardiac secreted peptide, atrial natriuretic factor (ANF). We have also studied relaxin's mechanism of vasorelaxation.

Method: Small resistance arteries isolated from gluteal biopsies, taken from patients (n=8) with coronary heart disease (CHD) and normal left ventricular systolic function, were studied on a wire myograph. After start up protocols to ensure vessel viability and endothelial integrity, each set of vessels was preconstricted with norepinephrine. Cumulative concentration response curves (CCRCs) were constructed comparing relaxin with ANF. CCRCs were also constructed for relaxin comparing arteries whose endothelium had been removed by the established method of intraluminal rubbing with a human hair.

Results: The threshold concentration required to produce a 10% relaxation response was 3pM for relaxin compared with 10nM for ANF. Relaxin was therefore 1000 fold more potent than ANF. ($P<0.05$ using comparison of curves one way ANOVA for repeated measures). Both relaxin and ANF achieved similar maximal response at the highest concentration used.

A statistically significant difference ($P<0.05$) was found between arteries whose endothelium had been removed, where relaxin's vasodilator response was almost completely abolished, compared to the arteries with intact endothelium.

Conclusion: The newly described cardiac hormone relaxin is a more potent vasodilator than ANF in human resistance arteries and is endothelium dependent. It may, therefore, be important in regulating vascular tone and manipulation of relaxin secretion, metabolism and/or receptors may be of therapeutic interest in cardiovascular disease.

1938 Endothelial and contractile function of small resistance artery from hypertensive and diabetic patients: effects of insulin

E. Porteri[1], D. Rizzoni[1], D. Guelfi[1], C. De Ciuceis[1], I. Sleiman[1], G. Boari[1], G.A.M Tiberio[2], E. Agabiti Rosei[1]. [1]*Dept.of Medical and Surgical Sciences, Chair of Internal Medicine, Brescia, Italy;* [2]*University of Brescia, Chair of General Surgery, Brescia, Italy*

We have previously demonstrated that high-dose insulin may induce an increase of the sensitivity to norepinephrine (NE) in mesenteric small resistance arteries of spontaneously hypertensive rats.

Objective: To evaluate the effect of low and high dose insulin on the dose-response curve to NE and acetylcholine (ACH) in subcutaneous small resistance arteries of hypertensive and diabetic patients.

Methods: Ten patients with essential hypertension (EH), 7 patents with non insulin-dependent diabetes mellitus (NIDDM) and 8 patients with both EH and NIDDM (EH+NIDDM) were included in the study. Subcutaneous small resistance arteries (relaxed diameter 160-280 mm) were dissected and mounted on a micromyograph (Mulvany's technique). A concentration-response curve (CRC) to NE (cumulative concentrations from 10^{-8} to 10^{-5} mol/L) and to acetylcholine (cumulative concentrations from 10^{-9} to 10^{-5} mol/L) was performed in the presence or absence of insulin 715 pMol/L (low dose, ld) and 715 nMol/L (high dose, hd).

Results are summarized in the Table (*=$p<0.05$ vs. basal). A significant reduction in the contractile response to NE was observed in the three groups after pre-incubation of the vessels with high-dose insulin (ANOVA between CRC to NE: EH: p=0.02, NIDDM: p=0.03, EH+NIDDM: p= 0.004). No statistically significant effect of low-dose insulin was detected. No difference in the CRC to ACH before or after pre-contraction with either low or high dose insulin was observed in any group (ANOVA=NS in any case).

	EH (n=10)	NIDDM (n=7)	EH+NIDDM (n=8)
Basal NE 10^{-5} mol/L (kPa)	91±47	96±31	105±31
NE 10^{-5} mol/L + low-dose insulin (kPa)	101±36	92±44	103±49
NE 10^{-5} mol/L + high-dose insulin (kPa)	67±30*	80±42*	88±32*

Conclusions: Insulin at high doses seems to induce a decrease in the reactivity to NE in subcutaneous small resistance arteries of patients with NIDDM or EH. This effect does not seem to involve endothelium-dependent mechanisms.

1939 Statins improve endothelial dysfunction in normocholesterolemic mineralocorticoid hypertension

M. Hermann[1], F. Ruschitzka[2], G.G. Camici[1], T.F. Lüscher[2]. [1]University Zuerich-Irchel, Physiology, Zuerich, Switzerland; [2]University Hospital, Cardiology, Zuerich, Switzerland

Background: Statins reduce cardiovascular morbidity and mortality. These beneficial effects, however, cannot be fully explained by their lipid-lowering potential. As such, we investigated the impact of rosuvastatin on endothelial function, the key event in early atherogenesis, in an experimental model of normocholesterolemic hypertension.
Methods: To further evaluate statin-mediated vascular effects, hypertension was induced in Wistar-Kyoto rats by inhibition of the enzyme 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2) which provides mineralocorticoid receptor specificity for aldosterone by metabolizing glucocorticoids to their receptor inactive 11-dehydro derivatives. Inhibition of 11β-HSD2 by liquorice-derived glycyrrhizic acid (GA) therefore results in sodium retention and hypertension. GA was added to the drinking water (3 g/L) for 21 days. From day 8 to 21 rosuvastatin (20 mg/kg/d) or placebo were added to chow. Endothelium-dependent and -independent function were assessed as response to acetylcholine (ACh, 10^{-10}-10^{-5} mol/L) and sodium nitroprusside (SNP, 10^{-10}-10^{-5} mol/L) in isolated aortic rings. In addition, vascular reactivity to endothelin-1 (ET-1; 10^{-10}-10^{-7} mol/L), norepinephrine (NE; 10^{-10}-10^{-5} mol/L) and potassium chloride (KCl, 100 mmol/L) were investigated.
Results: Blood pressure increased in 11β-HSD2 deficient rats treated with GA (175 vs. 153 mmHg in controls; $P<0.01$). Endothelium-dependent relaxations to acetylcholine (10^{-10}-10^{-5}) in aortic rings were blunted after GA treatment (p£0.005 vs. control) and completely blocked by NO-synthase inhibitor L-NAME, while responses to SNP remained unchanged. Rosuvastatin normalized NO-mediated endothelial function in hypertensive animals ($p<0.01$ vs placebo) although blood pressure and cholesterol levels were not affected by rosuvastatin treatment. In addition, vascular reactivity to norepinephine, but not to ET-1, was attenuated by rosuvastatin treatment ($p<0.05$ vs. control).
Conclusion: These data for the first time show that statins improve endothelial dysfunction in normocholesterolemic mineralocorticoid hypertension without affecting blood pressure and cholesterol levels.

1940 Inflammation induced hyporeactivity to vasoconstrictors can be reversed by antioxidants

F. Mittermayer, J. Pleiner, G. Schaller, M. Wolzt. *AKH-Wien, Clinical Pharmacology, Vienna, Austria*

Background: Hyporeactivity to exogenously administered catecholamines is present in acute inflammation and sepsis. The underlying mechanisms in humans are not fully revealed, but oxidative stress may play a significant role. Further it is unclear, whether this hyporeactivity is also detectable for vasoconstrictors which do not act via adrenoceptors.
Methods: In randomized, double blind cross over studies, forearm blood flow responses to Noradrenaline (NE), Vasopressin (VP), and Angiotensin II (ATII) were assessed before and after induction of acute systemic inflammation by low doses of E. coli endotoxin (LPS, 2000 IU/kg iv) or after placebo administration in 9 healthy volunteers. The effect of intraarterial Vitamin C (24 mg/min) or placebo on NE induced vasoconstriction was studied in 8 additional subjects 4 hours after LPS, respectively.
Results: The systemic inflammatory response was associated with systemic vasodilation, increased white blood count, elevated body temperature and reduced Vitamin C plasma concentrations. LPS significantly decreased the responses of FBF to NE by 59%, to VP by 51% and to ATII by 25% ($p<0.05$, all effects). Vasoconstriction to ATII was reduced to a lesser extent by LPS than the other constrictors ($p<0.05$). Coadministration of Vitamin C completely reversed the reduced responsiveness to NE, which was comparable to that observed under baseline conditions.
Discussion: Reduced responsiveness to vasoconstrictors in acute inflammation is not limited to adrenoceptor agonists, but also present with other vasoconstrictors. Oxidative stress may play an important role in the pathogenesis of hyporeactivity to vasoconstrictors during acute inflammation and sepsis.

THE UPS AND DOWNS OF ENDOTHELIAL FUNCTION

1942 Inhibition of Akt-phosphorylation by thrombin, histamine and lysophosphatidylcholine in endothelial cells. Differential role of protein kinase C

B. Thors[1], H. Halldorsson[1], G.D Clarke[1], G. Thorgeirsson[2]. [1]University of Iceland, Department of Pharmacology, Reykjavik, Iceland; [2]Landspitali-University Hospital, Medicine, Division of Cardiology, Reykjavik, Iceland

The serine/threonine protein kinase Akt is involved in embryonic vascular development and neoangiogenesis as well as in several endothelial cell functions, including activation of endothelial NO-synthase (eNOS) and promotion of endothelial cell survival. We have examined the effects of the G-protein activators thrombin and histamine as well as lysophosphatidylcholine (LPC), a mediator of vascular injury, inflammation and atherosclerosis, on Akt phosphorylation in cultured human umbilical vein endothelial cells (HUVEC). Akt phosphorylation was analyzed with the phosphospecific Akt (ser473) antibody by Western blotting. While epidermal growth factor (EGF) was a potent stimulator of Akt-phosphorylation histamine, thrombin and LPC blocked its activation when used in cotreatment with EGF. Following inhibition or downregulation of protein kinase C (PKC) the inhibitory effect of both histamine and thrombin on endothelial response to EGF was prevented. Furthermore, stimulation of PKC, using short term TPA treatment, markedly inhibited the stimulatory effects of EGF on Akt-phosphorylation. Conversely, while LPC also inhibited EGF mediated activation of Akt-phosphorylation, inhibition or downregulation of PKC did not prevent its inhibitory effect. Akt-phosphorylation was also increased by sphingosine-1-phosphate (S1P)treatment and this activity was influenced by the various cotreatments in the same way as the activation by EGF.
Overall, the present study demonstrated that the G-protein activators thrombin and histamine inhibited both EGF and S1P mediated Akt-phosphorylation in HUVEC by activation of PKC while the inhibitory effects of LPC were independent of PKC.

1943 Stretch-induced imbalance between endothelial nitric oxide and superoxide anion production: protective effects of quinaprilat and losartan

F. Cosentino[1], C. Delli Gatti[1], S. Shaw[2], M. Eto[1], M. Volpe[3], T.F. Lüscher[1]. [1]University of Zurich-Irchel, Cardiovascular Research, Zurich, Switzerland; [2]University of Bern, Clinical Research, Bern, Switzerland; [3]"La Sapienza" University, Experimental Medicine and Pathology, Rome, Italy

Nitric oxide (NO) and superoxide (O2-) are free radicals produced by cells of the blood vessels, and their interaction may play an important role in the pathogenesis of vascular disease. Mechanical forces such as pulsatile stretch are involved in O2- production.
To clarify the effect of quinaprilat and losartan on the balance of these free radicals, human aortic endothelial cells (HAEC) were exposed to pulsatile stretch in the presence and the absence of these compounds. Rhytmic stretching was given for 60 minutes by a Flexercell strain unit. O2- production was measured as the superoxide dismutase-inhibitable reduction of cytochrome c. In situ measurements of NO were performed by porphyrinic microsensor. Angiotensin II levels in cultured medium were significantly increased by pulsatile stretch (0.3±0.01 and 0.42±0.03* ng/ml for control vs stretch, respectively, n=6,*$P<0.05$). Stretch-induced production of O2- was inhibited by quinaprilat [7.1±1 vs 2.8±0.7* and 3.9±0.9*, 3±0.7*,1.1±0.8* nmol/60min/105cells for stretch vs control and stretch plus quinaprilat (10-8-10-6M), respectively, n=3-7,*$P<0.05$ vs stretch]. Losartan significantly reduced stretch-induced O2-production only at the highest concentration [3.9±1.2, 4.6±0.5 and 1.8±0.2* nmol/60min/105cells for stretch plus losartan (10-8-10-6M), respectively, n=3-7, *$P<0.05$ vs stretch]. Accordingly, NO concentrations were decreased by stretch (163±9, 275±12* nmol/L for stretch and control, respectively, n=9, *$P<0.05$). Both quinaprilat and losartan prevented the stretch-induced inhibition of NO release [189±16, 231±14*, 313±32* nmol/L for stretch plus quinaprilat (10-8-10-6M) and 118±7, 165±14, 238±19* nmol/L for stretch plus losartan (10-8-10-6M), respectively, n=9, *$P<0.05$ vs stretch].The restoring effects of quinaprilat and losartan on NO release were abolished by bradykininin B2 (Hoe140) and AT2(PD123319) receptor antagonists [175±8 and 111±8 nmol/L for quinaprilat (10-6M) plus Hoe140 (10-7M) and losartan (10-6M) plus PD123319 (10-7M), respectively, n=9]. Interestingly enough, the effect of losartan was also abolished by Hoe140 (147±17 nmol/L).
These results suggest that modulation of renin angiotensin system at different levels may equally affect the balance between NO and O2- production. Quinaprilat improves endothelial function by inhibiting stretch-induced O2- production and restoring NO release by inhibition of bradykinin degradation. Furthermore, this study provides direct evidence that also losartan exerts similar effects via AT2-mediated B2 receptor activation.

1944 Long-term upregulation of eNOS expression and activity in endothelial cells by proteasome inhibition

V. Stangl[1], M. Lorenz[1], S. Meiners[1], P.M. Kloetzel[2], G. Baumann[1], K. Stangl[1]. [1]Charité, Humboldt University, Cardiology, Campus Mitte, Berlin, Germany; [2]Charité, Humboldt University, Biochemistry, Campus Mitte, Berlin, Germany

One of the most important post-transcriptional pathways in eukaryotic cells is the ubiquitin-dependent degradation of proteins by the 26S proteasome. Proteasome inhibtion (PI) reduces restenosis and neointima formation by antiproliferative, antiinflammatory and proapoptotic mechanisms. Since these effects may be also mediated by nitric oxide (NO), we investigated in the present study how PI affects endothelial NO synthase (eNOS) regulation in endothelial cells. Bovine pulmonary arterial endothelial cells (BAEC) and human umbilical vein endothelial cells (HUVECs) were treated with the proteasome inhibitor MG132 for 24 and 48h. Incubation of the cells with MG132 in ultra-low doses (50-500 nM) significantly increased mRNA (online PCR) and protein levels (western blot) of eNOS by 2 to 3fold in a dose-dependent manner. Comparable results were obtained with MG262, whereas ALLM, a non proteasomal cathepsin inhibitor was ineffetive, indicating specificity of the reaction. eNOS activity determined by conversion of L-[3H]arginine to L-[3H]citrulline in vitro and in vivo was also significantly enhanced after PI for 24 and 48 h. Interestingly, time course experiments revealed that incubation of endothelial cells with a single dose of MG132 (50 nM-250nM) was sufficient to significantly enhance eNOS protein and enzyme activity up to 7 days. Western blots evidenced accumulation of poly-ubiquitinylated proteins in the cells demonstrating efficiency of PI after incubation with these very low doses used in our study. Since alpha-amanitin, an inhibitor of RNA polymerase II, strongly reduced overall eNOS mRNA without influencing PI-induced elevation of eNOS mRNA level, protein content or activity, we assumed that PI enhances eNOS by enhancing mRNA stability. These findings suggest a major role of the ubiquitin-proteasome pathway in regulating eNOS protein turnover, thereby providing a novel mechanism to enhance nitric oxide activity.

1945 Statins prevent downregulation of human endothelial NO-synthase gene expression by thrombin: role of Rho/Rho-kinase and protein kinase C

C. Barandier[1], X.F. Ming[1], S. Rusconi[2], Z. Yang[1]. [1]Institute of Physiology, University of, Fribourg, Switzerland; [2]University of Fribourg, Institute of Biochemistry, Fribourg, Switzerland

Thrombin generation and decrease in endothelial nitric oxide synthase (eNOS) gene expression play a pivotal role in acute ischemic cardiovascular events. HMG-CoA reductase inhibitors (statins) demonstrate great beneficial effects. We investigated the regulatory mechanisms of eNOS gene expression by thrombin and the protective role of HMG-CoA reductase inhibitors in cultured endothelial cells isolated from human umbilical veins. Stimulation of the cells with thrombin (4U/ml) for 24 hours down-regulated eNOS protein level (57% decrease). This effect of thrombin was prevented by the HMG-CoA reductase inhibitors simvastatin (10 μM) and cerivastatin (1 μM), and also abrogated by protein kinase C (PKC) inhibitor calphostin C (0.3 μM) or depletion of PKC (i.e. exposure of the cells to 0.1 μM of phorbol ester for 24 hours). Thrombin (4U/ml) activated RhoA (measured by pull-down assay) and Rho-kinase (measured by phosphorylation of the substrate MYPT-1) that was inhibited by simvastatin (10 μM). Calphostin C (0.3 μM), had no significant effect on RhoA, but inhibited Rho-kinase activation in response to thrombin. Similar to thrombin, adenoviral overexpression of a constitutively active RhoA (Rho63) or Rho-kinase (CAT) suppressed eNOS expression. The inhibition of eNOS gene expression by Rho63, but not CAT was abolished by PKC depletion. Thus, long-term stimulation of endothelial cells with thrombin leads to down-regulation of eNOS gene expression via activation of a sequential signalling cascade namely RhoA/PKC/Rho-kinase. Statins protect against endothelial dysfunction induced by thrombin via inhibition of RhoA, which may importantly contribute to the benefits of the drugs in prevention of ischemic cardiovascular events such as ischemic stroke or acute coronary syndromes.

1946 Increased endothelial tetrahydrobiopterin levels in GTPCH-transgenic mice

N. Alp[1], S. Cai[1], I. Smith[2], K. Channon[1]. [1]Dept of Cardiovascular Medicine, Oxford, United Kingdom; [2]John Radcliffe Hospital, Department of Biochemistry, Oxford, United Kingdom

Background There is reduced NO bioavailability in vascular disease states due to eNOS dysfunction. Tetrahydrobiopterin (BH4) is a required co-factor for NO production by eNOS. Supplementation of high dose BH4 improves endothelial dysfunction in humans and animals, but it is unclear whether intracellular BH4 levels are limiting in vascular disease. To investigate the role of BH4 in modulating eNOS function in vivo, we aimed to create transgenic mice with increased endothelial BH4 levels, by targeted over-expression of the rate-limiting enzyme in BH4 biosynthesis, GTP cyclohydrolase-1 (GTPCH).
Methods Transgenic mice were generated in a C57Bl6 background using a construct comprising human GTPCH cDNA, and the endothelial-specific mouse Tie-2 promoter. Founders were identified by genomic PCR, Southern blotting and FISH. Mouse organs were harvested at 6-8 weeks. BH4 levels in tissues and cells were measured with differential iodine oxidation and HPLC.
Results Several GTPCH-transgenic mouse lines were generated. One line had transgenic GTPCH expression by RT-PCR. BH4 levels in heterozygote transgenic heart, lung and aorta, were higher than in controls, but there was no difference in liver or plasma (table), and BH4 levels in transgenic endothelial cells were higher than in myocytes.

BH4 levels in heterozygote GTPCH-transgenic and wild-type mouse organs

Organ (n=3 per group)	BH4 levels (mean (SEM)) (pmol/mg protein)		P value (ANOVA)
	GTPCH-transgenic	Control	
Heart	7.6 (2.6)	0.5 (0.1)	0.06
Lung	25.7 (4.8)	9.2 (2.8)	0.03
Aorta	2.4 (0.6)	1.2 (0.7)	0.04
Liver	43.8 (20)	27.6 (6.5)	0.48
Plasma	7.3 (4.4)	5.2 (2.1)	0.69

Conclusions Targeted endothelial-specific GTPCH over-expression in transgenic mice results in increased endothelial BH4 levels. This is a promising in vivo model to investigate modulation of eNOS dysfunction by intracellular BH4 in vascular disease.Table

1947 ESR measurement of vascular xanthine-oxidase and NAD(P)H-oxidase activity in patients with coronary artery disease

S. Spiekermann[1], U. Landmesser[1], S. Dikalov[2], G. Gamez[2], N. Reepschläger[1], H. Drexler[1], B. Hornig[1], D.G. Harrison[2]. [1]Medizinische Hochschule, Abt. Kardiologie und Angiologie, Hannover, Germany; [2]Emory University, Division of Cardiology, Atlanta, United States of America

Increased vascular superoxide anion (O2-.) formation leads to inactivation of nitric oxide thereby contributing to impaired flow dependent endothelium-mediated vasodilation (FDD) in patients with coronary artery disease (CAD). However, the enzymatic sources of O2-. in human arteries are poorly characterized. We examined xanthine oxidase (XO) and NAD(P)H-oxidase activities in atherosclerotic (AS) and non-atherosclerotic (non-AS) coronary arteries by electron spin resonance spectroscopy (ESR) using the spin trap 1-hydroxy-3-carboxy-pyrrolidine (CPH). In AS arteries, XO and NAD(P)H oxidase activities were 13 ± 2 and 12 ± 2 nmol O2-. x μg-1 x min-1, respectively, i.e. significantly higher as compared to non-AS coronary arteries (7 ± 1.5 and 9.5 ±0.9 nmol O2-. x μg-1 x min-1,respectively; $P < 0.05$ for both compared to AS vessels). Furthermore, we examined endothelium-bound XO activity (released into plasma by heparin bolus injection) in 21 patients with CAD and 10 controls using ESR. FDD of the radial artery was determined in these subjects before and after infusion of the antioxidant vitamin C (25 mg x min-1, i.a.). Endothelium-bound XO activity was increased in patients with CAD (25 ± 4 vs 9 ± 1 nmol O2-.x μl-1 x min-1;$P < 0.01$), correlated inversely with FDD (r=-0.55; $P < 0.05$), and was positively related to the effect of vitamin C on FDD (r=0.54; $P < 0.05$).
Conclusion: These studies represent the first ESR measurements of xanthine oxidase and NAD(P)H oxidase in human vessels and strongly support the concept that increased activities of both enzymes contribute to increased vascular oxidant stress in patients with coronary artery disease. The inverse correlation of XO activity and endothelium-mediated vasodilation supports the concept that increased XO activity contributes to endothelial dysfunction in vivo and may thereby promote the atherosclerotic process.

LONG-TERM RESULTS OF VALUE SURGERY

1948 Doppler echocardiographic comparison of standard versus the haemodynamic-plus St Jude Medical Valve in aortic position: a population-based study

D. Mohty[1], S.G. Steven E Girard[2], Y.M. Youssef F Malouf[2], H.S. Hartzell V Schaff[2], M.E.S. Maurice E Sarano[2], F.A.M. Fletcher A Miller[2].
[1]*Cardiovascular Diseases,* [2]*Cardiology, Mayo Clinic, Rochester, USA*

Background: The Hemodynamic-Plus St Jude valve (HP) is a new type of mechanical prosthesis that has, in vitro, larger effective orifice area (EOA) than the standard SJ (SSJ) (1.63 & 2.06 cm^2 for 19 SSJ & 19 HP & 2.06 & 2.55 cm^2 for 21 SSJ & 21 HP respectively). However, it is unknown whether the better in vitro hemodynamics translate to better in vivo performance, & to a lower incidence of prosthesis-patient mismatch (PPM) (defined as EOA indexed to body surface area (BSA) <0.85 cm^2/m^2), both of which may affect long-term outcome.
Methods & Results: Between 1985 & 2000 at Mayo Clinic, 518 pt had aortic valve replacement using 19 or 21 mm St Jude prostheses. A first postoperative transthoracic echocardiography was performed within 134 days after surgery in 446 (86%) pt. EOA was calculated using the continuity method in 433 (84%) pt, & the mean gradient was measured using the simplified Bernoulli equation, in 438 (85%) pt. The table compares demographic & echo data of 19 SSJ to 19 HP & 21 SSJ to 21HP respectively.

	19 mm (n=183)		P	21mm (n=335)		P
	S-SJ	SJ-HP		S-SJ	SJ-HP	
H	66	117		184	151	
Sex (Female) %	94	88	0.3	66	45	0.0001
Age (years)	63±16	66±13	0.4	63±11	61±14	0.9
Ejection Fraction %	60±12	58±15	0.6	57±13	58±11	0.8
BSA (m^2)	1.62±0.2	1.7±0.2	0.004	1.79±0.2	1.86±0.2	0.0002
Mean gradient (mm Hg)	20±9	18±9	0.01	19±7	17±7	0.001
EOA (cm^2)	1.12±0.2	1.28±0.3	0.002	1.4±0.4	1.62±0.4	0.0001
EOA/BSA (cm^2/m^2)	0.7±0.16	0.76±0.2	0.09	0.8±0.25	0.89±0.24	0.0002
PPM (%)	86	70	0.04	66	46	0.001
7 years survival (%)	65±6%	48±8%	0.3	72±4%	56±9%	0.5

Conclusion: SJ-HP has, in vivo, significantly lower mean gradient & larger EOA than SSJ in both 19 & 21 mm sizes. Morever, the % of PPM is higher in pt with SSJ for both sizes. At 7 years, the hemodynamic advantage of SJ-HP does not appear to be associated with improved survival. Longer follow up may be necessary to determine whether the in vivo hemodynamic advantage of SJ-HP translates into improved survival.

1949 Clinical outcome after implantation of the Prima Edwards Stentless Bioprosthesis model 2500: a multicenter study

W. Konertz[1], P.M. Dohmen[1], H. Vanermen[2], R. Pillai[3], W. Daenen[4]. [1]*Charité Hospital, Humboldt University, Cardiovascular Surgery, Berlin, Germany;* [2]*O.L. Vrouwenziekenhuis, Thoracic and Cardiovascular Surgery, Aalst, Germany;* [3]*John Radcliffe Hospital, Oxford Heart Center, Oxford, United Kingdom;* [4]*Catholic University Louvain, Cardiac Surgery, Louvain, Belgium*

Purpose: This study was performed to collect prospective safety and effectiveness data of the Edwards Prima Stentless Bioprosthesis in patients requiring replacement of a native aortic heart valve.
Methods: Between 1991 and 1993 four centers implanted the Prima Stentless Bioprosthesis in 160 patients with the subcoronary technique using a common, prospective protocol. Patients were followed for both acute and long-term evaluation of complications, NYHA class improvement and hemodynamic measures. The mean age at implant was 70.6 ± 6.1 years, with 53.8% of the patients being male. The maximum follow-up was 8.2 years with a mean of 5.8 ± 2.1 years. The cumulative total data collected represents 934.4 patient-years.
Results: At the 1 and 4-5 year post implant interval, 93.8% and 75.0% of the patients, respectively, showed improvement in their last available NYHA classification versus the preoperative NYHA classification. The table shows the principal safety parameters. Rate of thromboembolism, thrombosis, AC-related hemorrhage, paravalvular leak and incidence of endocarditis through eight years post implant showed acceptable results as compared to the FDA OPCs for tissue valves. The effectiveness of the device was demonstrated by low mean gradients (15.9±1.1 mmHg fore size 21, 9.9±1.6 mmHg fore size 23, 8.8±1.9 mmHg fore size 25, 6.5±2.1 mmHg fore size 27 and 4.2±2.6 mmHg fore size 29) at 4-5 years follow up and absence of regurgitation.

Valve-related complications	Operative (%)	Postoperative (%/Pt-Yr)	Freedom from events (%)
expiration (all)	3.8	5.5	66.6 ± 19.2
valve related expiration	1.3	2.7	86.1 ± 16.1
valve related reoperation/explant	0.0	1.1	95.4 ± 10.2
structural valve deterioration	0.0	1.8	87.2 ± 15.6
hemolysis	0.0	0.2	100.0 ± 0.0

Conclusions: The Edwards Prima Stentless Bioprosthesis is safe and effective as an aortic valve replacement in the subcoronary configuration as evidenced by low rate of valve-related complications, the improvement in NYHA classification and the acceptable results of hemodynamic evaluation at one and five years post implant.

1950 Up to 8 years experience with the Ross procedure using the subcoronary and inclusion technique

C. Schmidtke, U. Stierle, H.H. Sievers. *Medical University of Luebeck, Cardiac Surgery, Luebeck, Germany*

Purpose Since the early 90's the pulmonary autograft is predominantly implanted as a full root replacement for less regurgitation is expected in the long term. However, there is a certain risk of dilation of the root over time bearing the potential to influence valve function. We favored since 8 years the original subcoronary and inclusion technique to preserve the root of the patient. Hemodynamic follow-up of the autograft implanted in this techniques is not well defined.
Methods Between 2/90 and 01/02 the Ross procedure was performed in 244 patients. The subcoronary and inclusion technique was performed in 231 patients (177 m/ 54 f), mean age 46.5±13.4 (15-70 years). The underlying aortic valve disease was an aortic insufficiency (AI) in n=75, stenosis in n=47, combined aortic valve disease in n=104 and an acute endocarditis in n=19 patients. Previous aortic valve surgery was performed in n=22. Last follow-up investigations including echocardiographic determinations of hemodynamic variables, autograft and homograft function were applied at a mean follow-up of 29.5±24.8 (0.1-84.5) months (543.7 patient years).
Results The hospital (n=2) and late mortality (n=2, non cardiac cause of death) were low. 2 patients were lost to follow-up. Late neurological events occurred in 4 patients. Reoperations n=5 (due to autograft insufficiency n=1, homograft stenosis n=2, homograft insufficiency n=1, auto- and homograft insufficiency n=1).
Autograft function was good (AI<=I°) in 96.3%, and acceptable (AI II°) in 3.7%. The maximum/ mean pressure gradient was 6.5±3.3 (2.1-25.9)/ 3.5±1.7 (1.2-13.2) mmHg. Homograft insufficiency was <=I° in 95.4%, II° in 4.1%, III° in 0.5%. Maximum and mean pressure gradients: 11.9±7.0 (2.2-42.6) and 6.2±3.7 (1.2-21.0) mmHg, respectively. Cardiac output was 5.4±1.7 l/min and ejection fraction 60±9.0%. Most patients were in NYHA class I (90.4%).
Conclusions Aortic valve replacement with a pulmonary autograft shows excellent hemodynamics with a low incidence of autograft failure or homograft obstruction at least in a short term period in the subcoronary or inclusion technique.

1951 Bicuspid valve preservation and concomitant repair of the ascending aorta and/or root

A.W. Erasmi, U. Stierle, H-H. Sievers. *University of Luebeck, Cardiac Surgery, Luebeck, Germany*

Purpose: The surgical strategy for treatment of the aortic root and valve in aneurysmal or dissecting disease of the ascending aorta involving the aortic root is controversial. A congenital malformed aortic valve may lead in most circumstances to a valve replacement even if the leaflets itself are unremarkable. We reviewed our experience with bileaflet valve preservation in aortic surgery.
Method: Between October 1993 and November 2001 we operated upon 59 patients with a bicuspid aortic valve who had either a combined aortic valve dysfunction and ascending aortic pathology (aneurysm: n=42, type A dissection: n=9) or an ascending aortic pathology alone (n=8). Among these were 14 patients (23.7%) in which the aortic valve could be preserved during replacement of the ascending aorta and the aortic root (n=11) or the supracommissural ascending aorta (n=3). The age was 44.9±18.0 years. All these patients had an aneurysm (diameter 6.3±1.2, range 4.4-10 cm), one patient presented with acute aortic dissection type A. The aortic valve was insufficient in 7 patients (grade 1: n=1, grade 2: n=4, grade 3: n=2) and mild stenotic (grade 1) in one patient. Only leaflets without calcification and with dense tissue for secure suture fixation were regarded appropriate for repair independent of root pathology. Predominantly plication of the prolapsing leaflet with the raphe was performed. In one patient plication of both leaflets was feasible.
We followed the patients clinically and echocardiographically for 27.5±27.7 month (range 0.2-92.8 month).
Results: No patient required reoperation. No hospital or late death occurred. Two patients presented dyspnoea according NYHA grade 2, the others were asymptomatic without limitations in life. None of the patients reported thromboembolic events. No patient had an aortic valve insufficiency higher than grade 1. Other echocardiographic examination data were: mean aortic valve pressure gradient 5.1±2.6 mmHg, ejection fraction 67.2±8.0%, cardiac output 5.4±1.6 l.
Conclusion: The midterm results (up to 8 years) of aortic valve preservation during surgery on the ascending aorta and aortic root are encouraging provided careful selection of patients and techniques are thoroughly performed including concomitant repair of the aortic root.

1952 Five years experience with mitral valve homografts

H. Gulbins, E. Kilian, A. Uhlig, E. Kreuzer, B. Reichart. *University Hopsital Grosshadern, Cardiac Surgery, Munich, Germany*

Introduction: We present our five years experience utilizing mitral HG's in mitral valve surgery. Patients and methods: 14 patients (mean age 46 ± 8 ys, 27-65 ys) had mitral HG's implanted. In 13 cases, the grafts were implanted in mitral position, once the septal leaflet of the tricuspid valve was replaced. The indications were mitral (n=6) or tricuspid endocarditis (n=1), mitral valve stenosis (n=3) and combined mitral valve disease (n=4). Complete mitral HG's were implanted in patients with combined mitral valve disease (n=4), mitral valve stenosis (n=3), and mitral valve endocarditis (n=1). Partial HG's were implanted in mitral (n=5) or tricuspid valve endocarditis (n=1). Preoperatively, the dimensions of the mitral valve were measured using transesophageal echocardiography (TEE). Surgery started with papillary muscle implantation with a side-to-side anastomosis to the recipients papillary muscle, followed by the annulus. For annular stabilization, a Carpentier ring was implanted. Follow-up was initiated six months postoperatively and then continued on a yearly basis, inlcuding clinical examination, ECG, and echocardiography. The following parameters were determined echocardiographically: left atrial size, left ventricular enddiastolic and endsystolic diameter, pressure gradient across the mitral valve (C/W-Doppler,Bernoulli-equiation), and mitral regurgitation. Results: All patients survived the operation. Intraoperative TEE revealed an insufficiency °I in 7 patients. Follow-up is complete in all patients (mean period of 30 months,6-66 m.). Two patients had repeat valve replacement due to newly aquired endocarditis. One more patient had to be reoperated due to chordal rupture one year postoperatively. In the remaining 11 patients, the morphological and functional state of the implanted HG's remained unchanged during follow-up. The freedom of valve-related events was 93% after one year and 75% after two years respectively. At six month follow-up, ECG and echocardiography revealed sinus rhythm and sufficient atrial contractions in all cases, so anticoagulation was discontinued in all patients. At the last follow-up, the pressure gradients were 3.4 ± 0.6 mmHg for complete HG's and 2.8 ± 0.6 mmHg for partial HG's. Conclusions: Mitral HG's can be used with acceptable mid-term results in selected cases with good left ventricular function and only slighty dilated left ventricles. Especially partial mitral HG's represent an additional technique for mitral valve repair. Their obvious sensibility to bacterial infections makes strict endocarditis-prophylaxis mandatory.

1953 Importance of the etiology in the outcomes of mitral valve repair: an 8-year follow-up

P. Stutzbach[1], H. Raffaelli[2], E. Gabe[2], A. Machain[2], C. Gomez[3], R.R. Favaloro[2]. *[1]Favaloro Foundation, Valvular Heart Disease, Buenos Aires, Argentina; [2]Favaloro Foundation, Surgery Department, Buenos Aires, Argentina; [3]Favaloro Foundation, Department of Anesthesia, Buenos Aires, Argentina*

Background: Mitral regurgitation prognosis should be made on the basis of the valve dysfunction etiology. This study analyzes 8-year outcomes of mitral valve repair (MVR) and assesses the significance of association between the etiology of mitral insufficiency and MVR outcomes.
Methods: From September 1992 through June 2001, 302 patients underwent MVR. Mean age was 58±14 years (range 21-82 years); 195 patients (65%) were men. The etiology was: myxomatous (Mx) in 187 patients (64%); ischemic (Is) in 62 patients (17%); rheumatic (Rh) in 18 patients (6%); secondary dilated cardiomyopathy in 11 patients (3.5%); infectious endocarditis in 13 patients (4.5%), and secondary aortic valve disease with ventricular dysfunction in 11 patients (3.5%). Freedom from events was studied by Kaplan Meier curves (confidence interval 95%): survival, reoperation, endocarditis, and thromboembolism. Mx etiology was compared to the rest of the etiologies using log rank test.
Results: Mean follow-up was 44±50 months.

	Hospital Mortality	Survival	Reoperation	Infectious Endocarditis	Thromboembolism
Total	6.3% (19/302)	89% (85-93%)	95% (92-97%)	98% (93-100%)	98% (93-100%)
Mx	3.8% (7/187)	91% (87-95%)	95% (91-98%)	99% (94-100%)	99% (94-100%)
Is	13% (8/62)	56% (45-67%)	98% (93-100%)	100%	99% (94-100%)
Rh	0% (0/18)	94% (84-100%)	83% (67-100%)	98% (93-100%)	96% (90-100%)
Dilated Cardio-myopathy	9% (1/11)	78% (61-100%)	100%	100%	
Infectious Endocarditis	7.6% (1/13)	90% (86-94%)	90% (86-94%)	100%	100%

Survival was significantly lower in patients with Is than in patients with Mx (p=0.03 and p=0.04). Rh showed a tendency for reoperation (p=0.05).
Conclusion: Patients with Mx undergoing MVR have better outcomes than those with Is and Rh. Thus, the results of MVR will clearly depend on the etiology of mitral insufficiency.

CARDIOVASCULAR DISEASES IN THE YOUNG: CONSEQUENCES LATER ON

1954 Effects of serum cholesterol levels on inflammatory markers and haemostatic/thrombotic mechanisms in children with familial hypercholesterolemia

M. Charakida[1], D. Tousoulis[2], I. Skoumas[2], E. Charakida[2], C. Antoniades[2], M. Toutouza[2], C. Stefanadis[2], P. Toutouzas[2]. *[1]Cardiology Unit Hippokration Hospital, Athens, Greece; [2]Athens University Medical School, Cardiology Unit Hippokration Hospital, Athens, Greece*

Background: It is well known that children with familial hypercholesterolemia (FH) are likely to establish premature coronary atherosclerosis. Furthermore it has been established that inflammatory process is an important component in the pathophysiology of endothelium and atherosclerosis. Proinflammatory markers such as vascular cell adhesion molecule-1 (sVCAM-1) and intercellular adhesion molecule-1(sICAM-1) have been proposed as new risk factors for cardiovascular disease. Apart from inflammation, haemostatic factors seem to play a pivotal role in the atherosclerotic process and several factors such as plasma levels of factor VII(fVII), von Willebrand factor (vWf) and fibrinogen are related to premature atherosclerosis and are affected in endothelial dysfunction. The purpose of our study was to investigate the impact of cholesterol levels on inflammatory, thrombotic and haemostatic markers in children with familial hypercholesterolemia.
Methods: We studied 21 children (aged 10-20) with FH and 17 controls of the same age. Serum levels of TNF-a, sICAM-1 and sVCAM-1 as well as plasma levels of fVII, VWF and fibrinogen were determined using enzyme linked immunosorbent assay (ELISA). Pearson's correlation was determined between total cholesterol and inflammatory and thrombotic/ fibrinolytic components.
Results: Serum cholesterol level was 316.4±16 mg/dl and 155±4.5mg/dl in FH group and in controls respectively. Serum level of cholesterol was correlated to fibrinogen plasma levels (r=0.4, p<0.04), to vWF levels (r=0.51, p<0.05), to VCAM-1 levels (r=0.62, p<0.62) and to ICAM-1 serum levels (r=0.66, p<0.05). No significant correlation was found between cholesterol and TNF-a and factor VII.
Conclusions: In children with familial hypercholesterolemia a significant correlation was found between serum cholesterol levels and inflammatory and thrombotic/haemostatic markers. These findings indicate that the increased inflammation and the thrombotic process observed in these children with high serum cholesterol may play an important role in the development of premature atherosclerosis.

1955 Relations of localization, heamodynamic changes and thrombus formation in coronary aneurysms having history with Kawasaki disease

S. Ogawa, R. Fukazawa, T. Ohkubo, M. Kamisago, Y. Uchikoba, D. Fukumi, E. Ikegami, Y. Katsube. *Nippon Medical School Hospital, Pediatrics, Tokyo, Japan*

Thrombus formation in coronary aneurysms (AN) is an important complication of Kawasaki disease (KD), which often occurs giant aneurysms and can cause myocardial ischemia and infarction. We hypothesized that ANs could exist at the coronary artery branching sites because of reduced shear stress, and reduced shear stress inside AN also could relate the mechanism of thrombus formation strongly. 111 children aged 2 to 16 years old who had left coronary abnormality by 2-D echo and were 1 to 15 years from the onset of KD were subjected. Patients had no significant stenosis in proximal and distal portion of AN and were divided into three groups by the maximum diameter of AN; giant aneurysms group (Group G: maximum diameter is more than 8mm, n=28), aneurysms group (Group A: maximum diameter < 8mm, n=44), and control group (Group N: normal-looking vessels by CAG, n=39). All patients had Aspirin and/or Warfarin. The averaged peak coronary flow velocity (APV) was measured in the middle of ANs in Group A and G, and branching sites of segment 5-6-11 in Group N using 0.0014-in Doppler flow guide wire (Cardiometrics), and shear stress were calculated by the simplified formula as: shear stress = 4mxAPV/(R/2), where m is blood viscosity measured by viscocimeter, R is maximum inner diameter of aneurysm or coronary vessel measured by CAG or IVUS. Also, IVUS were performed for detection of thrombus and measurement of coronary diameters. Localization of ANs were detected by CAG and IVUS.
Results: The values of APV and shear stress in Group G (2.3±0.7, 11.8±3.6) were significantly low as compared to those in Group A (17.6±4.2, 22.6±2.4) and N (9.9±1.8, 11.8±3.6). Also, there were significant differences in the values of APV and shear stress between Group A and N. Thrombus formations were detected 85.7% only in Group G. Moreover, localization of ANs were observed 88.6% at branching position and 11.4% at non-branchig position in Group A, and 100% at branching position in Group G.
Conclusions: Coronary aneurysms localized at the coronary artery branching position predominantly because of reduced shear stress. Stagnation of coronary flow and reduced shear stress may critical play a role of giant aneurysm and thrombus formation intra coronary aneurysms in children with Kawasaki disease.

1956 Echocardiographic characterization of thoracic aorta dimensions in patients with Turner Syndrome

L. Lanzarini[1], A. Fontana[2], D. Larizza[3], V. Calcaterra[3], M.E. Bernardo[3], C. Klersy[4], R. Rosso[2]. [1]Cardiology Department, [2]IRCCS Policlinico S. Matteo, Cardiology Dept., [3]IRCCS Policlinico S. Matteo, Pediatrics Dept., [4]IRCCS Policlinico S. Matteo, Biometry Service, Pavia, Italy

Pts with Turner Syndrome (TS) are frequently affected by aortic disease which may progress into dissection and may be the cause of excessive mortality.The aim of this study was to assess, with 2D-echocardiography (2DE), aortic diameters (aortic root, AoR; supraaortic ridge, SAoR; ascending thoracic aorta, ATAo; aortic arch,AoRC; descending thoracic aorta,DTAo; abdominal aorta,ABAo) and to investigate the clinical characteristics associated with aortic pathology in an unselected group of 67 karyotypically proven TS pts (mean age 22±9 yrs). The Aortic Root Ratio (AoRR)(expected/observed aortic root diameter, according to a formula that incorporates age and BSA), was calculated in every case (AoRR=1=normal). According to centile distribution of AoRR, the population was divided into 3 groups, G1: <25th centile, n=18 (27%), mean AoRR 0.93±0.04(range 0.83-0.98); G2: 25th-75th centile, n=32 (48%), mean AoRR 1.06±0.05(range 1-1.16); G3: >75th centile n=17 (25%), mean AoRR 1.31±0.09 (range 1.19-1.47). No significant differences were observed between groups considering karyotype distribution, age at observation, weight at birth, BSA, systolic blood pressure, presence of thickening of the nucal fold, hormonal therapy (growth, estrogen, thyroid),cardiac dimensions, left ventricular wall thickness, cardiac function. Body Mass Index (kg/m^2) was significantly higher in G1 compared to G2 and G3 (53±12 vs 21±4.5 and 2±4.3, $p<0.05$),whereas congenital lymphedema occurred more frequently in G3 compared to G2 and G1 (yes vs no: 39% vs 18% in G3, 52% vs 46% in G2 and 9% vs 36% in G1, $p<0.05$). Not only AoRR diameter was significantly higher in G3 compared to G2 and G1 ($p<0.0001$), but aortic dilation showed to significantly extend toward the aortic arch in G3 compared to G2 and G1: SAoR 22±6 vs 19±4 and 16.5±3 mm,$p<0.05$; ATAo 26±5 vs 22±4 and 20±2.5 mm,$p<.0005$; AoRC 23±6 vs 19±3.6 and 20±3 mm,$p<.005$, but not to the DTAo 14±3.9 vs 14±3.4 and 14±2.2 mm or to the ABAo 13.2±2.1 vs 12.7±2.4 and 12.4±1.5 mm, p=ns. **Conclusions:** 1) pts with TS may present with proximal aortic diameters that are frequently below (27% with AoRR<1) or above (25% with AoRR>1.1) the normal expected values; 2) small AoR are associated with a higher BMI, that means small stature and/or overweight; 3) dilated aortas are more common in pts with congenital lymphedema suggesting a linkage with a connective tissue disorder; 4) when the AoR is involved, dilation of the SAoR, ATAo and AoRC is usually the case, thus explaining the association between TS and type A dissecting aortic aneurysm.

1957 Changes in regional right and left ventricular systolic function in tetralogy of Fallot: an ultrasonic strain and strain rate imaging study

G. Di Salvo[1], B. Eyskens[2], L. Mertens[2], B. Bijnens[1], F. Weidemann[1], P. Claus[1], M. Gewilling[2], G.R. Sutherland[1]. [1]Dept. of Cardiology, [2]Pediatric Cardiology, University Hospital Gasthuisberg, Leuven, Belgium

Background: The quantification of regional myocardial function in Tetralogy of Fallot (TOF) by conventional echocardiography may be difficult because of the complex morphology of the right ventricle (RV) and the associated altered geometry of the left ventricle (LV). Ultrasound-based peak systolic strain (S) (%) and strain rate (SR) (unit S^{-1}) are new parameters for quantifying regional deformation. For normal myocardium, the first is altered by changes in end diastolic volume/stroke volume, while the second correlates with local Dp/Dt.
Methods: A Doppler Myocardial Imaging study (DMI) was performed in 54 TOF patients (mean age 11±3yrs) who had undergone surgical correction. Of these 44 pts had moderate/severe pulmonary regurgitation. None had significant pulmonary stenosis. All patients were asymptomatic. Data were compared with those of 30 age matched controls (12±4yrs). Longitudinal systolic strain was measured for basal, mid and apical segments of the LV lateral and septal walls and from the RV free wall.
Results: Long axis S in each RV segment was significantly ($p<0.0001$) lower in TOF (S: Basal -18±6, Mid -21±5, Apical -21±6) than in controls (S: Basal -36±11, Mid -45±13, Apical -34±11). Moreover, regional S in TOF was significantly reduced in each segment of LV lateral wall and septum compared to controls ($p<0.02$). In TOF, regional SR was significantly lower in all RV and LV segments compared to controls (table). Radial LV function was also significantly ($p<0.001$) reduced in TOF (SR: 3.0±0.9; S: 45±17; Controls: SR: 3.7±1.1; S: 58±12). RVEDD correlated significantly with S ($p<0.0001$,R=0.67), but not with SR.
Conclusions: SR and S provide complementary information and showed reduced regional deformation properties in both ventricles for both long axis and radial function in asymptomatic TOF. SR measurements would appear to be a new volume independent parameter of regional RV and LV contractility which may improve the understanding of functional changes in these complex pts.

	TOF Septum	Controls Septum	TOF LV Lateral	Controls LV Lateral	TOF RV	Controls RV
Base	-1.5±0.4*	-1.8±0.6	-1.2±0.7*	-2.2±1.1	-1.4±0.7*	-2.4±0.6
Mid	-1.4±0.3*	-1.9±0.6	-1.6±0.6**	-2.1±1.0	-1.6±0.6*	-2.8±0.7

1958 Superior quantification of pulmonary blood flow by MRI compared to lung perfusion scintigraphy in patients with Fontan circulation

S. Fratz[1], J. Hess[1], M. Schwaiger[2], S. Martinoff[3], H.C. Stern[1]. [1]Deutsches Herzentrum München, TUM, Congenital Heart Disease, [2]Klinikum rechts der Isar, TUM, Nuclear Medicine, [3]Deutsches Herzentrum München, TUM, Radiology, Munich, Germany

Background: Quantitative evaluation of pulmonary perfusion using lung perfusion scintigraphy in patients with atriopulmonary anastomosis (APA) or cavopulmonary connections (TCPC, PCPC) is difficult due to preferential draining of the venae cavae to one lung. Scintigraphy is the gold standard and phase-velocity magnetic resonance imaging (PV-MRI) in combination with flow analysis software (Massflow ®) is a new technique in determing pulmonary perfusion. The aim of this study was therefore to compare these two methods for quantitative evaluation of pulmonary perfusion ratios in patients with APA, TCPC, or PCPC.
Methods and Results: We studied 15 patients with APA, TCPC, or PCPC (16 ± 7 years old, four female). Twelve patients (15 ± 8 years old, three female) with a single pulmonary blood source supplied by a subpulmonary ventricle, ensuring complete mixing of the radioactive tracer before entering the pulmonary circulation, served as control. Pulmonary scintigraphy and PV-MRI were performed in all patients. Bland-Altman analysis showed a clinically unacceptable difference of 7.1% right pulmonary blood flow (27.2% upper and -13.0% lower limit of agreement) between the two methods in the study group. The two methods agreed excellently in the control group (difference: -1.6%, 4.0% upper and -7.2% lower limit of agreement), showing that the bad agreement in the study group was caused by the problems encountered using pulmonary scintigraphy in patients with APA, TCPC, or PCPC.
Conclusions: Flow quantification with PVC MRI is feasible in patients after Fontan like palliation. Due to preferential caval flow into either lung side in patients with Fontan like circulation PV-MRI is more accurate in evaluation of pulmonary perfusion ratios than lung perfusion scintigraphy. It does not need two injections on subsequent days into the upper and lower limb, respectively. Another benefit of MRI may lie in the possibility of quantifiing and showing the cause of pulmonary blood flow patterns in one session. Neither scintigraphy nor angiography can meet both demands in one examination.

1959 Haemodynamic status and right ventricular performance in infants with hypoplastic left heart syndrome after modified Norwood operation

Z. Kordon[1], A. Rudzinski[1], E. Malec[2], K. Januszewska[2], P. Werynski[1]. [1]Pediatric Cardiology, Krakow, Poland; [2]Dept. of Pediatric Cardiac Surgery, Polish-American Children Hospital, Krakow, Poland

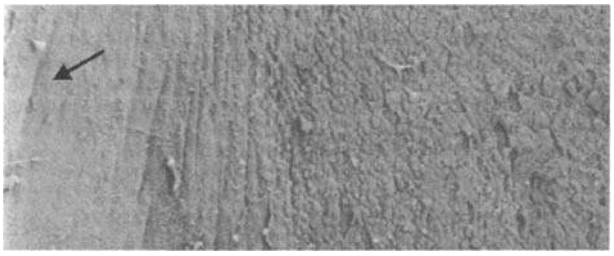
Objective: To stabilise the systemic circulation and to prevent circulatory collapse in infants with hypoplastic left heart syndrome (HLHS) after the classic Norwood operation, there has been recently reintroduced the modification of first stage of palliation by placement a right ventricle – to – pulmonary artery shunt (RV – PA). To assess the influence of RV – PA on right ventricular function and hemodynamic changes after this modification, early (1 to 5 mo) postoperative echocardiographic (ECHO) results were compared with the preoperative parameters.
Material: Since June 2001 to January 2002, 18 consecutive infants (13 M, 5 F), at the mean age of 17 days (3 – 41), weighing 2.3 to 4.3 kg with HLHS, underwent modified Norwood operation with PTFE grafts placed between RVOT and the confluence of PA using 5 mm in diameter grafts in 17 pts and 4 mm in 1 pt. Two infants (11.1%) died early postoperatively. The survivors (16 pts.) comprised the study material.
Methods: Based on ECHO studies a comparative statistic pre- and postoperative analysis was made of RV end-diastolic and systolic volume (EDV, ESV) by Levine method, pulmonary (Qp), systemic (Qs) and combined (Qp+Qs) blood flow indexed for BSA, Qp/Qs, RV ejection fraction (EF), Tei index (TI), RV anterior wall thickening fraction (AWTF), heart rate (HR) and systemic blood saturation (SO2) assessed by pulse oximetry.
Results: A significant post- vs preoperative decrease of mean values was noted in SO2 (78.2 vs 87.5%, p=0.001), HR (124 vs 146/min, p=0.009), Qp+Qs (7.8 vs 10.6 l/min/m^2, p=0.004), Qp (2.7 vs 8.1 l/min/m^2, $p<0.001$) and Qp/Qs (0.6 vs 3.7, $p<0.001$). The values of Qs (4.8 vs 2.4 l/min/m^2, p=0.001), TI (0.53 vs 0.38, p=0.04) and BSA (0.25 vs 0.21, p=0.003) were significantly increased, while mean values of EDV (75.7 vs 80.9 ml/m^2), ESV (43.8 vs 44.9 ml/m^2), EF (41.9 vs 44.1%) and AWTF (38.2 vs 55.2%) remained statistically unchanged.
Conclusions: 1. Modified Norwood operation influences on significant postoperative reduction of the combined right ventricular output, pulmonary blood flow, Qp/Qs and consequently systemic blood saturation, and normalises the systemic blood flow in infants with HLHS. 2. This modification does not affect the right ventricular anterior wall contractility and systolic function but may deteriorate their global function in early postoperative period.

CHARACTERIZATION OF THE VULNERABLE PLAQUE BY HEAT, ELASTICITY OR MORPHOLOGY

1960 Safety of the "contact with the wall" coronary thermography methods. Comparison with standard catheters

L. Diamantopoulos, W. Desmet, I. De Scheerder, Y. Huang, L. Xiaoshun, F. Van de Werf. *UZ Gasthuisberg Hospital, Interventional Cardiology, Leuven, Belgium*

Background: Sensor-based thermography is being curently used to study the arterial wall temperature. Sensors include thermistors and thermocouples. In order for these sensors to give a measurement, good thermal contact with the arterial wall has to be established. The purpose of this study was to examine the safety of such a "thermal contact" and evaluate the impact on the arterial wall.
Methods: We used a thermography catheter with 4 thermistor sensors. When the catheter is in measuring configuration, the sensors come in close contact with the arterial wall and a motorized pullback is engaged.We studied the proximal left anterior descending artery in 15 non-atherosclerotic pigs. Pigs were separated in 3 equal groups: In group A we performed a single thermographic scan for a total length of 40mm, using a pullback speed of 0,3mm/sec. In group B we performed a single pullback (same length and speed) of a balloon catheter without inflating it. In group C we performed the same, but this time using a stent catheter. Animals were sacrificed immediately, and histology and electron microscopy (SEM) were performed.
Results: SEM showed clearly that in the case of thermography the sensors caused minor denudation of the endothelium that was strictly limited to the sensor contact area, while the basic membrane was left unharmed. In the case of the not-inflated balloon catheter there was also endothelial denudation with unharmed basic membrane; denudation was worse in the case of the not-inflated stent catheter.



Stent-catheter passage:denudation (arrow).

Conclusions: From this study, it is clear that in reality there is no such thing as non-contact catheter. Every intracoronary catheter has an impact on the endothelium and its function. However, when these devices are carefully used, risks of events are relatively low.

1961 Arterial remodelling in acute coronary syndromes: correlation of intracoronary ultrasound characteristics with temperature of the culprit lesion

K. Toutouzas, C. Stefanadis, M. Vavouranakis, E. Tsiamis, S. Vaina, D. Tsekoura, C. Pitsavos, P. Toutouzas. *Hippokration Hospital, Dept of Cardiology, Athens, Greece*

Previous studies have shown positive remodelling of the atherosclerotic plaques in patients (pts) with acute coronary syndromes (ACS). Additionally, involvement of inflammation in the pathogenesis of ACS may lead to heat production. Therefore, we assessed the culprit lesions in pts with effort angina (EA) and ACS by intracoronary ultrasound, and correlated these findings with temperature (T) difference between the atherosclerotic plaque and the healthy vessel wall.
Methods: Twelve coronary lesions of pts with ACS and 13 lesions of pts with stable angina were studied. Lumen and external elastic membrane (EEM) areas were measured at both target lesion and proximal reference sites by intracoronary ultrasound before intervention. The remodelling index was defined as the ratio of the EEM area at the lesion to that at the proximal site. Positive and negative remodelling were defined as indices of >1.05 and <0.95, respectively and plaque area as: EEM area-lumen area at the lesion. Additionally, in all pts T was measured at the culprit lesion and at the normal vessel wall by a thermography catheter that was developed in our institution and the T difference was calculated.
Results: Pts of both groups were similar in age, reference vessel size, and percent diameter stenosis. Positive remodeling was more frequent in pts with ACS (table). In addition there was a good correlation between remodeling index and difference in plaque temperature in pts with ACS ($r=0.68$, $p<0.001$).
Conclusion: The present study showed that the extent of remodeling and the plaque area were greater in culprit lesions in pts with ACS. The association however of remodeling index and plaque area with increased T provides new insights about the involvement of inflammation in the pathogenesis of ACS.

	ACS	EA	P-Value
EEM Proximal Area (mm^2)	14.2±3.6	19.9±9.1	0.07
Plaque Area (mm^2)	12.08±4.1	9.97±3.2	0.05
EEM Stenosis Area (mm^2)	15.5±2.6	19.4±8.7	0.02
Remodeling Index	1.17±0.2	1.01±0.03	0.02
Positive Remodeling	64%	23%	0.001
Negative Remodeling	9%	54%	0.02
T difference	0.22±0.17	0.03±0.03	0.001

1962 Unstable atherosclerotic lesions tend to be disseminated in coronary arteries – Shift from a vulnerable plaque to a vulnerable patient

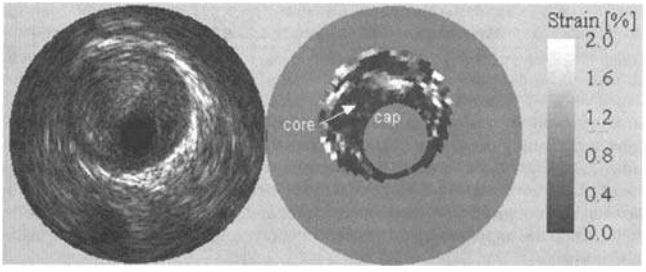
M. Kruk[1], J. Przyluski[2], Z. Chmielak[2], L. Kalinczuk[3], J. Pregowski[3], M. Demkow[2], A. Witkowski[2], W. Ruzyllo[2]. [1]*National Institute of Cardiology, General Cardiology Department, Warsaw, Poland;* [2]*National Institute of Cardiology, II Independent Haemodynamic Department, Warsaw, Poland;* [3]*Medical Academy, Warsaw, Poland*

Presence of vulnerable atherosclerotic plaque carries adverse prognosis in patients with coronary artery disease (CAD). Since development of unstable lesion depends substantially on systemic factors, it possibly may take place simultaneously in many sites, therefore causing disseminated instability.
Plaque vulnerability has been linked to its positive remodelling (+veR) on intravascular ultrasound (IVUS) and also with complex appearance on angiography.
Therefore we combined IVUS and angiography to assess whether vulnerable plaques are disseminated in coronary arteries.
Methods: Preinterventional IVUS pull back was performed in target lesion of 68 CAD patients (46 males, age 55.6±10,7). Remodeling index (RI) was defined as vessel area at the target lesion site divided by that of average reference segments. The RI>=1.05 was assumed as +veR. Coronary angiograms were analyzed and all plaques >=30% stenosis were classified into complex or smooth groups. Complex plaque was defined if irregularities, ulcerations, total occlusion or thrombus were present and the remaining accounted smooth.
Results: +veR was found in 30 and complex appearance in 15 out of 68 target lesions. Overall angiographically complex plaques were present in 73 out of 163 plaques identified on angiography. Plaques with +veR more often displayed complex angiographic appearance than plaques without +veR (11/30 vs 4/37 respectively; p=0,012) and more often were associated by other complex plaques within the same coronary vasculature (p<0,05, Mann-Whitney test).
Conclusion: Patients with positive remodeling of target lesion display increased number of associated complex plaques in major coronary arteries. This finding suggests that plaque vulnerability, if present tends to be a disseminated phenomenon.

1963 Detection of plaque composition with intracoronary elastography as validated with directional atherectomy

C.L. de Korte, S.G. Carlier, F. Mastik, J.A. Schaar, P.W. Serruys, A.F.W van der Steen. *Erasmus university, Thoraxcentre, Rotterdam, Netherlands*

Background: Intravascular Ultrasound (IVUS) Elastography determines the local strain of the vessel wall and plaque. The technique has proven to be able to identify fibrous and fatty plaque components in vitro based on the strain. In this study, intracoronary elastography is evaluated in patients that underwent directional atherectomy.
Methods: Data were acquired in coronary arteries of patients (n=7) referred for PTCA. Cross-sections were investigated with a 20 MHz Visions® catheter (Jomed, Rancho Cordova, CA) to determine the elastograms.
After the elastographic data acquisition, directional atherectomy was performed. A post intervention IVUS was performed to identify the region that was removed. The atherectomy specimens were stained for collagen, fat and macrophages. The plaques were classified as fibrous, fibro-fatty or fatty.
The mean strain of the resected areas was determined and correlated with the plaque type.
Results: The average strain in a fatty plaque (0.34%) was 2 times higher than the strain in fibrous plaques (0.16%). In an artery where a superficial and a deeper cut were performed (see figure), four times lower strain values were found in superficial cap tissue (0.08%) than in core tissue (0.34%). Histology revealed a cap of fibrous material and an atheromatous core containing fat and macrophages.



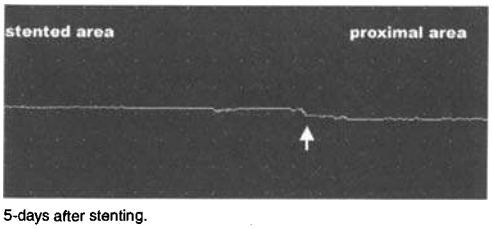
IVUS echogram and elastogram.

Conclusions: IVUS Elastography results acquired in patients were correlated with histology. Increased strain was observed in plaques containing fat and macrophages. Although exact matching of the atherectomy specimens and the IVUS cross-section remains challenging, this represents the very first attempt to correlate in vivo elastography to histology and these encouraging data warrant further ongoing investigations.

1964 The effect of stenting on the arterial wall temperature. The role of inflammation

L. Diamantopoulos, Y. Huang, L. Xiaoshun, T. Flint, W. Desmet, I. De Scheerder, F. Van de Werf. *UZ Gasthuisberg Hospital, Interventional Cardiology, Leuven, Belgium*

Background: The temperature of the arterial wall has been corelated to its inflammation status. In this study we used thermography to investigate the inflammation status of the arterial wall after stent implantation.
Methods: We catheterized 20 pigs with normal coronary arteries. Arterial wall temperature was studied with the ThermoSense coronary thermography system (Thermocore Medical Systems NV, Belgium) that uses a 4 thermistor-sensor catheter tip. A 60mm long normal segment was selected at the proximal right coronary artery. Temperature was mapped in this segment via a continuous pullback (0,3mm/sec). A 3.0/18mm Freedom stent (Global Therapeutics) was implanted in this area, and temperature was re-scanned. Then, pigs were randomized in two groups: group A to be re-scanned after 5 days and then sacrificed, and group B to be re-scanned after 8 days and then sacrificed. Histology and local macrophage concentration was studied in all cases.
Results: The temperature of the arterial wall before the stent placement was equal to the adjucent areas. Immediately after stent placement, the stented area had slightly lower temperature than the adjucent areas (DT=0,07°C p<0,01). 5 Days after the implantation, the stented area was significantly hotter than the adjucent areas (DT=0,169°C p=0,002); histological examination showed the highest macrophage concentration at the place of the stent. At the ninth day these temperature differences were reduced to non-significant levels (DT=0,002°C p=NS), and macrophage population was significantly lower.
Conclusions: Due to post-stent arterial wall inflammation, stented arterial segments show higher temperature around 5 days after implantation, while after 8 days these findings are back to almost normal levels.



5-days after stenting.

DRUG EFFECTS IN EXPERIMENTAL HEART FAILURE

1966 Molecular and morphological effects of clenbuterol on neonatal rat cardiac myocytes in culture

P.K. Bhavsar[1], L.E. Felkin[1], P.J.R. Barton[1], M.H. Yacoub[2]. [1]*Imperial College, Faculty of Medicine, London, United Kingdom;* [2]*Heart Science Centre, Harefield, United Kingdom*

Background: Optimal recovery from heart failure may require both reverse remodelling and the induction of physiological hypertrophy. We have previously demonstrated that treatment of rats with the beta2-adrenergic agonist clenbuterol results in a 20% increase in LV mass with normal systolic isovolumic parameters and diastolic function. This is accompanied by a 2-fold increase in the expression of atrial natriuretic peptide (ANP) but without changes in gene expression indicative of pathological hypertrophy. For these reasons clenbuterol is regarded as inducing physiological hypertrophy in vivo. However, it remained to be determined whether this is a direct action of clenbuterol on cardiac myocytes. The aim of this study was therefore to determine the molecular and morphological effects of clenbuterol on cardiac myocytes in culture.
Methods: A model system using neonatal rat cardiac myocytes in culture, where the cells are treated with clenbuterol (10μM) or the pathological hypertrophic agonist phenylepherine (PE; 10μM), has been developed. 48 hours after stimulation myocytes were examined under microscope for evidence of morphological change and real-time quantitative PCR (TaqMan) was used to determine expression of genes associated with cardiac hypertrophy. Namely, ANP, brain natriuretic peptide (BNP), alpha and beta myosin heavy chains (MHC), sarcoplasmic reticulum calcium ATPase (SERCA2A) and the glucose transporter GLUT1.
Results: Both clenbuterol and PE induced physical hypertrophy of the cardiac myocytes (1.75 fold increase in surface area as compared to untreated controls, $p<0.05$; N=3) and two fold increase in the expression of both ANP and BNP ($p<0.001$ vs control; N=5). Treatment with PE resulted in a two-fold induction of GLUT1 ($p<0.001$ vs control; N=4) and a three-fold induction of beta MHC ($p<0.001$ vs control; N=5) indicative of a pathological response. In contrast, clenbuterol did not induce any change in expression of alpha or beta MHCs, SERCA2A or GLUT1 (N=4).
Conclusion: We demonstrate that clenbuterol has a direct effect on cardiac myocytes which results in "phyiological" hypertrophic growth. Future studies will investigate the signal transduction pathways invoked during this response.

1967 MCP-1 expression in spontanenous hypertensive rats correlates with blood pressure reduction by angiotensin receptor blockade

T.M. Behr[1], S.S. Nerurkar[2], F.C. Barone[2], M. Berova[1], R.W. Coatney[2], R.N. Willette[2], C.E. Angermann[1], J.D. Sackner-Bernstein[3]. *[1]Medizinische Poliklinik, Kardiologie Abt., Würzburg, Germany; [2]GlaxoSmithKline, Cardiovascular Pharmacology Dept., King of Prussia, United States of America; [3]St. Luke's and Roosevelt Hospital, Dept. of Cardiology, New York NY, United States of America*

Neurohormonal and cytokine activation occur early in the development of heart failure (HF), yet the potential for these two systems to interact is incompletely defined. Prior studies have shown that in vascular tissues angiotensin II (AII) can upregulate expression of MCP-1, a potent chemoattractant for monocytes, macrophages and lymphocytes. The aim of this study was to establish whether AII antagonism influences MCP-1 expression in myocardium of an animal model of HF (spontaneous hypertensive rats-stroke prone - SHR-SP)

Methods: SHR-SP were randomly assigned to either standard rat chow (SRC), high salt/fat diet (SFD) or SFD with eprosartan (SFD-E), an AII type1 receptor antagonist, via osmotic minipump (25mg/kg/day) for 28 weeks. MCP-1 levels were determined by quantitative TaqMan real-time PCR, ELISA and immunohistochemistry. Macrophage infiltration into myocardium was quantified immunohistochemically as the total area and number (no) of macrophages per eyefield at 100x magnification. Echocardiography was done for cardiac function.

Results: See table.

	SRC	SFD	SFD-E
Mortality at 28 weeks	0%	90%	0%
MCP-1mRNA (copies of mRNA/ng total RNA)	994±140	4169±739*	2696±511#
MCP-1 protein (ng/mg total protein)	76±3	163±33**	71±5
Macrophage area (mm^2/eyefield)	2637±243	5387±700***	1363±331##
Macrophage no	44±4	91±12	23±6
Cardiac output (ml/min)	149±1.2	108.9±9.9**	162.8±5.6

(#p<0.05 vs. SRC), (*p<0.01 vs. SRC), (**p<0.05 vs. SRC and SFD-E), (##p<0.05 compared to SRC and p<0.001 compared to SFD), (***p<0.01 compared to SRC)

Conclusions: MCP-1 was significantly upregulated in this model of HF, and was associated with immune cell infiltration, ventricular dysfunction and disease progression. AII antagonism blunted MCP-1 expression, macrophage infiltration and significantly reduced mortality suggesting a key role for MCP-1 in the mechanism of action of eprosartan. MCP-1 appears to be an important therapeutic target in HF.

1968 Eplerenone, a novel aldosterone receptor antagonist, prevents progressive left ventricular dysfunction and remodelling in dogs with heart failure

H.N. Sabbah, G. Suzuki, H. Morita, V.G. Sharov, A. Todor, S. Goldstein. *Henry Ford Health System, Detroit MI, United States of America*

Background: Blockade of aldosterone receptors with spironolactone has been shown to improve survival and reduce morbidity in patients with CHF. In the RALES (Randomized Aldactone Evaluation Study) trial, spironolactone was associated with considerable side effects namely, gynecomastia or breast pain in 10% of patients. Eplerenone (EPL) is a novel aldosterone receptor antagonist that is devoid of these side effects. In this study, we examined the effects of EPL on the progression of LV dysfunction and remodeling in dogs with chronic heart failure (LV ejection fraction 30% to 40%) produced by multiple sequential intracoronary microembolizations.

Methods: Two weeks after the last microembolization, dogs were randomized to 3 months therapy with oral EPL (10 mg/kg twice daily, n=7) or to no therapy at all (Control, n=7). LV ejection fraction (EF), LV end-diastolic volume (EDV), LV end-systolic volume (ESV), LV end-diastolic wall stress (EDWS), and time constant of LV isovolumic relaxation (Tau) were measured before (PRE) and after 3 months of therapy (POST). Treatment effect was based on a comparison of the change in each hemodynamic parameter from PRE to POST between the two groups. Volume fraction of replacement fibrosis (VFRF), volume fraction of interstitial fibrosis (VFIF) and myocyte cross-sectional area (MCSA), an index of myocyte hypertrophy, were measured from LV tissue sections obtained at sacrifice.

Results: Compared to control, EPL prevented the progressive decline in EF (-7±1 vs 0±1, P<0.001) and the progressive increase in EDV (6±1 vs -1±2 ml, P<0.003) and ESV (9±1 vs -1±2 ml, P<0.001). Compared to control, EPL also decreased EDWS (14±5 vs -25±5 g/cm^2, P<0.001) and Tau (6±1 vs. -5±2 msec, P<0.002). Dogs treated with EPL showed a 34% reduction in VFRF, a 37% reduction in VFIF and a 28% reduction of MCSA compared to control (P<0.05).

Conclusion: In dogs with HF, chronic therapy with EPL prevented progressive LV systolic and diastolic dysfunction and attenuated LV remodeling. These findings indicate that EPL may be useful in the long-term treatment of chronic HF.

1969 Long-term heart rate reduction induced by the If current inhibitor ivabradine improves cardiac function and structure in rats with heart failure

P. Mulder[1], S. Barbier[1], V. Richard[1], J.P. Henry[1], F. Lallemand[1], F. Mahlberg-Gaudin[2], G. Lerebours[2], C. Thuillez[1]. *[1]UFR Medecine et Pharmacie, INSERM E9920, Rouen, France; [2]IRIS, Paris, France*

Heart rate reduction (HRR) could be beneficial in congestive heart failure (CHF), since it improves left ventricular (LV) filling and reduces myocardial O2 consumption. However, the effects of selective long-term HRR in CHF are unknown. Thus, we assessed, in a rat model of CHF (coronary ligation), the effects of long-term HRR induced by the selective If current inhibitor ivabradine (10 mg/kg/day as food admix for 3 months starting 7 days after ligation) at the end of the 3 month treatment period and again 3 days after treatment interruption. The table shows heart rate (HR, beats/min), LV systolic pressure (LVSP, mmHg), LV end-diastolic pressure (LVEDP, mmHg), LV dP/dtmax (10^3 mmHg/sec) as well as LV end-diastolic and end-systolic diameters (LVEDD and LVESD, mm), stroke volume (SV, ml/beat) and cardiac output (CO, ml/min) determined in anesthetized rats, using a Millar micro-tip and an echocardiograph (ATL, HDI 5000). After 3 months of treatment, ivabradine decreased LV collagen density (control: 3.4±0.1; ivabradine: 2.9±0.1%; p<0.05) and increased myocardial capillary density (control: 85±6; ivabradine: 103±4 capillaries per field; p<0.05).

Group	HR	LVSP	LVEDP	LVdP/dt	LVEDD	LVESD	SV	CO
1	385±13	133±5	16.8±3.7	7.0±0.5	10.5±0.1	9.4±0.2	0.41±0.03	157±9
2	299±8*	133±7	11.5±4.1	7.6±0.4	10.9±0.2*	8.9±0.3*	0.49±0.03*	162±13
3	388±13†	135±9	20.0±4.1	6.9±0.8	10.7±0.2	8.9±0.2*	0.49±0.02*	177±10*†

Group 1: CHF control; Group 2: CHF + ivabradine; Group 3: CHF after interruption. *: p< 0.05 vs. control; †: p<0.05 vs. ivabradine

In conclusion, in a model of CHF, long-term selective HRR by the If current inhibitor ivabradine improves left ventricular function and increases stroke volume, resulting, despite the HRR, in a preserved cardiac output. This improvement of cardiac function is related to the HRR itself, but also to the modifications of LV structure and/or myocytes properties as a consequence of long-term HRR, since the improvement of cardiac function persists after interruption of the treatment.

1970 Effect of different antiadrenergic interventions on the baroreceptor-heart rate reflex in post-myocardial infarction heart failure rats

L. Mircoli[1], L. Fedele[2], M. Benetti[2], A. Radaelli[3], A.U. Ferrari[2]. *[1]IRCCS Ospedale Maggiore, Divisione di Cardiologia, Milano, Italy; [2]Centro Fisiologia Clinica Ipertensione, Dipt Med., Prev. e Biotecnol. Sanit., Milano, Italy; [3]Div Cardioriabilitazione, Az Osp Vimercate, Seregno, Seregno, Italy*

Congestive heart failure (CHF) is characterized by sympathetic overactivity and by an impaired baroreceptor-heart rate reflex (BR-HR). To clarify whether the former alteration plays a causative role on the latter, we examined the effects on the BR-HR of chemical sympathecomy and chronic or acute β-adrenoceptor blockade. CHF developed within 4 weeks of an anterior MI (left anterior descending coronary artery ligation under ether anesthesia in 8 week-old Sprague-Dawley rats, Lig). Lig rats were treated as follows: i) vehicle (Veh-Lig, n=10); ii) chemical sympathectomy by 6-hydroxydopamine, 100 mg kg^{-1} i.p. twice weekly (Sx-Lig, n=11); iii) chronic beta-blockade by oral propranolol, 30 mg kg^{-1} day^{-1} (Pro-ch-Lig, n=6); iiii) acute β-blockade (vehicle alone for 4 weeks and iv Pro, 1 mg kg^{-1}, just before baroreflex testing (Pro-ac-Lig, n=6). Concurrent sham-ligated rats were studied and assigned to vehicle (Veh-Sham, n=10) or 6-hydroxydopamine (Sx-Sham, n=8) treatment. Left ventricular end-diastolic (LVED) dimension was measured by ecocardiography. BR-HR was evaluated by the extent of the bradycardic responses to graded bolus injections phenylephrine in the conscious, chronically instrumented rat. Sympathetic activity was estimated by plasma norepinephrine (NE, by HPLC). LVED dimensions were normal (<7 mm) in all sham-operated rats whereas they were increased (>9.5 mm) in all ligated rats. All groups had similar systemic arterial pressure (systolic range 110-130 mmHg) and heart rate (range 340-380 b min^{-1}) with the exception of the propranolol-treated rats which as expected were moderately bradycardic (305±12 b min^{-1}, pooled Pro-ch and Pro-ac rats, p<0.05 vs all other groups). Plasma NE was similar in all groups (range 150-200 pg ml^{-1}) except in Veh-Lig rats in which it was significantly elevated to 320±35 pg ml^{-1}. Baroreflex-sensitivity (expressed in b min^{-1} $mmHg^{-1}$) was 1.21±0.2 in Veh-Sham rats and was significantly elevated by sympathectomy alone (2.25±0.9 in Sx-Sham rats, p<0.01 vs Veh-Sham); it was drastically reduced by CHF with intact sympathetics (0.38±0.2 in Veh-Lig rats) but was distinctly preserved by CHF plus sympathectomy (1.99±0.9 in Sx-Lig rats). At variance with sympathectomy, chronic β-blockade only partially preserved baroreflex sensitivity (0.81±0.3 b min^{-1} $mmHg^{-1}$ in Pro-ch-Lig rats, p<0.05 vs Veh-Lig) whereas acute β-blockade had no effects (0.40±0.2 b min^{-1} $mmHg^{-1}$ in Pro-ac-Lig rats). Thus sympathetcomy but not β-blockade can virtually entirely prevent the CHF-related impairment of the baroreceptor-heart rate reflex.

1971 Cytosolic Ca^{2+} and force in femoral small resistance arteries from rats with congestive heart failure. Effect of exogenous noradrenaline

S. Trautner[1], O. Amtorp[2], S. Boesgaard[3], S. Haunsø[3], M. Sheykhzade[4].
[1]*Rigshospitalet, Cardiovascular Research Unit, Copenhagen, Denmark;*
[2]*Gentofte County Hospital, Department of Cardiology, Copenhagen, Denmark;* [3]*Rigshospitalet, Department of Cardiology, Copenhagen, Denmark;*
[4]*The Royal Danish School of Pharmacy, Department of Pharmacology, Copenhagen, Denmark*

In congestive heart failure (CHF), vasomotor drive to systemic resistance vessels is increased. Postganglionic sympathetic nerves release noradrenaline (NA), which binds to alpha-adrenergic receptors in the cell membrane of vascular smooth muscle cells (VSMC). This initiates a rise in intracellular Ca^{2+} ($[Ca^{2+}]_i$) and VSMC contraction. We evaluated the relationship between $[Ca^{2+}]_i$ and vasoconstriction in six rats with chronic left ventricular myocardial infarction (MI), and six sham operated (SO) rats. Nine weeks post-MI, $[Ca^{2+}]_i$/tension relationships were determined during cumulative administration of NA (10^{-9} - 10^{-4} M) to isolated femoral resistance arteries. We simultaneously recorded isometric tension development and $[Ca^{2+}]_i$, using the FURA-2 method. The CHF rats had infarctions of 48,5 ± 3,5% of the left ventricular internal circumference, measured on cross sections at papillary muscle level. CHF rats showed a 30% increase in ventricular mass (0,29 ± 0,02% of body weight ((BW)) versus 0,23 ± 0,01% in SO rats, $p<0,01$) and a 2,5 times increase in lung weight (0,76 ± 0,06% of BW versus 0,31 ± 0,02% in SO rats, $p<0,001$). No differences were found in baseline $[Ca^{2+}]_i$ between CHF (49 ± 8 nM) and SO rats (48 ±4 nM), nor in the maximum increase in $[Ca^{2+}]_i$ (199 ± 24 nM vs. 167 ± 29 nM in SO rats) or in maximum tension induced by NA (6.01 ± 1.03 N/m vs. 6.27 ± 1.29 N/m in SO rats). See figure. The present data do not support the hypothesis that either baseline $[Ca^{2+}]_i$ or the rise in $[Ca^{2+}]_i$ in response to exogenous NA are altered in resistance arteries of CHF rats compared to those of sham operated rats. These findings suggest that elevation in $[Ca^{2+}]_i$ at a given level of alpha-adrenergic stimulation does not contribute to the increased peripheral resistance in CHF.

NON-LIPID-LOWERING EFFECTS OF STATINS

1972 Statin treatment is associated with reduced heat release from human atherosclerotic plaques in patients with coronary artery disease

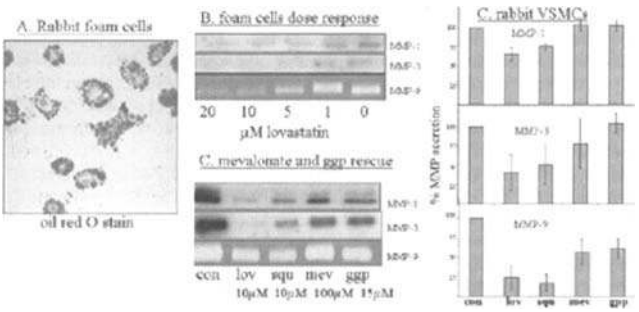
K. Toutouzas, C. Stefanadis, E. Tsiamis, S. Vaina, M. Vavouranakis, I. Kallikazaros, C. Pitsavos, P. Toutouzas. *Hippokration Hospital, Dept of Cardiology, Athens, Greece*

Background: Heat released from atherosclerotic plaques as a result of the local inflammatory process, may be measured in vivo by a thermography catheter. Statins seem to have antinflammatory effect which results in plaque stabilization. The aim of this study was to investigate the effect of statins on plaque temperature.
Methods: The study population included 72 patients (pts): 21 with effort angina (EA), 32 with unstable angina (UA) and 19 with acute myocardial infarction (AMI). Among the study group 37 pts received statins for more than 4 weeks and 35 pts were not receiving statins. We measured temperature difference (TD) between the atherosclerotic plaque and the proximal vessel wall (background temperature) with a thermography catheter, which has been designed and developed in our Institution.
Results: The statistical analysis showed that the mean value of TD was higher in the untreated group compared to the treated, with statin, group (0.56 ± 0.30°C vs. 0.29 ± 0.12°C, $p < 0.01$). Moreover, a progressive increase of TD by type of clinical syndrome was observed in both groups of the study (statin group; EA: 0.24 ± 0.15°C, UA: 0.26 ± 0.26°C, AMI: 0.40 ± 0.28°C, vs untreated group; EA: 0.41 ± 0.26°C, UA: 0.44 ± 0.28°C, AMI: 0.84 ± 0.52°C, $p < 0.05$). Multivariate analysis showed that treatment with statins was an independent factor for temperature variation, after taking into account the effect of clinical syndrome ($p < 0.05$).
Conclusions: Pts under treatment with statins have reduced heat production from the culprit coronary lesion. Thus, statins may have a favorable effect on plaque stabilization. This may be due to an additional anti-inflammatory effect of statins, beyond lipid lowering.

1973 Lovastatin inhibits metalloproteinase secretion by plaque resident cells via a prenylation dependent mechanism-a plaque stabilising effect

A J. Chase, Z. Luan, A C. Newby. *Bristol Heart Institute, University of Bristol, Bristol, United Kingdom*

Large clinical trials with HMG-CoA reductase inhibitors (statins) reveal early beneficial effects on cardiac events that are unrelated to angiographically defined regression. This suggests statins may directly affect plaque stability. Recent evidence shows statins reduce production of matrix metalloproteinases (MMPs). Such an effect would tend to preserve plaque collagen content and directly promote plaque stability. We investigated the effect of lovastatin on MMP secretion by vascular smooth muscle cells and foam cells, together the most important source of plaque MMPs.
Methods/Results: Rabbit vascular smooth muscle cells (VSMCs) were generated from aortic medial explants. Rabbit granuloma macrophages were recovered from subcutaneous polyurethane sponges in New Zealand White rabbits fed on a 1% cholesterol diet for 5 weeks. Cultured SMCs and foam cells were treated with different doses of lovastatin and MMP-1 and 3 secretion assessed by western blotting and MMP-9 by gelatin zymography. Lovastatin inhibited secretion of all 3 MMPs in a dose dependent fashion, (Fig.1B). This inhibition was reversed by exogenous mevalonate (meva) and geranylgeranyl-pyrophsphate (ggpp) but not squalene (squ) thus implicating isoprenoid synthesis dependence (Fig.1B,C). Lovastatin did not reduce MMP-1, -3, -9 or Tissue Inhibitor of MMPs (TIMP)-1 and –2 mRNA levels when investigated by RT-PCR.

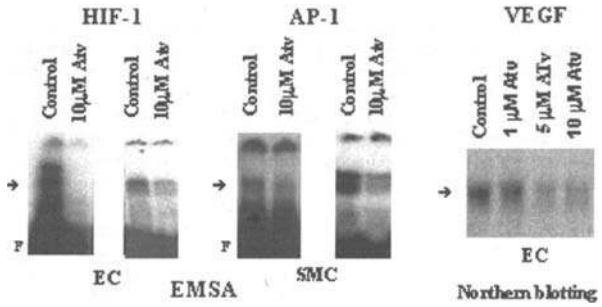


Conclusion: Lovastatin inhibits metalloproteinase secretion by SMCs and foam cells via a prenylation dependent mechanism implicating the rho GTPases. This lipid-lowering indepent effect of statins may underly their plaque stabilising properties and reduce clinical events.

1974 Atorvastatin decreases Vascular Endothelial Growth Factor (VEGF) – Involvement of inhibited AP-1 and HIF-1 expression

H. Alber[1], W. Dichtl[1], J. Dulak[2], M. Frick[1], S.P. Schwarzacher[1], O. Pachinger[1], F.F. Weidinger[1]. [1]*University of Innsbruck, Department of Cardiology, Innsbruck, Austria;* [2]*Institute of Molecular Biology, Department of Cell Biochemistry, Krakow, Poland*

Background: VEGF is suggested to be involved in atherosclerotic plaque growth by inducing neovascularization. HMG-CoA reductase inhibitors (statins) seem to have atheroprotective effects beyond their lipid-lowering properties. The aim of this study was to test the influence of atorvastatin (atv) on VEGF synthesis and transcription factors (AP-1, HIF-1) involved in VEGF gene expression.
Materials and Methods: Human endothelial (EC) and smooth muscle cells (SMC) were treated with different concentrations of atv (1-10μM). VEGF protein and VEGF mRNA (in EC) were assessed by ELISA and Northern Blotting, respectively. AP-1 and HIF-1 DNA binding was determined by EMSA. VEGF plasma levels were measured in 14 patients with coronary artery disease (CAD pts) before and after 2 months of atv therapy (20mg/d).
Results: Atv (1, 3 and 10 μM) treatment resulted in a significant decrease of VEGF release in SMC (59.0±10.4%, 58.4±7.3%, 64.9±5.3% of control cells; $p<0.0005$), which was similarly observed for EC. This reduction of VEGF protein was associated with a significantly attenuated activity of the transcription factors AP-1 and HIF-1 and with a diminished expression of VEGF mRNA (see figure). Furthermore, atv therapy reduced VEGF plasma levels in CAD pts (from 31.1±6.1 to 19.0±3.6 pg/mL; $p<0.05$). Similar results were obtained with simvastatin and lovastatin.



Conclusion: Assuming VEGF to contribute to plaque neovascularization and progression, the observed reduction of VEGF, possibly due to an inhibited AP-1 and HIF-1 expression, may represent a novel beneficial effect of statins.

1975 Atorvastatin decreases platelet superoxide anion production in hypercholesterolemic patients

V. Sanguigni[1], P. Pignatelli[2], D. Caccese[3], F. Pulcinelli[2], F. De Vito[3], R. Lauro[3], F. Violi[4]. [1]*University of Rome Tor Vergata, Internal Medicine, Rome, Italy;* [2]*University of Rome La Sapienza, Experimental Medicine, Rome, Italy;* [3]*University of Roma Tor Vergata, Internal Medcine, Rome, Italy;* [4]*University of Rome La Sapienza, Internal Medicine, Rome, Italy*

Background: Experimental studies have demonstrated that hypercholesterolemia is associated with enhanced cellular production of superoxide anion (O2-). The aim of this study was to assess whether the same phenomenon occurs in humans, too.

Methods: The study was divided in three parts. In the first part of the study we compared 28 patients with polygenic hypercholesterolemia and 25 sex-and-age matched normocholesterolemic subjects. In the second part 21 out of the 28 hypercholesterolemic patients were given atorvastatin 10 mg/day for 8 weeks. Lipid profile and platelet O2- release were measured at baseline and after atorvastatin. In the third part of the study, in order to assess the mechanism by which LDL cholesterol interferes with platelet production of O2-, human platelets were incubated with LDL cholesterol in the presence of either an inhibitor of the phospholipaseA2 enzyme, AACOCF3, or an inhibitor of NADH/NADPH oxidases, DPI.O2- was determined by chemiluminescience using a Bio-Orbit 1251. Platelet aggregation was analized following the Born method.

Results: Platelet formation of O2- was significantly higher in patients(2.11 nmoles/3x108 plts/min) than in controls(1.05 nmoles/3x108 plts/min) ($p< 0.001$) and significantly related to LDL cholesterol ($r=0.88$, $p< 0.001$). In patients with hypercholesterolemia, 8-week administration of atorvastatin 10 mg daily significantly reduced LDL cholesterol (-35%) and platelet production of O2- (-40%). The inhibition of O2- could be explained by atorvastatin cholesterol-lowering effect only to a certain extent, in that it was observed after 3 days of atorvastatin treatment only, and was not parallel to cholesterol reduction. Platelets incubated with LDL cholesterol showed an increased O2- production, which was significantly inhibited by AACOCF3 (-78%) and DPI (-56%).

Conclusions: LDL cholesterol increases platelet O2- production by activating PLA2 and NADH/NADPH enzymes. Inhibition of platelet O2- release by atorvastatin is partially related to cholesterol lowering effect, suggesting that other mechanisms could be responsible for the antioxidant activity of the drug.

1976 HMG-CoA reductase inhibitors promote the translocation of protein kinase Akt to membrane domains in endothelial cells

A. Skaletz-Rorowski[1], M. Lutchman[2], Y. Kureishi[2], D.J. Lefer[3], J.R. Faust[4], K. Walsh[2]. [1]*St. Elizabeth's Med Ctr, Univ. Münster, Münster, Germany;* [2]*St. Elizabeth's Med Ctr, Boston, MA, United States of America;* [3]*Health Sciences Ctr, Louisiana State University, Shreverport, LA, United States of America;* [4]*Dept. of Physiology, Tufts University School of Medicine, Boston, MA, United States of America*

Our recent results have shown that the HMG-CoA reductase inhibitors referred to as statins rapidly activate the protein kinase Akt/PKB in endothelial cells (EC) and endothelial precursor cells. This promotes EC survival, nitric oxide production and differentiation in vitro; cellular responses that contribute to new blood vessel growth and stabilization of the vascular network. In vivo, simvastatin was shown to promote collateral and capillary vessel formation in a normocholesterolemic rabbit model of vascular insufficiency. Here, we examine whether statins promote the translocation of Akt to the plasma membrane, an essential feature of Akt activation that is associated with cellular migration. Bovine aortic endothelial cells (BAEC) were transfected with an GFP-Akt (green fluorescent protein) fusion cDNA and then treated with statins under different experimental conditions. Our results show that low doses of simvastatin (0.5μM) rapidly induce the translocation of Akt to discrete sites in endothelial cell plasma membrane. Immunofluorescence microscopy images show that GFP-Akt colocalizes with F-actin-positive, FAK-negative lamellipodia and filopodia, which are essential structures for cellular migration. Translocation was not observed when a point mutation was incorporated in the lipid-binding, pleckstrin homology domain of Akt, demonstrating the specificity of this response. Similar to observations of GFP-Akt localization in transiently-transfected BAEC, endogenous Akt rapidly translocated to discrete sites at membrane ruffles in the simvastatin-treated cells (immunodetection of Akt with anti-Akt1 antibody).

Low doses of pravastatin also induced Akt translocation to membrane ruffles and filopodia. Treatment with L-mevalonate (200 μM) blocked the translocation of Akt by simvastatin. Pretreatment with the phosphoinositide 3-kinase (PI3-kinase) inhibitors LY294002 (7.5 μM) and wortmannin (250 nM) also blocked simvastatin-induced effects on Akt translocation. Finally, our data show that statin-induced translocation of Akt is a specific effect dependent on endothelial cells, because neither simvastatin nor pravastatin had a stimulatory effect on Akt translocation in vascular smooth muscle cells.

The results from this study show that statins induce PI3-kinase-dependent translocation of Akt to membrane structures in migratory cells. These findings, together with the previous results, suggest a new mechanism that can account for the ability of statins to improve endothelial cell function and contribute to new blood vessel growth.

1977 Simvastatin inhibits MMP-9 activity and smooth muscle cell invasion – Prevention of intimal hyperplasia in human saphenous vein

K E. Porter[1], N A. Turner[1], J. Naik[2], N J M. London[2]. [1]*University of Leeds, Institute for Cardiovascular Research, Leeds, United Kingdom;* [2]*University of Leicester, Department of Surgery, Leicester, United Kingdom*

Basement membrane degradation is a prerequisite for smooth muscle cell (SMC) migration and proliferation in vivo, both of which contribute to the development of intimal hyperplasia (IH) in saphenous vein (SV) bypass grafts. The activity of specific matrix-degrading enzymes produced by the SMC, particularly the gelatinases (MMP-2 and -9), is essential to these processes. HMG-CoA reductase inhibitors (statins) are widely prescribed as cholesterol-lowering drugs but interestingly, also appear to have beneficial effects on vascular SMC function that are independent of their cholesterol-lowering properties.

In organ cultures of the human long SV obtained from patients undergoing coronary artery bypass grafting, neointima formation was accompanied by increased tissue MMP-9 activity, measured by gelatin zymography. Simvastatin (0.5-5 μM), reduced neointimal thickness ($P=0.004$, $n=9$) and concomitant MMP-9 activity ($P=0.03$, $n=6$). Neointima formation in vein grafts requires both SMC proliferation and migration (invasion); we have shown previously that statins inhibit human SV- SMC proliferation. We therefore investigated whether inhibition of MMP-9 activity by simvastatin could reduce SMC migration through a basement membrane barrier (i.e. invasion). Using modified Boyden chambers, we investigated the effects of simvastatin on SMC invasion towards a chemotactic stimulus (10 ng/ml PDGF) over a 24-h period. In this model, SMC gelatinase activity is essential for basement membrane (Matrigel) degradation prior to migration. Simvastatin dose-dependently reduced SMC invasion by 54% (0.5 μM), 69% (1 μM) and 76% (5 μM) of that induced by PDGF alone ($P<0.01$, $n=5$).

Our observations suggest that increased MMP-9 activity contributes to IH in SV grafts. Simvastatin inhibits this response by reducing MMP-9 activity and SMC invasion. Inhibition of HMG-CoA reductase by statins results in reduced intracellular production of mevalonate, not only an essential precursor of cholesterol but also of several isoprenoids that are required for post-translational prenylation of small G-proteins involved in induction of MMP-9 gene transcription. Thus statins may be beneficial in the control of vascular disorders characterised by neointima formation beyond simple reduction of cholesterol.

GENETICS IN ATHEROSCLEROSIS

1978 Identification of a CETP-haplotype associated with low CETP and high HDL-C levels

M.W.T. Tanck[1], A.H.E.M. Klerkx[2], J.W. Jukema[3], P. de Knijff[4], A.H. Zwinderman[1]. [1]*Academic Medical Center, Clinical Epidemiology & Biostatistics, Amsterdam, Netherlands;* [2]*Academic Medical Center, Vascular Medicine, Amsterdam, Netherlands;* [3]*Leiden University Medical Center, Cardiology, Leiden, Netherlands;* [4]*Leiden University Medical Center, Human Genetics, Leiden, Netherlands*

Background: The cholesteryl ester transfer protein (CETP) gene is a candidate gene for CAD and several common CETP-polymorphisms have been associated with both CETP and HDL-C levels. To investigate the combined effect of polymorphisms, haplotype effects can be estimated. In the present study, CETP-haplotype effects on CETP and HDL-C levels were estimated using a novel method that also incorporates data of patients with multiple heterozygous genotypes.
Method: Information on four closely-linked CETP-gene polymorphisms (including -629 and TaqIB) and base-line CETP (mean 1.92 ± 0.52 g/l) and HDL-C (mean 0.92 ± 0.22 mmol/l) levels of 884 unrelated male patients with premature CAD of the REGRESS study was used. Based on the individual genotypes per locus (0/0, 0/1 and 1/1), haplotype pairs were assigned to each patient. In case of multiple heterozygous genotypes (49% of the patients), all haplotype pairs compatible with the genotype were determined and posterior probabilities were calculated for each pair using Bayes' theorem and estimated haplotype frequencies. Subsequently, the posterior probabilities were used as weights in a weighted linear regression model.
Results: Base-line CETP and HDL-C levels were not significantly ($P>0.05$) correlated in the REGRESS population. The effects (± SE) of the four most frequent CETP-haplotypes on base-line CETP and HDL-C concentrations are shown in the table. The two most frequent haplotypes (0 0 0 0 and 1 1 1 1) had significant ($P<0.0001$) opposite effects on both base-line CETP and HDL-C concentrations. Furthermore, effects of the least frequent alleles at the different loci appear to be additive. Homozygous carriers of the 1 1 1 1 haplotype are expected to have a 15% lower CETP concentration and a 9% higher HDL-C concentration compared to 0 0 0 0 homozygotes.

Haplotype effects

Haplotype	Frequency	CETP increase (g/l)	(SE)	HDL-C increase (mmol/l)	(SE)
0 0 0 0	53.6%	0.070	(0.015)	-0.020	(0.006)
1 1 1 1	27.3%	-0.080	(0.021)	0.018	(0.008)
0 1 1 1	9.9%	0.000	(0.029)	0.006	(0.010)
0 1 0 0	4.6%	-0.013	(0.032)	0.000	(0.011)

Conclusion: The common 1 1 1 1 haplotype is independently associated with lower CETP and higher HDL-C concentrations in males with premature CAD.

1979 Haplotype analysis of CETP gene polymorphisms in relation with coronary artery disease, HDL-cholesterol and CETP activity in the AtheroGene study

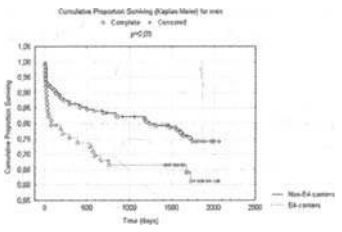
D. tregouet[1], S. Blankenberg[2], O. Poirier[1], C. Bickel[2], H.J. Rupprecht[2], J. Meyer[2], F. Cambien[1], L. Tiret[1] on behalf of AtheroGene Group. [1]*INSERM U525, Faculté de Médecine Pitié-Salpétrière, Paris Cedex, France;* [2]*Johannes Gutenberg University, Department of Medicine II, Mainz, Germany*

By catalizing transfer of cholesteryl ester from the core of HDL molecules to apoB containing lipoproteins, in exchange of triglycerides, the cholesteryl ester transfer protein (CETP) plays a key role in the pathogenesis of atherosclerosis. We investigated the relative contribution of CETP gene polymorphisms to the variability of CETP activity and HDL-cholesterol (HDLc) levels as well as their relation to coronary artery disease (CAD). The sample consisted of 1002 patients with documented CAD and 471 controls subjects. Five polymorphisms of the CETP gene were genotyped, one in the promoter region (G-629A), one in intron 1 (TaqIB) and three in the coding sequence (A373P, I405V and R451Q). CETP levels were lower in cases than in controls (38.0 vs 48.8; $p<10^{-4}$) as were HDLc levels (47.6 vs 59.0; $p<10^{-4}$). By univariate analysis, all polymorphisms were associated with CETP activity, explaining from 1.1% to 2.3% of the CETP variability. All polymorphisms were also associated with HDLc levels, explaining from 0.5% to 1% of the HDLc variability. Genotype effects were homogeneous in cases and controls. The -629A allele, which was associated with higher HDLc, tended to be less frequent in cases than in controls (0.44 vs 0.40; p =0.064). Allele frequencies of the other polymorphisms did not significantly differ between the two groups. Since these five polymorphisms were in strong linkage disequilibrium one with each other, an haplotype analysis was performed to better characterize the own contribution of each of them. The haplotype frequency distribution slightly differed between cases and controls (p = 0.044). The haplotype analysis revealed that the -629A and 405V alleles were independently associated with decreased CETP activity. Besides, the A373P polymorphism was shown to interact with the G-629A polymorphism on CETP activity (p = 0.014). The TaqIB and R451Q polymorphisms did not independently influence CETP activity. Jointly, haplotypes combining the G-629A, A373P and I405V polymorphisms explained 6% of the variability of CETP activity. A similar haplotype analysis on HDLc levels revealed that the -629A and 405V alleles were independently associated with increased HDLc levels and jointly explained 2.4% of HDLc variability. None of the other polymorphisms influenced HDL levels. After adjusting for HDLc levels, haplotype frequencies no longer differed between cases and controls (p = 0.13). In conclusion, haplotype analysis showed that several polymorphisms of the CETP gene influenced CETP activity and HDLc levels. The association of polymorphisms with CAD seemed to be mediated by HDLc.

1980 ApoE genotype predicts 90-day and 5-year mortality in male, but not in female, survivors of acute myocardial infarction

K. Hruska[1], G. Eggertsen[2], L. Berglund[2], S. Ahnve[1]. [1]*Karolinska Institute, Dept of Public Health Sciences, Stockholm, Sweden;* [2]*Karolinska Institute, Dept of Clinical Chemistry, Huddinge, Sweden*

Background: Coronary heart disease (CHD) is caused by a combination of genetic and environmental factors. The ApoE gene polymorphism is known to influence the risk of dying of CHD and appears to play a major role in this interaction. We studied whether ApoE genotype could predict short- and long-term mortality after an acute myocardial infarction (AMI)
Methods: 359 patients (253 men and 106 women) with AMI, consecutively admitted to the coronary care unit, were followed for approximately five years (range 3,8-5,6 years). No exclusion criteria were used. The mean age at the time of inclusion for men was 65,9 years (±12,7 SD, range 34-92) and for women 73,7 (±9,5 SD, range 41-91). ApoE genotype and lipid status were determined and subjects were classified as carriers or non-carriers of the e4 allele.
Results: Apart from lower HDL levels in male e4-carriers, there were no significant serum lipid concentration differencence depending on ApoE genotype. We found a markedly increased mortality in e4-carrying men, with a hazard ratio (HR) of 1,7. The difference was most pronounced during the first 90 days, with a 20,3% mortality among e4-carriers compared to only 8,5% for non e4-carriers (p=0,01). For men in the upper age quartile (>74 years) the deleterious effect of the e4 allele was most obvious, with an adjusted HR of 5,8, for the five year-follow-up. In women apoE genotype had no predictive value on mortality.



Kaplan-Meier graph of survival, men.

Conclusion: The ApoE e4 allele is an important mortality risk factor after AMI in men. The negative impact of the e4 allele seems to be even higher in men over 74 years. The markedly higher risk during the first 90 days may indicate that the ApoE polymorphism affects the stability of the atherosclerotic plaque, making carriers more susceptible to new events.

1981 Polymorphisms of the angiotensin-converting enzyme and interleukin-6 genes interact on long-term prognosis of patients with coronary artery disease

S. Blankenberg[1], O. Poirier[2], H.J. Rupprecht[1], V. Nicaud[2], C. Bickel[1], F. Cambien[2], J. Meyer[1], L. tiret[2] on behalf of the AtheroGene Group.
[1]*Johannes Gutenberg University, Department of Medicine II, Mainz, Germany;* [2]*INSERM, U525, Paris, France*

An I/D polymorphism of the angiotensin-converting enzyme (ACE) gene, which influences plasma and tissue ACE levels, has been reported to be associated with an increased risk of acute coronary syndrome. We investigated the potential association of the ACE I/D polymorphism with long-term prognosis in patients with coronary artery disease (CAD). Since angiotensin II is known to stimulate cellular production of interleukin-6 (IL-6), we also evaluated whether the ACE I/D and the IL6/G-174C polymorphisms might interact to modulate the risk of future cardiac event. The cohort included 1221 patients with proven CAD prospectively followed up during a mean period of 3.4 (maximum 5.2) years. Follow-up information was obtained about death from cardiac causes (n = 83), death from non cardiac causes (n = 33) and non fatal myocardial infarction (n = 51). The ACE/DD genotype (n = 367) was associated with an increased risk of future cardiac event (fatal or non fatal) (HRR, 95% CI = 1.44, 1.02-2.05), but did not influence non-cardiac mortality (HRR = 0.65, 0.28-1.49).
There was an interaction between the ACE I/D and the IL6/G-174C polymorphisms on the risk of future cardiac event. The ACE/DD genotype had no significant effect on risk in subjects with the IL6/GG or GC genotype, whereas in subjects with the IL6/CC genotype, the ACE/DD genotype was associated with a 4-fold increased risk (HRR = 4.26, 1.97-9.23). The interaction was present both in patients with stable angina or acute coronary syndrome at inclusion, and whether or not patients received treatment by beta-blockers or ACE-inhibitors. The ACE I/D polymorphism did not influence serum IL-6 levels, neither directly nor by interacting with the IL-6 polymorphism. This suggests that the interaction between the two polymorphisms might be mediated by a local co-expression of ACE and IL-6 within atherosclerotic plaques. In a sub-sample of 768 patients (63%) in whom ejection fraction (EF) was measured, the two polymorphisms appeared to interact on EF, the ACE/DD genotype having opposite effects on EF according to the IL6 genotype (EF = 61.1% in (GG+GC)/(II+ID), 65% in (GG+GC)/DD, 65.5% in CC/(II+ID) and 58.4% in CC/DD subjects, p = 0.0003 for interaction).
In conclusion, the IL6/G-174C and ACE I/D polymorphisms appear to interact on the long-term prognosis of patients with documented CAD, patients combining the IL6/CC and ACE/DD genotypes having the worst prognosis. This interaction is consistent with the notion that angiotensin II may contribute to the development of acute coronary syndromes through an inflammation-mediated process.

1982 The RANTES chemokine-403A polymorphism is associated with an increased risk of coronary artery disease and venous thrombo-embolism

E. Simeoni[1], M.M. Hoffmann[2], S. Fleury[1], W. März[2], G. Vassalli[1]. [1]*CHUV, Cardiology, Lausanne, Switzerland;* [2]*Albert-Ludwigs University, Clinical Chemistry, Freiburg, Germany*

Circulating platelets and chemoattractant cytokines (= chemokines) such as RANTES (Regulated on Activation, Normal T-cell Expressed and Secreted) play a major role in the activation of monocytes and endothelium, as well as in the recruitment of leukocytes into atherosclerotic plaques. RANTES deposition by platelets trigger monocyte arrest on inflamed and atherosclerotic endothelium. Therefore, RANTES may play an important role in the pathogenesis both of atherosclerosis and thrombosis. The -403A polymorphism in the RANTES promoter results in a new consensus binding site for GATA transcription factors and a ~8-fold increase in transcriptional activity. In the present study, we have tested the hypothesis that this polymorphism is associated with an increased risk both of coronary artery disease (CAD) and of venous thrombo-embolism (VTE). Because smoking alters platelet function, analysis was carried out in smokers and non-smokers.
Methods: Patients (pts.; n = 3,194) underwent coronary angiography because of stable angina or atypical chest pain. Genotyping was done by RFLP-PCR. Statistical analysis was done by the Fisher-exact test; odds ratios (95% CI) are given.
Results: Based on coronary angiography, pts. were subdivided into a CAD group (n = 2,689; age: 63.8 ± 10; smokers: n = 1,823) and a control group (C) with normal coronary arteries (n = 505; age: 56.7 ± 11.9; smokers: n = 237). The RANTES -403A allelic frequency was as follows: CAD = 0.200 vs. C = 0.172; p = 0.047; OR 1.20 (1.006-1.342). In smokers, the -403A allelic frequency was as follows: CAD = 0.194 vs. C = 0.152; p = 0.031; OR = 1.35 (1.035-1.755). In the CAD group, a history of VTE was found in 169 pts., but not in 2,520 pts. (= no-VTE). The -403A allelic frequency was as follows: VTE = 0.248 vs. no-VTE = 0.196; p = 0.025; OR = 1.35 (1.042-1.535); VTE vs. C: p = 0.003; OR 1.59 (1.182-2.136). In non-smokers, the -403A allelic frequency was as follows: VTE = 0.295 vs. no-VTE = 0.205; p = 0.019; OR = 1.63 (1.098-2.412).
Conclusions: The RANTES -403A polymorphism is associated with an increased risk of coronary artery disease, particularly in smokers. In CAD patients, this polymorphism is also associated with an increased risk of venous thrombo-embolism, which is more evident in non-smokers. These results suggest a significant role of RANTES in the pathophysiology both of coronary arteriosclerosis and venous thrombo-embolism, which may be due to enhanced RANTES expression in atherosclerotic lesions and increased RANTES deposition by activated platelets.

1983 A PPARα gene polymorphism is associated with myocardial infarction in individuals with positive family history

C. Hengstenberg[1], S.R. Holmer[2], B. Mayer[2], J. Erdmann[2], S. Mitsching[2], H. Löwel[3], G.A.J. Riegger[2], H. Schunkert[2]. [1]*University Hospital Regensburg, Cardiology, Regensburg, Germany;* [2]*University of Regensburg, Cardiology Dept., Regensburg, Germany;* [3]*GSF, Epidemilogy Dept., München, Germany*

Peroxisome proliferator-activated receptor a (PPARa) is a transcription factor involved in lipid metabolism, hemostasis, and inflammation. With respect to atherosclerosis, PPARa has been involved in expression of VCAM-1, tissue factor, and IL-6 levels; its role in the pathogenesis of myocardial infarction (MI), however, is unclear. We therefore investigated the association of a newly identified polymorphism in intron 7 (C2528G) with MI. To enhance the genetic component, we focussed the study on subjects with a positive family history.
Methods: We examined 6380 individuals by complete pheno- and genotyping. 1) MI families with at least two affected individuals (index patients suffering from MI <60 years)[n=968], 2) affected siblings [n=962], 3) non-affected siblings [n=888], 4) married-in spouses from MI families [controls; n=1114]. The findings in MI families were contrasted to 5) sporadic MI patients [n=582] and 6) participants of a population-based survey [n=1866].
Results: The overall allele frequency was in Hardy-Weinberg equilibrium but differed markedly between MI family members and married-in spouses (p<0.0001), but not between sporadic MI cases and survey controls. Between PPARa genotypes, there was no relevant difference in risk factors, such as systolic, diastolic blood pressure, cholesterol and its subfractions, in anthropometric or in history data (age at MI, age at inclusion, time between MI and examination).

Frequency of PPAR genotypes

Population	Total n=	CC, %	CG, %	GG, %	P vs. controls
MI index patients	968	80,0	17,6	2,5	< 0,0001
affected siblings	962	84,3	13,4	1,1	< 0,0001
non-affected siblings	888	84,7	13,6	1,7	< 0,0001
Controls	1114	67,1	29,9	3,1	
Sporadic MI patients	582	69,9	26,3	3,8	n.s.
Survey	1866	68,2	28,5	3,3	n.s.

Conclusion: The PPARa polymorphism is highly significantly associated with MI in individuals with a strong familial component as compared to both, sporadic MI cases, married-in spouses and population-based controls. The high condensation of potentially pathogenic alleles in individuals with a positive family history allows to detect disease-related genetic variants that may escape detection in an unselected sample.

STUNNING, HIBERNATION, PRECONDITIONING

1984 Activation of ATP-dependent potassium channels is trigger but not mediator of ischaemic preconditioning in pigs

P. Gres, R. Schulz, A. Skyschally, G. Heusch. *University of Essen, Pathophysiology, Essen, Germany*

Blockade of ATP-dependent potassium channels (KATP) with glibenclamide starting before the preconditioning ischemia and continued until the end of the index ischemia inhibits the reduction of infarct size by ischemic preconditioning (IP) in pigs (Am J Physiol 267: H1341-H1352, 1994). Studies in isolated buffer-perfused rabbit hearts suggested that activation of mitochondrial KATP may act as trigger rather than mediator of IP (Circ Res 87: 460-466, 2000). However, pigs are much closer to humans with respect to coronary blood flow and infarct development. Whether activation of KATP acts as trigger or mediator of IP in pigs in situ, is not yet known.

In 35 enflurane-anesthetized pigs the LAD coronary artery was perfused from an extracorporal circuit. Subendocardial blood flow (ENDO, ml/min/g, microspheres) and infarct size (IS, %, TTC) were measured. After 90 min of severe ischemia and 120 min reperfusion IS was 24.2±3.4 [SEM] (n=7 ENDO:0.045±0.009). IS was reduced to 6.5±5.6 ($p<0.05$, n=7, ENDO:0.048±0.026) by IP with one cycle of 10 min ischemia and 15 min of reperfusion. Glibenclamide given intravenously (0.5 mg/kg as a bolus followed by 50μg/min continuous infusion until the end of the index ischemia) did not change IS per se (20.0±2.3, n=7, ENDO:0.040±0.006). Whereas glibenclamide starting before the preconditioning ischema inhibited the infarct size reduction of IP (see above), its application starting just prior to the index ischemia did not affect infarct size reduction by IP (9.2±5.5, n=7, ENDO:0.045±0.010). Heart rate, left ventricular pressure and area at risk were comparable among the groups.

Conclusion: Activation of KATP acts as trigger and not mediator of infarct size reduction by ischemic preconditioning also in pigs in situ.

1985 Scavenging of free oxyradicals by ascorbic acid attenuates ischaemic preconditioning in pigs

A. Skyschally, R. Schulz, P. Gres, M. Thielmann, G. Heusch. *University of Essen, Pathophysiology, Essen, Germany*

The involvement of free oxyradicals in the signal transduction of ischemic preconditioning has been established in rats and rabbits. Data from larger mammals such as pigs in which the coronary circulation and infarct development are closer to that in man are lacking. We have therefore investigated the impact of the natural radical scavenger ascorbic acid on ischemic preconditioning in pigs.

In 32 anesthetized pigs the LAD coronary artery was perfused from an extracorporal circuit. Subendocardial blood flow (BF; ml/min/g; radioactive microspheres) and myocardial infarct size (% area at risk; TTC-staining) were determined.

In animals undergoing 90 min severe ischemia and 120 min reperfusion the infarct size averaged 26.9±3.9% (Mean±SEM; n=9; BF:0.048±0.070). Ischemic preconditioning by 10 min ischemia followed by 15 min reperfusion reduced infarct size to 6.4±2.4% (n=9; BF: 0.054±0.011; $p<0.05$).

The infusion of ascorbic acid (i.v.; 2g bolus/maintenance dose 25mg/min until the end of ischemia) starting 30 min before ischemia had no effect on infarct size per se (n=5; 24.0±7.7%; BF: 0.053±0.014). The same dosage of ascorbic acid given 30 min before the preconditioning ischemia largely abolished the infarct size reduction by ischemic preconditioning (n=9; 19.1±5.4%; BF: 0.046±0.010).

Group	Infarct size % Area at risk	Subendocardial blood flow ml/min/g
I/R (n=9)	25.5 ± 3.8	0.048 ± 0.01
IP+I/R (n=9)	5.2 ± 1.7 *	0.057 ± 0.01
A+I/R (n=3)	29.0 ± 4.7	0.044 ± 0.03
A+IP+I/R (n=9)	19.1 ± 4.0	0.045 ± 0.03

We conclude that scavenging of free oxyradicals with ascorbic acid attenuates the beneficial effect of ischemic preconditioning on infarct size in pigs. Therefore, free oxyradicals are also involved in the signal transduction cascade of ischemic preconditioning in pigs. Whether they act as triggers or mediators of ischemic preconditioning remains to be elucidated.

1986 Not only PKC activation after PC but also duration of ischaemia that induces myocardial stunning determine the anti-stunning effects of late PC

Y. Nishino, T. Miura, J. Sakamoto, T. Miki, K. Shimamoto. *Sapporo Medical University, Second Department of Internal Medicine, Sapporo, Japan*

In contrast to the effect of ischemic preconditioning (PC) on infarction, the phenomenological features of the late PC effect on myocardial stunning have not been well characterized. In this study, we assessed the roles of PKC-epsilon (a key kinase of PC) and the difference in anti-stunning effects of late PC depending on how myocardial stunning is induced. Methods: Rabbits were chronically instrumented with a balloon occluder around a circumflex artery and with a Doppler sensor in the circumflex region to monitor the thickening fraction (TF). Since post-infarct ventricular remodeling prevents PC from activating PKC-epsilon (Miki et al. Circulation 2001;104:II-209), we induced ventricular remodeling by ligating the left anterior descending artery in some rabbits to use them as a model of PKC dysfunction. Two weeks after surgery, conscious rabbits underwent either of two ischemia (I)/reperfusion (R) protocols (I/R-1 and I/R-2) on day 1 and day 2. I/R-1 and I/R-2 consisted of 5 cycles of 5-min I/5-min R and 3 cycles of 8-min I/5-min R, respectively. In pilot experiments, we confirmed that I/R-1 and I/R-2 induced the same degrees of severity of stunning despite the difference in the durations of ischemic episodes. Using separate rabbits, myocardial tissues were sampled for Western blotting of PKC. Results: Both I/R-1 and I/R-2 similarly increased the membrane fraction of PKC-epsilon from 52±3% in a non-ischemic condition to 61±3% and 74±3% of the total, respectively (both $p<0.05$). I/R-1 on day 1 significantly improved recovery from I/R-1 on day 2 (Total deficit of TF during 2-hr reperfusion [defTF] was 45% on day 1 vs. 37% on day 2, $p<0.05$.), but I/R-2 on day 1 failed to attenuate the stunning by I/R-2 on day 2 (defTF: 46% on day 1 vs. 44% on day 2, p = ns). I/R-1 on day 1 also failed to attenuate the myocardial stunning induced by I/R-2 on day 2 (defTF: 46% vs. 46%, p = ns). In the rabbits with post-infarct ventricular remodeling, PC induced neither PKC-epsilon translocation nor late PC effects (defTF after I/R-1: 41% on day 1 vs. 39% on day 2). Conclusions: The results support the notion that PKC-epsilon is necessary for the anti-stunning effect of late PC. The finding that a modest prolongation of each ischemic episode (i.e., from 5 to 8 min) did not change the severity of myocardial stunning but made the stunning refractory to late PC suggests that late PC primarily enhances tolerance against ischemic injury rather than reperfusion injury per se.

1987 Additional low dose dobutamine stress imaging is superior to magnetic resonance scar imaging (late enhancement) alone for the prediction of functional recovery

E. Wellnhofer[1], A. Olariu[1], A. Wahl[1], M. Gräfe[1], C. Klein[1], R. Capalneanu[2], E. Nagel[1], E. Fleck[1]. [1]*Deutsches Herzzentrum Berlin, Cardiology, Berlin, Germany;* [2]*Institutul Inimii, Cardiology, Cluj-Napoca, Romania*

Background: Recently, new MR techniques (late enhancement) have been shown to yield a high value for the prediction of functional recovery of hibernating myocardium (HM). Other methods (echocardiography [Echo] or magnetic resonance [MR]) using low dose dobutamine (5-10μg/kg/min) have been successfully used in clinical routine for years. The scope of this study was to determine the additional value of dobutamine stress Echo and MR in relation to late enhancement for the detection of HM.

Methods: In 26 consecutive patients with coronary artery disease (67±8 yrs, 3 female, EF 35±7%, wall motion score index 2.1±0.4), scheduled for revascularisation (PTCA 23, CABG 2) wall motion was evaluated semi-quantitatively (16-segments) by Echo and MR (Philips ACS, NT, 1.5 Tesla) before and 3 months after intervention. MR scar imaging (late enhancement; Gd-DTPA) was performed before revascularization and the transmural extent of scar was assessed. The analysis was based on 171 segments with wall motion abnormalities at rest.

Results: The majority 89% of the 72 segments with improved wall motion after revascularization was found in segments with <50% transmural extent of scar. Subgroup analysis with respect to the transmural extension of scar was performed. The results concerning the additional value of stress imaging by MR or echo for the diagnosis of HM in these subgroups are summarized in the table.

	M_PV+	M_PV-	M_LHR	M_P	E_PV+	E_PV-	E_LHR	E_P	N	PreV
no scar	0.74	0.67	10.1	0.001	0.71	0.54	3.7	0.05	61	0.56
scar<50%	0.77	0.81	26.9	<0.001	0.53	0.62	1.1	n.s.	74	0.43
scar>50%	-*	0.86	3.7	n.s.	-*	0.82	3.2	n.s.	36	0.17

M_ MR, E_ echo, PV+ positive predictive value, PV- negative predictive value, LHR likelihood ratio, P p-values, N number of segments of subgroup, PreV prevalence of HM in subgroups, -* positive predictive values are not valid as a result of the low prevalence of HM in this subgroup.

Conclusions: Especially in the subgroup of patients with scar < 50% additional dobutamine stress testing improves predictive value for hibernating myocardium. In this group, stress MR is superior to stress echo. In the subgroup of patients with scar > 50% of the wall thickness dobutamine stress testing does not improve diagnosis.

1988 Assessment of myocardial hibernation in patients with left ventricular dysfunction, coronary disease and type II diabetes

M. Pitt[1], K. Morita[2], R.S. Bonser[3], P.G. Camici[2], D.P. Dutka[4]. [1]*Heartlands Hospital, Department of Cardiology, Bimingham, United Kingdom;* [2]*MRC Clinical Sciences Centre, NHLI, London, United Kingdom;* [3]*Queen Elizabeth Hospital, Cardiac Surgery Dept., Birmingham, United Kingdom;* [4]*University of Cambridge, Medicine, Cambridge, United Kingdom*

A number of techniques delineate hibernating myocardium (HM) including dobutamine echocardiography (DE) that identifies contractile reserve and positron emission tomography (PET) that measures myocardial glucose uptake (MGU) using 18F-fluorodeoxyglucose (FDG). Myocardial insulin resistance is present in patients with coronary artery disease (CAD) and may be amplified in those with type II diabetes (DM). The relationship between MGU and inotropic response to dobutamine in dysfunctional but viable myocardium is unknown in type II diabetes. We therefore measured MGU and performed DE to assess myocardial viability in patients with impaired LV function and CAD referred for bypass surgery (CABG). PET and DE were analysed using a comparable 16 segment LV model. The definitions of viability were MGU >0.25μmol/min/g and improvement in wall motion of >1 grade at DE. HM was defined by functional improvement at echocardiography 6 months after CABG.

Patients and Methods: 55 patients (aged 62.0±9.0 yrs, 19 type II DM) with significant LV dysfunction and multivessel CAD were studied. Baseline LV ejection fraction (LVEF), resting wall motion score index (WMSI) and WMSI with dobutamine were similar in non-DM and DM patients (26.7±11.0% vs. 28.2±11.2%, 2.37±0.72 vs.2.24±0.67 and 1.59±0.52 vs.1.51±0.4 respectively, all p=ns).

Results: At DE, the number of dysfunctional viable segments per patient was similar irrespective of DM. However, a MGU of 0.25 μmol/min/g identified fewer segments as viable although patients with type II DM subsequently displayed a similar improvement in LV function following CABG (table).

	No diabetes	Type II diabetes	P
DvS PET	10.8 ± 4.0	7.8 ± 4.7	<0.01
DvS DE	10.7 ± 3.6	10.2 ± 4.2*	ns
LVEF 6months post CABG	37.2 ± 15.6	35.0 ± 11.5	ns
WMSI 6 months post CABG	1.72 ± 0.7	1.83 ± 0.62	ns

DVS: dysfunctional viable segments*: P<0.01 vs DVS PET in type II diabetics

Conclusions: PET may underestimate the extent of hibernating myocardium in type II DM. Clarification of the threshold value defining viability is required in order to optimise the identification of such patients who may benefit from revascularisation.

MONITORING ATRIAL SEPTAL DEFECT CLOSURE BY ECHOCARDIOGRAPHY

1989 TEE guidance of transcatheter ASD/PFO closure

Y. Schwartz[1], A. Lorber[2]. [1]*Rambam Medical Center, Pediatric Cardiology, Haifa, Israel;* [2]*Rambam Medical Center, Pediatric Cardiology, Haifa, Israel*

Transcatheter occlusion of PFO/ASD has become a popular, safe and effective alternative for surgery. The cornerstone of this therapeutic procedure is TEE guidance.

Objectives: The role of TEE and its efficacy were prospectively assessed in a series of 104 consecutive patients who were considered for transcatheter occlusion of interatrial shunts.

Patients & Methods: 44 patients (20F, 24M), mean age 50.5 (25-77)yrs, were referred due to a cryptogenic TIA/CVA. All PFO's were successfully occluded on first attempt (100%) with 10 CardioSeal/StarFlex, 1 Cardia and 33 Amplatzer devices.

60 patients (39F, 21M), mean age 25 (3.9-70)yrs, were referred due to an ASD diagnosed by TTE. 8 were found by TEE to have an unsuitable anatomy for device occlusion: 6 - huge (>36mm) defects, 1 - sinus venosus defect, 1 - severe mitral valve disease. The remaining 52 patients underwent successful occlusions with 7 CardioSeal/ StarFlex and 45 Amplatzer devices.

A single case of pericardial effusion has occurred during the early learning curve. There were no other immediate or late complications, median follow-up 15 (2-32) months.

Overall procedure time = 34 (17-65)min, fluoroscopy = 7 (2-11)min.

TEE imaging: HP-2500/4550, pediatric biplane transducer.

Results: 1. TEE has effectively guided all steps of the procedures.

2. TEE has accurately measured the exact size of all defects:

Mean TEE diameter = Fluro (!)

PFO nonstretched diameter = 5.16(3-9)mm, stretched = 11.6(8-15)mm,

ASD nonstetched = 12.1(8.8-25)mm, stretched = 19.8 (15-35)mm;

3. TEE has identified in detail the characteristic anatomy of each individual defect. Multiple defects were noted in 8 patients, all sucessfully treated with a single device.

4. TEE has enabled validation of optimal proper device placement.

5. Trivial color flow leaks were often detected by TEE at the end of the procedure (mostly through the occluding device and less often through its rims), yet no residual shunt was detected 1 week later.

6. TEE has identified in real-time the accumulation of pericardial fluid and enabled early dainage.

Conclusions: 1. TEE guidance is providing all the essential data for optimal device selection and performance of transcatheter PFO/ASD closure with minimal or no fluoroscopy.

2. Usage of a small pediatric TEE transducer is advantageous in adult patients undergoing this procedure and is not associated with decreased resolution.

3. Transcatheter PFO/ASD occlusion is a team-work effort requiring full and close cooperation between the echocardiographist and the interventionalist.

1990 The role of transoesophageal echocardiography to choose Amplatzer occluder device size in adult patients with secundum atrial septal defect

A. Carcagnì, L. Maiello, F. Milone, D. Zavalloni, R. Friolo, D. Trovè, M. Piras, P. Presbitero. *Istituto Clinico Humanitas, Interventional Cardiology, Rozzano, Italy*

Transcatheter closure of secundum atrial septal defect (ASD) with Amplatzer septal occluder (ASO) device is a safe and effective alternative to surgical closure in the adult population. Trans-esophageal echocardiography (TEE) provides important information in the selection of patients eligible for ASD closure device. However, ASO size is selected using stretched defect diameter or intracardiac echocardiography. The aim of this study is to investigate whether TEE enables precise determination of ASO device size.

Methods and Results: Between May 1999 and September 2001, 36 adult patients (21 female, mean age of 44.6+15.1 years) with ASD were evaluated by multiplane-TEE for percutaneous closure with ASO-device. Anatomical ASD diameter (edge-to-edge ASD borders), atrial septum length and ASD rims were measured by TEE. Moreover, rim thickness of 2.5 mm around the defect was selected as reference and a new diameter (procedural ADS diameter) was measured using the new borders. Stretched diameter was calculated.

The mean anatomical ASD diameter was 14.4+7.2mm (range 4 to 23 mm). The mean procedural ASD diameter measured 19.3 +8.3 mm (range 7 to 33 mm) and stretched defect diameter measured 19.5+8.4 mm (range 8 to 34 mm). ASO-device size was 19.8+ 8.2 mm (range 8 to 34 mm). The anatomical ASD diameter underestimated the ASO-device size by 5.4 mm ($p < 0.001$). Whereas, a good linear correlation between procedural ASD diameter ($r= 0.99$) and between stretched defect diameter and ASO size ($r= 1$) was assessed. Atrial septum length was 53.1+6.5 mm and the difference between atrial septum length and ASO-device diameter was 33.3 mm. ASO-device was implanted successfully in 94.4% (34/36) of patients. In 2 (5.6%) cases ASO closure failed because the defect was too large. In none patient obstruction of anatomical structures (Vena Cava, atrio-ventricular valves and venous sinus) was shown by TEE.

Conclusions: 1. Procedural ASD diameter measured by TEE enables precise determination of ASO device size and can be used instead of stretched defect diameter with reduction of time and cost of procedure 2. Adequate atrial septum lenght has to be present to avoid structural obstruction.

1991 Comparison of 2D and 3D transoesophageal echocardiography with the stretching balloon maneuver for atrial septal defect measurement

M. Pepi, G. Tamborini, A. Bartorelli, D. Trabattoni, E. Onorato, F. Susini, G. Pontone. *Fondazione Monzino, IRCCS, Centro Cardiologico, Milan, Italy*

Transcathether device closure has become a successful alternative to surgical repair of atrial septal defect (ASD). Information obtained by two-dimensional transesophageal echocardiography (2DTEE) play an important role in patient selection and ASD closure monitoring. However, 2DTEE often underestimates stretching balloon (SB) diameter, and the choice of device size is therefore based on invasive measurement. Three-dimensional TEE (3DTEE) measurements of ASD demonstrated to closely correlate to SB diameter. However, some ASD may be underestimated even with this new technique.

Aims: to compare side-by-side 3DTEE and BS measurements of ASD and to elucidate the anatomical characteristics of the atria and atrial septum that may lead to ultrasound vs. invasive underestimation.

Methods: forty ASD pts undergoing transcatheter closure with the Amplatzer device were enrolled in the study. 2DTEE monitoring, 3DTEE reconstruction and stretching balloon (SB) evaluation of the defect were performed in each patient. 3DTEE maximal diameter (3DD) and SB diameter (SBD) were compared. Left atrium area (transthoracic echocardiography), atrial septal thickness, systo-diastolic motility of fossa ovale tissue (2DTEE), septal defect maximal and minimal rim length and percent change of systo-diastolic defect area (3DTEE) were also measured.

Results: SBD (20.8±7 mm) and 3DD (19.6±6 mm) correlated significantly ($r=0.83$, E.S.=0.7 $p<0.001$). The systematic error (bias) between 3DTEE and SB values was 1.18 ± 4 mm (underestimation). Pts were divided in Group 1 (n=28) in which SBD - 3DD difference was lower than 1SD (4 mm), and Group 2 (n=12) in which SBD - 3DD was > 4 mm. No difference was found in echocardiographic data between the two groups, with the exception of atrial septal motility that was significantly higher in Group 2 (8.3±2.3 vs. 4.2±1.7 mm, $p<0.01$). All Group 1 pts had atrial septal motility < 6 mm, while 80% of Group 2 pts showed atrial septal mobility > 6 mm.

Conclusions: atrial septal motility and elasticity can affect echocardiographic accuracy in ASD size evaluation. Underestimation of echocardiographic vs. SB ASD sizing is likely due to increased balloon stretching of the fossa ovale tissue in pts with these anatomical features.

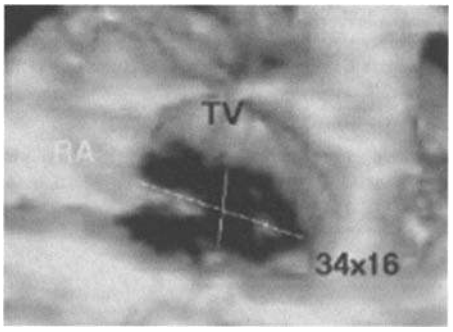
1992 Improved quantification of atrial septal defect size using transthoracic three-dimensional echocardiography before Amplatzer closure

J.D. Kasprzak[1], A. Sysa[2], M. Krzeminska-Pakula[1], M. Ciesielczyk[1], J.A. Moll[2], J. Masura[3], P. Dryzek[2], J. Drozdz[1]. *[1]Medical University, Cardiology IMW, Lodz, Poland; [2]Polish Mother's Health Centre, Cardiology, Lodz, Poland; [3]Deot. of Cardiology, Bratislava, Slovakia*

The aim of the study was to compare the usefulness of transthoracic three-dimensional echocardiography (3D) with transesophageal 2-dimensional echo (TEE) for the estimation of secundum atrial septal defect (ASD) dimensions, before interventional closure of defect with Amplatzer device.

Method: 16 children and young adults (3-20 years, 11±6) were studied prior to Amplatzer device implantation using 3D and TEE. 3D was performed using rotational acquisition at 3degree intervals from transthoracic windows (TomTec Echoscan 3.0). Long and short diameter of defect predicted mean diameter and area were by TEE and 3D. Results of measurements were compared to stretched balloon diameter and final Amplatzer waist diameter. All patients underwent successful implantation procedure without residual leaks after 6 months.

Results: Quality of 3D was good in 11 pts and satisfactory in 7. Mean stretched/Amplatzer diameter was 20±5/22±5mm and stretched/Amplatzer waist area 3.2±1.8/3.9±2.0 cm^2. Maximal diameters were severely underestimated by TEE and not by 3D: 14±4 vs 23±5 mm ($p<0.001$), with calculated areas of 1.2±0.6 vs 2.9±1.5cm^2 resp. ($p<0.001$). The results of 3D had good correlation and close agreement in Bland-Altman analysis to stretch diameter (r=0,87) with small underestimation of true size of implanted device by 3mm. TEE results underestimated defect size markedly (r=0,59, underestimation >6mm).



Conclusions: Transthoracic 3D is a feasible technique in young patients, and, as opposed to TEE, allows accurate transthoracic measurements of ASD diameter and reliable prediction of necessary Amplatzer size in young patients. 2-dimensional measurements suffer from significant underestimation of defect dimensions.

1993 Intracardiac echocardiography in the diagnosis and treatment of atrial septal defect and patent foramen ovale

M. Zanchetta[1], G. Rigatelli[2], L. Pedon[1], M. Zennaro[1], K. Dimopoulos[1], E. Onorato[3], P. Maiolino[1]. *[1]Cittadella General Hospital, Department of Cardiovascular Disease, Cittadella, Padua, Italy; [2]Cittadella General Hospital, Department of Cardiovascular Disease, Cittadella, Italy; [3]Clinica S. Rocco di Franciacorta, Operative Unit of Cardiology, Orne (Brescia), Italy*

Purpose: Traditional implantation method of Amplatzer devices for closure of interatrial communications uses balloon sizing (SBS) and transesophageal echocardiography (TEE). We propose a new method using intracardiac echocardiography (ICE) alone for the selection of the prosthesis and the monitoring of the procedure.

Materials and methods: Eighty consecutive patients (mean age 46.4±16.1 years) underwent transcatheter closure of atrial septal defect (ASD, 45 patients) or patent foramen ovale (PFO, 35 patients) using the Amplatzer devices. ICE was used for confirming the diagnosis, excluding the presence of associated anomalies, device size selection and monitoring of the procedure. ICE examination was standardized, defining 5 views (4 transverse and one longitudinal). Devices were selected aiming at full fossa ovalis coverage. Patients underwent transthoracic echocardiography (TTE) prior to discharge and at 3 months and TEE at 1 year.

Results: Transcatheter occlusion was successful in all patients and no periprocedural complications. In patients treated for ASD, mean defect diameter on ICE was 28.4±6.5 mm and mean device size was 28.8±5.6 mm. Complete occlusion was seen in 98,2%, 99,2% and 100% at predischarge TTE, 3 months-TTE and 1 year TEE respectively. Complete occlusion was seen in 100% of patients with PFO on predischarge TTE. In 48.5% associated septal aneurysm was seen. ICE also proved to be adequate in the evaluation of associated anomalies and in the monitoring of the deployment of the devices using the longitudinal 4 chamber view. In no cases were devices oversized, undersized or misaligned to the septum.

Conclusions: ICE-guided device selection and deployment aiming at full fossa ovalis coverage is safe and feasible. It increases patient comfort and acceptance of the procedure and can provide an effective alternative to TEE and stretched SBS.

1994 Right heart reverse remodelling after transcatheter closure of atrial septal defect

R.R. Brandt, T. Neumann, T. Dill, M. Rau, I. Faude, C.W. Hamm. *Kerckhoff Heart Center, Cardiology Dept., Bad Nauheim, Germany*

Atrial septal defect (ASD) is one of the most common congenital cardiac abnormalities. The pathophysiologic consequences of ASD result from left-to-right shunting with an increase in pulmonary blood flow and right heart volume overload. ASD closure corrects these hemodynamic abnormalities. The following study was conducted to analyze changes of right heart geometry following transcatheter ASD closure.

Twenty-seven patients (11 men, 16 women) underwent transcatheter closure of a secundum-type ASD with the Amplatzer septal occluder (median size 24 mm) at the age of 43 ± 15 years. All patients had a pulmonary-to-systemic flow ratio by oximetry (Fick method) of at least 1.5:1 and 22 of 27 patients had ASD-related symptoms. Color Doppler transesophageal echocardiography demonstrated complete occlusion without residual shunt in 26 patients and a small residual left-to-right shunt in one patient at 6 months. All patients underwent a complete transthoracic echocardiographic study before and 6 months after ASD closure. Measurements were performed in the apical four-chamber view. Right atrial area at end-systole (planimetry) decreased from 21.1 ± 5.5 cm^2 to 17.3 ± 4.4 cm^2 ($P<0.0001$). Right atrial volume (area-length-method) changed from 64 ± 24 ml to 47 ± 20 ml ($P<0.001$). Right ventricular end-diastolic diameter (inflow tract) decreased from 3.8 ± 0.4 cm to 3.3 ± 0.3 cm ($P<0.0001$). Right ventricular end-diastolic volume (RVV) was approximated by calculating the total volume of both ventricles and then subtracting the combined volume of the left ventricular cavity and interventricular septum. RVV decreased from 201 ± 51 ml to 149 ± 37 ml ($P<0.0001$). Right ventricular (RV) fractional area change as a measure of RV function did not change significantly (29.9 ± 6.0% to 32.2 ± 5.2%, P=NS).

Transcatheter closure of ASD corrects the hemodynamic abnormalities and causes regression of right heart volume overload at 6 months. This process may be related to the symptomatic improvement following ASD closure.

INFLAMMATION, CYTOKINE AND HEART FAILURE

1995 In vivo inhibition of tumor necrosis factor-alpha alleviates oxidative stress and reduces myocyte apoptosis in experimental heart failure

G. Moe[1], A. Konig[1], M. Romanova[1], X. Lu[2], Q.P. Feng[2]. [1]*St Michael's Hospital, Cardiology Dept., Toronto ON, Canada;* [2]*U. of Western Ontario, Medicine, London, Canada*

The pro-inflammatory cytokine tumor necrosis factor-alpha (TNF-alpha) is known to induce oxidative stress and trigger apoptosis in vitro. Robust expression of TNF-alpha, increased oxidative stress and apoptosis have been observed in the failing heart. Accordingly, the current study tested the hypothesis that TNF-alpha induced oxidative stress and apoptosis in vivo and therefore contributed to progressive LV dysfunction in heart failure (HF).
Dogs were randomly assigned to: 1) no pacing (controls, n=10), 2) chronic RV pacing for 4 weeks to severe HF (HF, n=10), and 3) pacing with concomitant treatment with etanercept, a chimeric TNF-alpha soluble receptor, 0.5 mg/kg twice weekly SC (HF-etanercept, n=10). Oxidative stress was assessed by LV tissue total aldehyde level measured using gas chromatography/mass spectroscopy and apoptosis was quantified using photometric enzyme immunoassay for cytoplasmic histone-associated DNA fragments (cell death ELISA). LV ejection fraction (LVEF) was assessed by echocardiography.
LV tissue total aldehyde level and absorbance for DNA fragments increased markedly in HF, signifying the presence of severe oxidative stress and increased apoptosis. This was accompanied by a significant reduction in LVEF, reflective of severe LV dysfunction. Treatment with etanercept normalized LV aldehyde levels, reduced absorbance for DNA fragments in the myocardium, and partially restored LVEF.

Effects of etanercept

	Control	HF	HF-etanercept
LVEF (%)	53 (2)	19 (3)*	26 (2)**
Aldehydes (pmol/100 mg)	7048 (448)	11760 (1410)*	6991 (516)**
Cell death ELISA (units)	0.62 (0.08)	1.26 (0.15)*	0.79 (0.10)**

Data, means (SE); * $p<0.05$ vs controls, ** $p<0.05$ vs HF

Our data demonstrate an important role of TNF-alpha in canine pacing-induced CHF. Specifically, increased TNF-alpha contributes to LV dysfunction, which is mediated in part by a local increase in oxidative stress and apoptosis in the failing heart.

1996 Decreased levels of the anti-inflammatory cytokine interleukin-10 in patients with chronic heart failure

C. Stumpf[1], S. Ropers[1], C. Lehner[1], S. Eskafi[1], A. Schmeisser[2], W.G. Daniel[1], C.D. Garlichs[1]. [1]*University of Erlangen-Nuremberg, Medical Clinic II, Erlangen, Germany;* [2]*Heart Center Univ of Dresden, Cardiology Dept., Dresden, Germany*

Background: Inflammation plays a significant contributory role in the pathogenesis of chronic heart failure (CHF). Previous data showed enhanced plasma levels of proinflammatory cytokines (i.e. TNF-alpha, IL-6) as well as persistent immune activation in patients with CHF. However, little is known about the regulation of antiinflammatory cytokines such as interleukin (IL)-10. IL-10, which is expressed in human atherosclerotic plaques, has potent deactivating properties in macrophages and T cells and thus acts as a down-regulator of cell-mediated immune responses. The aim of the present study was to assess whether serum concentrations of IL-10 significantly differed between patients with CHF and healthy control subjects.
Methods and Results: 33 patients with chronic heart failure (67.7 ± 11.2 years, mean ejection fraction 20.9+7.0%, NYHA II-IV, 17 of ischemic origin, 16 with idiopathic dilated cardiomyopathy) and 15 healthy controls (62.5±9.8 years) were examined. 13 patients were aspirin free and 20 patients were taking aspirin (100 mg/d). Serum IL-10 concentrations were measured using commercially available immunoassays. Patients with CHF showed significantly lower IL-10 concentrations as compared to controls (2.3+1.9 vs. 5.0+2.5 pg/mL, $p<0.001$). IL-10 serum concentration did not correlate with the NYHA-class. Aspirin therapy did not significantly influence serum levels of IL-10.
Conclusions: Our study demonstrates for the first time significantly reduced serum levels of IL-10 in patients with congestive heart failure. Since IL-10 is known as a potent anti-inflammatory cytokine, its decrease in CHF is an important component in the inflammatory response found in CHF.

1997 Platelets contribute to the inflammatory response in chronic heart failure via enhanced levels of CD154

C. Stumpf[1], S. Ropers[1], C. Lehner[1], S. Eskafi[1], A. Schmeisser[2], W.G. Daniel[1], C.D. Garlichs[1]. [1]*University of Erlangen-Nuremberg, Medical Clinic II, Erlangen, Germany;* [2]*Heart Center Univ of Dresden, Cardiology Dept., Dresden, Germany*

Background: Inflammation plays a contributory role in the pathogenesis of chronic heart failure (CHF). Previous data showed enhanced plasma levels of proinflammatory cytokines (i.e. TNF-alpha, IL-6) as well as persistent immune activation in patients with CHF. However, little is known about the role of CD154, an essential inflammatory mediator, in the pathophysiology of CHF. In intervention studies, blockade of CD154 significantly reduced inflammation in chronic inflammatory disease states such as rheumatoid arthritis and atherosclerosis. In addition, CD154 was identified on activated platelets, which is able to induce an inflammatory reaction within the vessel wall. In the current study, we focused on the expression of CD154 on platelets to further examine its inflammatory role in CHF.
Methods: We analysed the surface levels of CD154 on platelets in 33 patients with CHF of NYHA functional class II-IV (67.7+11.2 years, mean ejection fraction 20.9+7.0%, 17 of ischemic origin, 16 with idiopathic dilated cardiomyopathy) and 15 healthy controls (C, 62.5±9.8 y). 13 patients were aspirin free and 20 patients were taking aspirin (100 mg/d). Blood samples were drawn from a peripheral vein and immediately fixed with 1% paraformaldehyde. Another sample was centrifuged for preparation of platelet-rich plasma (PRP). Samples were thereafter stained with anti-CD154, anti-P-selectin and anti-CD61 (for identification of platelets). Platelets were analysed by flow cytometry.
Results: CHF patients showed significantly enhanced expression of platelet-bound CD154 and P-selectin as compared to healthy controls (CD154: 37.73+14.68 vs 9.35+5.65 mean fluorescence intensity [MFI], $p<0.001$; P-selectin: 5.19±1.79 vs 1.25+0.59 MFI, $p<0.001$). CD154 expression on platelets positively correlated with the increase in the NYHA-class. No significant correlation was detectable between the expression of CD154 and P-selectin in the study groups. Aspirin therapy did not significantly influence the expression of CD154 or P-selectin.
Conclusions: This first demonstration of enhanced levels of platelet-bound CD154 in patients with CHF suggests a contributory role of platelets to the inflammatory milieu found in CHF. Therefore, patients with CHF may benefit from pharmacological means (i.e. clopidogrel, statins), which interrupt the proatherogenic and proinflammatory CD40-CD154 pathway.

1998 Increased levels of proinflammatory cytokines correlate with a reduced expression of insulin-like growth factor-I in chronic heart failure

P.C. Schulze[1], S. Gielen[2], A. Linke[2], V. Adams[2], S. Moebius-Winkler[2], J. Kratzsch[3], R. Hambrecht[2], G. Schuler[2]. [1]*BWH, Harvard Medical School, Cardiovascular Research, Cambridge, United States of America;* [2]*University of Leipzig, Heart Center, Department of Cardiology, Leipzig, Germany;* [3]*University of Leipzig, Heart Center, Department of Clinical Chemistry, Leipzig, Germany*

Chronic heart failure (CHF) is associated with metabolic abnormalities leading to a progressive catabolic state. To assess the role of proinflammatory cytokines for the local expression of insulin-like growth factor-I (IGF-I) in this process, local levels of interleukin-1 beta (IL-1beta) and tumor necrosis factor alpha (TNFalpha) as well as IGF-I were analyzed in the skeletal muscle in addition to the determination of serum levels in a rat model of CHF.
Ligation of the left coronary artery (n=20) or sham operation (n=8) was performed in adult Wistar Kyoto rats (250g). After 12 weeks, all animals were assessed by echocardiography and cardiac catheterization for signs of CHF. Serum levels of IGF-I were measured by immunoassay and IL-1beta, IL-6 and TNFalpha concentrations assessed by ELISA. In quadriceps muscle, the expression of IGF-I, IGF-I receptor, IL-1beta and TNFalpha were assessed by RT-PCR and quantitative immunohistochemistry. Alterations in muscle fiber morphology were microscopically analyzed on tissue sections.
The expression of IGF-I significantly decreased in quadriceps muscle of animals with signs of CHF (0.47±0.07 versus 0.77±0.09 in Sham-OP; $p<0.05$). This reduction correlated with a decreased muscle fiber cross-sectional area ($r=0.62$; $p<0.01$) and inversely with the local expression of IL-1beta ($r=-0.49$; $p<0.05$). No significant differences in serum levels of IGF-I nor proinflammatory cytokines were found between the two groups.
The local expression of IGF-I is reduced in the presence of normal serum IGF-I levels in CHF. In addition to catabolic effects of proinflammatory cytokines, these findings are consistent with an involvement of altered local IGF-I levels in progressive skeletal muscle atrophy in CHF.

1999 Atrial fibrillation as an independant factor of increased circulating pro-inflammatory cytokines levels in heart failure

F.I. Parthenakis[1], A.N. Patrianakos[1], S.I. Chrysostomakis[1], E.N. Simantirakis[1], P.G. Tzerakis[1], D. Nikitovic[2], P.E. Vardas[3]. [1]*Heraklion University Hospital, Cardiology Dept., Heraklion, Crete, Greece;* [2]*Heraklion University Hospital, Clinical Chemistry - Biochemisty Dept., Heraklion, Greece;* [3]*Heraklion University Hospital, Cardiology, Heraklion, Greece*

Background: Proinflammatory cytokines play a pathogenic role in the development of congestive heart failure, and their circulating levels correlate with adverse outcome. Atrial fibrillation (AF) has been recognized as an independent factor of morbidity and mortality in these pts. Our study sought to investigate the relationship between chronic AF (>1 months) and circulating cytokine levels in pts with Idiopathic Dilated Cardiomyopathy (IDC).
Methods: We analyzed circulating levels of Tumor necrosis factor-a (TNF-a), and its soluble receptors sTNFr-1 and sTNFr- 2, Interleukine-1(IL-1) and -6 (IL-6) by immunobiological assay, in 92 pts, aged 59 ± 6 years, with IDC, angiographically proven, functional NYHA class II-III and Ejection Fraction (EF) 30.5±9.7%, in clinical stable condition during the last month. Seventy-two pts were in sinus rhythm (SR) and twenty in AF. A complete Echocardiographic study and cardiopulmonary exercise test with Naughton Protocol was performed in all pts, and maximal exercise duration and oxygen consumption at peak exercise (PVO2) were calculated.
Results: There was no significant difference between the two groups concerning age, left ventricular (LV) dimensions and volumes, LV Ejection Fraction and functional NYHA class, while left atrial (LA) dimensions were increased(46.2±5.8 vs 44±5.2 mm, p=0.05) in AF. Patients with AF had statistically significantly increased levels of IL-6 (6.2±3.2 vs 3.6±3.5 pg/ml, p=0.01), sTNFr1 (1.95±0.59vs 1.5±0.57pg/ml, p=0.01) and a trend of increased TNF-a (3.2 ±1.5 vs 2.6±1.1 pg/ml, p=0.07). Maximal exercise duration (548±283 vs 775±390 sec, p=0.03) and oxygen consumption at peak exercise(16.4±4.2 vs 18.1±3.2 ml/kgr/min, p=0.05) were also reduced in the AF patients group as compared to those in SR.
IL-6 was significantly correlated with AF (r=0.46, p=0.01), NYHA class (r=0.41, p=0.03), LVEF (r=-0.35, p=0.05), LA dimensions (r=0.38, p= 0.02) and RVEF (r=-0.39, p=0.05). Multivariate linear regression analysis showed that IL-6 (p=0.05) was independently associated with the presence of AF in these pts.
Conclusions: In idiopathic dilated cardiomyopathy, AF is an independent determinant of higher cytokine levels among pts with similar clinical and hemodynamic characteristics, supporting an increased proinflammatory status which may account for the reduced exercise performance in these patients.

2000 Influence of lipoproteins on cytokines and cytokine receptors in heart failure patients and the effect of short-term treatment with pravastatin

V. Conraads[1], J. Bosmans[1], A. Schuerwegh[2], L. De Clerck[2], F. Wuyts[3], C. Bridts[2], W. Stevens[2], C. Vrints[1]. [1]*University Hospital Antwerp, Cardiology, Edegem, Belgium;* [2]*University Hospital Antwerp, Immunology, Edegem, Belgium;* [3]*University Hospital Antwerp, Medical Statistics, Edegem, Belgium*

Background: The observation that low total cholesterol predicted poor survival in patients with heart failure, has questioned the beneficial effect of lipid-lowering in this population. We undertook a study to assess the relation between lipoprotein concentrations and the levels of interleukin (IL)-6, tumor necrosis factor (TNF)-alpha and the soluble TNF-alpha receptors. In a subset, we investigated the effect of pravastatin on cytokine and TNF-alpha receptor concentrations.
Methods and Results: 71 patients with heart failure due to coronary artery disease (CAD, n=36) or idiopathic dilated cardiomyopathy (IDCM, n=35) participated in the study. Plasma concentrations of lipoproteins, IL-6, TNF-alpha, soluble TNF-a receptor 1 (sTNFR1) and 2 (sTNFR2) were measured. In 58 patients, measurements were repeated after 1 month treatment with pravastatin 40 mg. Total cholesterol/HDL-cholesterol (CHOL/HDL) correlated with levels of TNF-alpha (r=0.24, p<0.05), sTNFR1 (r=0.32, p=0.008) and sTNFR2 (r=0.37, p=0.002). In the CAD group, CHOL/HDL and triglycerides (TG) correlated with sTNFR2 (r=0.48, p=0.005 for CHOL/HDL, r=0.40, p=0.02 for TG). No relation was found between lipoproteins and cytokines or sTNF-alpha receptors for IDCM patients. Pravastatin induced a significant decline in IL-6 (p=0.01) and sTNFR2 (p= 0.008) in patients with the highest concentrations before treatment.
Conclusion: An atherogenic lipid profile favored the inflammatory process in patients with heart failure due to CAD, whereas no relation between lipoproteins and proinflammatory cytokines or TNF-alpha receptors was detected in case of IDCM. Pravastatin, administered during 1 month, did not adversely affect cytokine and sTNF-alpha receptor levels in these patients. On the contrary, in patients with CAD, IL-6 and sTNFR2 were significantly lowered.

CAN WE BUILD A NEW HEART FROM STEM CELLS?

2009 Non-cardiac cells in human transplanted hearts rebuild cardiomyocytes

P. Müller[1], P. Pfeiffer[1], U. Seeland[1], J. Koglin[2], M. Böhm[1]. [1]*Universitätskliniken des Saarlandes, Innere Medizin III, Homburg, Germany;* [2]*Universitätsklinikum Großhadern, Medizinische Klinik I, München, Germany*

Stem cells able to differentiate into cardiomyocytes are discussed for cell replacement therapy to remodel damaged myocardium. A physiological or pathophysiological situation in which this phenomenon might be relevant is not known. Origin of cardiomyocytes in male patients having undergone sex-mismatched cardiac transplantation was studied to examine if cells containing a Y-chromosome body and therefore being of recipient origin are able to differentiate into cardiomyocytes.
Myocardial biopsies (n=21) were obtained from right ventricles of male patients (n=13) having undergone gender mismatched heart transplantation. Tissue from one nontransplanted male and myocardial biopsies from sex-matched heart transplanted patients served as controls. Cells from donor and recipient origin were identified by fluorescence in situ hybridization using probes specific for X- (DXZ1) and Y-chromosome (Y3.4) bodies on paraffin sections of the biopsies. The different cardiac cell types were identified using immunostaining procedures on the same tissue sections.
In 8 of 13 male recipients of female hearts cardiomyocytes of recipient origin were detected. In the positive biopsies, a mean (±SEM) of 0.18 ± 0.036 percent of the cardiomyocyte nuclei contained a Y-chromosome body. There was no detectable correlation to extent or number of rejection episodes, to time of transplantation or medical treatment regimen.
Cardiomyocyte regeneration in humans can occur by cells of non-cardiac origin, presumably bone marrow cells. This may lead to the development of new therapeutic strategies in the treatment of myocardial infarction, inflammatory heart disease or heart failure.

2010 Host cell-derived cardiomyocytes in sex-mismatch cardiac allografts

A. Bayes-Genis[1], M. Salido[2], F. Sole[2], M. Puig[1], V. Brossa[1], M. Camprecios[1], J.M. Corominas[2], J. Cinca[1]. [1]*Hospital de la Santa Creu i Sant Pau, Cardiology service, Barcelona, Spain;* [2]*Hospital del Mar -IMAS, Lab Citogenètica i Biologia Molecular, Barcelona, Spain*

Background: Mesenchymal stem cells are able to respond to tissue signals and differentiate into a phenotype characteristic of mature cells of that tissue. We sought to investigate whether adult human cardiomyocytes can be derived from recipient precursor cells in sex-mismatched cardiac allografts.
Methods ans Results: We studied four male patients who received hearts from female donors, and four female patients who received an allograft from a male donor. Four sex-matched transplant patients, two of each sex served as controls. Combined fluorescence in situ hybridization with probes specific for X- and Y-chromosomes and immunohistochemistry with alpha-actin was used to identify cardiac muscle cells four months and twelve months after transplantation. Slides were examined with a fluorescence microscope to detect the presence of male cells with one X and one Y signal in the nucleus, and female cells containing two X signals. Mature cardiomyocytes from the host (1 to 2%) were found in five endomyocardial biopsy specimens at four months, and in three specimens at twelve months. In addition, recipient cells negative for cytoplasmic alpha-actin were also identified (1 to 21% per slide). The number of infiltrating recipient cells was not associated with the degree of rejection of the sample or with the number of prior rejection episodes. Echocardiographic evaluation showed no improvement in cardiac performance in hearts from patients with more than 10% chimeric recipient cells.
Conclusions: Our data confirm the existence of mature cardiomyocytes derived from host cells, likely mesenchymal precursors, in the adult cardiac allograft in vivo.

2011 Transplantation of highly purified lentiviral transduced candidate stem cells from bone marrow in a porcine myocardial infarction model

J. Saw, P.M. Lansdorp, K. Qayumi, J. Van Ziffle, B. McManus, J.N. Hamburger. *Vancouver, Canada*

Introduction: Cell transplantation is a potential strategy to regenerate myocytes and improve function after myocardial infarction (MI). We transplanted highly purified autologous bone marrow (BM) derived gene marked candidate stem cells into infarcted myocardium to assess for improvement in myocardial function and myocyte regeneration.
Methods: Twelve young domestic swines underwent our study protocol. Nine pigs underwent iliac crest BM aspiration. BM cells were stained with Hoechst 33342 dye and sorted for side population "SP" cells by FACS. The SP cells were transfected with lentiviral vectors containing the green fluorescent protein (GFP) gene. All animals underwent left thoracotomy for coronary artery ligation 2 days after BM aspiration for SP injected pigs. The 2nd diagonal artery was ligated for 30min followed by reperfusion. Nine pigs were injected with autologous transduced SP cells with a 30 gauge tubuculin syringe. Control pigs (n=3) were injected with serum-free media without BM cells. Surviving animals were sacrificed at 4 weeks post-MI, and hearts removed for immunohistochemistry. Left ventricular functions were measured with Millar catheters and Sonometric crystals at baseline, immediate post-MI, and 4 weeks post-MI.
Results: Two BM injected pigs died 6 days post-MI, the remainder survived to 4 weeks. Quantity of sorted SP cells ranged from 15-64 thousand cells, with the exception of 1 pig (1.5 million cells). Control pigs had lower Emax immediately after ligation compared to baseline (2.83 vs 5.09, p=0.26); this was further reduced 4 weeks post-MI compared to baseline (1.36 vs 5.09, p=0.03). SP injected pigs had significantly reduced Emax immediately after ligation compared to baseline (2.11 vs 3.32, p=0.005), but returned to baseline level 4 weeks post-injection (3.38 vs 3.32, p=0.95). Similar trends were found for injected pigs with dP/dT+, dP/dT-, cardiac output, and stroke work. Preliminary histology of one pig which died at 6 days demonstrated positive anti-GFP stain in myocardium and capillary walls of border zone of the MI. Complete immunohistochemistry is pending.
Conclusions: Injection of autologous bone marrow derived gene marked SP cells into infarcted myocardium appeared to improve cardiac function measured at 4 weeks following transplantation. However, the small number of animals prevents definite conclusions. Support for injected cells contributing to myocard regeneration was obtained by detection of GFP-positive cells in border zone of MI at day 6 and completion of immunohistochemical analysis at 4 weeks post-MI is pending.

2012 Mobilization of endothelial progenitor cells during ischaemia

C. Heeschen[1], F.L. Johnson[2], A. Pathak[2], T. Quertermous[2], J.P. Cooke[2]. [1]*Molecular Cardiology, Frankfurt, Germany;* [2]*Stanford University School of Medicine, Div. of Cardiovascular Medicine, Stanford, United States of America*

The proportional contribution of endothelial progenitor cells (EPC) to postnatal neovascularization still remains to be clarified. In this respect, we observed a significant difference in angiogenic response between systemic and local treatment with nicotine. We investigated whether this is due to enhanced mobilization of EPCs by systemic nicotine treatment and related our findings to established factors like GM-CSF and statins.
Methods and Results: We employed a parabiotic model to identify EPC from reservoirs both inside and outside of the bone marrow. Male tie-2-LacZ FvB/N mice were connected to female wild type FvB/N mouse. Four weeks later, adjustment of blood cells between the animals had occurred. Hind limb ischemia was induced in the wild type mouse and animals were treated with nicotine, GM-CSF, cerivastatin or control. EPCs that incorporated into new or enlarging vessels during ischemia-induced revascularization were identified by co-localization for CD31 and LacZ. Non-bone-marrow-derived EPCs were identified by a reverse bone marrow transplantation (rBMT) model: male tie-2-LacZ FvB/N mice were transplanted with wild type FvB/N bone marrow and connected to female wild type FvB/N mice. Vessel density was significantly higher in animals treated with nicotine, GM-CSF, or cerivastatin as compared to control ($P<0.001$). Incorporation of EPCs in the control group was rare (1.6% of the vessels). In the nicotine group, however, EPCs were detected in 9.3% of the vessels ($P<0.001$; GM-CSF 21.5%, Cerivastatin 15.5%). In the rBMT model, still 1.0% and 5.1% of the vessels in the control and the nicotine group, respectively, contained EPCs. In mice with ischemic hind limbs, nicotine had stimulated the number of CD34/Flk-1-positive cells in bone marrow and spleen with a peak at 7 days (2.3- and 1.9-fold increase, respectively; $P<0.01$). In vitro studies demonstrated that nicotine induced expression of integrins (alpha-v, alpha-5, beta-1) on isolated EPCs.
Conclusions: We demonstrate that the relative contribution of EPCs to ischemia-induced angiogenesis in control animals is low. However, EPC incorporaton can be enhanced by systemic administration of nicotine, GM-CSF, and cerivastatin, respectively. Further, we show that EPCs can be mobilized from other sources than the bone marrow.

2013 Smooth muscle cells in transplant atherosclerotic lesions are originated from recipients, but not bone marrow progenitor cells

Y. Hu, F. Davison, M. Mayre, Q. Xu. *St George's Hospital Medical School, Cardiological Sciences, London, United Kingdom*

Smooth muscle cell (SMC) accumulation in the intima of vessels is a key event in the pathogenesis of transplant atherosclerosis. Traditional hypothesis that SMCs in the lesion are derived from the media of the donor vessel is challenged by recent observations, but their origins are not well established. Herein, we use a simplified model of artery allografts in transgenic mice to definitely identify the source of SMCs in transplant atherosclerosis. Aortic segments donated by BALB/c mice allografted to ROSA26 mice expressing beta-galactosidase (gal) in all tissues showed that neointimal cells derived exclusively from host cells. It was also demonstrated that SMCs of neointimal and atherosclerotic lesions in vessels allografted to mice expressing beta-gal only in SMCs (SM-LacZ) or to apoE-deficient/SM-LacZ mice were originated from recipient, but not donor vessels. Interestingly, bone-marrow transplantation of SM-LacZ beta-gal expressing cells into aortic allograft recipients revealed completely X-gal negative staining of neointimal and atherosclerotic lesions, although a population of X-gal+ cells in allografts in mice having ROSA26 beta-gal expressing marrow cells. When bone marrow cells from both ROSA26 and SM-LacZ mice were cultivated in vitro and stimulated with PDGF-BB, alpha-actin and beta-gal double-positive cells were identified, suggesting that bone marrow cells have an ability to differentiate into SMCs. Thus, we provide the definite evidence that SMCs of neointimal and atherosclerotic lesions in allografts are derived from recipients and that circulating and non-bone marrow-derived progenitor cells might be the source of SMCs in atherosclerotic lesions.

GENE THERAPY IN CORONARY AND MYOCARDIAL DISEASE

2021 Safety of catheter-based local intracoronary VEGF gene transfer in the treatment of chronic myocardial ischaemia and restenosis; KAT-trial

M. Hedman[1], J. Hartikainen[2], M. Syvänne[3], J. Stjernvall[3], A. Kivelä[2], M.S. Nieminen[3], M. Laakso[2], S. Ylä-Herttuala[4] on behalf of KAT-Trial study group. [1]*Kuopio University Hospital, Department of Medicine, Kuopio, Finland;* [2]*Kuopio University Hospital, Department of Medicine, Kuopio, Finland;* [3]*Helsinki University Central Hospital, Department of Cardiology, Helsinki, Finland;* [4]*University of Kuopio, A.I.Virtanen Institute, Kuopio, Finland*

Catheter-based intravascular gene transfer is a potential treatment for ischemic heart diseases. The objective of this study was to evaluate safety of local catheter-mediated VEGF -plasmid/liposome and VEGF-adenovirus gene therapy in patients with severe chronic ischemic heart disease.
Methods: 103 patients with coronary heart disease (NYHA II-IV) were recruited in this randomized, placebo-controlled, double-blinded phase II study. Gene transfer to coronary arteries was performed after coronary angioplasty (PTCA) with a perfusion-infusion catheter. Thirty seven patients received 2x10E10 pfu VEGF-adenovirus (VEGF-Adv), 28 patients VEGF -plasmid-liposome (VEGF-P/L; 2000 μg of DNA with 2000 μl of DOTMA:DOPE (1:1 w/w) liposome) and 38 control patients received Ringer lactate. Gene transfer was performed during 10 min injection time at the site of PTCA. Safety laboratory parameters and clinical symptoms were followed for 2 days at the hospital and during 6 months follow-up time. A questionnaire survey was performed 14 to 47 months after the gene transfer to evaluate late safety outcome of the treatment.
Results: Gene transfer to coronary arteries was feasible and well tolerated. Patients did not need additional medication during gene transfer and none of the patients developed hypotension during hospital stay. No major gene transfer–related side effects were detected during the follow-up. One death occurred in VEGF-Adv group 20 months after procedure and was considered unrelated to gene transfer. Two new cancers were diagnosed during long-term follow-up in VEGF-P/L group. Although increases in serum CRP, LDH, IL-6 and anti-Adv-antibody levels were seen in VEGF-Adv group, no significant abnormalities in other laboratory parameters were detected. Fever was seen in all study groups, but was most frequent in VEGF-Adv group (51% vs. 39% vs. 3%; VEGF-Adv vs. VEGF-P/L vs. placebo, respectively).
Conclusions: Catheter-based local gene transfer with either VEGF-P/L or VEGF-Adv during PTCA shows that: (i) intracoronary gene transfer can be performed safely, (ii) some inflammatory responses are present in VEGF-Adv group, (iii) no increase was detected in the incidence of new cancers or other serious adverse effects. Angioplasty combined with VEGF gene therapy is potentially applicable for the treatment of ischemic heart diseases.

2022 Efficient endothelial gene transfer with preserved vascular integrity by ultrasound-enhanced destruction of plasmid-loaded albumin microbubbles

C. Teupe[1], S. Richter[2], B. Fisslthaler[3], V. Randriamboavonjy[3], I. Fleming[3], R. Busse[3], A.M. Zeiher[1], S. Dimmeler[2]. [1]*University of Frankfurt, Cardiology, Frankfurt, Germany;* [2]*University of Frankfurt, Molecular Cardiology, Frankfurt, Germany;* [3]*University of Frankfurt, Inst. f. Kardiovaskuläre Physiologie, Frankfurt, Germany*

Local vascular gene therapy has enormous potential for the treatment of vascular disease. However, previous techniques used for vascular gene therapy were hampered by the destruction of the endothelial cell layer. Therefore we investigated whether diagnostic ultrasound-mediated destruction of plasmid-loaded albumin microbubbles is a feasible and efficient technique for local vascular gene delivery without impairment of the endothelial cell layer.

Methods and Results: Gas-filled microbubbles (3.0±1.2 μm) were created by sonication of 5% human albumin in the presence of plasmid DNA encoding for LacZ. Porcine coronary arteries were perfused (flow rate 2 ml/min) with DNA-loaded albumin microbubbles in vitro, exposed to diagnostic ultrasound (2.2 MHz, mechanical index 1.2, frame rate 172.9 frames/sec, 5 seconds) and further incubated for 24 hours. Detection of the β-galactosidase in LacZ transfected vessels revealed intense blue staining predominantly of the endothelial cells (>90%), while vessels perfused with an empty vector but otherwise treated identically showed no staining. Trypan blue staining of the endothelium and measurement of LDH activity in the perfusate excluded a cytotoxic effect of the treatment on the endothelial cell layer. Microscopy revealed no histologically detectable alterations of the vessel wall. Bradykinin-induced endothelium-dependent relaxation was similar in untreated control vessels and vessels exposed to microbubbles and ultrasound (pD2 (-logEC50): 9.28±0.07 vs. 9.87±1.35, p=0.68, n=4).

Conclusion: Our study demonstrates efficient gene transfer to the endothelial cell layer of conductance arteries by ultrasound-mediated destruction of albumin-coated microbubbles loaded with naked plasmid DNA. Despite efficient transgene expression, the structural and functional integrity of the transfected endothelial cell layer was well preserved after ultrasound treatment. Thus, this method appears to be ideally suited for gene delivery to the endothelial cell layer of conductance vessels.

2023 Antagonism of the renin angiotensin system counteracts cardiac angiogenic VEGF gene therapy

A. Siddiqui, V. Drvota, E. Wärdell, J. Gaber, C. Sylvén. *Karolinska Institute, Department of Cardiology, Stockholm, Sweden*

Background: Vascular endothelial growth factor (VEGF) is a potent endothelial cell specific mitogen with a proven efficacy to induce angiogenesis in variety of animal models. Angiotensin converting enzyme inhibitor and angiotensin-2 antagonists are common drugs used in cardiovascular diseases, which may counteract angiogenesis.

Aim: To test the hypothesis that angiotensin converting enzyme inhibition or angiotensin-2 antagonism may counteract cardiac phVEGF- A165 gene therapy for angiogenesis.

Methods: C57Bl/6, 6-8 week old mice were given a single intramyocardial injection of phVEGF-A165 (5mgm) via a thoracotomy (n=16). From day 1, one group (n=8) of mice received daily subcutaneous injection of enalapril (30mgm/kg) and a second group (n=8) got candesartan (20mgm/kg) for 10 consecutive days. Two separate groups of mice (n=7) received intramyocardial injection of normal saline or phVEGF-A165 alone as control. On day 10, hearts were harvested for cryosection and capillary count done by immunohistochemistry. With similar design, four groups (n=6 each) of mice were taken for determination of tissue expression of VEGF protein after 24 hours.

Results: Gene transfer of phVEGF- A165 alone increased myocardial capillary density 1.16 fold compared to control (602±57 vs 520± 31/sq. mm, P< 0.005). In candesartan treated mice phVEGF- A165 did not induce any angiogenesis and capillary density was in fact lower than in controls treated with saline (484±14 vs.520±31/sq. mm, P<0.001). Enalapril induced a tendency (P<0.10) to inhibition of phVEGF- A165 induced angiogenesis.VEGF-A165 immunoassay showed decreased expression of phVEGF-A165 in hearts treated with enalapril or candesartan compared to control (candesartan: 20±23 pg/ml, enalapril: 25±35 pg/ml vs. phVEGF- A165 alone 105±68 pg/ml, P<0.001).

Conclusions: Candesartan inhibits phVEGF-A165 induced cardiac angiogenesis while enalapril showed a tendency to inhibition. Also, candesartan inhibited endogenous capillarisation. In the expression chain from gene to capillary growth the angiotensin II inhibition exerts its effect at or before the formation of the VEGF protein.

2024 Lentiviral vectors efficiently transduce genes into human coronary endothelial and smooth muscle cells in vitro and into rat arteries in vivo

D. Cefaï, S. Fleury, E. Simeoni, G. Vassalli. *CHUV, Cardiology, Lausanne, Switzerland*

Retroviral vectors provide a potential for permanent gene modifications of target cells as a result of chromosomal integration. However, murine oncoretroviral vectors do not efficiently transduce genes into growth-arrested endothelial cells (EC) in vitro and EC in normal arteries in vivo, which have very low proliferation rates. Among retroviral vectors, lentiviral vectors are unique in that they transduce genes both into dividing and into nondividing cells.

Methods: Vesicular stomatitis virus-pseudotyped, multiply attenuated (deletions of nef, vif, vpr, vpu, env, tat) and self-inactivating (SIN; large deletion in the U3 region of the 3' long terminal repeat) vectors derived from human immunodeficiency virus (HIV)-1 were produced using a four-plasmid conditional packaging system. Cis-acting sequences including the woodchuck hepatitis virus posttranscriptional regulatory element and the central polypurine tract (cPPT) sequence from HIV-1 pol that enhances nuclear translocation were inserted into the vectors. The EGFP reporter gene was expressed under the control of various promoters including the cytomegalovirus (CMV), elongation factor-1alpha (EF-1alpha), phosphoglycerate kinase, and the endothelium-specific angiopoietin Tie-2 receptor promoter. Gene transfer was studied in human umbilical vein EC (HUVEC), human coronary artery EC (HCAEC) and human coronary artery smooth muscle cells (HCASMC) in vitro (by FACS), and in rat carotid arteries in vivo (by fluorescence microscopy).

Results: SIN vectors at a multiplicity of infection (MOI) of 3 transduced the EGFP gene into ~95% of HUVEC and HCAEC. Similar transduction rates were achieved in HCASMC with a MOI of 30. Gene transfer efficiency in HCAEC and HCASMC was 5 to 10-fold higher as compared to adenoviral vectors. Highest EGFP expression levels were achieved with the CMV and EF-1alpha promoters in both cell types, while the Tie-2 promoter also achieved high EGFP expression levels in HCAEC. SIN vectors at a MOI of 10 transduced ~20%, 35% and 60% of HCAEC after 30, 60 and 120 minutes, respectively. In vitro EGFP expression in HCAEC lasted for >4 weeks, whereas adenoviral expression was lost. SIN vectors transduced ~5% EC in rat arteries in vivo.

Conclusions: Multiply attenuated, self-inactivating lentiviral vectors transduce genes into human EC and SMC in vitro. The efficiency of gene transfer is higher than with adenoviral vectors. These vectors also efficiently transduce genes into rat arterial endothelium in vivo. Lentiviral vectors are a useful system for vascular gene delivery both in vitro and in vivo.

2025 Infarct size limitation by gene transfer of baculoviral P35 into rat myocardium

L. Bott-Fluegel[1], K.L. Laugwitz[2], H.J. Weig[2], A. Moretti[2], C. Faltermeier[3], C. Baumgartner[3], M. Knödler[3], M. Seyfarth[2]. [1]*Deutsches Herzzentrum München, München, Germany;* [2]*Klinikum Rechts der Isar, I. Med. Klinik, München, Germany;* [3]*Klinikum Rechts der Isar, Institut für Exp. Chirurgie, München, Germany*

Apoptosis plays a pivotal role in determining the extent of injury during myocardial infarction. Inhibition of apoptosis has been shown to protect myocardium from damage during ischemia and reperfusion. The aim of this study was to determine whether gene transfer of baculoviral protein p35, a potent inhibitor of apoptosis, into myocardium could limit infarct size. Methods: Male Wistar rats were directly injected into the left anterior ventricular wall with adenoviral vector encoding baculoviral p35. 72 hours later hearts were excised and mounted on a Langendorff apparatus and perfused. The left anterior descending artery was ligated for 30 minutes and reperfused for 2 hours. Area at risk and infarct size were determined by staining with bromophenolblue and triphenoltetrazoliumchloride (TTC), respectively. Apoptosis was assessed by staining cryosections for DNA-strand breaks (TUNEL-assay) and caspase-3 activity. Results: Infarct size was significantly reduced in animals treated with p35 (59±3% reduction, p<0.05), whereas no reduction was seen when only control vector was injected. TUNEL-positive nuclei and caspase-3 activity was diminished significantly only in animals treated with p35. Conclusion: Gene transfer of the baculoviral protein p35 into the left ventricular myocardium reduces apoptosis and limits infarct size after regional ischemia and reperfusion.

2026 VEGF expression in human macrophages is NFkB-dependent: studies using adenoviral gene transfer

S. Kiriakidis, C. Monaco, E. Andreakos, B. Foxwell, M. Feldmann, E. Paleolog. *Kennedy Institute of Rheumatology, Imperial College, London, United Kingdom*

Background Vascular endothelial growth factor (VEGF) is a multifunctional cytokine, as it can induce endothelial cell proliferation and migration, inhibit apoptosis and regulate physiological and pathological angiogenesis. VEGF is abundantly found in human atherosclerotic plaques. Although therapeutic angiogenesis via VEGF delivery represents a promising treatment for ischemic heart disease, it has been recently suggested that administration of VEGF enhances atherosclerotic plaque progression in experimental models. The mechanisms involved in VEGF production are still under investigation. The aim of our study was to dissect the intracellular signalling pathways involved in VEGF production in primary human macrophages, one of the major cell type expressing VEGF in atherosclerotic plaques.

Methods Elutriation-enriched monocytes were obtained from peripheral blood mononuclear cells from single donor plateletpheresis residues, and cultured in the presence of macrophage-colony stimulating factor for differentiation to macrophage-like phenotype. Macrophage were infected with adenoviral vectors encoding I kappa B alpha, the natural inhibitor of NFkB nuclear translocation (AdvIkBa), a kinase negative mutant of the upstream kinase IKK2, essential to NFkB activation (AdvIKK2dn), or without insert as control (Adv0). A multiplicity of infection of 100:1, at which the efficiency of infection was >95%, was used. After infection cells were stimulated with Lipopolysaccharide (LPS) or co-cultured with mouse fibroblasts transfected with a plasmid expressing CD40 ligand (CD40L). Alternatively cells were stimulated with recombinant soluble human CD40L. VEGF was measured by ELISA.

Results We observed that LPS-induced production of VEGF by macrophages was completely inhibited (>95%) following adenoviral transfer of IkBa. Engagement of CD40 on macrophages induces VEGF release at levels comparable to those obtained with LPS. We observed strong inhibition of the CD40L-induced VEGF production in macrophages following infection with AdvIkBa. However, expression of IKK2dn in macrophages decreased both LPS- and CD40L- induced VEGF production by approximately 50%, suggesting that in addition to IKK2 other kinases may be involved in NFkB activation.

Conclusions CD40-CD40L interaction leads to VEGF induction, suggesting that ligation of CD40 on macrophages could potentially promote expression of VEGF in the human atherosclerotic plaque. Moreover, this is, to our knowledge the first report that NFkB activation is required for LPS-induced and CD40L induced VEGF production in primary human macrophages.

EUROPEAN SOCIETY OF CARDIOLOGY LECTURE ON BASIC SCIENCES

2032 The sarcolemmal Na^+/Ca^{2+} exchanger critically contributes to hydroxyl radical-induced injury in rabbit ventricular myocytes

S. Wagner, G. Hasenfuss, H. Kögler. *University of Göttingen, Cardiology and Respiratory Care, Göttingen, Germany*

Background: Large amounts of reactive oxygen species (ROS) occur in the myocardium during reperfusion after ischemia and play a fundamental role in the development of reperfusion injury. Isolated cardiac myocytes, when exposed to ROS, undergo hypercontracture in association with cytosolic calcium overload and eventually cell death. We investigated the contribution of Ca^{2+} entry via the Ca^{2+}-uptake mode of the sarcolemmal Na^+/Ca^{2+} exchanger (NCX), which is an important regulator of Ca^{2+} homeostasis in cardiac myocytes, to this ROS-induced Ca^{2+} overload.

Methods: Rabbit isolated ventricular myocytes after 24h of culture were transiently exposed to hydroxyl radical (*OH) during an interval of 4min by addition of 100 μmol/L H2O2 to the superfusate (Krebs-Henseleit solution, $[Ca^{2+}]_o$ 1.75 mmol/L) in the presence of Fe3+/NTA (100 μmol/L, 200 μmol/L), which generates *OH via a Fenton reaction. Over a period of 30 minutes cell shape was monitored and the fraction of cells undergoing hypercontracture (Fhyper) was assessed. Following *OH exposure, Fhyper increases with time in a sigmoidal relationship that can be fitted with a Boltzman equation, from which the fraction of non-responder cells (Fnr) can be derived as a measure of susceptibility to radical-induced damage.

Results: *OH exposure under control conditions caused cells to hypercontract with Fnr = 0.29 ± 0.07. Preincubation with 100μmol/L melatonin, a radical scavenger highly specific for *OH, resulted in significant protection against radical-induced hypercontracture (Fnr = 0.69 ± 0.11; P = 0.001), confirming that hydroxyl radical represents the predominant ROS generated under these experimental conditions. Pretreatment of cells with 5 μmol/L KB-R7943, which is considered to specifically inhibit NCX-mediated Ca^{2+}-entry, also afforded significant protection against radical-induced hypercontracture by enhancing Fnr (0.29 ± 0.14 vs. 0.62 ± 0.14; P < 0.038), suggesting an essential contribution of NCX in calcium overload.

Conclusions: Ca^{2+}-entry via NCX is a critical mediator of *OH-induced injury in rabbit ventricular cardiomyocytes. Since NCX expression is upregulated in the failing heart, this molecule may represent a promising drug target to prevent ROS-induced damage in heart failure and ischemia/reperfusion.

2033 Evidence for active inflammation and interstitial remodelling in the hibernating human myocardium

N. Frangogiannis[1], S. Shimoni[2], G. Ren[1], S. Akrivakis[1], M. Ramchandani[3], M. Reardon[3], M. Entman[1], W. Zoghbi[2]. [1]*Baylor College of Medicine, Section of Cardiovascular Sciences, Houston, United States of America;* [2]*Baylor College of Medicine, Section of Cardiology, Houston TX, United States of America;* [3]*Baylor College of Medicine, Department of Surgery, Houston TX, United States of America*

Myocardial hibernation is associated with structural myocardial changes, which involve both the cardiomyocytes and the cardiac interstitium. We hypothesized that myocardial hibernation may be associated with an active inflammatory process leading to leukocyte recruitment in the cardiac interstitium. We obtained transmural myocardial biopsies guided by transesophageal echocardiography, from patients with ischemic ventricular dysfunction undergoing coronary bypass surgery. Among the 28 biopsied segments included in the study, 23 showed evidence of systolic dysfunction. The majority of dysfunctional segments (85.7%) were viable (201Tl uptake >60%). The samples were stained with markers for mast cells, mature resident macrophages and the monoclonal antibody Mac387, which labels newly recruited myeloid cells. Dysfunctional segments showed more extensive fibrosis and higher macrophage density than normal segments. Among the 23 dysfunctional segments, 12 recovered function as assessed with echocardiograms 3 months after revascularization. Segments with postoperative functional recovery had comparable macrophage and mast cell density with those showing persistent dysfunction. However, biopsied segments which subsequently recovered function contained significantly higher numbers of newly recruited Mac387 positive leukocytes (18.7±3.1 cells/mm^2, n=12 vs. 8.6±0.9 cells/mm^2, n=11 p=0.009). In addition, Monocyte Chemotactic Protein (MCP)-1, a potent mononuclear cell chemoattractant, was predominantly expressed in segments with recovery of function. Interstitial deposition of the matricellular protein tenascin, a marker of active remodeling, was higher in hibernating segments than in segments with persistent dysfunction (p<0.05), suggesting an active continuous fibrotic process. Myocardial hibernation is associated with an inflammatory response leading to active leukocyte recruitment. Dysfunctional myocardial segments, which show an active inflammatory reaction have a greater potential for recovery of function after revascularization. We postulate that revascularization may promote resolution of the ongoing inflammation, preventing further tissue injury and fibrosis.

2034 Beneficial effects of pre-infarction angina on the myocardial infarct size, myocardial viability, and functional recovery in reperfused Acute Myocardial Infarction

S. Koyanagi[1], N.Y. Naoko Yasugi[1], K.O. Keizaburou Oozono[2], S.S. Sigeki Sako[2], T.M. Takahiro Matsumoto[2], K.S. Kikuo Sakai[2], T. Hiroki[3]. *[1]National Fukuoka-Higasi Hospital, Cardiology, Koga; [2]National Kyushu Medical Hospital, Cardiology, Fukuoka; [3]Fukuoka University Chikushi Hospital, Internal Medicine, Fukuoka, Japan*

Purpose: Pre-infarction angina (PIA) may limit infarct size, but the effects of PIA on myocardial viability and long-term functional recovery are not well clarified. The aim of this study was to determine the effects of PIA on the infarct size assessed by nuclear perfusion imaging, myocardial functional reserve by low-dose dobutamine echocardiography (LDDE) and long-term functional recovery of the asynergic area in patients who underwent immediate PTCA following AMI.

Methods: Forty-six patients with AMI underwent immediate PTCA (mean age = 63 yrs old). PIA was defined as positive when typical chest pain occurred in 48 hours before AMI. Resting 201-Tl or 99m-Tc MIBI-SPECT was performed at 7~14 days after AMI, and the extent and severity score were obtained. LDDE (5~10 mcg/kg/min) was performed to detect myocardial viability, and wall motion score was obtained. Follow-up echocardiography was repeated 6 month later to detect regional functional recovery of the infarct area.

Results: Thirty of 46 patients (65%) had PIA. Wall motion score and defect score of SPECT were significantly lower in patients with PIA than in those without PIA (mean = 6.8 vs. 9.0 points, $p<0.05$, mean = 7.4 vs. 12.4 points, $p<0.01$, respectively). The number of patients with long-term functional recovery and myocardial viability determined by LDDE were higher in PIA than in those without PIA (63% vs. 31%, 57% vs. 25%, respectively, $p < 005$). The effects of PIA on functional recovery and myocardial viability determined by LDDE were more evident in patients in whom coronary reperfusion occurred within 6 hrs after acute myocardial infarction (86% vs. 22%, 79% vs. 22%, respectively, $p< 0.01$). These beneficial effects of PIA were unclear in patients with coronary reperfusion time greater than 6 hrs. The patients of PIA without regional functional recovery in spite coronary reperfusion within 6 hrs showed re-occlusion of the infarct-related arteries.

Conclusion: PIA induced smaller infarct size, greater myocardial viability and better long-term functional recovery of the infarct area in patients with AMI who underwent immediate PTCA. These beneficial effects are evident when coronary reperfusion occurred in 6 hrs after acute myocardial infarction, but they are not clear after 6 hrs.

NEW CARDIAC MARKERS

2035 The predictive value of soluble P-selectin T in patients with chest pain and a normal or non-diagnostic electrocardiogram

P.M. Van der Zee[1], R. Bholasingh[1], J.P. Van Straalen[1], O. Kamp[2], J.H. Cornel[3], R.J. de Winter[1]. *[1]Academic Medical Center, cardiology, Amsterdam, Netherlands; [2]VU academic hospital, cardiology, Amsterdam, Netherlands; [3]Medical Center Alkmaar, cardiology, Alkmaar, Netherlands*

Background: The glycoprotein P-Selectin is rapidly translocated from a-granules of platelets and Weibel-Palade bodies of endothelial cells to the cell surface on stimulation. Endothelial cell and platelet activation is also associated with a rise of blood concentration of a soluble form of this protein. Surface bound P-Selectin is suggested to be subsequently shed into the circulation. As activation of endothelial cells does not produce raised levels of soluble P-Selectin, platelets are thought to be the major source.

Raised levels of blood P-Selectin have been reported to be associated with cardiovascular events on admission.

Objective: The aim of this study was to assess the diagnostic value of soluble P-Selectin for myocardial infarction, and the prognostic value of P-Selectin for cardiovascular events in patients with chest pain and a normal or non-diagnostic electrocardiogram.

Patients and methods: We determined the predictive value of soluble P-Selectin on admission for detecting acute myocardial infarction (AMI: discharge diagnosis, Cardiac Troponin T >0,01 mg/l) or acute coronary syndromes (ACS: AMI or unstable angina) in 219 patients with chest pain of less than six hours duration and a normal or non-diagnostic electrocardiogram. Controls were patients without any cardiac event on admission or at 6 month follow-up. Analysis was performed using a Pearson Chi squared test. Cut-off level for soluble P-Selectin as reported in literature was 139 mg/l.

Results: Table 1 shows a 2 x 2 frequency table of occurrence of AMI and soluble P-Selectin level on admission.

Table 2 shows a 2 x 2 frequency table of occurrence of ACS and soluble P-Selectin level on admission.

Conclusion: In contrast to previous results, we found that in patients with chest pain of less than six hours duration and a normal or non-diagnostic electrocardiogram, soluble P-Selectin was unable to distinguish between patients with or without an acute coronary syndrome.

Table 1

	AMI	No event	Total
Sol. P-Selectin≥139 mg/l	11	25	36
Sol. P-Selectin<139 mg/l	50	107	157
Total	61	132	193

chi square = 0,023; p=0,881

Table 2

	ACS	No event	Total
Sol. P-Selectin≥139 mg/l	18	25	43
Sol. P-Selectin<139 mg/l	69	107	176
Total	87	132	219

chi square = 0,102; p=0,750

2036 Prognostic value of B-type natriuretic peptide in patients with acute coronary syndromes

C. Heeschen[1], C.W. Hamm[2], V. Mitrovic[2], H.D. White[3]. *[1]Molecular Cardiology, Frankfurt, Germany; [2]Kerckhoff Heart Clinic, Div. of Cardiology, Bad Nauheim, Germany; [3]Green Lane Hospital, Dept. of Cardiology, Auckland, New Zealand*

N-terminal pro-BNP (BNP) is a neurohormone precursor synthesized predominantly in ventricular myocardium. Although the circulating level of BNP has been shown to provide independent prognostic information in patients with transmural myocardial infarction, few data are available for patients with acute coronary syndromes in the absence of ST-segment elevation.

Methods: We measured BNP in plasma samples obtained a mean (±SD) of 8.5±2.6 hours after the onset of ischemic symptoms in 467 patients from the PRISM study.

Results: The baseline levels of BNP correlated with the risk of death and myocardial infarction at 30 days. The unadjusted rate of death increased in a stepwise fashion among patients in increasing quartiles of baseline BNP($P<0.001$). This association remained significant in subgroups of patients who had myocardial infarction without ST-segment elevation ($P<0.01$) and patients who had unstable angina ($P<0.01$). The adjusted hazard ratio for death and myocardial infarction in the second, third, and fourth quartiles of BNP were 3.1 (95% CI 1.1 to 12.0), 2.9 (95% CI 1.3 to 10.5), and 4.5 (95% CI 1.5 to 12.3). The level of BNP was also associated with the risk of recurrent angina at 30 days ($P<0.001$).

Conclusions: A baseline measurement of BNP, obtained within 12 hours after the onset of ischemic symptoms, provides indpendent predictive information for use in risk stratification across the spectrum of acute coronary syndromes.

2037 Early treatment with statins and selective COX-2 inhibitor decreases CRP in patients with unstable angina undergoing catheterization

D. Dudek, G. Heba, M. Chyrchel, J. Legutko, L. Rzeszutko, S. Bartus, J. S. Dubiel. *Institute of Cardiology, Jagiellonian University, Krakow, Poland*

Background: Elevated levels of C-reactive protein (CRP) in patients with unstable angina are associated with an increased risk of adverse cardiac events. We proved that there was more pronounced decrease of inflammatory markers in patients with unstable angina after combination of statin therapy and COX-2 inhibitor initiated immediately after percutaneous coronary intervention (PCI). The aim of this study was to assess if short period (3 days) of high dose statin therapy alone or in combination with COX-2 inhibitors administered before intervention could prevent further CRP elevation usually observed immediately after procedure.

Methods: 60 consecutive patients with unstable angina (II B,III B according to Braunwald) were studied 37 patients with CRP> 3 mg/l at baseline were randomized to three groups: gr. A received placebo, gr. B received 80 mg of atorvastatin, gr. C atorvastatin 80 mg and rofecoxib 25 mg. All patients received aspirin and ticlopidine before intervention and were scheduled to interventional procedure on 3-rd day. The levels of CRP were measured at baseline, day 3 and 48 hours after catheterization.

Results: Median CRP levels in group B were lower after 3 day of aggressive anti inflammatory treatment in comparison to placebo group. More pronounced decreased was observed in group C. The increase of CRP after angiography/PCI was also reduced in treated groups (see table). No adverse effects of tested medication (including thrombotic complications after COX-2 administration) were recorded.

Median CRP value

	A (mmol/l)	B (mmol/l)	C (mmol/l)
Baseline	4,00	4,26	7,71
Day 3	5,30	2,21	1,91
48 h after intervention	25,00	7,77	12,20

Conclusions: The combination of statins with COX-2 inhibitor administered before invasive treatment in patients with unstable angina is effective in lowering CRP levels in very short period of time. Attenuation of exaggerated inflammatory response before and during PCI could be crucial in reducing adverse cardiac events in these patients at follow-up.

2038 Ischaemia modified albumin (IMA™): a marker of ischaemia in patients presenting to the Emergency Department (ED) with cardiac chest pain

M.K. Sinha[1], D.C. Gaze[2], P.O. Collinson[2], J.C. Kaski[1]. [1]St George's Hospital Medical School, Cardiological Sciences, London, United Kingdom; [2]St George's Hospital, Chemical Pathology, London, United Kingdom

Purpose: Biochemical markers exist which allow the diagnosis of myocardial cell death (necrosis). However, no markers are available in the clinical setting that can accurately detect myocardial ischaemia that develops before or in the absence of cell necrosis. We used the Albumin Cobalt Binding (ACB™) Test to detect IMA as a marker of myocardial ischaemia in patients with acute chest pain. This test is based on the fact that exposure of circulating albumin to ischaemic myocardial tissue modifies the N-terminus of albumin such that its binding capacity to exogenous cobalt is reduced.
Methods: We prospectively measured IMA (by a rapid ACB assay) on 131 consecutive patients, 90 male, and 41 female, mean age 61 ± 12 years, attending our ED with acute chest pain suggestive of acute coronary syndrome (ACS). Patients underwent 12 lead ECG, creatinine kinase, and troponin T measurements at study entry. We compared discharge diagnosis with the admission IMA value. A final diagnosis of ACS or non ischaemic pain (NICP) was made by the treating physician on the basis of clinical symptoms, ECG changes, CK and cTnT levels and angiographic results, blinded to the IMA value.
Results: Final diagnosis was NICP in 44 patients (27 male, 17 female, mean age 56 ±15 years) and myocardial ischaemia in 87 (63 male, 24 female, mean age 63 ±10 years). Ischaemia was associated with typical transient ST changes in 28 patients (21%) and by ECG T wave inversion > 2mm in 5 patients (4%). 37 (28%) had angiography with > 70% stenosis in addition to chest pain and/or ST segment changes. Patients with ischaemic chest pain had a significantly higher mean IMA value (97.8 U/mL ±13.8) compared to patients with NICP (87.58 U/mL ±13.0), $p<0.005$. Patients with IMA >93.4 U/mL (the median of the overall IMA distribution) had a relative risk (RR) of 3.34 [95% Confidence Interval (CI) of 1.55 to 7.19] to have ischaemic heart disease compared to those with IMA <93.4 U/mL. ECG ST deviation as a predictor of ischaemic heart disease yielded a RR of 1.74 (95% CI 1.47-2.06).
Conclusions: This study showed that in patients with chest pain IMA is a sensitive marker of ischaemia. It compared favorably to the presentation ECG for predicting risk of ischemic heart disease and therefore IMA may be a useful practical tool to risk stratify patients presenting to the ED with acute chest pain.

2039 Expression of macrophage migration inhibitory factor, a pro-inflammatory cytokine, in atherosclerosis and acute myocardial infarction

C.M. Yu[1], K.W.H. Lai[1], I. Ng[2], S.W.L. Lee[1], Y.X. Chen[3], P.S. Li[1], K. Lam[1], H.Y. Lan[3]. [1]Dept. of Medicine, [2]Dept. of Pathology, Queen Mary Hospital, Hong Kong, Hong Kong; [3]Baylor College of Medicine, Dept. of Medicine, Texas, United States of America

Background: Macrophage migration inhibitory factor (MIF) is a pro-inflammatory cytokine that involves in the regulation of inflammatory and immune responses by recruiting and localizing inflammatory cells to the diseased areas. In cardiovascular system, MIF might be involved in the pathogenesis of atherosclerosis where inflammatory cells are aggregated; and macrophage and T-cell-mediated myocyte damage in acute myocardial infarction (AMI). This study investigated if MIF is actively involved in these conditions.
Methods: In human study, blood was taken from 128 patients with coronary artery disease (37 with AMI) and 31 normal controls for MIF levels. Human coronary plaques were obtained from 11 patients during percutaneous coronary intervention (PCI), and from 7 normal and 5 atherosclerotic coronary arteries at postmortem. In animal study, AMI was induced by ligating the left anterior decending coronary arteries of the 10-week Sprague-Dawley rats. They were killed at 3 hr, 6 hr, 1 day, 3 days and 7 days. The expression of MIF was examined by RT-PCR, in-situ hybridization, immunohistochemistry, Western blot and ELIZA. The macrophage infiltration was also detected by anti-CD68 antibody.
Results: In atherosclerotic coronary plaques, MIF expression was observed in 10 out of 11 cases and mainly localized in the fibroblasts. In post-mortem atherosclerotic coronary arteries, stronger MIF expression was observed in all cases and localized in both the plaques and smooth muscle cell layer of tunica media, but not in normal controls. In rats with AMI, MIF mRNA ($p<0.001$) and protein ($p<0.05$) were expressed early at the peri-infarct zone of the left ventricle, and to a lesser extent in the myocytes of non-infarct septum and right ventricle. Macrophage infiltrated into the infarct zone from day 1 ($p<0.01$) and progressively increased over the 2-week course ($p<0.01$). The plasma levels of MIF in patients with AMI were significantly elevated 2-3 folds during day 1 (3114±789 vs 633±130 pg/mL, $p<0.001$) and day 2 (2323±565 vs 626±129 pg/mL, $p<0.001$) when compared with controls, but was not seen in patients with angina or underwent PCI.
Conclusion: In human atherosclerosis, up-regulation of MIF in the plaque and smooth muscle cells may play a role in macrophage adhesion and disease progression. MIF is also expressed during AMI, and may act as a modulator of inflammatory-mediated myocyte damage.

2040 Elevation of interleukin-15 serum levels in patients with acute coronary syndrome

I. Spyridopoulos[1], K. Shatat[2], P. Mayer[2], D. Hilbert[2], W. Schöbel[2]. [1]Universitätsklinikum Frankfurt, Department of Cardiology, Frankfurt, Germany; [2]Medizinische Klinik III, Cardiology, TUEBINGEN, Germany

Several chemokines, such as interleukin-6 and TNF-alpha have been investigated as a marker for the inflammatory response during acute coronary syndromes. The presence of interleukin-15 (IL-15) has recently been demonstrated in human atherosclerotic plaques, suggesting a potential role in the pathogenesis of coronary artery disease. The underlying prospective study was designed to evaluate the role of IL-15 in patients (pts) with acute coronary syndrome.
4 patient (pts) groups were investigated: Healthy subjcts, in which coronary artery disease could be excluded by coronary angiography (Control), pts with angiographically documented stable angina (CAD), and pts with acute coronary syndrome, either with (AMI) or without (ACS) ST-elevation in the ECG. Pts with more than 2-fold elevation of the creatine-kinase above normal (>180 U/l) were defined as AMI. Pts with coexisting diseases other than hypertension or diabetes were excluded from the study. Serum chemokines were measured during the first 24 and 72 h (ACS or AMI) by ultra-sensitive ELISAs. IL-15 serum levels ranged between 1.8 and 8.0 pg/ml in pts with ACS or AMI, compared to 0.6 to 2.5 pg/ml in pts with CAD. IL-15 levels in pts with ACS or AMI were exclusively above the 75% percentile of the control or CAD group. IL-15 serum levels in the AMI group correlated well with IL-6 ($p=0.0051$) and IL-8 ($p=0.0117$) serum levels, which was not the case for the ACS group. There was no difference in IL-15 between the Control and Stable CAD group (see table).

Chemokine serum levels [pg/ml]

mean (± SEM)	Control (n=41)	CAD (n=40)	ACS (n=12)	AMI (n=12)
TNF-alpha	1.50 (0.15)	1.87 (0.12) NS	4.59 (1.04) #	3.94 (0.74) #
IL-6	0.80 (0.18)	0.82 (0.23) NS	24.08 (13.32) NS	77.04 (44.64) #
IL-8	14.66 (1.15)	15.65 (0.90) NS	75.05 (48.90) *	33.78 (10.16) NS
IL-15	1.50 (0.07)	1.43 (0.07) NS	2.95 (0.21) #	3.18 (0.62) #

NS not significant, *$p<0.05$, #$p<0.001$ (compared to Control). Maximum chemokine levels from the first 72h were used in ACS and AMI pts.

Conclusion: Serum levels of IL-15 were elevated only in pts with ACS or AMI, not with stable angina, indicating a possible role in the inflammatory response of the vessel wall during plaque rupture. In this preliminary and therefore small cohort, IL-15 seems to justify its anticipated adverse role in the vessel wall biology.

PRIMARY PERCUTANEOUS CORONARY INTERVENTION IN ACUTE MYOCARDIAL INFARCTION

2041 Pre-hospital infarction angioplasty triage (PHIAT): a considerable reduction in ischaemic time

N. Ernst[1], M-J. de Boer[2], A.W.J. van 't Hof[2], F. Hollak[3], J.C.A. Hoorntje[2], J-H. Dambrink[2], H. Suryapranata[2], F. Zijlstra[2]. [1]Isala Klinieken hospital Weezenlanden, Cardiology, Zwolle, Netherlands; [2]Isala Klinieken, hospital Weezenlanden, Cardiology, Zwolle, Netherlands; [3]RAV IJssel-Vecht, Zwolle, Netherlands

Background: Time from onset of symptoms to reperfusion therapy is of paramount importance for clinical outcome in patients (pts) with acute myocardial infarction (AMI). When considering primary PTCA, pre-hospital identification of pts with large AMI may result in a reduction of ischemic time by transporting them directly to a PTCA centre.
Methods: From pts identified in the ambulance as having AMI data on time intervals were registered. Transportation distances from the patient's home to the nearest hospital were calculated using postal codes.
Results: From November 1998 to December 2000, 254 pts were identified in the ambulance with large AMI. Immediate transfer and preparation of cath lab and personnel were initiated resulting in a mean door-to-balloon time of 43 minutes (min). If no pre-hospital triage would have been performed, 82 pts (32%) would initially have been admitted to the nearest community hospital without PTCA facilities. If they would subsequently have been referred to a PTCA centre the transporation distance would have increased from an actual 32 ± 9 kilometres (km) to a distance of 51 ± 11 km. Previous studies showed that the mean in-door-out-door time in a community hospital for pts who are candidates for primary PTCA is 45 min.
Conclusion: Pre-hospital identification of pts with large AMI in order to transport them directly to a PTCA centre leads to a considerable reduction in ischemic time as preparation of cath lab and personnel is already initiated. In 32% of pts pre-hospital triage prevents transportation to a centre without PTCA facilities. For this group of pts ischemic time would then increase with at least 60 minutes.

2042 The golden hour of primary angioplasty: reduced in-hospital mortality when door-to-TIMI 3 time is 60 min or less

J.M. Juliard[1], J.L. Golmard[2], D. Himbert[1], L.J. Feldman[1], H. Benamer[1], P. Aubry[1], A. Vahanian[1], P.G. Steg[1]. [1]*Hospital Bichat, Paris, Paris, France;* [2]*Hôpital Pitié Salpétrière, INSERM U436, Biostatistiques, Paris, France*

While there is a clear relation between time to treatment and survival benefit of thrombolysis for acute myocardial infarction (MI), there is controversy with respect to the same relation when pts are treated by primary angioplasty. Some multicenter studies have suggested that time from admission to angioplasty is better correlated with survival than the time from pain to recanalization. This retrospective single center study evaluated the impact on survival of the time from pain-to-admission and of the time from admission-to-TIMI 3 flow in the infarct-related-artery (IRA), in pts successfully treated with primary angioplasty for ST-segment elevation MI<=6 hours of symptom onset. There were 499 consecutive pts admitted 181±85 min after symptom onset. The mean age was 59±14yrs (26-91), 80% were males. Infarct location was anterior in 47% and 36% had a contraindication to thrombolysis. TIMI 3 flow was achieved in all pts, 54±28 min after admission (75% before 60 min), with stents placed in 36%. Overall in-hospital mortality was 3.2%. Using multivariate analysis, age (OR: 1.79 per 10 yrs, p=0.009), female sex (OR: 3.56, p=0.03) and time from admission-to-TIMI3 (OR: 1.27 per 15 min, p=0.01) were the three independent predictors of mortality. Neither time-to-admission nor time from pain-to-TIMI 3 flow were predictors of mortality. There was a sharp step-up in mortality when admission-to-TIMI 3 flow exceeded 60 min: 1.8% vs 6.7% for pts recanalized within 60 min of admission vs those recanalized later (p=0.01). In this single center study, the time from admission to TIMI 3 cannot be interpreted as a surrogate for center expertise.

Conclusion: there is no clear relation between the time from pain-to-recanalization and survival after primary angioplasty for acute MI. Conversely, there is a "golden hour" of very low mortality when pts can be successfully recanalized within 60 min of admission.

2043 Outcome of acute myocardial infarction patients admitted to hospitals with and without facilities for primary PTCA: data from the AMI-Florence registry

G M. Santoro[1], A. Barchielli[2], M. Margheri[1], M C. Landini[2], V. Lazzeri[2], G. Santoro[1], M. Torri[2], E. Buiatti[3]. [1]*Careggi Hospital, Florence, Italy;* [2]*Health Unit, Florence, Italy;* [3]*Tuscany Health Agency, Florence, Italy*

Background: It is unclear whether the outcome of patients (pts) with acute myocardial infarction (AMI) initially admitted to hospitals without PTCA facilities and then transferred to perform primary PTCA (P-PTCA) is different from that of pts directly admitted to hospitals with P-PTCA programs.

Methods: Data are derived from the AMI – Florence Registry, a prospective observational registry including all the Florence area residents who experienced AMI from March 1, 2000 to February 28, 2001 and were admitted to hospital within 12 hours from symptom onset. Florence area includes 7 hospitals, 5 without the facilities to perform P-PTCA and 2 with specific programs for P-PTCA.

Results: This analysis refers to the 423 pts with ST-elevation AMI included in the registry who underwent P-PTCA. Of these pts, 287 were directly admitted to the 2 centres with PTCA facilities (Group 1) and 141 were initially admitted to the 5 hospitals without PTCA facilities and then transferred to the 2 centres with invasive facilities (Group 2). In term of risk factors and clinical characteristics, a lower prevalence of history of angina was observed in Group 1 (28.7% vs 44.7%, p=0.001); Killip class >1 was observed in 17.7% of Group 1 and 24.8% of Group 2 (p=0.09); cardiogenic shock was present in 6% of Group 1 and 5% of Group 2 (p=0.66). Median time from symptom onset to admission was 135 min in Group 1 and 130 min in Group 2; median door (of the admission hospital)-to-balloon time was 25.5 min in Group 1 and 113 min in Group 2. Door-to-balloon time was < 60 min in 81% of Group 1 and 19% of Group 2 (p<0.0001). TIMI grade 3 flow was restored in 95% of Group 1 and 93.6% of Group 2 (p=ns). Left ventricular ejection fraction of the pts alive at discharge was exactly the same in Group 1 and Group 2 (mean 45±12%). Six-month mortality was 8.2% in Group 1 and 9.9% in Group 2. Comparing mortality in pts with door-to-balloon times < 60 min and >=60 min adjusted for Group 1 or Group 2, no significant difference in mortality was observed.

Conclusion: Despite their higher Killip class and longer door-to-balloon time, pts transferred from hospitals without P-PTCA facilities have an excellent outcome which is comparable to that of pts directly admitted to hospitals with P-PTCA facilities.

2044 Does pre-hospital management of myocardial infarction by medicalized mobile intensive care units improve the outcome of patients undergoing percutaneous coronary intervention

C. Loubeyre[1], K. Tazarourte[2], M.C. Morice[3], T. Lefèvre[4], Y. Louvard[4], P. Dumas[5], J.F. Piéchaud[3], C. Raghu[6]. [1]*Institut Cardiovasculaire Paris Sud, Hôpital Claude Galien, Quincy, France;* [2]*Service d'Aide Médicale d'Urgence, Melun, France;* [3]*Institut Hospitalier Jacques Cartier, Institut Cardiovasculaire Paris Sud, Massy, France;* [4]*Institut Hospitalier Jacques Cartier, Institut Cardiovasculaire Paris Sud, Massy, France;* [5]*Clinique du Bois de Verrières, Institut Cardiovasculaire Paris Sud, Antony, France;* [6]*Hôpital Claude Galien, Institut Cardiovasculaire Paris Sud, Quincy, France*

Background: The influence of prehospital care by Mobile Intensive Care Units (MICU) on the outcome of a mechanical reperfusion strategy has never been assessed. The logistics of pre-hospital management may reduce delays before reperfusion and improve the clinical results of primary angioplasty.

Methods: Between January 1998 and September 2001, 913 patients underwent percutaneous coronary intervention for acute myocardial infarction (AMI) in our institution. Three admission modalities were comparatively assessed: 616 patients (67.5%) were managed by medicalized MICUs before direct admission to catheterization laboratory; 114 patients (12.5%) presented directly to the emergency room and 183 patients (20%) were transferred from tertiary hospitals.

Results: Pre-hospital care patients were comparable with regard to age, male gender, MI location but were more likely to be smokers, to have a history of myocardial infarction and to be receiving thrombolytic therapy (in 20.8% vs. 2.6% for pre-hospital vs. in-hospital care respectively, p<0.0001). Pre-hospital patients had shorter onset to admission delays (254 ± 208 vs. 329 ± 292, p=0.003) and door to stent time (45 ± 53 vs. 77 ± 89 min, p<0.0001) as compared to in-hospital care patients. Patients managed by medicalized MICUs were less likely to have totally occluded arteries before intervention (60.9% vs. 76.2%, p=0.003). Final TIMI 3 grade flow exceeded 90% in all groups without significant differences. Pre-hospital care was associated with a significantly lower in-hospital mortality rate as compared to in-hospital care patients and transfer patients (2.3 vs. 6.1% and 7.1% p=0.004). Multivariate logistic regression analysis revealed that pre-hospital care was an independent predictor of survival (odds ratio, 95 percent confidence interval; p=0.006).

Conclusions: Pre-hospital care delivered by physicians in MICUs improves the outcome of AMI patients treated by percutaneous coronary intervention. The reasons may lie in delay reduction, earlier reperfusion of the infarct-related artery before mechanical reperfusion and improvement of hemodynamic status before admission.

2045 Acute myocardial infarction with normal coronary angiography does not exist. Review of 625 coronary angiograms from the PRAGUE-1 and -2 studies

P. Widimsky[1], B. Stellova[1], L. Lisa[1], L. Groch[2], M. Aschermann[3], M. Branny[4], M. Zelizko[5], T. Budesinsky[1] on behalf of PRAGUE Study Group Investigators. *[1]University Hospital Vinohrady, Cardiocenter, Praha 10, Czech Republic; [2]University Hospital St. Anne, Cardiology Clinic, Brno, Czech Republic; [3]University Hospital VFN, Cardiology, Prague, Czech Republic; [4]Hospital Podlesi, Cardiology, Trinec, Czech Republic; [5]IKEM, Cardiology Clinic, Prague, Czech Republic*

Aim: Despite the extensive existing literature on acute myocardial infarction (AMI) with normal coronary arteries (NCA) our experience with primary percutaneous coronary intervention (p-PCI) is different. Thus, we hypothetized, that NCA in the acute phase of evolving AMI does not exist.
Methods: "PRAGUE-1" and "PRAGUE-2" studies randomized patients with ST elevation AMI to immediate on-site thrombolysis or transport for p-PCI. 625 coronary angiograms performed within 2 hours of initial ECG were retrospectively analyzed for presence of NCA (defined as absence of visible angiographic signs of atherosclerosis, thrombosis or spontaneous spasm). Symptoms of ischemia were persisting during angiography in 563 pts., while in 62 pts. symptoms disappeared during the transportation to angiography.
Results: NCA were found in 13 patients (2% of all acute phase angiograms). The clinical characteristics of these patients:
* Pain was lasting at the time of acute phase angiography in 1 pt. (in 12 pts. pain disappeared during the transport - before the start of coronary angiography).
* ECG site of "AMI" was inferior in 7 pts., anterolateral in 5 and LBBB in one.
* Amplitude of ST elevations was 0-2 mm in 11 pts., >2 mm in 2.
* CK-MB was negative in 7 and positive in 6 pts., mean was 1,72 ukat/l
* LV function was normal in 6 pts., diffuse hypokinesis in 4 and regional akinesis in 3. Mean ejection fraction (EF) was 51%.
* The discharge diagnosis was small myocardial infarction in 4 pts. (= 0,6% of all pts.), acute myocarditis in 2 pts., dilatation cardiomyopathy in 2 pts., hypertension in 2 pts., pulmonary embolism in 1 pt. and misinterpretation of ECG (no cardiac disease) in 2 pts. All 4 patients with small AMI underwent angiography 30 – 90 minutes after the complete relief of the signs of acute ischemia. All had normal EF. Transient coronary spasm disappearing before angiography was assumed to be the cause for these small infarcts. Among 563 pts. catheterized during ongoing symptoms of ischemia none had normal coronary angiogram.
Conclusion: The incidence of normal coronary angiography in the acute phase of suspected AMI is 2%. Most of these cases represent wrong diagnosis. The incidence of normal coronary angiography in biochemically confirmed AMI is 0,6%. Normal coronary angiography (when performed during the ongoing symptoms of ischemia) in acute myocardial infarction does not exist.

2046 The time point of platelet blockade is critical in patients with acute myocardial infarction undergoing percutanous coronary intervention

M. Jaster, P. Schwimmbeck, S. Spencker, U. Rauch. *Universityhospital Benjamin Franklin, Klinik for Cardiology, Berlin, Germany*

Background: Blood thrombogenicity is high in patients with acute myocardial infarction (AMI). Newer trials point to the clinical benefit of early antiplatelet therapy when treating those patients with percutanous coronary intervention (PCI). Our study aimed to investigate whether the time point of abciximab administration (before versus during PCI) influences in vivo platelet-leukocyte interaction in patients with AMI.
Methods: 34 patients with AMI were treated with PCI. The time point of abciximab treatment was chosen 1.) one hour before coronary intervention and 2.) after the reopening of the infarct related artery had been acchieved, resulting in 8 times abciximab administration before and 26 times during PCI. Blood samples were obtained without torniquet before and immediately after intervention and the number of platelet-leukocyte aggregates in blood indicating the blood thrombogenicity was analysed by flow cytometry.
Results: In vivo platelet-leukocyte aggregation was comparable in patients treated one hours before and during intervention with abciximab (3,7% ± 1,0 versus 3,8% ± 1,2; n.s.). After performing the coronary intervention with successful reopening of the infarct related artery, there was a significant decrease in platelet-leukocyte aggregates in patients who received abciximab at an early time point one hour before the intervention had started (3,7% ± 1,0 before versus 3,4% ± 1,1 after intervention). In patients who received abciximab for the first time during coronary intervention and after vessel reopening, platelet-leukocyte aggregates were increased at the end of the intervention (3,8% ± 1,2 before versus 4,3% ± 1,4 after intervention); $p<0,05$.
Discussion: In order to reduce blood thrombogenicity in patients with an acute myocardial infarction, the time point of GPIIb/IIIa blocker administration has to be as early as possible before performing PCI. Our results confirm the clinical benefit reported in trials on AMI, in which abciximab was given as early as in the ambulance on the way to the hospital.

PERCUTANEOUS CORONARY INTERVENTION: VARIATIONS IN STENTING, CUTTING AND SPOTTING

2047 Direct stent implantation does not lead to a reduction in restenosis; a randomized controlled trial

A.J.J. IJsselmuiden, G.J. Laarman, F. Kiemeneij, T. Slagboom, R. vd Wieken. *OLVG, Intervention Cardiology, Amsterdam, Netherlands*

Objectives: This study compared the 6-month angiographic and clinical results of direct stenting versus stenting after balloon predilatation.
Methods: Four-hundred patients with angina pectoris and/or myocardial ischemia due to non-occlusive coronary stenoses in a single native vessel were randomized to either direct stenting versus stenting after predilatation. Demographic characteristics were evenly distributed in both groups. The angiographic results, and clinical outcomes associated with the two procedural strategies up to six month were compared.
Endpoint definitions: (1) Procedural success, (2) binary restenosis and (3) major adverse cardiac and cerebral events (MACCE) were defined as (1) a successful procedure without in-hospital events, (2) luminal narrowing >50% at six month and (3) composite incidence of death, myocardial infarction, ischemia-driven revascularization and cerebral events, respectively.
Results: Successful stent implantation was achieved in 98.3% for direct stenting and 97.8% for stenting preceded by predilatation, whereas the primary success rate of direct stenting was 88.3% (p=0.01). Procedural success rates were similar (96.0% vs. 94.5%). The angiographic follow-up at six month included 333 of the 400 patients (83%). The binary in-stent restenosis rates among the 163 direct stented and 166 predilated patients who underwent follow-up angiography were 23.1% and 18.8% respectively (p=0.32). At the end of a mean observation period of 185±25 days overall late MACCE had occurred between start procedure and the end of follow-up in 31 of 200 (15.5%) patients randomized to direct stenting, versus 33 of 200 (16.5%) randomized to predilatation (ns).
Conclusions: Direct stenting did not lead to a reduction in restenosis and was associated with similar procedural success rates and clinical outcomes as compared to the strategy of stenting preceded by balloon predilatation.

2048 Analysis of long-term results after primary stenting in comparison with balloon predilatation before stenting

I. Pershukov[1], T. Batyraliev[2], A. Samko[3], Z. Niyazova-Karben[2], V. Novomlinsky[1], F. Besnili[3], I. Aksoy[2], Y. Belenkov[3] on behalf of International Invasive Cardiology Research Group. *[1]Voronezh, Russian Federation; [2]Sani Konukoglu Medical Center, Cardiology, Gaziantep, Turkey; [3]Cardiology Research Complex, Clinical Cardiology, Moscow, Russian Federation*

Background: Primary stenting (PS) without predilatation (PD) may lead to reduced coronary vessel trauma. This could result in a lower rate of restenosis (RR).
The aim of our study was analysis of the influence of this strategy on long-term follow up (FU).
Material and methods: Last four years we prospectively registered all interventions in a database. The first treated lesion of each patient with FU angiography after 6 months or earlier with restenosis was eligible for evaluation. 1347 interventions with PTCA followed by stent implantation (ST) as well as 1104 with PS were analyzed by quantitative coronary angiography. First the balance of well-known predictors for restenosis like reference diameter (RD), lesion type, diameter stenosis before treatment and other factors was analyzed. Accounting for the bias created by the imbalance of some of these factors between the two treatment arms, the influence of the technique on long-term result was investigated by multifactorial ANOVA with regard to % diameter stenosis at FU. A multiple logistic and general stepwise regression analysis was performed with regard to binary restenosis rate (>50% stenosis at FU) and the amount of stents/lesion.
Results: PD was more often performed in type B2 or C lesions (77% vs. 45% in type A and B1, $p<0,001$), in small vessels (median RD 2.57 mm vs. 3.24 mm with PS, $p<0.001$) and in more severe stenoses (median diameter stenosis 96% vs. 79% in PS, $p<0.001$). Long-term results showed a smaller mean diameter stenosis at FU after PS (32% vs. 45%), which remained significant in MANOVA (p=0.02). Multiple logistic regression revealed as independent predictors for binary restenosis: type B2 or C lesions (OR 2.3, p=0.005), PS (OR 1.9, p=0.01), reference diameter (OR 1.7, p=0.02), Diabetes mellitus (OR 1.5, p=0.04) and multiple stenting (OR 1.8, p=0.01). Independent predictors by general stepwise regression for diameter stenosis before treatment (OR 1.0, p=0.05), multiple stenting were PS (OR 1.2, p=0.03) and type B2 or C lesions (OR 2.2, p=0.005).
Conclusion: Diameter stenosis at FU and restenosis rate are significantly lower with PS as compared with PD followed by ST. The amount of stents/lesion is significantly lower after PS vs. PD followed by ST too. Thus whenever PS without PD is feasible it must performed for improvement of long-term results of coronary interventions.

2049 Feasibility and safety of transradial coronary angiography followed by ad hoc percutaneous coronary intervention

F. Iarrazet, F. Philippe, F. Laborde, M. Slama, T. Folliguet, J. Bachet, A. Dibie. *Institut Mutualiste Montsouris, Cardiology, Paris, France*

Transradial artery cannulation is a useful alternative approach to the performance of diagnostic and interventional coronary procedures. The purpose of the study is to evaluate the safety of the radial (R) approach compared with the femoral (F) access in coronary angiography followed by had hoc PCI. A total of 591 patients (pts) met the clinical criteria of our comparative study (no cardiogenic shock or humeral approach). The pts were divided into 2 groups [R (328, 55%), F (263, 45%)]. We compared radiation dose and 1 year-outcome of major cardiac events (cardiac deaths, MI, CABG, repeat PCI) between groups. There were slight differences in baseline data between the both procedures [(R:F) mean age; 66 yo:65 yo, male gender; 77%:75%, prior MI; 27%:36%, $p< 0.05$, multivessel disease; 50%:60%, $p< 0.05$. Ten percent of R procedures were converted into femoral or humeral access. Failure to achieve PCI, to stent and to direct stent the lesion were identical (5% vs 5%, 0.6% vs 1.9%, 3% vs 4%, respectively). Radiation time were higher in the R group than in the F group (23±12 min vs 17±4 min, $p< 0.001$) as well as the dose area product value (27753±15750 R*cm^2 vs 21264±13427 R*cm^2, $p<0.001$). Non cardiac complications occurred in 5 (1.5%)R pts (2 vascular surgical repairs, 2 cerebrovascular events and one cardiac tamponade leading to death) and in 4(1.5%)F pts(4 vascular surgical repairs leading to one death). The cardiac event-free ratio were 13% in both groups [(R:F) death; 0.6%:1.1%, MI; 2%:2%, CABG; 0.9%:1%, repeat PCI; 9%:8%].

The radiation dose to patients, staff members and physicians is higher when the transradial cannulation is prefered to the femoral access for coronary angiography followed by had hoc PCI. Both methods give same immediate and long term results.

2050 Treatment of "false bifurcation lesions" with coronary stenting

T. Lefevre[1], Y. Louvard[1], M.C. Morice[1], P. Dumas[2], C. Loubeyre[3], O. Tavolaro[3]. *[1]Institut Hospitalier Jacques Cartier, Institut Cardiovasculaire Paris Sud, Massy, France; [2]Clinique du Bois de Verrières, Institut Cardiovasculaire Paris Sud, Antony, France; [3]Hôpital Claude Galien, Institut Cardiovasculaire Paris Sud, Quincy, France*

Background: Due to the axial plaque redistribution phenomenon in the side branch, "false bifurcation lesions" become frequently "true bifurcation lesions" after coronary stenting. Consequently, we have developed a systematic and simple strategy for stenting these lesions: wiring of both branches, then stenting of the main branch with a jailed wire, kissing balloon inflation and provisional T stenting of the side branch.

Methods: The purpose of this study was to retrospectively evaluate the immediate results and mid term outcome of this specific approach in type 2 lesions (Lesion proximal and distal to the bifurcation without significant lesion of the side branch), type 3 (lesion of the main branch proximal to the bifurcation) and type 4a (lesion distal to the bifurcation). All patients (cardiogenic shock excluded) had been prospectively included in a prospective single center observational database since January 1996 with 7-month follow-up and coronary angiogram in cases of clinical or stress test ischemia.

Results: Among 936 bifurcation lesions consecutively included, 452 (49%) were "false" and 319 treated by this approach. The clinical characteristics were similar in each group. Main characteristics and results are summarized in the table below:

	Type 2	Type 3	Type 4a
Patients (n)	120	95	79
Age (years)	64±12	62±13	63±13
LAD-diagonal (%)	55.4	32.5	52.2
Proximal reference (mm)	3.09±0.51	3.28±0.63*	3.14±0.59
Stenosis (%)	73.1±14.6*	69.6±15.3	66.6±12.5
Side branch stent (%)	18.5	19.5	14.9
Kissing balloon (%)	89.0	85.1	97.0
Angiographic success 2 branches (%)	96	95	100
In-hospital MACE (%)	4.4	1.3	1.5
Total 7-month MACE (%)	11.5	5.4	18.5*
TVR 7-month (%)	7.5	5.4	16.7*

* $p<0.05$

Conclusion: this study shows that provisional T stenting of the side branch for treating "false bifurcation lesions" is associated with a high success rate and acceptable MACE and TVR rates

2051 Low restenosis rate after spot stenting used as a standard procedure

U. Dietz, C.H. Dauer, H. Lambertz. *Deutsch klinik für Diagnostik, Kardiololgie, Wiesbaden, Germany*

The restenosis rates of short stents is lower than that of longer stents. However, stents with a length of > 10 mm are used for most procedures. We investigated the feasibility of routinely used spot stenting. The protocol suggested predilatation in order to achieve a sufficient result. In the case of a residual stenosis > 30% (immediately after PTCA or after waiting 5 min) and a length of the residual stenosis < 8 mm a short stent (< 10 mm) was implanted using an inflation pressure > 14 atm. A stent diameter was chosen as to achieve a 1.1 ratio to the diameter of the reference segment at the inflation pressure used. Spot stenting without predilatation was allowed at proximal sites of the LAD and RCA. This protocol was followed in 305 consecutive patients (pts.) receiving 337 coronary interventions (Int.). In 95 Int. no stent was used because of an optimal PTCA result (n=45), a small coronary diameter (n=26), treatment of a stent restenosis (n=19) or because of the presence of diabetes (n=5). A longer stent (>10 mm) was used in 41 Int. because of the necessity to cover a dissection (n=34) or a longer residual stenosis (n=7). Spot stenting was performed in 201 Int. (Multilink 8 mm 135x; NIR 9 mm 76x) with a nominal diameter of 3.2± 0.4 mm, implanted at an inflation pressure of 13.7 ± 3 atm. Procedural success was achieved in 97.7% of pts. During the 6 month follow-up one pt. died, all others were event free. Control angiography was done in 284/301 (94%) pts. eligible; target lesion revascularization rate (TLR) at 6 months was calculated for all patients.

Long-term Results

	No Stent	Long Stent	Spot Stent	All lesions
Restenosis	7/77 (9%)	7/39 (18%)	26/182 (14%)	40/298 (13.4%)
TLR	7/77 (9%)	5/41 (12%)	20/186 (11%)	32/301 (10.6%)

Conclusions: Spot stenting in feasible in most interventions yielding a low restenosis rate. The use of the proposed procedure reduces restenosis rates in all interventionally treated patients.

2052 Cutting balloon angioplasty is superior to balloon angioplasty and stent for the treatment of small coronary artery. "Dual center experience"

R. Iijima[1], M. Nakamura[2], H. Nakajima[1], T. Nishida[2], T. Tsunoda[2], Y. Ikari[1], K. Hara[1], T. Yamaguchi[2]. *[1]Mitsui memorial hospital, cardiovascular division, Tokyo, Japan; [2]Toho University School of Medicine, Third Dept. of Internal Medicine, Tokyo, Japan*

Background: The best interventional strategy to treat lesions in the small coronary artery has not been yet established. It has been proposed that cutting balloon angioplasty (CBA) may be effective strategy for the treatment of small coronary artery disease.

Methods: We analyzed a total of 255 small coronary artery disease from two institutions treated either by stent (65 lesions), CBA (65 lesions), and Balloon angioplasty (BA: 125 lesions). Small coronary artery was defined as a vessel with a reference vessel diameter of < 2.7mm. Six months angiographic follow-up was performed in all cases. Clinical events, angiographic restenosis, and QCA results was compared among 3 groups.

Results: There was no difference in baseline characteristics. Analyzed data are shown in table.

	BA	CBA	STENT	p value
No. of lesion	125	65	65	ANOVA
Diabetes Mellitus, %	37.5	42.2	32.8	ns
Ref diameter, mm	2.13±0.32	2.22±0.34	2.10±0.31	ns
Pre MLD, mm	0.63±0.34	0.72±0.33	0.57±0.37	ns
Pre % stenosis	71±15	68±14	73±17	ns
Lesion length, mm	14.3±7.7	12.7±9.0	14.8±6.0	ns
Post MLD, mm	1.76±0.30	2.10±0.40	2.30±0.30	<0.0001
Post % stenosis	25± 9	18±11	10± 7	<0.0001
Acute gain, mm	1.1±0.4	1.4±0.4	1.7±0.4	<0.0001
Late loss, mm	0.5±0.5	0.6±0.5	1.0±0.6	<0.0001
Loss index	0.47±0.47	0.47±0.42	0.62±0.34	ns
Restenosis rate, %	48.7	31.1	41.3	0.078
In hospital event, %	6.3	1.6	3.1	0.26

In hospital event = cardiac events included subacute stent thrombosis

Conclusions: The CBA for small coronary artery disease provided superior outcome in angiographic restenosis and safe compared to the other strategy. These findings suggested that CBA is a useful strategy for the treatment of small coronary artery disease.

PERCUTANEOUS CORONARY INTERVENTIONS: WHOM TO TREAT OR NOT TO TREAT

2053 Fractional flow reserve after stenting to predict repeated target vessel revascularization during follow-up

N. Pijls on behalf of the FFR-post-stent-Registry Investigators. *Catharina Hospital, Cardiology, Eindhoven, Netherlands*

Background: In-stent restenosis occurs in approximately 15% of patients despite optimum angiographic results. Coronary pressure measurement has been suggested as an additional physiologic method to optimize stent deployment. Aim of the present study was to investigate the predictive value of pressure-derived fractional flow reserve (FFR), measured immediately after stenting, for repeated target vessel revascularization (TVR) at 6-month follow-up.
Methods: In 750 patients in 15 hospitals, stent implantation was guided by coronary pressure measurement and post-stent FFR was calculated as the ratio of hyperemic coronary pressure just distal and just proximal to the stented segment. Patients were divided in 5 groups, according to the post-stent FFR: 0.96-1.0; 0.91-0.95; 0.85-0.90; 0.81-0.85; and 0.75-0.80.
Results: Baseline characteristics, procedural characteristics and angiographic results were completely comparable in all groups. A strong inverse correlation was found between post-stent FFR and need for TVR and event rate at 6-month, ranging from 4% in patients with complete normalization of FFR after stenting to 41% in the worst group (table). Patients with FFR <0.90 had a relative risk for restenosis that was almost 5x higher than in patients with FFR >0.90.

Post-stent FFR	0.75-0.80	0.81-0.85	0.86-0.90	0.90-0.95	0.96-1.0	all patients
number of pat	44	63	130	241	266	750
refer diam (mm)	2.8 ± 0.5	3.0 ± 0.6	2.9 ± 0.5	3.0 ± 0.6	3.2 ± 0.5	3.1 ± 0.6
post-stent stenosis	12 ± 9%	8 ± 13%	10 ± 10	7 ± 8%	7 ± 10%	9 ± 11%
TVR rate	41%	25%	20%	7%	4%	13%

Conclusion: FFR after stent implantation is a strong independent parameter to predict need for target vessel revascularization (TVR) at 6-month follow-up. Complete normalization of FFR after stent implantation can be achieved in 40% of the patients and is associated with a 6-month restenosis rate of 4% only.

2054 Coronary intervention in the elderly: comparison on immediate and long-term clinical outcome between octogenarians versus septuagenarians

F. Liistro[1], A. Chieffo[1], C. Sarais[1], C. Di Mario[2], F. Sgura[1], A. Castelli[1], D. Maccagni[1], A. Colombo[2]. [1]*Ospedale San Raffaele, Emodinamica, Milano, Italy;* [2]*Emo Centro Cuore Columbus, Emodinamica, Milan, Italy*

Background: Cardiologists will face more often the difficult clinical dilemma of the decision making for elderly patients with symptomatic coronary artery disease. The aim of this study is to evaluate the immediate and long-term clinical results following elective percutaneous coronary interventions in elderly patients comparing septuagenarians versus octogenarians.
Methods: Between January 1997 and August 2001, 521 consecutive patients,150 octogenarians (mean age of 83±2.86 yrs) and 371 septuagenarians (mean age of 73.3±2.7 yrs) underwent elective percutaneous coronary intervention (PCI) at our institutions. The data reported are related to all the patients in whom coronary intervention was performed or intended. Major Adverse Cardiac Event (MACE) was defined as death, Myocardial Infarction (MI) and repeated revascularization either by Re-PCI or Coronary Artery By-Pass Grafting (CABG). MACE occurrence in hospital and at 6-month follow-up was the study end-point.
Results: Octogenarians were more often females (34.6% vs 22.1%;p=0.039), with a lower rate of previous PTCA (10.6% vs 23.1%; p=0.0009) and more calcified lesions (26.6% vs 18.3%; p=0.04). No difference was found in terms of multi-vessel intervention between the two groups (37% in octogenarians vs 34% in septuagenarians; p=0.5). Angiographic success was higher in septuagenarians (99.4% vs 97.3%; p=0.0001) as the rate of complete revascularization (52.5% in septuagenarians vs 40% in octogenarians;p=0.04). No significant differences in hospital mortality (2% in octagenarians vs 0.5% in septuagenarians; p=0.1), MI (2% in octogenarians vs 1.6% in septuagenarians; p=0.7) and emergency repeated revascularization (0.2% vs 0.0%; p=0.1) were observed. At 6-month follow up, mortality (7.3% vs 2.7%; p=0.02) as well as MI (4.0% vs 1.8%: p=0.2) were higher in octogenarians but were counterbalanced by a lower rate of repeated revascularization (4.1% vs 11.3%; p=0.01) with no difference in terms of event-free survivals between the two groups (84.3 vs 84.6;p=0.9). Multivariate logistic regression (figure 1) showed that age(RR:1.1; 95%CI 1.01-1.20) and complete revascularization (RR:0.11;95%CI:0.02-0.53) are independent predictors of 6-month mortality.
Conclusion: PCI in octogenarians has a similar acute mortality but a higher late mortality than in septuagenarians. This higher mortality is possibly explained by the lower rate of complete revascularization achieved.

2055 Short-term outcome after percutaneous coronary interventions in patients affected by solid cancer and acute coronary syndromes

G. Sangiorgi[1], S. Castelvecchio[2], G.L. Carbone[2], D.R. Holmes[3], K.N. Garratt[3]. [1]*Istituto Policlinico S.Donato, Cardiovascular Diseases Dept., S. Donato Milanese, Italy;* [2]*Istituto Policlinico S.Donato, Cardiovascular Diseases Dept., S.Donato Milanese, Italy;* [3]*Mayo Clinic and Foundation, Cardiovascular Diseases, Rochester, MN, United States of America*

Background: The number of pts affected by tumours (K) and acute coronary syndromes (ACS) is increasing constantly in the industrialized countries. It is well known that pts affected by malignancies who need myocardial revascularization may benefit more from percutaneous intervention (PCI) than surgery (due to the severe decrease in immuno-system defenses during CABG). In addition, since malignancies induce an hypercoagulable/aggregation state, we hypothesized that pts affected by K and undergoing PCI may have a different clinical outcome compared to standard population cohort due to thrombotic complications. Methods and Results: Patients affected by K (n=233) and submitted to PCI at the Mayo Clinic from 1985 to 2000 were retrospectively compared with a standard general population cohort (n=699). Patients were matched as regard of age, sex, ejection fraction, clinical onset of ACS, and cardiovascular risk factors. Significant difference in MACE was present at thirty-day follow-up in the two study group (Table).

Table: 30-Days MACE after PCI

	Tumours (n=233)	Standard Population (n=669)	P value
Mortality (n, %)	11 (4.9)	17 (2.5)	.003
Death/MI	43 (18.5)	46 (6.9)	.0001
Death/ MI/TVR	50 (21)	63 (9.4)	.0001
Emergency CABG	3 (1.3)	8 (1.4)	NS
Coronary Embolization	18 (7.7)	11 (1.6)	.00001
Coronary Occlusion	2 (0.7)	5 (0.7)	NS
Branch Occlusion	12 (5.2)	23 (3.4)	NS
Cardiogenic Shock	11 (4.7)	29 (4.3)	NS

Conclusions: Pts affected by malignancies submitted to coronary intervention for ACS have a worst short-term clinical outcome compared to standard population. This may be due to a severe thrombophilic state leading to increased rate of thrombotic complications after PCI. Prospective clinical studies are necessary to understand if pharmacological intervention that inhibit the coaugulation/aggregation state may improve the clinical outcome of pts affected by both K and ACS submitted to PCI.

2056 Percutaneous coronary intervention of complex lesions is still associated with increased in-hospital and 1-year adverse event rates

R.L. Wilensky[1], J. Johnston[2], F. Selzer[2], D.O. Williams[3], B.D. Klugherz[1], W.K. Laskey[4], P.C. Block[5], K.M. Detre[2] on behalf of NHLBI Dynamic Registry. *[1]Hospital of the University of Pennsylv, Cardiovascular Division, Philadelphia, United States of America; [2]University of Pittsburgh, GSPH-Department of Epidemiology, Pittsburgh, United States of America; [3]Rhode Island Hospital, Division of Cardiology, Providence, United States of America; [4]University of Maryland, Division of Cardiology, Baltimore, United States of America; [5]Emory University, Division of Cardiology, Atlanta, United States of America*

Advances in percutaneous coronary intervention (PCI) have reduced complications but expanded the indications. This study evaluated whether the PCI of complex lesions is associated with increased adverse clinical events for up to 1 year after the procedure. A total of 4629 patients (pts) undergoing PCI between 7/97-2/98 and 2/99-6/99 were enrolled in the NHLBI Dynamic Registry. A complex lesion was defined as a significant stenosis with thrombus, calcification, ostial or bifurcation location or a chronic occlusion. The 2839 pts treated for complex lesions (61.3%) were significantly older and more likely to present with an acute coronary syndrome. PCI of a complex lesion was more likely to cause major dissection, distal embolization, side branch occlusion or persistent reduced blood flow (all $p<0.05$) and the procedural success rate was lower (89.9% vs 96.7%, $p<0.001$). Pts with complex lesions had increased in-hospital and 1-yr event rates ($p<0.001$, table).

Lesion complexity and clinical events

Complex?	In-hospital			One-Year		
	Death	Death/MI	MACE	Death	Death/MI	MACE
Yes	2.0%	5.2%	6.6%	6.2%	11.7%	27.2%
No	0.6%	2.4%	2.9%	3.7%	7.5%	23.3%

All differences $p<0.001$

Additionally, there was a significant trend ($p<0.001$) in increased in-hospital and 1-year death and death/MI rates with increasing number of treated complex lesions. Multi-variate analysis demonstrated that pts with thrombus had a greater incidence of in-hospital death/MI (OR=1.97; 95% CI= 1.35-2.87) while thrombus, calcification,and bifurcation were associated with a greater incidence of adverse events (Thrombus [OR=1.82 95% CI=1.30-2.56], calcification [OR 1.39, 95% CI=1.04-1.85], bifurcation [OR=1.46 95% CI=1.02-2.09]. At 1-yr calcified and bifurcation lesions were independently associated with increased death/MI/CABG (RR=1.18; 95% CI=1.00-1.40, RR=1.34, 95% CI 1.09-1.64, respectively).

In conclusion, PCI of complex lesions was associated with increased periprocedural, in-hospital and 1-yr adverse events. An increased in-hospital event rate was noted independently for thrombotic, bifurcation and calcified lesions. bifurcation and calcified lesions were independently associated with worse long-term event rates.

2057 Non-intervention strategy for patients with significant in-stent restenosis on angiography: 3-year clinical follow-up

H. Eltchaninoff, R. Carlot, C. Tron, C. Giron, A. Cribier. *Charles Nicolle, Cardiology Dept., Rouen, France*

In-stent restenosis remains a major limitation after coronary stent implantation with high recurrent restenosis rate after any interventional procedure.

The aim of our study was to evaluate the long-term clinical outcome of patients (pts) presenting with significant in-stent restenosis on repeat angiography and who were maintained on medical treatment alone with no revascularisation procedure. Clinical follow-up was obtained by phone.

Results: Between january 1996 and may 2000, we could retrospectively identify 258 pts presenting with significant angiographic (> 50% by QCA) in-stent restenosis: among them, 66 (26%) did not undergo percutaneous coronary intervention and/or bypass surgery and were maintained on medical treatment alone. This subset of Pts represented our study group. In this population, repeat angiography was either performed on systematic basis (44 Pts) or because of documented ischemia and or angina < class 2 of the Canadian Classification (22 Pts). Mean age was 61 ± 11 years and 86% were male. In-stent restenosis was diffuse in 84% and mean stenosis diameter was 57 ± 7%. Clinical indications for stent implantation were: unstable angina (28%), acute myocardial infarction (16%), stable angina (56%). Mean stent diameter was 3.0 ± 0.3 mm and mean stent length was 16.5 ± 5.5 mm. Vessel location was LAD in 51%, LCX in 19% and RCA in 26%. Ejection fraction was 62 ± 12% and 60% of pts were pluritroncular. Clinical follow-up was obtained at 33 ± 10 months in all pts: 2 pts died and none developed myocardial infarction. During follow-up, 6 pts (9%) only had target lesion revascularisation (repeat PTCA). Event-free survival was 86% at 33 months.

Conclusions: Medical treatment alone is associated with a good long-term clinical follow-up in selected patients with significant documented in-stent restenosis. Knowing the high recurrent restenosis rate after repeat interventional procedures for in-stent restenosis, medical treatment alone is a valuable alternative in non or pauci-symptomatic pts, even in case of diffuse restenosis.

2058 Asymptomatic restenosis after coronary artery stenting – Is re-PTCA indispensable?

A. Germing[1], S. von Dryander[1], W. Bojara[1], T. Lawo[1], M. Lindstaedt[1], A. Machraoui[2], B. Lemke[1]. *[1]BG-Kliniken Bergmannsheil, Cardiology and Angiology, Bochum, Germany; [2]DIAKO, Internal Medicine, Flensburg, Germany*

Background: Coronary artery stenting has reduced bailout situations and the restenosis rate after percutaneous coronary interventions (PCI) but restenosis still limitates the long-term outcome. The diagnosis of a hemodynamic relevant restenosis is not standardized and the treatment options of restenosis are discussed controversially.

Methods: In an unselected population of 397 patients we analyzed the therapeutic strategy in case of an angiographically assessed restenosis (diameter stenosis > 50%) three months after coronary artery stenting. Recurrent angina or myocardial ischemia had been required for the primary intervention.

Results: A total of 105 patients (61.1+10.1 years, 72.4% male) presented a significant restenosis in the target lesion measured by quantitative coronary angiography. Among the population with restenosis 65 patients (61.9%) presented recurrent angina, 50 patients (47.6%) showed myocardial ischemia during stress tests. Twenty-two patients (21%) had no angina and no ischemia. PCI of the target lesion was performed in 70 patients (66.7%), in 12 patients (11.4%) a surgical revascularization was recommended because of multivessel disease. A total of 24 patients (22.9%) with restenosis were treated without intervention. In this conservatively treated group 6/24 patients presented uncertain symptoms and unclear ischemia. In 2/6 patients a PCI had to be performed due to new angina in the following weeks.

Conclusion: Treatment strategies of restenosis after corononary artery stenting are not standardized. The indication for re-intervention should include clinical, functional, morphologic and prognostic factors. In case of absence of angina or myocardial ischemia an observant regimen seems to be reasonable.

PRIMARY STENTING IN ACUTE MYOCARDIAL INFARCTION. PERCUTANEOUS CORONARY INTERVENTION VERSUS THROMBOLYSIS

2059 A cautionary tale for multivessel stenting during acute myocardial infarction: significant vasoconstriction of non-culprit lesions

C.G. Hanratty, Y. Koyama, H.H. Rasmussen, G.I.C. Nelson, P.S. Hansen, M.R. Ward. *Royal North Shore Hospital, Department of Cardiology, St Leonards, Australia*

Recently there has been a worldwide trend towards multivessel stenting in the setting of myocardial infarction, treating nonculprit lesions as well as the infarct-related lesion. However, not infrequently we noted that nonculprit lesion severity was significantly exaggerated by vasoconstriction at the time of infarction, raising the possibility that many non-culprit lesions may not need to be treated. In this retrospective study we identified all patients in our infarct interventional database who had a lesion of >50% stenosis (by operator report) in a non-infarct related artery and had additional angiography within 9 months of the index infarction. Angiographic stenosis was measured in each study by the QCA Medis system in orthogonal planes by operators blinded to study sequence. Patients (n=46) were excluded if matching angiographic views were not obtained or when coronary artery bypass grafting had been performed to the study vessel. Mean (SD) minimal lumen diameter of non-culprit stenosis(n=59) increased significantly from infarct angiography (I) to non-infarct angiography (NI) (I 1.53 (0.51) vs NI 1.78 (0.65) $P < 0.0001$) while % stenosis reduced (I 49.3 (14.5) vs NI 40.4 (16.6) $P < 0.001$). Reference diameter was not significantly different (I 3.1 (0.8) vs NI 3.0 (0.8)). Medications, hemodynamics, clinical status and demographics were compared between studies but did not influence non-culprit stenosis severity on multivariate analysis. 10/59 lesions were > 50% stenosis during the infarct study and < 50% at the non-infarct study [MLD 1.14 (0.37) mm vs. 1.76 (0.70) mm, $p<0.0001$, and % stenosis 61.1 (9.1) % vs. 38.0 (6.3) %, $p<0.0001$]. We conclude that clinically significant vasoconstriction is common in non-culprit lesions at the time of infarction and aggressive intracoronary vasodilator administration may be advisable prior to treating non-culprit lesions at the time of infarction.

2060 Randomised comparison of direct stenting and stenting after predilatation in acute myocardial infarction. In-hospital results of DIRAMI trial

M. Gasior, M. Gierlotka, A. Lekston, K. Wilczek, T. Zebik, J. Szkodzinski, R. Wojnar, L. Polonski. *Silesian Centre for Heart Disease, III Card. Dep. Silesian School of Med., Zabrze, Poland*

Background: Data on utilisation of direct stenting technique during immediate angioplasty in acute myocardial infarction (AMI) patients (pts) are limited. The aim of this on-going study is to evaluate feasibility, safety and effectiveness of direct stenting in AMI.
Methods: Consecutive pts with AMI were randomised before angiography to direct stenting (DS) or stenting after balloon predilatation (PS). Exclusion criteria were pulmonary oedema and cardiogenic shock. After coronary angiography pts were excluded if the operator decided not to perform angioplasty or stenting. TIMI flow grade 0 or 1 were not considered a contraindication for DS. One-year clinical and angiographic follow-up is pending. Analysis was performed on an intention to treat basis.
Results: Between Nov. 2000 and Sep. 2001, a total of 248 pts were randomised: 125 to DS and 123 to PS. After coronary angiography 31 pts were further excluded. Final study groups comprised 110 and 107 pts in the DS and PS groups, respectively. Cross-over to predilatation occurred in 13 (11.8%) in DS group (inability to cross the lesion with a stent - 7, uncertain guidewire placement - 4, lesion type - 2 pts). Except 2 pts (1 per group) the stents were successfully implanted. Procedural and clinical in-hospital outcome is summarised in the table.

In-hospital outcome

	DS (N=110)	PS (N=107)	P
TIMI flow grade 3, %	95.4	93.5	0.52
TMP* grade 2 or 3, %	81.3	76.2	0.41
MLD, mm (SD)	2.66 (0.41)	2.70 (0.52)	0.46
Additional stent(s), %	12.7	14.9	0.63
Side branch occlusion, %	2.7	3.7	0.72
Fluoroscopy time, min (SD)	12.2 (7.5)	14.9 (7.7)	0.011
Procedure time, min (SD)	59 (22)	72 (31)	0.0006
Reocclusion or reinfarction, %	1.8	2.8	0.68
Death, %	0	1.9	0.24

* TMP (TIMI Myocardial Perfusion) grade was accessible in 83% in DS group and 78% of pts in PS group.

Conclusions: Direct stenting during angioplasty for AMI is feasible, safe and effective in a majority of patients suitable for stent implantation. Follow-up data are required to define the usefulness of direct stenting technique in patients with AMI.

2061 Does plaque characteristics influence the late outcome after primary stenting for acute myocardial infarction?

R. Gil[1], A. Gziut[2], T. Pawlowski[2], R. Zurawski[2], T. Dryja[2], S. Ciuka[2], A. Krzywkowski[2]. [1]*Invasive Cardiology Department, Central Hospital of Internal Affairs, Warsaw, Poland;* [2]*Pomeranian Academy of Medicine, Cardiac Catherisation Laboratory, Szczecin, Poland*

Background: Previous studies have reported that acute myocardial infarction (AMI) is mainly associated with a soft plaque accompanying positive arterial remodeling. The aim of the study was to assess the relationship between ultrasonic features of the lesion and late outcome in patients with AMI undergoing primary angioplasty.
Methods: The study population consisted of 53 patients (12 F; 41M; mean age 55 y) with totally occluded infarction related artery. Intracoronary ultrasound was performed after predilation (4-6 atm) with a small balloon (1,5-2,0 mm) using 20 MHz electronic probe (Avanar, Jomed Inc). Ultrasonic images were recorded during automatic pullback manouever (speed 1,0 mm/sec) for their qualitative and quantitative assessment. Media to media diameter and total vessel area were calculated in the proximal and distal reference segments and also at the site of artery occlusion. Additionally, a remodeling index was calculated (total vessel areas at: occlusion site /average of prox and dist reference segments). Its value below 0,95 was the cut off for negative remodeling. Studied population was divided into 2 groups: Gr 1 with negative remodeling (35 patients) and Gr 2 with positive remodeling (18 patients) in examined arteries. During 6 months follow-up we recorded evidence of MACE (death, myocardial infarction, target vessel revascularisation).
Results: Stent was implanted successfully in every patient. The mean nominal stent diameter was 3,34±0,26 mm in Gr 1, and 3,86±0,51mm in Gr 2 ($p<0,05$). Mean stent area after intervention was 7,54±2,31 vs 8,56±2,98 mm^2, respectively Gr1 vs Gr2, p=NS. Calcific plaque (arc of calcium >180) was found in 74% and 33% of cases in Gr 1 and Gr 2, respectively ($p<0,05$). Remodeling index was significantly smaller in Gr 1 in comparison with Gr 2 (0,64±0,21 vs 1,12±0,11; $p<0,05$). Furthermore mean plaque burden at the occlusion site was significantly smaller in Gr1 than in Gr2 (59,2±12,3 vs 68,7±14,1 respectively, $p<0,05$). During follow up, the evidence of MACE was significantly higher in Gr1 than in Gr2 (28% vs 12% respectively, $p<0,05$). The strong correlations between remodeling index and MACE (r=0,79, $p<0,05$) and arc of calcium and MACE (r=0,61, $p<0,05$) were also found.
Conclusion: Negative remodeling with accompaning significant calcification is very frequent in AMI related artery. This plaque presentation is related with worse late outcome after primary stenting.

2062 Primary PTCA compared to early thrombolysis in patients with acute myocardial infarction: Results of the Berlin Myocardial Infarction Registry

B. Maier[1], R. Matteucci Gothe[2], A. Mohadjer[2], S. Rux[2] on behalf of Berlin Myocardial Infarction Registry. [1]*Berlin Myocardial Infarction Registry, Berlin, Germany;* [2]*Berliner Herzinfarktregister, Berlin, Germany*

Introduction: There is evidence that primary percutaneous coronary intervention (PCI) after acute myocardial infarction (AMI) is an alternative to early thrombolysis if performed in a timely fashion by experienced interventionel cardiologists in high volume centers. Since Berlin has many high volume centers with experienced personnel, the study compared in-hospital mortality of patients with AMI treated with primary systemic thrombolysis and primary PCI.
Methods and results: Using data from the Berlin Myocardial Infarction Registry on 2945 patients with acute myocardial infarction in 1999/2000, in-hospital mortality of patients treated with primary PCI compared to those treated with thrombolysis was examined. 59% of all patients received reperfusion therapy. Patients who received reperfusion therapy had a much lower unadjusted in-hospital mortality rate than patients who did not receive reperfusion therapy (8.6% versus 19.3%, $p<0.05$). Of those patients who did receive reperfusion therapy, 57% received intravenous thrombolytic therapy, 43% received primary PCI. Patient characteristics were similar in both groups (age, sex, diabetes mellitus, congestive heart failure etc.). Statistically significant differences between both groups were observed only for: diagnostic first ECG, time since onset of symptoms to hospital <3hours, on site facility for invasive cardiovascular procedures in the admitting hospital ($p<0.05$).
After adjusting for significant differences in baseline and clinical characteristics (age, sex, diabetes mellitus, hypercholesterinaemia, congestive heart failure/previous MI at admission, cardiogenic shock/heart failure at admission, pulmonary oedema, anterior MI), the difference in in-hospital mortality between the patients treated with PCI and those treated with thrombolysis was not significant anymore (OR=0.67, 95%CI:0.41-1.1). A different methodological approach (case control study with individual matching) revealed the same results.
Summary: The data of the Berlin Myocardial Infarction Registry from 1999 and 2000 show that after adjustment for confounding parameters the difference in in-hospital mortality between the patients treated with primary PCI and those treated with thrombolysis was not statistically significant.

2063 Reperfusion therapy with thrombolysis or primary PTCA for acute myocardial infarction in the real world: data from the nation-wide French USIC 2000 registry

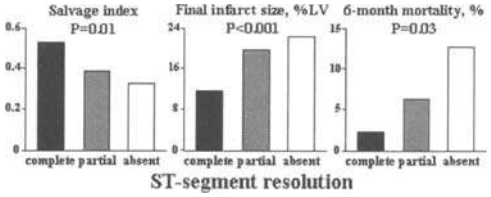
J.M. Lablanche[1], D. Blanchard[2], H. Ghobrial[3], G. Hanania[4], P. Gueret[5], J.P. Cambou[6], L. Vaur[3], N. Danchin[7] on behalf of the USIC investigators. [1]CHU Lille, Cardiologie, Lille, France; [2]Clinique St Gatien, Cardiologie, Tours, France; [3]Aventis, Paris, France; [4]Cardiologie, Aulnay sous Bois, France; [5]CHU Mondor, Cardiologie, Créteil, France; [6]Inserm U 518, Toulouse, France; [7]Cardiology Dept., Paris, France

Though randomised studies have shown that primary PTCA was superior to intravenous thrombolysis in patients with acute myocardial infarction, its applicability in everyday clinical practice may limit the extent of this beneficial effect. The nation-wide French USIC 2000 study is a registry which included all patients admitted to ICUs for AMI < 48 hours from symptom onset in November 2000. More than 80% of the ICUs in France participated in the study. Of the 2320 patients recruited, 974 had Q wave or ST segment elevation MI with reperfusion therapy with either primary PTCA within 24 hours of admission (group P, n=429) or thrombolysis (group T, n=545).
Baseline characteristics were quite similar for the 2 groups (age: 61 ± 14 vs 61 ±14; women: 23% vs 22%; hypertension: 38% vs 37%, current smoking; 24% vs 23%, history of CHF: 2% vs 2%). In Group P, however, diabetes mellitus (20% vs 14%, p=0.01), history of MI (17% vs 10%, p=0.0001), and history of PTCA (13% vs 6%, p=0.001) were more prevalent than in group T. More Group P patients had anterior myocardial infarction (46% vs 37%, p=0.002). A similar proportion of the patients (11% vs 12%) were referred from other institutions. In thrombolysed patients, 280 (51%) underwent subsequent PTCA within 24 hours. The in-hospital clinical course was similar in the 2 groups. Five-day mortality was 4.9% in group P vs 5.5% in group T (8.7% in patients with thrombolyis alone, 2.5% in patients with rescue PTCA). In both groups, 23% developed signs of heart failure. There was a trend to more intraventricular thrombus (1.2% vs 0.4%), but fewer incident strokes (0.2% vs 1.3%, p=0.07) in group P. Cumulative 5-day mortality or stroke was 4.9% in Group P vs 6.1% in Group T (p=ns). Using stepwise logistic regression analysis, mode of reperfusion therapy (thrombolysis or PTCA) was not an independent predictor of early outcome. In patients admitted within 6 hours of symptom onset, mortality was 4.7% in patients undergoing primary PTCA, vs 5.0% in patients treated with thrombolysis.
Conclusion: in this large "real world" registry, patients treated with intravenous thrombolysis or primary PTCA have quite similar baseline profiles. More than half of the patients treated with thrombolysis underwent rescue PTCA, which appears a safe procedure (5-day mortality: 2.5%). Early clinical outcome was not different with either mode of reperfusion therapy.

2064 Early ST-segment resolution correlates with myocardial salvage in patients with acute myocardial infarction treated with stenting or thrombolysis

G. Ndrepepa[1], J. Dong[1], A. Kastrati[1], J. Mehilli[1], S. Schmieder[1], M. Schwaiger[2], C. Schmitt[1], A. Schömig[1]. [1]Deutsches Herzzentrum, Cardiology Dept., Munich, Germany; [2]TU München, Klinik für Nuklearmedizin, Munich, Germany

Previous studies have shown that the degree of early ST-segment elevation resolution may predict final infarct size and clinical outcome in patients (pts) with acute myocardial infarction (AMI). Whether this parameter correlates with myocardial salvage determined by scintigraphy remains unknown.
Included in this study were 243 pts with AMI enrolled in the randomized STOPAMI 1&2 trials, which compared stenting with thrombolysis. Serial 12-lead ECGs were performed at baseline and after completing coronary stenting (n=122) or thrombolysis (n=121). ST-segment resolution was defined as complete (>= 70%), partial (< 70% to 30%) and absent (< 30%). Initial perfusion defect (area at risk) was assessed by Tc 99m sestamibi scintigraphy at baseline, final infarct size was assessed by a second scintigraphic study at 7-14 days and salvage index was the proportion of area at risk salvaged by reperfusion.
The ST-segment resolution was complete in 85 pts, partial in 80 pts and absent in 78 pts. The figure clearly shows that a higher degree of ST-segment resolution is associated with a greater salvage index, a smaller infarct size and a lower mortality at 6 months. The association between ST-segment resolution and myocardial salvage remained significant (P<0.01) after adjustment for other covariates. When stenting was compared with thrombolysis, it led to more ST-segment resolution (P<0.001), to a grater salvage index (P<0.001) and to a lower 6-month mortality (P=0.02).
Conclusion: The degree of early ST-segment elevation resolution on surface ECG correlates with myocardial salvage in scintigraphy in pts with AMI after reperfusion therapy. Therefore, ST-segment resolution may serve as a simple and useful means for comparing the efficacy of different reperfusion strategies.



PERCUTANEOUS CORONARY INTERVENTION IN ACUTE CORONARY SYNDROMES

2065 Intracoronary thrombus, distal flow and ischaemic events in non-ST-segment elevation acute coronary syndromes

P. Theroux[1], J. Nasmith[2], X.Q. Zhao[3]. [1]Montreal Heart Institute, Research Center, Montreal, Canada; [2]The Toronto Western Hospital, Acute Coronary Units, Toronto, Canada; [3]University of Washington, School of Medicine, Seattle, Canada

Introduction: Thrombus formation on an atherosclerotic plaque is a common finding in ACS. In this study, we correlated the severity of the thrombus with distal flow and adverse clinical outcomes.
Materials and Methods: The 1569 patients in the PRISM-PLUS who had coronary angiography 48 and 96 hours after initiation of antithrombotic therapy were studied. All angiographic data were centrally analyzed. Distal flow assessed by the TIMI flow grade and the corrected TIMI frame count (CTFC), and percent lumen diameter reduction (%LDR) by quantitative angiography.
Results: Thrombi were found in 674 patients (45%), normally distributed around a median of 50%LDR of the underlying plaque, half of them on stenoses 40% to 60%. Total %LDR of culprit lesions was 82% with thrombus and 78% without (NS); thrombi contributed to 31% of LDR, more so on more severe underlying stenoses. CTFC increased sharply with ^{3}75%LDR (slope=2.11) and less so when thrombi were present (slope=1.33). Matched for %LDR, thrombotic lesions had more TIMI grade 3 flow (73.4% vs. 45.7%, p<0.0001 for %LDM ^{3}75%). Death, MI, death/MI, and death/MI/refractory ischemia occurred more frequently with a thrombus (5.71% vs. 3.24%, p=0.034; 8.57% vs. 6.66%, p=0.221; 14.29% vs. 9.9%, p=0.021; 27.14% vs. 18.17%, p<0.0001), but could not be predicted by total % obstructive stenosis, % underlying stenosis, or CTFC.
Conclusions: In ACS thrombi frequently persist despite antithrombotic therapy, and contribute significantly to lumen diameter obstruction and strongly predict ischemic events. The thrombotic component, however, is less flow restrictive than plaques, supporting mechanisms other than flow obstruction to explain thrombi-associated ischemic events.

2066 Beneficial effect of first day PTCA for acute non-ST-segment elevation myocardial Infarction in clinical practice: results of the ACOS registry

A K. Gitt[1], M G. Gottwik[2], H. Wienbergen[1], R. Schiele[1], T. Heer[1], C. Meisenzahl[1], J. Senges[1] on behalf of the ACOS-Study-Group.
[1]*Herzzentrum Ludwigshafen, Cardiology, Ludwigshafen/Rhein, Germany;*
[2]*Cardiology, Klinikum Nürnberg Süd, Nürnberg, Germany*

Background: The VINO Study has reported a reduction in mortality and re-infarction by first day angioplasty (PTCA) in patients (pts) with acute coronary syndromes (ACS) without persistent ST-elevation. Data on the outcome of pts with non-ST-elevation myocardial infarction (NSTEMI) in clinical practice do not yet exist.
Methods: Since June 2000 consecutive pts with ACS have been enrolled into the ACOS-Registry (Acute Coronary Syndrome, 154 hospitals) in Germany. We analysed the impact of first day PTCA in patients with NSTEMI on hospital outcome.
Results: Out of 9065 consecutive patients with ACS, 3727 (41%) presented with NSTEMI, 880 of these patients (24%) received first day PTCA. Determinants in favour of first day PTCA were prior PTCA/CABG (OR 2,17; 1,68-2.81), age < 70 years (OR 2,10; 1,80-2,60) and male gender (OR 1,70; 1,31-2,10). Determinants against first day PTCA were diabetes mellitus (OR 0,77; 0,62-0,95) and prior myocardial infarction (OR 0,54; 0,42-0,70).

First day PTCA for NSTEMI

	NSTEMI with First day PTCA	NSTEMI without First day PTCA
n=	880	2847
Age (years)	64	71
Male Gender	78%	62%
Prior MI	16.0%	22.2%
Prior PTCA	18.4%	9.7%
Hypercholesteremia	54.5%	46.7%
Hypertension	66.4%	70.6%
Diabetes	25.0%	33.1%
Hospital mortality	0.9%	7.2%

p<0.01 for all parameters

After adjusting for differences in baseline characteristics and adjunctive therapy, first day PTCA in NSTEMI patients was associated with a 85% reduction of odds for hospital mortality (OR 0.15, 0.06-0.41).
Conclusion: Determinants for first day PTCA in acute NSTEMI were male gender, age < 70 years and prior PTCA or CABG. First day PTCA in acute NSTEMI was associated with a high 85% reduction of adjusted odds for hospital mortality. This high reduction might reflect an additional clinical selection bias for which we could not correct with the available parameters in the multivariate analysis.

2067 Clinical outcome of percutaneous coronary intervention in patients with non-ST-segment elevation acute coronary syndromes in catheterisation laboratory without on-site surgical back up

D. Dudek, T. Rakowski, J. Legutko, P. Turek, W. Mielecki, A. Dziewierz, S. Bartus, J S. Dubiel. *Institute of Cardiology, Jagiellonian University, Krakow, Poland*

Background: Percutaneous coronary interventions (PCIs) in patients (pts) with non ST elevation acute coronary syndromes (NSTE ACS) are recognized as interventions with high risk of adverse cardiac events. It could be important for catheterisation laboratories (cath-lab) without on site surgical back up. However, coronary stents and platelet glycoprotein IIb/IIIa receptor inhibitors improve safety of PCIs. The purpose of the study was to analyze the immediate and long term outcome of PCIs performed in cath-lab without on-site surgical back up in pts with NSTE ACS.
Methods: In a cohort of 479 consecutive pts (160 with NSTE ACS - group A, 319 with stable angina - group B) we analyzed short and long-term clinical outcome of PCIs performed in cath-lab located several kilometres from cardiac surgery department with effective transfer time < 30 minutes.
Results: Stent implantation rate (61,3% vs 50,2%; p= 0,04) and frequency of using IIb/IIIa blockers (17,5% vs 6,3%; p<0,001) was higher in group A. In hospital outcome was similar in both groups - A vs B: (death: 0,6 vs 0,6%; myocardial infarction: 2,5 vs 1,6%; urgent rePCI: 1,9 vs 1,3%). Acute PCI complications requiring urgent surgical operation occurred in 1 pt (0,6%) from group A and in 1 pt (0,3%) from group B. Those pts were successfully transferred for cardiac surgery. Kaplan Meier event-free survival was similar in both groups.
Conclusions: In the era of coronary stents and platelet glycoprotein IIb/IIIa receptor inhibitors there was no difference in short and long term outcome of PCIs between pts with NEST ACS and stable angina. The early aggressive approach to pts with ACS was feasible and safe in cath-lab without on site cardiac surgery. Surgical backup was still necessary for only few PCI complications.

2068 Angiographic and clinical outcomes after angioplasty in saphenous vein graft for acute myocardial infarction

L. leborgne, E. cheneau, A. ajani, D. cha, H. yazdi, A. pichard, L. satler, R. waksman. *washington hospital center, Medstar research institute, Washington, United States of America*

Objective: We compared in-hospital and six months outcomes of patients who underwent a primary percutaneous coronary intervention (PCI) of an acute myocardial infarction (AMI) related to a vein graft obstruction or a native artery.
Methods: From January 1994 to June 2001, 556 patients underwent a primary PCI in the first 24 hours of an AMI. In 52 patients the target vessel was an occluded saphenous vein graft (SVG) and in 504 patients it was a native artery (NA). All of them were prospectively enrolled in the cardiovascular research database. Myocardial infarction was confirmed by documented Creatine Phosphokinase-MB elevation. After discharge, clinical follow-up was performed via regular outpatient review and standardized telephone interview.
Results: There was no difference in patients demographic data between the two groups.In the SVG group the average graft age was 7.2 ± 5.4 years.
Respectively in the SVG group and in the NA group: Intra-aortic balloon pump was used in 29.7% vs. 28.1%, glycoprotein IIb/IIIa inhibitors and thrombolytics were respectively administered in 32.2% vs. 36.1% and 4.7% vs. 2.4%. At the time of the procedure, 43% of the grafts were totally occluded compared to 45% of the vessels in the NA group. During the procedure a distal embolization was observed in 18.6% vs. 4.2% (p<0.05). An Angiographic success (defined as a <50% diameter residual stenosis with TIMI flow grade 3) was obtained in 79,1% in the SVG group vs 91.6% in the NA group (p<0.05). A stent was implanted in 51.7% of SVGs vs. 43.6% of native arteries (p=NS).
In-hospital outcome and follow-up: Respectively in the SVG and NA groups, in-hospital mortality was 4.3% vs.3.1%. At six months, the mortality was 16.1% vs. 10.6% (p = NS) and the TLR-MACE (death, Q wave MI and TLR) was 42.9% vs 23.3% (p = 0.001). At one year, the mortality was 19.6% vs 13.6% (p = NS) and TLR-MACE was 51.1% vs. 29.6% (p = 0.003).
Conclusion: Primary PCI of AMI related to saphenous vein graft occlusion can be successful. Although, these patients are at high risk and have lower angiographic and clinical outcomes compared to patients with an acute infarct angioplasty on native artery.

2069 Primary PTCA in coronary artery bypass vein grafts in patients with acute myocardial infarction

U. Zeymer[1], A. Vogt[1], U. Tebbe[2], M. Weber[3], M. Gottwik[4] on behalf of the ALKK-Study Group.. [1]*Klinikum Kassel, Medizinische Klinik II, Kassel, Germany;* [2]*Klinikum Lippe-Detmold, Detmold, Germany;* [3]*Kreisklinik Dachau, Medizinische Klinik II, Dachau, Germany;* [4]*Klinikum Nürnberg, Medizinische Klinik 8, Nürnberg, Germany*

Percutaneous coronary intervention (PCI) in coronary artery bypass vein grafts has been shown to be associated with more adverse events compared to interventions in native coronary arteries.
Therefore we analyzed the outcome of patients with acute myocardial infarction treated with PCI within 24 hours after symptom onset. All consecutive interventions in 82 hospitals of the ALKK in Germany between 1992 and 2000 were prospectively recorded in a registry. Informations about in-hospital complications including death, re-myocardial infarction, urgent CABG, re-occlusion, and urgent re-PCI were available in more than 98% of the patients. During this period a total of 20,023 interventions were performed in patients with acute myocardial infarction within 24 hours after symptom onset. Of the latter 462 interventions were done in coronary artery bypass vein grafts. The in-hospital mortality rate was 13,8% compared to 8.7% in patients with PCI in native coronary arteries. TIMI 3 flow was achieved in 71,6% in vein grafts compared to 88.5% in native vessels. The use of stents was comparable with 53.1% versus 49.8%. Emergency surgery and re-PCI was necessary in 2.4% and 5.6% of the CABG patients.
Conclusion: Primary PCI in vein grafts in patients with acute myocardial infarction is associated with a lower procedural success rate and an increased in-hospital mortality rate compared to primary PCI in native vessels. Therefore the search for adjunctive therapies to improve outcome in these high risk patient group should be continued.

2070 Protect against reperfusion injury with ITF-1697 in acute myocardial infarction: PARI-MI trial

J. Vos[1], G.J. Laarman[2], H.R. Michels[3], A. Van 't Hof[4], M.L. Simoons[1], J.A. Kleijne[5], M. Ballabio[6], M. Sardina[6] on behalf of the PARI-MI investigators. [1]*Academisch Ziekenhuis Dijkzigt, Thoraxcentrum, Rotterdam, Netherlands;* [2]*Onze Lieve Vrouwe Gasthuis, Intervention Cardialogy, Amsterdam, Netherlands;* [3]*Catharina Ziekenhuis, Cathreine R&D, Eindhoven, Netherlands;* [4]*Isala Klinieken loc Weezenlanden, Cardiology, Zwolle, Netherlands;* [5]*Cardialysis, Clinical Trial management, Rotterdam, Netherlands;* [6]*Italfarmaco S.p.A, Milan, Italy*

Introduction: ITF1697 is a CRP-derived tetrapeptide which increases myocardial perfusion and reduces infarct size in various experimental animal models of ischemia and/or ischemia-reperfusion. It preserves the integrity of microcirculation and inhibits PMNs and platelet adhesion to the endothelium.
Objectives: To assess safety, preliminary efficacy and clinical outcome of prolonged i.v. infusion of ITF1697 in 4 dosages (0.1, 0.5, 1.0 and 2.0 μg/Kg/min),in pts with acute myocardial infarction(MI) eligable for primary PCI.
Methods: This was a randomised, double blind, multicentre, placebo-controlled, pilot, dose finding study.
After inclusion of 50 pts per group, an interim analysis was performed for safety and preliminary efficacy. Based on this analysis, 3 treatments (placebo and two active) were continued up to approx. 100 pts each. Safety was evaluated by incidence of bleeding, death, thrombotic events, serious adverse events (SAEs). Efficacy was measured by improved perfusion (TIMI-flow, TIMI frame count, Blush grade, ST-segment resolution) and reduced myocardial damage (enzymatic infarct size, left ventricular ejection fraction). Clinical outcome was assessed as measured by incidence of death, recurrent MI, recurrent ischemia and SAEs until discharge and 30-day follow-up. Analysis was performed in a central lab. Pts of both sexes with acute MI were enrolled if time from symptom onset was within 12 hrs, ST-segment elevation more than 0.2mV in two or more contiguous leads and sum of ST elevation more than 10mm. Planned use of thrombolytic agents was not allowed. I.V.infusion was started before procedure up to 24 hrs. Pts were followed until 1 month after treatment.
Results: Between Jan. 2001 and Dec. 2001, 11 sites enrolled 402 pts. Interim analysis did not evidence any safety concerns. Baseline characteristics were similar within the groups.
Data entry and statistical analysis is ongoing. Final data will be presented at the ESC meeting in Berlin 2002.

GENETICS OF DILATED CARDIOMYOPATHY

2071 Lamin A/C mutation in a family with dilated cardiomyopathy and conduction disease

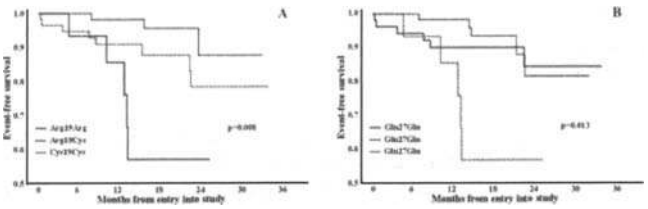
A. Perrot[1], J. Genschel[2], H.H.J. Schmidt[2], C. Özcelik[1], K.J. Osterziel[1]. [1]*Charité/Campus Buch & Virchow-Klinikum, Kardiologie, Berlin, Germany;* [2]*Charité, Campus Mitte, Gastroenterol., Hepatol. & Endokrinol., Berlin, Germany*

Dilated Cardiomyopathy (DCM) is a heart muscle disease characterized by left or biventricular dilatation and is a frequent cause of heart failure. Probably more than 25% of DCM cases are of familial ethiology. Mutations in the gene for lamin A/C were described for autosomal dominant DCM. We aimed to analyze this gene in a large kindred with DCM.
Methods: A large family comprised of 40 members was evaluated by physical examination, ECG, echocardiography, and heart catheterization according to WHO criteria. DNA was extracted from blood lymphocytes. We screened all 12 coding exons of the lamin A/C gene (LMNA) using polymerase chain reaction and direct automated sequencing with fluorescent dyes.
Results: We report here a three generation family with autosomal dominant familial DCM. In 20 out of 40 family members, we detected a heterozygote deletion of adenine at position 1397 in exon 8 of LMNA. The mutation is predicted to lead to a frameshift with a premature stop codon at position 479 and therefore to a truncated protein. Course and severity of the disease showed a great variability in the group of the family members with the mutation. Disease manifestation in this family began in adolescence with sinus or atrioventricular node dysfunction. Later these individuals showed a mild dilatation of the left ventricle, an impaired systolic function, and malignant tachyarrhythmias. The endstage of the disease manifested clinically as overt congestive heart failure.
Summary: We identified a mutation in the lamin A/C gene (1397delA) in a three generation family with autosomal dominant DCM characterized by ventricular dilatation, impaired systolic function, and conduction disease.

2072 β2-Adrenergic receptor gene polymorphisms are genetic susceptibility factors to idiopathic dilated cardiomyopathy

C. Forleo[1], P. Guida[1], S. Sorrentino[1], R. Romito[1], N. Resta[2], G. Guanti[2], P. Rizzon[1], M.V. Pitzalis[1]. [1]*University of Bari, Institute of Cardiology, Bari, Italy;* [2]*Human genetics, University of Bari, Bari, Italy*

Abnormalities of the beta-adrenergic pathway have been described in idiopathic dilated cardiomyopathy (DCM), some of them related to beta 2-adrenergic receptor (beta 2-AR) polymorphisms. We sought to assess whether functionally relevant polymorphisms in the beta 2-AR gene have a role in favouring DCM susceptibility or in modifying its evolution.
A total of 132 unrelated patients (pts) with DCM (WHO criteria) and 180 unrelated controls were included in an association study. Alleles and genotypes frequencies of the 5'leader cistron (LC) Arg19Cys, Arg16Gly, Gln27Glu, and Thr164Ile polymorphisms in the beta 2-AR gene were compared between pts and controls. The Gly16 allele (68% vs 56%, $p<0.005$) and the Gly16Gly genotype (48% vs 32%, $p<0.02$) frequencies were significantly higher in pts when compared with controls. Linkage disequilibrium among beta 2-AR polymorphisms was observed ($p<0.0001$). The pts were prospectively followed up for a median period of 17 months. Kaplan-Meier survival curves showed that pts who were homozygous for both of the 5'LC-Arg19 and the Glu27 alleles had a significantly higher risk to experience hospitalisation for heart failure (HF) in comparison with those carrying the other genotypes (RR=4.78, $p<0.005$) (Figure). After adjustment for age, NYHA functional class, and left ventricular ejection fraction the predicting value to HF events according to 5'LC-Arg19Arg and Glu27Glu genotypes remained significant with a relative risk of 3.57 ($p<0.05$).



In conclusion, our data show that the Gly16Gly genotype of the beta 2-AR gene confers an increased genetic susceptibility to develop DCM. Moreover, homozigosity for 5'LC-Arg19, Gly16, and Glu27 alleles allows to identify a subgroup of DCM patients at higher risk of HF worsening.

2073 Absence of mutation in 4 candidate genes in a large European population of dilated cardiomyopathy

E. Villard[1], N. Sylvius[1], L. Duboscq-Bidot[1], C. Bouchier[1], P. Sébillon[1], P. Charron[2], R. Isnard[2], M. Komajda[2]. [1]*Association C. Bernard, Pitié-Salpêtrière Hospital, Paris, France;* [2]*Pitié-Salpêtrière Hospital, Cardiology, Paris, France*

Dilated cardiomyopathy (DCM) is a chronic disorder of the heart muscle mainly characterised by ventricular dilatation and impaired systolic function. It is a heritable disorder in 25-30% of the cases, mainly transmitted as an autosomal dominant disease with incomplete penetrance. To date, 9 genes encoding cytoskeletal, contractile and nuclear inner membrane associated protein have been found mutated in this disorder. However, no major gene or mutation responsible for the disease has been identified, each mutation being found at best in a few family only, underlying the genetic heterogeneity of DCM.
As several other morbid genes has to be identified, we have screened a population consisting on 100 independent familial and sporadic cases for mutation in 4 candidate genes potentially involved in DCM: 1) beta-sarcoglycan and delta-sarcoglycan genes, encoding members of the dystrophin-associated protein complex, the later being previously implicated as a morbid gene in DCM and 2) phospholamban and the alpha-B56 subunit of protein phosphatase 2A (PP2AB56alpha) genes encoding proteins involved in the cardiac Ca^{2+} signalling pathway and located in DCM chromosomal loci identified by linkage analysis.
No deleterious mutations have been found in any of the 4 genes by PCR-SSCP and sequencing analysis. Then, in this rather large population of DCM patients, none of these gene could be considered as responsible for the disease.
Three strong candidate genes, beta-sarcoglycan, phospholamban and PP2AB56alpha, have been excluded for a role in familial DCM in our study. However, given the marked heterogeneity observed in familial DCM and the 70-90% power of mutation detection of PCR-SSCP, further screening might be needed on additional subjects before definitive exclusion of these three genes. Finally, this study confirm the previously reported low frequency of mutations in the delta-sarcoglycan gene as disease causing in familial DCM.

2074 Mutational analysis of lamin A/C gene in dilated cardiomyopathy without conduction defect and without skeletal muscular dystrophy

P. Charron[1], C. Bouchier[2], L. Dubosq-Bidot[2], G. Bonne[3], A. Millaire[4], A. Benaiche[1], K. Schwartz[3], M. Komajda[2]. [1]*Pitié-Salpêtrière Hospital, Cardiology Dept., Paris, France;* [2]*Hopital Pitie-Salpetriere, Ass. Cl. Bernard, Genetics Lab., Paris, France;* [3]*Hopital Pitie-Salpêtrière, INSERM U523 Dept., Paris, France;* [4]*Hopital Cardiologique, Cardiology Dept., Lille, France*

Aims: About 25% of idiopathic dilated cardiomyopathy (DCM) are familial with a large predominance of autosomal dominant transmission. The lamin A/C (LMNA) gene has been reported in familial DCM associated with conduction-system disease or skeletal muscle dystrophy. However, the involvement of the LMNA gene in patients with DCM without conduction defect and without skeletal muscle dystrophy, which are by far the large majority of cases, is unknown. Therefore, we performed a mutational analysis of the LMNA gene in such families.
Methods: We analysed the coding sequence of the LMNA gene in a Caucasian population of 35 independent probands with familial DCM and 17 sporadic cases, using a systematic PCR/SSCP/Sequencing methodology.
Results: (1) A new mutation (Glu161Lys) was identified in the alpha-helical rod domain of the lamin A/C in one family with a particular phenotype characterised by early atrial fibrillation without (3 among 5 adults) or with (2/5 adults) dilated cardiomyopathy, without conduction defect or skeletal muscle myopathy. (2) No mutation in the LMNA gene was found in other familial or sporadic cases with pure form of DCM. (3) Finally, new polymorphisms in the LMNA gene were identified in this study.
Conclusion: A specific phenotype characterised by early atrial fibrillation with or without DCM is associated for the first time with the LMNA gene. Conversely, mutations in the LMNA gene appear as a rare cause of isolated and classical DCM without significant conduction defect, skeletal muscle dystrophy, or early atrial fibrillation.

2075 A novel lamin A/C mutation (TRP190ARG) associated with familial dilated cardiomyopathy

L. Monserrat[1], M. Hermida[2], S. Barral[2], R. Laredo[2], B. Bouzas[1], M.G. Crespo[1], J. Muñiz[2], A. Castro-Beiras[1]. [1]*Hospital Juan Canalejo, Cardiology, A Coruña, Spain;* [2]*Universidad de A Coruña, Instituto Ciencias da Saude, A Coruña, Spain*

Background: Mutations of LMNA A/C gene, encoding lamin A/C, have been identified as causes of familial dilated cardiomyopathy (DCM). Our objective was the identification of LMNA A/C gene mutations in patients with familial DCM.
Methods and Results: After informed consent, genomic DNA of patients with familial DCM and of their relatives was isolated from frozen blood samples and coding regions of lamin A/C gene were PCR amplified, studied by SSCP and cycle sequenced.
A new mutation (Trp190Arg) was identified in exon 3 in two cousins with idiopathic DCM: a male that required cardiac transplant at age 45 years (left ventricular end diastolic diameter (LVEDD) 55 mm, ejection fraction 14%, right ventricular dilatation), and a 46 years old female with dyspnea, LVEDD of 59 mm and ejection fraction of 49%. Both of them had abnormal ECGs with very low voltages. Their mothers had died of cardiac causes in their forties. The Trp190Arg mutation was also present in the 19 years old son of the affected male, who had a normal echocardiography (LVEDD 46 mm, ejection fraction 58%) and a pathologic ECG with left ventricular hypertrophy and repolarization abnormalities. One of the 23 years old twin sons of the affected female, who also carried the mutation, had a normal echocardiography (LVEDD 55 mm with a body surface of 2 m^2, ejection fraction 62%) and a borderline ECG. His twin brother was completely normal. None of the affected patients had conduction system defects, signs of skeletal myopathy or lypodistrophy.
The mutation was confirmed by RFLP with Tha1. It was not present in more than 100 healthy controls and it affects a highly conserved region identical in Xenopus laevis, Gallus gallus, Rattus norvegicus and humans.
Conclusions: The Trp190Arg mutation in exon 3 of the LMNA A/C gene is associated with a severe form of familial DCM. The phenotype of this family suggests an electrocardiographic progression from an initial pattern of left ventricular hypertrophy towards very low voltages in the late stages of the disease.

2076 Mutations in dystrophin and lamins genes in patients with dilated cardiomyopathy

J. Toman[1], L. Fajkusová[2], Z. Lukás[3], S. Voháòka[4], P. Hude[1], L. Spinarová[1], M. Vytopil[4]. [1]*St. Anna's University Hospital, 1st Dept. of Medicine, Brno;* [2]*Research Institute of Child Health, Dept. of Genetics, Brno;* [3]*Masaryk University, Institute of Pathological Anatomy, Brno;* [4]*Masaryk University, Neurological Dept., Brno, Czech Republic*

Background: Mutations of dystrophin gene may cause Becker and Duchenne muscular dystrophy (BMD/DMD) and simultaneously dilated cardiomyopathy (DCM). One of the forms of Emery-Dreifuss muscular dystrophy (EDMD) is autosomal dominant one due to mutations of A/C lamins gene, and these patients may also suffer from AV blocks and/or DCM.
Aim: To detect mutations in genes for dystrophin and A/C lamins in patients with DCM and compare them with neurological and histopathological findings.
Patients and methods: We examined 37 pts with DCM (left ventricular dilatation with ejection fraction below 45%, coronary heart disease and acute myocarditis excluded), age 43.6±9.1 years, LVEF 28.4±8.8%, and 13 pts with permanent pacemakers for AV blocks, age 37.1±12.0 years. Clinical cardiological and neurological examination, electromyography (EMG), and evaluation of m. vastus lateralis biopsy for histology, histochemistry, and imunohistochemistry were performed. Genetic analyses consisted of detection of dystrofin gene mRNA expression from Pm, Pb a Pp promotors by means of reverse transcription, polymerase chain reaction (PCR) and DNA sequence analysis, and of analysis of muscle biopsies for mutations of A/C lamins gene by means of amplificated PCR, denaturating high-performance liquid chromatography (DHPLC) and sequence analysis.
Results: Neurological clinical signs of myopathy were found in 3 pts, EMG had myogenic picture in 20 pts, myogenic finding in muscle biopsy was detected in 8 pts. Genetic analyses: we found mRNA transcript from Pm promotor with deletion of exon 2 in 1 pt, mRNA transcript from Pb promotor with insertion of a part of the first intron in 1 pt, and mRNA transcript from Pm promotor with deletion of exon 3 and parts of exons 2 and 4 in 1 patient. Two mutations of A/C lamin gene were detected: in 1 pt with DCM and in 1 pt with pacemaker.
Conclusion: We detected mutations in dystrofin and lamins genes in several patients with DCM or AV blocks. It seems useful to broaden the spectrum of examinations for mutations of other cell proteins, to evaluate also relatives of our patients and to create the register of patients with DCM, BMD/DMD and EDMD in our area.

RESULTS FROM RECENT CLINICAL TRIALS: IMPLICATIONS FOR DRUG THERAPY IN PRACTICE

2077 Does carvedilol prevent and reverse cardiac cachexia in patients with severe heart failure? Results of the COPERNICUS study

S.D. Anker[1], A.J.S Coats[1], E.B. Roecker[2], A. Scherhag[3], M. Packer[4]. [1]*Royal Brompton Hospital, London, United Kingdom;* [2]*University of Wisconsin, Wisconsin, MD, United States of America;* [3]*F. Hoffmann-La Roche Ltd., PBA, Cardiovascular, Basel, Switzerland;* [4]*NYPH College of Physicians and Surgeon, Center for Heart Failure Research, New York, NY, United States of America*

In end-stage heart failure (HF), cachexia is common, is associated with increased morbidity, and fails to respond to conventional therapy. In a prespecified analysis of the COPERNICUS trial, we evaluated the impact of body mass index (BMI) on survival and the effects of placebo (PBO) and carvedilol (CRV) on the development of cachexia (weight loss => 6% during follow-up) in 2262 patients with no baseline edema.
There was a highly significant decrease in mortality with increasing BMI ($P<0.0001$). For each 1.0 unit increase in BMI, the risk of death decreased by 7.7%. Annual mortality rates for PBO and CRV in each BMI category are shown in the table. Baseline values for BMI did not influence the benefits of CRV on survival (P=0.97).

	Annual PBO mortality rate	Annual CRV mortality rate
BMI < 22 (n=279)	29.4%	20.8%
BMI 22 to < 25 (n=567)	25.2%	18.4%
BMI 25 to < 30 (n=932)	19.4%	10.3%
BMI => 30 (n=484)	8.0%	6.7%

During follow-up, 14.1% of PBO patients and 10.2% of CRV patients developed cachexia (P=0.005). CRV (but not PBO) patients showed a significant increase in weight, which was not related to fluid retention. Mean changes in weight in the CRV and PBO groups were +0.5 vs -0.1 kg (P=0.0002) after 4 months, +0.9 vs -0.1 kg (P<0.0001) after 8 months, and +1.1 vs +0.2 kg (P<0.0002) after 12 months of maintenance therapy.
Conclusion: In severe HF, CRV increases body weight and reduces the incidence of new cachexia. Given the association of body mass and survival, prevention and reversal of cachexia may contribute to the benefits of CRV in patients with severe HF.

2078 Betablockers use in severe and old patients with heart failure. Data from BRING-UP 2 study

S. Di Luzio, M. Gorini, C. Opasich, M. Porcu, L. Tavazzi, A.P. Maggioni on behalf of BRING-UP Investigators. *ANMCO Research Center, Florence, Italy*

Objective: To analyze the change in betablockers use in severe patients with heart failure (HF), and in those aged 70 years and more, before and after the COPERNICUS study.
Method: We compared the rate of prescription of BB in the BRING-UP 1 study (Betablockers in patients with congestive heart failure. Guided use in clinical practice) (year 1998-1999) and in the BRING-UP 2. These studies are observational, multicentric and have the aim to monitor and implement BB use in HF pts over the whole Italian Country. While BRING-UP 1 focussed the attention on all out-patient with HF and was conducted before the presentation of the COPERNICUS results, BRING-UP 2 has the aim to evaluate the applicability, the safety profile and the associated outcome of BB treatment in specific soubgroup of patients with HF, for whom there was evidence of undertreatment with BB (pts in NYHA class III and IV and patients aged 70 years or more).
Results: The results reported in the table show the rate (a) of patients already on treatment at the baseline visit of the two studies, (b) of those in whom treatment was started and (c) of those for whom the BB treatment was not prescribed.

Table: Use of betablockers in BRING-UP 1 and 2

	BRING-UP 1 NYHA III-IV (1063 pts)	BRING-UP 2 NYHA III-IV (1267 pts)
Already on betablockers	19%	33%
Started on betablockers	23%	30%
No betablockers p<0.001	58%	37%
	BRING-UP 1 (pts >70 years: 1024)	BRING-UP 2 (pts >70 years: 1529)
Already on betablockers	18%	33%
Started on betablockers	21%	28%
No betablockers p<0.001	61%	39%

Conclusion: In the last two years, in Italy significant increase in BB use in out-patients with severe heart failure and in the older age vas observed. This relevant changes could be due (a) to the intensive educational and research programs adopted by the National Societies of Cardiologist, and (b) by the results of RCTS, such as COPERNICUS, which seem to be well accepted and incorporated in real world clinical practice.

2079 Prescription of betablockers in patients with heart failure in different clinical settings: data from the TEMISTOCLE study

M. Ceseri, M. Annicchiarico, M. Cafiero, R. Lavecchia, A.M. Paci, G. Orsini, M. Scherillo, A.P. Maggioni on behalf of TEMISTOCLE Investigators. *ANMCO Research Center, Florence, Italy*

Background: The survival benefit due to beta-blocker treatment in patients with heart failure (HF) has been established by recent trials. However, the current use of this treatment in clinical practice is not well know.
Aims: To compare the rate of prescription at hospital discharge of beta-blockers in patients admitted for HF in Internal Medicines (IM) or in Cardiology (C) Departments.
Methods and Results: From 14 to 25 February 2000 baseline data from 2127 patients with CHF referred to 417 hospitals (250 IM and 167 C) were collected. Even if C prescribe beta-blockers more frequently than IM (17.8%. and 8.7%, p<.001), the largest part of the study population (82.9%) was not prescribed on beta-blockers. Table shows main contraindications and/or adverse reactions due to beta-blockers.

	IM (%)	C (%)
COPD	41.0	35.9
Diabetes	7.1	3.6
PVD	1.6	1.0
AVB >=2° or HR <50 BPM	2.4	6.0
Hypotension	4.5	12.0

A large number of patients were not prescribed on beta-blockers because of advanced age and HF severity. Among the different betablocker agents, carvedilol was the most used in both settings (76.0% in IM and 77.4% in C), followed by metoprolol (9.0% in C vs 6.4% in IM) and by atenolol (9.2% in IM vs 3.0% in C). For 12.2% of the pts (10.0% in IM vs 16.3% in C), there were no specific reasons for not prescribing betablockers.
Conclusions: The rate of patients treated with beta-blockers is rather low, particularly in patients admitted to IM. Age and advanced HF were still considered by participating doctors uncertain indications. Nationwide programs to narrow the gap between research and practice should be implemented.

2080 Randomised, double-blind, placebo-controlled study of carvedilol in heart transplant candidates: results from the EFICAT-multicenter-trial

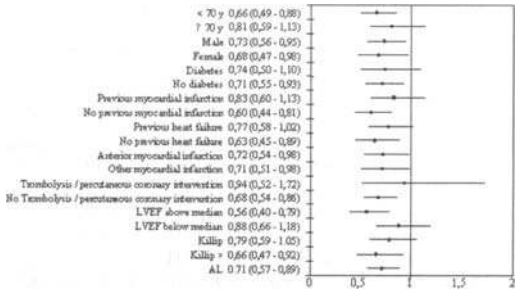
C.E. Angermann[1], A. Costard-Jaeckle[2], M.C. Deng[3] on behalf of EFICAT-Trial Study Group. *[1]Med. Poliklinik, Universität Würzburg, Cardiology, Würzburg, Germany; [2]Christian-Albrechts-University, Clinic for Cardiothoracic Surgery, Kiel, Germany; [3]Columbia University College, Heart Failure Center, New York, United States of America*

Background: In patients with severe heart failure (CHF) and in heart transplant candidates (HTC) the COPERNICUS- and EFICAT-Trial showed improvement of survival and pump function with Carvedilol (C). It remained to be analysed, however, whether the effect of C on ejection fraction (EF) depends on CHF etiology and, whether C influences left ventricular (LV) remodelling in HTC.
Methods: The study was designed as a randomised, double-blind, placebo(P)-controlled trial and conducted in 3 German transplant centers. Study duration was 12 months. HTC with cardiomegaly and advanced LV systolic dysfunction were eligible. Endpoints were the absolute changes from baseline to the latest available measurements of LVEF (radionuclide ventriculography) and LV end-diastolic and endsystolic dimensions (EDD, ESD, echocardiography), respectively, in C- and P-treated HTC.
Results: The trial prospectively randomized 118 HTC with end stage CHF of ischemic (I, n=44) or non-ischemic (NI, n=74) etiology, a mean ± SD (median) age of 53.3±9.8 (55.5) years and a mean LVEF at baseline of 19.9±6.6 (20.1)% with a change of +6.0±9.3 (+3.9)% in the C-treated and +0.7±7.1 (0.0)% in the P-treated group (p<0.008, Wilcoxon two-sided test). In the subgroups, the change in LVEF was in HTC-I +5.2±7.0 (+4.0)% in the C-treated vs. -5.3±6.8 (-5.5)% in the P-treated group (p<0.03); in HTC-NI the change in LVEF was +9.9±11.6 (+8.0) % in the C-treated vs. +2.7±7.6 (0.0)% in the P-treated group (p<0.04). The mean EDD and ESD at baseline were 73.8±8.2 (74.0)mm and 64.7±9.0 (64.0) mm in the C-treated and 75.8±9.1 (74.0) and 66.3±10.0 (66.5)mm in the P-treated group (all NS), with a change of -0.9±7.6 (-1.0) and -3.7±8.9(-2.5)mm in the C-treated and of +1.8±6.9 (1.0) and +0.1±7.4 (-1.0) mm in the P-treated group. In the subgroups, the changes in EDD were in HTC-I +2.3±8.6 (+1.0)mm in the C-treated and +4.3±6.3 (+4.0)mm in the P-treated group, in HTC-NI -3.0±6.2 (-3.0)mm in the C-treated and +1.1±7.1 (+1.0)mm in the P-treated group. The changes in ESD were in HTC-I +0.4±9.7 (0.0)mm in the C-treated and +2.7±8.6 (+2.0)mm in the P-treated group, in HTC-NI -6.1±7.5 (-5.0)mm in the C-treated and -1.2±7.3 (-2.0)mm in the P-treated group.
Conclusion: Even in HTC with end stage heart disease pharmacological therapy with C improves significantly LVEF over a prolonged period of time irrespective of CHF etiology. While the decrease in mean ESD probably reflects improved LV performance, the concomitant decrease in mean EDD observed only in HTC with NI-CHF suggests that reverse remodelling might be inducible by C-treatment.

2081 Effect of carvedilol on mortality and reinfarction in left ventricular dysfunction after infarction. A subgroup analysis from CAPRICORN study

J. Lopez-Sendon Hentsch[1], H. Dargie[2], W. Remme[3], N. Sharpe[4], W.S. Colucci[5], I. Ford[2] on behalf of the CAPRICORN Investigators and Committees. *[1]Hospital Gregorio Marañon, Cardiology, Madrid, Spain; [2]Glasgow, United Kingdom; [3]Amsterdam, Netherlands; [4]Auckland, New Zealand; [5]Boston, United States of America*

The long term clinical efficacy of carvedilol in patients with left ventricular dysfunction following acute myocardial infarction (AMI) was investigated in a double-blind randomised placebo controlled trial. 1959 patients with AMI and left ventricular ejection fraction (LVEF) of < 40% were included in 163 centres in 17 countries and randomly assigned to receive either carvedilol or placebo. 47% were treated with thrombolytics or primary percutaneous interventions and 97% with ACE inhibitors. Mortality or nonfatal reinfarction was analysed in subgroups by demographics, previous history and clinical profile of the patients.
Findings Carvedilol reduced all cause mortality by 23%, HR 0.77 (95% CI 0.60–0.98), p = 0.03 and non fatal myocardial infarctions by 41%, HR 0.59 (0.39 – 0.90), p = 0.01 and all cause mortality or non fatal MI by 29%, HR 0.71 (0.57 – 0.89), p = 0.002. The analysis showed a consistent positive trend in the reduction of reinfarction and all cause mortality or reinfarction in all subgroups by age, gender, previous history of diabetes, infarction, or heart failure, AMI location, revascularisation therapy, LVEF, and Killip class (Figure).



Mortality and reinfarction HR (95% CI).

Conclusions Carvedilol reduces mortality and nonfatal reinfarction in patients with left ventricular dysfunction or failure after AMI. Consistent positive trends were observed in all subgroups.

2082 Efficacy and safety of carvedilol in patients with low systolic blood pressure in the COPERNICUS study

J.L. Rouleau[1], H. Krum[2], H.A. Katus[3], A.J.S Coats[4], M. Tendera[5], P. Mohacsi[6], E.B. Roecker[7], M. Packer[8] on behalf of the COPERNICUS Study Group. *[1]Mount Sinai Hospital, Toronto, Canada; [2]Monash University, Clinical Pharmacology Medicine Dept., Prahran, Australia; [3]Lubeck University, Cardiology Dept., Luebeck, Germany; [4]Royal Brompton Hospital, Cardiology Dept., London, United Kingdom; [5]Silesian School of Medicine, Cardiology Dept., Katowice, Poland; [6]University Hospital Bern, Cardiology Dept., Bern, Switzerland; [7]University of Wisconsin, Madison, United States of America; [8]Columbia Presbyterian Medical Center, Circulatory Physiology, New York City, United States of America*

Background: Since survival trials with metoprolol and bisoprolol excluded patients with a systolic blood pressure (SBP) < 100 mm Hg, many physicians are reluctant to use beta-blockers in such patients, especially those with a vasodilatory effect.
Methods: We evaluated the effects of carvedilol (CRV) vs placebo (PBO) in 2289 patients with severe heart failure (HF) in the COPERNICUS study, of whom 132 had a SBP < 96 mm Hg and 264 had a SBP of 96-105 mm Hg at the time of randomization. Following initiation of treatment, SBP increased (CRV>PBO) in the patients with low SBP and fell transiently (CRV>PBO) in the patients with higher SBP.

	All-cause Mortality		Death or HF Hospitalization	
	1-year PBO rate	Hazard ratio (CRV:PBO)	1-year PBO rate	Hazard ratio (CRV:PBO)
< 96 mm Hg	34%	0.77	61%	0.74
96 - 105 mm Hg	25%	0.61	43%	0.75
106 - 115 mm Hg	18%	0.65	37%	0.78
116 - 125 mm Hg	17%	0.61	40%	0.54
> 125 mm Hg	15%	0.60	32%	0.68

Results (see table): Patients with low baseline SBP were at extremely high risk of a major clinical event, the magnitude of risk decreasing with increasing SBP. However, CRV decreased the risk of death and of death or HF hospitalization in all SBP subgroups, the magnitude of benefit being independent of SBP (interaction P=0.64 and P=0.80 for mortality and for death or HF hospitalization, respectively). The rate of permanent withdrawal decreased with increasing baseline SBP (P=0.0001), similarly for PBO and CRV (interaction P=0.25). Hypotension was reported as an adverse effect more with CRV than PBO overall; this difference was not accentuated in the low SBP subgroups.
Conclusions: These results provide the first evidence that CRV is effective and well tolerated in patients with severe HF and a low SBP.

FROM PERFUSION ASSESSMENT TO CLINICAL DECISION MAKING: THE ROLE OF CONTRAST ECHOCARDIOGRAPHY

2099 Is myocardial perfusion by echocardiography useful to select patients with chest pain for an early discharge in the emergency department?

A. Moraes, M. Carrinho, C. Medeiros, F. Morcerf, F. Salek, A.C. Nogueira, R. Morcerf, H. Dohmann. *Hospital Pro-Cardiaco, Echocardiography Dept., Rio de Janeiro, Brazil*

Background: We previously showed that myocardial perfusion is accurately assessed by Adenosine Contrast Echocardiography (ACE) with PESDA in pts with stable coronary artery disease (CAD). However its utility for pts undergoing a rapid evaluation for possible ischemia in a Chest Pain Center (CPC) has not yet been evaluated. Accordingly, we assessed the ability of ACE to determine the perfusion patterns of these pts to identify those with low-risk CAD for an early and safe discharge.
Methods: 75 pts (53 male, 59±14, 28-90 years) were admitted to a CPC to investigate possible ischemia due to CAD. First ECG and initial CK-MB were non-diagnostic. According to the chest pain characteristics 3 groups were formed: A- typical angina: 11 pts; B- suggestive of angina: 33 pts; and C- non-suggestive of angina: 31 pts. ACE with triggered (1:1) 2nd harmonic imaging, was visually assessed (2 independent investigators), at rest and after IV injection of adenosine (ADN), using PESDA, continuously infused at 1-2ml/min. Myocardial perfusion was defined as normal (negative for ischemia) or abnormal (reversible or fixed defects-positive). Coronary angiography (ANG) was obtained in 27 pts (in 11/11, 12/33 and 4/31 pts from groups A, B, and C respectively) within 48 hours from ACE. For each patient 3 LV territories (related to right coronary, circumflex and left anterior descending arteries) were considered.
Results: 81 territories were analyzed in pts with ANG with 33 related to coronary artery with obstruction >75% (all but one with abnormal perfusion); and 48 territories supplied by normal or no flow limiting (<75%) coronary artery (46 with normal perfusion). The sensitivity was 97%, the specificity was 95.8% and the global accuracy was 96.3%. Regarding to the 48 pts with no ANG, ACE was negative in 42 (15 and 27 in groups B and C respectively) that were discharged within 48 hours, and positive in 6 (all in group B) that were moved to a Coronary Care Unit for additional investigation.
Conclusion: ACE with PESDA is an accurate method to study myocardial perfusion in pts admitted to a CPC to elucidate the etiology of a chest pain providing useful informations for a safe and early discharge.

2100 Feasibility and diagnostic accuracy of real-time myocardial contrast echocardiography in detecting stress-induced perfusion defects

E. Dubart, K.G. da Silva, A. Hansen, G. Korosoglou, M. Rosenberg, N. Ferrari, J. Zehelein, H. Kücherer. *University of Heidelberg, Cardiology Dept., Heidelberg, Germany*

Background: Real-time myocardial contrast echocardiography (MCE) is discussed as a useful adjunct to stress testing but little is known about its feasibility and diagnostic accuracy.
Aim: We tested agreement between real-time Power Pulse Inversion imaging and 99mTc-Sestamibi-SPECT in evaluating myocardial perfusion on a segmental level. Methods: MCE (Optison, 8-10 ml/h) was performed at rest and during peak dipyridamole stress in 70 unselected patients (mean age: 63+9 years; 54m, 16f, 25 anterior-, 10 inferior-, and 11 lateral infarcts, 10 single-,32 multi vessel disease) with angiographically proven coronary artery disease undergoing SPECT imaging for clinical reasons. From apical four- and two chamber views and comparable SPECT views, 12 myocardial segments were scored for regional opacification/uptake by two pairs of blinded observers (0= absent, 1= mildly reduced, 2 = severely reduced, 3= normal). Ischemic segments by either method were defined as the difference of 1 grade between stress and rest images. 4 patients were excluded from the study due to really poor echographic window.
Results: Of 792 analysed segments 143 were inadequate for reading by MCE, mostly confined to basal segments. Interobserver variability was good (kappa=0,76). Overall agreement between the two methods was poor (59%, kappa=0,25) when including unreadable segments but good (82%, kappa=0,63) when excluding those segments. Highest concordance was found in apico-lateral (85%) and the lowest in basals segments (18%). Concordance between the methods was higher for diagnosing fixed defects (72%) and normal perfusion (88%), than for diagnosing reversible defects (65%). Conclusion: This study demonstrates that real-time MCE can detect perfusion defects during pharmacological stress and agrees reasonably well with 99mTc-Sestamibi-SPECT. However, diagnostic feasibility is limited in basal segments and caution should be exerted when diagnosing stress induced ischemia.

2101 Time course of improvement of microvascular perfusion and contractile function after successful reperfusion of acute myocardial infarction

P. Andrassy[1], M. Zielinska[2], C. Firschke[3]. [1]*Bajcsy-Zs. Hospital, Cardiology, Budapest, Hungary;* [2]*Clinic of Card. Med. Academy, Cardiology, Lodz, Poland;* [3]*Deutsches Herzzentrum, Cardiology, Munich, Germany*

We sought to investigate the time course of changes of microvascular perfusion and contractile function within the risk area (defined as segments with wall motion abnormality before reperfusion therapy) in patients with first acute myocardial infarction (AMI) before and after successful reperfusion therapy using venous myocardial contrast echocardiography (VMCE).
Methods: VMCE (3ml Optison in 27ml NaCl, 200ml/h, intermittent harmonic imaging, 4- and 2-chamber views (six segments each), off-line digital image processing) was performed in 49 patients (male n=42, median age 57 years) with AMI (infarct related artery (IRA): LAD n=20, RCA n=21, LCX n=8; CK max. 837±663 U/l) before and 3 hours, 14 days and 6 months after reperfusion therapy (percutaneous coronary intervention n=45, thrombolysis n=4). Videointensity (VI) of each risk area segment was normalized to the VI of the brightest normokinetic segment of the same view. Echocardiographic evaluation of contractile function (semiquantitative wall motion score) at rest was performed simultaneously with VMCE. Repeat coronary angiography was performed at day 14 in all 49 patients and in 45/49 patients after six months.
Results: Reperfusion therapy was successful in all patients. TIMI 3 flow was present in all patients at day 14 and after six months. Myocardial contractile function was initially abnormal in 200 of a total of 488 segments. The table shows normalized VI (%) and the wall motion score (WMS) of risk area segments (n=200)over time.

VI and WMS values over time

	Before reperfusion	After reperfusion	Day 14	Six month
VI %	40*(±26)	60 (±30)	65 (±32)	68 (±32)
WMS	2.87 (±0.34)	2.84 (±0.39)	2.26* (±0.87)	2.02* (±0.9)

(mean±SD; * indicates significant difference ($p<0.05$) compared to all other values in the same row)

Conclusions: In patients with successful reperfusion therapy of acute myocardial infarction, the main improvement of myocradial microvascular perfusion occurs immediately after reperfusion whereas recovery of contractile function is a prolonged process.

2102 Improved prediction of myocardial viability by contrast echo in dobutamine non-responsive myocardium early after acute myocardial infarction

J. Swinburn, A. Lahiri, R. Senior. *Northwick Park Hospital, Cardiology, Middlesex, United Kingdom*

Background: Prediction of myocardial viability in the infarct related myocardium has important therapeutic prognostic and implications. Dobutamine response of viable but dysfunctional segments may be prevented by critical stenosis of infarct related artery. Thus dobutamine echocardiography (DE) may underestimate the prediction of myocardial viability. We hypothesised that presence of microvascular integrity, detected by myocardial contrast echocardiography (MCE) in dobutamine non-responsive segments may enhance identification of myocardial viability.
Methods: Accordingly, 98 pts underwent low dose DE and intravenous MCE (Optison) on the same day, 3-5 days after acute myocardial infarction (AMI). Akinetic segments were assessed for dobutamine response, contrast opacification and recovery of function 6m after AMI (standard reference for myocardial viability).
Results: There were a total of 421 akinetic segments of which 111 segments recovered function at 6m. Of these, 45 segments did not show any dobutamine response. On the other hand, contrast opacification was present in 21 (47%) of these 45 dobutamine non-responsive segments. Sensitivity of DE for prediction of recovery of function was 59%. When contrast opacification was seen in the dobutamine non-responsive segments, sensitivity improved to 81% ($p<0.01$ compared to DE alone). The only independent predictor of recovery of dysynergic myocardium was the combination of DE and MCE.
Conclusion: In conclusion, MCE enhances detection of myocardial viability in dobutamine non-responsive segments early after AMI.

2103 Does real time perfusion during stress echocardiography increase the detection of viable myocardium?

M S. Dolan[1], S. Puri[2], A. El Shafei[2], J. St Vrain[2], J. Sklenar[2], M. Witrey[2], A. J Labovitz[2]. [1]*Saint Louis University Hospital, Internal Medicine/Cardiology, St. Louis, United States of America;* [2]*Saint Louis University School of Medic, Internal Medicine/Cardiology, St. Louis, United States of America*

Background: Assessment of reversibility and viability in patients with resting wall motion abnormalities during Dobutamine Stress Echocardiography (DSE) may not be easy. However, availability of myocardial perfusion techniques and detection of perfusion by quantitative analysis may identify reversible or viable segments more accurately.
Methods: Therefore, we studied seventy-nine patients with contrast Dobutamine Stress Echocardiography, either with intermittent triggered or real time perfusion. All patients had nuclear (sestimibi or thallium SPECT) and coronary angiograms. Patients were divided into three groups, based on presence of reversible or fixed defect or viability using nuclear. Wall thickening and perfusion analysis were performed. Ratio of normal wall thickness to abnormal was compared at base (WTRb) and peak (WTRp). Similarly ratio of perfusion in normal and infarcted regions were calculated at base (MPAb) and peak (MPAp).
Result: See Table. Sensitivity in the detection of viability increased from 52% to 62% (P=0.06) when quantitative perfusion analysis is added to visual innterpretation. Similarly there was a trend for higher accuracy for reversibilty with perfusion when compared to conventional visual interpretation(76% vs 69%, p=NS).

	WTRb	WTRp	MPAb	MPAp
Fixed	3.8	7.7	2.3	3.3
Viable	3.6	6.2	2.2	2.4
Reversible	3.7	11.4*	2.3	10.9*
P	NS	*0.05	NS	*0.001

Conclusion: Perfusion ratio is a sensitive marker for detecting viability and reversibility. Overall additive information derived from perfusion in conjunction with visual interpretation increases detection of reversible and viable segments in clinical setting of resting wall motion abnormality.

2104 Prediction of left ventricular remodelling in patients with acute myocardial infarction: role of intravenous myocardial contrast echocardiography

R. Rossini, G. Mengozzi, C. Palagi, M. Molfese, L. Garritano, A.S. Petronio, V. Di Bello, M. Mariani. *University of Pisa, Cardiothoracic Dept, Pisa, Italy*

Background: The development of left ventricular (LV) remodeling is crucial in patient (pt) outcome after an acute myocardial infarction (AMI). The extent of microvascular perfusion has been shown to predict the ultimate amount of myocardial damage and the extent of residual viability, which can favorably condition pt prognosis, by preventing LV remodeling.
Aim of this study was to assess the role of intravenous myocardial contrast echocardiography (IVMCE) in the prediction of LV remodeling in patients (pts) with AMI.
Methods: Seventy-two pts with AMI, successfully treated with acute PTCA, underwent IVMCE and low-dose dobutamine echocardiography (LDDE) during hospital admission but at least 3 days after AMI (4.9±1.1 days). IVMCE was performed with Levovist (4 gr) with Harmonic Power Doppler Imaging, with an end systolic triggering 1:4 cardiac cycle. IVMCE was graded semiquantitatively on a score of 0 (no visible contrast effect), 0.5 (patchy contrast enhancement) and 1 (homogenous contrast effect). Pts were considered to have microvascular impairment (IVMCE-), if < 50% of segments within the infarct related area had score 1. A mean perfusion score index (PSI) was calculated for each pt by averaging the contrast scores in the area at risk. At six-month follow-up a new echocardiogram was performed. Pts were also followed-up for the occurrence of adverse cardiac events (cardiac death, reinfarction, malignant ventricular arrythmia, congestive heart failure, target lesion revascularization) for 6 months.
Results: Sixty-three pts (55 male; 56±10 yrs) completed the study. Pts with a good perfusion at IVMCE (IVMCE+) showed a lower CK peak ($P<0.001$) and CK MB ($P<0.01$), a better wall motion score index (WMSI; 1.62±0.2 vs 1.86±0.2; $P<0.0001$) and a higher amount of myocardial viability at LDDE (-0.34±0.2 vs -0.22±0.2; $P<0.05$) compared with IVMCE- pts. At follow-up, a higher improvement in WMSI (-0.30±0.21 vs -0.07±0.3 $P<0.001$) was observed in IVMCE+ pts, while IVMCE- pts showed a higher incidence of adverse cardiac events (64% vs 22%; $P<0.005$) and an evident increase in LV end diastolic volume (EDV) from baseline to six-month follow-up (99±10 vs 136±26 ml; $P<0.0001$), implying LV remodeling. The results of canonical correlation analysis showed that PSI was significantly correlated to the variation of LVEDV ($r2 = 0.33$; $P=0.0001$). By stepwise multiple regression analysis, microvascular impairment at IVMCE was a significant independent predictor of LV remodeling ($P<0.0001$).
Conclusions: IVMCE seems to be an important diagnostic tool, able to early predict LV remodeling in pts with AMI.

IMPROVED ASSESSMENT OF MYOCARDIAL ISCHAEMIA BY TISSUE DOPPLER

2105 Tissue Doppler echocardiography and strain Doppler echocardiography: a head-to-head comparison in moderate and severe ischaemia

H. Skulstad[1], S. Urheim[2], T. Edvardsen[1], H. Ihlen[1], O.A. Smiseth[1].
[1]*Rikshospitalet, Department of Cardiology, Oslo, Norway;* [2]*Rikshospitalet, Institute of surgical research, Oslo, Norway*

Background: Tissue Doppler echocardiography (TDE) and Strain Doppler echocardiography (SDE) are noninvasive methods for measuring myocardial velocities and deformation, respectively. We compared the ability of the two methods to identify myocardial dysfunction during different degrees of ischaemia.
Methods: In 7 anaesthetized dogs we measured longitudinal myocardial velocities by TDE, strain by SDE, and dimensions by sonomicrometry. Flow in the left anterior descending coronary artery (LAD) was reduced by 57 ± 8% and 100%, and sonomicrometry in the LV anterior wall showed regional hypokinesis and dyskinesis, respectively (Table).
Results: (see table below)
During severe ischaemia TDE showed marked changes in IVC and IVR velocities, and Vsys2 reversed, consistent with dyskinesis (Table). Similarly, SDE showed systolic lengthening and marked post-systolic shortening. During LAD stenosis, which caused moderate hypokinesis there were only minor reductions in TDE velocities, and there was overlap with velocities in non-ischemic myocardium. However, SDE showed marked decrease in systolic strain and substantial post-systolic shortening, and this contractile pattern clearly identified ischemic myocardium.
Conclusion: During severe ischaemia both TDE and SDE identified dyskinetic myocardium. However, in hypokinetic myocardium velocities by TDE showed substantial overlap with values in non-ischemic myocardium, while SDE clearly distinguished ischaemic from non-ischemic regions. Therefore SDE appears to be more sensitive than TDE in identifying myocardium with moderate ischaemic dysfunction.

2106 Post-systolic shortening during dobutamine stress echocardiography: delayed contraction of viable dyssynergic myocardium

R. Rambaldi[1], D. Poldermans[2], J.J. Bax[2], E. Boersma[2], R. Valkema[2], D. Dunker[2], G.R. Sutherland[2], J.R.T.C. Roelandt[2]. [1]*" S Paolo" Hospital, Division of Cardiology, Milano, Italy;* [2]*AZR, Thoraxcenter, Rotterdam, Netherlands*

Background: Dobutamine stress echocardiography (DSE) interpretation remains limited by its subjective assessment of wall motion score during stress. Pulsed wave-tissue Doppler imaging (PW-TDI)-derived ejection phase (EP) and post-systolic shortening (PSS) velocities may help to render DSE objective.
Objectives: We evaluated the additional value of dobutamine challenge on both EP and PSS velocities to identify dysfunctional, but viable myocardial segments using F18-fluorodeoxyglucose(FDG)-SPECT as an independent reference.
Methods: 40 patients (26 males, mean age 57 ± 9 years) with ischemic severe left ventricular dysfunction (mean ejection fraction: 33 ± 10%) underwent DSE with PW-TDI. The six-segment model (posterior, anterior septum, lateral, inferior, anterior and posterior walls) of longitudinal contraction was used for PW-TDI at rest, low dose of dobutamine (10 μg/kg/min) and peak stress. EP and PSS velocities were analysed off-line. EP/PSS ratio was calculated. The optimal cut-off levels of myocardial velocity values for the assessment of myocardial viability were calculated by ROC-curves analysis. Myocardial viability by wall motion score during DSE was assessed if 2/3 of the segment showed a biphasic, sustained improvement or ischemic response. Viability by FDG-SPECT was assessed if 2/3 of the segment showed a normal or mildly reduced FDG uptake.
Results: out of 240 segments, resting severe dyssynergy was present in 168 (70%) segments. Myocardial viability in 61 (36%) segments by DSE and in 78 (46%) by FDG-SPECT. The agreement between PSS and DSE for myocardial viability was 65%, kappa 0.30 compared to 79%, kappa 0.59 for PSS vs FDG-SPECT. As compared to DSE, EP with PSS improved sensitivity for myocardial viability to 98% vs 79%, $p < 0.01$. Similarly, EP/PSS ratio at low dose of dobutamine improved sensitivity for myocardial viability: 96%. Cut-off values of PSS vs viability by FDG-SPECT were >5 cm/s at rest and >6 cm/s at low dose of dobutamine. Cut-off values of EP/PSS ratio vs viability by FDG-SPECT were >0.8 at rest and >0.3 at low dose.
Conclusions: The presence of PSS and a more sustained increase of PSS velocities during DSE were able to predict viable myocardium. EP and PSS improved DSE accuracy to recognize myocardial viability. PSS appears clinically confirming the delayed active contraction of dyssynergic myocardium.

Abstract 2105 – Table

Anterior Wall	V Ivc-neg (cm/s)	V Sys1 (cm/s)	V Sys2 (cm/s)	V Ivr-neg (cm/s)	SS by strain (%)	PSS by strain (%)	SS by crystals (%)	PSS by crystals (%)
Baseline	-1.4 ± 0.7	2.7 ± 0.9	1.4 ± 0.7	0.6 ± 0.4	12.6 ± 2.5	0.6 ± 0.6	11.2 ± 3.1	1.0 ± 0.5

LAD - occlusion	-4.6 ± 2.0 *	1.4 ± 0.4 *	-0.3 ± 0.5 *	2.5 ± 0.8 *	- 8.1 ± 3.4 *	8.4 ± 2.1 *	- 5.6 ± 2.5 *	8.4 ± 2.4 *

V Ivc = Peak negative velocity in the isovolumetric contraction period, V Sys1= Peak systolic velocity, V Sys2 = mid systolic velocity, V Ivr = Peak positive velocity in the isovolumetric relaxation period, SS=peak systolic shortening, PSS=post-systolic shortening. Mean ± SD. * $p < 0.05$.

2107 Myocardial elasticity by strain Doppler echocardiography – A method to identify viable myocardium

E. Lyseggen[1], H. Skulstad[2], S. Urheim[1], S.I. Rabben[1], M. Stugaard[1], O.A. Smiseth[1]. [1]*Rikshospitalet, Institute for Surgical Research, Oslo, Norway;* [2]*Rikshospitalet, Department of Cardiology, Oslo, Norway*

Introduction: Myocardium that has undergone irreversible ischaemic damage is characterized by tissue oedema and therefore a decrease in elasticity. We hypothesized that strain Doppler echocardiography (SDE) may be used to assess myocardial elasticity, and thereby identify viable myocardium.
Methods: In 5 anaesthetized dogs we measured LV pressure, myocardial long axis strain by SDE, and segment lengths by sonomicrometry. Ischaemia was induced by LAD occlusion and haemodynamic measurements were done repeatedly for 4 hours. Infarcted myocardium was identified by TTC-staining and myocardial oedema by dry/wet weight ratio. Systolic elasticity (compliance) was calculated as systolic lengthening by sonomicrometry divided by systolic pressure rise.
Results: During LAD occlusion the ischaemic segment became dyskinetic with systolic lengthening and post-systolic shortening (PSS). In each experiment TTC-staining indicated irreversible myocardial injury after 4 hours of ischaemia, and the dry weight/wet weight ratio was reduced by 16.0 ± 3.8% (± SEM, $p<0.05$) indicating myocardial oedema. Systolic lengthening and PSS decreased during the ischaemic period from 10 ± 1% to 6 ± 1% ($p<0.05$) and from 10 ± 1% to 5 ± 1% ($p<0.05$), respectively (fig. 1). Systolic lengthening and PSS correlated well with myocardial elasticity (fig. 2). Strains by SDE correlated well with strains by sonomicrometry ($r = 0.58$, $p<0.01$).

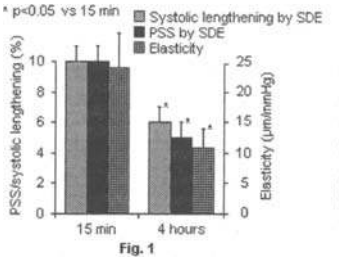

Fig. 1

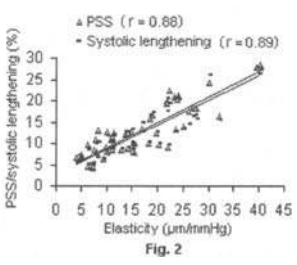

Fig. 2

Conclusions: The development of irreversible ischaemic myocardial injury is characterized by a decrease in systolic lengthening and PSS. This reflects decreased myocardial elasticity caused by tissue oedema. Thus, assessment of elasticity by SDE may help to determine if dyskinetic myocardium is viable.

2108 Impact of regional ischaemia on Doppler myocardial imaging parameters of left ventricular function during differing inotropic conditions

J.M. Strotmann[1], J. Broscheit[2], F. Weidemann[1], N. Eberbach[2], P. Steendijk[3], C.A. Greim[2], W. Voelker[1]. [1]*Medizinische Universitätsklinik, Würzburg, Germany;* [2]*University of Wuerzburg, Clinic of Anesthesiology, Wuerzburg, Germany;* [3]*University Leiden, Laboratory of Cardiovascular Research, Leiden, Netherlands*

Background: Recently, ultrasound based measurements of strain rate (by Doppler Myocardial Imaging (DMI)) have been shown to reflect regional myocardial contractility under various conditions of inotropic states. The following study evaluates the impact of different inotropic stimulation on myocardial function during normal perfusion and ischemia.
Methods and results: Six minipigs underwent complete anaesthesia and mechanical ventilation. A conductance catheter was placed into the left ventricle (LV) to obtain maximal endsystolic elastance (Ees) and dp/dtmax as the first derivative of LV pressure over time. An active coronary perfusion catheter was positioned in the proximal part of the coronary circumflex artery and blood for active perfusion was withdrawn from the femoral artery. DMI studies were done using a parasternal long axis view taking the posterior left ventricular wall as the region of interest. The following parameters were measured at baseline, after administration of dobutamine (10 µg/kg bodyweight) and esmolol (1-2.5 mg/kg bodyweight): Peak systolic strainrate (SR; unit 1/s), maximal endsystolic elastance (Ees) and dp/dtmax. After inducing regional myocardial ischemia by reducing the coronary blood flow to 7 ml/min the above mentioned measurements were repeated.
During normal coronary perfusion Ees and SR showed a significant correlation ($r=0.81$; $p < 0.001$). SR increased significantly after dobutamine administration and decreased after beta-blockade (4.8±0.8 vs 8.5±1.8 and 3.0±0.6). During regional ischemia SR was significantly reduced at baseline (4.8±0.8 vs 3.0±0.9), after dobutamine (8.5±1.8 vs 3.6±1.6) and after esmolol infusion3.0±1.6 vs 1.9±0.4) compared with each of these inotropic states at normal coronary perfusion. During ischemia there was a non-significant increase in SR after dobutamine and a significant decay after beta-blockade compared to baseline measurements (3.0±0.9 vs 3.6±1.6 and 1.9±0.4). Dp/dtmax and Ees as markers of global left ventricular function did not change due to regional ischemia.

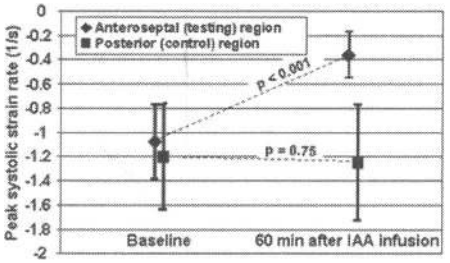
	basel/np	dobu/np	esmo/np	basel/isch	dobu/isch	esmo/isch
strainrate	4.8 (0.8)*	8.5 (1.8)#*	3.0 (0.6)#*	3.0 (0.9)	3.6 (1.6)	1.9 (0.4)#
elastance	7.5 (3.4)	22.1 (12.5)#	5.1 (1.6)	9.8 (4.5)	11.5 (5.5)	7.4 (4.5)
dp/dtmax	1847 (222)	5053 (1108)#	1299 (186)#	2048 (329)	4346 (703)	1031 (107)

Conclusion: SR reflects myocardial contractility well during normal perfusion. After regional ischemia, dobutamine failed to increase SR but esmolol administration lead to a decay of SR. Therefore, SR might still detect subtle changes of regional function in severely ischemic myocardium.

2109 Can strain rate echocardiography measure changes in local left ventricular function following pharmacologic inhibition of myocyte energetics?

M. Belohlavek[1], P.C. Anagnostopoulos[1], C. Pislaru[2]. [1]*Mayo Clinic, Internal Medicine, Rochester, United States of America;* [2]*Mayo Clinic, Physiology and Biophysics, Rochester, United States of America*

Background: We developed a pig model of non-ischemic inhibition of myocyte energetics using selective coronary administration of iodoacetamide (IAA). IAA inhibits creatine kinase (CK) and glyceraldehyde phosphate dehydrogenase (GADPH), which leads to cessation of cross-bridge cycling and uncouples myocardial contraction. We hypothesized that inhibition of regional myocardial energetics by IAA should decrease regional peak systolic strain rate, a measure of contractility, in the area at "metabolic" risk.
Methods: We administered 1 mg/kg of IAA via intracoronary catheter into a mid segment of the left anterior descending coronary artery in 15 pigs. Preservation of myocardial perfusion was verified by contrast echocardiography. Myocardial strain rates derived from tissue Doppler data were measured in the apical septal region at baseline and during a fully developed metabolic stress, ie, 60 minutes following IAA administration. Mid-posterior region served as a control. Myocardial biopsies for assessment of CK and GADPH activities in the apical septal region were obtained at baseline and 60 minutes after IAA administration to document metabolic inhibition.
Results: Peak systolic strain rates significantly decreased in the (IAA-affected) anteroseptal region but not in the (control) mid-posterior region (Figure). The local change in peak systolic strain rates was associated with a drop of CK and GADPH activities to <10% of the baseline value.

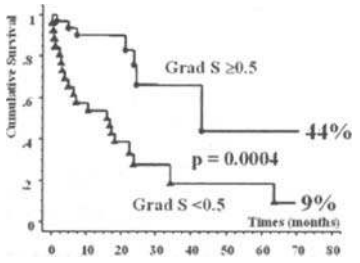


Conclusions: Functional effect of local pharmacologic inhibition of myocyte energy metabolism can be measured by quantitative analysis of regional contraction rates using strain rate echocardiography.

2110 Prognostic value of myocardial velocity gradient in patients with dilated cardiomyopathy: a tissue Doppler imaging study

C. Nafeh-Bizet, R. Lakhdar, F. Bauer, I. Schuster, A. Cribier, G. Derumeaux.
C.H.U. Charles Nicolle, Service de Cardiologie, Rouen, France

Tissue Doppler imaging (TDI) allows assessment of regional myocardial function by measuring deformation parameters such as velocity gradient between endocardium and epicardium (Grad, s^{-1}). To assess the prognostic value of systolic Grad in patients (Pts) with heart failure, we prospectively analyzed 70 Pts (53±12 yrs) with idiopathic dilated cardiomyopathy (DCM) by conventionnal echo-Doppler and TDI. NYHA class was II in 24 Pts, III in 24 and IV in 22. Mean left ventricular ejection fraction (EF) was 29±12%. Mean peak VO2 was 17±5 ml/mn/kg. Systolic Grad was measured within the posterior wall (mean value: 0.9±0.9s^{-1}).
During follow-up (20±16 months), major cardiac events occurred in 28 pts: 14 hospitalisations for worsening heart failure (11 leading to heart transplantation), 10 cardiac deaths, 4 ventricular tachycardia.
At univariate analysis, NYHA IV, peak VO2 < 16 ml/mn/kg, systolic pulmonary artery pressure > 35 mmHg, cardiac index < 2.7 l/mn/kg and systolic Grad < 0.5 were significantly predictive of cardiac events (figure: Kaplan-Meier analyses of cumulative rates of survival (%) in Pts stratified into 2 groups on the basis of systolic Grad value).
Multivariate logistic regression analysis (Cox model) revealed an independent predictive value of only two parameters: VO2max and systolic Grad.



Conclusion: In patients with DCM, regional myocardial function assessment by TDI is predictive of long term survival and might add useful information for clinical decision-making for cardiac transplantation.

COMPUTER DEMONSTRATION

2119 Implementing national guidelines on risk prediction and primary prevention of coronary heart disease in a cardiology information system

A.A. Becht[1], E.T. van der Velde[2], D.E. Atsma[2], M.K. Tuut[3]. [1]*Leyenburg Hospital, Dept. of Clinical Physics, The Hague, Netherlands;* [2]*Leiden University Medical Center, Dept. of Cardiology, Leiden, Netherlands;* [3]*Healthcare Improvement CBO, Dutch Institute for, Utrecht, Netherlands*

Purpose: The Dutch Institute for Healthcare Improvement (CBO) recently published a national consensus concerning both risk prediction and guidelines for primary prevention of coronary heart disease (CHD). The risk prediction charts for CHD and cardiac vascular disease (CVD) need manual operation and therefore its use during clinical routine is time-consuming. This paper presents an easy to use implementation of the CBO guideline in a large academic medical center.
Methods: The guideline is based on a risk prediction algorithm published in 1991 by the Framingham group. This nonproportional hazards Weibull accelerated failure time model was taken as an input for a Delphi based application, as part of the Cardiology Information System (CARIS) which was developed by the department of Cardiology, LUMC. The implemented risk factors are gender, age, systolic blood pressure, ratio of total cholesterol and HDL cholesterol, smoking and diabetes. The advanced programming environment makes it possible to evaluate also other prediction models, such as a Cox proportional hazards model.
Results: By selecting the patient, automatically the absolute risks on CHD and CVD are calculated and an advice is presented whether or not to treat the patient's bloodpressure or cholesterol. All parameters that are available in CARIS are filled in automatically. The remaining items are imported from the Hospital Information System. The application runs on a standard Windows-2000 PC. Routinely, the system is connected to the Hospital Information System, but for demonstration purposes it can also run as a stand-alone application. In clinical practice both the Weibull and the Cox models resulted in similar treatment advises.
Conclusions: Since no manual input is necessary, the risk estimation tool is quick and easy to use. Furthermore, patients can be shown how changes in lifestyle may effect their risk profile. At this moment the effect of the prediction tool is subject of further study. The tool will soon be also available on the LUMC-Cardiology website.

2120 A new computer-assisted fuzzy logic based approach in assessing the probability of significant coronary artery disease

R. Bogdan[1], S. Zahan[2], C. Medrea[3], C. Stanescu[3], R. Capalneanu[3], J-U. Voigt[1], F.A. Flachskampf[1]. [1]*Medical Clinic II, Friedrich-Alexander-University, Erlangen, Germany;* [2]*Technical University, Communications Dept., Cluj-Napoca, Romania;* [3]*Heart Institute, Cluj-Napoca, Romania*

Introduction: Due to the limited availability of coronary angiography facilities in some Eastern European countries we propose a new method, with better diagnostic performances than ECG treadmill test (TM), which can become a useful tool in selecting patients before invasive and expensive investigations. Fuzzy logic is a new and promising approach in the field of computer-assisted decision making. In this study, we tested the performance of a newly developed software in assessing the probability of significant coronary artery disease (CAD).
Methods: Based on the principles of fuzzy logic, we designed a program to calculate the individual probability of having relevant CAD. Risk factors, ECG treadmill test results and echo measurements at rest were weighted and processed according to fuzzy logic and not to binary logic rules. The Centre-of-Area- (COA) and the Mean-of-Maxims-Method (MOM) were used for defuzzification. To test the performance of the algorithm, we studied prospectively 152 patients (mean age 54±19years, 60 female, 92 male) with clinical suspicion of CAD. All patients underwent 99Tc-Sestamibi SPECT perfusion imaging, or coronary angiography, or both. We considered significant CAD in those cases with reversible defects at scintigraphy, or more than 50% coronary stenoses at coronary angiography. The program's output and the result provided by the classic TM alone were compared, for each patient, to the scintigraphic and/or angiographic diagnosis. Sensitivity(SENS), specificity(SPEC), positive and negative predictive values (PPV and NPV) were calculated.
Results: An or-linked combination of the defuzzification methods (COA or MOM) performed best. SENS of the algorithm vas cosiderably higher than classical TM (81% vs. 58%), with no major decrease of SPEC (SPEC 76% vs. 80%). Accordingly, PPV changed from 81% to 83% and NPV from 57% to 73%.
Conclusion: Our data show, that a computer-assisted processing of easily accessible basic patient data substantially improves the diagnosis accuracy of significant CAD and thus, reduces the need for invasive examinations.

POSTER DISPLAY IV

MODERATED POSTER SESSION IV

P2121 Inhibition of platelet activation in congestive heart failure by selective aldosterone receptor antagonism and angiotensin-converting enzyme inhibition

A. Schaefer[1], D. Fraccarollo[1], S. Hildemann[2], M. Christ[3], M. Eigenthaler[4], A. Kobsar[4], G. Ertl[1], J. Bauersachs[1]. [1]*Universitaetsklinik Wuerzburg, Medizinische Klinik - Kardiologie, Wuerzburg, Germany;* [2]*Pharmacia GmbH, Erlangen, Germany;* [3]*Klinik fuer Innere Medizin-Kardiologie, Philipps-Universität, Marburg, Germany;* [4]*Institut fuer Klinische Biochemie, Universitaetsklinik Wuerzburg, Wuerzburg, Germany*

Background: Increased risk of thrombembolic events in congestive heart failure (CHF) has been attributed to a hypercoagulable state including vascular endothelial dysfunction and platelet activation. The role of the activated renin-angiotensin-aldosterone system (RAAS) for platelet activation in CHF is currently unknown.
Methods and Results: After experimental myocardial infarction (MI), male Wistar rats were treated with placebo, the ACE inhibitor trandolapril (TR, 0.3mg/kg body weight/day), the selective aldosterone receptor antagonist eplerenone (EPL, 100mg/kg/day) or the combination of both (TR-EPL) for 10 weeks. Platelet-bound fibrinogen and surface-expressed P-selectin were not modulated in MI rats with LVEDP<15mmHg (10.9±0.6, and 19.3±3.5 mfu [mean fluorescence units]) compared with sham-operated animals (9.9±0.8, and 20.1±2.3 mfu), while they were significantly increased in CHF rats (LVEDP>15mmHg, 15.2±1.0, and 65.5±1.1 mfu, $p<0.001$ vs. sham-operation and MI). TR treatment significantly reduced platelet P-selectin expression while bound fibrinogen was not modulated. EPL reduced P-selectin expression to a comparable extent, while platelet-bound fibrinogen was normalized (10.2±1.2 mfu, $p<0.001$). A combination of EPL and TR even normalized P-selectin expression. Beneficial modulation of platelet activation by TR-EPL treatment was associated with the normalization of acetylcholine-induced, endothelial-dependent relaxation of rat aorta, and basal phosphorylation of the vasodilator-stimulated phosphoprotein (VASP). In contrast, treatment with TR or EPL alone was only partially effective.
Conclusions: Platelet activation was evident only in rats with severe CHF. Only the complete RAAS blockade with eplerenone and trandolapril normalized increased platelet activation presumably by improvement of endothelial-dependent NO-bioavailability leading to the normalization of decreased basal VASP phosphorylation, a key regulator of the initial sequences of platelet inhibition.

P2122 Improvement in acute treatment of myocardial infarction in clinical practice 1994-2001 resulted in a 28% reduction of hospital mortality

A K. Gitt[1], H. Wienbergen[1], R. Schiele[1], T. Heer[1], C. Meisenzahl[1], K. Bestehorn[2], M G. Gottwik[3], J. Senges[1]. [1]*Herzzentrum Ludwigshafen, Deparment of Cardiology, Ludwigshafen/Rhein, Germany;* [2]*MSD, Haar, Germany;* [3]*Department of Cardiology, Klinikum Nürnberg Süd, Nürnberg, Germany*

Background: The results of randomised trials showing the beneficial effect of reperfusion and adjunctive therapy on clinical outcome of patients (pts) with ST-elevation myocardial infarction (STEMI) had been implemented into the guidelines for the treatment of STEMI. It is unknown if therapy of STEMI changed in clinical practice and if these changes were associated with an improvement in outcome after STEMI.
Methods: Since 1994 consecutive pts with AMI have been enrolled into three large German AMI-registries to document pts characteristics, acute treatment and clinical outcome of AMI: MITRA (Maximal Individual Therapy of AMI) and MIR (Myocardial Infarction Registry) 1994–2000 at 271 hospitals and ACOS (Acute Coronary Syndrome Registry) since 2000 at 154 hospitals. A total of 97 hospitals participated in MITRA and MIR as well as in ACOS. Acute reperfusion and adjunctive treatment and the hospital mortality of STEMI were compared between the 2-year periods beginning with 1994 until 2001.
Results: Between 1994 and 2001 a total of 11802 consecutive pts with AMI were enrolled into the AMI-registries in these 97 hospitals.
Conclusion: Between 1994 and 2001 the acute treatment of STEMI in clinical practice in Germany significantly improved according to existing guidelines. This improvement in acute therapy was associated with a 28% decrease in hospital mortality of STEMI in Germany.

Improvement in therapy and outcome

P2123 Improvement of ventricular remodelling in rats with CHF: comparative and combined effects of aldosterone receptor blockade and angiotensin-converting enzyme inhibition

J. Bauersachs[1], D. Fraccarollo[1], A. Schäfer[1], S. Hildemann[2], P. Galuppo[1], G. Ertl[1]. [1]*Universitaetsklinik Wuerzburg, Medizinische Klinik, Wuerzburg, Germany;* [2]*Pharmacia GmbH, Erlangen, Germany*

The non-selective mineralocorticoid receptor antagonist spironolactone reduces mortality in patients with severe congestive heart failure (CHF), however its use is limited by considerable side effects. We investigated the effect of the selective mineralocorticoid receptor antagonist eplerenone alone and in co-administration with an ACE-inhibitor on hemodynamics and cardiac remodeling in rats with CHF after extensive myocardial infarction (MI). Rats were treated with placebo (P), the aldosterone receptor antagonist eplerenone (E, 100mg/kg/d), the ACE inhibitor trandolapril (T, 0.3mg/kg/d), or a combination of both for 9 weeks, starting ten days after coronary artery ligation. Left ventricular end-diastolic volume (LVEDV) was obtained by miniaturized impedance/micromanometer catheter (SPR-774, Millar Instruments).
Infarct size were similar among the experimental groups (MI size %: P CHF, 54.5±0.9; E CHF, 54.7±1.0; T CHF, 54.3±2.2; E+T CHF, 54.3±1.6). Despite comparable effects on LV systolic pressure [LVSP (mmHg): Sham, 138±3; P CHF, 110±3[1]; E CHF, 113±5[1]; T CHF, 112±1[1]; E+T CHF, 105±3[1]], the addition of the selective aldosterone receptor antagonist eplerenone to ACE inhibition significantly improved LV systolic [dP/dtmax (mmHg/s): Sham, 12371±375; P CHF, 7316±230[1]; E CHF, 8193±468[1]; T CHF, 8231±401[1]; E+T CHF, 8295±271[1 2]] and diastolic function [dP/dtmin (mmHg/s): Sham, 9614±419; P CHF, 4779±214[1]; E CHF, 5237±283[1]; T CHF, 5277±510[1]; E+T CHF, 5699±311[1 2]] and reduced LV end-diastolic pressure [LVEDP (mmHg): Sham, 4±0.5; P CHF, 21.8±2[1]; E CHF, 15.4±3[1]; T CHF, 16.9±4[1]; E+T CHF, 11.4±2[2]]. In addition, the combination of eplerenone and trandolapril prevented LV dilation [LVEDV (µl): Sham, 530±22; P CHF, 1150±97[1]; E CHF, 859±99[1 2]; T CHF, 890±61[1 2]; E+T CHF, 685±61[3]] and reduced right ventricular hypertrophy [RV/BW (mg/g): Sham, 0.49±0.01; P CHF, 1.13±0.05[1]; E CHF, 0.92±0.06[1 2];T CHF, 0.89±0.06[1 2]; E+T CHF, 0.71±0.05[1 3]] more effectively than either monotherapy. These data suggest synergistic improvement of cardiac failure by long-term aldosterone and ACE inhibition after MI.
(n=7-19) [1]$p<0.05$ vs. sham; [2]$p<0.05$, [3]$p<0.01$ vs. P CHF

P2124 N-acetylocysteine and fibrinolytic therapy for acute myocardial infarction: its influence on plasma chemotactic activity and C5a levels

A. Wykretowicz, A. Sajkowska, A. Szczepanik, P. Guzik, H. Wysocki. *Univ School of Medicine, Cardiology-Intensive Therapy, Poznan, Poland*

Background: Polymorphonuclear neutrophils are attracted into the area of reperfused myocardium and participate in reperfusion injury. It has been demonstrated that administration of n-acetylocysteine (n-ACC) in combination with streptokinase (STK) significantly diminished oxidative stress and improve ejection fraction in patients with acute myocardial infarction.
Methods: The aim of our study was to evaluate the influence of n-ACC on plasma chemotactic activity and C5a plasma levels, in patients with acute myocardial infarction (AMI). 29 patients with AMI were included in the study (22 men, 7 women, mean age 53 yrs). After randomization, n-ACC (or normal saline) infusion was started at 20 mg/min i.v. for 1 hr and 10 mg/min for 23 hrs. Ten minutes after starting of n-ACC infusion 1.5 mln units of STK was given. Peripheral blood was collected before starting of treatment and after 6, 12, 24 and 48 hrs. Plasma chemotactic activity was assessed with the use of modified Boyden chamber method. Control PMNs isolated from healthy subjects were used. Complement C5a plasma levels were assessed by the ELISA method (Enzygnost C5a micro, Behring).
Results: plasma obtained from patients with acute myocardial infarction significantly enhanced chemotaxis of control PMN (chemotactic index 0 hr 2.9±0.3, 6hrs 7.2±0.3, 12hrs 5.6±0.7, 24 hrs 5.2±0.5, 48 hrs 4.9±0.5, p=0.005, p=0.0003, p=0.0003, p=0.002, respectively), n-ACC infusion was associated with significantly diminished plasma chemotactic activity in blood samples obtained after 12, 24 and 48 hrs (p=0.04, p=0.03, p=0.01 respectively). C5a plasma levels were significantly increased, after 6hrs, in comparison to initial value, in patients treated with saline infusion (p=0.02), while there were no significant increase in C5a concentration in patients treated with n-ACC. Plasma isolated from patients treated with saline showed significant increase of C5a over the background level after 6, 12 and 24 hrs in comparison with blood isolated from n-ACC treated subjects.
Conclusions: n-ACC infusion in addition to STK treatment in patients with acute myocardial infarction is associated with diminished plasma chemotactic activity and lower C5a plasma levels.

P2125 The Euroheart failure survey: symptoms and quality of life

I. Manousos[1], J. Eastaugh[2], N. Freemantle[2], F. Follath[3], M. Komajda[4], K. Swedberg[5], J.G.F. Cleland[1] on behalf of The EuroHeart Failure Investigators.. [1]*University of Hull, Academic Cardiology, Hull, United Kingdom;* [2]*University of Birmingham, Primary Care and General Practice, Birmingham, United Kingdom;* [3]*University Hospital, Internal Medicine, Zurich, Switzerland;* [4]*C.H.U. Pitie-Salpetriere, Cardiology, Paris, France;* [5]*Sahlgrenska University Hospital Ostra, Medicine, Gothenburg, Sweden*

Background: Quality of life (QoL) is reported to be markedly impaired in heart failure and symptoms are often poorly controlled. However, quality of life and symptom severity have rarely been assessed in epidemiologically-representative populations of patients with heart failure.
Aims: To describe the self-assessed QoL of patients with heart failure in a large, international cohort of patients recently (12 weeks) discharged from hospital with a suspected diagnosis of heart failure using the EuroHeart failure QoL instrument.
Methods: The EuroHeart Failure survey included >11,000 patients with a suspected diagnosis of heart failure during a hospital admission. 25 countries belonging to the ESC participated. Surviving patients were invited to attend for interview 12 weeks after discharge at which time they were asked questions about their health, completed the symptom & QoL questionnaire (containing 35 questions with a 6-7 point rating-scale), had a brief physical examination and had a blood sample for BNP measurement taken. A reference population without known disease (UK only; N = 245, mean age 73 years) also completed the questionnaire.
Results: The reference population (mean age 73 years) rated their health as very good or good in 77% of cases (no patient rated themselves less than average) and their overall QoL as very good or good in 86% of cases (1% rated QoL as less than average). The reference population reported very little (<10% of cases) limitation due to breathlessness. The mean age of patients was 71 years (range 63 years in Hungary to 77 years in Sweden) and 48% were women. 45% were reported to have moderate or severe left ventricular dysfunction. 14% of patients died prior to the 12 week follow up visit. From a preliminary sample of 3,249 patients who completed follow-up, 1,444 cases of 'definite' heart failure were identified. One third of these patients reported breathlessness at rest or waking them from sleep while 78% continued to experience breathlessness limiting activities of daily living. Patients rated their health and QoL as poor in 40%and 35% of cases respectively and good or very good in only 11% and 20% of cases respectively. For all of the above variables there was a significant association between HF status and rating (alpha <.05).
Conclusions: Amongst patients who survive 12 weeks after discharge from hospital with a diagnosis of heart failure, troublesome symptoms remain common and patients perception of their quality of life is often poor.

P2126 Are heart failure patients in general practice receiving evidence-based pharmacotherapy?

L.G Pont[1], W.H. van Gilst[2], D.J.A. Lok[3], J.A. Kragten[4], F.M. Haaijer-Ruskamp[2] on behalf of The Dutch Working Group on Heart Failure. [1]*University of Groningen, Clinical Pharmacology-GUIDE, Groningen, Netherlands;* [2]*University of Groningen, Clinical Pharmacology, Groningen, Netherlands;* [3]*Deventer Hospital, Department of Cardiology, Deventer, Netherlands;* [4]*Atrium Medical Centre, Department of Cardiology, Heerlen, Netherlands*

Background: Internationally research indicates that pharmacotherapy for chronic heart failure (CHF) is sub-optimal. However, assessment of drug use in heart failure has traditionally focused on the use of individual agents without taking CHF severity into account. This study investigates investigate the pharmacological treatment of CHF in general practice with respect to the available evidence, incorporating both disease severity and the use of combination drug therapy.
Design: Cross-sectional survey
Setting: Dutch General Practice
Participants: 769 CHF patients participating in the IMPROVEMENT of HF study.
Outcomes: For each NYHA severity classification the minimum treatment each patient could expect, appropriate for their NYHA severity classification according to the scientific evidence available at the time of the study (1999) was defined. The proportion of patients receiving, at least, the minimum evidence-based regime per NYHA severity class was determined.
Results: The proportion of patients treated with each drug group increased with increasing CHF severity classification, with the exception of the beta-blockers. With respect to the current evidence, the proportion of patients receiving the minimum evidence-based regime suitable for their severity class decreased as NYHA severity class increased. After adjusting for age and sex, patients with less severe heart failure (NYHA classes 1 and 2) were four to eight times more likely to receive evidence-based treatment than those with more severe heart failure (NYHA class 3 and 4).
Discussion: This study indicates that many heart failure patients in general practice are not receiving evidence-based care when disease severity and combination drug therapy are taken into account. While prescribing of ACE inhibitors appeared adequate, prescribing of beta-blockers was low and indicates an area needing attention. Educational efforts aimed at the improvement of heart failure treatment in general practice are needed, with special consideration given to the role of beta-blockers in the treatment of heart failure.

P2127 Prognostic significance of heart rate variability among the patients with optimized beta-blocking medication after myocardial infarction

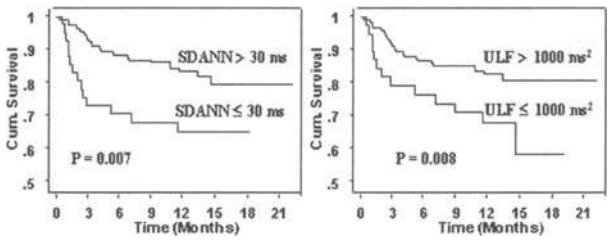
V. Jokinen, J.M. Tapanainen, K. Lindgren, T.H. Mäkikallio, H.V. Huikuri. *Oulu University Hospital, Department of Internal Medicine, Oulu, Finland*

Background: A large body of data has documented that various indices of heart rate variability (HRV) may predict subsequent mortality of the patients after an acute myocardial infarction (AMI). In none of these studies the cardiac medication has been optimized, e.g. 10-40% of the patients have been on beta-blocking (BB) medication. This study assessed the prognostic significance of various measures of HRV among a consecutive series of patients with an AMI in whom the cardiac medication was optimized according to contemporary guidelines.
Patients and methods: Traditional time and frequency domain measures along with the newer fractal measures of HRV were measured in 600 patients after the AMI. Predefined cutoff points for abnormal HRV measures were used. Cardiac medication was optimized with special emphasis on the BB therapy, which was used by 97% of the patients. The end-point was cardiac mortality.
Results: During the mean follow-up of 40±12 months, there were 45 cardiac deaths (7.5%). In univariate analysis, reduced standard deviation of N-N intervals(SDNN<70 msec)(p<0.01), ultra low frequency(lnULF<8,45)(p<0.05) and very-low frequency spectral component (lnVLF<5.30)(p<0.01), short-term fractal exponent (alfa1<0.65)(p<0.001), and long-term fractal exponent (beeta<-1.55)(p<0.001) predicted the subsequent cardiac death. In the multivariate Cox proportional hazards analysis by adjusting for age, diabetes and functional class, the reduced alfa1 remained as the only HRV variable that still predicted the cardiac death (hazards ratio 2.65, 95% CI from 1.37 to 5.13, p<0.01).
Conclusion: Most of the HRV indices retain their prognostic power among the patients with optimized BB therapy after AMI. However, after adjusting for clinical variables, altered short-term fractal exponent was the only HRV variable that still provided prognostic information.

P2128 Heart rate variability in hospitalized patients with decompensated heart failure predicts short-tem survival after discharge

D. Aronson[1], D.P. Horton[2], A.J. Burger[3]. [1]*RAMBAM Medical Center, Cardiology Dept., Haifa, Israel;* [2]*Scios Inc., Sunnyvale, United States of America;* [3]*Beth Israel Deaconess Hospital, Cardiology Dept., Boston, United States of America*

Introduction: Analysis of heart rate variability (HRV) has been used to study autonomic function in patients (pts) with heart failure (HF), and provides information on the risk of death in stable, ambulant pts. With progression from mildly symptomatic HF to decompensated HF, additional progressive autonomic dysfunction occurs. However, the relation between HRV and prognosis in the setting of decompensated HF requiring hospitalization is not known.
Methods: We studied 199 pts (131 men, age 60 ± 14 y) with previous HF, NYHA class III or IV, who were admitted to the hospital for acutely decompensated HF. Twenty-four hour Holter recordings were performed during hospital stay, and HRV parameters were calculated in the time and frequency domain. Cox proportional-hazards model was performed with the following covariates: age, gender, HF etiology, NYHA class, diabetes, sodium (Na) and creatinine levels, presence of ventricular tachycardia, and drug therapies.
Results: During follow-up of 312 ± 150 days, 40 pts (20.1%) died. In Cox's univariate analysis, predictors of death were Na < 132 mEq/L (p = 0.001), creatinine > 2.0 mg/dl (p = 0.034), and the following HRV measures: SDNN (p = 0.045), SDANN (p = 0.009), TP (p = 0.025), and ULF (p = 0.009). In multivariate analysis, SDANN (p = 0.006, RR = 2.7, 95% CI 1.3-5.6), TP (p = 0.01, RR = 2.5, 95% CI 1.2-5.0) and ULF (p = 0.007, RR = 2.6, 95% CI 1.3-5.3) were found to predict survival independently. SDANN and ULF dichotomized at 30 ms and 1000 ms^2, respectively, were the best predictors of mortality (Figure).



Kaplan-Meier survival curves.

Conclusion: The severity of autonomic perturbations during hospitalization for HF decompensation, as reflected by depressed HRV parameters, is a powerful indicator of short-term survival after discharge.

P2129 Effects of sertraline on platelet/endothelial biomarkers in depressed patients after acute coronary events

V.L. Serebruany[1], A. Glassman[2], A. Malinin[1], R. Krishnan[3], M. Finkel[4], C. Nemeroff[5], P. Gurbel[1], C.M. O'Connor[3]. [1]*Johns Hopkins University, Sinai Hospital, Baltimore, United States of America;* [2]*Columbia University, New York, United States of America;* [3]*Duke University, Durham, United States of America;* [4]*University of West Verginia, Charleston, United States of America;* [5]*Emory University, Atlanta, United States of America*

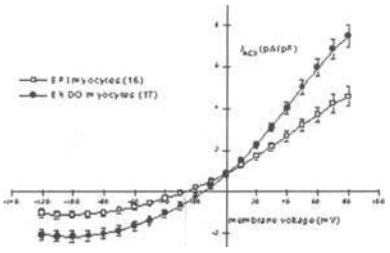
Background: Platelets could represent a missing link between incidence of depression and adverse clinical outcomes in patients after acute cardiovascular syndromes (ACS). However, it is still not clear how modern therapies of mood disorders including selective serotonin reuptake inhibitors (SSRI's) affect platelet function in such patients. We serially assessed release of established platelet/endothelial biomarkers in patients receiving sertraline versus placebo in a frame of the SADHART trial.
Methods: Plasma samples (baseline, week 6, and week 16) were collected from 5 sites in the US and Canada from patients treated with Zoloft (n=28), and placebo (n=36). Aspirin and clopidogrel were allowed in this study. Platelet factor 4 (PF4), beta-thromboglobulin (beta-TG), platelet/endothelial cell adhesion molecule-1 (PECAM-1), P-selectin, thromboxane (TxB2), prostacyclin (6-keto-PGF1a), vascular cell adhesion molecule–1 (VCAM-1), and E-selectin were measured by ELISA.
Results: At every time point after baseline for each biomarker measured, patients undergoing treatment with sertraline exhibited substantially less platelet activation than those receiving placebo. These differences reached statistical significance for PF4 (p=0.03), and beta-TG (p=0.04) at week 4, and for beta-TG (p=0.02), PECAM-1 (p=0.01), and P-selectin (p=0.02) at week 16 after randomization. There was a trend towards inhibition of prostanoids (TxB2, and 6-keto-PGF1a), and endothelial-released adhesion molecules (VCAM-1, and E-selectin) in patients treated with sertraline as well, although these changes were not significant.
Conclusion: Despite aggressive anti-platelet regimens including aspirin and clopidogrel, treatment with sertraline in depressed post-ACS patients is associated with the decreased release of platelet/endothelial biomarkers. Mild antiplatelet properties of SSRI's may represent an attractive additional advantage for using these agents in patients with coronary artery disease and ischemic stroke.

CELLULAR ELECTROPHYSIOLOGY

P2130 Regional differences in Na-Ca exchanger current density underlie a regional propensity to arrhythmogenesis

H.L Wallis, C. Sears, S. Bryant. *John Radcliffe Hospital, Cardiovascular Medicine Dept., Oxford, United Kingdom*

The Na-Ca exchanger current (INCX) contributes significantly to the transient inward current (Iti), which underlies delayed afterdepolarizations. We have measured transmural INCX density and assessed the regional propensity to arrhythmogenesis.
Methods: Myocytes were isolated from basal sub-endocardial (ENDO), mid-myocardial (MID) and sub-epicardial (EPI) regions of guinea-pig left ventricle. Membrane current was measured using the whole-cell patch-clamp technique at 35±1°C. INCX was elicited by a descending ramp protocol (+80 mV to -120mV) under selective conditions and assessed as the Ni-sensitive current. Arrhythmic behaviour was induced by a prolonged step depolarization to +60mV from -40mV after a series of 20 pre-conditioning pulses. Data are presented as mean±SEM (n).
Results: INCX density was significantly greater in ENDO than in EPI myocytes in both 'forward' (-120 to -30mV) and 'reverse' (+20 to +80mV) modes, ($p<0.001$, see fig.). The time to onset of arrhythmia was shorter ($p<0.001$) and the amplitude of Iti was greater ($p<0.05$) in ENDO (n=22) than in EPI (n=24) myocytes. In the presence of thapsigargin (1μM), which inhibits Ca^{2+} re-uptake into the sarcoplasmic reticulum, arrhythmias were abolished although Ca^{2+} flux via the NCX was still greater in ENDO myocytes.



Regional differences in INCX density.

Conclusion: INCX density is greater in ENDO than in EPI myocytes. This may contribute to both the prolonged action potential and to the greater propensity to arrhythmogenesis observed in ENDO rather than in EPI myocytes. In heart failure, INCX is upregulated, hence the sub-endocardial region may be the origin of potentially lethal arrhythmias.

P2131 Block of human IKur and Ito potassium channels by the new antiarrhythmic drug AVE 0118

R.F. Bosch[1], R. Laszlo[1], H. Goegelein[2], M. Bleich[2], A. Schneck[1], C. Mewis[1], A.E. Busch[2], V. Kuehlkamp[1]. [1]*University of Tuebingen, Department of Cardiology, Tuebingen, Germany;* [2]*Aventis Pharma Germany GmbH, DG Cardiovascular, Frankfurt, Germany*

The pharmacological treatment of supraventricular tachyarrhythmias, especially atrial fibrillation, is limited by the proarrhythmic potential of currently available drugs. It has been suggested that blockers of the ultrarapid delayed rectifier potassium current IKur might have little proarrhythmic side effects in the ventricle, as the functional channel is only expressed on the atrial level in human heart. Antiarrhythmic drugs that primarily act via block of IKur are not available at the moment. We present the pharmaocolical profile of a new compound AVE 0118 which has been shown to selectively delay repolarization in pig atrium.

Methods: Measurement of IKur, Ito and IK1 in isolated human atrial myocytes and of Kv1.5, expressed in CHO cells, by the use of patch clamp techniques. Kv4.3, HERG, KvLQT1/minK were expressed in Xenopus oocytes and currents recorded by two electrode voltage clamp.

Results: AVE 0118 was a potent blocker of IKur in human atrial cells with an EC50 of 14.4 nM. Kv1.5 channels in CHO cells were inhibited with an EC50 averaging 0.9 μM. Ito was also affected by AVE 0118, 10 μM decreased Ito peak current by 27 ± 8% and strongly altered kinetic properties of the current. The inactivation time constant was markedly shortened, from 33.6 ± 1.8 ms (control) to 11.5 ± 0.9 ms (AVE 0118), which lead to a strong decrease of the calculated net Ito current. Block of Kv4.3 showed similar characteristics to that of Ito. IK1 was only mildly blocked by high concentrations of AVE 0118 (-19.6% at 10 μM AVE 0118). HERG and KvLQT1/minK were not altered by AVE 0118.

Conclusions: AVE 0118 is a highly potent blocker of IKur in human atrium, it also affects Ito in higher concentrations. With a predominant block of IKur, the drug should delay repolarization mainly on the atrial level in human heart. This makes it a class III antiarrhythmic drug with a novel mechanism of action that could be beneficial for the treatment of supraventricular tachycardias, especially atrial fibrillation.

P2132 Altered calcium handling in a rabbit model of left ventricular dysfunction – implications for contractile function and arrhythmogenesis

F.R. Quinn[1], S.M. Cobbe[1], G.L. Smith[2]. [1]*University of Glasgow, Department of Medical Cardiology, Glasgow, United Kingdom;* [2]*University of Glasgow, IBLS, Glasgow, United Kingdom*

Background: Calcium (Ca) has a central role in the mechanical and electrical properties of cardiac myocytes. We investigated changes in cellular calcium handling in a rabbit infarct model of heart failure (8 weeks after coronary artery ligation) which exhibits left ventricular dysfunction, pulmonary and hepatic congestion and a propensity to arrhythmias.

Methods: Voltage clamp studies were performed at 37°C on enzymatically-isolated single cells, loaded with the Ca indicator Fura-2. Sodium-calcium exchanger (NCX) activity was estimated from the rate constant (RC) of Ca decay during 10 mM caffeine application. Sarcoplasmic reticulum Ca pump (SERCA) function was estimated from the RC of Ca decay after brief caffeine application in the presence of 10 mM Ni. SR Ca content was determined from the integral of the NCX current induced by caffeine application. These measures were each performed after 30 sec of 1 Hz stimulation and were corrected for non-NCX Ca removal mechanisms. NCX current density was determined from the Ni-sensitive current in response to a ramp protocol, with major interfering currents blocked and intracellular Ca buffered to 258 nM. Current density data were well fit by the model of NCX function of Weber et al (J Gen Physiol 2001; 117:119-131), which was used to determine V-Max. Allosteric regulation of NCX was studied by examining the outward NCX current through a range of Ca concentrations, using a voltage step protocol.

Results: Compared to sham-operated controls, in LVD cells the decay of the calcium transient was slowed (RC = 2.60±0.17 vs 3.46±0.31/s, p=0.01), there was reduced NCX current density (V-Max = 7.69±0.57 vs 12.19±0.56 A/F, p<0.0001) and reduced NCX activity (0.72±0.07 vs 1.29±0.13/s, p=0.0002). There was a significant increase in SR Ca content (80.58±5.94 vs 66.26±4.07 μmoles/l cell volume, p=0.03) and a trend towards reduced SERCA function (2.02±0.18 vs 2.46±0.32/s, p=0.12). Studies of allosteric regulation of NCX by Ca showed that in LVD cells the exchanger was more sensitive to Ca (Km for calcium activation 206±42 vs 375±62 nM, p=0.02).

Conclusions: Calcium handling is significantly affected in this model of LVD. The balance between NCX and SERCA activity is altered, such that diastolic relaxation is impaired, whilst SR Ca load is increased. These changes could increase the frequency of arrhythmogenic spontaneous Ca release. There is also evidence of altered regulation of NCX.

P2133 B3-subunits isoforms in the human myocardium have different effects on the single pore-forming subunit CaV1.2a of cardiac calcium channels

R. Hullin[1], I.F. Khan[2], P. Mohacsi[1], S. Herzig[2]. [1]*University Hospital Bern, Cardiology, Bern, Switzerland;* [2]*University of Cologne, Department of Pharmacology, Cologne, Germany*

Introduction: Voltage dependent L-type calcium channels are multi-subunit membrane proteins which are formed by the ion conducting pore (a1c-), and auxiliary subunits (b, a2d). b-subunits, in particular, have been shown to increase the activity of the pore subunit. In the human heart 3 different b-subunits genes are identified that encode the b1-, the b2- and the b3-subunit. In this study effects of the b2-subunit and two different b3-isoforms (b3a- and a truncated b3-isoform) on the poreforming subunit CaV1.2a are characterised.

Methods and Results: Using sequence specific oligonucleotide primers, a 1252bp full-length cDNA was cloned from non-failing human left ventricular myocardium which is identical to the b3a-subunit from a human thyroidoma cell line. Interestingly, a b3-splice variant was identified that does not contain the 20 nucleotide long exon 6 and results in a premature stop of transcription at nucleotide 632. In non-failing human heart expression of the full length b3a-isoform prevails (83/17%) but changes to 51/49% in the failing human heart. Furthermore, transcript sizes in non-failing/failing myocardium vary with respect to localization: left ventricle 3,5/3,5 kb, right ventricle of 3,2kb/- and right atrium of 3,2/3,5 kb. PCR experiments show that the different transcript sizes are due to variations in the untranslated region. For co-transfection experiments a CHO-cell line already stably transfected with the CaV1.2a of the rabbit L-type calcium channel was used. After cotransfection of a2d-1 and GFP together with either rabbit b2a-, b3a- or the truncated b3-form, fluorescent cells were studied at 24-72 h intervals. Expression of b3a- and the truncated b3-isoform resulted in increased availability of single channels (89,9±5,5%; 76,2±6,7%) compared to cotransfections without b-subunits (31,1±12,6%). In cells cotransfected with b2a, calcium channel availability was unchanged but open probability (12,4±6,3% vs. 0,63±0,21%), mean open time (0,4±0,05 ms vs. 0,18±0,03 ms) and ensemblage average current (174±74 fA vs. 10±1 fA) were increased compared to controls.

Summary and conclusions:

Because effects of both b3-subunit isoforms are rather similar, isoform shift in heart failure has no functional consequence. The b2a-subunit has the most pronounced effect on fast gating parameters, whereas b3-subunits take effect predominantly on the calcium channel availability but not on gating parameters.

P2134 Human atrial Na^+-K^+ pump current, and its sensitivity to voltage or extracellular K^+

A J. Workman[1], K A. Kane[2], A C. Rankin[1]. [1]*Glasgow Royal Infirmary, Medical Cardiology Dept., Glasgow, United Kingdom;* [2]*University of Strathclyde, Physiology and Pharmacology Dept., Glasgow, United Kingdom*

Introduction: The Na^+-K^+ pump is electrogenic and the pump current, Ip, contributes to the cardiac resting and action potential. However, Ip has not been recorded previously in human atrium. Aims: To determine the magnitude of human atrial Ip and to investigate its sensitivity to membrane potential and extracellular K^+ concentration, $[K^+]_o$. Methods: The whole cell patch clamp technique was used in single myocytes isolated enzymatically from the right atrial appendage of 5 patients undergoing coronary artery bypass surgery. All patients were in sinus rhythm. Results: With an intracellular (pipette) Na^+ concentration of 30 mM, in the presence of time-dependent ion current blockers (Ba2+, Ni2+ and Cs+), an increase in $[K^+]_o$ from 0 to 5.4 mM produced a marked and constant outward shift in the holding current density measured at -40 mV, from -0.03±0.06 to 0.81±0.09 pA/pF ($P<0.05$, n=14 cells). This current shift was fully reversed upon returning $[K^+]_o$ to 0 mM. The Ip blocker ouabain (10 micromol/L) had no effect on the holding current measured in the presence of 0 mM $[K^+]_o$, but abolished the current produced by 5.4 mM $[K^+]_o$ (n=4). Moreover, the magnitude of the K^+- and ouabain-sensitive currents was similar, at 0.84±0.06 and 0.94±0.10 pA/pF, respectively, indicating that the current generated by increasing $[K^+]_o$ was Ip. The steady-state current voltage relationship of Ip was measured between -120 and +60 mV, using voltage step pulses (300 ms duration, 0.1 Hz, n=5) or ramps (increasing at 36 mV/s, n=8). Ip was calculated by subtracting currents recorded in the presence of 0 mM $[K^+]_o$ from those recorded with 5.4 mM $[K^+]_o$. Ip was voltage-dependent, displaying a reduced current density at hyperpolarised potentials (eg: 0.39±0.11 pA/pF at -120 mV, compared with 1.91±0.28 pA/pF at +60 mV; $P<0.05$, n=8). Ip also displayed a marked sensitivity to $[K^+]_o$, as measured by the current shift at -40 mV in response to stepwise increments in $[K^+]_o$ between 0 and 10 mM, relative to the current recorded at 0 mM $[K^+]_o$. With $[K^+]_o$ at 1 and 10 mM, the Ip density was 0.41±0.06 and 0.86±0.09 pA/pF, respectively. The $[K^+]_o$ concentration-response curve yielded an EC50 of 1.4±0.3 mM (n=5). Conclusion: We report, for the first time to our knowledge, the presence of Na^+-K^+ pump current in human atrial cells. The observed increase in Ip density both at depolarised membrane potentials and elevated extracellular K^+ concentrations indicates a potential role for this current during atrial tachyarrhythmias.

P2135 Changes in conductance and connexin43 expression in myocytes from the canine infarct border zone

J. Yao[1], W. Hussain[2], P.M. Patel[2], P.A. Boyden[1], A.L. Wit[1], N.S. Peters[2]. *[1]Columbia University, College of Physicians & Surgeons, New York, United States of America; [2]Imperial College, St Marys Hospital, Cardiac Electrophysiology, London, United Kingdom*

Remodelling of gap junctions in the epicardial border zone (EBZ) of healing infarct is an important factor for arrythmogenesis. In this study, we investigated the voltage-dependence and kinetics of gap junctional channels (GJC) and changes in connexin43 (Cx43) expression in EBZ cells using double patch clamp and immunoconfocal techniques. Gap junctional conductance (Gj) in cell pairs from EBZ was reduced to 30±12 nS (mean±SE, n=24) at a transjunctional voltage (Vj) of +10 mV vs. 99±13 nS (n=36, P<0.005) in controls. Steady-state conductance-voltage relationships in both EBZ and control cell pairs could be described by a two-way Boltzmann function, but Vo (transjunctional voltage halfway between maximal and minimal Gj) in EBZ cells (n=11) was shifted to +85 and -82 mV from +64and -64 mV in controls (n=9). The decay phase of gap junctional currents at Vj beyond ±50 mV could be fitted with a double exponential function. Time constants of fast and slow components at a Vj of +80 mV were 969±223 ms and 3764±1124 ms (n=11) in EBZ cells, and 344±81 ms and 1723±368 ms (n=9, P<0.05) in controls. To determine the level of Cx43 expression, we labelled randomly selected cells for immunoconfocal quantification of Cx43 and cell volume from serial optical slices. EBZ cells displayed a near significant reduction in Cx43 expression (2509 ±1213μm^3 vs 3811 ±1379μm^3: p<0.06). Cell volume from infarct hearts was reduced compared to normal (21308 ± 5567μm^3 n=10 normal vs. 28225 ± 4208μm^3, n=8 EBZ: p< 0.001). However there was no change in Cx43 immunolabelling per unit cell volume. These results suggest that changes in voltage-dependence and kinetics of Gj in EBZ cells are due to modifications of Gap junctional function and are independent of Cx43 expression.

P2136 Role of IKr for electrophysiologic heterogeneity

P. Milberg, L. Eckardt, P. Kirchhof, L. Fabritz, S. Ramtin, N. Reinsch, G. Breithardt, W. Haverkamp. *Medizinische Klinik und Poliklinik C, Münster, Germany*

Experimental findings in isolated myocytes demonstrated regional differences in the contribution of the delayed rectifier current and its slow and rapid activating components IKs and IKr. It is unknown whether these regional differences play also a role in the intact heart. We therefore investigated regional effects of the IKr blocker erythromycin in isolated intact rabbit-hearts. Methods and Results: In 13 Langendorff-perfused rabbit hearts, 300μM erythromycin led to a significant increase in QT-interval and MAP-duration at eight simultaneous monophasic action potential (MAP) recordings around the heart from the base to apex (MAP90 increase: right-epicardial 18%, left-endocardial 18%, left-epicardial 10%, p<0.05). This significantly increased dispersion of repolarization estimated as the maximal difference of the MAP recordings. Under baseline conditions (cycle lengths 900 - 300 msec) longer mean MAP90 on the right epicardium than on the left side was observed (p<0.05). There was no difference between apical and basal MAP-recordings (p=ns). After infusion of erythromycin there were still no differences between the apex and the base of the heart, but an increase of interventricular dispersion of repolarization of 42%.

Conclusion: IKr-block leads to local differences in prolongation of action potential duration in the isolated rabbit heart, (right-epicardial>left-endocardial>left-epicardial) but to no differences between basal and apical regions. This indicates a difference in the contribution of IKr between the right and left ventricle and may contribute to the electrophysiologic effects and side effects of repolarization prolonging drugs.

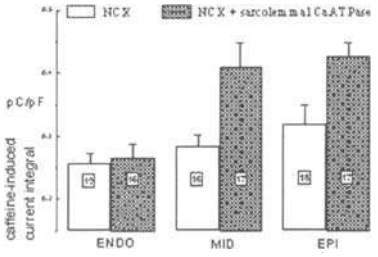
P2137 Regional differences in trans-sarcolemmal Ca^{2+} extrusion in left ventricular myocytes

H.L Wallis, C. Sears, S. Bryant. *John Radcliffe Hospital, Cardiovascular Medicine Dept., Oxford, United Kingdom*

Introduction: Relaxation is dependent on Ca^{2+} removal from the cytosol via sequestration into the sarcoplasmic reticulum (SR) and trans-sarcolemmal extrusion. This study investigates the regional contribution of both the Na-Ca exchanger (NCX) and sarcolemmal CaATPase to Ca^{2+} extrusion.

Methods: Sarcoplasmic reticulum Ca^{2+} content was assessed by rapid application of caffeine in single myocytes isolated from basal sub-endocardial (ENDO), mid-myocardial (MID) and sub-epicardial (EPI) regions of the guinea-pig left ventricle. The caffeine-induced inward current reflects electrogenic NCX activity. Sarcolemmal CaATPase activity was revealed by use of the specific blocker carboxyeosin (CXE, 20μM). The difference in the integral of the caffeine-induced current (pC/pF) in the presence and absence of CXE reflects the amount of Ca^{2+} extruded via the sarcolemmal CaATPase. Data is presented as mean±SEM.

Results: The effect of CXE on the caffeine-induced current was different in the three regions studied (p<0.05, see fig). After inhibition of the sarcolemmal CaATPase, the caffeine-induced current integral was significantly increased in EPI (by 34%) and MID (by 44%) myocytes but was unaltered in ENDO myocytes.



Regional Ca extrusion mechanisms.

Conclusions: These data show a significant regional difference in sarcolemmal CaATPase activity, being greater in MID and EPI than in ENDO myocytes. In ENDO myocytes cytosolic Ca^{2+} extrusion, via trans-sarcolemmal routes, is due almost solely to NCX. However, in MID and EPI myocytes the sarcolemmal CaATPase appears to act synergistically with the NCX, promoting more efficient relaxation in these regions.

NON-INVASIVE RISK STRATIFICATION

P2138 24-hour electrocardiogram analysis in the CHRISTMAS study

P.W. Macfarlane[1], G. Murray[2], J. McGowan[3], J.G.F. Cleland[4] on behalf of The Christmas Study Investigators. *[1]University of Glasgow, Medical Cardiology Dept., Glasgow, United Kingdom; [2]University of Edinburgh, Public Health Sciences, Edinburgh, United Kingdom; [3]Royal Infirmary, Medical Cardiology, Glasgow, United Kingdom; [4]University of Hull, Cardiology, Hull, United Kingdom*

Introduction: The CHRISTMAS Study was designed to determine whether the presence of hibernating myocardium predicts the degree of improvement in left ventricular (LV) ejection fraction with carvedilol in patients with LV dysfunction and heart failure due to ischaemic heart disease.

Aim: The aim of the present study was to determine whether a treatment effect could be detected in 24-hour ECG measurements made before and after therapy by comparing patients on Carvedilol with a control group on placebo.

Methods: 24-hour ECGs were recorded, using Spacelabs Burdick recorders, at baseline and 6 months later at the end of the study. All recordings were analysed centrally in the Core ECG Lab in Glasgow using a Spacelabs Burdick analyser.

Results: Data were available from 209 patients, 100 of whom were on carvedilol. There were 183 males (mean age 61.6(8.5) years) and 26 females (mean age 67.0(10) years). Significant differences between groups were noted at the study end (see table for mean values of ECG data). With Carvedilol, RMSSD increased, SDANN decreased, and total power at max (TPMAX) and min (TPMIN) LF/HF increased, while minimum, maximum and mean heart rate over 24 hours were all significantly reduced. No differences in SDNN or triangular index (TRIDX)were detected. However, there was a significant reduction in ventricular ectopic beats and in the number of episodes of non sustained ventricular tachycardia (NSVT) in the carvedilol group. There was no evidence that these results differed according to the presence or absence of hibernating myocardium.

	RMSDD	SDANN	SDNN	TRIDX	TPMAX	TPMIN	No. VES	NSVT
T B	34.34	106.27	117.56	23.97	1962	2258	1654	1.45
T F	41.55	100.41	118.32	25.34	3478	2897	895	0.13
P B	34.93	102.17	113.61	22.29	2270	3353	1519	1.18
P F	36.04	103.25	115.26	23.22	2479	1282	1764	1.26
p value	0.020	0.036	0.322	0.665	0.030	0.027	0.012	0.003

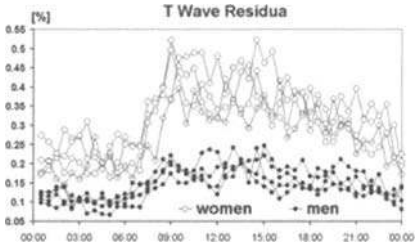
Baseline (B) and final (F) mean values of ECG measurements in the treated (T) and placebo (P) groups.

Conclusion: These results indicate that in patients with LV dysfunction of ischaemic aetiology, carvedilol exerts significant vagal effects and markedly reduces ventricular arrhythmias regardless of the presence or absence of hibernating myocardium.

P2139 Gender differences of depolarisation and repolarisation heterogeneity

V. Batchvarov, P. Smetana, A. Ghuran, K. Hnatkova, A.J. Camm, M. Malik. *St.George's Hospital Medical School, Department of Cardiological Sciences, London, United Kingdom*

Background: The risk of torsade de pointes (TdP) is higher in women, but the mechanism of this gender difference is not known. The non-dipolar ECG components (ECG residua) are considered to directly reflect local electrical events (i.e. electrical heterogeneity). We compared QRS residua (QRS-R) and T wave residua (T-R) of standard 12-lead ECGs and their circadian variation in healthy men and women.
Methods: 24-hour 12-lead digital ECGs (SEER MC, GE Marquette, one 10-second ECG/30 sec, 2880 ECGs/24 hours) were recorded 4 times (at baseline, after 1 day, 1 week, and 1 month) in 22 healthy men (age 27±7 years) and 24 healthy women (27±8 years). Using singular value decomposition, the 12-lead ECGs were reconstructed in an optimised 8-dimensional space, in which leads 1 to 3 represented the dipolar components (i.e. the heart vector), while leads 4 to 8 represented the non-dipolar components. QRS-R and T-R were expressed as proportion (%) of the whole ECG signal (i.e. dipolar + non-dipolar components).
Results: In all 4 recordings, T-R were significantly greater in women (0.31±0.01 vs 0.15±0.005%, p<0.0000001), while QRS-R were significantly greater in men (0.46±0.003 vs 0.32±0.002%, p<0.0000001). In women, T-R exhibited significant circadian pattern with midday peak, when the gender differences were further increased (Figure). No circadian pattern of QRS-R was detected in women or men.



Conclusions: Repolarisation heterogeneity is greater in women, while depolarisation heterogeneity is greater in men. Repolarisation heterogeneity and its gender difference exhibit circadian pattern. These findings might be linked to the gender difference in the risk of TdP and to the circadian variation in the frequency of arrhythmic events.

P2140 Linkage between mechanical alternans and ST-T electrical alternans in patients with chronic heart failure

M. Kodama[1], M. Hayashi[1], H. Tachikawa[1], T. Kashimura[1], Y. Aizawa[1], K. Watanabe[2], M. Nakazawa[3]. *[1]Niigata University School of Medicine, First Department of Internal Medicine, Niigata, Japan; [2]Niigata College of Pharmacy, Clinical Pharmacology, Niigata, Japan; [3]Niigata University, School of Health Science, Niigata, Japan*

Background and Purpose: Both progressive heart failure and sudden death due to ventricular fibrillation are major causes of death in patients with chronic heart failure. Mechanical alternans has been observed in patients with severe congestive heart failure, and it is a predictor of short life-expectancy. T wave alternans is a precursor of ventricular fibrillation in patients with acute coronary syndrome and long QT syndrome. To clarify the linkage between mechanical and electrical alternans, we investigated the occurrence of both alternans in 94 patients with chronic heart failure.
Methods: Study population contained 71 males, their mean age was 50.8±13.8. Mean LVEDVI was 127±42 and mean LVEF was 35±10%. Sixty-eight patients had sinus rhythm and remainder had atrial fibrillation. Mechanical alternans was defined when constant alternating pressure over 4 mmHg continued over 20 beats. ST-T electrical alternans was judged on standard surface ECG. Occurrence of alternans was examined at rest, during pacing tachycardia, and under stepwise dobutamine loading (2 - 4 - 8 microgram/kg/min).
Results: Prevalence of mechanical and electrical alternans were 19.1% and 4.4% at rest, 45.5% and 8.0% during pacing tachycardia, and 62.1% and 9.5% under dobutamine loading. Overall, 70 patients (74.5%) showed mechanical alternans and 10 patients (10.6%) showed T wave alternans under any condition. T wave alternans has always appeared with large mechanical alternans (mean alternating pressure 18.4±9.8 mmHg). There was no case who revealed T wave alternans without mechanical alternans. Patients with mechanical alternans revealed larger left ventricular endsystolic volume than those without, and lower left ventricular ejection fraction. Among patients with mechanical alternans, patients with electrical alternans showed lower EF than those without (27.5±4.4 and 35.1±10.2, p<0.002). Alternating pressure during electrical alternans was larger than that of mechanical alternans not accompanied by electrical alternans (18.4±9.6 mmHg vs 10.4±5.5 mmHg, p<0.05).
Conclusion: Frequency of T wave alternans was unexpectedly high in patients with chronic heart failure, especially under tachycardia or catecholamine exposure. Mechanical alternans is related to failing myocardium and ST-T electrical alternans may also be related to severer one. T wave alternans may depend on mechanical alternans.

P2141 Incidence, clinical determinants, and predictive value of microvolt T-wave alternans after acute myocardial infarction

T. Klingenheben, S. H. Hohnloser. *J.W. Goethe University, Dept. of Medicine, Div. of Cardiology, Frankfurt., Germany*

Background: Microvolt-level T-wave alternans (TWA) is associated with vulnerability to ventricular tachyarrhythmias. Its predictive value in pts following acute myocardial infarction (AMI) treated according to contemporary therapeutic guidelines, including a high incidence of β blocker administration, is not known.
Methods: In the present study, the incidence, clinical determinants and the predictive value of TWA (spectral method; CH2000, Cambridge Heart, Bedford, MA) were assessed in 197 consecutive AMI pts.
Results: Of 197 pts (58±11 years, 78% male; 51% anterior MI) 43 (21%) had a positive TWA. TWA was negative in 50% and incomplete/indetermined in 29% of pts. In pts with reduced LV function (EF<35%; N=50) the incidence of a positive TWA was twice as high as in those with EF>35% (34% vs 17%; p=0.02). Univariate comparison revealed no association of TWA results with other ECG-based noninvasive risk markers such as heart rate variability, baroreflex sensitivity, or QRS duration. On multivariate analysis only LVEF was an independent predictor of a positive TWA (X2=5.328; p=0.021). With respect to cardiac mortality and arrhythmic events during follow-up in this non-selected AMI population, TWA was only of borderline predictive value (RR 1.54, 95%C.I.: 0.57-4.14;p=ns).
Conclusion: The incidence of a positive TWA early following AMI is 21%. Pts with reduced LVEF have a higher probability of having a pathologic TWA result. However, the predictive value of TWA in unselected post AMI pts seems to be low.

P2142 Correlation between T-wave alternans and endomyocardial biopsy findings in patients with dilated cardiomyopathy

M. Zabel, M. Noutsias, U. Kühl, M. Pauschinger, C. Sticherling, S. Behrens, H.P. Schultheiss. *Klinikum Benjamin Franklin, Div. of Cardiology, Berlin, Germany*

Background: Patients with dilative cardiomyopathy (DCM) frequently suffer from malignant ventricular arrhythmias. T wave alternans (TWA) testing has been proposed for risk stratification but the incidence of positive test results seems markedly increased as compared to patients with coronary artery disease. The genesis of this increased TWA positivity is as yet unknown.
Objective: To compare TWA results with endomyocardial biopsy (EMB) findings in a typical population of DCM patients.
Methods: TWA was assessed in 103 DCM patients utilizing the Cambridge Heart exercise method. Positive TWA was defined as a TWA amplitude > 1.9 mV for > 1 min in > 1 ECG lead. Tracings were graded "indeterminate" if noise or premature ventricular beats prevented definite classification into positive or negative TWA or the heart rate threshold was not reached. EMB were analyzed with standardized histological (fibrosis) and immunehistological (CD2/CD3+ T-lymphocyte infiltration, expression of cell adhesion molecules/CAMs) techniques. Angiographic left ventricular ejection fraction (LVEF) averaged 38 ± 16%.
Results: In 51/103 patients (50%), TWA was graded positive, in 41/103 patients (40%) TWA was found negative, while the remaining tests were indeterminate. In 22/103 patients (21%) significantly increased CD2/CD3+ T-lymphocytes were found in the EMB specimen while 64/103 (62%) exhibited CAM abundance (CAMs), 68/103 patients (66%) showed interstitial fibrosis. TWA positivity was siginificantly associated with LVEF (47 ± 13% if TWA positive, vs. 27 ± 9% if TWA negative, vs. 42 ± 12% if TWA indeterminate, p < 0.004). In contrast, the TWA finding did not correlate with histological (interstitial fibrosis yes/no: 35/68=51% vs. 16/35=46% positive TWA results, p=ns) or immunohistological (CD2/CD3+ infiltrates yes/no: 12/22=55% vs. 39/81=48% positive TWA results, p=ns; CAMs yes/no: 28/64=44% vs. 23/39=59% positive TWA results, p=ns).
Conclusions: TWA testing yields a positive finding in 50% of DCM patients. The TWA result is unrelated to EMB findings but particularly depends on LVEF.

P2143 Value of ventricular repolarisation dynamicity for predicting implantable cardioverter therapy

P. Chevalier[1], H. Burry[2], M. Stumpf[1], G. Kirkorian[1], P. Touboul[1]. [1]*Louis Pradel, cardiology, Lyon, France;* [2]*Hôpital, Cardiology, Genevève, Switzerland*

Abnormal QT dynamicity may be associated with increased risk of ventricular arrhythmias. Our aim was to investigate whether QT dynamicity measured by Holter monitoring could predict implantable cardioverter (ICD) therapy.

Methods: Patients requiring an ICD had a 24-hour Holter done systematically after implantation at hospital discharge, and were followed-up prospectively. QT dynamicity was evaluated by the linear regression slope of QT intervals plotted against RR intervals (QT/RR), using a dedicated Holter algorithm. Heart rate variability (HRV) was calculated by 24-hour SDNN.

Results: 75 patients were included (age 58±15 years,69 men.84% of patients were on beta-blockers. Appropriate ICD therapy occurred in 45 patients (60%) over a mean follow-up of 38±13 months.Results of univariate analysis are in the table. Multivariate analysis also identified slope of diurnal QT/RR as an independant predictor of ICD therapy.

Table

	ICD therapy (m±SD)	No ICD therapy (m±SD)	p
Slope QT/RR day	0.22±0.06	0.18±0.06	0.004
Slope QT/RR morning	0.20±0.07	0.18±0.067	0.20
Slope QT/RR night	0.19±0.063	0.17±0.065	0.29
Slope QT/RR 24 Hour	0.21±0.073	0.19±0.08	0.09
SDNN 24 Hours	115±42	122±51	0.83
HR day (b/min)	100±11	95±13	0.75
HR night (b/min)	92±10	89±16	0.62
LVEF (%)	35±15	45±18	0.002
VF as presenting arrhythmia (%)	37	64	0.003

Results of univariate analysis

Conclusions: Increased diurnal QT/RR interval dynamicity is independently predictive of ventricular arrhythmias in patients with an ICD. HRV appears to be devoid of any value in our study, probably because most of the patients were on beta-blockers.

P2144 Improved diagnostic ability of high-resolutin electrocardiogram by combined assessment of QRS- and ST-T-microvariability and static time-domain parameters

M. Höher[1], J. Wöhrle[1], O. Grebe[1], H.A. Kestler[2]. [1]*University of Ulm, Cardiology Dept., Ulm, Germany;* [2]*University of Ulm, Neural Information Processing, Ulm, Germany*

Increased QRS- and ST-T micro-variability and ventricular late potentials are associated with an increased risk for malignant arrhythmias. However, the diagnostic power of the singular parameters is limited. In this study we investigated the diagnostic ability of a linear combination of both variant and static high-resolution ECG parameters.

Continuous and signal-averaged ECGs (16 bit, 2000Hz) were recorded from 51 healthy volunteers (age 24±4.2 ys) without any structural heart disease and no cardiac risk factors as well as from 44 patients (age 61±8.8 ys) with coronary heart disease, a history of myocardial infarction and inducible sustained ventricular tachycardia. Beat-to-beat micro-variability measurements of the QRS complex and the ST-T segment were based on 250 consecutive sinus beats per individual. QRS and ST-T micro-variation (QVI, TVI) was measured from the vector of standard deviations of the amplitude of corresponding points inside the normalized, spline-filtered signal. Signal-averaged ECGs were analyzed with the Simson method (QRSD, RMS, LAS). The diagnostic utility of the 5 singular parameters and all combinations of variables were evaluated by linear discriminant analysis maximizing the area under the receiver operator characteristic curve (AROC).

The singular parameters had the following values for AROC: QRSD: 0.868 (95% CI:[0.785; 0.925]), RMS: 0.736 [0.629; 0.823], LAS: 0.807 [0.710; 0.880], QVI: 0.758 [0.654; 0.841] and TVI: 0.759 [0.655; 0.843]. Among these QRSD was the most discriminative single variable. Combining QRS- and ST-T microvariability resulted in an area of 0.852 [0.758; 0.911]. The combination of QRS duration with either QRS- or ST-T variability proved to be almost equal (QRSD and TVI: 0.9 [0.822; 0.946], QRSD and QVI: 0.902 [0.825;0.947]). The combination of QRSD, QVI and TVI yielded the highest area of 0.929 [0.859; 0.963]. This parameter set had 89.5% accuracy, 86.4% sensitivity and 92.2% specificity in terms of VT patient detection.

We conclude that the combination of de- and repolarization variability with the static QRS duration markedly improves the detection of patients with inducible VT. The use of linear discriminant analysis together with ROC curves provides a powerful tool to evaluate the diagnostic ability of multivariate data sets.

P2145 VLF spectral band is superior in predicting mortality after myocardial infarction

J.K. Kanters[1], S.Z. Abildstrom[2], B.T. Jensen[3], C. Torp-Pedersen[4], E. Agner[5]. [1]*Laboratory of Experimental Cardiology, Dept. of Medical Physiology, København N, Denmark;* [2]*National Institute of Public Health, Copenhagen, Denmark;* [3]*Elsinore Hospital, of Internal Medicine, CCU, Helsingør, Denmark;* [4]*Gentofte University Hospital, Dept. of Cardiology, Copenhagen, Denmark;* [5]*Elsinore Hospital, Helsingør, Denmark*

Heart rate variability (HRV) is a well-known univariate risk factor of mortality after myocardial infarction. Recently the value of the standard deviation of all 24 h RR intervals (SDNN) has been disputed due to the high correlation of SDNN with the mean RR interval. The aim was to investigate whether frequency domain parameters of HRV had prognostic value in the era of ace-inhibition, betablockade and statins independent of ejection fraction and the pulse (meanRR).

Methods: We examined 101 patients with 24h holter monitoring and echocardiography (Ejection fraction=30 * Wall Motion Index (WMI)). The Holter recording was performed 1-6 days after MI using the Del Mar 563 Holter System. HRV was expressed as SDNN and in the frequency domain as ULF (0-0.0033 hz), VLF (0.0033-0.04 Hz), LF (0.04-0.15 Hz) and HF (0.15-0.4 Hz).

Results: During one-year follow-up 14 deaths occurred. The table shows the performance of the investigated parameters in a univariate Cox model. In the multivariate Cox model VLF was the best heart rate variability parameter and only WMI could add independent prognostic information.

	mean ± SE	p-value<
ln VLF (au)	18.09 ± 0.08	0.00002
Wall Motion Index	1.48 ± 0.04	0.0004
ln LF (au)	17.0 ± 0.09	0.001
AGE (y)	66.7 ± 1.3	0.006
meanRR (msec)	848 ± 14	0.009
SDNN (msec)	85 ± 2	0.009
ln ULF (au)	19.40 ± 0.06	0.02
ln HF (au)	16.38 ± 0.10	0.56 (NS)

Univariate Cox analysis.

Conclusion: The frequency domain parameter VLF is the best HRV parameter and contains prognostic information independent of ejection fraction and meanRR.

P2146 Onset of ventricular tachyarrhythmias is preceded by changes in heart rate variability

A. Zienciuk[1], A. Lubinski[2], E. Lewicka-Nowak[2], M. Kempa[2], T. Krolak[2], P. Zagozdzon[3], G. Swiatecka[2]. [1]*Medical University of Gdansk, II Dept. of Cardiology, Gdansk, Poland;* [2]*Medical University of Gdansk, II Dept. of Cardiology, Gdansk, Poland;* [3]*Medical University of Gdansk, Dept. of Epidemiology, Gdansk, Poland*

The aim of the work was to analyze if the onset of VTA is preceded by changes of heart rate variability (HRV) parameters in patients with ICD.

Methods: Time and frequency-domain analyses of HRV were performed in 54 sinus rhythm tachograms (mean duration 2 hours) recorded before onset of VTA retrieved from patients with ICD (Phylax XM, Mycrophylax Biotronik).

Results: Sudden decline in all HRV spectral components was observed 1-hour prior to VTA onset followed by gradual increase in high frequency (HF) and low frequency (LF) power for 30 minutes before the arrhythmia (HF: 13±18 vs. 29±36 ms^2 $p<0.0001$, LF: 24±32 vs. 54±66 ms^2, $p<0.0001$). Very low frequency (VLF) and total power remained at low values till VTA onset (VLF: 766 vs. 273 ms^2, $p<0.0001$). There was significant decrease in SDNN for analyzed period of sinus rhythm (70±30 ms vs. 43±31 ms, $p<0.0001$) and tendency towards shorter cycle lengths at VTA onset (809±104 vs. 767±182 ms).

Conclusions: Onsets of ventricular arrhythmias are preceded by significant changes in heart rate variability parameters already 1-hour before the arrhythmia.

P2147 HRV adjustment for age and mean RR interval disclose a different prognostic value of HRV measure in men and women with coronary heart disease

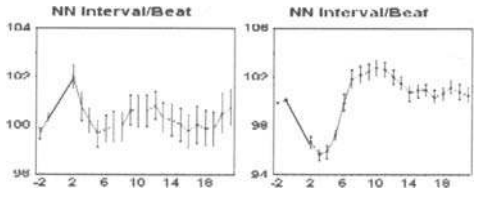
M. Sosnowski[1], B. Korzeniowska[1], J. Skrzypek-Wanha[1], Z. Czyz[1], E. Boczkowska-Gaik[1], P.W. Macfarlane[2], M. Tendera[1]. [1]*Silesian Heart Centre,Silesian Med.Sch, 3rd Division of Cardiology, Katowice, Poland;* [2]*University of Glasgow, Department of Medical Cardiology, Glasgow, United Kingdom*

Aim of the study.
An HRV dependence on age and mean RR interval (RRI) has been passed over in most studies that use the HRV analysis in risk stratification after MI and in heart failure. In this study we analyses whether HRV adjustment for age and RRI influences their prognostic value in the entire population and in men and women separately.
Methods: 382 patients (91f,291m, mean age 60±11 and 57±10, resp.), most of them with a healed MI (>3months) were enrolled into this study. 245 patients has undisturbed sinus rhythm, 68 had a frequent ventricular arrhythmia and 69 patients had atrial fibrillation. In each subjects a 24-hour ECG was recorded. HRV was analysed to obtain a commonly used measure (SDNN, ms) as well as an original index, HRV Fraction (HRVF,%) developed by the authors. The index has been previously shown to be applicable irrespective of cardiac rhythm disorders. Consequently, on basis of HRV analysis in a group of 302 apparently healthy subjects, a lower normal limit (LNL) for the adjusted SDNN and HRVF has been established according to the equations: SDNN = 82- 1.41age + 0.163RRI [±30%] and HRVF= 26.5 - 0.18age + 0.04RRI [±20%]. Different cut-points for both measures were applied: 1/arbitrary chosen (SDNN<70, HRVF<35%) and 2/below LNL after age- and RRI adjustment (aSDNN, aHRVF). The mean follow-up period was
19 ± 6 months. Total mortality was the end-point of this study.
Results: During the follow-up there were 50 deaths for any reason (13.1%). The mortality rate was lower in women (7/91, 7.7%) than in men (43/291, 14.8%). If arbitrary cut-points were considered, the reduced HRV was related to total mortality irrespective of gender. The log-rank values for men and women were 4.33 ($p<0.001$) and 2.88 ($p<0.01$) for SDNN<70ms, and 5.97 and 4.26 (both $p<0.001$) for HRVF<35%, respectively. When adjusted indices were used, the association of HRV and total mortality was held in men (log-rank 2.52($p<0.01$) for aSDNN, and 4.93($p<0.001$) for aHRVF. In women, however, the relation disappeared (log-rank 1.40 for both aSDNN and aHRVF).
Conclusions: The prognostic value of HRV analsis strongly depends on the chosen cut-points. If age and mean RR interval are taken into consideration, the prognostic value referes to men, while disappears in women. This suggest the necessity for re-evaluation of HRV indices' cut-points according to gender in future studies.

P2148 Different patterns of sinus pacemaker response to atrial and ventricular premature stimuli: mechanism of heart rate turbulence is still unclear

I. Savelieva, D. Wichterle, M. Harries, A.J. Camm, M. Malik. *St George's Hospital Medical School, Cardiological Sciences Dept., London, United Kingdom*

Background: Heart rate turbulence (HRT) represents a response of the sinus pacemaker to a ventricular (VPB) which consists of early acceleration phase (turbulence onset, TO) and late deceleration phase (turbulence slope (TS).
Objectives: To investigate whether phasic chronotropic response of sinus pacemaker to an APB is different from that to a VPB.
Methods: Thirty-seven pts (54±16 years, 32 men) referred for electrophysiologic evaluation for ventricular tachycardia (VT; 21 ischemic heart disease, 7 idiopathic, 9 other) underwent a stimulation protocol with single atrial and ventricular extrastimuli delivered with coupling intervals from 750 to 400 ms at a 50-ms step allowing a period of 20-sec of sinus rhythm between the stimuli. Atrial and ventricular TO and TS were calculated separately in pts with idiopathic VT and pts with ischemic cardiomyopathy and EF <0.40.
Results: In contrast to post-ventricular bi-phasic response of sinus rhythm (figure, right), a single APB caused initial brief deceleration of sinus pacemaker, followed by acceleration and late deceleration (figure, left). Three-phasic response was observed in both idiopathic and ischemic VT pts.



Sinus pacemaker response to stimulation.

Conclusions: Although APB can produce HRT operating via the same baroreceptor mechanism, the pattern of HRT post-APB is different from that post VPB, suggesting alternative mechanisma for "atrial" HRT.

P2149 QT dynamics: a new predictor of sudden death in CHF patients

D. Curnier[1], A. Pathak[2], J. Fourcade[2], M. Bousquet[3], J. Roncalli[2], J-M. Fauvel[2], J-L. Montastruc[4], M. Galinier[2]. [1]*UFRSTAPS, Paul Sabatier University, Toulouse cedex 4, France;* [2]*Hospital University Center, Department of Cardiology, Toulouse, France;* [3]*Cardiopulmonary Rehabilitation Center, ST Orens, France;* [4]*INSERM, Unité 317, Toulouse, France*

Background: QT dynamics are modified in patients with chronic heart failure (CHF) related to sympathovagal modifications. The autonomic nervous system can be investigated using heart rate variability (HRV) which is a marker of poor prognosis and mortality. The aim of this study is to examine the prognostic value of QT dynamics in total mortality and sudden death.
Methods: We prospectively included 170 CHF patients in sinus rhythm, with mean age of 56 years, and mean left ventricular ejection fraction of 28%. HRV time and frequency domains measured were obtained using 24 h. Holter ECG recordings. QT dynamics with QT/RR slope performed at the apex (QTa) and at the end of T wave (QTe) was obtained for 24 h.
Results: During the follow-up, 48 patients died, 21 patients died for sudden death. The 3 year mortality rate for sudden death was 14.1%. Qt dynamics were found to be a prognostic factor of sudden death using multivariate analysis with: QTe slope on 24 h. (cut off inf 0.28, Chi2=7.617, p=0.0058). Others Independent predictors for sudden death were: age (p=0.0205), no digoxine (p=0.0072), cardiothoracic ratio (p=0.0097) and creatinin (p=0.0003). Independent predictors for all-cause mortality in multivariate analysis were: Age (p=0.0007), Na (p=0.011) and SDNN (p=0.0004).
Conclusion: As described previously regarding ECG Holter parameter, SDNN was the best predictor of total mortality. QT dynamics demonstrate independent prognostic value of sudden death in CHF patients. These results were in accordance: SDNN reflects the global pattern of autonomic nervous system whereas QT dynamics reflects cardiac cell behavior implicated in sudden death.

P2150 The relationship between T-wave alternans and myocardial adrenergic nervous dysfunction in patients with dilated cardiomyopathy

M. Harada[1], A. Shimizu[2], M. Murata[3], M. Kubo[3], R. Mitani[3], Y. Dairaku[3], T. Matsumoto[3], M. Matsuzaki[3]. [1]*Yamaguchi University, Division of Cardiovascular Medicine, Ube, Japan;* [2]*Yamaguchi University, Faculty of Health Science, Ube, Japan;* [3]*Yamaguchi University, Division of Cardiovascular Medicine, Ube, Japan*

TWA is known as a predictor of lethal arrhythmia, myocardial adrenergic denervation is one of mechanisms that cause heterogeneity in a refractory period of ventricular myocardium and that result in the occurrence of lethal arrhythmia.
Objectives: The aim of this study is to confirm the relationship between the findings of T-wave alternans (TWA) and myocardial adrenergic nervous dysfunction using iodine-123 metaiodobenzylguanidine (MIBG) in patients with dilated cardiomyopathy.
Methods: TWA test and MIBG imaging were performed in 39 patients with dilated cardiomyopathy. We measured the alternans voltage of the vector magnitude (Valt) in the TWA test. We calculated the ratios of the heart to mediastinal activity in early images (e-H/M) and delayed images (d-H/M), and the washout rate (WR) using MIBG scintigraphy. Left ventricular ejection fraction (EF) with echocardiography and plasma norepinephrine level (NE) were also measured. Simple regression analysis was performed to evaluate the relationship between Valt and e-H/M, d-H/M, WR or EF, the analysis was also done between WR and NE.
Results: Thirty-two patients showed positive TWA and 7 patients did negative TWA. Significant negative correlations were shown between Valt and e-H/M or d-H/M (e-H/M: R=-0.40, $p<0.05$, Y=-5.0X+13.8; d-H/M: R=-0.55, $p<0.0005$, Y=-5.5X+14.7). There was significant positive correlation between Valt and WR (R=0.36, $p<0.05$, Y=0.06X+2.7), but there was no significant correlation between Valt and EF (R=0.29, p=0.07).
WR showed a significant positive correlation with NE (R=0.74, $p<0.001$). Since NE is considered to reflect the activity of the adrenergic nervous system, it was considered that WR also reflects the activity of the adrenergic nervous system.
Conclusions: These findings suggested that TWA was more closely affected by both myocardial adrenergic denervation and activation of adrenergic nervous system than by systolic dysfunction in patients with dilated cardiomyopathy.[3]

P2151 Temporal changes and prognostic significance of traditional and fractal measures of heart rate variability after acute myocardial infarction

V. Jokinen, J.M. Tapanainen, H.V. Huikuri. *Oulu University Hospital, Department of Internal Medicine, Oulu, Finland*

Background: Recent studies have suggested that fractal measures of heart rate variability(HRV) provide more powerful information than traditional time and frequency domain measures of HRV among selected patient groups with impaired left ventricular function. This study assessed the temporal changes and prognostic power of fractal and traditional measures of HRV after an acute myocardial infarction(AMI).
Patients and methods: Traditional time and frequency domain measures along with the newer fractal measures of HRV from 24-hour R-R interval recordings were measured at the baseline(n=414) and at one year after the AMI in a consecutive series of patients. The end-point of the study was cardiac death.
Results: All time and frequency domain measures of HRV increased during the one-year time course after AMI ($p<0.001$ for all, e.g. SDNN from 98±31 to 130±41 msec, $p<0.001$), but the fractal measures, such as a short-term scaling exponent alfa1(1.03±0.30 vs.1.04±0.26, NS) and power law slope beeta(-1.29±0.18 vs. -1.26±0.75, NS) did not change. When measured at one year after AMI reduced alfa1(<0.65) and beeta(<-1,55) were the only HRV indexes that predicted subsequent cardiac death; hazards ratio 4.83(95% CI 1.36-17.14, $p<0.05$) for alfa1 and hazards ratio 6.80(95% CI 1.97-23.51, $p<0.01$) for beeta.
Conclusion: In contrast to traditional HRV indices, fractal measures of HRV remain stable during the time course after AMI. Altered fractal heart rate behaviour is also a more powerful predictor of subsequent cardiac death when measured at one year from AMI.

P2152 internet-based continuous holter monitoring for the prevention of sudden cardiac death

S. Khoór[1], J. Nieberl[2], K. Fügedi[1], E. Kail[3]. [1]*Szent István Hospital, Cardiology, Budapest, Hungary;* [2]*Bion Ltd., Budapest, Hungary;* [3]*Budapesti Müszaki Egyetem, Budapest, Hungary*

We have developed a pocket 12 lead ECG equipment communicating with a mobile phone and transmit the recordings via GPRS to a virtual cardiology center. The aim of the main study was to change immediately the patient management with the use of telemedicine interaction in the case of disease worsening. In the first pre-study the we assessed the prognostic value of some heart rate variability (HRV) indexes in a case control study of 32 CHF patients with cardiac death and 32 matched CHF controls. All subjects had a 48-hour Holter recordings at baseline and the 2D Poincare plot indexes were determined. All of the three typical patterns (comet-, torpedo- and fan-shaped) were quantificated: the length (P-L), the area (P-A) and the highest variability extension (P-HVE). Univariate statistical analysis (Wald-chi) showed a significant association with the outcome (p-value of P-L: 0,02, P-A: 0,01, -HVE: 0,01).In the second pre-study a wavelet analysis was performed on the Holter recordings of the same population. For each 48 hour Holter recordings twelve high resolution ECG (HR-ECG) have been computed, corresponding to twelve time sequences equally spaced over the 48 hour period. The orthogonal wavelet transform (Meyer transform) have been applied on 512 points, extending from 128 ms before the beginning of the QRS complex up to 384 ms after ORS onset The decomposition was performed for 9 different scales and four different leads. We observed a significant differences in different time-frequency locations: during the QRS, at the end of QRS and in the ST segments: p-value for 8-32 Hz is 0.01, for 62-125 Hz 0.001. In the main study 28 CHF patients were monitored with a 48 hour Holter weekly for a 6 months period. The worsening parameters of the two models (shifting patient to the sudden cardiac group) indicate immediate change of management (admission to out/inpatient cardiology department). The results show a significant decrease of primer cardiac endpoints (CHF worsening, syncope, AMI and sudden cardiac death) matched to a control 28 CHF patient population: for monitored group 3/28 for control 11/28, p-value 0.01.

P2153 Heart rate recovery immediately after exercise as a predictor of mortality after an acute myocardial infarction

S.I. Nissinen, T.H. Mäkikallio, J.M. Tapanainen, M.P. Tulppo, H.V. Huikuri. *University of Oulu, Department of internal medicine, Oulu, Finland*

Background: Altered cardiovascular autonomic function has been shown to indicate an increased risk for death among the patients with a prior acute myocardial infarction (MI). An impaired heart rate (HR) recovery after the exercise has been recently shown to provide prognostic information among the mixed patient populations undergoing diagnostic exercise tests.
Methods: This study was designed to assess the predictive power of HR recovery in a consecutive serie of patients with an acute MI undergoing the predischarge exercise testing.
Results: Two hundred and twenty-nine post-MI patients who underwent exercise test after an acute MI were followed-up for a mean of 30±13 months. All the patients were on beta-blocking therapy at the time of exercise test. HR recovery was defined as the difference in the HR between the peak exercise and after 1 minute recovery. There were 17 deaths (7.4%) during the follow-up. An abnormal HR recovery, defined as a reduction of HR <12 bpm during the first recovery minute, predicted overall mortality with a hazards ratio of 5.0 (95% CI from 1.4 to16.7, $P< 0.02$) in univariate analysis. The most powerful predictor of all cause mortality was a combined variable of impaired weight adjusted exercise capacity and abnormal HR recovery with Hazard ratio 9.1; (95% CI from 3.2 to25.8, $p < 0.001$) in univariate analysis. Both impaired exercise capacity and abnormal HR recovery were, stronger predictors of death than conventional HR variability index standard deviation of N-N intervals measured from 24-hour ambulatory recording. After adjusting for age, functional class and ejection fraction, an impaired HR recovery remained as a significant independent predictor of death (adjusted hazards ratio 4.7 (95% CI from 1.3 to 16.6; $P<0.02$).
Conclusion: An impaired weight adjusted exercise capacity and abnormal HR recovery are powerful predictors of death among the patients surviving an acute MI. These simple measurements during the routine pre-discharge exercise test perform better in prediction of mortality than the traditional clinical or HR variability indices.

P2154 Temporal repolarization inhomogeneity after successful primary percutaneous coronary intervention for acute myocardial infarction: impact of admission troponin T

H. Bonnemeier, U.K. Wiegand, S. Schulenburg, E. Giannitsis, F. Hartmann, H.A. Katus, G. Richardt. *Medizinische Universität zu Lübeck, Medizinische Klinik II, Lübeck, Germany*

Objectives: This study sought to determine the temporal resolution of reperfusion arrhythmias and ventricular repolarization inhomogeneity after successful primary percutaneous coronary intervention (PCI) in acute ST-segment elevation myocardial infarction (AMI) depending on admission cardiac troponin-T (cTnT) status.
Background: Presence of admission cTnT identifies a high risk subgroup in patients with AMI. As a substantial number of these patients is suffering from malignant ventricular arrhythmias, we hypothesized that there is a relation between cTnT status on admission and inhomogeneity of ventricular repolarization.
Methods: Temporal fluctuations of ventricular repolarization were studied during and after primary PCI (TIMI 2 and 3) in 94 consecutive patients with a first AMI by continuous beat-to-beat QT-interval measurement, performed from Holter monitoring initiated on admission. CTnT levels on admission were >0.1ng/ml in 53 patients (cTnT+) and <0.1ng/ml in 41 patients (cTnT-).
Results: There were no significant differences in baseline clinical characteristics between both groups. The incidence of severe reperfusion arrhythmias was significantly higher in cTnT+ patients within the first two hours after recanalization. The course of QT-interval revealed a significant decline ($p<0.001$) after recanalization of the infarct related vessel within 10 hours in both groups, however, hourly values were significantly lower and normalization of parameters of QT-interval was more rapid in cTnT- versus cTnT+ patients in this period (QTc: 438.5±28.3 vs. 449.3±35.3 ms (hour 1)($p<0.01$); 413.6±35.8 vs. 420.1±39.2ms (hour 10)($p<0.05$)). QT-interval variability also significantly declined within four hours after PCI ($p<0.001$), and likewise cTnT- patients exhibited lower values in this period (QTSD: 29.7±6.8 ms vs. 33.5±10.5 (hour 1)($p<0.01$); 23.0±6.1 vs. 25.9±7.5 ms (hour 4)($p<0.01$)). Mean RR-interval was significantly lower in cTnT+ patients (716.5±80 vs. 773.3±109 ms ($p<0.01$)), and its increase after PCI was not as marked as in cTnT- patients.
Conclusions: Positivity of cTnT on hospital admission is associated with a significantly higher temporal inhomogeneity of ventricular repolarization and a higher incidence of malignant reperfusion arrhythmias suggesting a more advanced microvascular injury. Early successful primary PCI ultimately results in a significant recovery of parameters of QT-interval and mean RR-interval in all patients although it was significantly delayed in cTnT+ patients.

P2155 Both forms of preconditioning reduce QTc value in patients with first non ST-segment elevation myocardial infarction (NSTEMI)

C. Papadopoulos, H. Karvounis, A. Mitakidou, I. Stiliadis, G. Parharidis, G. Louridas. *AHEPA Hospital, Aristotle University, 1st Dept. of Cardiology, Thessaloniki, Greece*

Introduction: Preinfarction angina (PA) consists a strong clinical correlate to ischemic preconditioning (PC). The phenomenon of late appearance of the protective effect of PC recently is thought that may extend over a period of one to three days, unlike the protection afforded by the classic PC phenomenon. The aim of the present study is to evaluate the impact of both forms of PC on QTc value, in patients (pts) with a first NSTEMI.
Methods: 48 pts, with first NSTEMI and with angiographically proven poor or none collateral circulation (0-1 according to Rentrop classification) were enrolled in the study. All pts underwent coronary angiography in the first 72 hours from admission. Pts were divided into three groups. First group consisted of 20 pts who did not report PA (typical chest pain episodes lasting less than 20 minutes, PA-); second group consisted of 12 pts with PA within 24 hours prior to admission (24h PA+); and the third group consisted of 16 pts who reported PA within 24 to 48 hours prior to admission (48h PA+). A standard 12 lead ECG, was obtained at admission and discharge and QTc values were evaluated by two separate readers, using Bazzet's formula. The primary outcome was determined as the effect of PA on QTc value at discharge. We performed two series of analyses in regards to the outcome: group (24h PA+) pts versus (PA-) pts and group (48h PA+) pts versus (PA-) pts, reflecting the classic and the delayed form of PC respectively versus no PC effect. Statistical analysis was performed using t-test and statistical significance was defined as a p-value <0.05.
Results: There were no significant differences between the three groups concerning demographic data, infarct location, severity of coronary heart disease and therapy received. The table reviews all relevant QTc data.

	PA- (n=20)	24hPA+ (n=12)	p	PA- (n=20)	48hPA+ (n=16)	p
QTc admission (msecs)	417±59	432±19	NS	417±59	440±38	NS
QTc discharge (msecs)	455±53	412±50	0.015	455±53	417±29	0.033

The PC effect on QTc value

Conclusions: Both forms of preconditioning, similarly and significantly reduce QTc value at discharge in pts experiencing a first NSTEMI, documenting possible protection from future arrhythmic events and producing evidence for the true existence of the second window of protection of PC in humans.±

P2156 Simple cardiovascular reflex tests predict death during first 6 months after acute myocardial infarction

D.V. Abramkin[1], I.S. Yavelov[1], N.A. Gratsiansky[2]. [1]*Institute of Physico-Chemical Medicine, Center for Atherosclerosis, Moskva, Russian Federation;* [2]*Institute of Physico-Chemical Medicine, Center for Atherosclerosis, Moskva, Russian Federation*

Objective: To evaluate prognostic value of heart rate (HR) response to simple provocative maneuvers performed during hospitalization because of myocardial infarction (MI).
Material: 187 patients with acute MI (68,4% men) aged 34-75 (60.5±9.7) years. Methods. Valsalva maneuver (VM) with calculation of Valsalva ratio (VR) and deep breath test (DB) were performed on days 4-11 (7.8±0.9) of MI when 93.6% of patients received beta-blockers. Technique of DB test: a patient breathed 6 times per minute, from each of 6 breathing phases at first minute of test a mean of longest and shortest RR intervals was calculated and maximal and minimal HR determined, then difference of these HRs (HRD) was calculated.
Results: During period of follow up for 6.5±0.7 months there were 13 cardiovascular deaths (8 sudden). According to univariate logistic regression analysis result of VR was predictor of cardiovascular death together with such classical predictors as age, history of angina and MI, postinfarction angina, ejection fraction, and clinical heart failure (HF) on the day of test. Multivariate (step-up) analysis showed that independent predictors of cardiovascular death were history of MI, postinfarction angina, and VR (*OR* 0.001, 95% CI 0.0001-0.9). VR and ln HRD were in the list of univariate predictors of sudden death (OR 0.0001, 95% CI 0.0001-0.2 and OR 0.3, 95% CI 0.1-1.03, respectively) with age, history of MI, postinfarction angina, clinical HF on the day of test. Independent predictors of sudden death were ln HRD (OR 0.3, 95% CI 0.1-0.9) and clinical HF on the day of test.

VR and HRD in survivors and nonsurvivors

		Survivours	Nonsurvivours	p
Valsalva ratio	Cardiovascular mortality	1.2+0.2	1.1+0.07	0.02
	Sudden death	1.2+0.2	1.1+0.04	0.03
HRD	Cardiovascular mortality*	5.5 (3.6; 8.9)	3.3 (2.6; 9.6)	0.1
	Sudden death*	5.5 (3.6; 8.9)	3.2 (2.1; 9.3)	0.03

* medians (25, 75 percentiles)

Conclusion: HR response to VM and DB predict cardiovascular death during first 6 month after acute MI. While decrease of Valsalva ratio was primarily associated with cardiovascular mortality result of DB was more closely related to sudden death.

P2157 Cardiac arrhythmias and risk stratification after myocardial infarction (CARISMA): results of the pilot study

H.V. Huikuri[1], V. Mahaux[2], P-E. Bloch-Thomsen[3]. [1]*University of Oulu, Dept. of Int. Med., Div. of Cardiology, Oulu, Finland;* [2]*Medtronic Bakken Research Center, Maastricht, Netherlands;* [3]*University of Gentofte, Copenhagen, Denmark*

Background: CARISMA is a multicenter, observational study enrolling patients with an acute myocardial infarction (AMI) and an ejection fraction < 40% in whom the incidence of tachy- and bradyarrhythmias is prospectively assessed by means of an insertable loop recorder (ILR) providing automatic arrhythmia detection. At 6-weeks post-MI, extensive risk-stratification tests (EP-testing, Holter, HRV, late potentials, QT dispersion, T-wave alternans) are performed to assess their predictive value for life-threatening arrhythmias.
Results: The pilot study included 28 patients with a mean follow-up of 52 days. The ILR detected atrial tachyarrhythmias in 6 patients, non-sustained ventricular tachycardia (nsVT) in 2, idioventricular rhythm in 2, and intermittent 3° AV-blocks in 3. Four patients with nsVT documented either by ILR (n=2) or Holter (n=2) were inducible into sustained VT and received an ICD, and a pacemaker was implanted in the 3 patients with intermittent 3° AV-blocks.
Conclusions: ILR disclosed significant arrhythmias in a large proportion of patients shortly after their acute MI. An indication for implantable device therapy was also detected in a relatively high number of patients enrolled in the CARISMA pilot study.

P2158 Effects of aerobic exercise training on nonlinear dynamics and variability of heart rate in elderly people

H. Fukuta[1], J. Hayano[1], S. Ishihara[1], S. Sakata[1], S. Akita[1], S. Mukai[1], N. Takeshima[2], G. Kimura[1]. [1]*Nagoya City University Medical School, Third Department of Internal Medicine, Nagoya, Japan;* [2]*Nagoya City University, Institute of Natural Sciences, Nagoya, Japan*

Earlier studies have reported mixed results as to the effect of aerobic exercise training on heart rate (HR) variability and none of them reported the effects on nonlinear measures of HR dynamics. We analyzed the effects of 12-week supervised aerobic exercise training (60 minutes per session, three times a week) on HR dynamics and variability in 12 healthy elderly volunteers (age range; 64-77 years, 6 males). At baseline and the end of the exercise training, we obtained 24-hr ambulatory ECG and assessed irregularity and complexity of HR dynamics by approximate entropy (ApEn) and fractal correlation (short- and long-term fractal scaling exponents of detrended fluctuation analysis [alpha 1 and 2]), respectively, and HR variability by time- and frequency-domain measures (standard deviation of normal-to-normal R-R intervals [SDNN] and high-frequency [HF; 0.15 to 0.4 Hz], low-frequency [LF; 0.04 to 0.15 Hz], very-low-frequency [VLF; 0.0033 to 0.04 Hz] and ultra-low-frequency [ULF; <0.0033 Hz] power). After completion of the exercise training, oxygen uptake (*VO2*) at lactate threshold increased (15.9 ± 2.4 to 18.9 ± 4.2 [ml/kg/min], p = 0.026) and 24-hr mean HR decreased (73 ± 7 to 70 ± 7 [beats/min], p = 0.014). However, no significant changes were observed in either nonlinear measures of HR dynamics or any measure of HR variability (Table).

Changes in HR dynamics and variability

	Baseline	After Training	p
ApEn	1.15 (0.16)	1.19 (0.14)	p = 0.33
Alpha 1	1.17 (0.19)	1.13 (0.18)	p = 0.29
Alpha 2	1.13 (0.06)	1.13 (0.07)	p = 0.96
SDNN (ms)	146 (29)	138 (30)	p = 0.11
ln HF (ln[ms2])	5.25 (1.05)	5.62 (0.96)	p = 0.06
ln LF (ln[ms2])	6.01 (1.08)	6.20 (1.02)	p = 0.23
ln VLF (ln[ms2])	7.09 (0.59)	7.28 (0.58)	p = 0.14
ln ULF (ln[ms2])	9.60 (0.57)	9.75 (0.40)	p = 0.36

Values are means (SD). For abbreviations, see text.

Our results indicate that measures of HR dynamics and variability do not show changes coupled with an improvement of aerobic capacity or negative chronotropic effects induced by exercise training. At least in elderly people, prognostic associations reported for these measures seem unexplained by the effects of fitness level on these measures.

ATRIAL FIBRILLATION – STROKE

P2159 Relationship of plasma von willebrand factor and soluble p-selectin to echocardiographic findings in 1308 patients with atrial fibrillation

D.S.G. Conway[1], L.A. Pearce[2], B.S.P. Chin[1], R.G. Hart[2], G.Y.H. Lip[1]. [1]*City Hospital Birmingham, University Department of Medicine, Birmingham, United Kingdom;* [2]*University of Texas at San Antonio, San Antonio, Texas, United States of America*

Background: Several transthoracic echocardiographic (TTE) parameters have been shown to predict stroke in atrial fibrillation (AF), with left ventricular (LV) dysfunction the only independent predictor. AF is associated with increased levels of plasma von Willebrand factor (vWf, an index of endothelial damage/dysfunction) and soluble P-selectin (sP-sel, an index of platelet activation), but the relationship to TTE parameters is unclear.
Methods: We measured plasma vWf and sP-sel levels (ELISA) in 1308 participants (mean age 69,sd9 years; 75% male) enrolled in the Stroke Prevention in AF (SPAF) III trial and related these indices to TTE data (LV function, atrial size, valve disease).
Results: vWf levels were higher in patients with an abnormal mitral valve (151sd30 vs. 143sd31 iU/dl, p<0.001), LV fractional shortening <=25% (152sd29 vs. 145sd31 iU/dl, p=0.004) or large left atrial size (>median of 4.7 cm) (148sd30 vs. 144sd32 iU/dl, p=0.02). Compared to patients with normal LV function, vWf levels were significantly higher in patients with severe LV dysfunction (p=0.005), table 1. vWf levels were unaffected by moderate-severe mitral regurgitation (p=0.4). However, after adjusting for potentially confounding clinical factors known to affect vWf level in AF (age, prior stroke, body mass index, recent heart failure, diabetes), the relationships between TTE parameters and vWF were no longer statistically significant.

	Normal LV Function (n=988)	Mild LV Dysfunction (n=154)	Moderate LV Dysfunction (n=91)	Severe LV Dysfunction (n=76)	p
vWf (iU/dl)	145 (31)	148 (30)	152 (30)	156 (29)	0.005
sP-sel (ng/ml)	34 (13)	35 (15)	34 (12)	33 (11)	0.7

Relationship of vWf and sP-sel to Degree of Echocardiographic LV Dysfunction (values expressed as mean (sd))

sP-sel levels were higher in patients with an abnormal mitral valve (35sd14 vs. 33sd13 ng/ml, p=0.047), but statistical significance was quickly lost after adjusting for confounders and sP-sel was unrelated to other TTE findings (all p>0.5). Conclusion: TTE features which predict stroke and thromboembolism in AF were closely related to evidence of endothelial damage/dysfunction (vWf) but not platelet activation (sP-sel), although the observed relationships may be due to the presence of additional disease states.

P2160 Randomized study of aspirin versus warfarin for high-risk mitral rheumatic atrial fibrillation patients

P.L. Lavitola, G.S. Spina, R.O. Sampaio, F. Tarasoutchi, M. Nigri, M. Grinberg. *Heart Institute(InCor), University of Sao Paulo Medical School, Sao Paulo, Brazil*

Background: Aspirin has been shown to be an option to warfarin to prevent embolic events in some studies in non-rheumatic atrial fibrillation patients. In order to evaluate if these data may be applied to high-risk rheumatic patients - with mitral valve disease and atrial fibrillation - we performed a randomized, prospective trial.
Methods: We assigned 229 atrial fibrillation rheumatic patients, medium age: 50±12.23 years, 78% female, with either mitral stenosis (62.2%), mitral regurgitation (8.4%) or mitral bioprosthesis with mild regurgitation (29.9%) to receive aspirin, 200 mg/day (Aspirin group -AG), or warfarin (Warfarin group-WG), with a target international normalized ratio of 2 to 3. We performed clinical, laboratory and echocardiography analysis and patients were followed for 56.64±17.64 months. 110 patients were assigned to receive aspirin and 119 to warfarin. 90% had left atrial spontaneus contrast, and 17% had left atrial thrombus in transesophageal echocardiography (TEE) There were no statistical difference between these groups regarding to age, sex, mitral valve disease, functional New York Heart Association class, diabetes, cholesterol and trygliceride serum levels, smoking, left ventricular function and diameters, left atrial diameter, mitral valve area, and presence of left atrial thrombus or left atrial spontaneus contrast on TEE.
Results: We observed 15 (13.6%) embolic events (EE) in the AG and 24 (20.2%) EE in WG (p=ns), of which, 21 had INR<2 during EE. There were 21 gastrointestinal bleeding in WG and 09 in AG (p=0.034). Minor bleeding was also more frequent in the WG (p<0.01). Multivariate analysis identified triglyceride level over 250 mmol/dl (Odds ratio=5.72, 95% C.I. 1.64 – 20.31 and low density lipoprotein cholesterol over 160 mmol/l (Odds ratio=4.08, 95% C.I. 0.87 – 19.22) as risks factors for EE in the WG and in the AG, respectively.
Conclusions: 1. Aspirin had, in this population,the same efficacy as warfarin for the prevention of embolic events. 2. Warfarin had higher risk for haemorragic events than aspirin. 3. High lipoprotein serum levels were independent risk factors for embolic events in rheumatic mitral disease atrial fibrillation patients.

P2161 Repetitive premature atrial contractions as a risk factor for paroxysmal atrial fibrillation in patients with stroke

D. Wallmann[1], D. Tüller[1], P.-A. Nicolet[1], M. Arnold[2], E. Delacrétaz[1]. [1]*Inselspital Bern, Kardiologie, Bern, Switzerland;* [2]*Inselspital Bern, Neurologie, Bern, Switzerland*

Background: Paroxysmal atrial fibrillation (PAF) is a frequent cause of cerebrovascular insult (CVI). Ambulatory ECG often fails to demonstrate PAF. Repetitive ectopic atrial activity can trigger PAF in patients with atrial myopathy (substrate). The aim of this study was to correlate the frequency of premature atrial contractions (PACs) with the occurrence of PAF during the prospective follow-up of patients who suffered CVI.
Method: The frequency of PACs in 24 hr ambulatory ECGs was assessed in consecutive CVI patients with (n=46) and without (n=108) PAF, as well as in age and gender matched controls (51). Patients where grouped into quartiles according to the frequency of the PACs. Patients with CVI and without PAF were studied prospectively. An echocardiography was performed to determine the presence of a substrate for PAF and the cardiovascular risk factors (cvRF) were assessed. Occurrence of clinical episodes of PAF and its correlation with the presence of repetitive triggers in ambulatory ECG was assessed.
Results: After a mean follow-up of 22.6 months PAF occurred in 12 of 99 patients with CVI and initially without PAF. In the quartile with the most frequent PACs (>120/24 h) PAF was significantly more frequent than in the three other quartiles (7/22 pts vs. 5/77 pts, respectively, p<0,0001). The patients who developed PAF in the follow-up had significantly more frequent PACs than the group without PAF (143 ± 480/24h vs. 2237 ± 3866/24h, p<0,0001). There was no significant difference between the quartiles in respect of left atrial size, left ventricular mass, ejection fraction and the number of cvRF.
Conclusion: In patients with CVI and without PAF, there is a correlation between repetitive PACs (>120/24hr) and the subsequent occurrence of PAF. Thus, repetitive PACs are a marker of an increased susceptibility to develop PAF in the follow-up. An aggressive screening for PAF should be performed in patients with CVI and repetitive PACs.

P2162 Thrombin-antithrombin levels are directly associated with heart rate at entry in patients with non-valvular atrial fibrillation

L.A. Perez[1], R. Corbalan[1], M. Acevedo[1], S. Braun[1], D. Springmuller[1], G. Sepulveda[1], M.T. Lira[1], J. Pereira[2]. [1]*Catholic University Hospital, Cardiovascular Diseases, Santiago, Chile;* [2]*Catholic University Hospital, Thrombosis and Hemostasis, Santiago, Chile*

Atrial fibrillation (AF) represents a hypercoagulable state. However, the mechanisms through which AF produces this state are still not well understood. We sought to determine which clinical and echocardiographic markers were associated with a prothrombotic state assessed by determinations of the thrombin-antithrombin complex (TAT)in patients with non-valvular AF.
We studied 88 patients (50 males, mean age = 67 ± 14 years old), 58 with paroxysmal AF and 30 with chronic AF. We studied clinical, echocardiographic and thrombin-antithrombin levels in all the patients at baseline. Fifty percent of the patients were > 70 years old, 56% were hypertensives, 16% diabetics and 35% had associated CAD and/or dilated cardiomyophaty. Five patients reported previous embolic events. TEE, performed within in the first 3 days, showed that 57% of patients had an enlarged left atrium (>45 mm), 54% had left atrial echo contrast and/or presence of thrombus, and 13% had evidence of systolic left ventricular dysfunction. Mean heart rate at entry was 118 ± 29. Mean TAT levels at baseline were significantly higher in AF patients than in a matched control group in sinus rythm (32.6 ± 66 versus 2.7 ± 3.3 ng/L, p < 0.001). There was no significant difference in TAT levels between paroxysmal and chronic AF patients (34.2 ± 58 and 204.3 ± 425.1 ng/L respectively, p = 0.19). Elevated TAT levels were not related to age, history of hypertension or diabetes, structural heart disease, left atrial enlargement, atrial echo contrast and/or thrombus. After multivariate regression analysis, the only clinical parameter significantly related to elevated TAT levels was the heart rate at entry (r = 0.31, p = 0.02), even after adjustments for the classical clinical and echocardiographic risk factors for embolism and use of antiarrhytmic drugs before admission.
Conclusions: This study is the first to demonstrate that TAT levels, a marker of activation of coagulation, are directly associated with the heart rate at entry in patients with AF, independently of traditional risk markers. Heart rate control at entry might be an important bedside marker to modify the prothrombotic state of patients with AF.

P2163 Losartan decreases the risk of stroke in hypertensive patients with atrial fibrillation and left ventricular hypertrophy

B. Dahlöf[1], B. Hornestam[1], P. Aurup[2] on behalf of the LIFE Study Group.
[1]Sahlgrenska University Hospital/Östra, Medicine, Göteborg, Sweden; [2]Merck RL, Whitehouse Station, NJ, United States of America

Background: Atrial fibrillation is a common arrhythmia, and a strong risk factor for stroke. The risk for stroke is further increased in those patients with atrial fibrillation and concomitant arterial hypertension. The Losartan Intervention For Endpoint reduction in Hypertension (LIFE) Study included 9193 patients, (mean age 66.9 ± 7.0 years, 54% woman) with essential hypertension, (BP 174/ 98 mm Hg) and ECG documented left ventricular hypertrophy. Patients were randomised to double blind treatment with the angiotensin II antagonist (AIIA) losartan or the betablocker atenolol. Additional open label antihypertensive treatment to reach the target blood pressure of p < 140/90 mm Hg, except other betablockers, ACE inhibitors and AIIAs, was accepted. In a substudy patients with atrial fibrillation at baseline were included, and the effects on the risk of stroke were compared. **Results:** 324 patients, (mean age 70.5 ± 6.4 years, 42.3% female) were included, and followed for a mean of 4.8 years. 150 patients (70.0 ± 6.7 years, 41.3% female) were allocated to losartan and 174 (70.9 ± 6.1 years, 43.1% female) to atenolol. In the losartan group mean BP was 176.1/97.0 (± 13.6/9.9) mm Hg and Framingham risc score 26.9 ± 10.4, compared to 175.5/95.3 (± 13.9/10.5) mm Hg and 26.9 ± 10.4 in the atenolol group. Of the losartan allocated patients 33.3% had coronary heart disease (CHD), 12.7% cerebrovascular disease (CVD) and 21.3% diabetes mellitus (DM) compared to a prevalence of 29.3% CHD, 16.1% CVD and 27.6% DM in the atenolol group. In those patients allocated to losartan 12% (n= 18) of the patients experienced a stroke while 21.3% (n= 37) of the patients in the atenolol group had a stroke. This difference was statistically significant, p= 0.018, with an Adjusted Hazard Ratio of 0.5 (95% C.I. 0.29 - 0.89).
Conclusion: In hypertensive patients with left ventricular hypertrophy and atrial fibrillation, treatment with losartan in comparison with atenolol, significantly reduced the incidence of stroke. 11 patients treated with losartan instead of atenolol for 4.8 years will prevent one stroke.

P2164 Time required to achieve therapeutic anticoagulation with warfarin prior to cardioversion for atrial fibrillation

A. Navazio[1], P. Montanari[2], E. Catellani[1], A. Piazza[1], D. Giberti[2], A. Colli[1].
[1]Franchini Hospital, Dept. of Cardiology, Montecchio Emilia (RE), Italy; [2]Franchini Hospital, Dept of Internal Medicine, Montecchio Emilia (RE), Italy

Background: Anticoagulation with warfarin for three weeks and transesophageal echocardiography are two strategies used prior to cardioversion for atrial fibrillation to minimize the risk of thromboembolism. The degree of post-cardioversion atrial mechanical dysfunction and atrial electrical remodelling are directly related to the duration of atrial fibrillation.
Aim: The purpose of this study was to determine the actual time required to achieve therapeutic anticoagulation with warfarin prior to cardioversion.
Methods: Sixty-two (38 men) consecutive patients with non valvular atrial fibrillation who were started on warfarin therapy prior to an elective cardioversion procedure were identified. Patients were followed in a hospital anticoagulation service and the warfarin dose was adjusted using a predetermined nomogram to maintain an international normalized ratio (INR) of 2.0 to 3.0. Patients were scheduled to undergo cardioversion after the INR was greater than 2.0 for 3 consecutive weeks. The mean age of the patients was 66 ± 11 years, the mean duration of atrial fibrillation was 3.1 ± 2.2 months (range 0.5-6 months) and 42% pts had structural heart disease.
Results: The mean time required to achieve the first therapeutic INR was 1.8 ± 1.5 weeks (range 0.2-4.2). The mean time required to achieve 3 weeks of therapeutic anticoagulation was 5.2 ± 2.6 weeks (range 2.9-9.8 weeks). Patients underwent cardioversion 6.9 ± 2.7 weeks after initiation of warfarin (range 3.3-11.8 weeks).
Conclusion: When initiating warfarin therapy prior to cardioversion for atrial fibrillation, at least 6 weeks are required to achieve 3 weeks of therapeutic anticoagulation, even when patients are closely monitored by an anticoagulation service. Early cardioversion using a transesophageal echocardiography-guided approach would reduce the overall duration of atrial fibrillation by almost two months.

P2165 Evidence of a temporary prothrombotic state in patients in sinus rhythm after electrical cardioversion of persistent atrial fibrillation

D. Hogg[1], M. Cowie[2], I. Ford[3], M. Greaves[3]. [1]Cardiology Research Group, Aberdeen, United Kingdom; [2]Imperial College, National Heart & Lung Institute, London, United Kingdom; [3]University of Aberdeen Medical School, Haematology Research Group, Aberdeen, United Kingdom

Introduction: It is assumed that restoration of sinus rhythm (SR) reverses the prothrombotic state associated with persistent atrial fibrillation (AF). Electrical cardioversion (DC-CV) is used to restore SR but is associated with a temporarily increased risk of thromboembolism particularly within the first 10 days. The reasons for this are unclear.
Method: We describe the sequential changes in plasma concentration of tissue factor (TF), von Willebrand factor (vWF) and thrombin-antithrombin (TAT) in patients with persistent AF undergoing DC-CV. 46 patients were studied with 25 age- & sex-matched controls in SR.
Results: Plasma concentration of TF in patients was higher at presentation than in controls {127.3 (SD 57.0) pg/ml vs 86.1 (SD 38.2) pg/ml, P=0.01}. Plasma TF was higher at 10 days than 1 hour after DC-CV {135.8 (85.4) pg/ml vs 109.5 (54.2) pg/ml, P=0.03}. There was no change from baseline to 3 months in the 12 patients who remained in SR {127.4 (68.7) pg/ml vs 113.5 (70.9) pg/ml, P=0.18}. Plasma vWF in patients was elevated compared to controls {mean 2.00 (SD 0.60) IU/ml vs mean 1.38 (SD 0.46) IU/ml, P<0.001}. There was an increase in plasma vWF from 1 hour to 10 days post DC-CV, but only in those 21 patients remaining in SR {2.23 (0.48) IU/ml vs 2.49 (0.63) IU/ml, P=0.01}. There was no change from baseline to 3 months in patients who maintained SR {2.23 (0.71) IU/ml vs 2.21 (0.55) IU/ml, P=0.92}. In patients not on warfarin at presentation (n=22), plasma concentration of TAT was not different to controls {2.79 (SD 1.16) μg/ml vs 2.89 (SD 1.16) μg/ml, P=0.77}. TAT was higher at 10 days than 1 hour after DC-CV, with those maintaining SR significantly elevated from those who had relapsed to AF {2.08 (1.54) μg/ml vs 1.31 (0.42) μg/ml, P=0.04}, there was no difference in INR between these groups.
Conclusions: 10 days after DC-CV patients in SR had higher plasma TF, vWF and TAT compared to those in AF. But in those maintaining SR for 3 months there was no change from presentation. We postulate that this temporary prothrombotic state results from the altered haemodynamics associated with atrial stunning. This observation may explain the increased risk of thromboembolism in the 10 days after DC-CV.

RESYNCHRONIZATION THERAPY IN HEART FAILURE PATIENTS: PREDICTING FACTOR OF SUCCESS

P2166 Can we predict who is going to improve after the implant of a CRT device?

J.C. Spinelli[1], C. Butter[2], C. Stellbrink[3], M. Kloss[4], H. Kirkels[5], J. Vogt[6], A. Auricchio[4], P. Cuesta[1] on behalf of PATH CHF II Investigators. [1]Guidant Corporation, HF Therapy Research, Saint Paul, United States of America; [2]German Heart Institute, Berlin, Germany; [3]University Hospital RWTH, Aachen, Germany; [4]University Hospital, Magdeburg, Germany; [5]University Hospital, Utrecht, Netherlands; [6]Heart Center, Bad Oeynhausen, Germany

Recent clinical studies have demonstrated the ability of cardiac resynchronization therapy (CRT) to improve exercise capacity in severe heart failure (NYHA III-IV) patients with wide QRS. The goal of this study was to analyze the correlation between baseline clinical variables, including the acute response to pacing and the changes obtained in peak VO2 (DpVO2) after 3 months of CRT. Methods: We analyzed 64 patients with complete baseline values and complete pairs of pVO2 measurements before and after CRT from the PATH CHF II trial. The following clinical variables were analyzed: baseline LVEF, percent change in LV dP/dtmax with CRT (DdP/dtmax), baseline LVEDP, baseline pulse pressure (bPP), QRS width (QRSw), baseline pVO2 (bpVO2) and the difference between the maximum percentage increase in PP during acute application of CRT and the percentage increase in PP at the chronically programmed AV delay (PPmax-PPprog). A multivariate linear regression analysis between these variables and DpVO2 was used to quantify the ability of these parameters to predict changes in pVO2. Results: Changes in peak pVO2 were significantly correlated with the studied pre-implant clinical variables (p < 0.0001; r = 0.73). The resulting multivariate equation was: DpVO2 = 0.0431 * QRSw + 0.0353 * DdP/dtmax + 0.1074 * (PPmax-PPprog) - 0.3091 * bpVO2 - 0.0292 * bPP - 0.0856 * LVEDP - 0.0719 * LVEF + 2.8921. The p values for the coefficients were: 0.01, 0.08, 0.003, 0.006, 0.13, 0.01, 0.11 respectively. Conclusions: These data suggest that the change in pVO2 obtained after 3 months of CRT may be estimated from baseline clinical and hemodynamic data. The largest benefit in pVO2 was obtained by the patients who had the widest QRS with the largest acute response in dP/dtmax, the lowest PP response at the programmed AV delay, the lowest bpVO2, the lowest bPP, the lowest LVEDP and the lowest LVEF. The finding that the combination of a high optimum DdP/dtmax and a low PP percentage increase at the programmed AV delay is associated with a larger improvement in DpVO2 triggers a very important clinical question about the relative importance of optimizing preload versus optimizing resynchronization, strongly suggesting that setting the AV delay to optimize preload may not be the correct therapeutic target.

P2167 Predictive factors of long-term functional improvement after biventricular resynchronisation

A. Hamzaoui[1], H. Mansour[2], A. Amonchot[2], M. Leandri[2], J. Lipiecki[2], C. Cuenin[2], B. Citron[2], J. Ponsonnaille[2]. [1]*Henri Mondor Hospital, Cardiology, Aurillac, France;* [2]*CHRU Gabriel Montpied, Cardiology, Clermont Ferrand, France*

Purpose: The biventricular pacing has recently been proposed as a treatment of refractory heart failure. There is a paucity of data concerning the long term follow up after ventricular resynchronisation. This study analyse predictive factors of functional improvement after biventricular pacing.
Patients and method: From April 1997 to December 2000 successful implantation of biventricular pacemaker was performed in 29/31 (94%) of patients. The mean age was 70.2± 6.9 years, 75.9% were men, 56.2% were in NYHA class III and 43.8% in class IV. The sinus rhythm was present in 69% of patients. The patients with atrial fibrillation were treated systematically during the procedure by atrioventricular junction radio frequency. After a mean follow up of 16.1 ± 8.0 months, the NYHA class, Minnesota score, echocardiographic left ventricular ejection fraction (LVEF) and the number of hospitalisations were noticed for each patient.
Results: In the whole group, the LVEF improved from 23.6 ± 9.1% to 31.3 ± 11.4% (p=0.01), the NYHA class decreased from 3.45 ± 0.5 to 2.1 ± 0.6 (p = 0.01), and the Minnesota score decreased from 40.3 to 23.5 points (D = 42%; p < 0.01). The patients initially in NYHA class IV improved more than patients in class III (LVEF from 20.6 ± 7.4% to 32.6 ±12.2% vs. 25.9 ± 9.9% to 30.2 ± 11.0%, p = 0.03; NYHA class from 4.0 to 2.1 ± 0.7 vs. 3.0 to 2.1 ± 0.6, p = 0.02). The reduction of number of hospitalisations in the follow up, comparing to the period of 12 months preceding the procedure, were more important in the NYHA class IV (from 4.0 ± 1.2 to 0.3 ± 0.6 vs. 1.9 ± 1 to 0.4 ± 0.6; p = 0.002). The evolution of Minnesota score was comparable in the two groups.
Conclusion: During a follow up of 16 months after ventricular resynchronisation the functional improvement is more pronounced in patients initially in NYHA class IV to patients in class III.

P2168 Correlation of brain natriuretic peptide release and exercise capacity in patients with heart failure and cardiac resynchronization therapy

A.M. Sinha[1], K. Filzmaier[1], O.A. Breithardt[1], J. Graf[1], K.U. Markus[1], D. Kunz[2], P. Hanrath[1], C. Stellbrink[1]. [1]*Medical Clinic I, University Hospital Aachen, Aachen, Germany;* [2]*University Hospital Aachen, Institute for Clinical Chemistry, Aachen, Germany*

Background: Brain natriuretic peptide (BNP) levels are highly expressed in pathological hemodynamic conditions and correlate with cardiac functional parameters like left ventricular (LV) ejection fraction (EF) or LV wall stress. Cardiac resynchronization therapy (CRT) improves cardiac hemodynamics and functional status in patients (pts) with heart failure (HF) and left bundle branch block (LBBB). We investigated the effects of CRT on BNP levels, cardiopulmonary exercise testing (CPX) and 6 min walk testing (WT) in these pts.
Methods: 12 pts (6f, 6m, 63±8y) with severe HF (mean EF 21±5%, NYHA II 2 pts, NYHA III 9 pts, NYHA IV 1 pts), LBBB (QRS 165±31 ms) receiving CRT for dilative (8 pts) or ischemic cardiomyopathy (4 pts) were investigated. BNP levels were determined with the Triage BNP test (Biosite Diagnostics, USA) at rest. Cardiopulmonary exercise testing (CPX) was performed on a cycle with incremental work load. Maximum oxygen consumption (VO2max) and oxygen consumption at the anaerobic threshold (VO2-AT) were measured. A 6-minute walk test (WT) was performed on a 45 m long plain floor. BNP blood samples and CPX and WT data were collected before pacemaker implantation (basal) and after 15±11 weeks of continuous CRT (VDD mode). As BNP levels depend on renal function, serum creatinine and blood urea nitrogen (BUN) levels were simultaneously measured.
Results: The effects of CRT on BNP levels, CPX, WT and renal function are shown in the table.

Effects of CRT

	BNP (pg/ml)	VO2max (ml/min/kg)	VO2-AT (ml/min/kg)	WT (m) (m)	Creatinine (mg/dl)	BUN (mg/dl)
Basal	676±405 (232-1300)	12.9±3.2	9.9±2.4	310±119	1.5±0.6	68±35
CRT	380±290* (124-956)	16.0±3.8*	13.5±2.8*	414±69*	1.6±0.7	69±38
R		-0.61#	-0.66#	-0.62#		

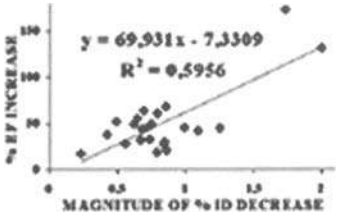
Mean ±SD; *p<0.05 vs basal; R = correlation vs BNP, #p<0.05

Conclusion: Chronic CRT leads to a significant decrease in BNP release and improvement of exercise capacity with an inverse correlation of functional tests (VO2max, VO2-AT, WT) to BNP release. Thus, decreasing BNP levels are an indicator of improved functional status during CRT and may therefore be used as a marker for therapeutic efficacy of CRT in patients with advanced HF and ventricular conduction disturbance.

P2169 Interventricular delay predicts clinical outcome in CHF patients undergoing resynchronization therapy

F. Zanon, S. Aggio, C. Bilato, E. Baracca, M. Carraro, G. Braggion, P. Zonzin. *General Hospital, Division of Cardiology, Rovigo, Italy*

Cardiac resynchronization by biventricular pacing (BiV) has recently become a valuable tool in the treatment of end stage congestive heart failure (CHF). Unfortunately, not all the patients (pts) benefit by this therapy and no predicting factors of favorable outcome have been unequivocally reported. To identify potential predicting parameters of clinical outcome, we performed acute haemodynamic evaluation on 23 pts (16 males, 72±13 years old) with cardiomyopathy of any etiology at the time of BiV implantation. All pts were in NYHA class III/IV despite optimal medical treatment, with a mean left ventricular ejection fraction (LVEF) of 23%±6 and QRS duration of 192±26 ms. During system implantation, systemic and pulmonary blood pressures were monitored before and 15 minutes after BiV was turned on, in order to evaluate systolic right and left pre-ejection periods and right and left ejection times. Interventricular delay (ID) was calculated as the difference between left and right pre-ejection period and increases proportionally with the severity of interventricular desynchronization. Evaluation of cardiac performance was done before and one week after implantation by echocardiography. After 15 minutes of BiV, a significant decrease of ID was observed (from 72±39 ms to 19±29 ms; p <0.001). At seven days, overall LVEF by echocardiography improved by more than 50% (from 23%±6 to 35%±7, p <0.001).



ID correlates with EF.

When expressed as magnitude of percentage decrease, ID calculated during acute haemodynamic evaluation, linearly and significantly correlates with the percentage increase of LVEF (r=0,771) (figure), suggesting that the degree of ID reduction predicts the outcome in short term period.

P2170 The degree of acute QRS shortening during cardiac resynchronization therapy is predictive of clinical improvement at long-term follow-up

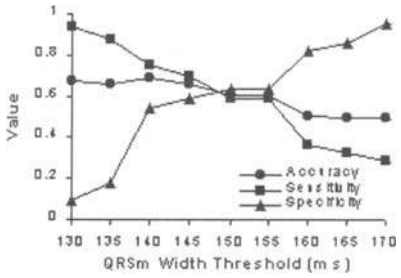
M. Tritto[1], G.S. Bargiggia[1], C. Fantoni[2], M. Romano[2], D. Salerno-Uriarte[1], P. Antognazza[1], T. Forzani[1], J.A. Salerno-Uriarte[2]. [1]*University of Insubria - Varese, Cardiology Dept. "Mater Domini", Castellanza, Italy;* [2]*Fond. Macchi, University of Insubria, Dept. Cardiovasc. Sci., H Circolo, Varese, Italy*

The response to cardiac resynchronization therapy (CRT) with biventricular pacing (BiVP) in pts with chronic heart failure (CHF) and atrio-ventricular and/or intra-ventricular dissynchrony is poorly predictable. We evaluated the role of demographic, ECG and pacing-related variables as clinical improvement predictors at long-term follow-up (mean: 19.3±7.4 mos; range: 6-34) in 36 consecutive pts (32 m, mean age 68±6 yrs) submitted to CRT because of drug-refractory CHF (NYHA class: III-IV), left ventricular (LV) ejection fraction (EF) < 35% (mean: 23.7±5.4%) and QRS duration > 150 ms (mean: 174±22 ms). In all pts the lateral LV wall was chronically paced through unipolar leads placed in coronary sinus (CS) tributaries. The right ventricular stimulation was performed in all cases from the apex. Mean right-to-left ventricular electrogram (RV-LV) delay measured 101±37 ms.
Methods and Results: Responders (R) were considered those pts fullfilling all the following criteria: > 1 NYHA class reduction, > 30% improvement of Minnesota score and 6-min walk distance, no further hospital admission for CHF during follow-up. Twentyfive pts (69%) were R. At univariate analysis, they significantly differed from non R pts because of a shorter paced QRS duration (131±6+17.8 vs 144.5±13.7 ms; p <0.04), and a greater BiVP-induced QRS reduction (Delta%) with respect to baseline (23.9±12.9 vs 14.2±10.1; p <0.03). Conversely, pt age, sex, CHF etiology, baseline NYHA class, Minnesota score and 6-min walk distance, prevalence of 1st degree atrio-ventricular block, permanent atrial fibrillation, LV pacing lead position within CS tributaries (antero-lateral, lateral or postero-lateral), and RV-LV delay were not significantly different in the 2 groups.
Conclusions: The BiVP-induced acute shortening of QRS duration significantly predicts the long-term response of CHF pts to CRT obtained through lateral LV wall stimulation.

P2171 Sensitivity and specificity of using QRS duration to predict chronic benefit in heart failure patients with cardiac resynchronization therapy

Y. Yu[1], B. Lamp[2], C. Butter[3], A. Auricchio[4], M. Kloss[4], S. Trautman[4], H. Kirkels[5], C. Stellbrink[6] on behalf of the PATH-CHF II investigators.
[1]Guidant-CRM, CHF Research Dept., St. Paul, United States of America; [2]Heart Center North Westphalia, Cardiology Dept., Bad Oyenhausen, Germany; [3]Charité CVK & German Heart Institution, Cardiology Dept., Berlin, Germany; [4]University Clinic of Magdeburg, Cardiology Dept., Magdeburg, Germany; [5]University Hospital, Utrecht, Germany; [6]University Hospital RWTH, Cardiology Dept., Aachen, Germany

Cardiac resynchronization therapy (CRT) has been shown to provide acute and chronic benefit to heart failure patients with interventricular conduction delay. Baseline maximum QRS duration (QRSm) has been widely used as a criterion to select heart failure (HF) patients for cardiac resynchronization therapy (CRT). The efficacy of QRSm to predict chronic benefit has not been analyzed. The aim of this study was to determine the sensitivity, specificity and accuracy of QRSm to predict chronic hemodynamic benefit.
Methods: Seventy-one heart failure patients from the PATH-CHF II clinical study (NYHA Class II-IV, QRS duration > 120 ms) with complete pairs of peak VO2 (pVO2) were analyzed. All patients received CRT for 3 months. Chronic benefit was measured by changes in pVO2 during exercise over the intrinsic baseline. Sensitivity, specificity and accuracy measures were calculated for several QRSm thresholds.
Results: Accuracy was highest (69%) at QRSm of 140 ms. At this threshold, the sensitivity and specificity were 76% and 55%, respectively.



Conclusions: QRSm is useful not only in screening patients for CRT, but also in predicting chronic benefit from CRT.

P2172 The use of tissue Doppler imaging to predict improvement of left ventricular ejection fraction after biventricular pacing

S G. Molhoek[1], J J. Bax[2], T. Marwick[3], L. van Erven[2], P. Voogd[2], P. Steendijk[2], E E. van der Wall[2], M J. Schalij[2]. *[1]Leiden University Medical Center, Cardiology, Leiden, Netherlands; [2]Leiden University Medical Center, Cardiology, Leiden, Netherlands; [3]University of Brisbane, Brisbane, Australia*

Background: Recent studies showed that biventricular (BV) pacing results in improvement of systolic left ventricular (LV) function, functional status and well being of patients with congestive heart failure. Tissue Doppler imaging (TDI) by echocardiography allows non-invasive, quantitative assessment of long-axis function with measurement of peak systolic velocity timing in relation to electrical activity. The aim of the present study was to evaluate whether improvement in LVEF post-pacing can be predicted in patients with heart failure using TDI.
Patients and methods: 25 patients with dilated cardiomyopathy (11 ischemic) were included. Patients had LVEF <35%, were in NYHA class III/IV with a QRS duration >120 ms. A routine 2D echo and TDI were performed on the day before and the day after implantation. LVEF was assessed using the biplane Simpson's method; improvement of LVEF 5% post-pacing was considered significant. From TDI, the following parameters were assessed: peak systolic velocity (PSV) and time interval from onset of QRS to PSV (TPV), and the septal to lateral delay in time to PSV. Moreover, TPV was assessed in 4 regions (anterior, inferior, lateral, septal), and an LV asynchrony score was derived from these measurements by averaging the TPV from all 4 regions.
Results: LVEF improved by 9±9% following pacing (from 22±5% before pacing to 31±10% post-pacing); 17 patients improved LVEF 5% or more. The change in PSV after pacing in the septal and lateral regions related significantly to the change in LVEF post-pacing. The change in asynchrony score (before vs post-pacing, indicating resynchronisation) was related to the change in LVEF ($y=120x+5.6$, $r=0.79$, $P<0.01$). Using a cut-off value in septal to lateral delay of $^{3}60$ ms gave a sensitivity of 82% and a specificity of 88% to predict improvement of LVEF post-pacing.
Conclusion: TDI allows evaluation of resynchronisation and may be used to predict improvement in LVEF post-pacing: assessment of septal to lateral delay in patients eligible for BV pacing can accurately predict which patients will improve in LVEF post-pacing and can be used for screening.

PREDICTORS OF ATHEROSCLEROSIS

P2173 In-stent restenosis is associated with progression of native coronary artery plaques

G. Bauriedel, D. Skowasch, A. Jabs, R. Andrié, J. Vaerst, B. Lüderitz.
University of Bonn, Med. Univ. Klinik und Poliklinik II, Bonn, Germany

Background: Although stenting leads to further reduction of restenosis, its effects on the progression of coronary artery disease are unclear. In the present retrospective study (1999-2001), we sought to identify lesional and procedural determinants that allow the prediction of in-stent restenosis (ISR) and/or of plaque progression, and that prove a possible relation between both forms of accelerated arteriosclerosis.
Methods: A total of 133 coronary target lesions of 100 patients treated by stent implantation was evaluated at the 6±2 month follow-up for ISR (defined as >50% diameter stenosis) and progression (defined as >20% increase of stenosis) of untreated coronary plaques (>30% stenosis) by use of quantitative coronary angiography. Clinical, angiographic and procedural determinants were analyzed for prediction of ISR and/or plaque progression.
Results: ISR >50% was seen in 60 of 133 (45%) cases categorized in focal (IB 15.7%, IC 23.6%, ID 13.5%) and diffuse ISR type (II 29.2%, III 13.5%, IV 4%). Longer lesion length (1.5±0.5 vs. 1.1±0.6; P=0.038), increased number of inflations (3.3±1.6 vs. 2.7±1.2; P=0.035), cumulative inflation time (P=0.046) and presence of diabetes (22 vs. 10%; P=0.048) were predictive of ISR. Within the same time window, angiographic progression was observed in 10 of 72 (13.9%) previously untreated lesions. Of note, plaque progression was influenced by the presence of ISR (P=0.044), since 9 cases were found associated with ISR, 5 of them with the focal and 4 with the diffuse type. Significant regression of plaques was not observed. In addition, the number of implanted stents (1.5±1.2 vs. 0.98±0.53; P=0.026) revealed significant relationship for occurrence of native plaque progression, whereas patient characteristics, medication and several preprocedural angiographic variables did not.
Conclusions: Our data demonstrate that procedural determinants of stent implantation/angioplasty may determine the long-term local result. Number of implanted stents and occurrence of ISR apparently favour the progression of preexisting mid-grade plaques. Conversely, these observations suggest a systemic intrinsic factor that propagates accelerated arteriosclerosis.

P2174 Hyperhomocysteinaemia is independently predictive of severity and extent of coronary artery disease

M. Qiao, P. Chook, A. Chan, P.Y.K. Poon, W.W.M. Chan, L.K.K. Tse, J.E. Sanderson, K.S. Woo. *The Chinese University of Hong Kong, Dept of Medicine & Therapeutics, NT, Hong Kong*

Background: Homocysteine is an emerging risk factor, associated with atherogenesis and increased risk of cardiovascular diseases. However, the direct relationship between homocysteine and the severity and extent of coronary atherosclerosis in coronary artery disease (CAD) patients has not been well established.
Methods: 631 consecutive CAD patients (83% male), aged<70 years with angiographically documented coronary disease (>50% luminal stenosis in >=1 vessel) were studied. Severity and extent of CAD were evaluated by modified Gensini score. Total plasma fasting (>12 hour) homocysteine (tHcy) collected at angiography was measured by immunoassay (IMx), and compared in mild to moderate CAD (score<22, n=428) and severe CAD (score >22, n=208) of matched age and gender.
Results: The 2 CAD groups were similar in smoking status (64%), body mass index, blood folate, vitamin B-12, glucose and lipid profiles and prevalence of diabetes mellitus. Vitamin B-12, tHcy, creatinine and prevalence of hypertension were significantly higher in severe CAD. On multivariate logistic analysis, hyperhomocysteinaemia (>=10μmol/l) (odds ratio=1.6; 95% CI=1.2-2.4; p=0.006) and elevated creatinine (odds ratio 2.0; 95% CI=1.2-3.3; p=0.006) were independently associated with severe CAD after adjustment for traditional coronary risk factors.

Clinical Parameter of CAD Patients

	Mild-to-Moderate	Severe CAD <n=208>	p-Value
Age (yr)	58.6±8.3	59.2±8.9	0.364
Coronary Score	14.2±5.1	30.3±6.4	0.0001
Hypertension (%)	50.9	60.6	0.022
Diabetes (%)	25.5	31.7	0.097
Dyslipidaemia (%)	33.9	36.6	0.672
Body Mass Index(Kg/m^2)	24.7±3.4	25.0±3.3	0.424
LDL-cholesterol (mmol/l)	2.6±1.5	2.8±1.6	0.591
Folate (nmol/l)	24.7±1.5	25.0±1.5	0.681
tHcy (umol/l)	9.9±1.4	10.8±1.4	0.007
Vitamin B-12 (pmol/l)	293.2±1.6	269.8±1.7	0.036
Creatinine (umol/l)	92.2±21.6	98.4±21.4	0.001

Conclusions: Hyperhomocysteinaemia is an independent determinant of severity and extent of atherosclerosis in CAD.

P2175 The relationship between wall thickness and shear stress in coronary arteries of patients

J.J. Wentzel[1], E. Janssen[1], J. Vos[2], J.C.H. Schuurbiers[1], R. Krams[2], P.W. Serruys[2], P.J. de Feyter[2], C.J. Slager[1]. [1]*Erasmus Medical Center Rotterdam, Hemodynamics, 3000 DR Rotterdam, Netherlands;* [2]*Erasmus Medical Center Rotterdam, Department of Cardiology, Rotterdam, Netherlands*

Background Atherosclerosis preferentially develops at average low shear stress locations. Shear stress controls lumen dimensions under physiological variations. We hypothesized that maintenance of lumen dimensions by shear stress control prolongs selective accumulation of plaque at low shear stress predilection locations only in early atherosclerosis, restricting the presence of an inverse relation between wall thickness and shear stress to this stage. Therefore, loss of lumen preservation and shear stress increase will change the relations between wall thickness and shear stress.

Methods and Results: In 14 patients, interventionally treated for coronary lumen narrowing, an angiographically normal artery (stenosis <50%) was investigated with ANGiography and ivUS (ANGUS) to provide 3D lumen and wall geometry. Selection of segments >5mm length in between side branches yielded 25 segments in 12 patients. Shear stress at the wall was calculated by computational fluid dynamics using a validated finite element software package (Sepran). Per segement shear stress and wall thickness data were measured at the same 16 different circumferential locations and averaged in the longitudinal direction. Linear regression analysis was used to relate wall thickness (WT) to shear stress (SS) (WT=a+b*SS). Wall thickness normalized to lumen diameter (WTn) <0.2 was defined normal. Largest arc of normal WTn defined reference (ref) cross sections. Lumen area (LA) defined area stenosis (AS): (LAref-LA)/LAref*100%. Media bounded area (MBA) defined vascular remodeling: (MBA-MBAref)/MBAref*100%. Average AS (ASav) <10% defined preserved lumen.

For the preserved lumens (n=11, ASav=1.7%, vs.0%: p=NS), wall thickness and shear stress were inversely related (slope (b):-0.00046 ± 0.00055 m^3/N, $p<0.05$) and vascular remodeling was positive (7±9%, vs. 0%: $p<0.05$). For the group showing lumen narrowing (n=13, ASav=18%±6%, vs. 0%: $p<0.05$), wall thickness and shear stress were not related (slope (b): 0.00019 ± 0.00052 m^3/N, p=NS) and vascular remodeling was absent (-3±6%, vs.0%: p=NS).

Conclusion These data show for the first time in human coronary arteries, that the presence of an inverse relationship between wall thickness and shear stress is related to lumen preservation and compensatory vascular remodeling and is absent with lumen narrowing.

P2176 Mediterranean diet phytochemicals inhibit endothelial activation through interference with redox-sensitive transcription factors

M A. Carluccio[1], L. Siculella[2], M. Massaro[1], M A. Ancora[1], E. Scoditti[1], F. Visioli[3], R. De Caterina[4]. [1]*CNR Institute of Clinical Physiology, Laboratory of Vascular Research, Lecce, Italy;* [2]*Department of Biology, University, Lecce, Italy;* [3]*Institute of Pharmacological Sciences, Milano, Italy;* [4]*Chair of Cardiology, Univ. of Chieti, Ospedale S. Camillo De Lellis, Chieti, Italy*

Epidemiological studies suggest that Mediterranean diets reduce the risk of cardiovascular disease. Monocyte adhesion to the endothelium is crucial in early atherogenesis, and redox-sensitive mechanisms are involved. The aim of our study was to evaluate whether typical Mediterranean diet phytochemicals affect endothelial leukocyte adhesion molecule expression and monocyte adhesion.

Methods and Results: We studied several phenols in Mediterranean foods, including oleuropein, hydroxytyrosol, tyrosol, and resveratrol, with or without antioxidant activity. Compounds (1-100 micromol/L) were incubated with human umbilical vein endothelial cells (HUVEC) for 30 minutes, followed by coincubation with bacterial lipopolysaccharide or cytokines to trigger adhesion molecule expression. Only oleuropein, hydroxytyrosol and resveratrol, possessing a marked antioxidant activity, reduced monocytoid cell adhesion to stimulated endothelium. This correlated with the inhibition of Vascular Cell Adhesion Molecule-1 (VCAM-1) mRNA and protein expression, assessed by Northern analysis and cell surface enzyme immunoassay, respectively. The inhibition of VCAM-1 was paralleled by reduction in the activation of the redox-sensitive transcription factors Nuclear Factor-kappaB (NF-kappaB) and Activator Protein–1 (AP-1), at electrophoretic mobility-shift assays. Trasfection studies using various VCAM-1 gene promoter constructs confirmed that phenolic antioxidants repressed VCAM-1 gene transcription, in part by inhibiting NF-kappaB. E-Selectin and intercellular adhesion molecule-1 (ICAM-1) expression were similarly inhibited, indicating a generalized effect on endothelial cell activation.

Conclusions: Mediterranean diet phytochemicals possessing antioxidant activity may inhibit early events in atherogenesis modulating endothelial gene expression, and can thus be exploited pharmacologically.

P2177 Elevated plasma levels of lipid peroxidation are associated to an early onset of UA

P. Fabbi, S. Garibaldi, P. Altieri, S. Nasti, M. Balbi, G. Ghigliotti, A. Barsotti, C. Brunelli. *University of Genova, Dept. of Internal Medicine, Cardiology, Genova, Italy*

Atherosclerosis (ATS) in humans is associated to increased production of free radicals: particularly, an accelerated lipid peroxidation and lipoxidative aging of proteins in the vascular wall has been demonstrated in pts with ATS.

Since age is an established determinant of levels of oxidative stress in subjects without CV disease and influence pathological changes in the redox balance, we studied the extent of oxidative damage in pts with recent unstable angina (UA) according to different age of onset.

We compared EDTA plasma levels of malondialdehyde (MDA), assayed by HPLC method, in 40 male pts with early (age <56) or late onset (age >64) of UA. A control group (Controls) of healthy subjects (n=35) similarly divided by age was also enrolled for the study.

Pts with UA were characterized by more elevated levels of lipid peroxidation products than Controls (1,6 ±0,7 vs 1,1±0,3 nmol/ml $p<0.0001$).

Furthemore early onset UA pts showed higher MDA levels when compared to late onset UA pts.

Traditional risk factors for ATS were not significantly different between pts with early and late onset of UA (see table). Moreover, none of the risk factors considered showed significant correlation with oxidative stress.

	Early UA	Late UA
MDA, nmol/ml	1.8±0.1*	1.4±0.1
BMI, kg/m^2	27.2±0.7	25.7±0.7
HDL, mg/dl	38.8±1.9	39.9±1.5
LDL, mg/dl	128.0±10.8	127.7±8.3
Von Willebrand Factor, %	141.5±22.6	195.5±27.3
Fibrinogen, mg/ml	386.0±27.8	415.2±22.8
Family Hx ATS, %	63	54
Hx Dyslipidaemia, %	86	75
Hx Hypertension, %	67	64
Smokers, %	58	40

Characteristics of Patients with Early UA and Late UA. Mean ± S.E; *$p<0.01$ vs Late UA.

Intrestingly, while MDA levels increase as a function of age in Controls, this trend whose reversed in UA pts.

Elevated levels of MDA in pts with early UA point to the relevance of oxidative mechanism for development of accelerated coronary atherosclerosis.

P2178 High body iron stores predispose for early vascular modifications in b-thalassemia major patients

I. Kallikazaros, C. Tsioufis, A. Spanos, P. Zambaras, C. Stefanadis, P. Toutouzas. *Hippokration Hospital, State and Athens University Cardiology, Athens, Greece*

Although previous studies have been reported that increased serum ferritin levels were associated with an excess risk of acute myocardial infarction, several questions regarding the relation of increased body iron stores with the atherosclerotic process remain unresolved.

Methods: For this purpose, we investigated the relation of early carotid atherosclerotic changes to body iron status on B-Thalassemia major patients, a population with chronic iron overload. Intima-media thickness (IMT) of the common carotid artery (CCA) was evaluated by high resolution B-mode Ultrasonography (Biosound 2000 II Sa) in 45 B-Thalassemia major patients (mean age 16±4 years). Our subjects were free from any known risk factors for cardiovascular disease. Body iron status was assessed by the mean serum concentration of ferritin in the last five years. The findings were compared to those obtained from 20 age and sex matched normal individuals.

Results: IMT of CCA in B-Thalassemia patients was 0.78±0.1 mm while in normal subjects was 0.54±0.2 mm ($p<0.001$). Mean serum level of ferritin in the last five years in the B-Thalassemia patients was 2720±1980 ng/ml and in normal subjects was 105±45 ng/ml ($p<0.001$). There was a strong positive correlation between IMT of CCA and level of ferritin in B-Thalassemia group ($r=0.82$, $p<0.005$).

Conclusion: The IMT of the CCA increased in proportion to the increased serum levels of ferittin. These data provide evidence that the body iron status plays an important role in the progress of early atherosclerotic changes. However, further studies are required to investigate the effects of multiple blood transfusions to cerebrovascular complications associated with B-Thalassemia major patients.

P2179 Characteristics of coronary patients with a family history of atherosclerotic disease

C. Saely[1], S. Aczel[1], P. Langer[1], T. Marte[1], H. Drexel[2]. [1]*VIVIT-Institute, Feldkirch, Austria;* [2]*LKH-Feldkirch, Innere Medizin, Feldkirch, Austria*

Background: Family history of atherosclerotic disease increases the risk of coronary atherosclerosis (CA). Therefore, the risk factor profile of coronary patients with a family history of atherosclerotic disease is of particular interest.
Methods: We investigated 641 consecutive patients undergoing coronary angiography. Of these patients, 219 had 1, and 101 had 2 or more first degree relatives with atherosclerotic disease (single and multiple family history, respectively); 321 patients had no first degree relative with atherosclerotic disease (no family history).
Results: Among patients with single and multiple family history, the prevalence of significant CA (defined as the presence of stenoses >= 50%) was not increased compared to patients with no family history (60% and 65% vs. 60%; p=n.s.). There were more women (35% vs. 25%; p=0.008 and 48% vs. 25%; p<0.001) and fewer smokers (54% vs. 68%; p=0.004 and 52% vs. 68%; p=0.003) in these groups. Compared to patients with no family history, mean total cholesterol (227 vs. 216 mg/dl; p=0.048), HDL cholesterol (52 vs. 47 mg/dl; p=0.008), apolipoprotein A1 (155 vs. 144 mg/dl; p=0.002), and median Lipoprotein(a) values (26 vs. 13 mg/dl; p=0.004) were significantly higher in patients with multiple but not in those with single family history.
Conclusions: Among patients referred to coronary angiography, CA is not more prevalent in patients with a family history of atherosclerotic disease than in those without a family history. Patients with multiple, but not with single family history exhibit elevated serum levels of both markers of increased atherosclerotic risk (total cholesterol, lipoprotein(a)), as well as, surprisingly, markers of decreased risk (HDL cholesterol, ApoA1).

P2180 Long-term effects of diet and exercise on obesity-related vascular dysfunction in children

K.S. Woo[1], P. Chook[1], C.W. Yu[2], R.Y.T. Sung[2], M. Qiao[1], C.W.K. Lam[3], D.S. Celermajer[4]. [1]*The Chinese University of Hong Kong, Dept of Medicine & Therapeutics, NT, Hong Kong;* [2]*The Chinese University of Hong Kong, Department of Paediatrics, Hong Kong, Hong Kong;* [3]*The Chinese University of Hong Kong, Department of Chemical Pathology, Hong Kong, Hong Kong;* [4]*The University of Sydney, Department of Cardiology, Sydney, Australia*

Background: Obesity in children is independently associated with arterial endothelial dysfunction, a key event of atherogenesis. This is partially reversible with diet control, or more so with combined diet control and structured exercise programme for 6 weeks. However the longer-term effect of these regimens has not been documented.
Methods: 82 obese children (age 8-11 year, body mass index >23) randomized to 6-week diet control or diet plus exercise programme, were followed up for 1 year. Of the exercise group, 22 consented to continue weekly exercise programme, and 19 children pulled out at 6 weeks but continued 2-monthly diet monitoring programme, together with the original 41 diet only children. Brachial artery flow-mediated dilation (FMD, endothelium-dependent) was assessed by high resolution ultrasonography at baseline and 1 year.
Results: Significant improvement with near normalization of FMD (from 6.9±1.5% to 8.6±1.8%; p<0.001) was seen in children continuing exercise, less so in children who pulled out (from 6.7±2.3% to 7.4±2.5%; p=0.025) but not in children on diet control only (6.9±2.0% to 7.1±1.5%; p>0.5). There was significant improvement in waist-hip ratio (W/H ratio), and body fat content (p<0.005) but not body mass index in all 3 groups, but improvement in low density lipoprotein cholesterol (from 3.0±0.9mmol/l to 2.7±1.0mmol/l; p<0.005), high density lipoprotein cholesterol (from 1.2±0.3mmol/l to 1.5±0.3mmol/l; p<0.0001) and fasting insulin levels (from 156±101pmol/l to 118±74pmol/l; p<0.0001) in exercise group only. On multivariate analysis, exercise training were independently correlated to long-term improvement in FMD (partial R=0.47; F value=4.2; p=0.002).
Conclusion: Obesity-related vascular dysfunction in otherwise healthy young children is reversible at 1 year with diet plus regular exercise, less so in those who gave up exercise programme, but not with diet control only.

P2181 Pulse-wave velocity in individuals with one or two parents afflicted with coronary artery disease – A comparative study

H. Marcoyannopoulou-Fojas, N. Papageorgakis, A. Schoenfeld, G. Fojas, G. Jullien. *Athens, Greece*

Purpose: To compare the Pulse Wave Velocity (P.W.V.) in subjects with negative family history of coronary disease and individuals with a family history of one or two parents afflicted by coronary artery disease.
Method: Arterial wall elasticity was determined indirectly by P.W.V. using an electronic device which recorded the left external carotid and left dorsalis pedis pulses simultaneously with a single lead ECG. The time delay between the two pulses is computed automatically. A faster P.W.V. would indicate decreased arterial wall elasticity.
Materials: A total of 108 clinically asymptomatic subjects, of average heights, non obese, with normal blood pressure and ECG in sinus rhythm and normal blood sugar and lipid profiles were studied. There were 38 males and 70 females. Of these 108 individuals, 63 had a negative family history of coronary artery disease(CAD), 32 had one parent suffering from CAD and 13 had both parents with CAD.
Results: The mean time of PWV among the subjects whose parents do not have coronary artery disease was 0.1613 sec. (Min.-0.10 & Max.-0.21 sec.) For the individuals with only one parent suffering from CAD the mean time of PWV was 0.1553 sec. (Min. 0.10 sec. and Max. 0.21 sec.); while those with both parents afflicted with CAD, the mean time of PWV was 0.1354 sec. (Min.- 0.10 sec. and Max. - 0.16 sec.) These differences in time are statistically significant. It is evident that the individuals without family history of CAD have a longer time of PWV compared to the subjects with family history of CAD. Interestingly, when we subdivide the latter group into those with one afflicted parent and two afflicted parents, we note that the latter has a significantly much slower time of PWV compared to the former. If we assume that decreased time of PWV indicates decrease of arterial wall elasticity and therefore increased risk of development of CAD, then individuals with only one afflicted parent are at lower risk compared to those with two afflicted parents.
Conclusion: Subjects without any history of coronary disease have lower risk of developing coronary artery disease. Individuals with two parents afflicted with CAD have a higher risk of developing CAD compared to those who have only one afflicted parent.

P2182 Sequential analysis of the low density lipoprotein receptor and apolipoprotein B genes of hypercholesterolemic patients from Central Europe

R. Plewa[1], M. Luczak[1], A. Bolewski[2], J. Wierzchowiecki[2], T. Siminiak[2]. [1]*University of Poznan, Poland, Dept. Molecular Biol. & Biotechnology, Poznan, Poland;* [2]*District Hospital, Department of Cardiology, Poznan, Poland*

Familial hypercholesterolemia (FH) is an autosomal dominant disorder caused by mutation in the low density lipoprotein receptor gene (LDLR). Several different mutations of the LDLR gene were identified.
The purpose of the study was to evaluate LDLR mutations in patients with hypercholesterolemia in a Central European population. We analyzed the LDL receptor gene using the single-strand conformation polymorphism (SSCP) and direct sequencing technique. The range of serum cholesterol and LDL-cholesterol was 250-450 and 200-400mg/dl in FH patients. In a screening of the LDLR gene mutations of 54 consecutive patients with familial hypercholesterolemia, we discovered new point mutations in 18 exon: one-nucleotide deletion (Asp2731), thirteen-nucleotide deletion (Val2734), C2623A causing Leu850Ile, T2786C, G2728A. Mutations was also located in three different exons (4,7,8); C518G causing a Cys152Trp in exon 4, T1012A causing Cys317Ser in exon 7 and T1102C causing Cys347Arg in exon 8. The mutation in exon 4 and 7 was previously reported in a compound heterozygote for familial hypercholesterolemia.
FH can be caused not only by defects in the LDLR but also by mutation in apolipoprotein B causing decreased LDLR binding affinity, so called familial defective apolipoprotein B (FDB). Three different missense mutation in 26 exon of ten patients were found: Pro2712Leu substitution, Arg3500Gln leads to a defective binding of apolipoprotein B to the LDL receptor and a novel point mutation 3532Ile.
Since novel LDLR and lipoprotein B mutations were found, we conclude that genetic determination of FH is related to the population studied. Functional importance of the mutations in patients with FH remains to be established.

P2183 Superiority of amlodipine over enalapril in reversing carotid artery intima-media thickening in hypertensive patients

K. Stumpe, E. Fritschka, U. Jörger, M. von Buquoy, D. Schremmer, M. Ludwig on behalf of the ARES Study Group. *Medical University Clinic Bonn, Internal Medicine, Bonn, Germany*

Objective: Intima-media thickening (IMT) of the common carotid artery (CCA) predisposes to the development of atherosclerosis and has been shown to correlate with coronary events and stroke. The multicenter double-blind Amlodipine Regression Study (ARES) was designed to compare the effect of the long-acting dihydropyridine calcium antagonist amlodipine (A) with that of the ACE-inhibitor enalapril (E), administered for a 2-year treatment period, on CCA-IMT in hypertensive patients (HP).
Methods: 218 HP aged 35 to 75 y. with sonographically proven CCA-IMT (far wall) of the leading side => 0.8 and =< 1.5 mm were randomly assigned to receive either A (5-10 mg/d) or E (10-20 mg/d). HCTZ was added if required to achieve blood pressure (BP) control. Ultrasonography was performed at baseline and after 12 and 24 months. Outcome results are available for 92 HP treated with A and 97 PH treated with E.
Results: After 24 months of treatment BP was reduced similarly by A and E. CCA-IMT had decreased by 0.11 mm to 0.76 mm in the A-treated group, but by only 0.08 mm to 0.81 mm in the E-treated group ($p<0.05$ for difference between treatments). Regression of CCA-IMT of 0.1 mm or more was observed in 68,5% of A-treated but in only 49,5% of E-treated HP. No correlation between fall in BP and changes in CCA-IMT was observed.
Conclusion: 2 years of effective antihypertensive treatment based on A is superior to that based on E in reversing CCA-IMT of HP indicating that A may have a more favourable effect on atherosclerosis development than E. The absence of a correlation between the fall in BP and the decrease in CCA-IMT suggests that mechanisms in addition to BP reduction might have contributed both to regression of the CCA wall lesions and to the difference in treatment effects between A and E.

P2184 Global fibrinolytic capacity in coronary artery ectasia

A. Dogan[1], B. Tunc[2], O. Gedikli[3], A. Ayata[2], C. Nazli[3], A. Altinbas[4], O. Ergene[3]. [1]*Sevket Demirel Heart Center, Cardiology, Isparta, Turkey;* [2]*Suleyman Demirel University, Paediatry, Isparta, Turkey;* [3]*Suleyman Demirel University, Cardiology, Isparta, Turkey;* [4]*Suleyman Demirel University, Cardiology, Isparta, Turkey*

Objective: Global fibrinolytic capacity (GFC) is a new, easy and reliable technique for evaluating the effectiveness of the entire fibrinolytic system. Current literature suggests that ectatic coronary arteries are subject to thrombus formation and distal microembolization. We invastigated GFC and other hemostatic parameters in patients with coronary ectasia.
Methods: Twenty-five patients with coronary ectasia (14 men, 11 women, mean age:58.4±8 years) and 25 control subjects with angiographically documented normal epicardial coronary arteries (13 men, 12 women, mean age:56.3±9 years) were enrolled in the study group. Patients who have diabetes mellitus, hyperlipidemia, hematologic disorders, hepatic or inflammatory diseases and patients with a history of thromboembolic events were not included in the study group. None of the patients with coronary artery ectasia had a history of previous acute Q-wave or Non-Q wave myocardial infarction (MI).
Results: There was no significant difference between two groups with regard to the age, sex and body mass-index. D-Dimer and GFC levels in patients with coronary ectasia were significantly higher than those of the control group (0.67±0.56 vs 0.41±0.26, p=0.04; 4.61±2.1 vs 3.14±2.11, p= 0.017; respectively). There were no significant differences between the two groups with regard to prothrombin time and activated partial thromboplastin time (p=0.48, p=0.068, respectively). Antithrombin III, Fibrinogen, Protein C and Protein S levels were also similar in both groups (p=0.42, p=.0.68, p=0.23 and p= 0.31, respectively).
Conclusion: The results of this study suggests that the micro-thromboembolic events in patients with coronary ectasia may contribute to the activation of fibrinolytic system and this phenomenon may cause increase in the levels of D-Dimer and GFC. Increased fibrinolytic activity might have a protective role in these patients otherwise prone to acute ischemic events.

LIPID-LOWERING DRUGS

P2185 Statins increase the expression of collagen I receptors in humanen VSMCs

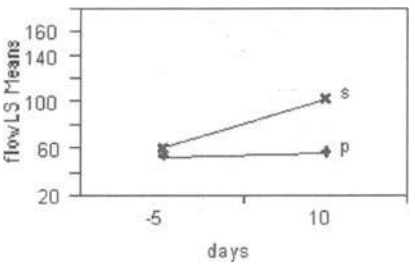
K. Graf, K. Kappert, P. Stawowy, F. Blaschke, S. Goetze, E. Fleck. *Deutsches Herzzentrum Berlin, Cardiology, Berlin, Germany*

3-Hydroxy-3-Methylglutaryl Coenzym A Reductase (HMG-CoA) inhibitors have direct vascular effects that contribute to plaque stability. In the present study we demonstrate that the HMG-CoA reductase inhibitors atorvastatin and pravastatin augment the adhesion of human (HSMCs) and rat aortic smooth muscle cells (RASMCs) to collagen I via induction of alpha2beta1-integrin receptors. Atorvastatin (0.1 μM) increased the adhesion of HSMCs to collagen I up to 2-fold ($p<0.01$) and pravastatin (1.0 μM) up to 1.8-fold ($p<0.01$) after treatment for at least 24 hours. This increase in adhesion was concentration-dependent and was observed for treatment periods from 16 to 72 hours. Inhibition of isoprenoid synthesis with mevalonate and geranyl-geraniol prevented the statin-induced effect on human and rat VSMCs. Flow cytometry revealed an increased expression of alpha2- and beta1-integrins after treatment with atorvastatin (0.1 μM) at 24 and 48 hours. Atorvastatin increased levels of beta1-integrin mRNA after 12 and 24 hours treatment in HSMCs, which was inhibited by mevalonate. Furthermore, atorvastatin (0.1 μM) and pravastatin (1.0 μM) inhibited chemotaxis of HSMCs on collagen I, which was also reversed by mevalonate treatment. In contrast, inhibition of beta1-integrins with a specific antibody nearly doubled ($p<0.01$) the rate of chemotaxis.
These data indicate that the chemotactic activity in HSMCs is inhibited in part by upregulation of alpha2beta1-integrin receptors. The present study indicates that HMG-CoA reductase inhibitors increase cell-matrix interaction with collagen I via induction of alpha2beta1-integrins and increased adhesion to collagen I.

P2186 Pre-operative simvastatin therapy improves resting myocardial blood flow after CABG

M.I. Dotani[1], A. Morise[1], G. Prabhakar[2], R. Haque[1], A. Jain[1], G. Hobbs[1], C.M. Gibson[3]. [1]*WVUH, Cardiology, Morgantown, United States of America;* [2]*WVUH, Cardiothoracic surgery, Morgantown, United States of America;* [3]*BIDMC, Cardiology, Boston, United States of America*

Introduction: Prior studies have demonstrated improved cardiovascular outcomes after initiation of lipid-lowering therapy. We hypothesized that pre-operative simvastatin therapy would be associated with improved myocardial blood flow following CABG.
Methods: In this prospective double blind study, patients with 3-vessel disease (CAD) were randomized to simvastatin 40mg or placebo (4 patients in each arm). Patients underwent myocardial flow imaging by PET scan 5±1 days pre-CABG and at 10+1days post-CABG. No change in medical therapy was made. All patients were started on simvastatin therapy after second PET scan. Total duration of therapy was for 15±1 days. 64 regions of myocardium were analyzed.
Results: The mean number of coronary bypass conduit per patient was 4±1. Baseline characteristics were similar between the groups. All the other variables including venous vs. arterial conduits, concurrent drug therapy, bypass time, cross clamp time and number of vessel bypassed were not significantly different between the two groups. There was no significant difference in flow between the two arms pre-CABG. While flow did not improve following CABG in the placebo arm (delta 2.9 ml/100gm/min, 95% CI. -6.3, 12.1 p=NS), flow in the simvastatin arm did improve significantly (delta 41.3 ml/100gm/min, 95% CI. 32.1, 50.5 $p<0.00001$).



Legend: p=placebo s=simvastatinstatin and myocardial flow.

Conclusion: Administration of simvastatin before CABG was associated with a significant improvement in myocardial blood flow on PET scan whereas placebo administration was not. A potential mechanism includes a reduction in reperfusion injury. While provocative, these findings require further confirmation in large number of patients and the relation to clinical events require further evaluation

P2187 Sevelamer: a new synthetic polymer for haemodialysis patients with antiatherosclerotic properties

P. Raggi. *Tulane University, Cardiology, New Orleans, United States of America*

Background: Patients affected by end-stage renal disease (ESRD) demonstrate extremely high cardiovascular morbidity and mortality. Abnormal calcium and phosphorus metabolism as well as abnormalities of lipid metabolism appear to be related to such poor prognosis. Sevelamer (SVL) is a non-absorbed polymer indicated for phosphorus chelation in ESRD that might also have other antiatherosclerotic properties.
Method: 200 ESRD patients undergoing maintenance hemodialysis were randomized to SVL or traditional calcium salts (CaS) as treatment for hyperphosphatemia. Serial measurements were made during one year of follow-up for the following parameters: coronary artery calcium score (CCS), a marker of atherosclerosis, by electron beam tomography (EBT); serum lipids and high sensitivity C-reactive protein (hs-CRP).
Results: At the end of one year the CCS progressed significantly in CaS but not SVL treated patients (median change 25% vs 6%; p=0.02). The following variables decreased significantly in the SVL treated patients: total cholesterol (- 41 mg/dL, p<0.0001), LDL (-38 mg/dL, p<0.0001), ApoB (-25%, p<0.0001) and hs-CRP (-1 mg/L, p<0.05) while ApoA increased significantly (+3%, p<0.04). No change was noted for tryglycerides, HDL or Lp(a) with SVL. All serological variables remained unchanged in CaS patients during the course of the study.
Conclusions: SVL is a new non-absorbed polymer with potentially useful antiatherosclerotic properties. This drug may offer an important advantage over other therapies currently employed for hyperphosphatemia in ESRD by favorably altering lipoproteins and reducing arterial inflammation.

P2188 Effect of statin therapy on arterial elasticity in dilated cardiomyopathy

M. Kurpesa, E. Trzos, M. Kidawa, M. Krzeminska-Pakula, Z. Bednarkiewicz. *Medical Academy/Bieganski Hospital, Cardiology Dpt., Lodz, Poland*

Patients with dilated cardiomyopathy (DCM) have depressed left ventricular (LV) function. Decreased arterial elasticity rises LV afterload and leads to progression of heart failure in such group of patients. Pulse wave velocity (PWV) provides an indirect, non-invasive measurement of the mechanical properties of arteries. Statins by influence on migration and proliferation of smooth muscle cells may improve arterial elasticity. Statins are recommended in the treatment of patients with coronary artery disease even in those without hyperlipidemia. However, the usefulness of statins in DCM is not established. The aim of the study was to assess the influence of statins on arterial elasticity in DCM.
Material and methods: The study group consisted of 36 pts with DCM and hypercholesterolemia. They were randomized into Group I (18 pts who received statin) and Group II (18 pts who received placebo). Groups were comparable according to demographic characteristics and treatment of DCM. Before and following 6 months of treatment PWV was evaluated using a computer system COMPLIOR-Colson. For automatic measurement of PWV pressure waveforms were digitized at rate 500 Hz for carotid-femoral distance. 10 healthy volunteers constituted a control group.
Results: PWV in control group remained unchanged following study period (7,01± 0,6 m/s initial vs 7,2 ± 0,4 after 6 months). Initial PWV in both DCM groups was similar (11,7 ± 0,8 m/s in Group I vs 12,0 ± 0,6 m/s in Group II). After 6 months PWV in Group I was significantly lower (8,5 ± 0,8 m/s, p<0,05 vs initial). In Group II PWV decreased to 11,1 ± 1,1 m/s but this value did not differ significantly from the initial measurement.
Conclusion: Addition of statin to conventional treatment improves arterial elasticity in patients with dilated cardiomyopathy.

P2189 Effects of lipid-lowering treatment with atorvastatin on endothelial function in patients with ischaemic heart failure

C. Antoniades, D. Tousoulis, S. Brilli, C. Tentolouris, K. Marinou, C. Pitsavos, C. Stefanadis, P. Toutouzas. *Hippokration Hospital, Cardiology Unit, Athens University, Athens, Greece*

Background: Previous studies have shown that endothelial function is compromised in patients with heart failure and coronary artery disease. Moreover, treatment with statins improves endothelial function in patients with hypercholesterolemia. However, the effect of statins on endothelial function and ejection fraction in patients with ischemic heart failure is not known.
Methods: In this double blind placebo controlled study, 38 patients with ischemic heart failure (32 males 6 females aged 64.8±3.4 years) were enrolled. 18 patients received atorvastatin 10mg/day (group A) while 16 patients received placebo (group B) for 4 weeks. All patients were NYHA II to IV. Forearm blood flow was measured using venous occlusion strain-gauge plethysmography. Endothelium dependent flow mediated vasodilation (FMD) was expressed as the % change from baseline to maximal flow during reactive hyperemia. Endothelium independent flow (NTG%) was expressed as the % change from baseline to post sublingual nitroglycerin administration flow. Ejection fraction of the left ventricle was estimated with Simpson's method. All values are expressed as mean±SEM.
Results: Blood pressure, heart rate, basal forearm blood flow, NTG% and body weight remained unchanged in both groups. After 4 weeks of treatment, FMD was significantly increased in group A (from 44.2±4.4 to 96.5±12.1%, p<0.01) while remained unaffected in group B (from 46.1±6.1 to 53.5±4.0%, p=NS). Ejection fraction was also improved in group A (from 26.00±0.92 to 28.70±1.0%, p<0.05) while remained unaffected in group B (from 27.1±1.2 to 28.1±0.91%, p=NS).
Conclusions: These findings indicate that atorvastatin treatment for 4 weeks significantly improves endothelial function and ejection fraction in patients with ischemic heart failure. These findings may provide evidence for an additional effect of statins beyond lipid lowering.

P2190 The benefit of early use of lipid-lowering drugs at discharge in patients with acute coronary syndromes is greater in patients with heart failure

S. Gottlieb[1], J. Leor[2], A. Shotan[2], H. Hod[2], V. Boyko[2], A. Caspi[3], S. Behar[2] on behalf of ACSIS 2000 Investigators. *[1]Bikur Cholim Hospital, Cardiology, Jerusalem, Israel; [2]Heart Institute, Neufeld Cardiac Research Institute, Tel-Hashomer, Israel; [3]Kaplan Hospital, Heart Institute, Rehovot, Israel*

The early use of lipid lowering drugs (LLD) after acute coronary syndromes (ACS) is not yet well established. The benefit of reducing cholesterol in congestive heart failure (CHF) has recently been questioned by observations of a negative relationship between cholesterol and mortality. It has therefore been suggested that it is important to maintain elevated cholesterol levels in pts with CHF. No prospective trials have yet been carried out to test the efficacy of reducing cholesterol in pts with CHF.
Methods: We assessed the impact of early LLD use at discharge from hospital after ACS on 30-day outcome among pts admitted to all 26 hospitals in Israel participating in ACSIS 2000.
Results: Among 2,131 consecutive ACS survivors, 618 pts (29%) had CHF on admission or during their hospitalization course (CHF+), and 1,513 pts did not have CHF (CHF-). LLD (99% statins) at discharge was given to 251 pts (41%) in the CHF+ subgroup, and to 853 pts (56%) in the CHF- subgroup. In both subgroups, pts discharged on LLD (LLD+) were younger, and included more often pts with hyperlipidemia (HPL), and prior revascularization (p<0.01 for all). Mean total cholesterol during the acute phase of ACS was higher in LLD+ than in LLD- pts, in both CHF+ and CHF- subgroups: 219±50 vs. 185±42 mg/dl, and 213±44 vs. 187±34 mg/dl, respectively, p<0.0001 for both). Thirty-day mortality rate in CHF+ pts was lower in LLD+ vs. LLD- pts (4.6% vs. 8.9%, respectively, p<0.05; age-adjusted OR=0.53, 95% CI 0.25-1.07), while in CHF- pts, the beneficial effect of early LLD use was smaller (0.9% vs. 1.6%, respectively, p=0.19; OR=0.86, 95% CI 0.30-2.38).
Conclusions: This observational national survey suggests that LLD given early in the setting of ACS exerts a greater short-term benefit in pts with CHF than in counterparts without CHF. Ongoing randomized trials will determine whether this striking beneficial effect is related to selection bias or to other protective effects of statins.

P2191 Effect of simvastatin on endothelial damage markers and clinical outcomes in acute coronary syndromes

P. Tricoci, C. Melloni, G. Melandri, V. Cervi, L. Tomasi, A. Branzi. *Policlinico Sant'Orsola, Istituto di Cardiologia, Bologna, Italy*

Acute coronary syndromes (ACS) are characterized by plaque inflammation, endothelial dysfunction and thrombosis. Therapeutic strategies should theoretically address to all pathogenetic mechanisms involved. In this randomized controlled study we evaluated the effects of early treatment with simvastatin (S) on markers of plaque inflammation, endothelial damage and thrombosis in 76 patients with ACS and 11 age-matched controls. Blood samples were drawn within 48 hrs from symptoms onset and 3 months after randomization into a treatment group (S 40 mg plus diet) or diet alone. C-reactive protein (CRP), thrombomodulin (TMB), t-PA, PAI-1, fibrinogen (FGN), fragment 1+2 (F1+2), vWF, and antibodies against oxidized-LDL (ox-LDL-AB) were obtained at baseline and after 3 months. There were no differences in baseline characteristics and concomitant treatments. The major adverse clinical events (MACE) considered were death, myocardial infarction, re-hospitalization for ACS. Simvastatin reduced the LDL cholesterol from 148±40 mg/dl to 92±29 mg/dl (p=0.0021); diet alone was unsuccessful in this regard (136±30 mg/dl vs 129±34 mg/dl). Simvastatin also reduced MACE from 19.4% to 10.0% (p=NS.).

Results: see the table.

	S baseline	S 3-month	p	Diet baseline	Diet 3-month	p
TMB	26±9	30±11	0.009	27±13	27±13	NS
PCR	1.05±1.64	0.22±0.23	0.00002	1.52±2.04	0.80±0.86	0.002
F1+2	2±3	5±6	0.009	6±8	5±4	NS
vWF	87±26	72±17	0.0001	90±26	75±16	0.02
ox-LDL-ab	235±208	307±230	0.002	224±120	251±125	NS
PAI-1	30±20	43±32	0.006	40±33	45±30	NS
t-PA	21±16	8±4	0.005	19±11	9±5	0.002
FGN	287±119	271±58	NS	305±121	274±68	NS

In conclusion early treament with simvastatin 40 mg in ACS results in several changes in markers of endothelial damage that are not observed in the diet group and do not appear related to inflammation. Noteworthy is the increase in TMB levels observed in the simvastatin group. The observed effects on clinical outcomes deserves further investigation in larger studies.

P2192 Prevention of nitrate tolerance by long-term treatment with statin

D. Fontaine[1], J. Fontaine[1], A. Otto[1], G. Berkenboom[2]. [1]*Free University of Brussels, Basic Physiol & Pharmacol, Brussels, Belgium;* [2]*Erasme Hospital, Cardiology Dept., Brussels, Belgium*

Recent studies have shown that statin seems to upregulate the endothelial NO synthase pathway (eNOS) and may, therefore, enhance NO availability, a direct scavenger of O2- and an inhibitor of oxidative enzymes.

Methods: To assess whether the oxidative stress produced by an in vivo exposure to nitroglycerin (NTG) is attenuated by statins, 4 groups of normocholesterolemic rats were treated; group 1 received pravastatin (20 mg/kg/d p.o) and group 2 atorvastatin (10mg/kg/d) both for 5 weeks and the last 3 days, a cotreatment with the statin plus NTG (50 mg/kg/d, sub-cutaneous injections b i d); group 3 (NTG) received only NTG (50 mg/kg/d, b i d for 3 days) and group 4 served as control. Rings of thoracic aortas from these groups were studied in organ baths.

Results: Relaxations to NTG (0.1 nM to 0.1 mM) were determined on phenylephrine-preconstricted rings and O2- production (counts/10s/mg) was assessed by lucigenin chemiluminescence technique. In goup 3 (NTG), the concentration-response curves to NTG were significantly shifted to the right: the pD2 (-log NTG concentration evoking a half maximal relaxation) was 5.9±0.3 (n=9) vs 7.2±0.1 in group 4 (not exposed to NTG, n=9) and O2- production was enhanced (946±51 vs 617±76, P<.05). In contrast, groups 1 (n=11) and 2 (n=7) behaved as group 4 (pD2 values were 7.3±0.2 and 6.9±0.1; O2- production was 528±28 and 647±124). The protective effect on nitrate tolerance disappeared when L-NAME (an eNOS inhibitor, 100 mg/kg/d) was coadministered with NTG in groups 1 and 2. Moreover, in groups 1 and 2, before NTG exposure, aortic cGMP content, reflecting endothelium-derived NO availability, was significantly enhanced (P<.05 vs control) whereas NAD(P)H oxidase activity was decreased.

Conclusion: Long-term statin treatment protects against nitrate tolerance by counteracting NTG-induced increase in O2- production. This protection seems to involve the eNOS pathway, probably an inhibition of oxidative enzymes by enhanced NO availability.

P2193 Effects of lipid-lowering therapy with bezafibrate on endothelial function and aortic stiffness in patients with type 2 diabetes mellitus

H. Watanabe[1], M. Kakihana[2]. [1]*KINU Medical Association Hospital, Department of Cardiology, Mitsukaido City, Japan;* [2]*Ibaraki Prefectural University, Ami, Japan*

Dyslipidemia characterized by elevated triglyceride (TG) and reduced HDL-cholesterol (HDL-C) has been reported in patients with type 2 diabetes mellitus (DM). This study was designed to evaluate effects of bezafibrate on endothelial function and aortic stiffness. Twenty well-controlled diabetic patients (type 2) with elevated TG (TG>150 mg/dL) were randomized to receive or not receive bezafibrate (treatment group, n=10, no treatment group, n=10). By using ultrasound with a 7.5-MHz transducer, the brachial artery diameter was measured at rest and during reactive hyperemia (flow-mediated dilatation, FMD), and before and after 0.3 mg of sublingual nitroglycerin (nitroglycerin-induced dilatation, NID). And we also measured aortic PWV (pulse wave velocity) by using a non-invasive technique to evaluate aortic stiffness. These measurements were performed in 12-hour overnight fasting condition at baseline and after 12 months of the treatment. At baseline, there was no difference in lipid parameters, fasting glucose level, HbA1c, brachial artery diameters, %FMD (%increase in diameter during hyperemia), %NID (%increase in diameter after NTG), and PWV among two groups. After 12 months, triglyceride and LDL-C levels were significantly decreased, and HDL-C level was significantly increased in the treatment group (TG: -40%; LDL-C: -13%; HDL-C: +19%), but they were not changed in the no treatment group. %FMD and PWV were improved after 12 months of treatment with bezafibrate. On the other hand, %NID, fasting glucose level and HbA1c did not change after 12 months.

		Baseline	12 months	
FMD (%)	Treatment	6.1±1.2	9.9±2.0*	p<0.05
	No treatment	6.0±1.1	6.4±1.8	
NID (%)	Treatment	13.2±3.7	13.6±3.5	
	No treatment	13.0±3.2	13.4±3.1	
PWW (cm/s)	Treatment	1529±84	1125±64*	p<0.05
	No treatment	1561±76	1488±58	

Mean±SD, *p<0.01 vs Baseline.

Conclusion: Lipid-lowering therapy with bezafibrate restores endothelial function and aortic stiffness in patients with type 2 DM.FMD and PWV in patients with type 2 DM

P2194 Atorvastatin inhibition of CD40 expression attenuates CD154-mediated interleukin-12 expression in human endothelial cells

A.H. Wagner, M. Gebauer, B. Gueldenzoph, M. Hecker. *University of Goettingen, Dpt. of Cardiovascular Physiology, Goettingen, Germany*

CD40-CD40 ligand (CD154) interactions not only play an important role in an exaggerated Th1 or Th2 immune response but also in the pathogenesis of atherosclerosis. 3-Hydroxy-3-methylglutaryl CoA (HMG-CoA) reductase inhibitors (statins) exert potent anti-inflammatory effects independently of their cholesterol lowering action.

Methods: We have investigated the effects of statins on interferon g (IFNg)/tumor necrosis factor a (TNFa)-induced CD40 expression both in human cultured endothelial cells (HUVEC) and in the pre-monocytic cell line THP-1 by reverse transcription-polymerase chain reaction (RT-PCR) and Western blot analysis. Cytokine-dependent activation of transcription factors was judged by electrophoretic mobility shift analysis (EMSA). Finally, the effects of atorvastatin on endothelial cell-leukocyte interaction (parallel plate flow chamber) and CD40/CD154-mediated IL-12p40 expression (RT-PCR) were employed.

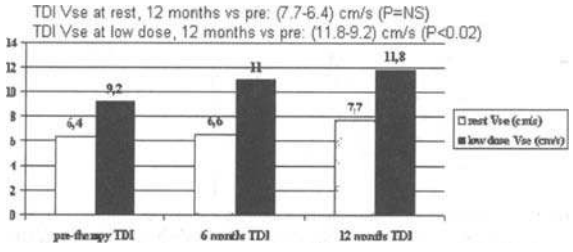
Results: Preincubation of cells with atorvastatin (10 μM) inhibited IFN-g/TNF-a-induced CD40 expression by approximately 50% at the mRNA and protein level and could not be reversed by mevalonic acid (400 μM). Moreover, EMSA revealed significant inhibition of STAT-1 and IRF-1 transcription factor translocation to the nucleus (1 h pre-incubation with statins, 3 h cytokine-incubation). Brief (1 h) pre-incubation of either cell type with atorvastatin, cerivastatin or pravastatin (1-10 μM) inhibited IFNg plus TNFa stimulated CD40 expression in these cells by approximately 50%, an effect that was also not reversed by the HMG-CoA reductase product mevalonic acid (400 μM). Furthermore EMSA demonstrated atorvastatin inhibition of the NF-kB plus STAT-1-dependent de novo synthesis of IRF-1 which governs IFNg plus TNFa stimulated expression of CD40 in these cells. Consequences of this statin-dependent down-regulation of CD40 expression in the endothelial cells were a decrease both in endothelial cell-leukocyte interaction and CD154-induced interleukin-12 expression.

Conclusions: These findings suggest that by interfering with IFNg-dependent CD40 expression in endothelial cells and monocytes, statins are capable of attenuating CD40/CD154-mediated pro-inflammatory reactions, and this may contribute to their cardioprotective action.

P2195 The effect of atorvastatin on myocardial contractile reserve assessed by tissue Doppler imaging during dobutamine stress echocardiography

M. A. Bountioukos, D. Poldermans, J.J. Bax, F.B. Sozzi, E.C. Vourvouri, A.F. Schinkel, M. Kertai, J.R. Roelandt. *Thoraxcenter, Erasmus Medical Center, Department of Cardiology, BA302, Rotterdam, Netherlands*

Aim: To determine the effect of atorvastatin on myocardial contractile reserve in patients with moderate hypercholesterolemia. BACKGROUND: Statin therapy has been shown to exert a beneficial effect on cardiovascular system beyond cholesterol lowering action. One of the mechanisms that have been proposed is an effect on impaired flow-mediated vasodilation.
Methods: Ten patients (age 56±12, 8 male) with peripheral vascular disease (PVD) and without a history of myocardial infarction or treatment with statins in the past were studied. All patients underwent dobutamine stress echocardiography (DSE) before the initiation of atorvastatin therapy (10mg daily) and 6 and 12 months later. Pulsed-wave tissue Doppler imaging (TDI) was performed using a six-segment model and myocardial systolic ejection velocities (Vse) were measured at rest and during low dose dobutamine infusion. There were no changes in medical therapy and no major cardiac events occurred during this period. The Student's t test was used for statistical analysis and P values <0.05 were considered statistically significant.
Results: Rest and low dose rate-pressure product (in bpm X mmHg) during DSE were 10958 and 11662 before therapy, 9240 and 10666 at 6 months and 9986 and 10740 at 12 months respectively (P=NS). Rest and low dose dobutamine wall motion score indexes as well as ejection fractions were not changed significantly. Figure 1 shows the changes in myocardial Vse at rest and during low dose DSE.



Conclusions: Atorvastatin caused a significant increase of myocardial Vse during low dose DSE in moderately hypercholesterolemic patients with PVD after 12 months of treatment. The underlying mechanism could be a beneficial effect of atorvastatin on an impaired myocardial contractile reserve.

P2196 HMG-CoA reductase inhibitor (statin) blocks VEGFR-2-mediated endothelial migration

S. Kliche, H. Frank, N. Meyer, J. Waltenberger. *Ulm University Medical Center, Internal Medicine II, Ulm, Germany*

Statins (HMG-CoA reductase inhibitors) have been shown to reduce vascular inflammation, to increase endothelium-derived NO production, to stimulate the formation and differentiation of endothelial progenitor cells and to stimulate angiogenesis in a rabbit hindlimb model. Statins inhibit the cholesterol biosynthesis and protein isoprenylation. Isoprenylation of GTPases is necessary for intracellular trafficking, membrane association and activity. VEGF-A is a key regulator of endothelial function such as migration and cytoskeleton rearrangement through VEGFR-2 (KDR), which is controlled by activation of the GTPase Rac. The purpose of this study was to elucidate the role of statins on VEGFR-2-mediated endothelial migration.
Porcine aortic endothelial cells expressing VEGFR-2 (PAEC/KDR) were used for this study. Migration was assessed in a chemotaxis assay using a 48-well modified Boyden chamber. For action cytoskeleton analysis, actin was stained with rhodamine isothiocyanate-conjugated phalloidin and examined using a confocal laser scanning microscope. Rac activity was analysed using a PAK-1-GST pulldown assay. Membrane and cytosolic proteins were seperated using a particulate fraction assay followed by Western blot analysis.
VEGF-A-induced migration and cytoskeleton rearrangement of PAEC/KDR was significantly reduced in the presence of statins and was reconstituted in the presence of mevalonate. Analysing PAEC/KDR separated proteins into membrane and cytosolic fractions, we found an accumulation of Rac in the cytosolic fraction in the presence of different statin concentrations. Likewise, Rac activity was significantly decreased.
In conclusion, our results show that HMG-CoA reductase inhibitors can block important VEGF-A-mediated endothelial functions with implications for VEGF therapy.

P2197 Efficacy and safety of simvastatin versus atorvastatin: results of the comparative HDL-C efficacy and safety study (CHESS)

C.M. Ballantyne[1], C.M. Hustad[2], Z. Yuan[2], P. DeLucca[2], J. Palmisano[2]. *[1]Baylor College of Medicine, Houston, Texas, United States of America; [2]Merck & Co., Inc., West Point, Pennsylvania, United States of America*

Objectives: To assess the comparative efficacy of simvastatin 80 mg (S) versus atorvastatin 80 mg (A) on HDL-C (primary) and Apolipoprotein (Apo) A-I values and to evaluate the effects of S and A on ALT/AST and clinical GI adverse events (AEs).
Methods: In a multicenter, randomized, double-blind, parallel-dose study, 917 patients with hypercholesterolemia were treated with S or A for 24 weeks. Prespecified times for assessment of efficacy were 6/12 weeks and 18/24 weeks (mean of weeks 6 and 12 and weeks 18 and 24).
Results: S increased HDL-C and Apo A-I values significantly more than A at weeks 6/12 and 18/24 overall and across all baseline HDL-C subgroups (<40 mg/dL, >=40 mg/dL). Consecutive elevations in ALT/AST greater than 3X upper limit of normal occurred in significantly fewer patients treated with S than with A (2/453 (0.4%) versus 13/464 (2.8%), p=0.007), with a majority of elevations observed in women (S 1/199 (0.5%); A 11/209 (5.3%)). At the primary 6/12 week time point, A and S lowered LDL-C by 53.5 ± 0.6% and 45.4 ± 0.6% and triglycerides by 34.1 ± 1.4% and 25.8 ± 1.4%, respectively (p<0.001).

Mean % change in HDL-C and Apo A-1

Weeks	HDL-C	HDL-C	Apo A1	Apo A1
	S (N=436)	A (N=430)	S (N=423)	A (N=420)
6/12*	8.9 ± 0.6	3.6 ± 0.6	4.9 ± 0.7	-0.9 ± 0.7
18/24*	8.3 ± 0.7	4.2 ± 0.7	3.7 ± 0.7	-1.4 ± 0.7

*p<0.001 for S versus A

Conclusions: S 80 mg increased HDL-C and Apo A-1 significantly more than A 80 mg at weeks 6/12 and 18/24 of treatment. Significantly fewer elevations in ALT/AST occurred in patients treated with S.

P2198 Differences in the effects of fluvastatin on lipoprotein subclasses distribution and on endothelial function are dependent on triglyceride levels

E. Moriguchi[1], V. Portal[2], J.L. Vieira[2], R. Rodrigues[2], A. Nakashima[3], H. Itakura[3]. *[1]Pontifícia Universidade Católica do RS, Departamento de Geriatria, Porto Alegre, Brazil; [2]Instituto de Cardiologia, Epidemiology, Porto Alegre, Brazil; [3]Tsukuba Res. Inst., Ibaraki, Japan*

Background: The highly atherogenic small/dense LDL particles are more prevalent in those with triglyceride (TG) levels above 150 mg/dl.
Methods and Results: The present study compared the effects of fluvastatin on lipoprotein subclasses and on the endothelial function in coronary patients with plasma TG levels below and above 150mg/dl, when adjusted to LDL-cholesterol (LDL-C) levels. The study included 19 coronary patients with plasma LDL-C above 130 mg/dl after 6 weeks of NCEP step II diet. They were allocated in two groups: low TG group (TG<150mg/dl, n=13) and high TG group (TG>150mg/dl, n=6). All of them received fluvastatin 40 to 80 mg/day, titrated to bring the LDL-C below 100mg/dl, for 24 weeks. Nuclear magnetic resonance spectroscopy of plasma was used to assess the concentrations of total cholesterol (TC), TG, LDL-C, HDL-C and lipoproteins subclasses. Brachial artery flow mediated vasodilatation measurement by Doppler echography was used as an index for endothelial function. Statistical methods: Two-way ANOVA repeated measures with Scheffe's test. Low and high TG groups presented differences in TG and HDL-C levels. TC and LDL-C had no differences. After 24 weeks of fluvastatin (all comparisons are low TG vs. high TG groups), TC changed from 212±23 to 180±17mg/dl (p=0.002) vs. 222±43 to 167±28mg/dl (p=0.0007), TG from 113±25 to 119±43mg/dl (p=0.98) vs. 213±31 to 143±27mg/dl (p=0.01), LDL-C from 148±23 to 116±18mg/dl (p=0.0006) vs. 156±48 to 106±28mg/dl (p=0.0004), HDL-C from 37±7 to 40±8mg/dl (p=0.38) vs. 30±6 to 37±9mg/dl (p=0.03). Changes in lipoproteins subclasses distribution: small/dense LDL particles (L1) from 23±27 to 25±22mg/dl (p=0.99) vs. 105±67 to 19±18mg/dl (p=0.002). Endothelial function: all the cases that presented paradoxical response at the week zero in the high TG group were turned to physiological response at week 24, while there were no changes in the low TG group.
Conclusion: Only in high TG group, there were: significant decrease in the small and dense LDL subclasses (L1) concentration and improvement of endothelial function on those that presented paradoxical response before the treatment with fluvastatin.

P2199 Short-term treatment with simvastatin diminished plasma index of neutrophils degranulation

A. Wykretowicz, E. Deskur-Smielecka, A. Szczepanik, H. Wysocki. *Univ School of Medicine, Cardiology-Intensive Therapy, Poznan, Poland*

Background: Several data suggest that simvastatin has an anti-inflammatory activity. Polymorphonuclear neutrophils (PMN) play an important role in inflammatory reaction due to their ability to release enzymes from secretory granules. Plasma levels of beta-glucuronidase, stored in azurophilic granules and lysozyme stored in both specific and azurophilic granules are used as markers of neutrophils degranulation. The aim of our study was to evaluate prospectively serum concentration of lysozyme and beta-glucuronidase in hypercholesterolemic patients treated with simvastatin.
Methods: Peripheral blood samples were collected from 19 hypercholesterolemic patients (mean serum cholesterol level 302 mg/dl) before and after 8 and 12 weeks of cholesterol-lowering therapy with simvastatin (20 mg/day). Serum lysozyme levels were decreased significantly after 12 weeks (10.9±0.5 vs 9.3±0.6 ug/ml, p=0.01) of treatment but not after 8 weeks of therapy(10.3±0.5 ug/ml, p=0.37), while beta-glucuronidase serum concentrations were significantly diminished after 8 weeks (3.9±0.8 vs 1.4±0.4 ug/ml, p=0.03) and 12 weeks of simvastatin treatment (2.1±0.6 ug/ml, p=0.02). Lysozyme and betaglucuronidase significantly correlated with plasma cholesterol concentrations (r=0.4 p=0.003, r=0.3 p=0.02, respectively).
Conclusions: Short-term treatment with simvastatin significantly reduces polymorphonuclear neutrophils degranulation markers

P2200 The effect of statin therapy on exercise induced ischaemia and endothelium dependent vasodilation in patients with cardiac syndrome-X

M. Kayikcioglu, L. Can, S. Payzin, H. Kultursay, I. Soydan. *Ege University Medical School, Cardiology Dept., Izmir, Turkey*

Background: The pathophysiologic mechanism in cardiac syndrome-X has been suggested as an impairment in endothelial function of the coronary microvasculature, resulting in inadequate coronary flow reserve. Aim of this study was to determine whether statins have any effect on endothelial functions and exercise induced ischemia in syndrome-X.
Methods: Study population consisted of prospectively enrolled 35 patients (pts) with cardiac syndrome-X. All pts had typical exertional chest pain, positive exercise testing, and normal coronary angiograms. Pts with left ventricular hypertrophy, hypertension, diabetes mellitus, and LDL levels >150 mg/dl were excluded. Twenty pts were randomized to pravastatin(40 mg/day) for 3 months irrespective of lipid values. Endothelial functions were assessed with high-resolution vascular ultrasound(7.5 mHzprobe) which measured the changes in brachial artery diameter in response to hyperemic flow. Lipid measurements, symptom limited exercise tests(modified Bruce protocol), and vascular ultrasound images were obtained before and at the end of therapy.
Results: Baseline clinical characteristics of the groups were similar. After the treatment, LDL levels decreased significantly in the statin group (p=0.005). Brachial artery flow mediated dilatation (FMD) improved significantly in the statin group (p=0.002). Total exercise time, and time to 1mm ST depression were significantly increased after statin therapy. Ischemic ECG findings during exercise test disappeared completely in 5 (25%) pts in the statin group. Meanwhile, there were no significant changes in lipid levels, FMD and exercise test parameters in the control group.

Comparison of groups

	Pravastatin group		Control group	
	Baseline	3rd month	Baseline	3rd month
LDL(mg/dl)	121±31	97±19	116±28	119±24
FMD(%)	9.3±5.1	15.2±5.9	10.4±8.2	9.1±7.6
Total exercise time (min)	8.1±1.9	11±1.7	9.4±2.6	8.9±2.6
Time to 1mm ST depression (min)	2.9±1.6	6.1±2.2	3.3±1.2	3.1±1.6

Conclusion: Statin therapy have beneficial effects both on exercise induced ischemia and endothelial functions in pts with cardiac syndrome-X.

P2201 Clinical benefits of statin therapy initiated prior to percutaneous coronary intervention in patients with history of unstable angina pectoris

M. Kruk[1], J. Przyluski[2], Z. Chmielak[2], J. Pregowski[3], L. Kalinczuk[3], A. Debski[2], A. Witkowski[2], W. Ruzyllo[2]. [1]*National Institute of Cardiology, General Cardiology Department, Warsaw, Poland;* [2]*National Institute of Cardiology, II Independent Haemodynamic Department, Warsaw, Poland;* [3]*Medical Academy, Warsaw, Poland*

Background: Early invasive treatment of patients with unstable angina is a currently accepted approach. Culprit atherosclerotic lesions may remain potentially vulnerable for months following the acute event, which may worsen prognosis following coronary intervention (PCI) in those patients. Further data indicate that statin therapy may passivate unstable atherosclerotic plaques. Therefore we hypothesised, that coronary plaque passivation with statins initiated prior to PCI may improve clinical outcome in terms of major acute coronary events (MACE)(MI, death, revascularisation) as well as target vessel revascularisation (TVR) in patients with potentially unstable lesions.
Methods: We prospectively assessed 168 consecutive pts (121 men, mean age 57,1±9,1) with history of unstable angina within preceding 6 months, who underwent PCI. Follow-up was available for all the patients at mean of 9,4±3,8 months. Influence on clinical outcome of classical risk factors for coronary artery disease (sex, age, BMI, smoking, family history, DM, hypertension, hyperlipidemia), number of PTCA, stents, statin therapy initiated prior to intervention, and statin therapy continued during follow-up were assessed by multivariate analysis.
Results: 82 out of 168 patients (48,8%) had been receiving statins prior to PCI whereas during follow-up 114 (67,9%) patients were on statins. During follow-up 37 pts (22%) had MACE of which 24 pts (14,3%) had TVR. Patients on statins prior to PCI had fewer MACE and TVR (table). Statin pretreatment was the strongest independent predictor of MACE (OR 0,32;95%CI 0,14-0,72;p=0,005) and TVR (OR 0,34; 95%CI 0,13-0,94; p=0,038) in a multivariate model.

	statin pre-PCI (n=82)	no statin pre-PCI (n=86)	p
TVR % (n)	9% (7)	20% (17)	0,038
MACE % (n)	12% (10)	31% (27)	0,003

Conclusions: Statin pretreatment is independently related to better mid-term clinical outcome after PCI following unstable angina. Our results suggest that pharmacological plaque passivation with statins initiated prior to coronary intervention may reduce clinical restenosis. Therefore it should be considered for all patients awaiting coronary intervention, especially in those with conceivably unstable plaque.

P2202 Use of statins is associated with improved arterial stiffness in patients with coronary artery disease

J. Lekakis[1], A. Protogerou[1], Th. Papaioannou[2], M. Tsitsirikos[1], C. Papamichael[1], K. Stamatelopoulos[1], J. Kanakakis[1], S. Stamatelopoulos[1]. [1]*Alexandra University Hospital, Dept. of Clin. Therapeutics, Athens, Greece;* [2]*Alexandra University Hospital, Clin. Therapeutics, Athens, Greece*

Arterial stiffness may influence the prognosis of patients (pts) with coronary artery disease (CAD). To identify factors which affect arterial stiffness in those pts, we examined 235 pts undergoing coronary angiography for CAD (age 61.3±10.9 years, 208 men) with radial artery applanation tonometry and pulse wave analysis; augmentation index (AI) was used as an indirect index of arterial stiffness. In all pts flow-mediated dilatation of the brachial artery (index of endothelial function) and intima-media thickness of the carotid artery were also measured. AI in pts was related to peripheral systolic (r=0.26, p<0.001) and mean blood pressure(r=0.26, p<0.001) and heart rate (r=-0.539, p<0.001). Endothelial function, blood lipids, carotid artery IMT, extent of CAD (Gensini score) and BMI were not related to AI (ns). From the analysis of medication used, calcium antagonists, ACE inhibitors, beta blockers, diuretics and nitrates did not influence AI. One hundred pts were on treatment with statins; pts on statin therapy had higher percentage of previous myocardial infarction (p=0.003) and higher Gensini score (p<0.001). Pts on statins did not differ from pts without statins regarding heart rate, age, endothelial function, carotid artery IMT, ankle-brachial index, BMI, cholesterol, triglycerides, LDL and HDL-cholesterol. Systolic blood pressure was lower (116±17 vs 127±17 mmHg, p<0.001) and AI was better in the group of statins (19.1±15.2 vs 24±18.5%, p=0.038). In conclusion, pts with CAD on statin therapy appear to have lower arterial stiffness despite the more extended coronary artery disease; this effect on stiffness is independent of lipid-lowering effects; a beneficial effect of statins on arterial stiffness through reduction of the arterial pressure cannot be excluded.

P2203 Statin therapy within the initial 24 hours of acute myocardial infarction: insight into why mortality is reduced

R.S. Wright[1], K.A. Bybee[2], B.D. Powell[2], B.A. Williams[2], A.G. Rosales[2], D.R. Holmes[2], S.L. Kopecky[2], J.G. Murphy[2]. *[1]Mayo Clinic, Rochester, United States of America; [2]Mayo Clinic, Rochester, United States of America*

Background: Several observational studies have demonstrated an association between use of statin therapy during hospitalization in patients with acute myocardial infarction (AMI) and lower in-hospital mortality. No work has examined the potential clinical mechanisms for this observation. Several large randomized clinical trials remain ongoing with regard to this issue.
Methods: We analyzed 3226 patients with AMI admitted to our CCU from 1988 until 2001. Patients were divided into two groups: those receiving statin therapy (n=220) and those not receiving statin therapy (n-=3006) during the initial day of hospitalization over the study period. We included ST elevation and non-ST elevation AMI. We analyzed overall mortality and cause-specific mortality between both groups.
Results: Of the total group of patients with AMI, only 220 were given statin therapy during the initial 24 hours of hospitalization. In-hospital mortality was reduced in those receiving statin therapy (2.7%, 6/220) compared to the non-statin group (9.2%, 277/3006), p=0.001. The unadjusted odds ratio with regard to risk reduction of mortality was 0.28 (0.12-0.68). We observed no overall differences with regard to death from recurrent ischemia (3/6 vs 99/277), cardiac arrhythmia (0/6 vs 2/277), CHF (2/6 vs 46/277), mechanical complications (0/6 vs 15/277), stroke (0/6 vs 10/277) or hemorrhage (0/6 vs 1/277), p=ns. The median time to death appeared slightly longer in the statin group (132 hours, 25th percentile-75th percentile 72-168 hours) compared to the non-statin group (72 hours, 24-192 hours), p=0.3.
Conclusion: Use of a statin agent during the initial 24 hours following hospitalization for AMI was associated with reduced in-hospital mortality in our population. Additionally, the timing of death was later in those who received statin therapy compared to those not treated with a statin. The mechanism for the reduction in mortality appeared unrelated to an arrhythmogenic, ischemic or cardio-embolic mechanism. Further work is necessary to elucidate the mechanisms by which statin therapy reduce early mortality in AMI.

P2204 Dual effects of HMG-CoA reductase inhibitors on vascular endothelial growth factor synthesis

M. Frick[1], J. Dulak[2], R. Zwick[1], H. Alber[1], W. Dichtl[1], S.P. Schwarzacher[1], O. Pachinger[1], F. Weidinger[1]. *[1]Division of Cardiology, Department of Medicine, University of, Innsbruck, Austria; [2]Jagiellonian University, Department of Cell Biochemistry, Krakow, Poland*

Background: HMG-CoA reductase inhibitors (statins) exert pleiotropic effects on the vascular wall independent of the reduction in plasma cholesterol. Moreover, both pro- and anti-angiogenic activities of statins have been recently demonstrated. The aim of this study was to elucidate whether the angiogenic effects of statins are due to dose- and/or cell-dependent properties.
Methods: We investigated the effect of different concentrations (0.01 to 10 μM) of atorvastatin, simvastatin and lovastatin on the basal and induced [by IL-1β, S-Nitroso-N-acetyl-D,L-penicillamine (SNAP - an NO-donor) and lysophosphatidylcholine (LPC)] synthesis of vascular endothelial growth factor (VEGF) in human vascular smooth muscle cells (HVSMC), microvascular endothelial cells (HMEC-1) and umbilical vein endothelial cells (HUVEC).
Results: In HVSMC statins decreased the basal, cytokine and SNAP-induced release of VEGF. Additionally, statins diminished SNAP- or LPC-induced VEGF synthesis in HMEC-1. In contrast, low concentrations of statins increased intracellular VEGF protein and enhanced VEGF mRNA expression in HUVEC significantly. In addition, an in vitro assay showed increased tube formation by HUVEC after treatment with low concentrations of statins (0.1-1μM). At higher concentrations (10 μM) the proangiogenic effect of statins was no longer evident and VEGF synthesis was decreased.
Conclusion: Our data show that statins exert dual effects on VEGF synthesis. They promote the production of small amounts of this growth factor in primary endothelial cells but they inhibit the release of high amounts of VEGF by smooth muscle cells or an immortalized endothelial cell line. This dual, modulatory effect may partially explain the benefit of statins seen in large clinical trials.

INFECTION IN ATHEROSCLEROSIS

P2205 Elevated proinflammatory mediators correlate with the progression of P. gingivalis infection atherosclerosis in an ApoE (+/–) murine model

E. Messas[1], A. Hagege[1], M. Desnos[1], R.A. Levine[2], S. Amar[3]. *[1]hopital europeen georges pompidou, cardiologie 1, paris, France; [2]Massachusetts General Hospital, Cardiac Ultrasound Laboratory, Boston, United States of America; [3]Boston University, Periodontology and Oral Biology, Boston, United States of America*

Background: Recent studies have demonstrated that Porphyromonas gingivalis (P.g.), a pathogen implicated in periodontal diseases, is capable of accelerating atherosclerosis lesions in a heterozygote ApoE+/- mice model. However the underlying causal effect remains unknown. The purpose of this study was to correlate the time course of systemic proinflammatory markers with the progression of murine atherosclerosis.
Materiel and Method. Ten-week old, male ApoE +/- mice fed either a high-fat diet (HFD) or regular chow were inoculated intravenously with live P.g. (10 pwr(7) CFU) or vehicle once per week for 10, 14 or 24 consecutive weeks (n = 5 per group for each time point). Histomorphometry of plaque cross-sectional area in the proximal aortas, en face measurement of plaque area over the aortic trees, P.g. 16S ribosomal DNA amplification with PCR, ELISA for systemic proinflammatory proteins as interleukin 1beta (IL-1beta) and acute phase protein serum amyloid A (SAA) were performed.
Results: The level of IL-1beta and SAA was found to correlate significantly with the progression of atherosclerosis observed ApoE+/- mice fed HFD (r^2=0.80). The same profile, of elevated proinflammatory mediator was found in ApoE+/- mice fed chow diet, yet to a lesser extent (r^2= 0.69). Finally, P.g. was detected by PCR in atherosclerosis lesion only at 24 weeks.
Conclusion: The present data demonstrate that 1) atherosclerosis lesions at 10 and 14 weeks result probably from the effects of P.g-triggered systemic inflammatory processes; 2) whereas at 24 weeks atherosclerosis lesions result from the combination effect of systemic inflammatory processes as well as P.g-induced local aortic endothelial cell dysfunction. This highlights the importance of controlling the inflammatory load in the prevention of atherosclerosis lesions.

P2206 Chlamydia pneumoniae in the atherosclerotic plaques of patients with coronary artery disease. Does it have prognostic implications?

J. Garcia, J. Zamorano, R. Moreno, A. Suárez, E. Culebras, J. Castañón, M. Gil, L. Sánchez-Harguindey. *Hospital Clinico San Carlos, Cardiology Dept., Madrid, Spain*

C. pneumoniae (CP) has been implicated in the pathogenesis of coronary artery disease, but whether antichlamydial antibodies and the presence of CP in the coronary atherosclerotic tissue are related to prognosis remains unclear. This study sought to evaluate the prognostic significance of the presence of DNA of CP in the coronary atherosclerotic lesiόns of patients with unstable angina.
Methods: 76 coronary specimens from 45 patients with unstable angina undergoing bypass surgery were subjected to nested polymerase chain reaction (PCR) for CP. Antichlamydial IgG, IgA and IgM were also examined. Patients were followed during a two-year period.
Results: DNA of CP was detected in 57 (75%) of 76 atherosclerotic lesions: 39 patients showed a positive PCR result in at least one plaque. 44 (97,7%) of the 45 patients showed a positive serological result: IgG was positive in 39 (86,6%) patients, IgM in 5 (11,1%) and IgA in 42 (93,3%). At least one adverse event occurred in 21 (46,6%) of the 45 patients at two years: death in 9 (20%), recurrent angina in 12 (26,6%), revascularization in 6 (13,3%) and myocardial infarction in 2 (4,4%) patients. The composite endpoint of death, myocardial infarction, recurrent angina and revascularization at 2-year follow-up did not differ according to the presence or absence of CP in the atherosclerotic plaques or to the serologic results.

Outcome according to serology

	Free of endpoint at 2 years	p value
PCR +	5/24 (20,8%)	0.12
PCR -	1/21 (4,7%)	
IgG +	4/24 (16,6%)	0.49
IgG -	2/21 (9,5%)	
IgM +	2/21 (9,5%)	0.64
IgM -	3/24 (12,5%)	
IgA +	2/24 (8,3%)	0.54
IgA -	1/21 (4,7%)	

Conclusions: The presence of CP in the coronary atherosclerotic plaques of patients with unstable angina did not identify a higher group of patients for presenting adverse events in the follow-up. A positive serological (IgG, IgM, IgA) result against CP was not related to a worse prognosis, either.

P2207 Cytomegalovirus expression in specimens from stable and unstable coronary lessions

M. Loukas[1], M. Dabrowski[2], A. Bartczak[3], M. Kiedrowski[3], M. Kamionek[3], T. Wagner[3], J. Waltenberger[1]. *[1]Ulm University Medical Center, Department of Internal Medicine II, ULM, Germany; [2]Hospital Bielanski, Department of Cardiology, Warsaw, Poland; [3]Institute of Rheumatology, Department of Pathology, Warsaw, Poland*

Background: Infection with human Cytomegalovirus (HCMV) has been reported in several epidemiological studies to play an important role in the pathogenesis of atherosclerosis. However, the frequency of HCMV detectable in atherosclerotic plaques and the possible effect on the pathogenesis of atherosclerosis remains to be established.
Materials and Methods: We examined 100 coronary atherosclerotic plaques derived from postmortem examinations, and 40 atherectomized specimens obtained via Directional Coronary Atherectomy (DCA) from coronary arteries from patients clinically diagnosed with either stable (n=62, 44,3%) or unstable angina (n=78, 55,7%). All specimens were analysed for the presence of HCMV DNA sequences using Polymerase Chain Reaction. Furthermore each specimen was stained with immunohistochemical methods using polyclonal and monoclonal antibodies for the presence of CD4+, CD8+ T-lymphocytes as well as for the detection of HCMV early antigen. Morphometrical analysis of each atherosclerotic plaque was performed using the digital image analysis software Lucia.
Results: HCMV was found to be present in 41 out of 140 specimens (29.28%) included in our study. HCMV infected cells expressed a diffuse nuclear or an apparent cytoplasmic staining corresponding to early or late stage of infection respectively. From these 41 specimens, 32 were derived from unstable coronary lesions (78.04%). This statistically significant difference was accompanied by a three-fold increase in CD4+ and CD8+ T-lymphocyte infiltration in HCMV-positive specimens compared with HCMV-negative ones.
Conclusions: In our study the presence of HCMV was considerably higher in unstable plaques and may be the trigger for activating T lymphocytes, which are proven to be one of the most important factors contributing to the progression of atherosclerotic plaques and to the development of unstable coronary lesions.

P2208 Are fungi involved in atherosclerosis?

J-P. Elkaim[1], E. Moalic[2], J. Mansourati[1], L. Doucet[3], P. Gouny[4], J-A. Barra[4], A-M. Le Flohic[2], J-J. Blanc[1]. *[1]University Hospital of Brest, Cardiology Dept., Brest, France; [2]University Hospital of Brest, Department of Microbiology, Brest, France; [3]University Hospital of Brest, Department of Anatomo-Pathology, Brest, France; [4]University Hospital of Brest, Cardiovascular Surgery, Brest, France*

Objectives: There is growing evidence of a relationship between some infective agents (chlamydia pneumoniae and cytomegalovirus) and atherosclerotic process. We sought to determine a similar implication between fungi and atherosclerosis.
Methods: We studied atherosclerotic arterial fragments from 30 pts (24 M) undergoing peripheral vascular surgery (aorta, carotid, femoral and iliac arteries) and 30 fragments of non-atherosclerotic internal mammary arteries from pts undergoing bypass surgery (27 M). In the mean time, aortic valve fragments from 30 pts (16 M) undergoing valve replacement for aortic stenosis were analyzed. Each fragment was separated in 2 pieces: one for mycological analysis and the other for direct microscopic examination and culture on specific mediums. All fragments were manipulated with strict cautions in order to prevent any external contamination.
Result: Ten arterial fragment cultures (16.6%) showed fungal growth: 9 fragments originating from atherosclerotic lesions (9/30; 30%) and one from an internal mammary artery (1/30; 0.3%, $p<0.05$). Three fungal species were identified: Aspergillus, Cladosporium and Trichoderma. No correlation was found between the presence of fungi and atherosclerosis risk factors. None of the aortic valve fragments showed any fungal growth.
Conclusion: This study shows a significantly high affinity of some fungus species to atherosclerotic arterial intima but no affinity to pathological aotic valves or normal arteries. Further investigations are needed to clarify fungal involvement in atheroscerotic process.

P2209 Infectious pathogen burden and atherosclerosis: unstable atherosclerotic plaques contain T cells that respond to Epstein Barr Virus

O.J. de Boer, P. Teeling, A.C. van der Wal, A.E. Becker. *Academic Medical Center, Cardiovascular Pathology, Amsterdam, Netherlands*

Background: T cell activation is an essential feature in the chain of events eventually leading to the development of acute coronary syndromes. Cytokines, especially interferon-gamma secreted by Th1 T cells are considered to have plaque destabilizing properties. However, at present it is not clear which antigens are responsible for this local activation of T lymphocytes. Several studies, including those from our laboratory have shown that the common infectious pathogen C.pneumoniae is able to activate T cells from human atherosclerotic lesions. Seroepidemiological studies however have suggested that also other pathogens may be involved. Therefore, we studied the possibility that Epstein Barr Virus (EBV), another common pathogen could be involved also in local intraplaque T cell activation
Methods: T cells were isolated from human carotid endartherectomy specimens (n=11) and T cell lines were generated. B lymphocytes from the same patients were transformed with EBV and cell lines generated. Proliferative responses of T cells using autologous EBV-B cells as antigen presenting cells (APC) were measured by ^{3}H-thymidine incorporation. A stimulation index (SI) > 3 was considered as a responding T cell line. The specificity was further analyzed by inhibiting antibodies against MHC class I and II antigens. In addition, the presence of EBV in atherosclerotic tissue (n=29) and normal vesselfragments (n=8) was analyzed by PCR.
Results: 4/11 patients showed a specific significant response against EBV (mean SI= 15.2). This response was usually both partly MHC class I and II restricted. PCR analysis showed EBV DNA in the plaques of 19/29 patients (66%). EBV DNA was never present in normal vessels (0/8 specimens)
Conclusions: These results suggest that besides C.pneumoniae also the common pathogen EBV may be involved in the local activation of T cells in atherosclerotic plaques, an observation which is in line with the current concept of the role of a "pathogen burden" in atherosclerotic disease.

P2210 Chlamydia pneumoniae induces monocyte migration through extracellular matrix via EMMPRIN and matrix metalloproteinase activation

R. Schmidt[1], V. Redecke[1], Y. Breitfeld[1], C. DaCosta[2], T. Miethke[2], A. Schömig[1], F-J. Neumann[1], A.E. May[1]. *[1]Deutsches Herzzentrum, TU München, München, Germany; [2]Mikrobiologie & Hygiene, TU München, München, Germany*

Proteolytic activity of matrix metalloproteinases (MMP) is thought to promote cell migration and the rupture of the atherosclerotic plaque. We have studied the effects of Chlamydia pneumoniae (C.pn.) on the initiation of matrix degrading activity in monocytes with special regard to the role of the "Extracellular MMP-Inducer" EMMPRIN. Infection of monocytic MonoMac6 cells or isolated monocytes with C. pn. for 48 hours significantly enhanced the mRNA and surface expression of the urokinase receptor (uPAR), membrane-type-1-MMP (MT1-MMP) and of EMMPRIN [quantitative RT-PCR, flow cytometry]. Antibody-crosslinking of EMMPRIN resulted in 2-fold baseline secretion of MMP-9 and enhanced C.pn.-induced MMP-9 secretion by 2-fold indicating a central role for EMMPRIN as a MMP inducer. C. pn. significantly enhanced the secretion of soluble uPAR and uPA as well as induced matrix degrading activity of the two gelatinases MMP-2 and MMP-9 [ELISA, SDS-PAGE-zymography]. Transmigration of C.pn.-infected monocytic cells through extracellular matrix components ("matrigel") was maximally enhanced (comparable with PMA-stimulation) and was inhibited by the MMP-inhibitor GM6001 (100%), recombinant TIMP-1 (51%) or TIMP-2 (50%), but not by the non-inhibiting control peptide for GM6001. Consistently, C. pn. stimulated monocytic cell migration through endothelial cell monolayers (HUVEC). The LPS-inhibitor polymyxin B abrogated LPS-induced matrigel invasion, but not C. pn.-induced cell invasion indicating, that endotoxin did not play a major functional role for C.pn.-induced cell invasion.
Conclusion: C.pn. induces monocytic matrix degradation and matrix invasion via activation of a proteolytic cascade involving the plasminogen and MMP activation system. This activation pathway seems to be independent of chlamydial LPS. These data indicate, that C.pn. may (1) promote monocyte recruitment into the atherosclerotic plaque and (2) contribute to the development of cardiovascular complications such as plaque rupture by the activation of matrix degradation.

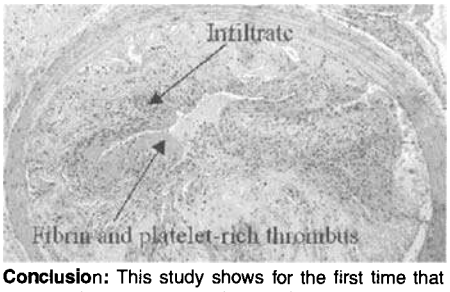
P2211 Influenza infection exerts prominent inflammatory and thrombotic effects on the atherosclerotic plaques of apo E-deficient mice

M. Madjid[1], S. Litovsky[1], A. Akhtar[1], P.R. Wyde[2], S.W. Casscells[1], M. Naghavi[1]. [1]*Center for Vulnerable Plaque Research, Unv. of Tex-Houston and Tex Heart Ist., Houston, United States of America;* [2]*Baylor College of Medicine, Dept. of Mol. Virology & Microbiology, Houston, United States of America*

The role of infection in the development and complications of atherosclerosis has been the focus of much attention. We have previously reported that influenza vaccination was associated with reduced risk of recurrent myocardial infarction. Here, we report the effect of influenza A virus on the apo E -/- mouse, an animal model of atherosclerosis.

Methods: Twenty-four apo E -/- mice over 24 months old were injected with 1 LD50 (lethal dose 50) of influenza A virus intranasally. Ten wild-type C57BL/6 infected mice and 11 non-infected age-matched apo E -/- mice served as controls. Animals were sacrificed 3, 5 and 10 days after inoculation. Multiple aortic sections were studied histologically.

Results: The infected mice showed marked increase in intimal cellularity compared to the non-infected apo E -/- mice. No aortic abnormalities were seen in infected wild-type mice. Ten infected apo E -/- mice had a prominent subendothelial infiltrate composed of a heterogeneous group of cells that stained positively for smooth muscle cell actin, F4/80 (macrophages) and CD3(T lymphocytes). Infected animals with the focal cellular infiltrate had clusters of platelets in the lumen overlying the infiltrate. One case of subocclusive platelet aggregation and fibrin-rich thrombus was seen. Neither the subendothelial infiltrate nor the large platelet clusters and thrombus were seen in the non-infected mice.



Conclusion: This study shows for the first time that influenza infection promotes inflammation, growth, and thrombosis of atherosclerotic plaques. This may prove useful as a model for studying the roles of infection and inflammation in atherogenesis.

NEUROHUMORAL CONTROL MECHANISMS IN HEALTH AND DISEASE

P2212 Co-stimulation of different guanylyl-cyclase receptors in healthy men

M. Komarek, R. Schindler, R. Steden, W. Kiowski, H.P. Brunner-La Rocca. *University Hospital, Cardiology, Zurich, Switzerland*

Differences in the effects of natriuretic peptides (NP) are still poorly understood. In particular, most of the known effects of both ANP and BNP are conducted by stimulation of the guanylyl-cyclase type A receptor. However in contrast to ANP, the effects of BNP are believed to be preserved in chronic heart failure. Recent findings in experimental studies support the presence of a BNP-specific receptor. We, therefore, investigated the haemodynamic effects of co-infusion of ANP, BNP, and as a control CNP, in addition to submaximal local dosage of ANP in the forearm vasculature of healthy subjects. Furthermore, in half of the subjects infusions were maintained for 5 times half-lives of the peptides to investigate if rapid desensitisation is present in humans.

Methods: In 11 healthy, male volunteers, arterial response to intra-arterial infusion of ANP (60pmol/100ml forearm volume/min) to cause submaximal NPR-A stimulation was measured. Then, co-infusion of either ANP, BNP or CNP in randomised order was administered to assess additional vascular response. After a washout period adjusted to the plasma half-live of the administered NP, ANP was restarted, followed by co-infusion of one of the NP not yet infused. After a further washout period, ANP was restarted, followed by co-infusion of the NP not yet co-infused. In 6 of the subjects, infusion time was adjusted to plasma half-lives of the peptides (5 times), and in 5, infusions were given for 5 minutes each.

Results: ANP alone caused the expected vasodilation from 2.7±0.3 to 6.0±0.9 ml/min/100ml forearm volume (FAV; $p<0.004$). This response remained unchanged in the group receiving short infusions (6.2±0.8 to 6.6±1.1 ml/min/100ml FAV), but was significantly reduced in the group receiving infusions over a longer period of time (6.5±1.2 to 4.5±0.7, $p<0.05$; response different between groups $p<0.05$). Co-infusions of ANP, BNP, and CNP caused a small additional vasodilation (mean 0.8±0.2 ml/100ml FAV/min, $p<0.01$). However, this additional vasodilation was identical in 3 groups, but blunted over time in the group receiving long infusions.

Conclusions: There seems to be rapid desensitisation of the guanylyl-cyclase type A receptor. Although our data do not support the presence of a BNP-specific receptor, the lack of additional response to stimulation of the type B receptor by CNP does not exclude it. Furthermore, the vasodilatory capacity through stimulation of guanylyl-cyclase receptors seems to be limited, irrespectively if one or more than one type of these receptors is stimulated.

P2213 ANP but not CNP modifies forearm vascular tone in CHF

M. Schmitt[1], A.J.M. Broadley[2], P. Gunaruwan[1], J.S.W. Taylor[1], L. Lee[1], J.C. Cockcroft[1], A. Struthers[3], M.P. Frenneaux[1]. [1]*Wales Heart Research Institute, Department of Cardiology, Cardiff, United Kingdom;* [2]*Wales Heart Research Institute, Department of Cardiology, Cardiff, United Kingdom;* [3]*Wales Heart Research Institute, Cardiology Dept., Cardiff, United Kingdom*

Background: Previous in vitro studies comparing the vascular effects of atrial natriuretic peptide (ANP) and c-type natriuretic peptide (CNP) in animal vessels indicated that arteries are the major site of action for ANP whilst CNP acts mainly on veins. We recently demonstrated that ANP causes marked forearm venodilation in healthy controls. In this study we compared the effects of ANP and CNP on forearm blood flow (FBF) and venous capacitance in subjects with chronic heart failure (CHF).

Methods: We infused incremental doses (0.05μg/min, 0.5μg/min, 1μg/min) of ANP (n=13) or CNP (n=7) into the brachial artery of 20 subjects with CHF (NYHAII/III). Changes in baseline forearm venous volume, compliance and tone were assessed in all patients using radionuclide plethysmography. In brief; Following radiolabelling of red cells, venous pressure/volume relations (PVR) were constructed by obstructing venous outflow in a stepwise manner for 1 minute. During each 1-minute interval a dynamic picture of the forearm was recorded using a gamma camera. Vascular volume was plotted against occluding cuff pressure. Forearm blood flow was measured in 11 subjects (ANP; n=5/CNP; n=6) using strain gauge plethysmography. Natriuretic peptide (NP) (20 subjects) levels and cGMP (15 subjects) production were measured by radio-immuno assay.

Results: (mean±SEM). NP levels in the venous effluent of the infused arm increased from 95±17pg/ml to 251±40pg/ml (ANP 1μg/min) and from 10±1pg/ml to 1253±49pg/ml (CNP 1μg/min); $P<0.01$ for both. ANP infusion caused a modest increase in FBF from 2.6±0.3ml/100ml forearm volume (fv) to 3.9±0.9ml/100ml fv; P=0.1. This was associated with an increase in cGMP from 7.2±1.3pg/ml to 25±5.6pg/ml.; P=0.01). CNP infusion did not change FBF; 2.6±0.4ml/100ml fv to 2.9±0.2ml/100ml fv; P=NS, despite a modest increase in cGMP from 10.3±1pg/ml to 15.4±4pg/ml; P=0.2. However, whilst ANP infusion caused a dose-dependent parallel upward shift of the PVR (reflecting venodilation) associated with an increase in forearm venous volume (2%; P=0.2, 5%; $P<0.01$ and 14%; $P<0.001$), CNP had no significant effects on forearm venous volume (-2%, 1%,7%, P=NS for all).

Conclusion: ANP but not CNP modifies venous capacitance in CHF.

P2214 The angiotensin II response to an acute exercise stimulus and the angiotensin converting enzyme genotype

A. Jones[1], J. Sanders[2], S. Hurret[2], J. Goldstone[2], P. Gohlke[3], S. Humphries[2], H. Montgomery[2]. [1]University College London, London, United Kingdom; [2]University College London UK, London, United Kingdom; [3]University of Kiel, Kiel, Germany

Background: The angiotensin converting enzyme (ACE) insertion/deletion (I/D) polymorphism is associated with resting ACE activity such that DD>ID>II. The D allele is strongly associated with increased exercise-induced left ventricular hypertrophy (LVH) and cardiovascular risk. We therefore examined the relation between ACE genotype, exercise, circulating ACE and Angiotensin II.
Methods: Seventeen (9DD, 8II) healthy, male (22.9±1.9 years, 178.6±2.8 cm, 71.9±2.2kg) participants who performed 20 minutes of exercise on a fixed ergometer at 70% of Vo2 max. Venous samples were taken at rest, immediately after exercise and 40 minutes post-exercise and plasma extracted. ACE assays were analyzed by a fluorometric method using Z-Phe-His-Leu as substrate. Angiotensin II samples were drawn into chilled tubes containing a renin inhibitor with plasma and shock frozen in liquid nitrogen. Paired t-tests examined the whole-group change in ACE and Angiotensin II with ANOVA for genotype differences. All figures: mean±sem, ACE activity (nmol His/Leu/ml/min), Angiotensin II (pg/ml plasma).
Results: Baseline ACE activity was significantly different ($p<0.001$) between the II (24.9±1.8), and DD subjects (45.5±2). The whole-group increase in ACE activity with exercise (5.7±0.7) was significant ($p<0.001$), with the difference in ACE between II (29.9±2.1 and 27.2±2.1) and DD (51.8±3 and 48.6±2.3) subjects persisting ($p<0.001$) for both immediate and 40mins post-exercise. Baseline Angiotensin II was no different between genotypes (2.8±1.2 and 2.6±1.5, DD and II respectively, p=0.9). Angiotensin II levels rose significantly (27.6±2.7, $p<0.001$), but were no different between genotypes immediately post-exercise (25.6±2.9 and 33.9± 5.3 for DD and II subjects, p=0.2). However, there was a significant difference 40 minutes after exercise (increased 19.2±4.6, and 6.2±1.6 for DD and II respectively, p=0.03).
Conclusions: This is the first report that DD subjects demonstrate a greater rise in Angiotensin II at 40min post-exercise than II subjects. This may reflect increased levels of circulating ACE persisting after exercise. The hypertrophic and vasoconstricting action of Angiotensin II may thus facilitate the increased LVH in DD subjects with exercise.

P2215 Norepinephrine release is reduced in cardiac tissue of diabetic patients

C. Burgdorf[1], D. Richardt[2], T. Kurz[2], R. Tölg[2], A. Nötzold[3], E.G. Kraatz[3], H.H. Sievers[3], G. Richardt[1]. [1]Universitätsklinikum, Medizinische Klinik II, Lübeck, Germany; [2]Universitätsklinikum, Medizinische Klinik II, Lübeck, Germany; [3]Universitätsklinikum, Klinik für Herzchirurgie, Lübeck, Germany

Background: Cardiac sympathetic nerve activity has substantial pathophysiologic and prognostic implications in heart diseases. We therefore sought to relate patient characteristics to norepinephrine release in specimens of atrial tissue obtained during bypass surgery.
Methods: Norepinephrine release was determined in incubated human atrial tissue under baseline conditions as well as during electrical field stimulation (5 min, 5 V, 4 Hz) and was measured by high performance liquid chromatography with electrochemical detection.
Results: Stimulation-induced norepinephrine release was reduced by approximately 25% in atrial tissue from diabetics (n = 19) as compared to nondiabetics (n = 43) (46 ± 5 vs. 62 ± 4 pmol/g; $p < 0.05$), whereas baseline release did not differ (14 ± 2 vs. 17 ± 2 pmol/g). Conversely, neither baseline nor stimulation-induced norepinephrine release was altered in patients with arterial hypertension (n = 40) compared to those without respective attribute (n = 22) (baseline norepinephrine 16 ± 2 vs. 17 ± 2 pmol/g and stimulation-induced norepinephrine 54 ± 4 vs. 62 ± 5 pmol/g). Analysis of cardiac function and norepinephrine release in 56 patients revealed a positive correlation of baseline release and preoperative left ventricular ejection fraction ($r = 0.32$, $p < 0.05$), while stimulation-induced release was not correlated with ejection fraction ($r = 0.22$). Finally, no correlation was found between age and cardiac norepinephrine release (baseline and stimulation-induced norepinephrine release each $r = 0.02$, $n = 62$).
Conclusions: In atrial tissue of diabetic patients stimulation-induced norepinephrine release from sympathetic nerve endings is reduced and this may contribute to sympathetic neuropathy. Furthermore, patients with impaired cardiac function had reduced norepinephrine release probably due to depletion of transmitter stores. Other characteristics such as age or arterial hypertension were not related to altered norepinephrine release.

P2216 Enhanced vasoconstriction in chronic heart failure: a potential consequence of increased ET-1 and failed natriuretic peptide counter-regulation

M. Yousufuddin[1], W. Shamim[2], M. Flather[2], M. Henein[2], T. Mohieddine[2], M. Amrani[2], A J S. Coats[2]. [1]Cleveland Clinic Foundation, Cardiology Departement (F-25), Cleveland, United States of America; [2]National Heart and Lung Institute, Department of Clinical Cardiology, London, United Kingdom

Background: Peripheral vasoconstriction is increased during exercise as is neurohumoral actovation as part of compensatory and counter-regulatory mechanisms in patients with chronic heart failure (CHF).
Objectives: To assess brachial artery (BA) reactivity in association with plasma levels of endothelin-1 (ET-1) and cardiac natriuretic peptides - atrial (ANP) and brain (BNP)natriuretic peptide, in response to graded increment in exercise intensity to determine the balance between major compensatory mechanisms.
Methods: Fifteen-men aged 56.7±8 (Mean±SD)years with NYHA class I-IV CHF and LV ejection fraction < 35% (radionuclide),cardiac index 1.5±0.22 L/M^2/min, mean pulmonary capillary wedge pressure 21.0±9.3mm Hg were studied. Using high-resolution (3-11MHz linear array transducer)ultrasound (SONOS 5500, Hewlette Packard, USA)technique with a resolution capability of 0.1mm, we measured BA diameter at rest and within 90 seconds after leg exercise (arm held non-active) to determine BA reactivity in response to submaximal (SME)and maximal (ME) exercise. Cardiopulmonary exercise testing was performed to determine peak O2 consumption (VO2)using breath-by-breath gas analysis (AMIS 2000, Denmark). SME was defined as 80% of the subjects's ME capacity as measured by recent exercise testing prior to study. ME was terminated after the subject has reached a state of exhaustion, which was performed after an interval of 60-90min to allow recovery from SME. Venous blood samples were obtained at baseline and peak SME and ME testing for the measurement of lactate, ET-1 (Biotrak ET-1 ELISA System, Amersham, England)ANP and BNP(immunometric assay,Shionara, France).
Results: VO2 increased from 18.1±5.5 to 22.3±7.3 ml/kg/min(P=0.002) and blood lactate from 1.88±0.36 to 2.5±0.58mmol/L($P<0.0001$) with increment from SME to ME. BA showed a graded decrease in its diameter, inferred as an increase in constriction (calculated as % change in diameter from baseline)from 6.1±4.7% to 7.2±4.6% (P=0.004)with increment in exercise intensity. Plasma levels of ET-1 (2.06±0.60 to 2.5±0.61pmol/L;P=0.0001)showed a similar increment but ANP (47.1±37.8 to 38.4±28.4pmol/L;P=0.16)and BNP (28.4±24.1 to 31.3±27.3pmol/L;P=0.15)levels demonstrated initial increase with no further rise with increase in exercise intensity.
Conclusion: Incremental BA constriction and plasma ET-1 levels with graded increase in exercise suggest an exaggerated vasoconstrictor state in CHF. Lack of appropraite rise in plasma levels of ANP and BNP indicate an insufficient counter-regulation.

CONGENITAL HEART DISEASE, RIGHT HEART AND MISCELLANEOUS

P2217 Aberrant tendinous chords with tethering of tricuspid leaflets: an unknown congenital anomaly causing severe tricuspid regurgitation in adults

R. Kobza, E. Oechslin, D.J. Kurz, R. Jenni. University Hospital, Cardiology, Zurich, Switzerland

Background: We describe a novel mechanism of tricuspid regurgitation in adults due to tethering of the tricuspid valve leaflets by aberrant tendinous chords.
Methods: The last 13'500 consecutive echocardiographic studies from our facility were reviewed to identify patients with severe tricuspid regurgitation. Tethering was defined as aberrant tendinous chords to one or more tricuspid valve leaflets resulting in incomplete coaptation and tricuspid regurgitation.
Results: Ten patients (5 male and 5 female, mean age = 38 years, range = 12 - 73 years) with aberrant tendinous chords tethering one or more tricuspid valve leaflets were identified. One or more of each of the tricuspid valve leaflets were found to be affected. Tethering was the only mechanism of tricuspid regurgitation in three patients, whereas it was associated with short primary tendinous chords (i.e. with normal insertion at the leaflet tip) in seven patients. Six patients had associated congenital heart disease (atrial septal defect, congenitally corrected l-transposition of the great arteries, d-transposition of the great arteries, situs inversus with congenitally corrected d-transposition of the great arteries and two patients with pulmonary stenosis).
Conclusions: Tethering of the tricuspid valve leaflets due to aberrant tendinous chords is a distinct and previously unrecognised cause of tricuspid regurgitation in adults. This anomaly is frequently associated with short non-aberrant tendinous chords. Awareness of this mechanism of tricuspid regurgitation is of high clinical relevance and must be taken into consideration during reconstructive surgery of the tricuspid valve.

P2218 Unicuspid, bicuspid and quadricuspid aortic valves diagnosed by transoesophageal echocardiography

B. Schneider[1], R. Bauer[2], E. Schlemminger[3], H-H. Sievers[4].
[1]Städt.Krankenhaus Süd, Klinik für Kardiologie, Lübeck, Germany; [2]Allg. Krankenhaus St. Georg, II. Medizinische Abteilung, Hamburg, Germany; [3]Allg. Krankenhaus St. Georg, Herzchirurgische Abteilung, Hamburg, Germany; [4]Universitätsklinikum, Klinik für Herzchirurgie, Lübeck, Germany

Background: The bicuspid aortic valve (BAV) is the most frequent congenital malformation of the heart, whereas unicuspid (UAV) and quadricuspid aortic valves (QAV) are very rare. Incidence and associated lesions in patients undergoing TEE have not been well described.
Methods and Results: Over a 10-year period, 4827 adult patients were studied by TEE and prior TTE. QAV was present in 3 patients (0.06%). 1 patient (age 32) with associated ventricular septal defect had 4 equal valve cusps and showed normal QAV function. The second patient (age 59) with associated fibromuscular subaortic stenosis had 1 small and 3 large cusps with grade IV aortic regurgitation. A third patient (age 46) with isolated QAV had 4 unequal cusps with grade II aortic regurgitation. No QAV had evidence of stenosis or endocarditis. BAV was diagnosed in 38 patients (0.8%, 8f, 30m, mean age 48 y) and was regurgitant (n=17), stenotic (n=2), both stenotic and regurgitant (n=12) or showed normal BAV function (n=7). Associated lesions were: aortic valve (n=5) or mitral valve prolapse (n=1), aortic aneurysm/ dissection (n=3), mitral valve aneurysm (n=5), and subvalvular aortic stenosis, sinus of Valsalva aneurysm, aortic coarctation or aortic arch atresia (1 patient each). Infective endocarditis was present in 11 patients (active n=9, remote n=2, only BAV n=5, BAV and/ or mitral valve n=6). Diagnosis of UAV was made in 1 patient (age 45) with pure aortic regurgitation of grade IV caused by high leaflet redundancy with leaflet prolapse and associated endocarditis. There was no stenosis in this unicommissural valve. 1 UAV, 1 QAV and 19 BAV patients underwent aortic valve replacement with surgical confirmation of the valve morphology and associated lesions. The incidence of congenitally abnormal valves in TEE patients compares well with the figures reported in the literature for autopsy series.
Conclusion: QAV is rare, in case of unequal cusps regurgitant, and occurs alone or in association with other congenital abnormalities. BAV is found more frequently, may be stenotic and/or regurgitant and is prone to infective endocarditis. Associated lesions in BAV patients may be congenital but frequently are acquired. UAV is extremely rare and may present in adults with pure aortic regurgitation without stenosis.

P2219 Preparticipation cardiovascular athletic screening examination using echocardiography in 6610 children and adolescents: a 12 years' experience

C. Dellos[1], H. Bilianou[1], E. Adamopoulou[1], M. Zairis[2], E. Challi[1], S. Foussas[1]. [1]Tzanio Hospital, Cardiology Dept., Piraeus, Greece; [2]Piraeus, Greece

Background: Preparticipation Cardiovascular Screening Examination (P.C.S.E.) is considered mandatory for the safe training of young athletes for the prevention of sudden death as well for the early diagnosis of cardiac abnormalities that require limited athletes' participation, medical or interventional treatment, follow-up and chemoprophylaxis. During the last 12 years we examined an exceptionally high number of children and adolescents for P.C.S.E. The aim of the study was to estimate the incidence and the type of cardiac abnormalities in young athletes and to evaluate the contribution of the echocardiography to that purpose.
Methods: We examined 6610 children and adolescents (5-19 yrs, mean 11) without known cardiac disease. A detailed medical history, physical examination, electrocardiogram and an echocardiogram were performed from the same physician.
Results: Two hundred and thirty participants (3.5%) demonstrated cardiac abnormalities: 70 (1.1%) aortic valve diseases (bileaflet AV, regurgitation, stenosis), 57 (0.6%) shunts (ASD, VSD, PDA), 82 (1.2%) mitral valve prolapse, 12 (0.2%) pulmonary valve stenosis, 5 (0.08%) WPW, 1 hypertrophic cardiomyopathy, 1 dilated cardiomyopathy, 1 coarctation of the aorta and 1 primary pulmonary hypertension.
Conclusion: 1) A significant number of children and adolescents demonstrate major cardiac abnormalities statistically considerably greater than the one that it is referred to incidents of congenital heart disease during birth. 2) Low incidents of hypertrophic cardiomyopathy (major cause of sudden death during training) and of mitral valve prolapse highlights the fact that the echocardiographic findings of these abnormalities appear progressively until adulthood and the non discovery during childhood or adolescence does not exclude them. 3) echocardiography contributes to its maximum in diagnosis of cardiac abnormalities in athletes under the precondition that a detailed medical history and a careful interpretation of ECG precedes and special care is taken to avoid false positive results of the test which are the major problem of the overusage of the method.

P2220 Effects of different training protocols on right ventricular myocardial function in competitive athletes: a tissue Doppler study

A. D'Andrea[1], P. Caso[1], S. Severino[1], B. Liccardo[2], B. Sarubbi[2], G. Tagliamonte[2], G. Cice[2], R. Calabrò[2]. [1]Ospedale Vincenzo Monaldi, Cardiology Dept., Naples, Italy; [2]Second University of Naples, Cardiology Dept., Naples, Italy

Hemodynamic overload due to long-term physical training involves both left (LV) and right (RV) ventricular chamber, inducing changes in cardiac structure globally described as "athletes heart". Although standard Doppler echocardiography has been widely used to distinct athlete's heart from pathologic LV hypertrophy, few reports have described the RV myocardial adaptation to extensive physical exercise. Aim of the study was therefore to analyze the different involvement of RV myocardial function in LV hypertrophy induced by either endurance or strength training in top level athletes.
Methods: Standard Doppler echo and pulsed Tissue Doppler (TD) of mitral and tricuspid annulus were performed in 36 competitive endurance athletes (long-distance swimmers) (ATE) and in 28 strength-trained athletes (short-distance swimmers) (ATS). By use of TD, the following parameters of myocardial function were assessed: systolic peak velocities (Sm), pre-contraction time, contraction time, early (Em) and late (Am) diastolic velocities, Em/Am ratio, relaxation time.
Results: the two groups were comparable for age and sex, but ATS at rest showed higher heart rate, systolic blood pressure, and body surface area. LV mass index and fractional shortening did not significantly differ between the 2 groups. However, ATS showed increased sum of wall thickness (septum + posterior wall) ($p<0.001$) and relative wall thickness, while LV stroke volume and both LV and RV end-diastolic diameters ($p<0.001$) were greater in ATE. All transmitral and transtricuspid Doppler indexes were higher in ATE, with increased E/A ratios. TD analysis showed in ATE higher Sm, Em and Em/Am ratio as well as longer relaxation time both at mitral and at tricuspid annulus level. Distinct multiple linear regression models evidenced independent positive association between RV peak Em velocity and LV end-diastolic diameter (beta: 0.75; $p < 0.0001$) in ATE, and independent direct correlation of RV peak Sm velocity with sum of wall thickness (beta: 0.62; $p < 0.001$) and LV end-systolic stress in ATS. Conclusions: Early diastolic RV myocardial function is positively influenced by preload increase in ATE, while increased afterload and LV wall thickness seem to induce mainly an enhancement of regional RV systolic function in ATS.

P2221 Assessment of systolic right ventricular function by Doppler tissue imaging of the tricuspid annulus

D. Tüller, M. Steiner, M. Kabok, C. Seiler. *Swiss Cardiovascular Center Bern, Cardiology, Bern, Switzerland*

Background: Peak systolic velocity obtained by Doppler Tissue Imaging (DTI) of the mitral annulus has been shown to correlate with systolic left ventricular function. The intention of our study was to assess whether such a relation exists between the peak systolic velocity of the tricuspid annulus and systolic right ventricular function.
Method: We examinded 225 patients (pts) divided in three groups (group 1: 95 pts without cardiovascular disease; group 2: 59 pts with impaired right ventricular function: group 3 71 pts with impaired left ventricular function or pulmonary hypertension but normal right ventricular function) by transthoracic echocardiography. The mean value of three methods to determine right ventricular ejection fraction (monoplane Simpson's method; biplane pyramidal approximation; monoplane ellipsoid approximation) was used as reference for systolic right ventricular function (RVEF). Tricuspid annular velocities were recorded by pulsed wave DTI at the lateral tricuspid annulus.
Results: RVEF was significantly lower in group 2 (38±14%) in comparison to group 1 (67±6%) and 3 (67±6%) as expected from the inclusion criteria. Left ventricular ejection fraction values in group 2 (46±17%) and group 3 (53±15%) were less than in the control group 1 (68±4%; $p<0.001$). Peak systolic velocity at the lateral tricuspid annulus (TVLAT) differed in the three groups. TVLAT was significantly lower in group 2 than in group 1 and 3 (9.8±2.4 cm/s vs. 15.6±2.5 cm/s and 14.6±3.9 cm/s; $p<0.001$). Linear regression analysis showed a correlation between TVLAT and RVEF ($R=0.57$; $p<0.0001$). A cut-off value of TVLAT <12.5 cm/s has a sensitivity of 85%, a specifity of 80% and a positive predictive value of 58% to detect an RVEF<55%. The negative predictive value of the test (TVLAT <12.5cm/s) is 94%.
Conclusion: Diminished peak systolic velocity of the lateral tricuspid annulus obtained by pulsed wave DTI can be used as a marker for impaired systolic right ventricular function possibly regardless of systolic left ventricular function. A peak systolic velocity of the lateral tricuspid annulus of >12.5cm/s accurately predicts normal right ventricular function.

P2222 Clinical studies of right ventricular wall motion by pulse-wave Doppler tissue imaging in patients with coronary artery disease

L.L. Cheng, X.H. Shu, X. Shen. *Zhongshan Hospital, Fudan University, Department of Cardiology, Shanghai, China*

Objectives: The right ventricular (RV) wall motion by pulse-wave Doppler tissue imaging (PW-DTI) in patients with coronary artery disease has not yet been well investigated. The aim of this study was to evaluate RV wall motion qualitatively and quantitatively by PW-DTI, and its clinical significance. Methods: The study population included 32 consecutive patients who underwent coronary angiography. Based on the conronary lesions, patients were devided into three groups. Group A consisted of 11 patients with normal coronary arteries. Group B included 15 patients with right coronary narrowing. Group C comprised 6 patients with normal right coronary arteries and stenotic left coronary arteries. Volume sampling of PW-DTI was placed at the basal, middle and apical segment of the RV free wall in the apical 4-chamber view.The peak systolic velocity (Vs), the systolic velocity integral (VTI-S), the early peak diastolic velocity (Ve), the late peak diastolic velocity (Va), the the onset of early diastolic wave (Q-E), the time interval from the onset of QRS wave of the ECG to the peak diastolic velocity (Q-E)was determined. Results: (1) In the middle segment of the RV free wall, Q-E and Q-Ep in Group B were significantly longer than those in Group A (p=0.001, p=0.049 respectively). In the apical segment of the RV wall, Q-E in Group B was significantly longer than that in Group A as well (p=0.048). (2) In the basal segment of the RV wall, Q-E in Group C was significantly longer than that in Group A (p=0.02). In the middle segment of the RV free wall, Q-E and Q-Ep in Group C were significantly longer than those in Group A (p=0.01, p=0.04 respectively). (3) In the middle segment of the RV wall, S-VTI in Group B was significantly lower than that in Group C (p=0.018). In the apical segment of the RV wall, Vs in Group B was significantly lower than that in Group C (p=0.03). (4) No significant difference of Ve and Va were found in each segment among all groups (all $p>0.05$). Conclusions: Our findings demonstrate that the prolongation of Q-E and Q-Ep in the middle segment of the RV free wall indicates coronary narrowing, and the decrease of S-VTI in the middle segment of the RV free wall or the lowering of Vs in the apical segment of the RV free wall indicates right coronary stenosis. PW-DTI is a new noninvasive method to detect coronary artery disease.

P2223 Evidence for significant ischaemic right ventricular dysfunction during dobutamine stress echocardiography

C.A. O'Sullivan, C. Daly, A. Duncan, W. Li, M. Henein. *Royal Brompton Hospital, Cardiac Dept., London, United Kingdom*

Background: In clinical practice the concern is always focused on the effect of coronary artery disease on the left ventricle, even during stress.
Aim: To assess right ventricular (RV) behaviour in addition to that of the left ventricle during stress echocardiography in order to identify markers of dysfunction that may contribute to the patient symptoms.
Subjects: We studied 33 patients (mean age 58±5 years, 30 males) with triple vessel coronary artery disease using the conventional dobutamine stress Echocardiography protocol starting with 5μg/kg/min with similar incremental doses every 3 minutes for up to eight stages. RV function was assessed from M-mode recording of the free wall amplitude of motion and spectral Tissue Doppler (TD) for its systolic and diastolic velocities. RV filling velocities were also measured from the pulsed wave Doppler recordings. The findings were compared with those from 15 control subjects (mean age 58±11 years).
Results: At rest- Right ventricular size was normal, inlet diameter <3.5 cm, and free wall amplitude, shortening and lengthening velocities not different from controls. RV filling velocities were slightly reduced in patients but E/A ratio was maintained.
At peak stress: RV free wall amplitude failed to increase compared to controls (2.3±0.6 vs 3.0±0.5 cm, $p<0.001$. The peak TD systolic velocity increased as in controls suggesting maintained RV inotropic function. In contrast to normal behaviour, early TD diastolic velocity failed to increase (11.0±4.0 vs 14±3.5 cm/s, $p<0.001$) and 8/33 patients developed significant post ejection shortening ($P<0.001$). This contributed to the fall in RV E/A ratio from 1.1±0.3 to 0.76±0.4, $p<0.001$.
Conclusion: In patients with multivessel coronary artery disease, the right ventricular free wall may demonstrates ischaemic disturbances, similar to those seen on the left side with stress. This may contribute to patient's symptoms and exercise intolerance known in coronary artery disease.

P2224 Anatomical changes of right heart after percutaneous atrial septal defect closure with Amplatzer device

A. Carcagnì, L. Maiello, F. Marsico, D. Parenti, M. Piras, S. Salvaderi, P. Presbitero. *Istituto Clinico Humanitas, Interventional Cardiology, Rozzano, Italy*

Background: Percutaneous atrial septal defect (ASD) closure with Amplatzer septal occluder (ASO) device is a safe and effective technique in reducing left to right shunt. However, the response of the adult's right heart after device closure is incompletely understood. The aim of this study is to evaluate the right heart response to ASD device closure in an adult population at 6 months.
Methods and Results: Between May 1999 and September 2001, 36 adult patients (21 female) with a mean age of 44.6+15.1 years (range 26 to 84) had a percutaneous ASD closure with ASO-device. A trans-thoracic (TTE) echocardiography evaluation was done at 24 hours and at 6 months after procedure. Right ventricle outflow diameter (RVOTD), right ventricle inlet diameter (RVID), right atrium width (RAW) and right atrium length (RAL) were measured
The mean ASD diameter was 14.4+7.2 mm and mean ASO-device size was 19.8+ 8.2 mm. ASO-device was implanted successfully in 94.4% (34/36) of patients. A residual shunt of 3 mm was shown in only one patient. The TTE was performed in all patients in whom ASO device was deployed successfully. Mean RAL and mean RVOTD reached significant reduction at six months compared with TTE post-procedural measurements (53.1+6.5 vs 48.5+ 5.2 mm, $p<0.005$ and 41.2+ 6.7 vs 35+5.1mm, $p<0.005$ respectively). Mean RVID size showed a trend toward shortening without reaching significance at six months (44.2+ 4.3 vs 42.6+4.5 mm, p: 0.056). Mean RAW did not change significantly (46.4+4.5 vs 44.9+ 5.1 mm, p: 0.08).
Conclusions: After percutaneous ASD closure device RAL and RVOTD had a significant reduction at six month. However, morphology of the right heart did not return completely to normal suggesting an impaired ability of the right heart to remodel after prolonged volume overload in these older patients.

P2225 Acute changes in right ventricular wall deformation after transcatheter atrial septal defect closure. An ultrasound strain and strain rate study

T. Kukulski[1], P. Banaszak[2], J. Bialkowski[2], M. Szkutnik[2], A. Duszanska[1], Z. Kalarus[1]. [1]*Silesian Center for Heart Diseases, 1st Dept. of Cardiology, Zabrze, Poland;* [2]*Silesian Center for Heart Diseases, Department of Paediatric Cardiology, Zabrze, Poland*

Background: The assessment of right ventricular (RV) function by conventional echocardiography is still not satisfactory. Strain and strain rate imaging are the new techniques for quantitation of regional myocardial function for both left and right ventricles.
Purpose: To verify a hypothesis that strain and strain rate indices can identify the local changes in wall deformation due to the acute volume unloading of the right ventricle.
Methods: 15 consecutive pts with ASD t.II (defect size:1.3± 0.6cm),aged 7-68 years(33±22;7M,8F) referred for transcatheter septal closure were scanned within 24 h hours before and after closure procedure using conventional Mmode (RVDD/RVDS) and Doppler (Ao VTI, Pulm VTI) imaging. Additionally high frame rate Colour Tissue Velocity data were acquired in apical 4ch view and analyzed off-line (Speqle®)to derive longitudinal systolic strain rate (SR sys), maximal strain (S max) and systolic velocity (V sys)for the RV free wall, septum and LV lateral wall. T paired test was used to compare the measurements before and after closure.
Results: The mean heart rate was 81±18 before procedure and 78±16 after closure (p=ns). Within 24 h after procedure we observed significant reduction in RV diameter (RVDS:2.6±0.5 vs 2.3±0.2 cm, p=0.02; RVDD:3.0±0.6 vs 2.5±0.2cm, p=0.01) and pulmonary flow (PulmVTI: 22.0±8.0 vs 15.7±2.8, p=0.03. Longitudinal S max measured at medial part of the Rv wall decreased significantly (36±10% vs 28±9%, p=0.001), however SR sys and Vsys remained stable (2.0±0.4 1/s vs 2.0±0.7 1/s, ns and 9.0±2.6 cm/s vs 9.8±2.3 cm/s, ns respectively). After the closure of septal defect regional function among septal and LV lateral segments remained unchanged.
Conclusions: Strain and strain imaging is a feasible method to quantitate longitudinal RV wall regional function. In this clinical model of acute RV volume reduction strain measurements reflect the changes in deformation induced by volume unloading of the RV. Strain rate indices are less volume dependent and may better characterize contractile conditions of the right ventricular myocardium.

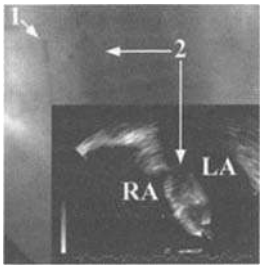
P2226 Intracardiac and intraluminal echocardiography: standard approaches and clinical benefit

T. Bartel[1], T. Konorza[2], G. Caspari[2], S. Müller[3], R. Erbel[1]. [1]University Essen, Dept. of Cardiology, Essen, Germany; [2]University Essen, Dept. of Cardiology, Essen, Germany; [3]University Innsbruck, Dept. of Cardiology, Innsbruck, Austria

Background: In some clinical scenarios, transoesophageal echocardiography (TEE) have limitations. This study sought to test whether intracardiac and intraluminal echocardiography (ICLE) including two-dimensional, M-mode, and Doppler analysis with a miniaturised, multiple-frequency transducer tipped catheter is suitable to guide catheter interventions.

Method: ICLE was employed in 10 animals using 6 standard approaches. In 12 patients undergoing device closure of patent foramina ovalia (PFO) (n = 6) or atrial septal defects (ASD) (n = 3), or aortic stent implantation in DeBakey type III dissection (n = 3), interventional procedures were guided by ICLE and, for comparison, also by TEE.

Results: Standard approaches to the atria and the abdominal aorta are introduced: 1 – transvenous imaging of the abdominal aorta; 2 - transatrial imaging of the interatrial septum, the atria, the pulmonary veins, and the ventricles. ICLE was found to be helpful for guiding specific interventional procedures, especially device closure of atrial septal defects and patent foramina ovalia. In comparison with the conventional TEE-guidance, the technique reduces fluoroscopy time: 6.5 min. vs. 8.9 min., $p < 0.0011$. In contrast to the examinations by use of TEE, neither general anesthesia nor sedation was required using ICLE. After aortic stent implantation, flow in the false lumen of the abdominal aorta was demonstrated being brought to a standstill. ICLE also helps to effectively protect side branches originating close to the stent. Complications did not occur.



1 - ultrasound cath., 2 - closure-device.

Conclusions: ICLE adds to conventional TEE and promises to become a clinical alternative for guiding interventional procedures. With the patient in a supine position, ICLE is better tolerated than TEE.

P2227 Potential value of intracardiac echocardiography during invasive electrophysiologic procedures

R. Citro[1], V. Ducceschi[1], A. Salustri[2], M. Galderisi[3], M. Santoro[1], G. Bottiglieri[1], L. Petraglia[1], G. Gregorio[1]. [1]San Luca Hospital, Department of Cardiology, Vallo della Lucania, Italy; [2]S. Pertini Hospital, Echocardiography Laboratory, Rome, Italy; [3]Federico II University, Division of Emergency Medicine, Naples, Italy

Background and aim of the study: Interventional electrophysiology often requires accurate identification of cardiac anatomical structures in order to improve radiofrequency catheter ablation (RFCA) results. Aim of our study was to test the usefulness of intracardiac echocardiography (ICE) to guide RFCA procedures.

Populations and methods: We selected 10 patients (6 males; mean age 64+8 years) with frequent episodes of paroxysmal atrial fibrillation or flutter (7 pts) or left sided accessory pathways (3 pts) candidate to RFCA procedures. ICE was performed via left femoral or right internal jugular vein with a 9F-9MHz mechanical echo catheter with a rotating ultrasound trasducer (Ultra-ICE Boston Scientific).

Results: ICE was feasible in all patients without complications. Echocardiographic images were evaluated on-line by an experienced cardiologist and presented to the electrophysiologist in order to properly guide the interventional procedure. ICE allowed identification and location of the following anatomical structures: venae cavae orifices, right atrial appendage, crista terminalis, fossa ovalis, Koch triangle, tricuspid annulus. In particular, in patients submitted to atrial flutter and/or fibrillation ablation procedures, continuity of the cavotricuspidal isthmus and the intercaval lesions was confirmed. One of the major advantages of ICE was the possibility to monitor and guide transeptal puncture and to identify pulmonary veins orifices in order to allow a precise mapping of atrial fibrillation triggering foci. Finally, proper electrocatheter adherence to the endocardium before ablation and formation of microbubble or coagulum and pericardial effusion during ablation were easily verified. ICE guided RFCA procedures resulted in a reduced radiations exposure time for both patient and operator (13±6 min vs 21±7 min, $p<0,05$, when compared to a similar matched group of patients who underwent only fluoroscopy guided procedures).

Conclusions: ICE during interventional electrophysiologic studies is feasible and safe. It allows a comprehensive visualization of cardiac structures that can not be precisely identified by fluoroscopy. ICE guided RFCA represents a promising technique that makes interventional procedures potentially safer and more effective.

P2228 Usefulness of a personal ultrasound Imager at the outpatient cardiology clinic

E.C. Vourvouri, D. Poldermans, A.F.L Schinkel, F.B. Sozzi, M.A. Bountioukos, H. Karvounis, J.J. Bax, J.R.T.C. Roelandt. Cardiology Department, Thoraxcenter, Erasmus Medical Center, Rotterdam, Netherlands

Background: Recently, small personal ultrasound imagers (PUI) with excellent imaging performance became available. These devices can be integrated in the physical cardiovascular examination.

Aim: To determine the diagnostic performance and cost-effectiveness of a new PUI (OptiGoTM, Philips Medical Systems) at the cardiology outpatient clinic, using a standard high-end ultrasound system (SE) as a reference.

Methods: 213 new patients (mean age 53 ± 17, 167 male) referred to the cardiology outpatient clinic were enrolled in the study. All patients underwent an examination with the PUI and subsequently a complete echocardiographic study with a SE by a second investigator blinded to the results of the other. The diagnosis of the PUI was compared to the clinical diagnosis/question of the referring physician. Cardiovascular findings were divided into abnormalities of major and minor significance. Major findings were considered those who led to further diagnostic evaluation or alter the prognosis or the therapeutic management of the patient. Unsuspected significant findings were noted and all PUI data were compared with those obtained with the SE.

Results: The PUI was able to answer/confirm the requested clinical question/diagnosis in 198/213 (93%) patients. In the remaining 7% of the patients a SE examination did not add any further information and a transoesophageal study was regarded as necessary for the evaluation of cardiac source of embolism. A further hemodynamic assessment with the Doppler feature was regarded as useful in 29 (13,6%) patients. The agreement between the two devices for the detection of major abnormalities was 97%, kappa=0,92. The PUI missed major abnormalities in 4 (1,8%) patients. 7 out of 57 patients (12,2%) diagnosed normal with the PUI showed minor abnormalities with the SE. 75 of 124 (60%) major abnormal findings detected with the PUI were additional and unsuspected findings. The negative predictive value of the PUI in identifying patients with significant abnormalities was 98% and the positive predictive value 96%. As the clinical question could be answered with the use of the PUI in 93% of the patients, a further echo analysis with the SE could have been avoided in 75,6% of patients.

Conclusion: Echocardiographic assessment of new patients with a PUI at the outpatient clinic of the cardiology department can lead to instant diagnosis and to detection of unsuspected significant findings. This can lead to an improvement of the health care service in terms of better patient's care and of cost savings.

P2229 Comparison between echocardiographic studies made with new portable devices and conventional echocardiographic studies

J. Quiles, M.A. García-Fernandez, P. Avanzas, R. Rosas, M. Martinez, M. Moreno, J. Bermejo, A. Sanchez. HGU Gregorio Marañón, Cardiology department, Madrid, Spain

Background and objectives: New miniaturized echocardiographic devices are actually available. Previous studies show an improvement in the detection of important cardiovascular pathology compared with physical examination, however, its diagnostic accuracy in comparison with the results obtained using a high level echocardiographic platform is still not kwnown. The purpose of this study is to compare the result of examinations made with these devices, and the results obtained in the echocardiography laboratory, in order to add evidence to similar recent studies.

Methods: Two hundred and eleven consecutives unselected patients were imaged by cardiologists with experience in echocardiography (level III training) and then compared with the standard examination performed at echocardiographic laboratory with an upper platform and interpreted by an experienced echocardiographer.

Statistical analysis

	HD	Standard	p
Pericardial Effusion	6.16%	6.64%	0.656
LV enlargement	16%	17%	0.638
LA enlargement	50%	60%	0.003
LV hypertrophy	24%	35%	0.000
RV enlargement	5.6%	8.5%	0.134
Aortic root enlargement	0.94%	4.7%	0.011
regional motion abnormalities	3.6%	3.89%	0.587
Aortic regurgitation	28%	32%	0.207
Mitral regurgitation	53%	63%	0.05
Tricuspid regurgitation	41%	49%	0.015

The number of diagnoses with the handheld device (HD) and standard study are shown and also the statistical significance.

Results: We did not found statistical differences estimating the global and regional left ventricular systolic function, the presence of pericardial effusion and ventricular chamber enlargement. The device however failed detecting left ventricular hypertrophy, left atrial enlargement and the presence and severity of regurgitation, underestimating its degree. **Conclusions:** Although its limitations due to the characteristics of the device, when used by cardiologists trained in echocardiography it can be useful, providing important information, however a significative number of diagnoses are missed.

P2230 Significance of leucocyte count changes during stress echocardiography

M. Deljanin Ilic[1], S. Ilic[2], P. Milosavljevic[2], Lj. Nikolic[1], D. Marinkovic[2], B. Ilic[2]. [1]*Institute of Cardiology, Echo Lab, Niska Banja, Yugoslavia;* [2]*Institute of Cardiology, Clinical Cardiology, Niska Banja, Yugoslavia*

The aim of this study was to assess whether positive exercise stress echocardiography (ESE) uncovered presence of acute inflammation and whether transient, stress induced myocardial ischemia (m.i.) accelerated inflamatory process.

Methods: In the study group of 48 patients (32 male and 16 female; mean age 59.3 ± 5.3 years) with known or suspected coronary artery disease submaximal or symptom limited bicycle ESE was performed. ESE identified ischemia by the occurrence of wall motion abnormality (WMA) with stress - positive ESE. In all patients before and after ESE wall motion score (WMS) was calculated. At baseline and after ESE, in all pts total and differential white blood cell count (WBCC) were measured.

Results: During ESE 28 (58.3%) patients had new, transient WMA, while 20 (41.7%) pts were without ischemia. Baseline values of total WBCC and neutrophil count were significantly higher in patients with positive compared to those with negative ESE ($P<0.05$ and $P<0.05$). After ESE in patients with stress induced WMA value of total WBCC increased significantly (from 7.8 ± 2.6 to 9.2 ± 2.3 x 109/L, $P<0.05$) as well as the value of neutrophil count ($P<0.05$). In patients without stress induced WMA, during ESE total WBCC slightly changed (from 6.3 ± 1.9 to 5.9 ± 2.1 x 109/L, NS) as well as neutrophil count (NS). After ESE the difference in total WBCC and neutrophil count between patients with positive and patients with negative ESE become more pronounced ($P<0.001$ and $P<0.001$). In patients with positive ESE and increased WMS less or equal 3, total WBCC increased by 15.3% and by 32.7% in patients with increased WMS > 3 compared to baseline values.

Conclusion: Our results suggest that an acute inflammatory process may be present in patients with positive ESE and that stress induced m.i. accelerated inflammation which is demonstrated throughout significant increased in leucocite and neutrophil count.

P2231 Diagnostic precordial cardiac ultrasound: any effect of somatic DNA in humans?

N. Vesentini, L. Venneri, M. Cipollini, M. Pianelli, C. Kusmic, E. Pasanisi, R. Barsacchi, E. Picano. *Institute of Clinical Physiology, PISA, Italy*

Background: In vitro studies show DNA damage in cells exposed to ultrasound in the frequency and power range of current cardiac diagnostic use. These effects Background: In vitro studies show DNA damage in cells exposed to ultrasound in the frequency and power range of current cardiac diagnostic use. These effects can be magnified by high mechanical index imaging amplifying cavitation phenomena underlying DNA damage. Comet assay is a sensitive method to detect DNA damage.

Aim: to assess the effects of diagnostic cardiac ultrasound on DNA of circulating lymphocytes.

Methods: 14 patients (7 males, age= 65 ± 9 years) referred for a diagnostic echocardiogram were scanned under standardized imaging conditions (Agilent Philips Sonos 5500, S3 1.6/3.2 MHz transducer, 2D imaging mode, harmonic fusion, Mechanical Index=1.6, total imaging time=30 minutes). Peripheral blood samples for Comet assay were obtained before (baseline), after 30' ultrasound scanning (ultrasound on), and 30' following the end of the exposure (ultrasound off). Comet assay was scored from 1 (= mild damage) to 4 (= severe damage). 100 lymphocytes were assessed for each stage in each patient, and the global Comet score per patient was the sum of individual cell scores.

Results: Comet damage score was 19±10,3 (mean±SEM) at baseline, 27.1±7.7 with ultrasound on and 29.6±14.7 with ultrasound off. Number of damaged cells (any Comet score) was 10±5 at baseline, 12.5±4 with ultrasound on and 14.9±6 with ultrasound off.

Conclusion: At frequency, power and exposure duration commonly employed in clinical practice, diagnostic cardiac ultrasound does not usually induce a significant DNA damage in circulating lymphocytes, even when aggressive imaging with high mechanical index is utilized.

P2232 The effect of coronary angioplasty on left atrial mechanical functions

M.K. Erol, E. Bozkurt, M. Yilmaz, M. Acikel, Y. Gurlertop, A. Borekci, H. Senocak. *Ataturk University, Cardiology Dept., Erzurum, Turkey*

Background: Left ventricular stroke volume is considered to be composed of the left atrial (LA) passive emptying volume, active emptying volume and conduit volume. In the initiation of left ventricular dysfunction, a redistribution of left atrial reservoir, conduit and booster functions is a potentially important adaptation mechanism to maintain cardiac output. The aim of this study was to assess the effect of coronary angioplasty on left atrial mechanical functions.

Methods: Left atrial maximal (LAVmax), minimal (LAVmin) and at the onset of systole (LAVp) volumes were measured just before and after 24 hours procedure according to the biplane modified-Simpson method in 20 patients (14 male, 6 female; mean age 51.2±2.7 years) undergoing successfully coronary angioplasty. And following LA emptying functions were calculated: LA passive emptying volume = LAVmax - LAVp, LA passive emptying fraction = LA passive emptying volume/LAVmax, Conduit volume =Left ventricular stroke volume-(LAVmax- LAVmin), LA active emptying volume = LAVp- LAVmin, LA active emptying fraction = LA active emptying volume/LAVp, LA total emptying volume = (LAVmax -LAVmin), LA total emptying fraction = LA total emptying volume/LAVmax.

Results: Coronary angioplasty was applied to left anterior descending artery in 6 patients, left circumflex artery in 8 patients and right coronary artery in 6 patients. LAVmax (18.4±6.7 vs 18.5±6.1 cm^3/m^2), LAVmin (7.7±3.2 vs 7.7±2.8 cm^3/m^2) and LAVp (14.4±5.9 vs 13.5± 5.9 cm^3/m^2) were not significantly different before and after procedure ($p>0.05$). LA passive emptying volume (3.99±1.26 vs 5.01±1.33 cm^3/m^2; $p<0.05$) and passive emptying fraction (0.23±0.06 vs 0.30±0.12%; $p<0.05$) increased significantly after coronary angioplasty. A decrease was found in LA active emptying volume (6.75±3.06 vs 5.84±3.95 cm^3/m^2) active emptying fraction (0.46±0.10 vs 0.38±0.28%) and conduit volume (15.06±9.96 vs 11.60±6.46, p=0.08)) after procedure, but the differences were not statistically significant. LA total emptying volume (10.74±3.68 vs 10.86±3.89 cm^3/m^2) and total emptying fraction (0.58±0.07 vs 0.59±0.09%) were found similar after procedure ($p>0.05$).

Conclusion: The results of this study suggest that coronary angioplasty led to an increase in left atrial passive emptying functions, but a decrease conduit and active emptying functions, and thus total emptying functions remained steadily. And it indicates that coronary angioplasty reverse compensatory redistribution of LA function in patients with coronary artery disease.

P2233 Low reproducibility of two-dimensional echocardiographic image plane positioning

J. A. van der Heide, H.F.J Mannaerts, G. Valocik, O. Kamp, C.A. Visser. *VU Medical Center, Cardiology, Amsterdam, Netherlands*

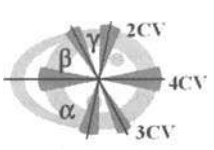
Background In two-dimensional echocardiography, image plane positioning based on anatomical landmarks may not always be reproducible because of random image plane positioning error. At serial examinations, different parts of the left ventricle might be sampled.

Methods Twenty subjects (12 myocardial infarction and 1 mitral valve prolaps patient, and 7 healthy volunteers) underwent transthoracic three-dimensional echocardiography using the TomTec Freehand ® method. Off-line, 2-, 3- and 4-chamber views (CV) were reconstructed based on anatomical landmarks, and angles between image planes measured (see figure). These "virtual examinations" were repeated after 3 weeks.

Results For values and intra- and interobservervariation of alpha (the angle between the 2- and 4-CV), beta (2- and 3- CV) and gamma (3- and 4- CV), see table.

	Alpha	Beta	Gamma
Angle	79,1± 10,3	66,6 ± 8,2	33,7 ± 6,6
Intra-observervariation	-3,2 ± 4,3	4,8 ± 4,6	-1,5 ± 3,9
Inter-observervariation	-1,1 ± 11,9	5,5 ± 11,2	-5,2 ± 8,7

values expressed as mean ± 1 SD, in degrees



Conclusions Based on anatomical landmarks, numerous similar echocardiographic cross-sections can be obtained, however with low reproducibility. This may lead to changes in image plane positioning at serial examinations, sampling of different parts of the left ventricle, and to inconsistencies in wall motion analysis and two-dimensional volume measurements.

P2234 Three-dimensional aortic flow profiles after aortic valve replacement

S. Mottl-Link[1], I. Wolf[2], M. Hastenteufel[2], H.P. Meinzer[2], C.F. Vahl[1], R. De Simone[1], S. Hagl[1]. [1]*University Heidelberg, Cardiac Surgery, Heidelberg, Germany;* [2]*Deutsches Krebsforschungszentrum, Div. Medical and Biological Informatic, Heidelberg, Germany*

Background/Objectives: Three-dimensional (3D) echocardiographic reconstruction can provide dynamic 3D images of intracardiac color flow. Fluid dynamic characteristics of the valve are known to be related to complications such as haemolysis, valve thrombosis, thromboembolic events, calcification and prosthetic valve endocarditis. The aim of the present study was to visualize turbulent stress during systole downstream of the aortic valve and to compare normal and artificial aortic flow profiles.

Methods: Transesophageal echocardiography was performed intraoperatively in patients with normal aortic flow (n=15) and after aortic valve replacement with different types of prostheses (n=20). 3D flow visualization was obtained by the EchoAnalyzer software with improved orientation and angle correction which was developed by our institutions.

Results: Normal aortic flow showed a nearly parabolic profile with peaks slightly laterally displaced from the center. Typical downstream flow profiles could be visualized in artificial aortic valves. For example Star-Edwards showed a pattern with negative velocities in the centre surrounded by high positive velocities (like a king's crown). In Medtronic Hall negative and positive velocities were divided approximately along the diameter (like a diadem). Downstream of St. Jude Medical two high velocity peaks were separated by a nearly linear gap along the diameter (like a bishop's mitra).

Conclusion: 3D reconstruction opens new perspectives for non-invasive diagnosis of prosthetic valve function since it discloses complex flow patterns in patients. Up to now measurements of flow profiles could only be achieved in in-vitro experiments.

NOVEL APPROACHES IN MYOCARDIAL SCINTIGRAPHY

P2235 In vivo monitoring of the fate of transplanted indium-111-labeled endothelial progenitor cells in a rat model of myocardial infarction

A. Aicher[1], W. Brenner[2], M. Zuhayra[2], C. Badorff[1], S. Massoudi[2], E. Henze[2], A.M. Zeiher[1], S. Dimmeler[1]. [1]*University of Frankfurt, Molecular Cardiology, Frankfurt, Germany;* [2]*University of Kiel, Dept of Nuclear Medicine, Kiel, Germany*

Endothelial progenitor cells (EPCs) can contribute to neovascularization of ischemic heart tissue. Infusion of ex vivo cultivated EPCs was shown to improve vascularization and left ventricular function after myocardial ischemia. At present, the fate of transplanted EPCs has been monitored by DiLDL-labeling or viral infection with GFP or LacZ. However, both techniques are limited by the need to sacrifice the animal, which precludes its use in humans. Therefore, we investigated whether radioactive labeling with Indium-111 is a possible tool to monitor the distribution and the homing of EPCs in vivo.

Human EPCs were isolated out of peripheral blood and were characterized by the expression of endothelial marker proteins (KDR, VE-cadherin, eNOS). After 3 days of culture, EPCs were detached and radioactively labeled with Indium-111-oxin (10 MBq/10(6) EPCs in 1 ml EBM medium without supplements). EPCs incorporated about 79±2% of the applied radioactivity. Control experiments confirmed that the viability of the EPCs was not affected by the labeling procedure.

After removal of the free radioactivity by centrifugation, EPCs were injected in sham-operated or infarcted athymic immunodeficient nude rats and scintigraphic images of the animals were acquired using a gamma camera. Images were continuously obtained over the first hour and repeated at 24 h, 48 h, and 96 h after injection. Then, the animals were sacrificed and specific radioactivity was measured in different tissues. 24 h to 96 h after i.v. injection, the majority of EPCs was localized in the spleen and liver. After 96 hours, only 1.01±0.29% of the radioactivity was detected in the heart of sham operated animals. The ratio of specific radioactivity in heart to peripheral muscle tissue was 1.05±0.16 in sham-operated animals. Following the induction of myocardial infarction by ligation of the LAD, this ratio increased to 1.69±0.39. Similar findings were obtained when radioactive EPCs were injected directly into the left ventricle: the heart to muscle radioactivity ratio increased from 1.6 in sham-operated animals to 4.0, when EPCs were infused 24 hours after infarction.

Conclusion: Radioactive labeling with indium-111 is a feasible method to detect the fate of transplanted progenitor cells in vivo, which could also be applicable to the sequential clinical monitoring of cell therapy. Initial results suggest that only a minor portion of total EPCs are detected in the myocardium under basal condition, whereas myocardial infarction profoundly increased cardiac homing of EPCs.

P2236 Effect of coronary revascularization on myocardial perfusion, function and wall thickness as assessed by quantitative gated SPECT

S. Hida, T. Chikamori, Y. Usui, H. Yanagisawa, T. Hatano, T. Morishima, H. Iino, A. Yamashina. *Tokyo Medical University, Second Department of Internal Medicine, Tokyo, Japan*

The development of quantitative gated SPECT (QGS) enables the assessment of LV perfusion, function and wall thickness by a single examination. Accordingly, QGS was applied to assess the benefit of coronary revascularization in patients with CAD; 120 of those patients were evaluated before and 6 months after elective coronary revascularization. With coronary revascularization, a significant improvement was observed in global EF (49±12 to 52±12%; p<0.001). In 187 revascularized segments, reversibility score (0.8±0.6 to 0.2±0.4; p<0.0001), rest defect score (0.8±0.8 to 0.5±0.6; P<0.0001), wall motion asynergic score (1.1±0.9 to 0.8±0.8; p<0.0001), and end-diastolic wall thickness (8.1±1.3 to 8.6±1.5; p<0.025) improved significantly. Even in 101 non-revascularized segments, reversibility score (0.3±0.5 to 0.1±0.3; p>0.01), wall motion asynergic score (0.8±0.9 to 0.5±0.8; p<0.0001) and end-diastolic wall thickness (8.0±1.3 to 8.5±1.6; p<0.001) also improved significantly. In 43 of these non-revascularized segments, in which the improvement of LV wall motion was detected, the incidence of >90% stenosis (22/43 vs 15/58; p<0.01) and collateral circulation (34/43 vs 15/58; p<0.0001) were higher than in 58 segments in which no improvement of LV wall motion was observed. These results indicate that improvement in myocardial ischemia, hibernation and LV function with coronary revascularization can be assessed in detail by applying QGS. In particular, the beneficial effects were demonstrated even in the non-revascularized segments through good collateral circulation in which blood flow was improved by revascularization.

P2237 Reduced cardiac sympathetic innervation contributes to elevated proinflammatory cytokines levels in patients with congestive heart failure

F.I. Parthenakis[1], A.P. Patrianakos[1], V.K. Prassopoulos[2], E.A. Papadimitriou[1], S.I. Koukouraki[2], N.S. Karkavitsas[2], P.E. Vardas[3]. [1]*Heraklion University Hospital, Cardiology Dept., Heraklion, Crete, Greece;* [2]*Heraklion University Hospital, Radiology Dept., Heraklion, Greece;* [3]*Heraklion University Hospital, Cardiology, Heraklion, Greece*

Background: In heart failure (HF) both plasma and myocardial tissue levels of cytokines are increased. Experimental animal studies showed that cytokines production might be regulated in part, by sympathetic nervous system (SNS) stimulation of cardiac beta-adrenergic receptors. The cardiac response to sympathetic stimulation is impaired in HF and this may contribute to elevated levels of circulating cytokines. The cardiac fixation of 123-Metaiodobenzylguanidine (MIBG) a norepinephrine analogue, was developed to visualize sympathetic innervation, has the potential to mirror the whole myocardial adrenergic pathway disintegrity and has been found to be reduced in HF.

Objectives: We evaluated the relationship between MIBG cardiac uptake and circulating levels of pro-inflammatory cytokines in patients with idiopathic dilated cardiomyopathy (IDC).

Methods: Thirty-seven patients (7 women, mean age 54 ±11,3 y) with angiographically proven IDC, NYHA class II-III, with Left Ventricular ejection fraction (LVEF) 31,1 + 8,1%, underwent a planar MIBG study and early (10 min) and late (4 hour) heart to mediastinum uptake ratio and washout rate were calculated. Twenty age-matched normal (N) individuals who served as a control group underwent the same procedure. Blood sampling of all patients with IDC for circulating plasma levels of Interleukin -1(IL-1), Interleukin-6(IL-6), TNF-a and its soluble receptors sTNFr1 and sTNFr2 were measured by immunoassay. None of study pts were on beta-blockers or suffered from diabetes mellitus.

Results: The IDC group had significantly reduced MIBG uptake values at 10 min (1,6 ±1.15 vs 1,91 ±0,08, p<0,001) and 4 hrs (1,48 ± 0,17 vs 1,84 ±0,12, p<0,001) and increased WO (7 ± 4%vs 3 ±3%, p<0,005), compared to the control group. Univariate analysis showed that in the patients' group early and late MIBG uptake correlated significantly with NYHA class(r=-0,70,p<0,001 and r=-0,63, p<0,001), LVEF (r=-0,38,p=0,05 and r= -0,34 p=0,01), IL-1 (r=-0,53, p=0,01 and r=-0,50, p=0,01) and sTNFr2 (r=-0,70, p=0,001 and p=-0,61, p=0,001) respectively.Multivariate regression analysis revealed that MIBG at 4 hours was independently associated with sTNFr2 (p=0,01).

Conclusions: The reduced cardiac sympathetic innervation in CHF is related to elevated circulating IL-1 and sTNFr2 levels. The impaired response to increased sympathetic stimulation in CHF may be accompanied by a chronic inflammation state, which further leads to a vicious cycle and cardiac function deterioration.

P2238 Calculation of normal limits of left ventricular ejection fraction and volumes using gated SPECT: the influence of isotope, gender and body habitus

P. McGlinchey[1], K. Ashfield[2], W. McNair[2], N.P.S. Campbell[2]. [1]*Belfast, United Kingdom;* [2]*Royal Victoria Hospital, Regional Medical Cardiology Centre, Belfast, United Kingdom*

Introduction: Single photon emission computerised tomography (SPECT) with 201Tl or 99mTc agents has an important role in patients with coronary artery disease(CAD). Gated SPECT provides data on left ventricular (LV) function, including LV ejection fraction (LVEF), LV end-systolic (LVESV) and LV end-diastolic volumes (LVEDV).

There is incomplete information on the role of influencing factors on gated SPECT, with few studies examining normal populations. The role of body habitus on LV functional measurements is observational, with higher LVEFs and smaller volumes noted in smaller hearts. Higher LVEFs have been noted in women.

The objectives of this study were to (1)determine normal values for LVEF in men and women; (2)to determine if either tracer may be used to estimate LVEF; (3) to determine if height, weight and gender impact on LVEF and (4) to determine if the effect of gender on LVEF is due to differences in body habitus between men and women.

Subjects: Subjects met the following criteria: (1) no past history of CAD;(2)normal resting ECG;(3) normal stress test;(4) normal myocardial perfusion and wall motion on SPECT.

Results: 245 patients (106 men, 139 women, mean age 52.7 ± 9.2 years met the entry criteria. The mean LVEF was 60.0 ± 9.5%.

Mean weight and height were higher in men ($p<0.0005$). The LVEF was smaller in men (55.5% vs. 64.5%, $p<0.0005$). LVEDV and LVESV were higher in men($p<0.0005$).

Measurements of LV volumes and LVEF were similar when either isotope was used.

LVEF correlated in a negative manner with weight($r=-0.360$, $p<0.0005$) and height ($r= -0.512$, $p<0.0005$). The relationship of LVEF with weight ($r= -0.252$, $p=0.003$)and height existed only for women ($r= -0.340$, $p<0.0005$) Both LVEDV and LVESV correlated with height and weight, again only in women ($p<0.0005$).

A derived equation connecting LVEF, weight and height in our female population was: LVEF = (280 ± 74) x weight -0.1880 x height -1.1626

Conclusions 1. The normal mean LVEF in men is 55.5 ± 7.7% and 64.5 ± 8.9% in women.

2. Either thallium or technetium tracers may be used measure LV function.

3. There is a negative relationship of both height and weight with LVEF. This relationship is present only in women. This relationship is probably explained by differences in stature between men and women. A height of 1.68 m represents the 90th centile in women but only the 20th centile in men. Similarly, a weight of 80 kg is the 75th centile in women but only the 30th centile in men.

LVEF in women will be overestimated in women. This can be corrected for by use of our formula.

P2239 Stress scintigraphy with dual isotope imaging can accurately document ischaemic preconditioning

M. Koutelou[1], A.A. Theodorakos[1], VT. Tsapaki[1], D.V. Cokkinos[2]. [1]*Onassis Cardiac Surgery Center, Nuclear Medicine, Athens, Greece;* [2]*Onassis Cardiac Surgery Center, Cardiology, Athens, Greece*

Background: Ischemic preconditioning (IP) induced by exercise (EX) has been well documented by electrocardiography. We assessed the contribution of myocardial scintigraphy, which can be expected to provide more quantitative information.

Methods: Twenty one patients (pts) with angiographically proven coronary artery disease (CAD), normal ventricular function and chronic stable angina underwent two treadmill (TR) EX tests with tomographic perfusion studies, using thallium-201 (TL) for the first study and tetrofosmin-Tc 99m (TET) for the second 30-60 minutes later, followed by rest perfusion study using TET, 4 hours later. Pts with a history of previous myocardial infarction, unstable angina or previous CABG or PTCA were excluded. The first TR EX was symptom limited and the second was terminated at the same time. TL and TET were injected at the same EX time for both studies. The mean age was 64.1±9 years (19 male, 2 female). Three, two and single vessel disease were equally distributed. The distribution of TL and TET uptake was analysed qualitatively as follows: anterior, septal, apical, inferior and lateral segment. The images were graded on a 5-point scale 0 (no uptake) to 2 (definitely reduced) and 4 (normal). The score was derived by summing the uptake of the segments. Also the tomographic images were analysed quantitatively (Bull's eye method), to yield total defect size. Differences between the two TR EX tests were compared.

Results: Maximum ST depression did not differ significantly between 1st and 2nd study 2.2±1.04 vs 2.2±1.4 (NS); the time in seconds of onset of ischemic changes was 282±152 vs 328±177 respectively ($p=0.01$) and the time of the angina 228±94 vs 265±103 ($p=0.01$). The score of EX perfusion was 22±3 in the 2nd study vs 17.5±5 ($p=0.0001$) and the total defect size was 14±5.9 vs 18±5.72 in the first ($p<0.0001$).

Conclusions: a. Exercise-induced IP can be documented by stress scintigraphy. b. The perfusion improvement in the second EX study is much greater than that potentially attributable to differences of myocardial uptake between Tl-201 and TET.

P2240 Relationship between extent of denervated viable myocardium, electrophysiologic abnormalities and outcome after acute myocardial infarction

M. Simoes[1], P. Barthel[2], I. Matsunari[1], S. Nekolla[1], G. Schmidt[2], M. Schwaiger[1], F.M. Bengel[1]. [1]*Technische Universitaet Muenchen, Nuklearmedizinische Klinik, Munich, Germany;* [2]*Technische Universitaet Muenchen, Erste Medizinishce Klinik, Munich, Germany*

Objectives: This study aimed at investigating the correlation between sympathetic denervation of viable myocardium in the risk area of AMI using 201Tl/123I-MIBG scintigraphy, and the electrophysiologic (EP) disturbances predisposing to ventricular arrhythmias. Methods: 67 consecutive post-AMI patients (58±11 y.o., 49 m, thrombolytic therapy: 28,4%, Primary PTCA/Stenting: 55,2%). Rest 201Tl and 123I-MIBG SPECT were quantitatively analysed using polar maps. Scintigraphic defects were identified by using a threshold of 50% of the maximum pixel value. Mismatch area corresponding to viable but denervated myocardium was obtained by the difference between defect sizes. EP studies focused on the detection of 3 classes of abnormalities potentially related to genesis of ventricular arrhythmias: 1. delayed depolarization, using signal averaging EKG (QRS width, terminal RMS, terminal LAS); 2. delayed repolarization, by rest EKG measurements (QTc interval, spatial QT dispersion); 3. imbalance of cardiac autonomic tone by heart rate variability analysis in Holter. Frequency of ventricular premature couplets (VPCs), couplets, salvos was also derived from Holter. Follow-up information was obtained by mail/phone every 6 months.Results: The 201Tl and 123I-MIBG myocardial scintigraphy defect sizes were respectively 14.3 ± 16.4% and 38.4 ± 22.2%, resulting in a mismatch area of 25.8 ± 16.3%. The mismatch size was mildly, but significantly correlated with prolonged repolarization process assessed by QTc interval ($p<0.001$, $R = 0.4$) and with delayed depolarization evaluated by RMS signal ($p<0.01$, $R = 0.37$). Follow-up period was 4.3 ± 1 years, and only 2 patients presented cardiac death (mismatch sizes of 47.4% and 36.9%). Conclusions: In pts after early agressive revascularization for AMI, the amount of viable but denervated myocardium in the infarction area is correlated to slow depolarisation and repolarisation processes that could contribute to the genesis of late potentials. Despite these findings, the observed long-term prognosis was excellent.

P2241 Effects of timing of functional recovery after revascularization on rest 201Tl SPECT accuracy in patients with chronically occluded LAD

G. De Luca. *"Federico II" University, Division of Cardiology, Naples, Italy*

Introduction: Despite the growing interests on the revascularization (REV) of patients with chronically occluded vessels (COV), few data have been published about rest TL SPECT (TL) in predicting functional recovery (FR), and in particular the effects of the timing of FR on its accuracy. We selected patients with chronically occluded LAD since the major impact of LAD and anterior myocardial territory on global left ventricular function and prognosis.

Methods and Materials: From a consecutive series of patients undergoing evaluation of myocardial viability at our Institute, we selected patients (pts) undergoing REV of chronic occluded LAD (> 1 month). Thus 27 pts(58±12 ys, 3 female) represented our final population. They underwent rest-redistribution 201Tl SPECT and echocardiogram at rest before revascularization, at three months (3M, all patients) and 1 year (12M, 18 patients) after revascularization. Different cut-offs for images at rest were tested according to the outcome at 3 and 12 M.

Results: Regional FR was observed in 60/112 (53%) at 3M and in 50/73 (68%) segments at 12M ($p < 0.05$ vs 3M). Regional WMSI changed from 1.99 ± 0.49 to 1.61 ± 0.5 at 3M ($p < 0.001$ vs baseline), to 1.42 ± 0.43 at 12M ($p < 0.001$ vs baseline; $p < 0.01$ vs 3M). Global ejection fraction improved from 40 ± 9% to 45 ± 10% at 3M ($p < 0.0001$ vs baseline) to 48 ± 7 at 12M ($p < 0.0001$ vs baseline; $p < 0.05$ vs 3M). Among the different tested thresholds, 60% of Tl uptake conferred the best accuracy at 3M (69%) whereas 55% of Tl uptake conferred the best accuracy at 12M (66%).

Conclusions: Our study demonstrated that regional and global ventricular functional recovery is only partially completed at 3M in comparison with 12M, in patients with chronic occluded LAD undergoing revascularization. The observed late functional recovery at 12M explained the better accuracy observed for lower cut-offs at 12M in comparison with 3 M. Thus a cut-off of 55% instead of 60% should be used to better predict long-term functional recovery after revascularization of chronically occluded LAD.

P2242 Recovery of left ventricular function by carvedilol is associated with improvement of myocardial perfusion in acute myocardial infarction

K. Fujii, S. Yamada, A. Takarada, T. Hayashi, H. Ueno, J. Shite, K. Yamashiro, T. Kajiya. *Himeji Cardiovascular Center, Cardiology, Himeji, Japan*

Background and purpose: Carvedilol has been shown to reduce mortality and ischemic events after acute myocardial infarction (AMI) through beta-blocking and antioxidant actions, but the mechanism of beneficial effects is not fully elucidated. We serially studied the effects of carvedilol on left ventricular function as well as myocardial perfusion using Tc-99m tetrofosmin ECG-gated SPECT (TF) in patients with AMI.

Methods: Forty-eight patients who underwent successful percutaneous coronary intervention (PCI) for their first anterior AMI were recruited. A few days after PCI, they were prospectively assigned into Carvedilol (N=24) and Control (N=24) groups. Baseline TF was performed 10-14 days (sub-acute), and was repeated 3 months (chronic) after the onset. Myocardial perfusion was evaluated from ECG-gated end-diastolic polar map image. Myocardium was divided into 17 segments for analysis of regional perfusion and segmental score was graded by 5 degrees (0: normal - 4: defect). The total defect score (TDS) were calculated as the sum of defect scores. Left ventricular ejection fraction (LVEF) was obtained using automated quantitative method.

Results: Baseline characteristics were similar between Carvedilol and Control (age: 60.4±10.6 vs. 61.5±9.9 years, CPK: 4998±2638 vs. 4890±2206 IU/L, sub-acute TDS: 33.7±5.5 vs. 33.3±4.7, LVEF: 41.9±11.7 vs. 42.5±11.2%, n.s.). Concomitant therapy, including aspirin, angiotensin-converting enzyme inhibitors, nitrates and diuretics were similar in both groups. There was no cardiac events (cardiac death or re-hospitalization) during the three months. At chronic TF study, heart rate decreased (-6.3± 8.0 vs. +1.3±12.0/min, p=0.02), LVEF improved (+7.7± 9.7 vs. +1.8±9.2%, p=0.04) and TDS decreased (-2.7±4.7 vs. 0.0±4.3, p=0.03) in Carvedilol treatment group compared with Control.

Conclusion: Carvedilol improves both LV function and myocardial perfusion in AMI with reperfusion therapy. Beta-blocking action and vascular endothelial protection through antioxidant action might be mechanisms for its beneficial effects.

P2243 Accuracy of quantitative myocardial stress perfusion imaging in the detection of coronary allograft vasculopathy after heart transplant

A. Alessi[1], R. Sara[2], G. Cavenaghi[1], E. Devoto[1], F. Turazza[3], M. Frigerio[3], O. Parodi[1]. *[1]Institute of Clinical Physiology, CNR sect. of Milan, Niguarda Hospital, Milan, Italy; [2]Niguarda Hospital, Department of Oncohaematology, Milano, Italy; [3]Niguarda Hospital, Department of Cardiology, Milano, Italy*

Background and Objectives: Coronary allograft vasculopathy (CAV) is the main factor that limits long-term survival after heart transplantation (HTx). We evaluated the accuracy of 2 quantitative methods to assess flow maldistribution from myocardial perfusion single photon emission tomography (SPECT) imaging.

Methods: 88 HTx recipients (mean age 51±12 yrs) underwent dipyridamole-stress sestamibi imaging at a mean interval of 40 months from HTx. Stress and rest images were quantitatively analyzed by 2 methods (Q1 and Q2) and compared with a sex-matched normal database. The database was obtained from a HTx population with one year post-HTx SPECT, normal coronary angiography and normal resting echocardiography, without rejection episodes. Q1 analyzed myocardial segments, matched to the coronary-tree distribution, in the bull's eye map. The size of perfusion defects was expressed as percent of count activity in a vascular territory and in the whole left ventricle. Q2 determined the segmental distribution of radioactivity from short axis slices. The computer expressed myocardial uptake of 16 segments in the apical, middle and basal cardiac slices as percent of count activity with respect to maximum activity. Data were also qualitatively (QL) evaluated by 16 segment analysis and a 4 point perfusion score. Q1, Q2 and QL analyses were compared with coronary angiography; CAV was classified according to Gao et al.

Results: Q1 analysis showed a better accuracy than Q2 and QL to identify CAV, very high sensitivity and negative predictive value and a good specificity. Accuracy of Q1, Q2 and QL analysis are shown in the table.

values in percent	Q1	Q2	QL
Sensitivity	100	77	100
Specificity	83	60	57
Positive predictive value	50	25	29
Negative predictive value	100	94	100
Accuracy	85	63	64

Conclusions: Quantitative analysis of perfusion stress imaging, in conjunction with a normal database of HTx recipients, provides a good accuracy in CAV detection, which favourably compares with previous SPECT or stress-echocardiography studies. This approach seems appealing in risk stratification and prediction of prognosis of HTx patients.

P2244 Non-invasive quantification of the total ischaemic burden – correlation with clinical and angiographic findings

M.J. Zellweger[1], M. Weinbacher[2], A. Zutter[2], M. Gutmann[2], J. Müller-Brand[3], M.E. Pfisterer[2]. *[1]Basel, Switzerland; [2]Basel University Hospital, Cardiology Dept., Basel, Switzerland; [3]Basel University Hospital, Nuclear Medicine Dept., Basel, Switzerland*

Background: Not only the presence/absence of myocardial ischemia, but also the extent of the ischemic burden provides important information for clinical decision making and prognosis. We tested the hypothesis that a simple ischemia score derived from myocardial perfusion SPECT (MPS) in a large patient cohort reflects the severity of coronary artery disease and thus adds evidence for clinical decision making.

Methods: 570 consecutive patients who underwent dual isotope (Tl-201-rest/Tc-99m sestamibi stress) MPS and subsequent coronary angiography (cath) were evaluated. MPS was interpreted by visual scoring of perfusion images using a 20 segments' model and a scale of 0 to 4. Summed scores were calculated by adding the 20 SPECT segment scores. A summed stress score (SSS), summed rest score (SRS) and summed difference score (SDS=SSS-SRS, [extent of ischemia]) were derived. A stenosis >74% on cath was considered significant. We then calculated receiver operating curves (ROC) to define SDS, that best divided the pts in two groups of having relevant coronary artery stenoses.

Results: ROC revealed an SDS of <3 and >=3 to be the best cutoff of having small amount and relevant amount of ischemia, respectively. For results see table.

Small versus relevant amount of ischemia

	SDS<3 (200)	SDS>=3 (370)	p
Angina during test	58 (29%)	187 (51%)	<0.001
Ischemic ECG	31 (16%)	156 (42%)	<0.001
n of vessels with >74% stenosis	0.9 ± 1.0	1.6 ± 1.0	<0.001
No significant stenosis	113 (57%)	33 (9%)	<0.001
Triple vessel disease	22 (11%)	91 (25%)	<0.001
LAD stenosis >74%	70 (35%)	240 (65%)	<0.001
Proximal LAD stenosis >74%	29 (15%)	107 (29%)	<0.001
Ejection fraction (by cath)	65 ± 14%	62 ± 13%	0.03

n=number

Conclusion: The extent of ischemia (SDS) is easily quantified by MPS and is a good non-invasive predictor of the severity of coronary artery disease. In contrast to other signs of ischemia such as angina and ST-changes, the 20-segment system allows localization and non-invasive quantification of the ischemic burden which is important for clinical decision making.

PERCUTANEOUS CORONARY INTERVENTION: ADJUNCTIVE THERAPY, COMPLICATIONS

P2245 Predictors of CK-MB release in patients undergoing percutaneous coronary intervention with stents and GP IIb/IIIa inhibitors

A. Kini, P. Lee, C.A. Mitre, M. Kim, M.E. Duffy, M. Kamran, J. Suleman, S.K. Sharma. *Mount Sinai Medical Center, Cardiology Dept., New York, NY, United States of America*

Background: Coronary stent implantation, the main mode (up to 90%) of percutaneous coronary intervention (PCI), is associated with higher CK-MB release (compared to balloon angioplasty), largely due to side branch closure and distal micro and macro thromboembolism. GP IIb/IIIa inhibitor (GPI) use during stenting has been shown to decrease CK-MB release. Reliable predictors of CK-MB release in the era of stenting and GPI have not been described.
Methods: We analyzed 1026 consecutive patients without myocardial infarction (MI) undergoing stenting, with normal baseline values of CK-MB, who received GPI during PCI. Among these, 874 (85%) patients had normal CK-MB release (<16 U/L) and 152 (15%) had CKMB elevation higher or equal to 16 U/L, with 1-3x normal in 11%, 3-5x normal in 2% and >5x normal in 2%. Significant characteristics are shown in the table.
Results: Among the clinical and angiographic characteristics, specific type of GPI, hypertension, diabetes mellitus, angina class, peripheral vascular disease, cerebro-vascular accident, previous MI, bypass surgery, vessel intervened, ACC/AHA B2/C lesion, restenotic lesion, calcification, and dissection were similar between the two groups. Multivariate predictors of CK-MB release: age ($p<0.008$), female sex ($p<0.04$), LVEF ($p=0.06$), slow-flow ($p<0.0001$) and side branch closure ($p<0.0006$).

Characteristics	Normal CKMB (n=874)	Elevated CKMB (n=152)	p
Age (yrs)	64.8±11	68.1±11	0.001
Female sex (%)	30	40	0.01
Lesion length (mm)	12.4±6.1	14.4±13	0.003
Thrombus (%)	2.2	3.3	0.001
Side branch closure (%)	0.2	9.2	0.001
Slow flow (%)	2	14.4	<0.0001

Conclusions: In the era of stent and GPI use during PCI, the incidence of peri-procedural CK-MB elevation seems to be lower than historical controls of stenting without GPI (up to 30%). Markers of diffuse atherosclerosis (such as advanced age and long lesion) and procedural complications continue to be the predictors of CK-MB release. Based on the above observation, a prospective model was constructed for same day discharge (14-15 hours post PCI) after angiographical successful stenting and 12-hour GPI infusion.

P2246 is clopidogrel inferior to ticlopidine in preventing subacute stent thrombosis?

P. Wenaweser, M. Rotter, S. Windecker, C. Seiler, O.M. Hess, B. Meier, F.R. Eberli. *Swiss Cardiovascular Center Bern, Bern, Switzerland*

Background: Platelet inhibition with aspirin and thienopyridines is essential for prevention of subacute (>24 hours) stent thrombosis (ST). Ticlopidine and clopidogrel have been shown to be similary effective in the prevention of ST during the first 30 days. The purpose of the present study was to determine ST in a retrospective analysis comparing ticlopidine and clopidogrel treatment.
Patients and methods: A total of 4453 patients were included in the present analysis. In a first observation period from Nov. 1995 to Jan. 1999 (group 1, n=1806 patients) aspirin 100mg/d plus ticlopidine 2x250mg/d (for 2 weeks) was given, whereas in a second period from Feb. 1999 to Jan. 2002 (group 2, n=2647 patients) aspirin 100mg/d plus clopidogrel 75mg/d (for 4 weeks, after a loading dose of 300mg) was administered.
Results: Subacute ST was observed in 65 patients, 15 (0.83%) in group 1 and 50 (1.89%, p=0.003) in group 2. ST occurred after a mean of 8.7 days in group 1 and 22.3 days (p=0.04) in group 2, respectively. Late ST (>28 days) was found only in clopidogrel- (n=17), but not in ticlopidine-treated (p=0.009) patients. 34% of all ST in group 2 occurred late (>28 days) after stent placement (mean= 50.1 days, range 28-110 days). The only predictor for late ST was TIMI flow 0 before PCI (p=0.04). Procedural data in patients with ST were similar in those with ticlopidine- and clopidogrel-treated patients (stenosis severity before and after intervention, lesion length, lesion type A-B-C, vessel diameter, stent length, maximal inflation pressure, TIMI flow before and after intervention and persistent dissection after stenting). The use of GPIIb/IIIa-antagonists and the indication (acute infarction, unstable, stable angina) for percutaneous coronary intervention (PCI) was comparable in the two groups with ST.
Conclusions: The rate of subacute ST was significantly lower in ticlopidine- than clopidogrel-treated patients. Late ST (>28 days) only occurred in patients receiving clopidogrel, especially in those with TIMI flow 0 prior to PCI. These data suggest that clopidogrel is less effective in preventing subacute ST and is associated with the phenomenon of late ST. Thus, patients after coronary stenting should receive either ticlopidine or higher doses of clopidogrel for prevention of ST.

P2247 How rapidly are platelets inhibited by a 300 mg clopidogrel loading dose given at the time of intervention compared to pretreatment

P.A. Gurbel, A.I. Malinin, M.J. Buczkowski, K.P. Callahan, V.L. Serebruany. *Sinai Hospital, Baltimore, United States of America*

Background: The effect of a 300 mg loading dose of clopidogrel administered in the catheterization laboratory at the time of coronary stenting versus pretreatment on the kinetics of platelet inhibition is unknown.
Methods: Patients undergoing elective stenting (n=103) were treated with either 300 mg clopidogrel at the time of the procedure (TP) or at 3-6 (3-6 pre) or 24 hours (24 pre)prior to the prcedure. Platelet-rich plasma aggregation (PPA) (5μ mol ADP), and flow cytometry of platelet receptors were serially performed. All patients received 325mg aspirin and 75mg clopidogrel daily post procedure. GP IIb/IIIa inhibitors were not used.
Results: PPA was most inhibited at 2 and 24 hours post-stenting by loading 24 hours prior to the procedure ($p<.05$) (see table). PAC-1 (mean fluorescence intentsity) was mildly reduced by clopidogrel (78±46, baseline, 62±40, day 5, $p<0.05$). No effect was seen on platelet-leukocyte aggregate formation.

	PPA (% Inhibtion)		
Time of assessment	TP	3-6 pre	24 pre
2h post	14± 4	18 ± 7	35 ± 15*
24h post	35 ± 11	33 ± 16	47 ± 23*
5d post	31 ± 13	41 ± 12	41 ± 14

*$p<.05$ compared to TP and 3-6 pre

Conclusion: Pretreatment with 300 mg clopidogrel 24 hours prior to intervention gives the best early post procedure inhibition of ADP-induced plateelt aggregation. Loading with clopidogrel followed by 75mg daily mildly reduces activation of GPIIb/IIIa but does not affect the formation of platelet-leukocyte aggregates.

P2248 Abciximab in percutaneous coronary intervention in patients over 75 years of age

K. Reis-Santos, J. Ferreira, C. Aguiar, P. Araujo Goncalves, D. Cavaco, A. Timóteo, M. Almeida, R. Seabra-Gomes. *Santa Cruz Hospital, Cardiology, Carnaxide, Portugal*

Background: The benefit of abciximab administration in patients (pts) submitted to coronary percutaneous intervention (PCI) is established in the entire clinical spectrum of coronary artery disease. Recently, trials evaluating the benefit of the association of abciximab with fibrinolytics revealed a high rate of hemorrhagic complications in pts over 75 years of age. On the other hand, the influence of abciximab in the sub-group of pts over 75 submitted to PCI has not been specifically evaluated.
Objectives: Evaluation of the efficacy and safety of abciximab in pts over 75 submitted to PCI.
Population and methods: 168 pts over 75 years submitted to PCI were studied retrospectively. Two groups were considered: with abciximab (G1: 88 pts, 57 men, mean age 78 years) and without abciximab (G2: 80 pts, 54 men, mean age 78 years). No significant differences were found in the two groups regarding demographic characteristics, indication for intervention, severity of coronary artery disease and left ventricular systolic function. There was no difference between the two groups in stent use (G1: 85% Vs G2: 84%) or multivessel intervention (G1: 38% and G2: 34%). The efficacy of abciximab was evaluated by the combined occurrence of death, myocardial infarction (MI) or urgent revascularisation (UrgRev) before discharge and the combined occurrence of death or MI at one year. Safety was evaluated by the frequency of hemorrhagic complications, isquemic stroke and thrombocytopenia.
Results: The table shows the results of clinical events in the two groups.

		With Abciximab	Without Abciximab	p
In-hospital	– Death/MI/UrgRev	0%	1.25%	0.962
	– Complications			
	Hemorrhagic	10.2%	3.75%	0.184
	Arterial access	6.8%	3.75%	0.590
	Hemorrhagic stroke	0%	0%	–
	Other major	3.4%	0%	0.279
	Ischemic stroke	0%	3.75%	0.211
	Thrombocytopenia	3.2%	0%	0.740
1-year follow-up	– Death	0%	6.6%	0.183
	– MI	2%	4.9%	0.757
	– Death/MI	2%	9.9%	0.194

Conclusion: In the present population of pts over 75 years submitted to PCI, the administration of abciximab was associated with a trend for increased risk of bleeding but better efficacy.Events in the two groups

P2249 Nitroglycerine infusion after coronary angioplasty does not influence a short-term outcome

J. Forys, J.Z. Peruga, W. Religa, M. Plewka, J. Drozdz, M. Kidawa, M. Krzeminska-Pakula, J.D. Kasprzak. *Lodz, Poland*

Background.The influence of nitroglycerine infusion on patients after elective coronary angioplasty is not established, although this regimen is routinely used in some centers.

Purpose: Nitroglycerine Administration after Percutaneus Intervention (NAPI) study was testing efficacy of routine nitroglycerine infusion in the 1st day after PCI (percutaneus coronary intervention) in a randomized single-centre clinical trial.

Methods and Results: We randomly assigned 100 patients who were undergoing elective PCI to treatment with nitroglycerine (50 patients, aged 58±6 years, dose up to 100 micrograms/min under blood pressure control) or placebo (50 patients, aged 57±5 years; p=NS). Patients with acute myocardial infarction, known intolerance to nitrates, and hemodynamic instability during PCI were excluded. Patients who were randomized to placebo group had possibility to receive nitroglycerine infusion according to attending physician's discretion. Endpoints were assessed in hospital and after 30 days, incl.: cardiac death, myocardial infarction, postprocedural chest pain unstable angina and repeated PCI.

There were no differences during inhospital stay between those receiving nitroglycerine and receiving placebo, respectively: deaths (0% vs 0%, p=NS), myocardial infarctions (0% vs 0%, p=NS), postprocedural chest pain (0% vs 2%, p=NS), repeated PCI due to unstable angina (0% vs 2%,p=NS).

Similar, outhospital follow up at 30 days after procedure revealed no significant differences in cardiac events between studied groups.

Conclusions: Routine use of intravenous nitroglycerin after PCI has no influence on both inhospital and short-term outhospital outcome, inluding cardiac death, myocardial infarction, postprocedural chest pain, unstable angina and repeated PCI.

P2250 Statins in general and atorvastatin in particular do not affect platelet inhibition with clopidogrel during coronary stenting

V.L. Serebruany[1], S.R. Steinhubl[2], A. Malinin[1], K.P. Callahan[1], P. Gurbel[1]. *[1]Johns Hopkins University, Sinai Hospital, Baltimore, United States of America; [2]Willford Hall Medical Center, San Antonio, United States of America*

Background: Platelet activation following stent implantation is well documented and may affect both short- and long-term clinical outcomes. Clopidogrel is widely used to produce sustained platelet inhibition in order to prevent further ischemic events in patients with atherothrombosis. Certain clinical scenarios exist when treatment with clopidogrel is combined with the chronic use of statins. It has been recently reported that some statins, and atorvastatin in particular, may selectively interfere with clopidogrel, limiting the ability of this ADP-receptor blocker to inhibit platelet function.

Methods: We analyzed the data from the PRONTO (Plavix Reduction of New Thrombus Occurrence) trial, which evaluated platelet inhibition produced by loading dose clopidogrel pre- and post-stenting to determine whether the use of statins influence the ability of clopidogrel to inhibit platelets. Platelets were assessed by conventional plasma aggregometry induced by 5μM ADP and by expression of GP IIb/IIIa (CD41b), and PECAM-1 (CD31) by whole blood flow cytometry at baseline, at discharge, and at day 5 following stent implantation.

Results: Data from 100 patients were analyzed. Twenty-five patients were treated with a statin, (9 of those patients received atorvastatin) and 75 were not on statin therapy. Platelet inhibition by clopidogrel was identical in all groups, and resulted in 35-40% inhibition of aggregation, more than 50% reduction of GP IIb/IIIa expression, and 40-45% reduction of PECAM-1 expression at day 5 when compared with the baseline values. These effects were independent of statin use.

Conclusion: The study results suggest there are no apparent interactions between clopidogrel and statins.

P2251 Comparison of eptifibatide and abciximab in the in-hospital outcomes and thrombocytopenia during percutaneous coronary intervention

M. Suleiman, L. Gruberg, M. Halabi, E. Nikolsky, E. Grenadier, M. Boulus, W. Markiewicz, R. Beyar. *Rambam Medical Center, Department of Cardiology, Haifa, Israel*

Background: During percutaneous coronary intervention (PCI), glycoprotein IIb/IIIa inhibitors have significantly reduced the incidence of 30-day ischemic events. However, each one of the three currently available agents has different pharmacological characteristics, safety, efficacy and costs. There has not been a direct assessment of whether there are differences between eptifibatide and abciximab in the rates of major adverse cardiac events, major complications and thrombocytopenia.

Methods: A total of 642 patients underwent PCI at our institution between 1/2000 and 5/2001 and were treated with either eptifibatide of abciximab during the procedure. In-hospital clinical outcomes were evaluated. Total thrombocyte counts were performed 2 and 4 hours after initiation of the drug treatment. The selection of a IIb/IIIa inhibitor was arbitrary and left at the discretion of the operator.

Results: Baseline clinical characteristics, concomitant drug treatment and angiographic characteristics were similar between eptifibatide and abciximab. In-hospital death (1.2% vs. 1%, p=0.8), stroke (0%) and target vessel revascularization rates (1.2% vs. 1%, p=0.8) were also similar between the two groups, respectively. Bleeding complications and platelet counts are shown in the table.

	Eptifibatide (n=342)	Abciximab (n=300)	p
Major bleeding (%)	1.7	0.7	0.2
Minor bleeding (%)	4.6	3.0	0.2
Hematoma (%)	7.7	6.3	0.6
Platelet <100,000 cells/L (%)	0.3	6.0	<0.001
Platelet <50,000 cells/L (%)	0	3.3	<0.001
Platelet <20,000 cells/L (%)	0	1.6	0.01
Platelet >50% reduction (%)	0	2.0	0.008

Conclusions: 1) Both agents, eptifibatide and abciximab, proved to have the same rate of in-hospital major adverse cardiac events, bleeding and vascular complications. 2) There was a significantly higher incidence of thrombocytopenia <4 hours after initiation of abciximab, including four patients who developed profound thrombocytopenia (<20.000 cells/L). 3) Although thrombocytopenia was not associated with increased bleeding complications, it triggered immediate cessation of the drug treatment.

P2252 Angiotensin-converting enzyme (ACE) inhibitor treatment of patients with the ACE DD genotype and effect on restenosis after coronary stent placement

W. Koch[1], M. Elchinger[2], J. Mehilli[2], A. Ehrenhaft[2], N. von Beckerath[2], A. Schömig[2], A. Kastrati[2]. *[1]Deutsches Herzzentrum München, München, Germany; [2]Deutsches Herzzentrum München, München, Germany*

Unexpected results of a recent study including 546 patients suggested that treatment with an ACE inhibitor increased the risk of restenosis after coronary stent placement in the subgroup of subjects carrying the DD genotype of the ACE gene I/D polymorphism (n=91). We tested this finding in a much larger, consecutive series of patients with coronary artery disease who were treated with coronary stenting (n=2222). ACE genotype distribution was in Hardy-Weinberg equilibrium, with 612 patients (28%) typed as DD homozygotes. Of these, 403 (66%) received an ACE inhibitor after the procedure for at least 1 year. Clinical (death; myocardial infarction, MI; target vessel revascularization TVR) and angiographic outcome measures of the DD patients were evaluated during the first year after the intervention and correlated with ACE inhibitor treatment. The occurrence of restenosis (defined as a 50% or greater diameter stenosis) was determined by coronary angiography in 495 DD patients (81%) at 6 months. As shown in the table, treatment of DD carriers with ACE inhibitors did not lead to any risk increase for clinical and angiographic adverse outcomes if compared with the DD patients not receiving an ACE inhibitor.

	+ ACE inhibitor	- ACE inhibitor	P value
Death, 1y (%)	1.7	2.4	0.58
Death or MI, 1y (%)	4.2	6.2	0.28
TVR, 1y (%)	20.6	24.9	0.23
Loss index	0.56	0.56	0.99
Restenosis rate (%)	34.0	31.4	0.55

Clinical and angiographic outcome aftery coronary artery stenting

Conclusion: In line with previous trials which assessed the use of ACE inhibitors as a preventive strategy for restenosis, we did not find any protectice effect in this regard, even not in patients homozygous for the D allele. This result, however, is in contrast with a recent trial showing a negative impact of an ACE inhibitor in patients carrying the DD genotype.

P2253 A randomized comparison of clopidogrel and aspirin versus ticlopidine and aspirin after the placement of coronary-artery stents

C. Mueller[1], H. Roskamm[2], P. Hunziker[1], S. Marsch[1], A.P. Perruchoud[1], F.J. Neumann[2], H.J. Buettner[2]. *[1]University hospital Basel, Medical Intensive Care Unit, Basel, Switzerland; [2]Herz-Zentrum, Cardiology Dept., Bad Krozingen, Germany*

Background: Randomized trials comparing clopidogrel and ticlopidine after coronary stenting with a restricted use of intravenous glycoprotein IIb/IIIa inhibition have reported a higher incidence of thrombotic stent occlusion with clopidogrel at 30 days. The aim of the present study was to compare clopidogrel and ticlopidine with regard to cardiovascular death during long-term follow-up.
Methods and Results: After successful stent implantation during elective or emergency percutaneous coronary intervention, 700 patients with 899 lesions were randomly assigned to receive a four-week course of either 500 mg ticlopidine (n=345) or 75 mg clopidogrel (n=355) in addition to 100 mg aspirin. Concomitant medications included statins in 85% of patients. Cardiovascular death was the primary endpoint and recorded for three years.
Cardiovascular and all-cause mortality were significantly lower in patients assigned to receive ticlopidine. Cardiovascular death occurred in 8 patients (2.3%) with ticlopidine versus 26 patients (7.3%) with clopidogrel (hazard ratio with ticlopidine as compared with clopidogrel, 0.30; 95% confidence interval 0.14 to 0.66; p=0.003). The combined endpoint of cardiovascular death or nonfatal myocardial infarction was present in 19 patients (5.5%) assigned ticlopidine as compared with 40 patients (11.3%) assigned clopidogrel (hazard ratio 0.45; p=0.005). All-cause mortality was 2.6% with ticlopidine but 8.2% with clopidogrel (hazard ratio 0.30; p=0.002).
Conclusions: After the placement of coronary-artery stents in unselected patients, ticlopidine was associated with a significantly lower mortality as compared to clopidogrel. This raises concern about the current practice of substituting clopidogrel for ticlopidine after stenting and highlights the urgent need for further long-term studies on this topic.

P2254 Atorvastatin given at the time of coronary artery stent implantation reduces the systemic inflammatory response

A. gaspardone, F. versaci, I. proietti, F. tomai, A.S. ghini, O. skossyreva, P.A. gioffrè, L. chiariello. *UNIVERSITA' DI ROMA TOR VERGATA, CATTEDRA DI CARDIOCHIRURGIA, ROME, Italy*

Successful coronary artery stent implantation (SI) is followed by a marked systemic inflammatory response as indicated by the rise of plasma levels of C-reactive protein (CRP). In turn, persistently elevated levels of CRP after SI are predictive of post-procedural coronary events in both patients with stable and unstable angina. We carried out a prospective study aimed at assessing the acute effect of statin treatment on CRP levels after SI.
We studied 223 patients with stable angina and normal preprocedural CRP levels (<5 mg/L) undergoing single vessel SI. Eighty-five patients were on treatment with statins initiated >6 months before SI (Pre-stat), 62 patients received 80 mg atorvastatin immediately after SI (Stent-stat) and 76 patients did not receive statins neither before or after SI (No-stat). CRP levels were assessed at baseline, 24 and 48 hours after SI.
Demographic, angiographic and procedural variables were similar in the 3 groups and SI was successful in all patients. Total and LDL-cholesterol levels were lower in the Pre-stat than in No-stat and Stent-stat groups (182±34 vs 203±38 and 208±36 mg%, p<0.001 and 108±31 vs 126±36 and 130±29 mg%, p<0.001). Baseline CRP levels in the Pre-stat group were lower than those in the No-stat and Stent-stat groups (2.8±0.8 vs 3.3±0.5 and 3.1±1.2 mg/L, p=0.003). At 24 and 48 hours after SI, CRP levels in the No-stat group were higher than those in the Pre-stat and Stent-stat groups (8.3±10.4 vs 5.1±4.7 and 6.7±9 mg/L, p=0.05 and 16.2±15.7 vs 9±8.5 and 10.8±10.3 mg/L, p=0.005). CRP plasma levels at 24 and 48 hours in the Pre-stat and Stent-stat groups were similar.
Thus, in patients with stable angina undergoing successful SI, high dose of atorvastatin given on the day of the procedure reduces the systemic inflammatory response to a level comparable to that observed in patients pre-treated with statins for >6 months. As high level of CRP after successful SI are predictive of cardiovascular events the reduction of the systemic inflammatory response by high dose of atorvastin may be clinically beneficial.

P2255 Influence of platelet glycoprotein IIIa P1A polymorphism on mean platelet volume and inflammatory response after coronary stent implantation

T. Kottmann[1], C. Piper[1], C. Hoffmann[1], M. Schmidt[2], K. Kleesiek[2], D. Horstkotte[1]. *[1]Heart Center North Rhine-Westphalia, Department of Cardiology, Bad Oeynhausen, Germany; [2]Heart Center North Rhine-Westphalia, Inst Laboratory Transfusion Medicine, Bad Oeynhausen, Germany*

Background: The PlA(2) allele of platelet glycoprotein IIIa (PlA) polymorphism has been identified as an independent risk factor for restenosis after coronary stent placement (ST). It's influence on the mean platelet volume (MPV), an indirect parameter for activated platelets, and the inflammatory response after ST is unknown.
Methods: Between September and December 2001 we enrolled 48 patients (44 men, mean age: 64±9 years) before ST. PI(A) polymorphism was analyzed and levels of C-reactive protein (CRP), platelet count (PC) and MPV were determined before ST, 3h, 6h, 12h, 24h, 48h, and 7 days thereafter.
Results: In our cohort the distribution of the genotypes was: 75% for PI(A1/A1), 23% for PI(A1/A2) and 2% for PI(A2/A2)

n=48	P1(A)	before	3h	6h	12h	24h	48h	7 days
CRP	A1(1)	0.2±0.2	0.2±0.2	0.2±0.2	0.3±0.2*	0.6±0.3**	0.9±0.7**	0.9±1.4*
(mg/dl)	A2(2)	0.3±0.2	0.3±0.2	0.3±0.2	0.4±0.3**	0.9±0.6**	1.0±0.7**	0.5±0.4**
PC	A1	231±61	225±55	227±51	230±59	233±57	232±58	251±51
(G/l)	A2	219±50	205±51**	205±52	203±47*	208±44	207±42	234±39
MPV	A1	9.6±1.1	9.5±1.6	9.7±2.0	9.6±1.1	9.3±1.1	9.5±0.9	9.6±1.7
(fl)	A2	9.8±0.9	10.3±2.0	11.4±1.6*	10.2±0.7	10.2±1.0	10.2±0.8	9.8±0.7

(1): genotype A1/A2; (2) genotype A1/A2 or A2/A2. *p<0.05, ** p<0.01

Before ST no differences were found between carriers and non-carriers of PI(A2) concerning levels of CRP, PC and MPV. Independent on the genotype, CRP levels increased after ST. In patients who were homozygous for PI(A1), PC and MPV did not change after ST, while PC decreased significantly and MPV increased significantly in carriers of the PI(A2) allele.
Conclusions: 1. Before ST there are no differences in MPV, PC and CRP levels between carriers and non-carriers of the PI(A2) allele. 2. After ST the inflammatory response is not influenced by the genotype of PI(A) polymorphism. 3. MPV increases and PC decreases in carriers of the PI(A2) allele only. Therefore the increased risk for restenosis in carriers of the PI(A2) allele may be caused by platelet activation.

P2256 Failed coronary stent deployment: single center experience

E. Nikolsky[1], M. Kapeliovich[2], S. Petcherski[2], E. Grenadier[2], M. Boulos[2], L. Gruberg[2], W. Markiewicz[2], R. Beyar[2]. *[1]Rambam Medical Center, Division of Invasive Cardiology, Haifa, Israel; [2]Rambam Medical Center, Division of Invasive Cardiology, Haifa, Israel*

Background: Stents have revolutionized percutaneous coronary interventions (PCI) impacting acute and long-term results. Despite the rapid improvement in stent design, failure of stent deployment is not a rare event. Aim: To assess frequency and causes of stent deployment failure (failing in delivery or deployment) in routine clinical practice, as well as short- and long-term outcome in patients (pts) with failed stenting. Methods and results: Between January 1997 and December 2001 stent assisted PCI was performed in 3291 pts. Delivery of total 4896 stents was attempted. Indications for stenting included suboptimal result after balloon angioplasty (65; 43.9%), provisional (50; 33.8%) and bailout stenting (33; 22.3%). A total 175 stents in 148 pts (4.5%) failed to be deployed. Reasons for stent deployment failure were vessel- (severe tortuosity or/and calcification of the lesion) [138; 92%] or stent-related (balloon rupture or failure to inflate the balloon) [12; 8.1%]. Peripheral stent embolization occurred in 10 pts (0.3%). Deployment of another stent instead of the failed one was successful in the majority of pts (106; 71.6%). In 13 (8.8%) pts a second attempt was unsuccessful. In 29 (19.6%) pts no new stent deployment was attempted. In-hospital major adverse cardiac events (MACE) were observed in 6 (4%) pts: emergent coronary artery bypass surgery (3), MI (2) and urgent re-PCI (1). At 1-year follow-up, 16 MACE occurred in 13 pts (8.8%) [6 of them had no stent during the index procedure]: cardiac death (1), MI (2) and TVR (13). One-year event free survival in the whole group was 91.2%. No events were registered in pts with stent embolization. Conclusions. 1. The rate of stent deployment failure in our series was 4.5%. 2. The main reasons for stent deployment failure were unfavorable vessel characteristics. 3. The use of another stent was successful in a high percentage (72%) of cases. 4. Stent failure was associated with favorable short- and long-term results.

P2257 Procedural complications during percutaneous coronary intervention in a 10 year period from 1989 to 1998. Results from the Danish PTCA Register

P. Thayssen[1], L.O. Jensen[1], E. Kassis[2], K. Rasmussen[3], K. Saunamäki[4], L. Thuesen[5]. [1]Odense University Hospital, Dept. of Cardiology, Odense C, Denmark; [2]Gentofte Hospital, Dept. of Cardiology, Gentofte, Denmark; [3]Aalborg Hospital, Dept. of Cardiology, Aalborg, Denmark; [4]Rigshospitalet, Dept. of Cardiology, Copenhagen, Denmark; [5]Skejby Hospital, Dept. of Cardiology, Aarhus, Denmark

Background: Old age has been claimed to be a specific risk in percutaneous coronary intervention (PCI). During the 10 year period from 1989 to 1998 data from all PCI procedures in Denmark were prospectively recorded in a central database, and data have now been analysed with regard to procedural complications occurring within 24 hours after PCI.
Methods: Angiographic baseline characteristics, outcome of PCI and procedural complications were analysed in a total of 13.886 consecutive procedures, performed in 10.896 patients having 19.472 lesions dilated.
Results: The number of procedures per million inhabitants increased sixteen fold from 47 in 1989 to 753 in 1998. Mean age was 59 ± 10.1 year, women were significantly older than men (61 ± 10.2 vs. 58 ± 10.0; p<0.000001). From 1989 to 1998 the mean age increased significant from 56 ± 9.3 to 60 ± 10.5 (p<0.000001), whereas gender ratio remained unchanged 3:1. Multivariate logistic regression analyses of MACE (myocardial infarction=MI, coronary artery bypass grafting=CABG, and death) identified the following independent predictors for procedural complications (table):

MACE	Predictor	Relative Risk	95% C.I.	p
MI	Age	1.02	1.01-1.04	< 0.001
	Female gender	1.43	1.11-1.84	0.006
	Stenting	1.24	1.01-1.54	0.044
CABG	Stenting	0.41	0.31-0.55	< 0.001
Death	Age	1.07	1.05-1.10	< 0.001

In general MACE decreased from 5.0% in 1989 to 2.9% in 1998 (p=0.003). MI occurred in 2.1% of all procedures. The overall procedural related frequency of MI did not decrease during the 10 year period, but in patients < 75 years old the risk decreased (p=0.007), while the risk in patients older than 75 years remained unchanged. CABG decreased significant from 3.2% in 1989 to 0.6% in 1998 (p<0.001). Procedural related mortality remained unchanged around 0.5%.
Conclusion: During a 10 year period (1989-98) total MACE within 24 hours following PCI decreased significantly mainly due to a significant decrease in procedure related acute CABG and the increasing use of stents. Age and gender were independent risk factors for procedural MI, whereas only age was an independent predictor for death.

P2258 What is the adverse event rate of patients awaiting a percutaneous coronary intervention? An 18 month longitudinal study

S. Talwar, C. Vorwerk, C.J. Burrell, J.G. Motwani, G.A. Haywood. *Plymouth, United Kingdom*

Background: The aim of this study was to assess the risk of adverse coronary events (AE) in patients awaiting elective Percutaneous Coronary Intervention (PCI) from a UK population, where the waiting lists for PCI were upto 18 months.
Methods: The observational cohort was composed of 147 outpatients (117 males, median age 59.5 years [range 31-79 years], 69.4% patients had single vessel coronary artery disease (CAD) and 70.7% patients were on a statin) placed on a waiting list for PCI between October 1998 and September 1999. Primary major AE were Death or nonfatal AMI or need for urgent hospital admission due to UA or significant angiographic progression of CAD whilst on the waiting list.
Results: After a median follow-up of 14 months [range 1-25 months], 41(27.9%) patients experienced a major cardiac AE. One patient (0.68%) died, one patient (0.68%) was admitted with an AMI and 13 patients (8.8%) were admitted with UA as emergencies. 26 patients (17.7%) had significant angiographic progression of CAD at the time of their check angiogram prior to PCI. Three of these patients developed a new occlusion and 9 were referred for CABG. Thirteen (8.8%) patients anginal symptoms significantly improved whilst waiting for PCI. Their names were removed from the PCI waiting list. Three (2%) patients at the time of their check angiogram prior to PCI had developed significant angiographic regression of their CAD and did not require PCI.
Conclusion: On the PCI waiting list there is a high rate of CAD progression necessitating surgical revascularisation. There is also a high incidence of emergency UA admissions. In the current environment with long waits, the rate of death or AMI are low. A policy of proceeding with PCI at the time of the angiogram would prevent emergency admissions and thereby promote efficient bed usage.

P2259 Safety of administration of protamin after coronary angioplasty

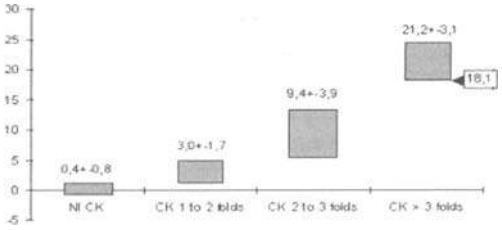
F. Lohne, N.E. Klow, M. Brekke, S. Stavnes. *Ulleval University Hospital, Heart Lung Center, Oslo, Norway*

Purpose: To study coronary safety of immediate reversal of heparin with protamin after successful PTCA, as well as puncture complications, time to mobilization, and patient comfort.
Methods: 100 patients with femoral puncture and a successful PTCA were prospectively randomized to protamin reversal and immediate sheath removal or sheath removal after three hours. Exclusion criteria were insulin dependant diabetes, myocardial infarction within the last 14 days and the need for GP IIb/IIIa platelet inhibitors. 34 women and 66 men were included, mean age 64 ± 11, range 42 - 82. When randomized to protamin, the activated clotting time was measured and the dose of protamin was given accordingly. All patients were followed up after 24 hours and 30 days.
Results: 50 patients were randomized to receive protamin. 78 patients had treatment of one vessel, 19 patients two vessels and 2 patients three vessels. Stents were implanted in 91 patients (91%). At six month two vessels were occluded (4%) and seven (14%) had recurrent stenosis in the protamin group, 4% and 10% respectively for the control group. However, four patients had early symptoms in the protamin group and only one in the control group, requiring reintervention. Pseudoaneurims were seen in one patient in the protamin group and two in the controls. Ten patients (20%) in the non-treated group had hematomas of any size, one large and one medium sized. Fifteen patients (30%) in the treated group had hematomas of any size, 1 large and five medium sized. The time to mobilization was significantly shorter for the protamin group, 10 hours vs. 17 hours. The overall patient discomfort from compression, bed rest and groin pain was less in the protamin group.
Conclusion: Reversal of heparin with protamin immediately after PCI improved the patient comfort and the practical handling of the patients having femoral puncture. Howerver, there was a trend toward more cardiac complication and further studies are recommended before this treatment should be used routinely.

P2260 Revisited values of Troponin I for the diagnosis of myocardial infarction after PTCA: results from the prospective French VIGILANCE Registry

D. Blanchard[1], J.L. Guermonprez[2], N. Danchin[2] on behalf of the BX Velocity Registry. [1]Clinique Saint-Gatien, Tours, France; [2]HEGP, Paris, France

Though troponin rise is now considered by many to be a marker of poorer outcome after PTCA, there is less evidence to this than for post-procedural CK rise.
The aim of the present study was therefore to determine the relationship between CK and troponin post-procedural levels in a population prospectively included in a multicentre registry of patients undergoing placement of a Cordis BxVelocity ® stent. Troponin I and CK were analysed before PTCA and on the morning following the procedure; all measurements were made at a central core laboratory.
191 patients with both normal CK (<170U) and normal Troponin I (<1U) values before PTCA were included in the study.
For the whole group, we observed a rise in CK and Troponin I values after PTCA (Troponin I from 0.1±0.2 to 0.9±2.7 p<.0001, CK from 51.1±29.3 to 80.1±104.4 p<.0001). Troponin I was >= 1U in 32 patients (16.7%), CK was >= 170U in 17 patients (8.9%). There was a significant correlation between CK and Troponin I (r = 0.878, p<0.0001).
Furthermore, when the values for Troponin I were analysed according to CK values (normal, >1 to 2, >2 to 3 and > 3 times the upper limit of normal). Only very high (> 18 U) troponin values corresponded to CK increase above 3 times the upper limit of normal, a threshold considered diagnostic of clinically relevant myocardial damage in most studies.



Troponin values vs CK range.

In conclusion, if CK measurements are replaced by Troponin I measurements after PTCA only the highest values of Troponin I correspond to the threshold used for CK values.

P2261 Does stent design affect platelet activation? Results of the platelet activation in stenting (PAST) study

P.A. Gurbel, K.P. Callahan, M.J. Buczkowski, A.I. Malinin, V.L. Serebruany. *Sinai Hospital, Baltimore, United States of America*

Background: Platelet activation induced by coronary artery stenting affects clinical outcomes and may be related to stent design. However, little is known about how platelet activation may be altered by the specific design of a stent.
Methods: Patients (n=53) were randomly assigned to stenting with a closed-cell (NIR, Boston Scientific) or open-cell (TETRA, Guidant) stent. Patients were treated with aspirin and were loaded with 300 mg clopidogrel in the cath lab and received 75 mg daily thereafter. All stents were depolyed at > 12 atm. GPIIb/IIIa inhibitors were not used. Platelet aggregation (5μ mol ADP and 1μg/ml collagen); and flow cytometry (mean fluorescence intensity (MFI)) to multiple platelet receptors and platelet-leukocyte aggregates (CD 151+ 14) were serially determined at baseline, and at 2 hours (2h), 24 hours (24h), 5 days (5d) and 30 days (30d) post procedure.
Results: Stenting was successful in all patients. Markers of platelet activation were less following NIR implantation: 30d ADP aggregation (%) (32.3±6.1 vs 44.5± 18.9, p=.02); 24h CD 31 (136±48 vs. 110±48,p=.04); 24h (104±45 vs 91±31 p=.048) and 30d CD 151 (99±33 vs 81±32, p=.03);24h (93±40 vs. 77±24, p=.018)and 30d CD 151+14 (84±35 vs. 72±31, p=.045); 30d PAC-1 (88±41 vs 72±30, p=.025); and 2h (22±13 vs 18±5, p=.045) and 24h CD 107a (24±12 vs. 17±4, p=.03).
Conclusions: In this randomized prospective trial, platelet activation; indicated by enhanced aggregation and expression of multiple receptors; was greater during the 30 days following implantation of an open-versus a closed-cell stent. Stent-dependent platelet activation may be relevant to the propensity for subacute thrombosis and restenosis associated with a particular stent design.

P2262 Coronary microembolisation – Its role in chronic total coronary occlusions and interventions

P. Bahrmann, M. Jantz, H.R. Figulla, G.S. Werner. *Friedrich-Schiller-Universität, Klinik für Innere Medizin III, Jena, Germany*

Introduction: After recanalisation and stenting of chronic total coronary occlusions (TCO), a reduced coronary flow velocity reserve (CFVR) and rise in collateral resistance (Rcoll) are frequently observed. Coronary microembolisation may account for these observations.
Methods: In 71 patients (age 64 ± 10 years; 65 men, 6 women) with TCO (duration >4 weeks), PTCA was performed with successful stent implantation in all lesions. Before PTCA viable myocardium was detected by stress echocardiography or nuclear imaging techniques. In order to calculate Rcoll coronary pressure was measured before the first balloon inflation and after PTCA had been completed. In order to determine CFVR coronary Doppler flow velocity was measured after PTCA had been completed. Before and over a period of 24 hours after intervention creatine kinase (CK) and cardiac troponin (cTNI) were monitored.
Results: CFVR was <2.0 in 52% of all patients. A rise in Rcoll was observed in 84% of all patients. The incidence of CK and cTNI elevation above the 99% confidence limit was only 6% of all patients. These patients with CK and cTNI elevation did not show a significant difference of CVFR and rise in Rcoll as compared to patients without CK and cTNI elevation. CVFR or rise in Rcoll did not correlate with CK or cTNI elevation.

Interventional results

	All patients	CK normal	CK elevated	P
Patients (n)	71	67	4	-
Baseline APV (cm/s)	29.0 ± 15.1	29.1 ± 14.9	27.7 ± 20.4	NS
Hyperemic APV (cm/s)	54.0 ± 25.3	54.0 ± 24.7	54.2 ± 39.5	NS
CFVR	2.0 ± 0.6	2.0 ± 0.6	2.0 ± 0.2	NS
FFR	0.84 ± 0.08	0.85 ± 0.07	0.77 ± 0.21	NS
Rcoll before PTCA (mmHg/(cm*s)	9.6 ± 8.7	9.4 ± 8.5	14.0 ± 13.8	NS
Rcoll after PTCA (mmHg/(cm*s)	20.5 ± 17.2	20.5 ± 17.4	21.8 ± 17.8	NS

APV=Average Peak Velocity, CFVR= Coronary Flow Velocity Reserve, FFR=Fractional Flow Reserve, Rcoll=Collateral Resistance.

Conclusion: Coronary microembolisation is not a likely cause for the microvascular dysfunction and changes of collateral function after PTCA of TCO.

PAEDIATRIC CATHETER INTERVENTION

P2263 Is transcatheter closure of ostium secundum atrial septal defect superior to surgery?

G. Butera, M. Chessa, R.M. Bini, M. Drago, A. Giamberti, G. Pome, A. Frigiola, M. Carminati. *Policlinico San Donato, Pediatric Cardiology Dept., San Donato Milanese, Italy*

Background: Surgical ASD closure provides excellent results. With the current rise of percutaneous techniques, a comparison is needed.
Aim: To compare percutaneous and surgical closure of ASD.
Patients and methods: Between December 1988 and August 2001 909 consecutive patients underwent ASD closure in our institution. From 4/96 to 08/01, 478 pts underwent percutaneous ASD closure (Group A). Two devices were used: Amplatzer Septal Occluder in 347 pts (72.6%) and CardioSEAL/StarFLEX in 131 pts (27.4%). From 12/88 to 08/01, 443 consecutive pts underwent ostium secundum ASD surgical repair (Group B). There was a slight difference in mean age between the two groups (Group A: 28.6±19.8 yrs vs Group B 21.4±19.25 yrs; p=0.02).
Results: Hospital stay was lower in Group A (3.2±0.9 days vs 10.1±2.6 days; p<0.0001).Total number of complications was higher in Group B (43% vs 11%; p<0.0001) as well as clinically relevant complications (19% vs 3.8%; p:0.002). In Group A major complications included: (a) device embolisation needing surgical retrieval (12 pts; 2.5%); (b) surgical repair of femoral vessels (4 pts; 0.8%); (c) arrhythmias (11 pts; 2.3%); (d) trombus formation on the device (2 pts; 0.4%). In Group B complications included: minor transient complications in 24% of the pts (arrhythmias, respiratory infections, pericardial effusion, anemia, pneumothorax,others); severe transient in 18.3% (arrhytmias, sever bleeding, heart failure, transient complete AV block, cardiac tamponade); severe with sequelae in 3 pts (0.7%) (neurologic, chronic cardiac failure). Transfusion rate was 5%. Surgical drainage for pericardial or pleural effusion or for pneumothorax was needed in 4.5%. Chest reopening for severe bleeding was in 0.5%. Re-operation for patch detachement occurred in 2 pts. No early deaths occurred in both groups. Residual shunt at discharge was trivial and there were no differences between the two groups. Five pts of Group A and 5 pts of Group B were treated for a significant residual shunt after surgical ASD closure.
Costs were higher in Group B (8096±1171 vs 7791±2928 Euro; p=0.04).
Conclusions: Percutaneous ASD closure provides excellent results, with lower complication, no sequelae, shorter hospital stay and reduced costs.

P2264 Amplatzer occluder device in adult patients with secundum atrial septal deffect: a single center experience

A. Carcagnì, L. Maiello, F. Milone, F. Marsico, D. Zavalloni, M. Bonemazzi, P. Presbitero. *Istituto Clinico Humanitas, Interventional Cardiology, Rozzano, Italy*

Background: Secundum atrial septal defect (ASD) is a common congenital heart disease in adulthood. Amplatzer septal occluder (ASO) device is one of the most recent devices that have undergone to investigation. However, data from adult population with this device are limited. This study evaluates the immediate and at 6 months outcome of the percutaneous ASDs closure with the ASO-device in an adult population in a single centre experience.
Methods and Results: Between May 1999 and September 2001, 36 adult patients (21 female) with a mean age of 44.6+15.1 years (range 26 to 84) were considered for a percutaneous ASD closure with ASO-device after transesophageal echocardiography (TEE). A coronary angiography was performed in patients older than 40 years or with multiple coronary artery disease risk factors. Clinical evaluation and transthoracic echocardiogram (TTE) were done at 24 hour and at 6 months.ASD diameter on TEE was 14.4+7.2 mm (range 4 to 23 mm). The mean stretched defect diameter measured 19.5+8.4 mm (range 8 to 34 mm) and mean ASO-device size was 19.8+ 8.2 mm (range 8 to 34 mm). ASO-device was implanted successfully in 94.4% (34/36) of patients. A trivial shunt was assessed by TEE examination in 14 patients (38.9%) and residual shunt = 3 mm in one patient who had a very pliable posterior rim. In 2 (5.6%) cases ASO closure failed because the defect was too large. In 3 (8.3%) of the 36 patients an associated coronary artery disease was assessed. A percutaneous transcatheter coronary angioplasty (PTCA) was successfully performed before ASO deployment.
At 6 month 2 (5.6%) of the 36 patients developed a supra-ventricular arrhythmia and needed medical treatment. No shunt was assessed on TTE in the patients in whom a trivial shunt was visible after procedure and a reduction of the bigger residual shunt was shown by TTE examination
Conclusions: 1. TEE examination aloud a good screening of the ASD that may benefit of ASO closure device (However, in 5.6% of cases ASO device can not be implanted because of ASD too large or pliable rims, even after TEE examination). 2. Transcatheter closure of ASDs is a safe and effective alternative to surgical closure in most of the adult patients with excellent immediate and middle-term outcome. 3. Combined PTCA and percutaneous ASD closure are safe and effective. Non-invasive tests to detect myocardium ischemia are advisable in every adult patient who is undergoing percutaneous ASD closure.

P2265 Short and intermediate term results of tanscatheter closure of atrial septal defect with Amplatzer septal occluder

J.K. Wang. *National Taiwan University Hospital, Pediatrics, Taipei, Taiwan, Province of China*

Aim.This study was conducted to evaluate the short and intermediate-term results of transcatheter closure of atrial septal defect (ASD) with the Amplatzer septal occluder.
Material and Methods: During a 3 years period, between January 1999 and December 2001, 117 patients underwent attempted transcatheter closure of ASD using the Amplatzer septal occluder in this institution. After hemodynamic studies, an AGA balloon sizing catheter was used to measure the stretched diameters of the defect. A sizing plate was also used to evaluate the accuracy of the measurment of the sizing catheter. All patients underwent general anesthesia with transesophageal echocardiographic monitoring of the procedure. The diameter of the device used was equal to or slightly larger than the stretched diameter if the stretched diameter was < 20 mm. An increment of 2 mm of the stretched diameter was selected as the size of the device, if the stretched diameter > 20 mm.
Results: The Amplatzer device was deployed in 114 patients. In the initial period of the study, the procedure was abandoned because of stretched diameter of the defect > 30 mm in 3 patients. Of the 114 patients, 35 were male, 79 females with ages ranging from 2.5 to 66 years. The mean stretched diameter measured with balloon catheter and sizing plate were 17.3 + 5.2 mm (ranging from 6.2 to 32.4 mm) and 17.6 + 5.6 mm, respectively. Deficiency of anterior superior rim (< 2mm) was found in 58 patients. Seven had multiple fenestrated ASD. An aneurysm of the atrial septum was found in 8. Only one device was deployed in all patients except one who had implantation of two devices. One patient complicated with compete atrioventricular block which recovered 3 days later. Two had small-to moderate amount of pericardial effusion after diagnostic catheterization and angiogram, which subsided in the 2 patients in one month follow-up. All patients received aspirin for 6 months. Echocardiography at 1 day, 3 months, 6 months & 12 months follow-up showed residual shunt in 21/114 (18%), 5/108 (5%), 2/86 (2%), and 2/74 (3%), respectively. The two patients who had residual shunt 12 months after ASD closure had multiple perforated defects. One had several episodes of migraine during follow-up.
Conclusion: Amplatzer septal occluder is safe and effective in the closure of ASD. Deficiency of anterior superior rim did not render difficulties in ASD closure.

P2266 Interventional closure of patent foramen ovale with the Amplatzer PFO occluder: complications and follow-up results in 126 patients

T. Trepels, S. Ostermayer, K. Billinger, U. Krumsdorf, K. Horvath, H. Sievert. *Cardiovascular Center Bethanien, Frankfurt, Germany*

Purpose: Patients with paradoxical embolism through a patent foramen ovale (PFO) are at risk to suffer from recurrent embolic events. Transcatheter PFO closure has been proposed to prevent recurrent paradoxical embolism. We are reporting our experience using the Amplatzer device.
Methods: Since 8/1994 catheter PFO closure was performed in our center in 535 adult patients. In 126 cases we implanted an Amplatzer PFO Occluder. The mean age of these patients was 49 ± 12 years (range 22- 76 years). In these patients 171 embolic events had occurred before closure (average 1.4 per patient). The defect size (stretched diameter) ranged from 3 to 21 mm (mean 9 ± 3).
Results: The implantation of the device was successful in all patients. The procedure was performed in local anesthesia in 113/126 patients. The mean procedure duration was 34 ± 16 minutes (mean fluoroscopy time 5.3 ± 3.9 min). Patients were discharged after a hospital stay of 0.8 ± 0.4 days. An initial residual shunt could be detected in 39 patients (transesophageal contrast echocardiography). In their last follow up 2 patients still had a small residual shunt. As acute complication occurred one device perforation after 24 hours (surgery uneventful). During follow-up (0.5 to 26 months) the following complications occurred: Recurrent embolic event: n=1, paroxysmal atrial fibrillation: n=5 (cardioversion and medical treatment successful in all of them), on- device thrombus formation n=2.
Conclusion: Transcatheter PFO closure with the Amplatzer PFO occluder is a safe procedure. Midterm results show an effective prevention of recurrent embolic events. Randomized trials are necessary to show long- term prevention.

P2267 Percutanous closure of atrial septal defects in patients with severe pulmonary hypertension – Follow-up results in 48 consecutive patients

T. Trepels, S. Ostermayer, K. Billinger, U. Krumsdorf, K. Horvath, H. Sievert. *Cardiovascular Center Bethanien, Frankfurt, Germany*

Purpose: We report our experience with the transcatheter closure of atrial septal defects (ASD) in 48 patients with severe pulmonary hypertension (Psyst>50 mmHg).
Methods: Since 8/1992 catheter closure of an ASD was performed in our center in 361 adult patients. In 48/361 patients the systolic pulmonary artery pressure was elevated above 50 mmHg. The mean age was 65±10 years. The stretched diameter of the defects ranged from 13 to 34 mm (20±6), the systolic pulmonary artery pressure ranged from 50 to 110 mmHg (63±14). We used 8 different devices.
Results: The implantation was successful in all 48 patients. The mean procedure time was 56 ±25 minutes (fluoroscopy time 11±9 minutes). Mean hospital stay was 1.4 ± 1.1 days. As complications occurred: Embolisation n=1 (surgery uneventful), pericardial effusion n=1, thrombus n=1, atrial fibrillation n=4. Transesophageal echocardiograpy showed a complete closure in the last follow up in 39 patients. The Qp:Qs ratio decreased from 2.1 ±0.7 before closure to 1.0 ±0.3 after 6 months ($p<0,001$).The mean pulmonary artery pressure decreased from 36 ±9 mmHg to 28 ±8 mmHg ($p<0,001$). The right ventricular diastolic diameter (M-Mode) was reduced from 44 ±6 to 37 ±7 mm ($p<0,05$).
Conclusion: Transcatheter closure of ASD is a safe procedure in elderly patients with pulmonary hypertension. It leads to a significant decrease of pulmonary artery pressure and right ventricular dilatation.

FETAL CARDIOLOGY

P2268 Fetoscopic cardiac interventions in fetal sheep carry a low risk for the occurrence of brain damage detectable following completion of gestation

T. Kohl[1], M. Westphal[2], J. Reckers[3], M.A. Große Hartlage[2], D. Kienitz[1], H. Van Aken[1], W. Paulus[4], C. Rickert[4]. *[1]Münster University Children's Hospital, Department of Pediatric Cardiology, Münster, Germany; [2]Münster University Medical School, Department of Anesthesiology, Münster, Germany; [3]University Children's Hospital, Department of Pediatric Cardiology, Göttingen, Germany; [4]Münster University Hospital, Institute of Neuropathology, Münster, Germany*
